Managers are listed by pairs of data items: *Availability Manager Object Type* and *Availability Manager Name*. The managers are simulated down the list and calculate a control status for use by the AirLoopHVAC or PlantLoop. The priority of each manager used for a specific loop is based on the rules described above. Availability managers are not currently used for condenser loops. The availability managers, along with the AirLoopHVAC and PlantLoop object, report the control status calculated each simulation timestep. These report variables can be used to prioritize the managers according to the required control strategy. Six managers are accommodated in the list by default, however, this IDD specification is extensible. Additional pairs may be added by directly editing the IDD.

Field: Availability Manager <x> Object Type

The key word defining the type of manager, e.g. AvailabilityManager:NightCycle.

Field: Availability Manager<x> Name

The name of a AvailabilityManager object defined elsewhere in the input file.

The IDD specification:

```
AvailabilityManagerAssignmentList,
  \min-fields 3
  \extensible:2 - repeat last two fields, remembering to remove ; from "inner" fields.
A1 , \field Name
     \type alpha
     \required-field
     \reference SystemAvailabilityManagerLists
A2 , \field Availability Manager 1 Object Type
     \required-field
     \type choice
     \key AvailabilityManager:Scheduled
     \key AvailabilityManager:ScheduledOn
     \key AvailabilityManager:ScheduledOff
     \key AvailabilityManager:NightCycle
     \key AvailabilityManager:DifferentialThermostat
     \key AvailabilityManager:HighTemperatureTurnOff
     \key AvailabilityManager:HighTemperatureTurnOn
     \key AvailabilityManager:LowTemperatureTurnOff
     \key AvailabilityManager:LowTemperatureTurnOn
     \key AvailabilityManager:NightVentilation
A3 , \field Availability Manager 1 Name
     \required-field
     \type object-list
     \object-list SystemAvailabilityManagers
-- etc to # of system availability manager sets entered
```

An example of this statement in an IDF is:

```

AvailabilityManagerAssignmentList,
Collector Loop Availability Manager List,  !- Name
AvailabilityManager:HighTemperatureTurnOff,  !- System Availability Manager Type 1
High Temperature Turn Off Availability Manager,  !- System Availability Manager Name 1
AvailabilityManager:LowTemperatureTurnOn ,  !- System Availability Manager Type 2
Low Temperature Turn On Availability Manager,  !- System Availability Manager Name 2
AvailabilityManager:DifferentialThermostat,  !- System Availability Manager Type 3
Differential Thermostat Availability Manager;  !- System Availability Manager Name 3

```

AirLoopHVAC:OutdoorAirSystem

The Outside Air System (object AirLoopHVAC:OutdoorAirSystem) is a subsystem of an AirLoopHVAC. It handles the mixed air portion of the primary air system: the system relief air, the outside air inlet, and any components and controllers associated with the system relief air and outside air streams. From the perspective of the primary air loop the Outside Air System is treated as a single component. As a subsystem, it can contain one or more components and controllers.

The input for the Outside Air System consists of a system name, a controller list name, an equipment list name, and an availability manager list name. The controller list simply lists, by type and unique name, all the controllers in the subsystem. The controllers will be simulated in list order. The equipment list lists all the components in the subsystem, by type and name. The equipment is simulated in list order. Finally, the availability manager list gives the type and name of the availability managers used by the subsystem.

The equipment inlet/outlet must be sequential with no loops - the simulation can only handle a straight-through air path, both on the primary air side and on the secondary air side, if any. Heat exchanger secondary air inlets need to be independent of the primary air stream – usually relief air is used.

Field: Name

The unique, user assigned name for a single instance of an Outside Air System. Any other object referencing this Outside Air System will use this name.

Field: Name: Controller List Name

This field is the name of a AirLoopHVAC:ControllerList object. A AirLoopHVAC:ControllerList is simply a list of controllers giving both controller name and type. This Controller List specifies all the controllers that will act on this outside air system. The order of the controllers in the list is significant: controllers are simulated sequentially in the order given in the Controller List. Typically the Controller List would contain a Controller:OutdoorAir. If there are chilled water or hot water coils in the outdoor air system, each such coil will need a Controller:WaterCoil.

Field: Outdoor Air Equipment List Name

This field is the name of an AirLoopHVAC:OutdoorAirSystem:EquipmentList object. An AirLoopHVAC:OutdoorAirSystem:EquipmentList is simply a list of components giving both component name and type. This Outdoor Air Equipment List specifies all the components that will be simulated in this outside air system. The order of the components in the list is significant: components are simulated sequentially in the order given in the Outdoor Air Equipment List. Typically the equipment list would contain at least an OutdoorAir:Mixer. If there is more than one component, the components must be listed in order from the outside air to the OutdoorAir:Mixer (the OutdoorAir:Mixer is last).

Field: Availability Manager List Name

This field is the name of a AvailabilityManagerAssignmentList object. An Availability Manager List is a list of Availability Managers giving both Availability Manager Object Type and Name. **Use of this input is optional.** This field may be omitted; it is not currently used by the program.

The full IDD specification follows:

```

Outdoor Air System Outputs

The impact of using outside air/mechanical ventilation is described in the section: Outdoor Air Ventilation Report Variables.

AirLoopHVAC:OutdoorAirSystem:EquipmentList

Used to specify the components in the outdoor air system. The components will be simulated in the order in which they occur in the list.

Field: Name

The user designated unique name of an instance of an Air Loop Equipment List. Any object referencing this Air Loop Equipment List will do so using this name.

Field Set (Component Object Type,, Component Name) up to 8

After the identifying name, the list consists of up to 8 pairs of data items:

Field: Component <x> Object Type

This field specifies the keyword for the type of component used.

Field: Component <x> Name

This field is the unique name of the component specified in the previous field. This named object must appear in the IDF.

The IDD specification:

```
AirLoopHVAC:OutdoorAirSystem:EquipmentList,
  \memo List equipment in simulation order
  A1 , \field Name
  \required-field
  \type alpha
  \reference AirLoopOAEquipmentLists
  A2 , \field Component 1 Object Type
  \required-field
  A3 , \field Component 1 Name
  \required-field
  A4 , \field Component 2 Object Type
  A5 , \field Component 2 Name
  -- etc to # of sets entered
```

An example from an IDF:

```
AirLoopHVAC:OutdoorAirSystem:EquipmentList,
  OA Sys 1 Equipment,
  HeatExchanger:AirToAir:FlatPlate,OA Heat Recovery 1,
  OutdoorAir:Mixer, OA Mixing Box 1;
```

OutdoorAir:Node

The OutdoorAir:Node object declares an HVAC system node for outdoor air conditions. The program automatically sets the air conditions at these nodes to correspond to the ambient

environmental conditions at the beginning of every timestep. The outdoor air node is typically used as the inlet air node to an HVAC component such as the OutdoorAir:Mixer object. Multiple OutdoorAir:Node objects can be used in an input file, however, duplicate node names are not allowed.

The *Height Above Ground* field is used to adjust the weather file air conditions, e.g., outdoor dry-bulb and wet-bulb air temperatures, for atmospheric variation with height. This variation can become a significant factor when modeling tall buildings. See the Engineering Reference section on Atmospheric Variation for a description of the algorithm for variation of atmospheric properties with height. A blank entry or a value less than zero for this field indicates that the height will be ignored and the weather file conditions will be used.

OutdoorAir:Node and **OutdoorAir:NodeList** both set a node to outdoor air conditions. **OutdoorAir:Node** modifies the weather file conditions if a height has been specified. **OutdoorAir:NodeList** does not have a height input and always uses the weather file conditions without modification. The same node name may not be used with both of these objects.

Field: Name

The unique name for this outdoor air node.

Field: Height Above Ground

The height [m] of the node above ground level. A value greater than zero allows the weather file conditions, e.g., outdoor dry-bulb and wet-bulb air temperatures, to be adjusted according to atmospheric variation with height.

A blank entry or value less than zero indicates that the height will be ignored and the weather file conditions will be used.

The IDD specification:

```
OutdoorAir:Node,
  \memo This object sets the temperature and humidity conditions
  \memo for an outdoor air node. It allows the height above ground to be
  \memo specified. This object may be used more than once.
  \memo The same node name may not appear in both an OutdoorAir:Node object and
  \memo an OutdoorAir:NodeList object.
A1, \field Name
  \required-field
  \type alpha
N1 ; \field Height Above Ground
  \note A value less than zero indicates that the height will be ignored and the weather file
  conditions will be used.
  \type real
  \units m
  \default -1.0
```

An example IDF:

```
OutdoorAir:Node,
  OA Node 1; !- Name

OutdoorAir:Node,
  Floor 10 Outdoor air Inlet Node, !- Name
  30.0; !- Height Above Ground {m}
```

OutdoorAir:Node outputs:

The ambient dry-bulb air temperature and flow rate at the outdoor air node can be monitored using the system node output variables:

```
HVAC,Average,System Node Temp[C]
```

```
HVAC,Average,System Node MassFlowRate[kg/s]
```

e.g.

```
Report Variable,
Floor 10 Outdoor air Inlet Node,
System Node Temp,
Hourly;
```

OutdoorAir:NodeList

The program needs to know which HVAC system nodes are inlets for outdoor air. Knowing this, the program can set the conditions at these nodes to the outdoor conditions at the start of each major timestep. The OutdoorAir:NodeList provides the means for specifying which nodes are outdoor air nodes.

The input is flexible: there may be one or more OutdoorAir:NodeList in each input file. Each list contains up to 25 names. The names can be the name of a unique HVAC system node, or the name of a Node List which will contain the actual node names. Duplicate node names are ignored.

OutdoorAir:Node and **OutdoorAir:NodeList** both set a node to outdoor air conditions. **OutdoorAir:Node** modifies the weather file conditions if a height has been specified. **OutdoorAir:NodeList** does not have a height input and always uses the weather file conditions without modification. The same node name may not be used with both of these objects.

Field: Node or NodeList name

The name of an HVAC system node or of a NodeList object. There can be up to 25 names.

The IDD specification:

```
OutdoorAir:NodeList,
  \memo This object sets the temperature and humidity conditions
  \memo for an outdoor air node using the weather data values.
  \memo to vary outdoor air node conditions with height above ground
  \memo use OutdoorAir:Node instead of this object.
  \memo This object may be used more than once.
  \memo The same node name may not appear in both an OutdoorAir:Node object and
  \memo an OutdoorAir:NodeList object.
A1 , \field Node or NodeList Name 1
    \required-field
    \type alpha
A2 , \field Node or NodeList Name 2
    \type alpha
A3 , \field Node or NodeList Name 3
    \type alpha
-- etc to # of node or node lists entered
```

An example IDF:

```
OutdoorAir:NodeList,
  OutsideAirInletNodes;

NodeList,OutsideAirInletNodes,
  Outdoor air Inlet Node;
```

OutdoorAir:Mixer

The OutdoorAir:Mixer is the most common component used in an outdoor air system. The outdoor air mixer has 2 inlet air streams: the system return air and the outdoor air. It has 2 outlet air streams: the system relief air and the mixed air. This is a passive component. It takes the inlet mass flows and conditions plus the relief air mass flow and calculates the

mixed air flow rate and conditions (as well as the relief air conditions). The inlet and relief mass flow must be set outside the component – most commonly by an outdoor air controller. The OutdoorAir:Mixer can also be used in compound components such as a fan coil unit.

Input for this object is very simple: a unique name plus the node names of the 2 inlet nodes and the 2 outlet nodes.

Field: Name

A unique user assigned name for a particular outdoor air mixer component. Any reference to this component by another object will use this name.

Field: Mixed Air Node Name

The name of the HVAC system node which is the outlet for the mixed air stream.

Field: Outdoor Air Stream Node Name

The name of the HVAC system node which is the inlet for the outdoor air stream.

Field: Relief Air Stream Node Name

The name of the HVAC system node which is the outlet for the system relief air.

Field: Return Air Stream Node Name

The name of the HVAC system node which is the inlet for the return air stream.

The IDD specification:

```

OutdoorAir:Mixer,
  \memo Node names cannot be duplicated within a single OutdoorAir:Mixer object.
A1, \field Name
  \required-field
  \type alpha
  \reference OutdoorAirMixers
A2, \field Mixed Air Node Name
  \note Name of Mixed Air Node
  \required-field
A3, \field Outdoor Air Stream Node Name
  \note Name of Outdoor Air Stream Node
  \required-field
A4, \field Relief Air Stream Node Name
  \note Name of Relief Air Stream Node
  \required-field
A5; \field Return Air Stream Node Name
  \note Name of Return Air Stream Node
  \required-field
    
```

An IDF example:

```

OutdoorAir:Mixer,
  ZonelWindACOAMixer,           ! name
  ZonelWindACOAMixerOutletNode, ! mixer outlet node
  ZonelWindACOAINode,          ! mixer OA node
  ZonelWindACExhNode,         ! mixer relief node
  ZonelWindACAirInletNode;    ! mixer inlet node
    
```

Group – Airflow Network

Overview

The Airflow Network model provides the ability to simulate multizone airflows driven by wind and also by a forced air distribution system. The model can also simulate the heat and moisture gains or losses from the air distribution system itself (e.g., ductwork). When modeling an air distribution system, the current version of the Airflow Network model is

restricted to a single forced air system (i.e., AirLoopHVAC object) with a constant volume supply air fan (Fan:ConstantVolume or Fan:OnOff). The capabilities of the model are to:

- Simulate zone pressures due to envelope leakage and forced air distribution during HVAC system fan operation
- Simulate node pressures in a forced air distribution system during HVAC system fan operation
- Calculate multizone airflows due to forced air, wind, and surface leakage, including adjacent zones and outdoors, during HVAC system fan operation
- Simulate distribution system airflows, including supply and return air leaks, during HVAC system fan operation
- Simulate air distribution system node temperatures and humidity ratios during HVAC system fan operation
- Calculate duct conduction losses during HVAC system fan operation
- Calculate vapor diffusion losses of ducts during HVAC system fan operation
- Calculate sensible and latent loads on the surrounding zones due to supply and return air leaks in the air distribution system during HVAC system fan operation
- Simulate zone pressures due to envelope leakage driven by wind when the HVAC system fan is off or if no air distribution system is specified
- Calculate multizone airflows due to wind and surface leakage, including adjacent zones and outdoors when the HVAC system fan is off or if no air distribution system is specified
- Allow zone exhaust fans to be included as part of the airflow network
- For airflow networks with a forced air distribution system, calculate zone sensible and latent loads for two different supply air fan operation modes as required: cycling fan, cycling compressor (CyclingFanAndCompressor) and continuous fan, cycling compressor (ContinuousFanWithCyclingCompressor)

Summary of Objects

Before describing the Airflow Network input objects in detail, we list all of the objects and then give a short description of what the objects do.

The Airflow Network input objects are:

AirflowNetwork:SimulationControl
AirflowNetwork:Multizone:Zone
AirflowNetwork:Multizone:Surface
AirflowNetwork:MultiZone:Component:SimpleOpening
AirflowNetwork:MultiZone:Component:DetailedOpening
AirflowNetwork:MultiZone:Surface:Crack
AirflowNetwork:MultiZone:ReferenceCrackConditions
AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea
AirflowNetwork:MultiZone:Component:ZoneExhaustFan
AirflowNetwork:MultiZone:ExternalNode
AirflowNetwork:MultiZone:WindPressureCoefficientArray
AirflowNetwork:MultiZone:WindPressureCoefficientValues
AirflowNetwork:Distribution:Node
AirflowNetwork:Distribution:Component:Leak
AirflowNetwork:Distribution:Component:LeakageRatio
AirflowNetwork:Distribution:Component:Duct
AirflowNetwork:Distribution:Component:ConstantPressureDrop
AirflowNetwork:Distribution:Component:ConstantVolumeFan
AirflowNetwork:Distribution:Component:Coil
AirflowNetwork:Distribution:Component:HeatExchanger
AirflowNetwork:Distribution:Component:TerminalUnit

AirflowNetwork:Distribution:Linkage

- **AirflowNetwork:SimulationControl** defines basic run parameters for the air flow calculations and specifies whether wind pressure coefficients are input by the user or, for rectangular buildings, calculated by the program.
- The **AirflowNetwork:Multizone:Zone** object specifies the ventilation control that applies to all of the openable exterior and interior windows and doors in the corresponding thermal zone. Surface-level ventilation control can be used to override the zone-level ventilation control if required (see **AirflowNetwork:Multizone:Surface** object below).
- **AirflowNetwork:Multizone:Surface** object indicates whether a heat transfer surface (wall, window, etc.) has a crack or opening and references an **AirflowNetwork:MultiZone:Surface:Crack**, **AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea**, **AirflowNetwork:MultiZone:Component:SimpleOpening**, **AirflowNetwork:MultiZone:Component:DetailedOpening** or **AirflowNetwork:MultiZone:Component:ZoneExhaustFan** object that gives the air flow characteristics of that crack, opening, or zone exhaust fan. The **AirflowNetwork:Multizone:Surface** object can also be used to specify individual ventilation control for openable exterior and interior windows and doors.
- **AirflowNetwork:MultiZone:ReferenceCrackConditions** is used to normalize crack information that is based on measurements of crack air flow.
- **AirflowNetwork:Distribution:Node** represents air distribution system nodes for the **AirflowNetwork** model. A set of an **AirLoopHVAC** and **ZoneHVAC:EquipmentList** nodes is a subset of the **AirflowNetwork:Distribution:Nodes**.
- **AirflowNetwork:Distribution:Component** objects consist of **Leak**, **LeakageRatio**, **Duct**, **ConstantPressureDrop**, **ConstantVolumeFan**, **Coil**, and **TerminalUnit**. The components provide a relationship between pressure and airflow. The **Leak** and **Leakage** components can be used to simulate supply and/or return leaks in an air distribution system. The **Duct** and **ConstantPressureDrop** components can be used to deliver forced air into conditioned spaces. The components **ConstantVolumeFan**, **Coil**, and **TerminalUnit** reference normal **EnergyPlus** objects. The **Airflow Network** model gets information from these objects to perform an airflow network simulation.
- **AirflowNetwork:Distribution:Linkage** object represents a connection between two node objects and an **AirflowNetwork** component. The node objects can be an **AirflowNetwork:Distribution:Node**, **AirflowNetwork:MultiZone:ExternalNode** or **AirflowNetwork:Multizone:Zone**.

If you input wind pressure coefficients, **AirflowNetwork:Multizone:Surface** also has an associated **AirflowNetwork:MultiZone:ExternalNode** that, via the **AirflowNetwork:Multizone:WindPressureCoefficientArray** and **AirflowNetwork:MultiZone:WindPressureCoefficientValues** objects, gives the wind pressure distribution vs. wind direction for that node and, implicitly, for the cracks and openings in the exterior surfaces associated with that node.

Figure 76 shows the relationships among **AirflowNetwork:Multizone** objects and between **AirflowNetwork:Multizone** objects and regular **EnergyPlus** objects. In this figure an arrow from object A to object B means A references B, i.e., one of the inputs in A is the name of object B. For example, one input for **AirflowNetwork:Multizone:Surface** is the name of a heat transfer surface, and another is the name of a crack or opening object. The arrow between **AirflowNetwork:Multizone:Surface** and **AirflowNetwork:MultiZone:ExternalNode** is shown dashed to indicate that this reference is not used when wind pressure coefficients are calculated by the program rather than being input by the user.

Figure 76 also shows the relationships among **AirflowNetwork:Distribution** objects and between **AirflowNetwork:Distribution** objects and regular **EnergyPlus** objects. The **AirflowNetwork:Distribution:Linkage** objects link two nodes from

AirflowNetwork:Distribution:Node and/or AirflowNetwork:Multizone:Zone objects with a component defined in the object AirflowNetwork:Distribution:Component. The solid arrows show a reference from object A to object B. The dashed arrows indicate the components which can be used in a linkage object. The red arrows pointing to the Zone object indicate the components that interact with the zone air. For example, the temperature in a zone where a supply leak terminates is used to calculate duct leakage energy loss. The temperature in a zone where a duct component is located is also used to calculate duct conduction loss.

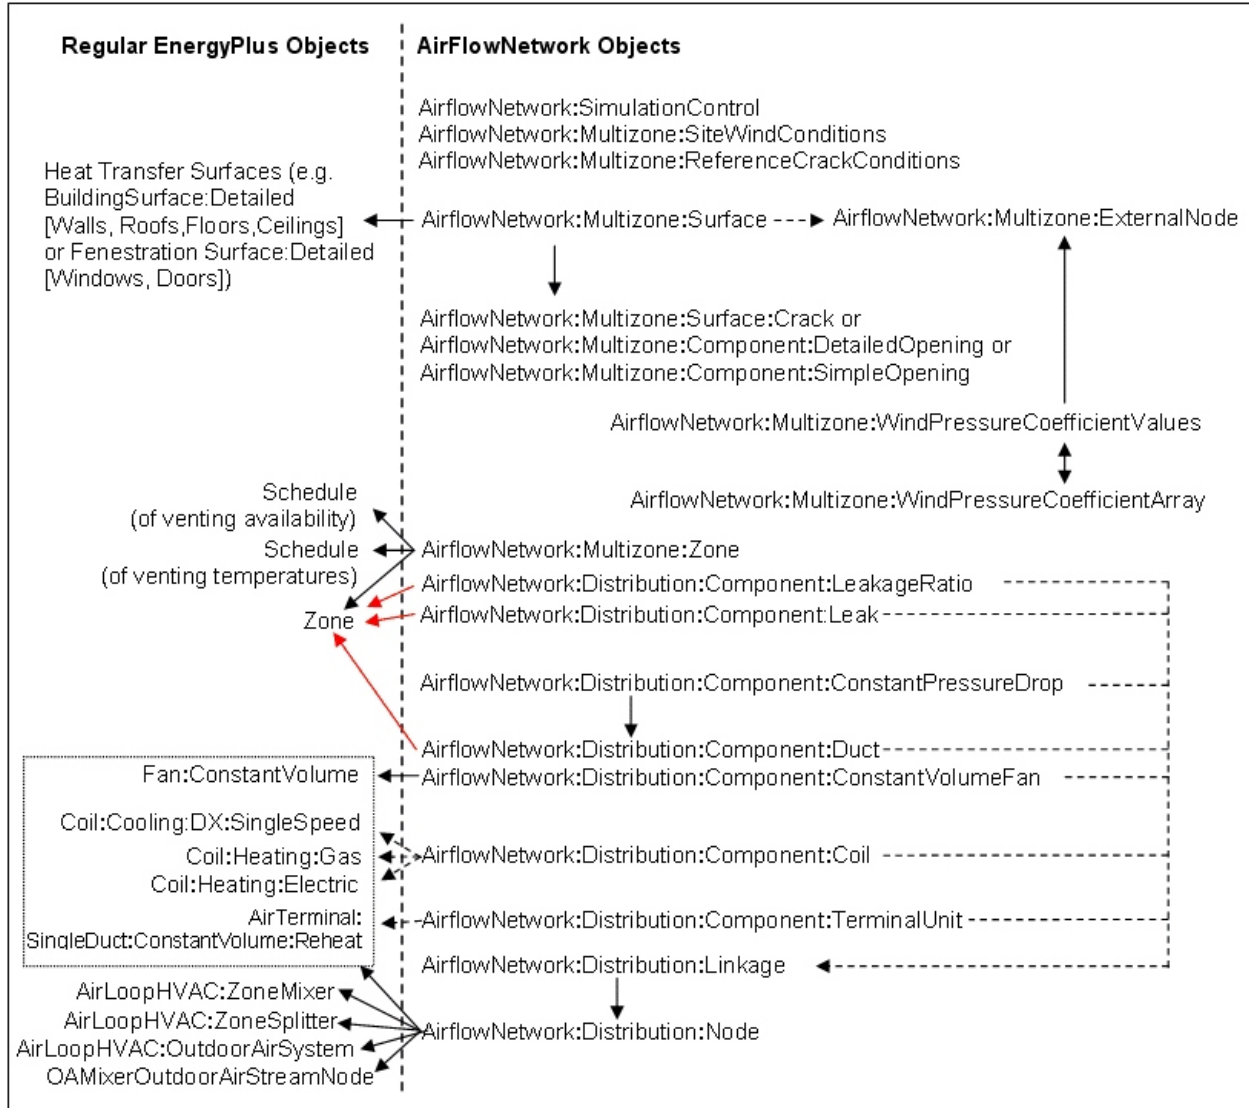

Figure 76. Relationships among AirflowNetwork objects (right-hand side) and between AirflowNetwork objects and regular EnergyPlus objects. An arrow from object A to object B means that A references B.

Much of the information needed for the air flow calculation is automatically extracted from the building description for thermal modeling. This includes things like the volume and neutral height of the zones, and the orientation and location of the building surfaces that contain cracks or openings through which air flows. From all of this information the program creates a “pressure-flow network” that is solved each timestep using iterative solution methods to obtain the unknown pressures and air flows.

Figure 77 shows a plan view of a very simple air flow network that you can construct using the above AirflowNetwork objects. There are three thermal zones, Zone-1, Zone-2 and Zone-3. There are openable exterior windows—Window-1, Window-2 and Window-3—and

openable interior doors—Door-12 and Door-23. Two External Nodes are indicated. ExternalNode-1 is associated with the façade that contains Window-1 and Window-2. ExternalNode-2 is associated with the façade containing Window-3.

One possible air flow pattern is shown in this figure. The actual air flow pattern in a particular timestep, and the size of the flows, depends on many factors, such as (1) What is the wind pressure distribution seen by the exterior windows? (2) Are the exterior windows open or closed, and if open, how far are they open? (3) Are the interior doors open or closed? (4) What are the air temperature differences between zones and between zones and the outdoor air (which affect buoyancy flows)?

Figure 77. Plan view of a simple air flow network showing a possible air flow pattern in which all of the windows and doors are open.

Figure 77 shows a possible air flow pattern in which all of the windows and doors are open. Associated with the external nodes are wind pressure coefficient distributions as a function of wind direction that are input using two `AirflowNetwork:Multizone:Wind Pressure Coefficient` objects. The nature of the air flows through the windows and doors is specified using `AirflowNetwork:MultiZone:Component:DetailedOpening` and `AirflowNetwork:MultiZone:Component:SimpleOpening` objects. The Airflow Network model calculates the flows each system timestep depending on various factors, including wind direction and speed, size and vertical position of openings, outdoor air temperature, and zone air temperatures.

What the Airflow Network Model Can and Cannot Do

Here is a list of some of the things that the Airflow Network calculation can and cannot model.

Can Do

- 1)** Air flow through cracks in exterior or interzone surfaces.
- 2)** Air flow through cracks around windows and doors when closed.
- 3)** Natural ventilation (i.e., air flow through open or partially open exterior windows and doors).
- 4)** Zone level control of natural ventilation (all windows/doors in a zone that are defined with a component opening object have identical controls).
- 5)** Individual surface control of natural ventilation for a subsurface (window, door, or glassdoor).
- 6)** Modulation of natural ventilation to prevent large zone air temperature swings.
- 7)** Interzone air flow (i.e., air flow through open interzone windows and doors, and through cracks in interzone surfaces).
- 8)** Dependence of air flow on buoyancy effects and wind pressure.
- 9)** Dependence of wind pressure on wind speed, wind direction and surface orientation.
- 10)** Supply and return air leaks in an air distribution system.
- 11)** Account for the effect of supply-air and/or return-air leakage on zone pressure when a forced air distribution system is present and is operating.
- 12)** When duct leakage is modeled and the HVAC system is on, interzone airflow or infiltration/exfiltration can occur due to changes in zone pressure.
- 13)** Bi-directional flow through large vertical openings. See discussion below under AirflowNetwork:MultiZone:Component:DetailedOpening and AirflowNetwork:Multizone:Component:SimpleOpening.
- 14)** Calculate air flows and pressures in ducts or other components of a forced air distribution system.
- 15)** Calculate zone loads when the supply air fan cycles on and off during a system timestep using the CyclingFanAndCompressor fan operation mode (Fan:OnOff).
- 16)** Determine the impact of zone exhaust fans on air flows, pressures, air temperatures/humidity levels and energy consumption.

Cannot Do or Restricted

- 1)** The model is restricted to using a constant volume fan (Fan:ConstantVolume and Fan:OnOff) and cannot model variable volume fan equipment.
- 2)** Air circulation and/or air temperature stratification within a thermal zone. For example, you should not try to divide a high space, such as an atrium, into subzones separated by artificial horizontal surfaces that have cracks or openings with the expectation that AirflowNetwork will give you a realistic temperature in each subzone and/or a realistic air flow between subzones.
- 3)** The model is restricted to eleven types of coils that can be in the air distribution system (Coil:Cooling:DX:SingleSpeed, Coil:Heating:Gas, Coil:Heating:Electric, Coil:Heating:DX:SingleSpeed, Coil:Cooling:Water, Coil:Heating:Water, Coil:Cooling:Water:DetailedGeometry, Coil:Cooling:DX:TwoStageWithHumidityControlMode, Coil:Cooling:DX:MultiSpeed, Coil:Heating:DX:MultiSpeed, and Coil:Heating:Desuperheater).

- 4) The model is restricted to a single type of air distribution equipment terminal units (AirTerminal:SingleDuct:ConstantVolume:Reheat).
- 5) Pollutant transport cannot currently be modeled.
- 6) Supply and return leaks are not allowed in an AirLoopHVAC. They can only be modeled in the Zone Equipment portion of the air loop (i.e., return leaks may be modeled between the zone return node and the zone mixer inlet or the zone mixer outlet and the zone equipment loop outlet; and supply leaks may be modeled between the zone equipment loop inlet and the AirLoopHVAC:ZoneSplitter inlet node or the AirLoopHVAC:ZoneSplitter outlet node and the zone supply node).
- 7) An air distribution system must be located inside the building (i.e., the ducts must pass through zones within the building).
- 8) Zone exhaust fans must be defined in ZoneHVAC:EquipmentConnections objects.

The input specifications consist of five main sections: **AirflowNetwork:SimulationControl object**, **AirflowNetwork multizone data objects**, **AirflowNetwork distribution node objects**, **AirflowNetwork distribution component objects**, and **AirflowNetwork distribution linkage objects**. Each of these object types is described in detail below.

AirflowNetwork:SimulationControl

The basic run parameters for this model are defined in this unique object which has the following input specifications:

Field: Name

This is a unique character string associated with this instance of the AirflowNetwork:SimulationControl object. At this time, only one AirflowNetwork:SimulationControl object can be specified in an input data file (idf).

Field: AirflowNetwork Control

The following selections are available to control the Airflow Network simulation:

MultizoneWithDistribution: Multizone air flow calculations are performed during all simulation timesteps, including the impacts of the air distribution system when a HVAC system fan is operating. Any **ZoneInfiltration**, **ZoneVentilation**, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are not simulated.

MultizoneWithoutDistribution: Multizone air flow calculations are performed during all simulation timesteps, but the air distribution system portion of the network is not modeled even if it is specified in the input data file. Any **ZoneInfiltration**, **ZoneVentilation**, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are not simulated.

MultizoneWithDistributionOnlyDuringFanOperation: Multizone air flow calculations, including the impacts of the air distribution system, are only performed when the HVAC system fan is operating. Any **ZoneInfiltration**, **ZoneVentilation**, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are used when the HVAC system fan is OFF (if none are specified, then no air flow calculations are performed when the fan is OFF).

NoMultizoneOrDistribution: No multizone air flow calculations (with or without the air distribution system portion of the network) are performed during the simulation. Any **ZoneInfiltration**, **ZoneVentilation**, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are simulated (if none are specified, then no air flow calculations are performed). Note: Having an input data file with no AirflowNetwork:SimulationControl objects gives the same impact – no multizone air flow calculations. However, this choice is provided as a convenience to the user to easily disable the multizone air flow calculations for an input data file that already contains AirflowNetwork objects.

Field: Wind Pressure Coefficient Type

Determines whether the wind pressure coefficients are input by the user or calculated. The choices are **Input** or **SurfaceAverageCalculation**, with the default being SurfaceAverageCalculation.

If INPUT, you must enter an AirflowNetwork:MultiZone:WindPressureCoefficientArray object, one or more AirflowNetwork:MultiZone:ExternalNode objects, and one or more AirflowNetwork:MultiZone:WindPressureCoefficientValues objects.

The second choice, SurfaceAverageCalculation, should only be used for **rectangular** buildings. In this case surface-average wind pressure coefficients vs. wind direction are calculated by the program for the four vertical facades and the roof based on user entries for “Building Type,” “Azimuth Angle of Long Axis of Building,” and “Ratio of Building Width Along Short Axis to Width Along Long Axis” (see description of these fields below). With this choice you do **not** have to enter any of the following objects: AirflowNetwork:MultiZone: Wind Pressure Coefficient Array, AirflowNetwork:MultiZone:ExternalNode and AirflowNetwork:MultiZone:WindPressureCoefficientValues.

Field: AirflowNetwork Wind Pressure Coefficient Array Name

This is the name of the AirflowNetwork:MultiZone:WindPressureCoefficientArray object that contains wind directions corresponding to the wind pressure coefficients given in the AirflowNetwork:MultiZone:WindPressureCoefficientValues objects.

A value need be entered only if Wind Pressure Coefficient Type = INPUT (see description of previous field).

Field: Height Selection for Local Wind Speed Calculation

Determines whether the local wind speed is calculated based on either given external node heights or surface opening heights. The choices are **ExternalNode** or **OpeningHeight**, with the default being OpeningHeight. The local outdoor wind speed calculation procedure is given in the section of “Local Wind Speed Calculation” in the Engineering Reference. The calculation procedure requires the height input.

If **ExternalNode**, the heights given in the AirflowNetwork:MultiZone:ExternalNode objects are used to calculate local wind speeds. Used only if Wind Pressure Coefficient Type = INPUT (see description of previous field).

If **OpeningHeight**, the number of the AirflowNetwork:MultiZone:ExternalNode objects has to be equal to the number of external surfaces defined in the AirflowNetwork:MultiZone:Surface objects. The centroids in the z direction of the AirflowNetwork:MultiZone:Surface objects are the heights used in the local wind speed calculation. The input is required if Wind Pressure Coefficient Type = INPUT (see description of previous field).

If Wind Pressure Coefficient Type = **SurfaceAverageCalculation**, a value in this field is not required and a blank may be entered. The default choice is used internally to generate the AirflowNetwork:MultiZone:ExternalNode objects

Field: Building Type

Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The choices for Building Type are LowRise and HighRise, with the default being LowRise.

LowRise corresponds to a rectangular building whose height is less than three times the width of the footprint (w_{short} in Figure 78) and is less than three times the length of the footprint (w_{long} in the same figure).

HighRise corresponds to a rectangular building whose height is more than three times the width of the footprint (w_{short} in Figure 78) or is more than three times the length of the footprint (w_{long} in the same figure).

Field: Maximum Number of Iterations

The maximum number of iterations allowed in finding an AirflowNetwork solution. If the number of iterations at each simulation timestep is above the maximum number of iterations defined by this field, the program could not find the solution and a Severe error is issued and the program is aborted. The default value is 500.

Field: Initialization Type

Designates which method is used for AirflowNetwork initialization. The choices for Initialization Type are LinearInitializationMethod and ZeroNodePressures, with the default being ZeroNodePressures.

Field: Relative Airflow Convergence Tolerance

The solution is assumed to have converged when $\left| \frac{\sum \dot{m}_i}{\sum |\dot{m}_i|} \right|$ is less than the value specified for this input field. This convergence criteria is equivalent to the ratio of the absolute value of the sum of all network airflows ($\left| \sum \dot{m}_i \right|$) to the sum of network airflow magnitudes ($\sum |\dot{m}_i|$). The default value is 1.0×10^{-4} .

Field: Absolute Airflow Convergence Tolerance

The solution is assumed to have converged when the summation of the absolute value of all network airflows ($\sum |\dot{m}_i|$) is less than the value specified for this input field. The default value is 1.0×10^{-6} .

Field: Convergence Acceleration Limit

If the ratio of successive pressure corrections is less than this limit, use Steffensen acceleration algorithm (Ref. AirflowNetwork Model in the EnergyPlus Engineering Reference). The range for this field is -1 to 1, with the default value being -0.5.

Field: Azimuth Angle of Long Axis of Building

Gives the orientation of a rectangular building for calculating wind pressure coefficients. This is the smaller of the angles, measured clockwise, between North and the long axis of the building (see Figure 78). Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The range for this input is 0 to 180, with the default value being 0.

Field: Ratio of Building Width Along Short Axis to Width Along Long Axis

This is the aspect ratio of a rectangular footprint. It is given by the width of the footprint along its short axis divided by the width along the long axis (see Figure 78). If the footprint is square, the value of this field is 1.0. Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The range for this input is > 0 to 1, with the default value being 1.

Figure 78. Footprint of a rectangular building showing variables used by the program to calculate surface-average wind pressure coefficients. The angle α is the “Azimuth Angle of Long Axis of Building.”
 W_{short}/W_{long} is the “Ratio of Building Width Along Short Axis to Width Along Long Axis.”

Below is the input data dictionary description for the AirflowNetwork:SimulationControl object.

AirflowNetwork:Multizone data objects are used to calculate multizone airflows. This section describes the input requirements for the following objects:

- AirflowNetwork:MultiZone:Zone

AirflowNetwork:Multizone data objects are used to calculate multizone airflows. This section describes the input requirements for the following objects:

- AirflowNetwork:MultiZone:Zone
- AirflowNetwork:MultiZone:Surface
- AirflowNetwork:MultiZone:Surface:Crack
- AirflowNetwork:MultiZone:ReferenceCrackConditions
- AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea
- AirflowNetwork:MultiZone:Component:DetailedOpening
- AirflowNetwork:MultiZone:Component:SimpleOpening
- AirflowNetwork:MultiZone:Component:ZoneExhaustFan
- AirflowNetwork:MultiZone:ExternalNode
- AirflowNetwork:MultiZone:WindPressureCoefficientArray
- AirflowNetwork:MultiZone:WindPressureCoefficientValues

A detailed description for each of these objects is provided below.

AirflowNetwork:Multizone:Zone

This object allows control of natural ventilation through exterior and interior openings in a zone, where “opening” is defined as an openable window or door. (Note that only window, door or glass door subsurfaces in a zone that are specified using AirflowNetwork:MultiZone:Component:DetailedOpening or AirflowNetwork:Multizone:Component:SimpleOpening and have an associated AirflowNetwork:Multizone:Surface object are considered to be openings). The control will be applied in the same way to all of the openings in the zone.

This object is required to perform Airflow Network calculations. Note that ventilation control for all openings is provided at the zone level as default and individual ventilation control of a surface opening can be used to override the zone-level control (see the AirflowNetwork:Multizone:Surface object description below).

Field: Zone Name

The name of the EnergyPlus thermal zone corresponding to the AirflowNetwork zone.

Field: Ventilation Control Mode

Specifies the type of zone-level natural ventilation control.

Let T_{out} equal the outdoor air temperature, T_{zone} equal the previous timestep's zone air temperature, T_{set} equal the Vent Temperature Schedule value, H_{zone} equal the specific enthalpy of zone air from the previous timestep, and H_{out} equal the specific enthalpy of outdoor air. Then the four allowed choices for Ventilation Control Mode are:

NoVent: All of the zone's openable windows and doors are closed at all times independent of indoor or outdoor conditions. The Venting Availability Schedule is ignored in this case. This is the default value for this field.

Temperature: All of the zone's openable windows and doors are opened if $T_{zone} > T_{out}$ **and** $T_{zone} > T_{set}$ **and** Venting Availability Schedule (see below) allows venting.

Enthalpy: All of the zone's openable windows and doors are opened if $H_{zone} > H_{out}$ **and** $T_{zone} > T_{set}$ **and** Venting Availability Schedule allows venting.

Constant: Whenever this object's Venting Availability Schedule allows venting, all of the zone's openable windows and doors are open, independent of indoor or outdoor conditions. Note that "Constant" here means that the size of each opening is fixed while venting; the air flow through each opening can, of course, vary from timestep to timestep.

Field: Ventilation Control Zone Temperature Setpoint Schedule Name

The name of a schedule of zone air temperature set points that controls the opening of windows and doors in the thermal zone to provide natural ventilation. This setpoint is the temperature above which all the openable windows and doors in the zone will be opened if the conditions described in the previous field Ventilation Control Mode are met.

The Ventilation Control Zone Temperature Setpoint Schedule Name applies only to windows and doors in the zone that are specified using AirflowNetwork:MultiZone:Component:DetailedOpening or AirflowNetwork:MultiZone:Component:SimpleOpening and have an associated AirflowNetwork:MultiZone:Surface object.

(The discussion under the field Window/Door Opening Factor in the AirflowNetwork:MultiZone:Surface object describes how the actual opening area of a window or door in a particular timestep is determined.)

Modulation of Openings

The following five fields can be used to modulate the window/door openings when Ventilation Control Mode = Temperature or Enthalpy. These fields determine a factor between 0 and 1 that multiplies the opening factor of each window and door in the zone according to the control action shown in Figure 79 for Ventilation Control Mode = Temperature and in Figure 80 for Ventilation Control Mode = Enthalpy. Modulation of the openings can reduce the large temperature swings that can occur if the windows/doors are open too far when they are venting, especially when there is a large inside-outside temperature difference.

The modulation takes the following form when Ventilation Control Mode = Temperature:

$$T_{zone} - T_{out} \leq [\text{Lower Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor}] \rightarrow \text{Multiplication factor} = 1.0$$

$$[\text{Lower Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor}] < T_{zone} - T_{out} < [\text{Upper Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor}] \rightarrow \text{Multiplication factor} < 1.0$$

Open Factor] → Multiplication factor varies linearly from 1.0 to [Limit Value on Multiplier for Modulating Venting Open Factor]

$T_{\text{zone}} - T_{\text{out}} \geq$ [Upper Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor] → Multiplication factor = [Limit Value on Multiplier for Modulating Venting Open Factor]

One way of “tuning” the following modulation control parameters is to perform a sensitivity analysis for winter and/or summer design days to determine what combination of values causes the biggest reduction in zone air temperature fluctuations due to venting.

Note that the default values for the following fields are such that, if none of the fields are specified, the default values are assigned.

Field: Minimum Venting Open Factor

See Figure 79 or Figure 80. This field applies only if Ventilation Control Mode = Temperature or Enthalpy. This value may be from zero to 1.0, with the default being 0.0.

Field: Indoor and Outdoor Temperature Difference Lower Limit For Maximum Venting Open Factor

See Figure 79. This field applies only if Ventilation Control Mode = Temperature. This value may be from zero to less than 100°C, with the default being 0°C. The value for this field must be less than the value specified for the following field.

Field: Indoor and Outdoor Temperature Difference Upper Limit for Minimum Venting Open Factor

See Figure 79. This field applies only if Ventilation Control Mode = Temperature. This value must be greater than 0°C, with the default being 100°C. The value for this field must be greater than the value specified for the previous field.

Field: Indoor and Outdoor Enthalpy Difference Lower Limit For Maximum Venting Open Factor

See Figure 80. This field applies only if Ventilation Control Mode = Enthalpy. This value may be from zero to less than 300,000 J/kg, with the default being 0 J/kg. The value for this field must be less than the value specified for the following field.

Field: Indoor and Outdoor Enthalpy Difference Upper Limit for Minimum Venting Open Factor

See Figure 80. This field applies only if Ventilation Control Mode = Enthalpy. This value must be greater than zero, with the default being 300,000 J/kg. The value for this field must be greater than the value specified for the previous field.

Field: Venting Availability Schedule Name

The name of a schedule that specifies when venting is available. A zero or negative schedule value means venting is not allowed. A value greater than zero means venting can occur if other venting control conditions (specified by Ventilation Control Mode and Vent Temperature Schedule Name) are satisfied. This schedule name should not be confused with Vent Temperature Schedule Name.

If a Venting Availability Schedule Name is not specified, it is assumed that venting is always available.

Using Venting Availability Schedule allows you to turn off venting at certain times of the day (at night, for example), of the week (on weekends, for example), or of the year (during the winter, for example).

If used with Ventilation Control Mode = Constant, the ventilation rate is constant only when this schedule allows venting; otherwise the ventilation rate is set to zero.

If Ventilation Control Mode = NoVent, this schedule has no effect.

Figure 79. Modulation of venting area according to inside-outside temperature difference.

Figure 80. Modulation of venting area according to inside-outside enthalpy difference.

Note: In order to establish an airflow network, each AirflowNetwork:Multizone:Zone object must have at least two surfaces defined with AirflowNetwork:Multizone:Surface objects, so that air can flow from one

zone into other zones (or to outdoors) through the network (air mass flow conserved). In addition, for all AirflowNetwork:Multizone:Surface objects facing the same Zone (ref. BuildingSurface:Detailed), at least two different environments must be defined for the other side of these surfaces (e.g., an external node and an adjacent zone, two adjacent zones, or two external nodes).

Below is the input data dictionary description for the AirflowNetwork:Multizone:Zone object.

AirflowNetwork:Multizone:Surface

The AirflowNetwork:Multizone:Surface object specifies the properties of a surface “linkage” through which air flows. This linkage is always associated with a heat transfer surface (wall, roof, floor, or a ceiling) or subsurface (door, glass door, or window) with both faces exposed to air. The linkage specifies two connected nodes: two zone nodes defined in AirflowNetwork:MultiZone:Zone objects based on inside and outside face environment for an interior surface, or a zone node defined in an AirflowNetwork:MultiZone:Zone object based on inside face environment and an external node defined in an AirflowNetwork:MultiZone:ExternalNode object for an exterior surface. The associated leakage component for this surface can be a crack (or surface effective leakage area) in an exterior or interior heat transfer surface or subsurface, or an exterior or interior window, door

or glass door (heat transfer subsurface) that can be opened to allow air flow. The allowed surface air leakage components are:

- AirflowNetwork:MultiZone:Surface:Crack
- AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea
- AirflowNetwork:MultiZone:Component:DetailedOpening
- AirflowNetwork:MultiZone:Component:SimpleOpening
- AirflowNetwork:MultiZone:Component:ZoneExhaustFan

The two “opening” components are used to modulate openness based on required conditions.

The AirflowNetwork:Multizone:Surface object allows a heat transfer surface or subsurface to have one crack (or one surface effective leakage area object), or a subsurface (i.e., window, door or glass door) to have one opening (detailed or simple).

An interior heat transfer surface (BuildingSurface:Detailed) whose surface name is used as the input for the Outside Boundary Condition Object field represents a floor without ground contact and is not allowed as an AirflowNetwork:Multizone:Surface. A heat transfer surface defined in the BuildingSurface:Detailed:ExteriorNaturalVentedCavity is also not allowed.

Field: Surface Name

This is the name of the corresponding surface (wall, roof, ceiling, floor, window, door or glass door).

Information on this surface is used by the program as follows:

- (1) For a linkage associated with an exterior heat transfer surface: air flow through this linkage is between the outside environment and the thermal zone to which the surface belongs.
- (2) For a linkage associated with an interior (i.e., interzone) heat transfer surface: air flow through this linkage is between the thermal zones separated by the surface (i.e., the thermal zone associated with the inside face environment and the thermal zone associated with the outside face environment).
- (3) This heat transfer surface determines the height of the linkage, which is used in calculating buoyancy-related flow through the linkage.

Note: It is possible to define an interzone surface twice in EnergyPlus, once in each of the zones that the surface separates. Previously this was a requirement of EnergyPlus (prior to version 2.0), but now it is optional and the user also has the option of only defining the surface once (EnergyPlus defines the second surface automatically within the program). For each interzone surface, use only one (of possible two) interzone surface names in the AirflowNetwork:Multizone:Surface object for “Surface Name.” **Do not** enter two AirflowNetwork:Multizone:Surface objects corresponding to the two possible interzone names. This would cause the air flow through the surface to be counted twice.

Field: Leakage Component Name

The name of the AirflowNetwork:MultiZone:Surface:Crack, AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea, AirflowNetwork:MultiZone:Component:SimpleOpening, AirflowNetwork:MultiZone:Component:DetailedOpening or AirflowNetwork:MultiZone:Component:ZoneExhaustFan object associated with this air flow linkage.

If the name of an AirflowNetwork:MultiZone:Component:DetailedOpening or AirflowNetwork:MultiZone:Component:SimpleOpening is given here, then the Surface Name in the previous field must be that of a window, door or glass door heat transfer subsurface. Otherwise an error message will be reported.

If the name of an AirflowNetwork:MultiZone:Surface:Crack object or AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea object is given here, the program will position the crack at the average height of the associated heat transfer surface or subsurface. The user can define multiple heat transfer surfaces (e.g., split a wall into several surfaces) to be more precise in establishing the crack location. Similarly, the user can define multiple heat transfer surfaces if a wall, for example, has multiple cracks or openings that need to be defined individually.

If the name of an AirflowNetwork:MultiZone:Component:ZoneExhaustFan is given here, then the Surface Name in the previous field must be that of an exterior heat transfer surface. The zone name defined in the Zone Name field for this heat transfer surface must be the same zone name defined in the ZoneHVAC:EquipmentConnections object (which references a ZoneHVAC:EquipmentList containing the name of the corresponding zone exhaust fan). Otherwise an error message will be reported. When this zone exhaust fan is operating for a simulation timestep, all surface-level controls described below are ignored for that timestep.

Field: External Node Name

The name of the associated AirflowNetwork:MultiZone:ExternalNode object, which determines the wind pressure coefficients for the heat transfer surface. Used only if Surface Name is for an exterior surface.

If Wind Pressure Coefficient Type = SurfaceAverageCalculation in the AirflowNetwork:SimulationControl object, this field is not used and a blank may be entered. If the surface is an interior (i.e., interzone) surface, leave this field blank.

Field: Window/Door Opening Factor, or Crack Factor

If this linkage is associated with an AirflowNetwork:MultiZone:Component:DetailedOpening or AirflowNetwork:MultiZone:Component:SimpleOpening object (which means it is an openable window or door), then this field is called “Window/Door Opening Factor” and represents the value of the Opening Factor that is in effect when the Vent Temperature Schedule (defined in the AirflowNetwork:MultiZone:Zone object) indicates that this window or door is open.

The AirflowNetwork model uses a combination of factors to determine the actual opening area for a window or door when it is venting. For example, consider a window that is 1.5m high and 2.0m wide (excluding frame). Assume that the AirflowNetwork:MultiZone:Component:DetailedOpening for this window has Type of Large Vertical Opening = 1 (non-pivoting window), Height Factor = 0.5 and Width Factor = 0.8. Then when the window is fully open, the opening area = height of opening (0.5x1.5) times width of opening (0.8x2.0) = 0.75x1.6 = 1.2 m². If the Window/Door Opening Factor is 0.75, then the opening area = 0.75x1.2 = 0.9 m².

If, in addition, the window is in a thermal zone for which opening modulation has been specified (ref: AirflowNetwork:MultiZone:Zone) and the multiplication factor due to modulation is 0.3 in a particular timestep, then the actual opening factor that timestep = 0.3x0.75 = 0.225 and the actual opening area that timestep = 0.3x0.9 = 0.27 m².

If this linkage is associated with an AirflowNetwork:MultiZone:Surface:Crack object, the following crack air flow equation is used.

$$Q = (\text{Crack Factor}) * C_T * C_Q (\Delta P)^n$$

Where

Q = air mass flow (kg/s)

C_Q = air mass flow coefficient (kg/s @ 1 Pa)

C_T = reference condition temperature correction factor (dimensionless). See AirflowNetwork:MultiZone:Surface:Crack object.

ΔP = pressure difference across crack (Pa)

n = air flow exponent (dimensionless)

The following fields control venting. They are used only when Name of Associated Heat Transfer Surface is that of an openable exterior or interior window, door or glass door. They only apply to openings, and do not apply to surface cracks, effective leakage area or zone exhaust fans. If none of these fields is specified, or if Ventilation Control Mode = ZoneLevel, venting is controlled by the AirflowNetwork:Multizone:Zone object for the thermal zone containing the window or door (ref: AirflowNetwork:Multizone:Zone Data).

Field: Ventilation Control Mode

Specifies the type of surface-level natural ventilation control.

Let T_{out} equal the outdoor air temperature, T_{zone} equal the previous timestep's zone air temperature, T_{set} equal the Vent Temperature Schedule value, H_{zone} equal the specific enthalpy of zone air from the previous timestep, and H_{out} equal the specific enthalpy of outdoor air. Then the four allowed choices for Ventilation Control Mode are:

NoVent: The openable window or door associated with this surface is closed at all times independent of indoor or outdoor conditions. The Venting Availability Schedule is ignored in this case.

Temperature: The openable window or door associated with this surface is opened if $T_{zone} > T_{out}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule (see below) allows venting.

Enthalpy: The openable window or door associated with this surface is opened if $H_{zone} > H_{out}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule allows venting.

Constant: Whenever this object's Venting Availability Schedule allows venting, the openable window or door associated with this surface is open, independent of indoor or outdoor conditions. Note that "Constant" here means that the size of this opening is fixed while venting; the air flow through this opening can, of course, vary from timestep to timestep.

ZoneLevel: Venting of the window or door is not controlled individually, but is controlled instead at the zone level. This means that the venting is determined by the AirflowNetwork:Multizone:Zone object for the thermal zone containing the window or door (ref: AirflowNetwork:Multizone:Zone object). This is the default value for this field.

AdjacentTemperature: This choice is used for an interior surface only. The openable interior window or door associated with this surface is opened if $T_{zone} > T_{adjacent\ zone}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule (see below) allows venting, where $T_{adjacent\ zone}$ is the adjacent zone temperature.

AdjacentEnthalpy: This choice is also used for an interior surface only. The interior openable window or door associated with this surface is opened if $H_{zone} > H_{adjacent\ zone}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule allows venting, where $H_{adjacent\ zone}$ is the adjacent zone specific enthalpy.

Field: Ventilation Control Zone Temperature Setpoint Schedule Name

The name of a schedule of zone air temperature set points that controls the opening of a window or door associated with this surface to provide natural ventilation. This setpoint is the temperature above which this openable window or door will be opened if the conditions described in the previous field Ventilation Control Mode are met.

The Ventilation Control Zone Temperature Setpoint Schedule applies only to a window or door attached to this surface that is specified using

AirflowNetwork:MultiZone:Component:DetailedOpening or
 AirflowNetwork:MultiZone:Component:SimpleOpening.

(The discussion under the field Window/Door Opening Factor in this object describes how the actual opening area of a window or door in a particular timestep is determined.)

Modulation of Openings

The following five fields can be used to modulate this window/door opening when Ventilation Control Mode = Temperature or Enthalpy. These fields determine a factor between 0 and 1 that multiplies the opening factor of this window or door according to the control action shown in Figure 79 for Ventilation Control Mode = Temperature and in Figure 80 for Ventilation Control Mode = Enthalpy. Modulation of this opening can reduce the large temperature swings that can occur if the window/door is open too far when it is venting, especially when there is a large inside-outside temperature difference.

The modulation takes the following form when Ventilation Control Mode = Temperature:

$T_{\text{zone}} - T_{\text{out}} \leq [\text{Lower Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor}] \rightarrow \text{Multiplication factor} = 1.0$

$[\text{Lower Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor}] < T_{\text{zone}} - T_{\text{out}} < [\text{Upper Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor}] \rightarrow \text{Multiplication factor varies linearly from 1.0 to } [\text{Limit Value on Multiplier for Modulating Venting Open Factor}]$

$T_{\text{zone}} - T_{\text{out}} \geq [\text{Upper Value on Inside/Outside Temperature Difference for Modulating the Venting Open Factor}] \rightarrow \text{Multiplication factor} = [\text{Limit Value on Multiplier for Modulating Venting Open Factor}]$

One way of “tuning” the following modulation control parameters is to perform a sensitivity analysis for winter and/or summer design days to determine what combination of values causes the biggest reduction in zone air temperature fluctuations due to venting.

Note that the default values for the following fields are such that, if none of the fields are specified, modulation will not occur.

Field: Minimum Venting Open Factor

See Figure 79 or Figure 80. This field applies only if Ventilation Control Mode = Temperature or Enthalpy. This value may be from zero to 1.0, with the default being 0.0.

Field: Indoor and Outdoor Temperature Difference Lower Limit For Maximum Venting Open Factor

See Figure 79. This field applies only if Ventilation Control Mode = Temperature. This value may be from zero to less than 100°C, with the default being 0°C. The value for this field must be less than the value specified for the following field.

Field: Indoor and Outdoor Temperature Difference Upper Limit for Minimum Venting Open Factor

See Figure 79. This field applies only if Ventilation Control Mode = Temperature. This value must be greater than 0°C, with the default being 100°C. The value for this field must be greater than the value specified for the previous field.

Field: Indoor and Outdoor Enthalpy Difference Lower Limit For Maximum Venting Open Factor

See Figure 80. This field applies only if Ventilation Control Mode = Enthalpy. This value may be from zero to less than 300,000 J/kg, with the default being 0 J/kg. The value for this field must be less than the value specified for the following field.

Field: Indoor and Outdoor Enthalpy Difference Upper Limit for Minimum Venting Open Factor

See Figure 80. This field applies only if Ventilation Control Mode = Enthalpy. This value must be greater than zero, with the default being 300,000 J/kg. The value for this field must be greater than the value specified for the previous field.

Field: Venting Availability Schedule Name

The name of a schedule that specifies when venting is available. A zero or negative schedule value means venting is not allowed. A value greater than zero means venting can occur if other venting control conditions (specified by Ventilation Control Mode and Vent Temperature Schedule Name) are satisfied. This schedule name should not be confused with Vent Temperature Schedule Name.

If a Venting Availability Schedule Name is not specified, it is assumed that venting is always available.

Using Venting Availability Schedule allows you to turn off venting at certain times of the day (at night, for example), week (on weekends, for example), or year (during the winter, for example).

If used with Ventilation Control Mode = Constant, the ventilation rate is constant only when this schedule allows venting; otherwise the ventilation rate is set to zero.

If Ventilation Control Mode = NoVent, this schedule has no effect.

Note: In order to establish an airflow network, each AirflowNetwork:Multizone:Zone object must have at least two surfaces defined with AirflowNetwork:Multizone:Surface objects, so that air can flow from one zone into other zones (or to outdoors) through the network (air mass flow conserved). In addition, for all AirflowNetwork:Multizone:Surface objects facing the same Zone Name (ref. BuildingSurface:Detailed), at least two different environments must be defined for the other side of these surfaces (e.g., an external node and an adjacent zone, two adjacent zones, or two external nodes).

Below is the input data dictionary description for the AirflowNetwork:Multizone: Surface object.

```

AirflowNetwork:MultiZone:Surface,
  \min-fields 4

AirflowNetwork:MultiZone:ReferenceCrackConditions

This object specifies the reference conditions for temperature, humidity, and pressure which correspond to the AirflowNetwork:MultiZone:Surface:Crack object.

Field: Name

The name of this Reference Crack Conditions object. This name is referenced by an AirflowNetwork:MultiZone:Surface:Crack object.

Field: Reference Temperature

The reference temperature in °C under which the Surface Crack Data were obtained. The default value is 20°C.

Field: Reference Barometric Pressure

The reference barometric pressure in Pa under which the Surface Crack Data were obtained. The default value is 101325 Pa.

Field: Reference Humidity Ratio

The reference humidity ratio in kg/kg under which the Surface Crack Data were obtained. The default value is 0 kg/kg.

Below is the input data dictionary description for the AirflowNetwork:MultiZone:ReferenceCrackConditions object.

```

```

AirflowNetwork:MultiZone:Surface:Crack

This object specifies the properties of air flow through a crack and the associated measurement conditions. The following power law form is used that gives air flow through the crack as a function of the pressure difference across the crack:

$$Q = (\text{Crack Factor}) * C_T * C_Q (\Delta P)^n$$

Where

Q = air mass flow (kg/s)

C_Q = air mass flow coefficient (kg/s-Paⁿ @ 1 Pa)

C_T = reference condition temperature correction factor (dimensionless)

ΔP = pressure difference across crack (Pa)

n = air flow exponent (dimensionless)

$$C_T = \left[\frac{\rho_o}{\rho} \right]^{n-1} \left[\frac{v_o}{v} \right]^{2n-1}$$

where

ρ = Air density at the specific air temperature and humidity ratio conditions [kg/m³]

v = Air kinetic viscosity at the specific air temperature condition [m²/s]

ρ_o = Air density at the reference air conditions provided by the object AirflowNetwork:MultiZone:ReferenceCrackConditions specified in the field Reference Crack Conditions [kg/m³]

ν_o = Air kinetic viscosity at the reference air temperature provided by the object AirflowNetwork:MultiZone:ReferenceCrackConditions specified in the field Reference Crack Conditions [m²/s]

Note: The correction factor shown above is use for this particular component as specified.

Field: Name

This is a name for this AirflowNetwork:MultiZone:Surface:Crack object. It is referenced by an AirflowNetwork:Multizone:Surface object.

Field: Air Mass Flow Coefficient at Reference Conditions

The value of the air mass flow coefficient, C_Q , in the crack air flow equation. It has units of kg/s at 1Pa. This value must be greater than zero.

Field: Air Mass Flow Exponent

The value of the exponent, n , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65.

Field: Reference Crack Conditions

The name of the AirflowNetwork:MultiZone:ReferenceCrackConditions object which specifies the conditions under which the air mass flow coefficient was measured. If the user omits this field and only one AirflowNetwork:MultiZone:ReferenceCrackConditions object is defined in the input data file, then those reference crack conditions will be used. If the user omits this field and either zero or more than one AirflowNetwork:MultiZone:ReferenceCrackConditions objects are defined in the input data file, then the default conditions for the AirflowNetwork:Multizone: Reference Crack Conditions object will be used.

Below is the input data dictionary description for the AirflowNetwork:MultiZone:Surface:Crack object.

```
AirflowNetwork:MultiZone:Surface:Crack,

ReferenceCrackConditions; !- Reference Crack Conditions

```

AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea

The effective leakage area (ELA) object is used to define surface air leakage. It has five fields. The relationship between pressure and airflow may be expressed as:

$$\dot{m} = ELA * C_d \sqrt{2\rho} * (\Delta P_r)^{0.5-n} (\Delta P)^n$$

where

\dot{m} = Air mass flow rate [kg/s]

ELA = Effective leakage area [m²]

ρ = Air density [kg/m³]

ΔP_r = Reference pressure difference [Pa]

ΔP = Pressure difference across this component [Pa]

C_d = Discharge coefficient [dimensionless]

n = Air mass flow exponent [dimensionless]

Field: Name

This is a name for this AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea object. It is referenced by an AirflowNetwork:MultiZone:Surface object.

Field: Effective Leakage Area

This numeric field is used to input the effective leakage area in square meters. The effective leakage area is used to characterize openings for infiltration calculations (ASHRAE Handbook of Fundamentals, 1997, pp 25.18). This value must be greater than zero.

Field: Discharge Coefficient

This numeric field is used to input the discharge coefficient. This value must be greater than zero, with a default value of 1.0.

Field: Reference Pressure Difference

This numeric field is used to input the reference pressure difference [Pa]. This value must be greater than zero, with a default value of 4.0 Pa.

Field: Air Mass Flow Exponent

This numeric field is used to input the pressure difference exponent. The valid range of the exponent is from 0.5 to 1.0, with a default value of 0.65.

Note: There are two common sets of reference conditions: $C_d = 1.0$ and $\Delta P = 4$ Pa, or $C_d = 0.6$ and $\Delta P = 10$ Pa

Below is the input data dictionary description for the AirflowNetwork:MultiZone: Surface Effective Leakage Area object.

```

AirflowNetwork:MultiZone:Component:DetailedOpening

This object specifies the properties of air flow through windows and doors (window, door and glass door heat transfer subsurfaces) when they are closed or open. The fields are similar to those for AirflowNetwork:MultiZone:SurfaceCrack object when the window or door is closed, but additional fields are required to describe the air flow characteristics when the window or door is open. These additional fields include opening type, opening dimensions, degree of opening, and opening schedule.

The AirflowNetwork model assumes that open windows or doors are vertical or close to vertical; for this reason they are called “Large Vertical Openings.” Such openings can have air flow moving simultaneously in two different directions depending on stack effects and wind conditions (for example, flow from inside to outside at the top of a window and from outside to inside at the bottom). AirflowNetwork models such two-directional flow, but only for vertical openings.

It is assumed that the air flow through a window opening is unaffected by the presence of a shading device such as a shade or blind on the window. Also, the calculation of conductive heat transfer and solar gain through a window or door assumes that the window or door is closed.

The AirflowNetwork model does not have a model for bi-directional flow through large horizontal openings. For this reason, **AirflowNetwork:MultiZone:Component:DetailedOpening should not be used for horizontal openings**. The best modeling technique in this case is to put an AirflowNetwork:MultiZone:Surface:Crack object in a horizontal surface and use a large air mass flow coefficient. Crack flow is assumed to be uni-directional in any given timestep (but can reverse flow direction from timestep to timestep).

A subsurface multiplier may be used to represent multiple subsurfaces and calculates total air flow when the subsurface (window, glassdoor, or door) is either closed or open. The total airflow across the surface is equal to the airflow based on the surface geometry multiplied by the subsurface multiplier.

Field: Name

The name of this AirflowNetwork:MultiZone:Component:DetailedOpening object. It is referenced by an AirflowNetwork:MultiZone:Surface object.

Field: Air Mass Flow Coefficient When Opening is Closed

Crack flow is assumed when the window or door is closed. The units for this air mass flow coefficient ($C_{Q, unit\ length}$) are different from the units for C_Q (kg/s at 1 Pa pressure difference) defined in an AirflowNetwork:MultiZone:Surface:Crack object. There is no default but the entered value must be greater than zero. The program will automatically generate four cracks around the perimeter of the window or door—one along the bottom, one along the top, and one on each side. The temperature correction factor used in the AirflowNetwork:MultiZone:Surface:Crack object is not used for this component to calculate air mass flow rate.

Field: Air Mass Flow Exponent When Opening Is Closed

Crack flow is assumed when the window or door is closed. In this case, the value of this field is the exponent, n , in the crack air flow equation. The valid range for this exponent is 0.5 to 1.0, with the default value being 0.65.

Field: Type of Rectangular Large Vertical Opening (LVO)

This alpha field specifies the type of rectangular window or door. (Open windows or doors are also called Large Vertical Openings (LVOs). The choices for the opening type are **NonPivoted** (LVO Type 1) and **HorizontallyPivoted** (LVO Type 2) with the default being **NonPivoted**. The NonPivoted type represents a regular window or door. The HorizontallyPivoted type represents a window with a horizontal axis ((i.e., a horizontally-pivoting window) and cannot be used for a door.

Field: Extra Crack Length or Height of Pivoting Axis

Specifies window or door characteristics that depend on the LVO type.

For LVO Type 1 (rectangular non-pivoted windows and doors) this field is the extra crack length in meters due to multiple openable parts, if present. “Extra” here means in addition to

the length, calculated by the program, of the cracks on the top, bottom and sides of the window/door.

For LVO Type 2 (rectangular horizontally-pivoted windows) this field gives the height of the pivoting axis measured from the bottom of the glazed part of the window (m).

Field: Number of Sets of Opening Factor Data

This is the number of the following sets of data for opening factor, discharge coefficient, width factor, height factor, and start height factor. From two to four of these sets must be defined. The first set should be for Opening Factor = 0.0 and the last set should be for Opening Factor = 1.0. For example, if only two sets are defined, the first set should be for Opening Factor = 0.0 and the second set should be for Opening Factor = 1.0, as shown below in the IDF example below.

An “opening factor” refers to the amount that a window or door is opened. The program linearly interpolates each timestep between the values of discharge coefficient, width factor, etc., in these sets using the opening factor for the window or door for the timestep. (See discussion under the field Window/Door Opening Factor in the AirflowNetwork:Multizone:Zone object for a description of how the AirflowNetwork model determines the time-step value of the opening factor.)

Field Group: Opening Factor, Discharge Coefficient, Width Factor, Height Factor, Start Height Factor

Each field is described for as many groups as required in the previous field (number of sets of opening factor data). As the final field has specific requirements, this field (n) will be described.

Field: Opening Factor 11

The first opening factor of a window or door. This value must be 0.0. The default value is also 0.0.

For LVO Type 1 (rectangular non-pivoted window or door), the Opening Factor corresponds to the fraction of window or door that is opened.

For LVO Type 2 (rectangular horizontally-pivoted windows), the Opening Factor is determined by the window opening angle. For example, an opening angle of 45° corresponds to an Opening Factor of 0.50 since the maximum opening angle is 90°.

Field: Discharge Coefficient for Opening Factor 1

The discharge coefficient of the window or door for Opening Factor 1. The range is greater than 0.0 to less than or equal to 1.0. The default value is 0.001. The Discharge Coefficient indicates the fractional effectiveness for air flow through a window or door at that Opening Factor.

Note: In the following, “window width” and “window height” are glazing dimensions; they do not include the frame, if present.

Field: Width Factor for Opening Factor 1

The Width Factor of the rectangular window or door for Opening Factor 1. The Width Factor is the opening width divided by the window or door width (see Figure 81). The range is 0.0 to 1.0. The default value is 0.0. Note that the width factor applies to rectangular windows or doors where the width is assumed constant along the entire height of the opening.

Field: Height Factor for Opening Factor 1

The Height Factor of the rectangular window or door for Opening Factor 1. The Height Factor is the opening height divided by the window or door height (see Figure 81). The range is 0.0

to 1.0. The default value is 0.0. Note that the height factor applies to rectangular windows or doors where the height is assumed constant along the entire width of the opening.

Field: Start Height Factor for Opening Factor 1

The Start Height Factor of the window or door for Opening Factor 1. The Start Height Factor is the Start Height divided by the window or door height (see Figure 81). The range is 0.0 to 1.0. The default is 0. Start Height is the distance between the bottom of the window or door and the bottom of the window or door opening. The sum of the Height Factor and the Start Height Factor must be less than 1.0 in order to have the opening within the window or door dimensions.

Figure 81. Window (or door) showing geometrical factors associated with an opening through which air flows.

Field: Opening Factor <n>

When Number of Sets of Opening Factor Data = n, the value of Opening Factor n must be set to 1.0.

Field: Discharge Coefficient for Opening Factor <n>

The discharge coefficient of the window or door for Opening Factor n. The range is greater than 0.0 to less than or equal to 1.0. The default value is 1.0.

Field: Width Factor for Opening Factor <n>

The Width Factor of the rectangular window or door for Opening Factor n. The Width Factor is the opening width divided by the window or door width (see Figure 81). The range is 0.0 to 1.0. The default value is 1.0.

Field: Height Factor for Opening Factor <n>

The Height Factor of the rectangular window or door for Opening Factor n. The Height Factor is the opening height divided by the window or door height (see Figure 81). The range is 0.0 to 1.0. The default value is 1.0.

Field: Start Height Factor for Opening Factor <n>

The Start Height Factor of the window or door for Opening Factor n. The Start Height Factor is the Start Height divided by the window or door height (see Figure 81). The range is 0.0 to 1.0. The default is 0.

When the opening factor value (as described under the field Window/Door Opening Factor in the AirflowNetwork:Multizone:Surface object) is between two Opening Factor field values, the values of Discharge Coefficient, Width Factor, Height Factor, and Start Height Factor are linearly interpolated.

Below is the input data dictionary description for the object.

AirflowNetwork:MultiZone:Component:SimpleOpening

This object specifies the properties of air flow through windows, doors and glass doors (heat transfer subsurfaces) when they are closed or open. The AirflowNetwork model assumes that open windows or doors are vertical or close to vertical. The second and third fields are similar to those for AirflowNetwork:MultiZone:Surface:Crack, when the window or door is closed, but additional information is required to describe the air flow characteristics when the window or door is open. This additional information is specified in the last two fields. Compared to the

object `AirflowNetwork:MultiZone:Component:DetailedOpening`, which requires more inputs at different opening factors, this object needs comparatively less inputs. For this reason it is called a simple opening. This opening also allows for the possibility of two-way flow due to temperature and resulting density differences. Therefore, it is possible to have a positive pressure difference at the top of the opening, and a negative pressure difference at the bottom (or vice versa) when the neutral height is between the bottom and top heights of the associated surface. This object's openness can also be modulated based on the same opening factor control as an `AirflowNetwork:MultiZone:Component:DetailedOpening` object. However, the opening factor is only applied to the subsurface width. The opening width is equal to opening factor multiplied by the subsurface width.

A subsurface multiplier may be used to represent multiple subsurfaces and calculates total air flow when the subsurface (window, glassdoor, or door) is either closed or open. The total airflow across the surface is equal to the airflow based on the surface geometry multiplied by the subsurface multiplier.

Field: Name

This is a name for this `AirflowNetwork:MultiZone:Component:SimpleOpening` object. It is referenced by an `AirflowNetwork:MultiZone:Surface` object.

Field: Air Mass Flow Coefficient When Opening is Closed

The value of the air mass flow coefficient, $C_{Q,unit\ length}$, in the simple opening air flow equation. It has units of kg/s-m at 1Pa. The temperature correction factor is not applied for mass flow calculation.

Field: Air Mass Flow Exponent When Opening is Closed

The value of the exponent, n , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65.

Field: Minimum Density Difference for Two-Way Flow

This numeric field is used to input the minimum density difference above which two-way flow may occur due to stack effect. Density differences less than this value result in one-way flow. The minimum value for this field is greater than zero.

Field: Discharge Coefficient

This numeric field is used to input the discharge coefficient. This value must be greater than zero.

Below is the input data dictionary description for the object.

```

AirflowNetwork:MultiZone:Component:ZoneExhaustFan

This object specifies the properties of air flow through an exterior heat transfer surface with a zone exhaust fan. The zone exhaust fan turns on or off based on the availability schedule defined in the corresponding ZONE EXHAUST FAN object. When the exhaust fan mass flow rate is greater than zero, the airflow network model treats this object as a constant volume fan. When the fan is off based on the availability schedule, the model treats this object as a crack.

When the fan is on, the air mass flow rate modeled for the airflow network is based on the value defined in the Max Flow Rate field of the ZONE EXHAUST FAN object. The airflow direction is from the corresponding zone to outdoors.

When the fan is off, the following power law form is used that gives air flow through the crack as a function of the pressure difference across the crack:

$$Q = (\text{Crack Factor}) * C_T * C_Q (\Delta P)^n$$

Where

Q = air mass flow (kg/s)

C_Q = air mass flow coefficient (kg/s-Paⁿ @ 1 Pa)

C_T = reference condition temperature correction factor (dimensionless)

ΔP = pressure difference across crack (Pa)

n = air flow exponent (dimensionless)

$$C_T = \left[\frac{\rho_o}{\rho} \right]^{n-1} \left[\frac{\nu_o}{\nu} \right]^{2n-1}$$

where

ρ = Air density at the specific air temperature and humidity ratio conditions [kg/m³]

ν = Air kinetic viscosity at the specific air temperature condition [m²/s]

ρ_o = Air density at the reference air conditions provided by the object AirflowNetwork:MultiZone:ReferenceCrackConditions specified in the field Reference Crack Conditions [kg/m³]

ν_o = Air kinetic viscosity at the reference air temperature provided by the object AirflowNetwork:MultiZone:ReferenceCrackConditions specified in the field Reference Crack Conditions [m²/s]

Note: The correction factor shown above is used when the exhaust fan is off. The airflow direction is based on the pressure difference between the zone and outdoors.

Field: Name

This is the name for this instance of the AirflowNetwork:MultiZone:Component:ZoneExhaustFan object. This name must be the same name defined in the Fan:ZoneExhaust object. It is referenced by an AirflowNetwork:Multizone:Surface object.

Field: Air Mass Flow Coefficient When the Zone Exhaust Fan is Off at Reference Conditions

The value of the air mass flow coefficient, C_Q , in the crack air flow equation. It has units of kg/s at 1Pa. This value must be greater than zero. The value is used when the fan is off.

Field: Air Mass Flow Exponent When the Zone Exhaust Fan is Off

The value of the exponent, n , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65. The value is used when the fan is off.

Field: Reference Crack Conditions

The name of the AirflowNetwork:MultiZone:ReferenceCrackConditions object which specifies the conditions under which the air mass flow coefficient was measured. If the user omits this field and only one AirflowNetwork:MultiZone:ReferenceCrackConditions object is defined in the input data file, then those reference crack conditions will be used. If the user omits this field and either zero or more than one AirflowNetwork:MultiZone:ReferenceCrackConditions objects are defined in the input data file, then the default conditions for the AirflowNetwork:Multizone: Reference Crack Conditions object will be used.

Below is the input data dictionary description for the AirflowNetwork:Multizone:Component Zone Exhaust Fan object.

```

AirflowNetwork:MultiZone:ExternalNode

External nodes in the AirflowNetwork model define environmental conditions outside of the building. These conditions include wind pressure coefficients that vary from façade to façade and can be highly dependent on the building geometry.

AirflowNetwork:MultiZone:ExternalNode objects do **not** have to be entered if Wind Pressure Coefficient Type = SurfaceAverageCalculation in the AirflowNetwork:SimulationControl object.

Field: Name

The external node name is associated with a particular building façade. This name is referenced by the External Node Name field of an AirflowNetwork:MultiZone:WindPressureCoefficientValues object (which gives wind pressure coefficients for the façade as a function of angle of wind incident on the façade) and by the External Node Name field of an AirflowNetwork:MultiZone:Surface object.

Field: External Node Height

Designates the reference height, in meters, used to calculate relative pressure. The default value is 0 meters.

Field: Wind Pressure Coefficient Values Object Name

The name of a specific AirflowNetwork:MultiZone:WindPressureCoefficientValues object (which gives wind pressure coefficients for the façade as a function of angle of wind incident on the façade).

Below is the input data dictionary description for the AirflowNetwork:Multizone: External Node object.

```
AirflowNetwork:MultiZone:ExternalNode,

AirflowNetwork:MultiZone:WindPressureCoefficientArray

The reference height and wind directions are first specified under the AirflowNetwork:MultiZone:WindPressureCoefficientArray object. The user may specify up to 36 different wind directions in ascending order. These are then referenced by AirflowNetwork:MultiZone:WindPressureCoefficientValues objects defined for each AirflowNetwork:MultiZone:ExternalNode.

The AirflowNetwork:MultiZone:WindPressureCoefficientArray object is unique and needs to be entered only if Wind Pressure Coefficient Type = INPUT in the AirflowNetwork:SimulationControl object. If Wind Pressure Coefficient Type = SurfaceAverageCalculation, this object is not required.

Field: Name

The name of this AirflowNetwork:MultiZone:WindPressureCoefficientArray object. This name is referenced by each AirflowNetwork:MultiZone:WindPressureCoefficientValues object which, for each AirflowNetwork:MultiZone:ExternalNode, gives the wind pressure coefficients at each of the wind directions listed in the AirflowNetwork:MultiZone:WindPressureCoefficientArray. This name is also referenced by the AirflowNetwork:SimulationControl object, indicating that this AirflowNetwork:MultiZone:WindPressureCoefficientArray and the pressure coefficients in the associated AirflowNetwork:MultiZone:WindPressureCoefficientValues objects will be used in the air flow simulation.

Field: Wind Direction 1-Wind Direction N

Each field references the wind direction corresponding to the first through the Nth WPC value in each of the AirflowNetwork:MultiZone:WindPressureCoefficientValues objects. *N* can be as high as 36.

Below is the input data dictionary description for the object.

```
AirflowNetwork:MultiZone:WindPressureCoefficientArray,
  \min-fields 3
  \memo Used only if Wind Pressure Coefficient (WPC) Type = Input in the
AirflowNetwork:SimulationControl
  \memo object. Number of WPC Values in the corresponding
AirflowNetwork:MultiZone:WindPressureCoefficientValues
  \memo object must be the same as the number of wind directions specified for
  \memo this AirflowNetwork:MultiZone:WindPressureCoefficientArray object.
A1 , \field Name
  \required-field
  \reference WPCSetNames
  \type alpha
  \note Enter a unique name for the object.
N1 , \field Wind Direction 1
  \required-field

```

AirflowNetwork:MultiZone:WindPressureCoefficientValues

This object specifies up to 36 wind pressure coefficients (WPCs) for an AirflowNetwork:MultiZone:ExternalNode. These coefficients are defined for each of the wind directions defined in the unique AirflowNetwork:MultiZone:WindPressureCoefficientArray object. In the air flow calculation, interpolation of the specified WPC values is done for time-step values of wind direction.

AirflowNetwork:MultiZone:WindPressureCoefficientValues objects need to be entered only if the Wind Pressure Coefficient Type = INPUT in the AirflowNetwork:SimulationControl object. If Wind Pressure Coefficient Type = SurfaceAverageCalculation, this object is not required and is not used.

Field: Name

The name of this WindPressureCoefficientValues object. This name can be referenced by multiple AirflowNetwork:MultiZone:ExternalNode objects.

Field: WindPressureCoefficientArray Name

Name of the associated AirflowNetwork:MultiZone:WindPressureCoefficientArray, which lists the wind direction corresponding to each wind pressure coefficient value in this AirflowNetwork:MultiZone:WindPressureCoefficientValues object.

Field: Wind Pressure Coefficient Value 1 to Wind Pressure Coefficient Value N

The WPC (wind pressure coefficient) value for the building façade indicated by the External Node Name field above. This WPC value corresponds to the first wind direction in the AirflowNetwork:MultiZone:WindPressureCoefficientArray. Note that WPC values can be positive, negative or zero.

Obtaining WPC values

WPC values can be obtained from wind tunnel measurements, CFD calculations, or from published values for different building shapes.

For **rectangular buildings** EnergyPlus will automatically calculate surface-averaged Cp values for the walls and roof of the building if you specify Wind Pressure Coefficient Type = SurfaceAverageCalculation in the AirflowNetwork:SimulationControl object. In this case you do not have to enter any AirflowNetwork:MultiZone:WindPressureCoefficientValues objects.

Wind pressure coefficients are reported in the eplusout.eio either from inputs using "INPUT" as the choice for the Wind Pressure Coefficient Type field defined in the AirflowNetwork:SimulationControl object, or from internal calculation using SurfaceAverageCalculation as the choice for the Wind Pressure Coefficient Type field defined in the same object. Below is an output example from the eplusout.eio file:

```

```

The previous sections of this AirflowNetwork model discussion describe input objects used for multizone airflow calculations. The following sections describe input objects used for air distribution system simulations. These objects work when control option “MultiZone with Distribution” or “MultiZone with Distribution Only During Fan Operation” is defined in the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object.

The first section presents the input object for distribution system nodes. Although thermal zones are required to perform air distribution system simulations, the thermal zones are already defined in the multizone input section (described previously), so that there is no need to repeat the inputs for thermal zones when modeling an air distribution system. The same is also true for surface air leakage. This section has only one object: `AirflowNetwork:Distribution:Node`.

AirflowNetwork:Distribution:Node

The `AirflowNetwork:Distribution:Node` object is used to represent air distribution system nodes for the `AirflowNetwork` model. The EnergyPlus nodes defined in an `AirLoopHVAC` are a subset of the nodes used to simulate the distribution system using the `AirflowNetwork` model. For example, the inlet node of a fan and the outlet node of a coil defined in an `AirLoopHVAC` must be defined as nodes using the `AirflowNetwork:Distribution:Node` object. A set of EnergyPlus Zone Equipment nodes is also a subset of the `AirflowNetwork:Distribution:Nodes`. For example, zone inlet and outlet nodes must be defined as nodes using the `AirflowNetwork:Distribution:Node` object. In addition, although mixers and splitters are defined as objects with inlet and outlet nodes within EnergyPlus, the `AirflowNetwork:Distribution:Node` object treats mixers and splitters as single nodes. The node objects are referenced by `AirflowNetwork:Distribution:Linkage` objects.

In summary, all nodes used to define an `AirLoopHVAC` (except splitters, mixers, and outdoor air systems which are treated as single nodes) and its connections to a thermal zone must be specified as `AirflowNetwork:Distribution:Nodes`. If distribution system air leaks are to be modeled, additional `AirflowNetwork:Distribution:Nodes` may be defined along with `AirflowNetwork:Distribution:Components` (e.g., leak or leak ratio) to define the air leakage characteristics.

Note: Supply and return leaks are not allowed in an `AirLoopHVAC`. They can only be modeled in the Zone Equipment Loop (i.e., return leaks may be modeled between the zone return node and the zone mixer inlet or the zone mixer outlet and the zone equipment loop outlet; and supply leaks may be modeled between the zone equipment loop inlet and the `AirLoopHVAC:ZoneSplitter` inlet node or the `AirLoopHVAC:ZoneSplitter` outlet node and the zone supply node).

Field: Name

The name of an air distribution system node. This node name is referenced by an `AirflowNetwork:Distribution:Linkage` and in the output listing. Each node should have a unique name within the `AirflowNetwork:Distribution:Node` objects (however, the node name may be used elsewhere as regular EnergyPlus node names such as the fan inlet node or coil outlet node).

Field:Component Name or Node Name

Designates node names defined in another EnergyPlus object, so that the `AirflowNetwork:Distribution:Node` object is able to get input parameters and node conditions from the associated EnergyPlus node or object. The actual node name is entered here and represents a node already defined in an `AirLoopHVAC` or zone equipment loop. This field is left blank if the EnergyPlus Node Type field below is entered as Mixer, Splitter, Outdoor air System, or Other.

Field: Component Object Type or Node Type

This choice field distinguishes the node type for the EnergyPlus node or object name defined above. Five node types are available:

- **AirLoopHVAC:ZoneMixer**: Represents an `AirLoopHVAC:ZoneMixer` object defined in EnergyPlus

- **AirLoopHVAC:ZoneSplitter:** Represents an AirLoopHVAC:ZoneSplitter object defined in EnergyPlus
- **AirLoopHVAC:OutdoorAirSystem:** Represents an AirLoopHVAC:OutdoorAirSystem object used in EnergyPlus
- **OAMixerOutdoorAirStreamNode:** Represents an external node name specified as an Outdoor Air Stream Node Name in the OutdoorAir:Mixer object when the AirLoopHVAC:OutdoorAirSystem object is used.
- **OutdoorAir:NodeList:** Represents an external node name defined in the OutdoorAir:NodeList object when the AirLoopHVAC:OutdoorAirSystem object and an exhaust energy recovery system (air-to-air heat exchanger) are used.
- **OutdoorAir:** Represents an external node name defined in the OutdoorAir:Node object when the AirLoopHVAC:OutdoorAirSystem and an exhaust energy recovery system (air-to-air heat exchanger) are used.
- **Other:** Represents a type not already defined above.

Note: Both the OutdoorAir:NodeList and OutdoorAir:Node node types represent a node to outdoor air conditions. Either one of these node types can be used to represent an external node when an air-to-air heat exchanger is used to recover energy from the exhaust air stream as part of an AirLoopHVAC:OutdoorAirSystem object. Node type OAMixerOutdoorAirStreamNode does not represent an external node when an OutdoorAir:NodeList or OutdoorAir:Node object is specified. If no exhaust heat recovery system (i.e., air-to-air heat exchanger) is specified in the AirLoopHVAC:OutdoorAirSystem, the node type OAMixerOutdoorAirStreamNode represents an external node.

Field: Node Height

Designates the reference height in meters used to calculate relative pressure. The default value is 0 meters.

Below is the input data dictionary description for the AirflowNetwork:Distribution:Node object.

```
AirflowNetwork:Distribution:Node,

The next section describes AirflowNetwork Distribution Components, with 7 available types listed below. All required fields for each component represent a relationship between pressure difference and airflow. The components are referenced in AirflowNetwork:Distribution:Linkage objects.

- AirflowNetwork:Distribution:Component:Leak
- AirflowNetwork:Distribution:Component:LeakageRatio
- AirflowNetwork:Distribution:Component:Duct
- AirflowNetwork:Distribution:Component:ConstantVolumeFan
- AirflowNetwork:Distribution:Component:Coil
- AirflowNetwork:Distribution:Component:HeatExchanger

- AirflowNetwork:Distribution:Component:TerminalUnit
- AirflowNetwork:Distribution:Component:ConstantPressureDrop

AirflowNetwork:Distribution:Component:Leak

This component may be also called a power law component and is used to represent a supply or return air leak in an air distribution system. Its relationship between pressure difference and airflow may be expressed as:

$$\dot{m} = C_T C (\Delta P)^n$$

where

\dot{m} = Air mass flow rate through the component [kg/s]

C = Air mass flow coefficient (kg/s at 1 Pa pressure difference)

ΔP = Total pressure loss across the element [Pa]

n = Air mass flow exponent

C_T = Temperature correction factor

$$C_T = \left[\frac{\rho_o}{\rho} \right]^{n-1} \left[\frac{\nu_o}{\nu} \right]^{2n-1}$$

where

ρ = Air density at the specific air temperature and humidity ratio conditions [kg/m³]

ν = Air kinetic viscosity at the specific air temperature condition [m²/s]

ρ_o = Air density at air conditions of 20°C, 0 kg/kg and 101325 Pa [kg/m³]

ν_o = Air kinetic viscosity at an air temperature of 20°C [m²/s]

Note: The correction factor shown above is use for this particular component as specified.

Field: Name

A unique name identifying a supply or return air leak in an air distribution system. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component leak.

Field: Air Mass Flow Coefficient

This numeric field is defined as the air mass flow coefficient at 1 Pa pressure difference across this component. Valid entries must be greater than zero.

Field: Air Mass Flow Exponent

This numeric field is defined as the pressure difference exponent across the component. Valid entries are from 0.5 to 1.0, with the default value being 0.65.

Below is the input data dictionary description for the AirflowNetwork:Distribution: Component Leak object.

```

AirflowNetwork:Distribution:Component:Leak,
  \min-fields 3
  \memo This object defines the characteristics of a supply or return air leak.
A1 , \field Name
  \required-field
  \type alpha
  \reference AirflowNetworkComponentNames
  \note Enter a unique name for this object.
N1 , \field Air Mass Flow Coefficient
  \required-field
  \type real
  \units kg/s
  \minimum > 0
  \note Defined at 1 Pa pressure difference across this component.
  \note Enter the coefficient used in the following equation:
  \note Mass Flow Rate = Air Mass Flow Coefficient * (dP)^Air Mass Flow Exponent
N2 ; \field Air Mass Flow Exponent
  \type real
  \units dimensionless
  \minimum 0.5
  \maximum 1.0
  \default 0.65
  \note Enter the exponent used in the following equation:
  \note Mass Flow Rate = Air Mass Flow Coefficient * (dP)^Air Mass Flow Exponent

```

An IDF example is provided below:

```

AirflowNetwork:Distribution:Component:Leak,
  MainSupplyLeak,      !- Name of Supply or Return Leak
  0.0001,              !- Air Mass Flow Coefficient {kg/s}
  0.65;                !- Air Mass Flow Exponent {dimensionless}

AirflowNetwork:Distribution:Component:Leak,
  ZoneSupplyLeak,     !- Name of Supply or Return Leak
  0.01,               !- Air Mass Flow Coefficient {kg/s}
  0.65;              !- Air Mass Flow Exponent {dimensionless}

```

AirflowNetwork:Distribution:Component:LeakageRatio

The leakage ratio component is generally used to define supply and return leaks with respect to a constant fan flow. This object requires 5 inputs. The relationship between pressure and airflow may be expressed as a power law element:

$$\dot{m} = C_{equ} (\Delta P)^n$$

where

ρ = Air density [kg/m³]

ΔP = Total pressure loss across the element [Pa]

n = Air mass flow exponent

C_{equ} = Equivalent air mass flow coefficient

$$C_{equ} = r * Q_r * \rho * (\Delta P_r)^{-n}$$

where

r = Effective leakage ratio [dimensionless]

Q_r = Maximum airflow rate [m³/s]

ΔP_r = Reference pressure difference [Pa]

n = Air mass flow exponent [dimensionless]

Field: Name

A unique name identifying a supply or return air leak (ratio with respect to the constant volume fan flow rate) in an air distribution system. This unique name will be referenced in an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Effective Leakage Ratio

This numeric field is used to input the effective leakage ratio. This value must be greater than zero and less than or equal to 1. The effective leakage ratio is used to characterize supply and return leaks with respect to the constant fan flow (supply or return air leak flow rate divided by the maximum air flow rate for the fan).

Field: Maximum Flow Rate

This numeric field is used to input the maximum flow rate for a constant volume fan [m^3/s]. This value must be greater than $0 \text{ m}^3/\text{s}$.

Field: Reference Pressure Difference

This numeric field is used to input the reference pressure difference [Pa]. This value must be greater than 0 Pa.

Field: Air Mass Flow Exponent

This numeric field is used to input the pressure difference exponent. The value of the exponent can be from 0.5 to 1.0, with the default value being 0.65.

Note: The reference pressure difference is defined as the difference between pressures of originate and terminate nodes for supply and return leaks. In general, it may require that a simulation be performed with an initial guess for reference pressure difference using design day conditions. After obtaining pressures at the leakage nodes, more realistic reference pressure differences can be entered. It should be pointed out that since pressures at the nodes vary with temperature and other conditions, the effective leakage ratio is only an estimate. In other words, the exact leakage ratio may not be available.

Below is the input data dictionary description for the AirflowNetwork:Distribution: Component Leakage Ratio object.

```

AirflowNetwork:Distribution:Component:LeakageRatio,
  \min-fields 5
  \memo This object is used to define supply and return air leaks with respect to the fan's maximum
  \memo air flow rate.

```

AirflowNetwork:Distribution:Component:Duct

This object represents a duct component and requires 9 input fields, one alpha field and 8 numeric fields. The relationship between pressure and airflow across the component may be expressed as (2001 ASHRAE Handbook of Fundamentals, Chapter 34):

$$\dot{m} = \sqrt{\frac{2\rho A^2 \Delta P}{fL/D + \sum C_d}}$$

where

\dot{m} = Mass flow rate of air through the component [kg/s]

ρ = Air density [kg/m³]

A = Cross sectional area [m²]

ΔP = Total pressure loss across the component [Pa]

L = Duct length [m]

D = Hydraulic diameter [m]

C_d = Dynamic loss coefficient due to fitting [dimensionless]

f = Friction factor

The friction factor can be calculated using the nonlinear Colebrook equation (ASHRAE Handbook of Fundamentals, 1997. p. 2.9, Eq. 29b)

$$\frac{1}{\sqrt{f}} = 1.44 + 2 * \log\left(\frac{D}{\varepsilon}\right) - 2 * \log\left(1 + \frac{9.3}{\text{Re} * \varepsilon / D * \sqrt{f}}\right)$$

where

ε = Surface roughness [m]

Re = Reynolds number = $\frac{\rho V D}{\mu}$

Field: Name

A unique name for an AirflowNetwork duct component in an air distribution system. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Duct Length

This numeric field is used to input duct length [m]. This value must be greater than zero.

Field: Hydraulic Diameter

This numeric field is used to input hydraulic diameter, which is defined as:

$$D_h = \frac{4A}{P}$$

where

D_h = Hydraulic diameter [m]

A = Duct cross sectional area [m²]

P = Perimeter of cross section [m]

Field: Cross Section Area

This numeric field is used to input cross section area [m²]. The model assumes that this element has no area change along its length. Otherwise, effective cross sectional area is required.

Field: Surface Roughness

This numeric field is used to input surface roughness [m]. This value must be greater than zero, and the default value is 0.0009 m.

Field: Coefficient for Local Dynamic Loss Due to fitting

This numeric field is defined as a coefficient for dynamic loss [dimensionless]. It represents dynamic loss due to fittings (such as an elbow).

Field: Overall Heat Transmittance Coefficient (U-Factor) from Air to Air

This numeric field is defined as the overall heat transmittance coefficient (U value, W/m²-K) from air to air, including film coefficients at both surfaces.

Field: Overall Moisture Transmittance Coefficient from Air to Air

This numeric field is defined as the overall moisture transmittance coefficient (kg/m^2) from air to air, including film coefficients at both surfaces.

Below is the input data dictionary description for the AirflowNetwork:Distribution: Component Duct object.

```

AirflowNetwork:Distribution:Component:Duct,
  \min-fields 8
  \memo This object defines the relationship between pressure and air flow through the duct.

```

AirflowNetwork:Distribution:Component:ConstantVolumeFan

This component represents a constant volume fan in the air distribution system (AirLoopHVAC). The air flow rate and air conditions (temperature and humidity) are obtained from the associated Fan:ConstantVolume or Fan:OnOff object.

Field: Fan Name

The name identifying an AirflowNetwork constant volume fan in an air distribution system. This name must be the same as the name of the associated Fan:ConstantVolume or Fan:OnOff object. This name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Supply Fan Object Type

This choice field defines the type of fan. The only valid choices are Fan:OnOff and Fan:ConstantVolume, with the default being Fan:ConstantVolume. Both cycling and continuous fan operating modes are allowed for Fan:OnOff. Only the continuous fan operating mode is allowed for Fan:ConstantVolume.

Note: Make sure that the volumetric air flow rates for the fan, coils, and parent components (e.g., unitary system or furnace) are the same so that fan energy and air distribution system losses/gains are properly calculated.

Below is the input data dictionary description for the AirflowNetwork:Distribution: Component Constant Volume Fan object.

```
AirflowNetwork:Distribution:Component:ConstantVolumeFan,
  \min-fields 2
  \memo This object defines the name of the constant volume supply Air Fan used in an Air loop.
A1 , \field Fan Name
    \required-field
    \type alpha
    \object-list FansCVandOnOff
    \reference AirflowNetworkComponentNames
    \note Enter the name of the constant volume fan in the primary air loop.
A2 ; \field Supply Fan Object Type
    \type choice
    \key Fan:OnOff
    \key Fan:ConstantVolume
    \default Fan:ConstantVolume
```

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:ConstantVolumeFan,
Supply Fan 1,         !- Name of Constant Volume Fan
Fan:ConstantVolume; !- Supply fan type
```

AirflowNetwork:Distribution:Component:Coil

This component represents a cooling or heating coil. The main purpose for this object is to get calculated values (air flow and temperature/humidity conditions) from the associated coil models.

Field: Coil Name

The name identifying an AirflowNetwork cooling coil or heating coil defined in an air loop. This name must be the same name as the associated coil object. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Coil Object Type

This field requires input of the coil type used in the AirflowNetwork model. The available choices are:

- Coil:Cooling:DX:SingleSpeed
- Coil:Heating:Gas
- Coil:Heating:Electric
- Coil:Heating:DX:SingleSpeed
- Coil:Cooling:Water
- Coil:Heating:Water
- Coil:Cooling:Water:DetailedGeometry
- Coil:Cooling:DX:TwoStageWithHumidityControlMode
- Coil:Cooling:DX:MultiSpeed
- Coil:Heating:DX:MultiSpeed
- Coil:Heating:Desuperheater

Field: Air Path Length

This numeric field is used to input air path length for the coil [m]. This value must be greater than 0 meters.

Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter of a coil's air path, which is defined as:

$$D_h = \frac{4A}{P}$$

where

D_h = Hydraulic diameter [m]

A = Duct cross section area [m²]

P = Perimeter of cross section [m]

For this component, the relationship between airflow and pressure is similar to the component AirflowNetwork:Distribution:Component:Duct. However, the model assumes very small surface roughness (10^{-4}) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings is ignored.

Note: Make sure that the volumetric air flow rates for the fan, coils, and parent components (e.g., unitary system or furnace) are the same so that fan energy and air distribution system losses/gains are properly calculated.

Below is the input data dictionary description for the object.

```

AirflowNetwork:Distribution:Component:Coil,
  \min-fields 4
  \memo This object defines the name of a coil used in an air loop.
A1 , \field Coil Name
  \required-field

  \key Coil:Cooling:DX:MultiSpeed
  \key Coil:Heating:DX:MultiSpeed
  \key Coil:Heating:Desuperheater
  \note Select the type of coil corresponding to the name entered in the field above.
N1 , \field Air Path Length
  \required-field
  \type real
  \units m
  \minimum> 0
  \note Enter the air path length (depth) for the coil.
N2 ; \field Air Path Hydraulic Diameter
  \required-field
  \units m
  \type real
  \minimum> 0
  \note Enter the hydraulic diameter of this coil. The hydraulic diameter is
  \note defined as 4 multiplied by the cross section area divided by perimeter.

```

An IDF example is provided below:

```

AirflowNetwork:Distribution:Component:Coil,
  ACDXCoil 1,           !- Name of Associated EnergyPlus Coil
  Coil:Cooling:DX:SingleSpeed,  !- EnergyPlus Coil Type
  0.1,                 !- Air Path Length {m}
  1.00;                !- Air Path Hydraulic Diameter {m}

AirflowNetwork:Distribution:Component:Coil,
  HP Heating Coil 1,   !- Name of Associated EnergyPlus Coil
  Coil:Heating:DX:SingleSpeed,  !- EnergyPlus Coil Type
  0.1,                 !- Air Path Length {m}
  1.00;                !- Air Path Hydraulic Diameter {m}

```

AirflowNetwork:Distribution:Component:HeatExchanger

This component represents an air-to-air heat exchanger typically used in combination with a cooling coil to enhance dehumidification or in an outside air system to recover energy from exhaust air to pretreat incoming outdoor ventilation air. The cooling coils with enhanced dehumidification are defined in the two objects `CoilSystem:Cooling:DX:HeatExchangerAssisted` and `CoilSystem:Cooling:Water:HeatExchangerAssisted` using one of three heat exchanger objects specified below. The exhaust air energy recovery system also has the same restriction using the one of three heat exchanger objects. The main purpose for this object is to obtain calculated values (air flow and temperature/humidity conditions) from the associated heat exchanger models for the airflow network calculations.

Field: Heat Exchanger Name

The name identifying an AirflowNetwork heat exchanger defined in an air loop. This name must be the same name that is used in the associated heat exchanger object. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Heat Exchanger Object Type

This field requires input of the heat exchanger type. The available choices are:

- HeatExchanger:AirToAir:FlatPlate
- HeatExchanger:AirToAir:SensibleAndLatent
- HeatExchanger:Desiccant:BalancedFlow

Field: Air Path Length

This numeric field is used to input air path length for the heat exchanger coil [m]. This value must be greater than 0 meters.

Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter of a heat exchanger coil's air path, which is defined as:

$$D_h = \frac{4A}{P}$$

where

D_h = Hydraulic diameter [m]

A = Duct cross section area [m²]

P = Perimeter of cross section [m]

For this component, the relationship between airflow and pressure is similar to the component AirflowNetwork:Distribution:Component:Duct. However, the model assumes very small surface roughness (10^{-4}) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings are ignored.

Note: When a heat exchanger is used as a component of either CoilSystem:Cooling:DX:HeatExchangerAssisted or CoilSystem:Cooling:Water:HeatExchangerAssisted, the heat exchanger acts as two components in an air primary loop. For example, an air-to-air heat exchanger has a component connected to the supply air side (equivalent to a supply coil) and a component connected to exhaust air side (equivalent to an exhaust coil). The desiccant heat exchanger has a component connected to regeneration air side (equivalent to a regeneration air coil) and a component connected to process air side (equivalent to a process air coil). Therefore, each air-to-air heat exchanger used in this configuration requires two linkage objects (instead of only one linkage object as required for other AirflowNetwork components).

When a heat exchanger is used in an exhaust air energy recovery system (i.e., in an AirLoopHVAC:OutdoorAirSystem object to recover waste heat from exhaust air to pretreat incoming outdoor ventilation air), the heat exchanger is treated as a single component. The AirflowNetwork model only connects the two nodes associated with the incoming outdoor ventilation air, while the two exhaust nodes are not defined as part of the AirflowNetwork model. Therefore, each heat exchanger component used in an exhaust air energy recovery system has only one linkage object, similar to AirflowNetwork coil components.

Below is the input data dictionary description for the AirflowNetwork:Distribution:Component:HeatExchanger object.

```
AirflowNetwork:Distribution:Component:HeatExchanger,
  \min-fields 4
  \memo This object defines the name of an air-to-air heat exchanger used in an air loop.
A1 , \field HeatExchanger Name
    \required-field
    \type alpha
    \reference AirflowNetworkComponentNames
    \note Enter the name of an air-to-air heat exchanger in the primary Air loop.
A2 , \field HeatExchanger Object Type
    \required-field
    \type choice
    \key HeatExchanger:AirToAir:FlatPlate
    \key HeatExchanger:AirToAir:SensibleAndLatent
    \key HeatExchanger:Desiccant:BalancedFlow
    \note Select the type of heat exchanger corresponding to the name entered in the field above.
N1 , \field Air Path Length
    \required-field
    \type real
    \units m
    \minimum > 0
    \note Enter the air path length (depth) for the heat exchanger.
N2 ; \field Air Path Hydraulic Diameter
    \required-field
    \units m
    \type real
    \minimum > 0
    \note Enter the hydraulic diameter of this heat exchanger. The hydraulic diameter is
    \note defined as 4 multiplied by the cross section area divided by perimeter.
```

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:HeatExchanger,
  OA Heat Recovery 1,      !- HeatExchanger Name
  HeatExchanger:AirToAir:SensibleAndLatent, !- HeatExchanger Object Type
  0.1,                    !- Air Path Length {m}
  1.00;                   !- Air Path Hydraulic Diameter {m}

AirflowNetwork:Distribution:Component:HeatExchanger,
  Desiccant Heat Exchanger 1, !- HeatExchanger Name
  HeatExchanger:Desiccant:BalancedFlow, !- HeatExchanger Object Type
  0.1,                    !- Air Path Length {m}
  1.00;                   !- Air Path Hydraulic Diameter {m}
```

AirflowNetwork:Distribution:Component:TerminalUnit

This component represents a terminal unit for reheating the incoming supply air. The main purpose is to get calculated values from the terminal unit models.

Field: Terminal Unit Name

A name identifying an AirflowNetwork terminal unit defined in a zone equipment list. This name must be the same as the associated terminal unit object. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Terminal Unit Object Type

This field requires input of the terminal unit type used in the AirflowNetwork model. The only available type is AirTerminal:SingleDuct:ConstantVolume:Reheat.

Field: Air Path Length

This numeric field is used to input the air path length for the terminal unit [m]. This value must be greater than 0 meters.

Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter for the terminal unit's air path, which is defined as:

$$D_h = \frac{4A}{P}$$

where

D_h = Hydraulic diameter [m]

A = Duct cross section area [m²]

P = Perimeter of cross section [m]

It should be noted that the relationship for this component between airflow and pressure is similar to the component `AirflowNetwork:Distribution:Component:Duct`. However, the model assumes very small surface roughness (10^{-4}) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings is ignored.

Note: The `AirflowNetwork:Distribution:Component:TerminalUnit` object is used to represent an `AirTerminal:SingleDuct:ConstantVolume:Reheat` object in an `AirflowNetwork` simulation. The `AirflowNetwork:Distribution:Component:TerminalUnit` should not be used to represent any other air terminal unit types. When the `ZoneHVAC:EquipmentList` object specifies an `AirTerminal:SingleDuct:Uncontrolled` object, the `AirflowNetwork:Distribution:Component:Duct` object should be used instead.

Below is the input data dictionary description for the object.

```
AirflowNetwork:Distribution:Component:TerminalUnit,
  \min-fields 4
  \memo This object defines the name of a terminal unit in an air loop.
A1 , \field Terminal Unit Name
  \required-field
  \type alpha
  \reference AirflowNetworkComponentNames
  \note Enter the name of a terminal unit in the AirLoopHVAC.
A2 , \field Terminal Unit Object Type
  \required-field
  \type choice
  \key AirTerminal:SingleDuct:ConstantVolume:Reheat
  \note Select the type of terminal unit corresponding to the name entered in the field above.
N1 , \field Air Path Length
  \required-field
  \type real
  \units m
  \minimum> 0
  \note Enter the air path length (depth) for the terminal unit.
```

```
N2 ; \field Air Path Hydraulic Diameter
  \required-field
  \units m
  \type real
  \minimum> 0
  \note Enter the hydraulic diameter of this terminal unit. The hydraulic diameter is
  \note defined as 4 multiplied by the cross section area divided by perimeter.
```

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:TerminalUnit,
  Reheat Zone 1,                !- Name of Associated Energyplus Terminal Unit
  AirTerminal:SingleDuct:ConstantVolume:Reheat, !- EnergyPlus Terminal Unit Type
  0.1,                          !- Air Path Length {m}
  0.44;                          !- Air Path Hydraulic Diameter {m}
```

AirflowNetwork:Distribution:Component:ConstantPressureDrop

This component represents a constant pressure drop component. It is generally used to simulate a constant pressure drop filter. The mathematical equation may be written as:

$$\Delta P = const$$

Field: Name

A unique name identifying an AirflowNetwork constant pressure drop component in an air distribution system. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Pressure Difference across the Component

This numeric field is used to input the pressure difference across the element [Pa].

Note: This object should be used with caution. Each node connected to this object can not be a node for a mixer or splitter, a node in an AirLoopHVAC, or a node in a zone configuration loop. It is recommended that duct components be specified at both ends of this object.

Below is the input data dictionary description for the object.

```
AirflowNetwork:Distribution:Component:ConstantPressureDrop,
  \min-fields 2
  \memo This object defines the characteristics of a constant pressure drop component (e.g. filter).
  \memo Each node connected to this object can not be a node of mixer, splitter, a node of air primary
  \memo loop, or zone equipment loop. It is recommended to connect to a duct component at both ends.
A1 , \field Name
  \required-field
  \type alpha
  \reference AirflowNetworkComponentNames
  \note Enter a unique name for this object.
N1 ; \field Pressure Difference Across the Component
  \required-field
  \units Pa
  \type real
  \minimum> 0.0
  \note Enter the pressure drop across this component.
```

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:ConstantPressureDrop,
SupplyCPDComp, ! Name of Constant Pressure Drop Component
1.0;          ! Pressure Difference Across the Component [Pa]
```

AirflowNetwork:Distribution:Linkage

The AirflowNetwork:Distribution:Linkage represents a connection between two AirflowNetwork:Distribution:Node objects and an AirflowNetwork component defined above. In addition, the relative height from node height to linkage height for each node is required.

Field: Name

The name identifies the linkage for later reference and in the output listing. Each linkage should have a unique name.

Field: Node 1 Name

Designates a node name where airflow starts. The node name should be defined in an AirflowNetwork:Distribution:Node object.

Field: Node 2 Name

Designates a node name where airflow ends. The node name should be defined in an AirflowNetwork:Distribution:Node object.

Field: Component Name

Designates an AirflowNetwork component name associated with the two nodes. The component name should be one of the AirflowNetwork:Distribution:Component... object names.

Field: Thermal Zone Name

Designates a thermal zone where the linkage is located. The information provides the ambient conditions for duct elements to calculate duct conduction losses (only used if component is AirflowNetwork:Distribution:Component:Duct).

Below is the input data dictionary description for the AirflowNetwork:Distribution: Linkage object.

```
AirflowNetwork:Distribution:Linkage,
  \min-fields 4
  \memo This object defines the connection between two nodes and a component.
A1 , \field Name
  \required-field
  \type alpha
  \note Enter a unique name for this object.
  \reference AirflowNetwork LinkageNames
A2 , \field Node 1 Name
  \required-field
  \type alpha
  \object-list AirflowNetwork NodeNames
  \object-list ZoneNames
  \note Enter the name of zone or AirflowNetwork Node.
A3 , \field Node 2 Name
  \required-field
  \type alpha
  \object-list AirflowNetwork NodeNames
  \object-list ZoneNames
  \note Enter the name of zone or AirflowNetwork Node.
A4 , \field Component Name
  \required-field
  \type object-list
  \object-list AirflowNetworkComponentNames
  \note Enter the name of an AirflowNetwork component. A component is one of the
  \note following AirflowNetwork:Distribution:Component objects: Leak, LeakageRatio,
  \note Duct, ConstantVolumeFan, Coil, TerminalUnit, ConstantPressureDrop or HeatExchanger.
A5 ; \field Thermal Zone Name
  \type object-list
  \object-list ZoneNames
  \note Only used if component = AirflowNetwork:Distribution:Component:Duct
  \note The zone name is where AirflowNetwork:Distribution:Component:Duct is exposed. Leave this field
blank if the duct
  \note conduction loss is ignored.
```

An IDF example is provided below:

```

AirflowNetwork:Distribution:Linkage,
Main Link 1,                !- Name of Linkage
EquipmentInletNode,        !- Node 1 Name
SupplyMainNode,            !- Node 2 Name
MainTruck1,                 !- Component Name
Attic Zone,                 !- Thermal Zone Name

```

AirflowNetwork Outputs

The AirflowNetwork nodes in the following output variables includes zones defined in AirflowNetwork:Multizone:Zone objects, external nodes defined in AirflowNetwork:MultiZone:ExternalNode objects, and nodes defined in AirflowNetwork:Distribution:Node objects.

The AirflowNetwork linkage used in following output variables includes surfaces defined in AirflowNetwork:Multizone:Surface objects, and linkages defined in AirflowNetwork:Distribution:Linkage objects. The surface linkages represent airflows through surface cracks or openings between two zones or between a zone and outdoors. The distribution linkages represent airflows in an air distribution system.

HVAC,Average,AirflowNetwork Surface Average Pressure Difference [Pa]
HVAC,Average,AirflowNetwork Surface Pressure Difference During ON cycle [Pa]
HVAC,Average,AirflowNetwork Surface Pressure Difference During OFF cycle [Pa]

```

AirflowNetwork Node Temperature [C]

This is the AirflowNetwork node temperature output in degrees C. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, this value for AirflowNetwork:Distribution:Node objects reflects the temperature when the fan is operating (ON).

AirflowNetwork Node Humidity Ratio [kg/kg]

This is the AirflowNetwork node humidity ratio output in kg/kg. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, this value for AirflowNetwork:Distribution:Node objects reflects the humidity ratio when the fan is operating (ON).

AirflowNetwork Node Total Pressure [Pa]

This is the AirflowNetwork node total pressure in Pa with respect to outdoor barometric pressure. The total pressure is the sum of static pressure, dynamic pressure, and elevation impact at the node's relative height. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, the value for AirflowNetwork:Distribution:Node objects reflects the total pressure when the fan is operating (ON). The total pressures for nodes associate with AirflowNetwork:Multizone:Zone objects are reported in different output variables (below).

AirflowNetwork Average Zone Pressure [Pa]

This is the AirflowNetwork average zone total pressure in Pa with respect to outdoor barometric pressure. This output is only available when a Fan:OnOff object is used in the air distribution system. The average zone pressure is weighted by the system fan part-load ratio using the calculated zone pressures during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Average zone pressure = (Zone pressure during on cycle * Part-load ratio) + Zone pressure during off cycle * (1.0 – Part-load ratio)

AirflowNetwork Zone Pressure During ON cycle [Pa]

This is the AirflowNetwork zone total pressure in Pa with respect to outdoor barometric pressure when the air distribution system fan is operating (ON). This output is only available when a Fan:OnOff object is used in the air distribution system. When the fan part-load ratio is equal to 0.0, this pressure value will be zero because the air distribution system is not simulated when the fan is off for the entire timestep.

AirflowNetwork Zone Pressure During OFF cycle [Pa]

This is the AirflowNetwork zone total pressure in Pa with respect to outdoor barometric pressure when the air distribution system fan is not operating (OFF). This output is only available when a Fan:OnOff object is used in the air distribution system. Even if the fan part-load ratio is equal to 1.0, the pressure calculated as if the fan were not operating (OFF) is reported.

AirflowNetwork Wind Pressure [Pa]

This is the AirflowNetwork wind pressure output in Pa. The wind pressure depends on several factors, including wind speed, wind direction, the wind-pressure coefficient (C_p) values for the AirflowNetwork:MultiZone:ExternalNode associated with the heat transfer surface and the site wind conditions.

When Wind Pressure Coefficient Type = “Input” in the AirflowNetwork:SimulationControl object, the output represents external node pressures driven by wind defined in an AirflowNetwork:MultiZone:ExternalNode object. When Wind Pressure Coefficient Type = “SurfaceAverageCalculation” in AirflowNetwork:SimulationControl, the program assumes five external nodes:

- FACADE1 Representing north orientation
- FACADE2 Representing east orientation
- FACADE3 Representing south orientation
- FACADE4 Representing west orientation
- ROOF Representing horizontal orientation

In this case, the output represents the wind pressures for the five external nodes defined above.

AirflowNetwork Mass Flow Rate from Node 1 to 2 [kg/s]

This is the AirflowNetwork linkage mass flow rate output in kg/s in the direction from Node 1 to Node 2. It reports surface airflows through a crack or opening, and through linkages defined in an AirflowNetwork:Distribution:Linkage object. The surface linkage is divided into two types of surfaces, exterior surface and interior surface. Node 1 for an exterior surface linkage is a thermal zone and Node 2 is an external node. The value of AirflowNetwork Mass Flow Rate from Node 1 to 2 represents the flow rate from a thermal zone to outdoors. The flow direction through an interior surface crack or opening is defined from a thermal zone defined by a surface’s Zone Name (Node 1) to an adjacent thermal zone defined by a surface’s OutsideFaceEnvironment (Node 2). For an AirflowNetwork:Distribution:Linkage object, the value represents the air mass flow rate flowing from Node 1 to Node 2.

It should be pointed out that in general, each linkage has one directional flow at any given time, either from Node 1 to 2 or from Node 2 to 1. However, there are two components which may have flows in both directions simultaneously: AirflowNetwork:MultiZone:Component:DetailedOpening and AirflowNetwork:MultiZone:Component:SimpleOpening.

When a Fan:OnOff object is used, the air mass flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air mass flow rates when the fan is off are zero for the distribution system air linkage objects. The air mass flow rates for the AirflowNetwork:Multizone:Surface object are reported in different output variables (below).

AirflowNetwork Mass Flow Rate from Node 2 to 1 [kg/s]

This is the AirflowNetwork linkage mass flow rate output in kg/s in the direction from Node 2 to Node 1. It reports airflows from surfaces through a crack or opening, and from linkages defined in an AirflowNetwork:Distribution:Linkage object. Node 1 and Node 2 for a surface or subsurface are defined in the same manner as AirflowNetwork Mass Flow Rate from Node 1 to 2.

When a Fan:OnOff object is used, the air mass flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air mass flow rates when the fan is off are zero for the distribution system air linkage objects. The air mass flow rates for the AirflowNetwork:Multizone:Surface object are reported in different output variables (below).

AirflowNetwork Average Mass Flow Rate from Node 1 to 2 [kg/s]

This is the AirflowNetwork linkage average mass flow rate in kg/s in the direction from Node 1 to Node 2 defined in the AirflowNetwork:Multizone:Surface objects. This output is only available when a Fan:OnOff object is used in the air distribution system. The average mass flow rate is weighted by the system fan part-load ratio using the calculated air mass flow rates during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Average surface mass flow rate = (Surface mass flow rate during on cycle * Part-load ratio) + Surface mass flow rate during off cycle * (1.0 – Part-load ratio)

AirflowNetwork Average Mass Flow Rate from Node 2 to 1 [kg/s]

This is the AirflowNetwork linkage average mass flow rate in kg/s in the direction from Node 2 to Node 1 defined in the AirflowNetwork:Multizone:Surface objects. This output is only available when a Fan:OnOff object is used in the air distribution system. The average mass flow rate is weighted by the system fan part-load ratio using the calculated air mass flow rates during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

AirflowNetwork Volume Flow Rate from Node 1 to 2 [m³/s]

This is the AirflowNetwork linkage volume flow rate output in m³/s in the direction from the Node 1 to Node 2. It is defined in the same manner as AirflowNetwork Mass Flow Rate from Node 1 to 2.

When a Fan:OnOff object is used, the air volume flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air volume flow rates when the fan is off are zero for the distribution system air linkage objects. The air volume flow rates for the AirflowNetwork:Multizone:Surface object are reported in different output variables (below).

AirflowNetwork Volume Flow Rate from Node 2 to 1 [m³/s]

This is the AirflowNetwork linkage volume flow rate output in m³/s in the direction from Node 2 to Node 1. It is defined in the same manner as AirflowNetwork Mass Flow Rate from Node 2 to 1.

When a Fan:OnOff object is used, the air volume flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air volume flow rates when the fan is off are zero for the distribution system air linkage objects. The air volume flow rates for the AirflowNetwork:Multizone:Surface object are reported in different output variables (below).

AirflowNetwork Average Volume Flow Rate from Node 1 to 2 [m³/s]

This is the AirflowNetwork linkage average volume flow rate in m³/s in the direction from Node 1 to Node 2 defined in the AirflowNetwork:Multizone:Surface objects. This output is only available when a Fan:OnOff object is used. The average volume flow rate is weighted by the system fan part-load ratio using the calculated air volume flow rates during the fan on and off periods for the system timestep.

Average surface volume flow rate = (Surface volume flow rate during on cycle * Part-load ratio) + Surface volume flow rate during off cycle * (1.0 – Part-load ratio)

AirflowNetwork Average Volume Flow Rate from Node 2 to 1 [m³/s]

This is the AirflowNetwork linkage average volume flow rate in m³/s in the direction from Node 2 to Node 1 defined in the AirflowNetwork:Multizone:Surface objects. This output is only available when a Fan:OnOff object is used. The average volume flow rate is weighted by the system fan part-load ratio using the calculated air volume flow rates during the fan on and off periods for the system timestep.

AirflowNetwork Linkage Pressure Difference [Pa]

This is the pressure difference across a linkage in Pa. The linkage includes both objects: AirflowNetwork:Multizone:Surface and AirflowNetwork: Distribution:Linkage.

When a Fan:OnOff object is used, the pressure differences reported for the AirflowNetwork:Distribution:Linkage objects are the values calculated when the fan is operating (ON). It is assumed that the pressure differences when the fan is off are zero for the distribution system air linkage objects. The pressure differences defined in the AirflowNetwork:Multizone:Surface are reported in different output variables (below).

AirflowNetwork Surface Average Pressure Difference [Pa]

This is the average pressure difference across a linkage in Pa for the AirflowNetwork:Multizone:Surface objects only when a Fan:OnOff object is used. The average pressure difference is weighted by the system fan part-load ratio using the calculated pressure differences during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Surface Average Pressure Difference = (Surface Average Pressure Difference during on cycle * Part-load ratio) + Surface Average Pressure Difference during off cycle * (1.0 - Part-load ratio)

AirflowNetwork Surface Pressure Difference During ON cycle [Pa]

This is the pressure difference across a linkage in Pa for the AirflowNetwork:Multizone:Surface objects only when the air distribution system fan is operating (ON). This output is only available when a Fan:OnOff object is used. When the fan part-load ratio is equal to 0.0, this pressure difference value will be zero because the air distribution system is not simulated when the fan is off for the entire timestep.

AirflowNetwork Surface Pressure Difference During OFF cycle [Pa]

This is the pressure difference across a linkage in Pa for the AirflowNetwork:Multizone:Surface objects only when the air distribution system fan is not operating (OFF). This output is only available when a Fan:OnOff object is used. Even if the fan part-load ratio is equal to 1.0, the pressure difference calculated as if the fan were not operating (OFF) is reported.

Window/Door Venting Opening Factor []

The current time-step value of the venting opening factor for a particular window or door. When the window or door is venting, this is the input value of the opening factor (see AirflowNetwork:Multizone:Surface, Window/Door Opening Factor) times the multiplier for

venting modulation (see description of next output variable, “Opening Factor Multiplier for AirflowNetwork Venting Modulation”). For example, if the input Window/Door opening factor is 0.5 and the modulation multiplier is 0.7, then the value of this output variable will be $0.5 \times 0.7 = 0.35$.

Opening Factor Multiplier for AirflowNetwork Venting Modulation []

This is the multiplier on a window or door opening factor when venting modulation is in effect. See “Modulation of Openings” under AirflowNetwork:Multizone:Zone for a description of how the multiplier is determined.

When modulation is in effect the value of the multiplier is between 0.0 and 1.0. When modulation does not apply the value of the multiplier may be -1.0. When modulation applies but the surface is not venting, the value is -1.0. This is summarized in the following table. In this table, “Zone” means a thermal zone for which AirflowNetwork:Multizone:Zone has been specified. See AirflowNetwork: Multizone:Zone for definition of “Ventilation Control Mode.”

Table 22. Value of opening factor multiplier for different venting conditions.

Is surface in a Zone?	Ventilation Control Mode	Is surface venting?	Value of opening factor multiplier
Yes	Temperature	Yes	0.0 to 1.0
		No	-1.0
	Enthalpy	Yes	0.0 to 1.0
		No	-1.0
	Constant	Yes	1.0
	NoVent	No	-1.0

Inside Temp Setpoint for AirflowNetwork Venting [C]

The time-step value of the venting setpoint temperature for the zone to which the surface belongs. This setpoint is determined from the Vent Temperature Schedule input (ref: AirflowNetwork:Multizone:Zone).

Venting Availability []

A value of 1.0 means venting through the surface can occur if venting control conditions are satisfied. A value of 0.0 means venting through the surface cannot occur under any circumstances. This value is determined by the Venting Availability Schedule input (ref: AirflowNetwork:Multizone:Zone or AirflowNetwork:Multizone: Surface).

AirflowNetwork Infiltration Sensible Gain Rate [W]

The average convective sensible heat gain rate, in Watts, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature; otherwise, the sensible gain rate is set to 0.

When a Fan:OnOff object is used, this reported value is weighted by the system run time fraction using the calculated infiltration sensible gain rate during the system on and off cycles for the reporting period:

$$\text{Infiltration Sensible Gain Rate} = (\text{Infiltration Sensible Gain Rate during on cycle} * \text{Run time fraction}) + \text{Infiltration Sensible Gain Rate during off cycle} * (1.0 - \text{Run time fraction})$$

AirflowNetwork Infiltration Sensible Gain [J]

The average convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature; otherwise, the sensible gain rate is set to 0.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible gain during the system on and off cycles for the reporting period:

Infiltration Sensible Gain = (Infiltration Sensible Gain during on cycle * Run time fraction) + Infiltration Sensible Gain during off cycle * (1.0 – Run time fraction)

AirflowNetwork Infiltration Sensible Loss Rate [W]

The average convective sensible heat loss rate, in Watts, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible loss rate during the system on and off cycles for the reporting period:

Infiltration Sensible Loss Rate = (Infiltration Sensible Loss Rate during on cycle * Run time fraction) + Infiltration Sensible Loss Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Infiltration Sensible Loss [J]

The average convective sensible heat loss, in Joules, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible loss rate during the system on and off cycles for the reporting period:

Infiltration Sensible Loss = (Infiltration Sensible Loss during on cycle * Run time fraction) + Infiltration Sensible Loss during off cycle * (1.0 – Run time fraction)

AirflowNetwork Infiltration Latent Gain Rate [W]

The average convective latent heat gain rate, in Watts, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period, when the outdoor humidity ratio is higher than the zone air humidity ratio.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent gain rate during the system on and off cycles for the reporting period:

Infiltration Latent Gain Rate = (Infiltration Latent Gain Rate during on cycle * Run time fraction) + Infiltration Latent Gain Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Infiltration Latent Gain [J]

The total convective latent heat gain, in Joules, to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent gain during the system on and off cycles for the reporting period:

Infiltration Latent Gain = (Infiltration Latent Gain during on cycle * Run time fraction) + Infiltration Latent Gain during off cycle * (1.0 – Run time fraction)

AirflowNetwork Infiltration Latent Loss Rate [W]

The average convective latent heat loss rate, in Watts, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent loss rate during the system on and off cycles for the reporting period:

Infiltration Latent Loss Rate = (Infiltration Latent Gain Loss Rate during on cycle * Run time fraction) + Infiltration Latent Loss Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Infiltration Latent Loss [J]

The total convective latent heat loss, in Joules, to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent loss during the system on and off cycles for the reporting period:

Infiltration Latent Loss = (Infiltration Latent Gain Loss during on cycle * Run time fraction) + Infiltration Latent Loss during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Sensible Gain Rate [W]

The average convective sensible heat gain rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period. The mixing-volume is defined as incoming volume flow from other adjacent zones where the air temperature is higher than the temperature in this zone. For example, there are two zones (Zone 2 and Zone 3) adjacent to this zone (Zone 1). Zone 1 receives airflows from both Zone 2 and Zone 3. The air temperature is 21°C in Zone 1. The air temperatures are 20°C in Zone 2 and 22°C in Zone 3. The sensible gain rate only includes heat gain from Zone 3 with respect to Zone 1. The energy received from Zone 2 is considered as a sensible loss, instead of a gain, because the air temperature in Zone 2 is lower than in Zone 1.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible gain rate during the system on and off cycles for the reporting period:

Mixing Sensible Gain Rate = (Mixing Sensible Gain Rate during on cycle * Run time fraction) + Mixing Sensible Gain Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Sensible Loss Rate [W]

The average convective sensible heat loss rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible loss rate during the on and off cycles for the reporting period:

Mixing Sensible Loss Rate = (Mixing Sensible Loss Rate during on cycle * Run time fraction) + Mixing Sensible Loss Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Sensible Gain [J]

The total convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible gain during the on and off cycles for the reporting period:

Mixing Sensible Gain = (Mixing Sensible Gain during on cycle * Run time fraction) + Mixing Sensible Gain during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Sensible Loss [J]

The total convective sensible heat loss, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible loss during the on and off cycles for the reporting period:

Mixing Sensible Loss = (Mixing Sensible Loss during on cycle * Run time fraction) + Mixing Sensible Loss during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Latent Gain Rate [W]

The average convective latent heat gain rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent gain rate during the on and off cycles for the reporting period:

Mixing Latent Gain Rate = (Mixing Latent Gain Rate during on cycle * Run time fraction) + Mixing Latent Gain Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Latent Gain [J]

The total convective latent heat gain, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent gain during the on and off cycles for the reporting period:

Mixing Latent Gain = (Mixing Latent Gain during on cycle * Run time fraction) + Mixing Latent Gain during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Latent Loss Rate [W]

The average convective latent heat loss rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent loss rate during the on and off cycles for the reporting period:

Mixing Latent Loss Rate = (Mixing Latent Loss Rate during on cycle * Run time fraction) + Mixing Latent Loss Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Latent Loss [J]

The total convective latent heat loss, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent loss during the on and off cycles for the reporting period:

Mixing Latent Loss = (Mixing Latent Loss during on cycle * Run time fraction) + Mixing Latent Loss during off cycle * (1.0 – Run time fraction)

AirflowNetwork Duct Leak Sensible Gain Rate [W]

This is the average sensible heat gain rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system. This value is averaged over the reporting period. A sensible heat gain occurs when duct air is warmer than zone air. It should be pointed out that when multiple supply air leaks are present in a single zone, the output value is the summation of all the supply air leak gains in this zone. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Sensible Gain [J]

This is the total sensible heat gain, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Sensible Loss Rate [W]

This is the average sensible heat loss rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system. This value is averaged over the reporting period. A sensible heat loss occurs when duct air is cooler than zone air. It should be pointed out that when multiple supply air leaks are present in this zone, the output value is the summation of all the supply air leak losses in this zone. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Sensible Loss [J]

This is the total sensible heat loss, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Latent Gain Rate [W]

This is the average latent heat gain rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system for the reported time period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Latent Gain [J]

This is the total latent heat gain, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Latent Loss Rate [W]

This is the average latent heat loss rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system for the reported time period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Latent Loss [J]

This is the total latent heat loss, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Conduction Sensible Gain Rate [W]

This is the average sensible heat gain rate, in Watts, of duct conduction to a specific zone where the ducts are located. This value is averaged over the reporting period. A sensible heat gain occurs when duct air is warmer than the zone air. It should be pointed out that when ducts are located in different zones, the total duct conduction loss should be the summation of the duct conduction losses in these zones. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Conduction Sensible Gain [J]

This is the total sensible heat gain, in Joules, to a specific zone due to duct conduction summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Conduction Sensible Loss Rate [W]

This is the average sensible heat loss rate, in Watts, of duct conduction to a specific zone where the ducts are located. This value is averaged over the reporting period. A sensible

heat loss occurs when duct air is cooler than the zone air. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Conduction Sensible Loss [J]

This is the total sensible heat loss, in Joules, to a specific zone due to duct conduction summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Diffusion Latent Gain Rate [W]

This is the average latent heat gain rate, in Watts, of vapor diffusion through the walls of the air distribution system to a specific zone where the ducts are located. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Diffusion Latent Gain [J]

This is the total latent heat gain, in Joules, to a specific zone due to duct vapor diffusion summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Diffusion Latent Loss Rate [W]

This is the average latent heat loss rate, in Watts, of duct vapor diffusion to a specific zone where the ducts are located. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Diffusion Latent Loss [J]

This is the total latent heat loss, in Joules, to a specific zone due to duct vapor diffusion summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Sensible Gain Rate [W]

This is the average total sensible heat gain rate, in Watts, in a specific zone caused by the forced air distribution system. The total sensible gain rate is the sum of duct leakage sensible gain rate and duct conduction sensible gain rate. This value is averaged over the reporting period. The multizone airflow sensible gain rate is excluded in this output report variable. The output of multizone airflow sensible gain is reported in the previously-described output variables AirflowNetwork Infiltration Sensible Gain Rate and AirflowNetwork Mixing Sensible Gain Rate. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Sensible Gain [J]

This is the total sensible heat gain, in Joules, in a specific zone caused by the forced air distribution system. The total sensible gain is the sum of duct leakage sensible gain and duct conduction sensible gain. This value is summed over the reporting period. The multizone airflow sensible gain is excluded in this output report variable. The output of multizone airflow sensible gain is reported in the previously-described output variables AirflowNetwork Infiltration Sensible Gain and AirflowNetwork Mixing Sensible Gain. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Sensible Loss Rate [W]

This is the average total sensible heat loss rate, in Watts, in a specific zone caused by the forced air distribution system. The total sensible loss rate is the sum of duct leakage sensible loss rate and duct conduction sensible loss rate. This value is averaged over the reporting period. The multizone airflow sensible loss rate is excluded in this output report variable. The output of multizone airflow sensible loss rate is reported in the previously-described output variables AirflowNetwork Infiltration Sensible Loss Rate and AirflowNetwork Mixing Sensible Loss Rate. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Sensible Loss [J]

This is the total sensible heat loss, in Joules, in a specific zone caused by the forced air distribution system. The total sensible loss is the sum of duct leakage sensible loss and duct conduction sensible loss. This value is summed over the reporting period. The multizone airflow sensible loss is excluded in this output report variable. The output of multizone airflow sensible loss is reported in the previously-described output variables AirflowNetwork Infiltration Sensible Loss and AirflowNetwork Mixing Sensible Loss. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Latent Gain Rate [W]

This is the average total latent heat gain rate, in Watts, in a specific zone caused by the forced air distribution system. The total latent gain rate is the sum of duct leakage latent gain rate and duct conduction latent gain rate. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Latent Gain [J]

This is the total latent heat gain, in Joules, in a specific zone caused by the forced air distribution system. The total latent gain is the sum of duct leakage latent gain and duct diffusion latent gain. This value is summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Latent Loss Rate [W]

This is the average total latent heat loss rate, in Watts, in a specific zone caused by the forced air distribution system. The total latent loss rate is a sum of duct leakage latent loss rate and duct diffusion latent loss rate. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Latent Loss [J]

This is the total latent heat loss, in Joules, in a specific zone caused by the forced air distribution system. The total latent loss is the sum of duct leakage latent loss and duct diffusion latent loss. This value is summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

NOTE: The following report variables should not be confused with similar report variables for the infiltration, mixing, and cross mixing objects (Ref. Infiltration Output, Mixing Output, or Cross Mixing Output). The report variables described below refer to infiltration, mixing, and cross-mixing when an Airflow Network Simulation is performed. The following report variables are always used to describe infiltration, mixing, and cross mixing when the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to “MultizoneWithoutDistribution” or “MultizoneWithDistribution”. In this case the report variables for the infiltration, mixing, and cross mixing objects will always be 0.

In contrast, the following report variables are only used to describe infiltration, mixing, and cross mixing when the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to “MultizoneAirflowWithDistributionOnlyDuringFanOperation” and the fan is operating. When the fan is not operating, the report variables for the infiltration, mixing, and cross mixing objects are used.

In the case where the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to “NoMultizoneOrDistribution”, the following report variables are not used and the report variables for the infiltration, mixing, and cross mixing objects are used instead.

AirflowNetwork Infiltration Sensible Gain [J]

The total convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period. This value is calculated for each

timestep when the outdoor dry-bulb temperature is higher than the zone temperature, otherwise the sensible gain is set to 0. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Infiltration Sensible Loss [J]

The total convective sensible heat loss, in Joules to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Zone Infiltration Volume [m3]

The volume of outdoor air flow into the zone from window/door openings and cracks in the exterior surfaces of the zone (i.e., the sum of ventilation and crack flows from the exterior into the zone). Note that AirflowNetwork Zone Infiltration Volume will be zero if all of the flows through the zone's exterior surfaces are out of the zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration volume calculated during the fan on and off periods for the simulation timestep.

AirflowNetwork Zone Infiltration Mass [kg]

The mass of air corresponding to the AirflowNetwork Zone Infiltration Volume. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration mass calculated during the fan on and off periods for the simulation timestep.

AirflowNetwork Zone Infiltration Air Change Rate [ach]

The number of air changes per hour produced by outdoor air flow into the zone from window/door openings and cracks in the exterior surfaces of the zone (i.e. the sum of ventilation and crack flows from the exterior into the zone). Note that, like Zone Infiltration Volume, Zone Infiltration Air Change Rate will be zero if all flows through the zone's exterior surfaces are out of the zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration air change rate calculated during the fan on and off periods for the simulation timestep.

AirflowNetwork Zone Mixing Volume [m3]

This is a measure of interzone air flow for each thermal zone. It is the volume of air flow into the zone from adjacent zones through window/door openings and cracks in the interior heat transfer surfaces of the zone. This variable does not include flows that are from the zone to adjacent zones. Note that Zone Mixing Volume will be zero if all flows through the zone's interior surfaces are out of the zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the mixing volume calculated during the fan on and off periods for the simulation timestep.

AirflowNetwork Zone Mixing Mass [kg]

The mass of air corresponding to the AirflowNetwork Zone Mixing Volume. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the mixing mass calculated during the fan on and off periods for the simulation timestep.

Group – Zone Equipment

There are five main zone equipment statements that must be used to describe a block of zone equipment as shown in the below figure “Zone Equipment Input Syntax Map”.

Types of Zone equipment are listed below and shown below in figure “Zone Equipment”.

Table 23. Available Zone Equipment Types

Air Distribution Equipment	AirTerminal:SingleDuct:Uncontrolled AirTerminal:SingleDuct:ConstantVolume:Reheat AirTerminal:SingleDuct:VAV:Reheat AirTerminal:SingleDuct:VAV:NoReheat AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan AirTerminal:DualDuct:ConstantVolume AirTerminal:DualDuct:VAV Powered Induction Units (Series and Parallel)
Zone Forced Air Units	ZoneHVAC:IdealLoadsAirSystem ZoneHVAC:FourPipeFanCoil ZoneHVAC:WindowAirConditioner Unit Ventilator/Heater Air-to-Air Heat Pumps Unitary Systems (heat only and heat/cool) Furnaces (heat only and heat/cool) Energy Recovery Ventilator:Stand Alone AirLoopHVAC:UnitaryCoolOnly
Radiative/Convective Units	Baseboard Heaters Low Temp Radiant Systems High Temp Radiant System

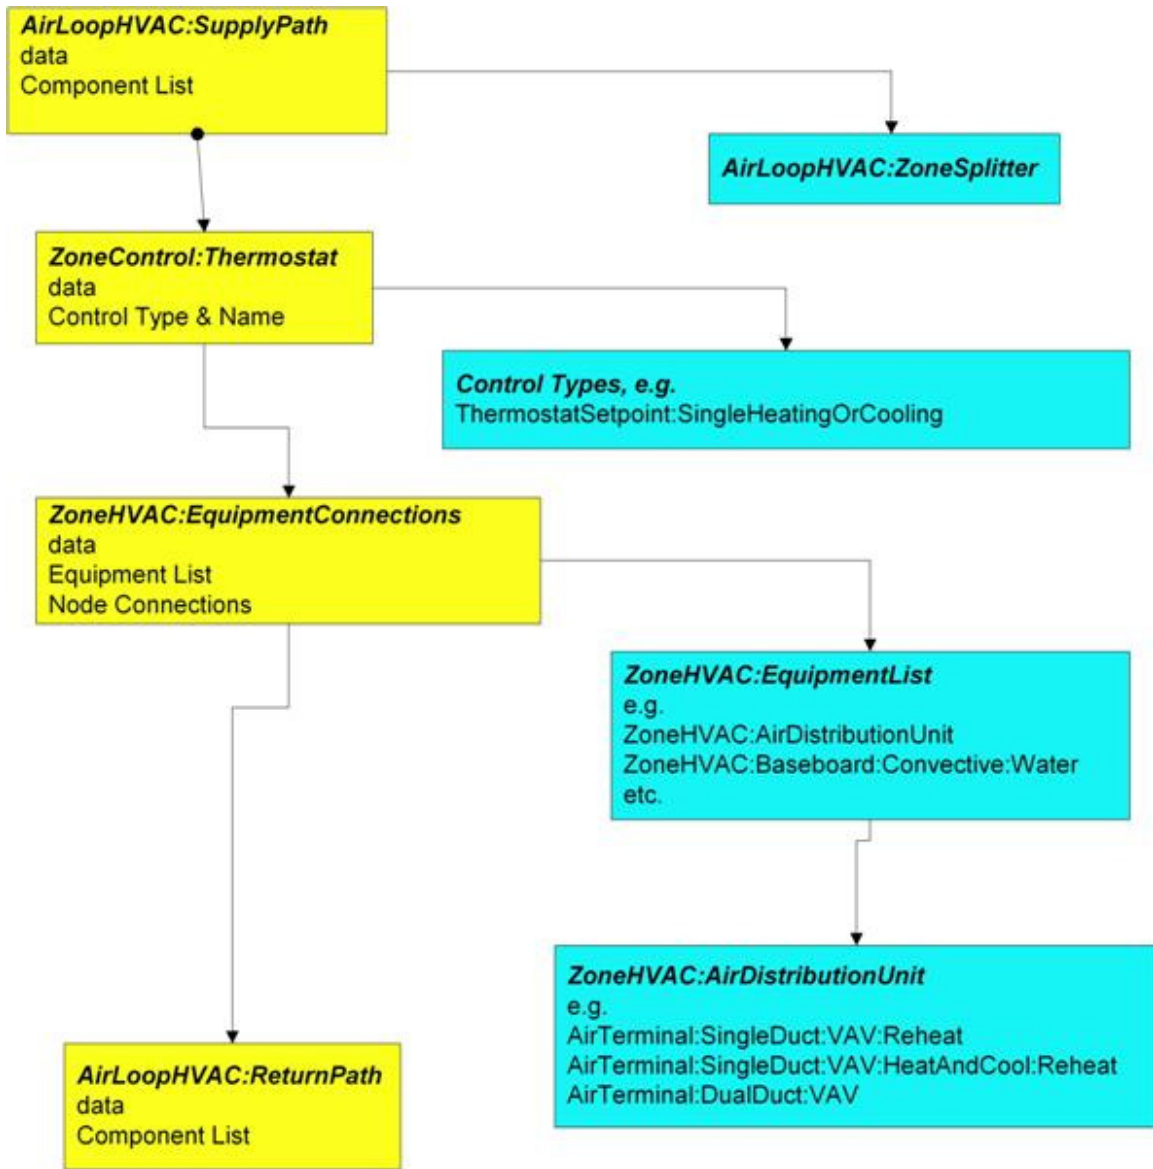

Figure 82. Zone Equipment Input Syntax Map

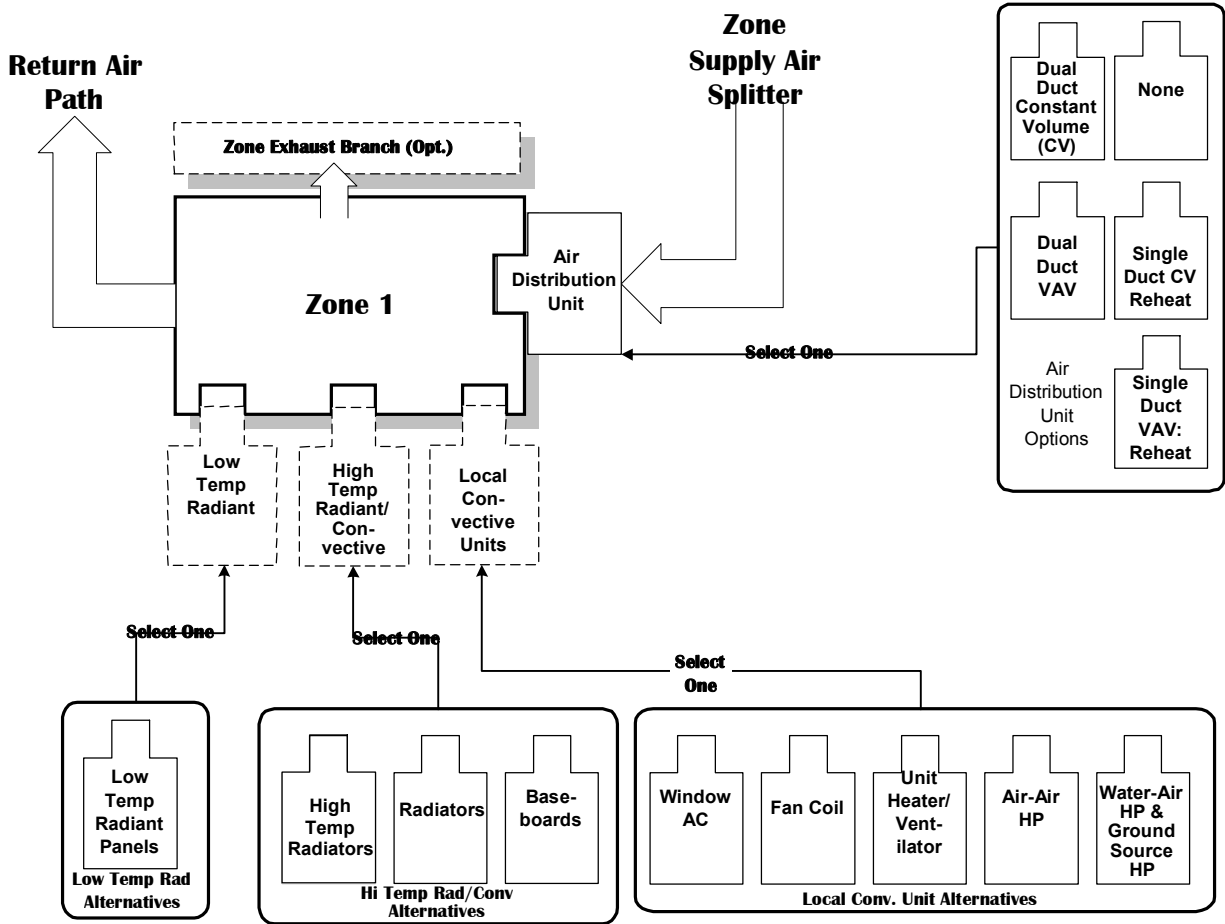

Figure 83. Representative Zone Equipment

The following figure (Air Loop/Zone Equipment Node Diagram) illustrates the connection between the zone equipment and the air loop systems.

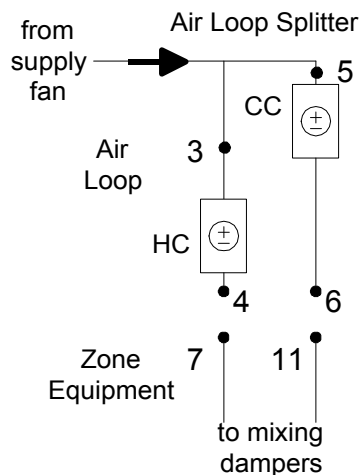

Figure 84. Air Loop/Zone Equipment Node Diagram

Each zone served by an HVAC system must have three additional statements to complete the zone equipment specification. An ZoneHVAC:AirDistributionUnit allows equipment typically found within the zone inlet ductwork (such as dampers, reheat coils, etc.) to be

attached to the supply air stream for a particular zone. A ZoneControl statement will allow the conditions in the zone to be managed. Finally, a ZoneHVAC:EquipmentConnections statement describes all of the pertinent information about the zone from an HVAC perspective. Each of these statements is described in more detail below.

ZoneHVAC:AirDistributionUnit

The ZoneHVAC:AirDistributionUnit object gives further information on what air loop equipment (air terminal units) will be serving a particular zone. The ZoneHVAC:AirDistributionUnit is the part of the system that is supplied from a common main air handler simulated in the Air Loop Simulation and includes the equipment that controls or tempers the air going to each individual zone according to the desired thermostatic control. The current options for ZoneHVAC:AirDistributionUnit terminal unit types are:

```
AirTerminal:DualDuct:ConstantVolume
AirTerminal:DualDuct:VAV
AirTerminal:SingleDuct:ConstantVolume:Reheat
AirTerminal:SingleDuct:VAV:Reheat
AirTerminal:SingleDuct:VAV:NoReheat
AirTerminal:SingleDuct:SeriesPIU:Reheat
AirTerminal:SingleDuct:ParallelPIU:Reheat
AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction
AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan
AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat
AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat
```

Connections between the air distribution unit, the supply air duct, and the zone are specified in the input syntax for the air distribution unit and the AirLoopHVAC:ZoneSplitter. The input syntax also explicitly defines an outlet identifier. This implies a connection to a zone through a NodeList for zone inlets (see the ZoneHVAC:EquipmentConnections statement). The air distribution unit is limited to one combined component-controller unit; because controls are normally based on the zone thermostat and can work in parallel or series in complex fashion. Since the control and the flow resolution can be complex, each air distribution unit is unique in addressing these combinations and therefore only one is allowed per zone.

The Air Distribution unit also allows the user to specify leaks in the supply air duct system. These inputs are used in the EnergyPlus Simplified Duct Leakage Model (SDLM). This model simulates a specific configuration: supply leaks to a return plenum in a commercial VAV or CV system. The system must have a constant static pressure setpoint. Within these limitations SDLM allows the user to easily evaluate the energy penalty due to duct leakage.

Field: Name

Unique identifying name of the air distribution unit.

Field: Air Distribution Unit Outlet Node Name

Outlet node name for the air distribution unit to the attached zone.

Field: Air Terminal Object Type

Single combined component/controller unit for that attached zone. Selection of components as listed above.

Field: Air Terminal Name

The unique identifying component name.

Field: Nominal Upstream Leakage Fraction

This is the leakage upstream of the terminal unit as a fraction of the design flow rate through the unit. It is the leakage fraction at the design flow rate. It is used to calculate a leakage flow rate which is then held constant while the system air flow varies. This input is optional; the default is zero.

Field: Constant Downstream Leakage Fraction

This is the leakage downstream of the terminal unit as a fraction of the current flow rate through the terminal unit. This fraction is held constant, so the leakage flow rate will vary proportionally with the supply air flow rate. This input is optional; the default is zero.

ZoneHVAC:EquipmentConnections

Finally, the ZoneHVAC:EquipmentConnections statement defines the remaining details about each thermal zone from an HVAC perspective (besides the controls which were defined above). As with other statements, the first two items in this object are the keyword and an identifying name which links the zone back to its geometrical input, internal gains, etc. and other statements in the HVAC section of the input. The next three items are names of lists (equipment, air inlet nodes, and air exhaust nodes) that are described in more detail below.

Note that if there are no air exhaust nodes from the zone that field is left blank. And if there are no air inlet nodes, that field is left blank. Finally, two node names are necessary to complete the zone-HVAC description. The first node is the main air node for the zone upon which the air heat balance is performed. The other node begins the return air path from the zone.

Note that all nodes mentioned in the ZoneHVAC:EquipmentConnections input must be unique. That is, all nodes in all the ZoneHVAC:EquipmentConnections statements referenced by the “Zone Air Inlet Nodes”, “Zone Air Exhaust Nodes”, “Zone Air Node Name” and “Zone Return Air Node Name” cannot have any node name appearing more than once.

Field: Zone Name

Name links this equipment list back to the heat balance for the zone.

Field: Zone Conditioning Equipment List Name

List of zone equipment for this zone in a ZoneHVAC:EquipmentList object. This list will consist of air distribution units or other direct convection or radiant equipment, i.e. window air conditioner, baseboard, fan coils, etc.

Field: Zone Air Inlet Node or NodeList Name

There can be more than one air inlet node depending on how many pieces of equipment are in the ZoneHVAC:EquipmentList. Generally there will be one air inlet node for each piece of zone equipment that delivers conditioned air to the zone. Components such as electric or hot water baseboards and radiant systems do not require zone air inlet nodes. If there is only one node – its name can be put in this field. If there is more than one node, this must be the name of a node list object (a node list object can also contain only one node name). If this field is not required (as in the baseboard system), it should be blank.

Field: Zone Air Exhaust Node or NodeList Name

List of exhaust nodes leaving the zone for exhaust fans, zone energy recovery, etc. However these nodes are also used as sources of zone air for zone components such as fan coil units, unit heaters and ventilators, and window air conditioners. For each such component attached to a zone there should be a unique zone exhaust node acting as the inlet node to the component. If there is only one node – its name can be put in this field. If there is more than one node, this must be the name of a node list object (a node list object can also contain only one node name). If there are no air exhaust nodes, this field should be blank.

Field: Zone Air Node Name

The conditions at this node represent the average state of the air in the zone. For zones modeled as fully mixed the conditions at this node are assumed to represent the air in the entire zone. This field is required for all ZoneHVAC:EquipmentConnections statements.

Field: Zone Return Air Node Name

The name of the return air node which attaches the zone to the return air path described above. Even if there is no return air or no return air path a unique name must be entered in this field. The conditions at this node represent the state of the air leaving the zone including any heat gain from light-heat-to-return.

SPACE3-1 Node,     !- Zone Air Node Name
SPACE3-1 Out Node; !- Zone Return Air Node Name

```

ZoneHVAC:EquipmentList

The first list encountered in the ZoneHVAC:EquipmentConnections statement is the ZoneHVAC:EquipmentList. As with most lists in the EnergyPlus input scheme, there is the defining keyword and an identifying name. In the case of the zone equipment list, each item in the list has four fields associated with it. The first two are the typical type keyword and identifying name pair. The remaining two items help define the cooling and heating priority of that piece of equipment, respectively. The priorities should be integers with a “1” being the highest priority, a “2” being the next highest priority, etc. Since there are separate inputs for heating and cooling, equipment can be prioritized appropriately for the different conditioning seasons. Note that an ZoneHVAC:AirDistributionUnit or AirTerminal:SingleDuct:Uncontrolled must be listed in this statement if there is a forced air system serving the zone from the air loop.

Field: Name

Unique identifying name.

Field Set (Zone Equipment: Object Type, Name, Cooling Priority, Heating Priority)

This set is used together in order to prioritize the equipment for heating and cooling. The #1 priority equipment will try to meet the entire demand with its capacity and then pass the results on to the #2 and so on for both heating and cooling. This field set is extensible by duplicating the last four fields.

Field: Zone Equipment <x> Object Type

Type of zone equipment such as air distribution unit, baseboard, window air conditioner, etc. The current legal types are listed in the following table:

Table 24. Legal Zone Equipment Types (ZoneHVAC:EquipmentList)

Legal Zone Equipment Types
AirTerminal:SingleDuct:Uncontrolled

```

An example of this statement in an IDF is:

```

ZoneHVAC:EquipmentList, Zone1Equipment,
  ZoneHVAC:AirDistributionUnit, Zone1DualDuct, 1, 1;

```

The Zone Inlets and Zone Exhaust are specified in a normal NodeList statement, named such that the ZoneHVAC:EquipmentConnections can find them.

For example, in the IDF:

```

NodeList,
  Zone1Inlets,
  Zone 1 Reheat Air Outlet Node;

NodeList,
  Zone2Inlets,
  Zone 2 Reheat Air Outlet Node;

NodeList,
  Zone3Inlets,
  Zone 3 Reheat Air Outlet Node;

```

Group – Air Distribution Equipment

The systems described in the Air Distribution Units (ADU's) are shown below. These single description ADU's contain the reference to the components and the actual controls in one block of input. The idea is that the control volume is drawn tightly around the controls and loosely around the components. This allows complex interactions to take place between all of the components that respond to the Zone Thermostatic Control output. The coils that are referenced in the ADU's are explained fully in the "Coils" section of this manual.

AirTerminal:SingleDuct:Uncontrolled

Central system air is usually supplied to a zone through a terminal unit such as a single duct VAV reheat box. Sometimes, however, it is desirable to supply central system air directly to a zone without any zone level control or tempering. An example would be a single zone reheat system.

The control zone receives supply air directly from the central system since the supply air temperature has been adjusted to control the temperature in the control zone. The slave zones then have baseboards or reheat coils to allow some temperature adjustment. The AirTerminal:SingleDuct:Uncontrolled object creates the capability of supplying central system air directly to a zone. Its input consists of the object name, an availability (on/off) schedule, and a node name. This node is both a zone inlet node and an outlet node of the AirLoopHVAC:ZoneSplitter.

For the objects to work correctly, it is important in any systems including Direct Air objects for the sum of the maximum zone air flow rates to be equal to the maximum central system flow rate. The zone maximum flow rates are specified in the zone terminal unit or direct air inputs. The central air system flow rate is specified in the AirLoopHVAC input and also in the air loop branch and central fan inputs.

Field: Name

A unique user assigned name for each AirTerminal:SingleDuct:Uncontrolled component. Any other component that needs to use this direct air component will refer to it by this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the component can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the direct air component can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the direct air component must be off for the hour

Field: Zone Supply Air Node Name

The name of the node to which the direct air component is supplying air. This should be one of the supply air nodes for the zone the direct air component is serving. This node should also be an outlet node of a AirLoopHVAC:ZoneSplitter component.

Field: Maximum Air Flow Rate

The design maximum volume flow rate (m^3/sec) specified for the AirTerminal:SingleDuct:Uncontrolled object. This field is autosizable.

The IDD definition is shown below.

```

```

AirTerminal:SingleDuct:ConstantVolume:Reheat

The AirTerminal:SingleDuct:ConstantVolume:Reheat or terminal reheat system is a constant volume reheat system. The systems cooling capabilities are provided by way of cooling coil that supplies cooling to the entire supply air volume. The cooling coil is controlled by a controller setpoint specified for the cooling coil. Zone control is accomplished by heating (reheating) the airflow into each zone as determined by the zone thermostat. Currently the reheat can be supplied by a electric, gas, or hot water coil that tries to meet the zone demand.

Field: Name

Unique name for the terminal reheat Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The outlet node from the ADU to the zone. This is the same node as the reheat component air outlet node.

Field: Air Inlet Node Name

The air-inlet node name that connects the air splitter to the individual zone ADU. This is the same node as the reheat component air inlet node.

Field: Maximum Air Flow Rate

The design constant volume flow rate (m³/sec) specified for the terminal reheat ADU.

Control Fields:

The last several fields for this object describe the type of reheat coil that is being used and how it is controlled. Most of the fields pertain to the hot water coil since the gas and electric coil are much more simplified.

Field: Hot Water or Steam Inlet Node Name

For the hot water reheat coil there is a node on the water side that would control the flow to the coil capacity to allow the coil to meet the zone demand. This control location is the name of the control node for the terminal reheat ADU. For the gas and electric coil this is left blank.

Field: Reheat Coil Object Type

The valid reheat component objects currently available are:

```
Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam
```

Field: Reheat Coil Name

Reheat Coil Object name being simulated with this ADU. Applicable for all coils.

Field: Maximum Hot Water or Steam Flow Rate

This field is 0 for gas and electric coils. Set to the maximum design water flow (m³/sec) for the hot water coil

Field: Minimum Hot Water or Steam Flow Rate

This field is zero for gas and electric coils. Set to the minimum design water flow (m³/sec) for the hot water coil, normally set to be a shut off valve that is set to zero.

Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved for by iteration. The iterative solution uses an interval halving routine and needs a termination criteria that is set with the Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand as the criteria, i.e. 0.001. The default for the field is 0.001.

```

AirTerminal:SingleDuct:VAV:Reheat

AirTerminal:SingleDuct:VAV:Reheat - Variable air volume (VAV) systems control the dry-bulb temperature inside a zone by varying the supply air volume instead of the air temperature. At full cooling the VAV damper is fully open supplying the specified maximum air flow rate. As the cooling load decreases, the damper closes until it reaches the minimum stop specified by the zone minimum air flow fraction.

VAV systems can be used for interior or perimeter zones with a common fan system, air temperature control, and reheating devices. The VAV concept may vary according to the VAV box locations, air temperature controls and types of heating elements. Heating can usually be provided by use of reheat coils or thermostatic baseboard.

Field: Name

Unique name for the AirTerminal:SingleDuct:VAV:Reheat Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Damper Air Outlet Node Name

The VAV damper outlet node. This is the outlet node of the damper and the inlet node of the reheat coil.

Field: Air Inlet Node Name

The air inlet node name that connects the air splitter to the individual zone ADU. This is *not* the same as the air inlet node of the reheat component: it is upstream of that node. This is the inlet node to the terminal unit and the damper

Field: Maximum Air Flow Rate

The design maximum volume flow rate (m³/sec) specified for VAV ADU.

Field: Zone Minimum Air Flow Method

This field is used to select how the program will determine the minimum flow rate to the zone while the system is operating. The minimum flow rate is modeled as a fraction of the maximum flow rate. There are two choices: Constant and Scheduled. If Constant is entered, then the program will use the value for minimum flow fraction entered in the following field. If Scheduled is entered, then the program will obtain the value for minimum flow fraction from the schedule named in the field below called Minimum Air Flow Fraction Schedule Name.

Field: Constant Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the previous field is set to Constant. If the previous field is set to Scheduled (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then this field is optional and can be used to separately control the air flow rate used for sizing normal-action reheat coils.

Field: Minimum Air Flow Fraction Schedule Name

The name of a schedule that determines the value of the minimum air flow fraction. The schedule should contain fractions from 0.0 to 1.0. These values will define the minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the previous field is set to Scheduled. If the previous field is left blank (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then the air flow rate used for sizing normal-action reheat coils is the average of the minimum and maximum values in this schedule. The air flow rate used for reheat coil sizing is reported with other component sizing information as "Reheat Coil Sizing Air Volume Flow Rate."

Control Fields:

The last several fields for this object describe the type of reheat coil that is being used and how it is controlled. Most of the fields pertain to the hot water coil since the gas and electric coil are much more simplified.

Field: Hot Water or Steam Inlet Node Name

For the hot water reheat coil there is a node on the water side that would control the flow to the coil capacity to allow the coil to meet the zone demand. This control location is the name of the control node for the terminal reheat ADU. For the gas and electric coils, or if there is no reheat coil, this is left blank.

Field: Reheat Coil Object Type

The valid reheat component objects currently available are:

```
Coil:Heating:Water  
Coil:Heating:Electric  
Coil:Heating:Gas  
Coil:Heating:Steam
```

If there is no reheat coil, use Single Duct:VAV:NoReheat instead of this object.

Field: Reheat Coil Name

Reheat Coil Object name being simulated with this ADU. Applicable for all coils. If there is no reheat coil, use object AirTerminal:SingleDuct:VAV:NoReheat instead of this object.

Field: Maximum Hot Water or Steam Flow Rate

This field is 0 for gas and electric coils. Set to the maximum design water flow (m³/sec) for the hot water coil. If there is no reheat coil, this is left blank.

Field: Minimum Hot Water or Steam Flow Rate

This field is zero for gas and electric coils. Set to the minimum design water flow (m³/sec) for the hot water coil, normally set to be a shut off valve that is set to zero. If there is no reheat coil, this is left blank.

Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved for by iteration. The iterative solution uses an interval halving routine and needs a termination criteria that is set with the Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand as the criteria, i.e. 0.001. The default for the field is 0.001.

Field: Damper Heating Action

During heating operation, there are two control options for the damper controlling the air flow in the VAV terminal unit as the zone moves above or below the zone setpoint. With both control options, the damper is at the minimum air flow rate whenever the zone temperature is between the cooling and heating setpoints.

With **Normal** (the default) action, the damper will remain at the minimum air flow rate during heating operation. As the heating load increases, the water flow rate in the reheat coil will be increased to maintain temperature in the zone until the maximum water flow rate is reached.

With **Reverse**, as the heating load increases, the unit starts at minimum air flow and minimum hot water flow. The hot water flow is increased until it reaches maximum flow, then the air damper starts to open to meet the load. This option is used if the minimum air flow rate is not adequate to serve the peak heating load.

The IDD specification is:

AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan

The VAV terminal unit with variable-speed fan and reheat coil is an air system terminal unit consisting of a variable speed fan in series with a heating coil. These units are usually employed in underfloor air distribution (UFAD) systems where the air is supplied at low static pressure through an underfloor plenum. The fan is used to control the flow of conditioned air that enters the space. When the fan is off the plenum pressure drives the minimum air flow through the terminal unit. At maximum cooling the fan runs at its maximum speed. At full heating the fan runs at its heating maximum – usually less than the cooling maximum flow rate. Thus this unit has two separate maximum flow rates – one for heating and one for cooling.

For cooling, control is maintained simply by varying the fan speed. For heating, the unit first tries to meet the heating load by varying the heating coil output while keeping the air flow at minimum (fan off). If this is not adequate the fan turns on and operates in variable flow mode up to the heating maximum flow rate.

This unit is modeled in EnergyPlus as a compound component – a variable speed fan and a heating coil in series in the air stream. The unit is blow through – the fan is upstream of the heating coil.

Field: Name

A unique user assigned name for a particular VS fan VAV reheat terminal unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Cooling Air Flow Rate

The maximum volumetric air flow rate through the unit in cubic meters per second when the thermostat is calling for cooling. Normally this is the same as the unit's fan maximum volumetric flow rate.

Field: Maximum Heating Air Flow Rate

The maximum volumetric air flow rate through the unit in cubic meters per second when the thermostat is calling for heating.

Field: Zone Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. For this unit this is the flow rate when the fan is off.

Field: Air Inlet Node Name

The name of the HVAC system node that is the air inlet node for the terminal unit. This is also the air inlet node for the unit's fan.

Field: Air Outlet Node Name

The name of the HVAC system node that is the air outlet node of the unit. This same node will be the unit heating coil's air outlet node. This node is also a zone inlet node.

Field: Heating Coil Air Inlet Node Name

The name of the HVAC system node that is the air inlet node of the unit's heating coil. The same node is the outlet node of the unit's fan. This is an internal node of this compound component.

Field: Hot Water or Steam Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the unit's hot water heating coil. This should be the same node as the water inlet node of the hot water coil. For gas or electric coils this field should be left blank.

Field: Fan Object Type

The type of fan in the terminal unit. At this time the only type of fan allowed is *Fan:VariableVolume*.

Field: Fan Name

The name of the particular fan object in this terminal unit.

Field: Heating Coil Object Type

The type of heating coil in the terminal unit. The valid choices are:

Coil:Heating:Water Coil:Heating:Electric Coil:Heating:Gas Coil:Heating:Steam

Field: Heating Coil Name

The name of the heating coil object contained in this terminal unit.

Field: Maximum Hot Water or Steam Flow Rate

The maximum hot water volumetric flow rate in m³/sec through the unit's heating coil. If the heating coil is not a hot water coil this field should be left blank.

Field: Minimum Hot Water or Steam Flow Rate

The minimum hot water volumetric flow rate in m³/sec through the unit's heating coil. If the heating coil is not a hot water coil this field should be left blank.

Field: Heating Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified

output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{unit,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq \textit{ConvergenceTolerance}$$

The default is 0.001.

AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan Outputs

There are no outputs for the VS fan VAV reheat terminal units.

AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat

Variable air volume (VAV) systems typically control the dry-bulb temperature inside a zone by varying the supply air volume instead of the supply air temperature (ref: AirTerminal:SingleDuct:VAV:NoReheat). Reheat coils may be required to avoid overcooling (ref: AirTerminal:SingleDuct:VAV:Reheat).

This terminal unit is slightly different from the Single Duct:VAV:Reheat terminal unit. Both operate the same in cooling mode: the damper opens as needed to provide additional sensible cooling to the zone. The difference between the two is in heating mode. For the Single Duct VAV Reheat terminal unit, the air flow rate is reduced to the minimum value (max air flow rate x zone minimum air flow fraction) when zone heating is required and the reheat coil output is modulated to meet the zone heating load. For the AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat terminal unit, the air flow rate in heating mode is increased to meet higher zone heating loads (similar to what is done in cooling mode). If additional heat is required (beyond what the terminal unit can provide with its damper fully open), then the reheat coil is modulated as needed to meet the additional heating load.

This terminal unit model was originally developed and tested for use with the changeover-bypass VAV unitary system.

Figure 85. Single Duct VAV Heat and Cool Reheat Schematic

Field: Name

Unique user-defined name for this Air Distribution Unit (ADU).

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether or not this component is available to operate during a given time period. If a schedule value is greater than zero then the system is available to operate; otherwise, the system is unavailable for that time period.

Field: Damper Air Outlet Node Name

This alpha field defines the name of the VAV damper air outlet node. This is the outlet node of the damper and the inlet node of the reheat coil.

Field: Air Inlet Node Name

This alpha field defines the name of the air inlet node that connects the air splitter to the individual zone ADU. This is *not* the same as the air inlet node of the reheat component: it is upstream of that node. This is the inlet node to the terminal unit and the damper.

Field: Maximum Air Flow Rate

This numeric field defines the design maximum volumetric flow rate (m³/sec) specified for this VAV ADU. This flow rate must be greater than 0 or can be autosized.

Field: Zone Minimum Air Flow Fraction

This numeric field defines the minimum air volumetric flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates as needed to maintain the heating set point specified in the Zone Control:Thermostatic object. This value must be between 0 and 1.

Control Fields:

The last several fields for this terminal reheat component describe the type of reheat coil that is being used and how it is controlled. Most of the fields pertain to the hot water coil since the gas and electric coil are much more simplified.

Field: Hot Water or Steam Inlet Node Name

For the hot water reheat coil there is a node on the water side that would control the water flow rate to allow the coil to meet the zone demand. This control location is the name of the control node for this terminal reheat ADU. For the gas and electric coils this field is left blank.

Field: Reheat Coil Object Type

The valid reheat component objects currently available are:

```
Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam
```

If no reheat coil is required, use AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat instead of this object.

Field: Reheat Coil Name

Unique coil name being simulated with this ADU. Applicable for all coils. If there is no reheat coil, use AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat instead of this object.

Field: Maximum Hot Water or Steam Flow Rate

This field is ignored for gas or electric reheat coils. If using a hot water or steam reheat coil, set to the maximum design water or steam volumetric flow rate (m³/sec) for the hot water or steam coil. This flow rate can be autosized.

Field: Minimum Hot Water or Steam Flow Rate

This field is ignored for gas and electric coils. Set to the minimum design water volumetric flow rate (m³/sec) for the hot water or steam coil, normally set to be a shut-off valve that is set to zero.

Field: Air Outlet Node Name

This is the air outlet node for the ADU and is then connected to the zone. This is the same node as the air outlet node of the reheat component.

Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted and this field is not used. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved by iteration. The iterative solution uses an interval-halving routine and needs a termination criteria that is set with this Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand. The default value for this field is 0.001.

The IDD specification is shown below:

AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat Outputs

System,Average,Damper Position

Field: Damper Position

This output field is the damper position required to meet the zone load. This is the average value over the simulation timestep being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

AirTerminal:SingleDuct:VAV:NoReheat

Variable air volume (VAV) systems control the dry-bulb temperature inside a zone by varying the supply air volume instead of the air temperature. At full cooling the VAV damper is fully open supplying the specified maximum air flow rate. As the cooling load decreases, the damper closes until it reaches the minimum stop specified by the zone minimum air flow fraction.

VAV systems can be used for interior or perimeter zones with a common fan system and air temperature control. The VAV concept may vary according to the VAV box locations and air temperature controls. Heating can be provided if necessary by use of baseboard.

Field: Name

Unique name for the VAV Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The VAV damper and Unit outlet node.

Field: Air Inlet Node Name

The air inlet node name that connects the air splitter to the individual zone ADU.

Field: Maximum Air Flow Rate

The design maximum volume flow rate (m³/sec) specified for VAV ADU. This is autosizable.

Field: Zone Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default).

The IDD specification is:

0.47, !- Maximum air flow rate {m3/s}
0.5; !- Min air flow fraction
```

AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat

Variable air volume (VAV) systems typically control the dry-bulb temperature inside a zone by varying the supply air volume instead of the supply air temperature (ref: AirTerminal:SingleDuct:VAV:NoReheat). Reheat coils may be required to avoid overcooling (ref: AirTerminal:SingleDuct:VAV:Reheat).

This terminal unit is slightly different from the AirTerminal:SingleDuct:VAV:NoReheat terminal unit. Both operate the same in cooling mode: the damper opens as needed to provide additional sensible cooling to the zone. The difference between the two is in heating mode. For the Single Duct VAV NoReheat terminal unit, the air flow rate is reduced to the minimum value (max air flow rate x zone minimum air flow fraction) when zone heating is required. For the AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat terminal unit, the air flow rate in heating mode is increased to meet higher zone heating loads (similar to what is done in cooling mode).

This terminal unit model was originally developed and tested for use with the changeover-bypass VAV unitary system. This object may be used when the central heating coil is sufficient to maintain the heating set point temperature. Additional heating may be provided, if necessary, by use of Single Duct:VAVHeatandCool:Reheat or Baseboard Heater objects.

Figure 86. Single Duct VAV Heat and Cool NoReheat Schmatic

```

AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat Outputs

```
System,Average,Damper Position
```

Field: Damper Position

This output field is the damper position required to meet the zone load. This is the average value over the simulation timestep being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

AirTerminal:SingleDuct:SeriesPIU:Reheat

The series powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a fixed flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The fan runs at a constant volume flow rate whenever the unit is on. The fan is downstream of the primary and secondary air inlets. The variable mixing is accomplished by a damper in the unit's primary air supply inlet duct. This damper can move from fully open (100% primary air, 0% secondary air) to a minimum stop that is specified in the input description. At full cooling the damper will be fully open. At minimum cooling and for heating the damper will be at the minimum stop and the secondary air flow will be at its maximum.

The EnergyPlus model of the series PIU terminal unit is composed of three components: a zone mixer, a constant volume fan, and a heating coil (hot water, electric, or gas).

Field: Name

A unique user assigned name for a particular series powered induction terminal unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Air Flow Rate

The maximum volumetric air flow rate through the unit in cubic meters per second. Since this is a constant air volume unit, this is also the design, rated air flow rate of the unit.

Field: Maximum Primary Air Flow Rate

The maximum volumetric air flow rate of primary air through the unit in cubic meters per second. This is the primary air flow rate at full cooling load when the primary air damper is fully open. Usually this quantity is the same as the total unit flow rate, but it can be less.

Field: Minimum Primary Air Flow Fraction

The minimum volumetric air flow rate of primary air through the unit expressed as a fraction of the maximum volumetric air flow rate of primary air. This input can be 0.0.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air

Field: Secondary Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary or recirculated air.

Field: Outlet Node Name

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

Field: Reheat Coil Air Inlet Node Name

The name of the HVAC system node which is the inlet node of the unit's heating coil. This is also the outlet node of the unit's fan.

Field: Zone Mixer Name

The name of an zone mixer component (object: AirLoopHVAC:ZoneMixer) which composes part of the unit. Note that some of the input for the mixer will duplicate input fields of the powered induction unit. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the PIU; the other inlet node of the zone mixer should be the same as the secondary air inlet node of the PIU. The outlet node of the zone mixer should be the same as the inlet node of the PIU fan.

Field: Fan Name

The name of a fan component which composes part of the unit. Note that the fan's maximum flow rate should be the same as the maximum air flow rate of the PIU and the type of fan object must be Fan:ConstantVolume. The fan's inlet node should be the same as the zone mixer's outlet node. The fan's outlet node should be the same as the heating coil's air inlet node.

Field: Reheat Coil Object Type

The type of coil in the PIU. The valid choices are:

```
Coil:Heating:Water  
Coil:Heating:Electric  
Coil:Heating:Gas  
Coil:Heating:Steam
```

In other words the PIU may have a hot water, gas, electric or steam reheat coil.

Field: Reheat Coil Name

The name of the heating coil component which composes part of the unit. Note that the heating coil's air inlet node is the same as the fan outlet node and the heating coil's air outlet node is the same as the PIU outlet node.

Field: Maximum Hot Water or Steam Flow Rate

The maximum hot water volumetric flow rate in m³/sec through the unit's heating coil. If the heating coil is gas or electric this field should be blank.

Field: Minimum Hot Water or Steam Flow Rate

The minimum hot water volumetric flow rate in m³/sec through the unit's heating coil. If the heating coil is gas or electric this field should be blank.

Field: Hot Water or Steam Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the unit. This should be the same node as the water inlet node of the unit's hot water coil. For gas or electric heating coils, this input should be blank.

Field: Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{PIU,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq ConvergenceTolerance$$

For gas or electric heating coils, this input should be left blank. The default is 0.001.

HVAC,Average,PIU Heating Rate[W]
 HVAC,Sum,PIU Heating Energy[J]
 HVAC,Average,PIU Sensible Cooling Rate[W]
 HVAC,Sum,PIU Sensible Cooling Energy[J]

PIU Heating Rate[W]

This field reports the dry air heating addition rate of the series PIU terminal unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the terminal unit.

PIU Heating Energy[J]

This field reports the dry air heat addition of the series PIU terminal unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

PIU Sensible Cooling Rate[W]

This field reports the dry air sensible heat extraction rate of the series PIU terminal unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the terminal unit.

PIU Sensible Cooling Energy[J]

This field reports the dry air sensible heat extraction of the series PIU terminal unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

AirTerminal:SingleDuct:ParallelPIU:Reheat

The parallel powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a variable total flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The secondary and primary air streams enter the unit in parallel. The fan sits in the secondary air stream and runs only when secondary air is needed. The primary air inlet contains a damper that can move from fully open (maximum primary air) to a minimum stop (minimum primary air).

At full cooling load the primary air damper is fully open and the fan is off. The primary air flow is at maximum and there is little or no secondary air flow. As the cooling load decreases, the primary air damper gradually closes and the secondary air flow remains close to zero. At some point, usually when the primary air flow has reached the minimum, the fan switches on and secondary air is induced. The heating coil will switch on as needed to meet any heating demand.

The EnergyPlus model of the parallel PIU terminal unit is composed of three components: a constant volume fan, a zone mixer, and a heating coil (hot water, electric, or gas).

Field: Name

A unique user assigned name for a particular parallel powered induction terminal unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Primary Air Flow Rate

The maximum volumetric air flow rate of primary air through the unit in cubic meters per second. This is the primary air flow rate at full cooling load when the primary air damper is fully open.

Field: Maximum Secondary Air Flow Rate

The maximum volumetric air flow rate of primary air through the unit in cubic meters per second. This flow rate can be any amount but is commonly less than the maximum primary air flow rate.

Field: Minimum Primary Air Flow Fraction

The minimum volumetric air flow rate of primary air through the unit expressed as a fraction of the maximum volumetric air flow rate of primary air. This input can be 0.0.

Field: Fan On Flow Fraction

The fraction of the primary air flow at which fan turns on. In the parallel PIU the fan operation is intermittent. If the primary air flow is above this fraction of the maximum, the fan is off. Otherwise it is on.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air

Field: Secondary Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary or recirculated air.

Field: Outlet Node Name

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

Field: Reheat Coil Air Inlet Node Name

The name of the HVAC system node which is the inlet node of the unit's heating coil. This is also the outlet node of the unit's zone mixer.

Field: Zone Mixer Name

The name of an zone mixer component (object: AirLoopHVAC:ZoneMixer) which composes part of the unit. Note that some of the input for the mixer will duplicate input fields of the powered induction unit. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the PIU; the other inlet node of the zone mixer should be the same as the air outlet node of the fan. The outlet node of the zone mixer should be the same as the inlet node of the heating coil.

Field: Fan Name

The name of a fan component which composes part of the unit. Note that the fan's maximum flow rate should be the same as the maximum secondary air flow rate of the PIU and the type of fan object must be Fan:ConstantVolume. The fan's inlet node should be the same as the PIU secondary air inlet node. The fan's outlet node should be the same as one of the zone mixer's inlet nodes.

Field: Reheat Coil Object Type

The type of coil in the PIU. The valid choices are:

```
Coil:Heating:Water  
Coil:Heating:Electric  
Coil:Heating:Gas
```

Coil:Heating:Steam

In other words the PIU may have a hot water, gas, electric or steam reheat coil.

Field: Reheat Coil Name

The name of the heating coil component which composes part of the unit. Note that the heating coil’s air inlet node is the same as the zone mixer’s outlet node and the heating coil’s air outlet node is the same as the PIU outlet node.

Field: Maximum Hot Water or Steam Flow Rate

The maximum hot water volumetric flow rate in m³/sec through the unit’s heating coil. If the heating coil is gas or electric this field should be blank.

Field: Minimum Hot Water or Steam Flow Rate

The minimum hot water volumetric flow rate in m³/sec through the unit’s heating coil. If the heating coil is gas or electric this field should be blank.

Field: Hot Water or Steam Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the unit. This should be the same node as the water inlet node of the unit’s hot water coil. For gas or electric heating coils, this input should be blank.

Field: Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{PIU,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq ConvergenceTolerance$$

For gas or electric heating coils, this input should be left blank. The default is 0.001.

PIU Heating Rate[W]

This field reports the dry air heating addition rate of the parallel PIU terminal unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the terminal unit.

PIU Heating Energy[J]

This field reports the dry air heat addition of the parallel PIU terminal unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

PIU Sensible Cooling Rate[W]

This field reports the sensible heat extraction rate of the parallel PIU terminal unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the terminal unit.

PIU Sensible Cooling Energy[J]

This field reports the dry air sensible heat extraction of the parallel PIU terminal unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction

The four pipe induction terminal unit provides local hot water heating or chilled water cooling of induced zone air which then mixes with centrally conditioned supply air. An air conditioning system consisting of these terminal units is effectively a mixed central air / local hydronic system. The centrally conditioned air supplied to the induction terminal units is constant volume at quite high pressure. The central air is discharged through a nozzle in the terminal unit, inducing a flow of room air over a hydronic heating/cooling coil. The coil is connected either to a single inlet and outlet pipe (2 pipe unit) or to 2 inlets and 2 outlets (4 pipe unit). The heated or cooled induced air mixes with the centrally conditioned air before being discharged into the zone. The terminal units are usually expected to do only sensible cooling – any dehumidification is done by the central air conditioning system.

The EnergyPlus model of the four pipe induction terminal unit is a compound component consisting of a hot water heating coil, a chilled water cooling coil, and an air mixer. The unit has two inlet air streams: the centrally conditioned supply air and the induced air from the zone. The induced air passes first through the heating coil, then through the cooling coil and finally through the mixer. The central supply air goes directly into the mixer. The water flow through the hot or cold water coil is varied to meet the zone air conditioning requirement. Note that EnergyPlus models the four pipe induction terminal unit as having separate heating and cooling coils whereas real units have only a single coil used for both heating and cooling. Note also that the four pipe induction unit model can be used to model a two pipe unit by simply adjusting the heating and cooling coil schedules so that the heating coil is off when the cooling coil is on and vice versa.

Field: Name

A unique user assigned name for a particular four pipe induction terminal unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Total Air Flow Rate

The maximum volumetric air flow rate discharged from the unit in cubic meters per second. Since this is a constant air volume unit, this is also the design, rated air flow rate of the unit. Note that this is the total discharge flow rate – including both central supply and induced air.

Field: Induction Ratio

The ratio of induced air flow rate to primary supply air flow rate. The default is 1.0 –the supply air induces an equal amount of zone air.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air

Field: Induced Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary or recirculated air. This should be the same node as one of the zone exhaust nodes.

Field: Air Outlet Node Name

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

Field: Hot Water Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the unit. This should be the same node as the water inlet node of the unit's hot water coil.

Field: Cold Water Inlet Node Name

The name of the HVAC system node which regulates the flow of cold water through the unit. This should be the same node as the water inlet node of the unit's chilled water coil.

Field: Heating Coil Object Type

The type of heating coil in the terminal unit. The choices are:

Coil:Heating:Water

In other words the unit may have a hot water coil only.

Field: Heating Coil Name

The name of the heating coil component which composes part of the unit. Note that the heating coil's air inlet node is the same as the terminal unit's induced air inlet node. The heating coil's air outlet node is the same as the cooling coil's air inlet node.

Field: Maximum Hot Water Flow Rate

The maximum hot water volumetric flow rate in m³/sec through the unit's heating coil.

Field: Minimum Hot Water Flow Rate

The minimum hot water volumetric flow rate in m³/sec through the unit's heating coil.

Field: Heating Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{unit,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq \text{ConvergenceTolerance}$$

The default is 0.001.

Field: Cooling Coil Object Type

The type of cooling coil in the terminal unit. The choices are:

Coil:Cooling:Water

Coil:Cooling:Water:DetailedGeometry

In other words the unit must use only the water cooling coils.

Field: Cooling Coil Name

The name of the cooling coil component which composes part of the unit. Note that the cooling coil's air inlet node is the same as the heating coil's air outlet node. The cooling coil's air outlet node is the same as one of the zone mixer's inlets.

Field: Maximum Cold Water Flow Rate

The maximum cold water volumetric flow rate in m³/sec through the unit's cooling coil.

Field: Minimum Cold Water Flow Rate

The minimum cold water volumetric flow rate in m³/sec through the unit's cooling coil.

Field: Cooling Convergence Tolerance

The control tolerance for the unit cooling output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{unit,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq \text{ConvergenceTolerance}$$

The default is 0.001.

Field: Zone Mixer Name

The name of an zone mixer component (object: AirLoopHVAC:ZoneMixer) which composes part of the terminal unit. Note that some of the zone mixer's inputs will duplicate some of the terminal unit's inputs. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the terminal unit; the other inlet node of the zone mixer should be the same as the cooling coil air outlet node. The outlet node of the zone mixer should be the same as the outlet node of the terminal unit.

AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction Outputs

There are no specific outputs for the four pipe induction terminal units.

AirTerminal:SingleDuct:ConstantVolume:CooledBeam

The Cooled Beam system is a mixed air-hydronic system. A central, single-duct forced-air system supplies conditioned ventilation air to the zones. Sensible cooling is done by chilled water circulating through ceiling mounted cooled beam units. Chilled water flow rate through the cooled beam units is varied to meet the zone sensible cooling load. Any dehumidification is done by the central ventilation air system. Heating is usually accomplished with hot water radiators. Thermodynamically, the cooled beam system resembles the four-pipe induction unit.

To model a typical cooled beam system the user will need to define a conventional central constant volume forced air system. This system will normally be 100% outside air delivered at a fixed supply temperature (which could be reset by schedule or by outside air temperature). On the supply side of this air loop there will be the usual central AC equipment: outside air mixer, fan, heating and cooling coil. On the zone equipment (demand) side of the loop, the chilled beams will be represented as terminal units. Additional zone equipment (such as baseboard heaters) will be needed to handle heating loads.

Although the cooled beam equipment in a zone is treated by the program as a single terminal unit, the actual installation will have multiple beams in each zone. The program (in its sizing calculation for the system) figures out how many beams of what length are needed to meet the zone design load.

Field: Name

A unique user assigned name for a particular chilled beam unit. Any reference to this unit by another object will use this name.

Field: Unit Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be

on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Cooled Beam Type

Two types of units are modeled: *Active* or *Passive*. In the active unit, primary air is supplied through the beam, inducing some secondary zone air into contact with the coil. This unit acts as an active convector. The passive unit is simply a passive, finned convector. Primary air is supplied through a normal diffuser.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air. Note that this field should be specified for both types of unit, even though supply air does not pass through the passive unit.

Field: Supply Air Outlet Node Name

The name of the air node that connects this terminal unit to the zone. The will be the same as one of the zone inlet nodes. The name of this node must be entered even if the actual beams are passive and is not actually supplying air to the zone.

Field: Chilled Water Inlet Node Name

The name of the chilled water inlet node.

Field: Chilled Water Outlet Node Name

The name of the chilled water outlet node.

Field: Supply Air Volumetric Flow Rate

This is the air flow rate in cubic meters per second of the supply air entering the zone. This input would normally be autosized based on the ventilation requirement (see Zone Sizing).

Field: Maximum Total Chilled Water Volumetric Flow Rate

The maximum chilled water flow rate (in cubic meters per second) for the unit. This input would normally be autosized based on the zone design load.

Field: Number of Beams

The number of individual cooled beam units in the zone. Normally this unit would be autocalculated by the program based upon the previous field and the nominal flow rate for a single beam unit (set by the program to 0.07 kg/s).

Field: Beam Length

The length of an individual beam in meters. Normally this will be autocalculated by the program based upon the number of beam units and the zone design sensible cooling load. 1 to 4 meters is a typical length range.

Field: Design Inlet Water Temperature

The nominal or design inlet water temperature in degrees Celsius. The default is 15C.

Field: Design Outlet Water Temperature

The nominal or design outlet water temperature in degrees Celsius. The default is 17C.

The following inputs are parameters used to characterize the performance of the chilled beam units. Values for a given unit can be obtained from the manufacturer. The parameters are used in the following equations.

$P_{beam} = A \cdot K \cdot \Delta T$	beam cooling output per unit length W/m
$K = \alpha \cdot \Delta T^{n1} \cdot v \rho^{n2} \cdot \omega^{n3}$	coil heat transfer coefficient W/(m ² K)
$v \rho = (Q_{in} / \alpha_o) \cdot \rho_{air}$	room air mass flow rate across coil kg/(m ² s)

$$q_{in} = K_1 \bullet \Delta T^n + K_{in} \bullet q_{pr}$$

room air volumetric flow rate across coil per
unit length m³/(s-m)

ΔT is the room air –water temperature difference (average water temperature is used) in degrees C.

ω is the water velocity in m/s.

q_{pr} is the supply air flow rate per unit length m³/(s-m)

Field: Coil Surface Area per Coil Length

Surface area on the air side of the beam per unit beam length. The units are square meters per meter. The default is 5.422. This is A in the above equations.

Field: Model Parameter α (a)

This is α in the above equations. The default is 15.3

Field: Model Parameter n_1

This is n_1 in the above equations. The default is 0.

Field: Model Parameter n_2

This is n_2 in the above equations. The default is 0.84.

Field: Model Parameter n_3

This is n_3 in the above equations. The default is 0.12.

Field: Model Parameter α_0 (a)

This is α_0 in the above equations. It is the free area of the coil in plan view (for the air flow) per unit beam length. The units are square meters per meter. The default is 0.171.

Field: Model Parameter K_1 (K1)

This is K_1 in the above equations. The default is 0.005.

Field: Model Parameter n

This is n in the above equations. The default is 0.4.

Field: Coefficient of Induction K_{in} (Kin)

The coefficient of induction K_{in} in the above equations. The default is 2.0 for active beams and 0.0 for passive beams.

Field: Pipe Inside Diameter

The water pipe inside diameter in meters. The default is 0.0145.

Cooled Beam Cooling Rate [W]

Sensible cooling by the beams in the zone, exclusive of any cooling or heating done by the supply air.

Cooled Beam Cooling Energy [J]

Sensible cooling by the beams in the zone, exclusive of any cooling or heating done by the supply air.

Cooled Beam Supply Air Cooling Rate [W]

Sensible cooling by the supply air to the zone, exclusive of any cooling done by the beams.

Cooled Beam Supply Air Cooling Energy [J]

Sensible cooling by the supply air to the zone, exclusive of any cooling done by the beams.

Cooled Beam Supply Air Heating Rate [W]

Heating by the supply air to the zone, exclusive of any cooling done by the beams.

Cooled Beam Supply Air Heating Energy [J]

Heating by the supply air to the zone, exclusive of any cooling done by the beams.

AirTerminal:DualDuct:ConstantVolume

The AirTerminal:DualDuct:ConstantVolume simulation or the typical Multizone is described by this Air Distribution Unit (ADU). Multizone systems condition all the air in a central apparatus and distribute it to the conditioned zones through two parallel ducts. One duct carries cold air and the other warm air, providing air sources for both heating and cooling at all times. In each conditioned zone, a mixing valve responsive to a room thermostat mixes the warm and cold air in proper proportions to satisfy the prevailing heating or cooling load of the space. The Multizone ADU is the specific component that leads to the zone containing the mixer and the mixing damper and then connecting to the zone. The total airflow to each room is kept constant while the proportion of hot air to cold air is adjusted to maintain the temperature in each zone at the desired level.

Field: Name

Unique name for the Multizone ADU.

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The outlet node from the ADU to the zone.

Field: Hot Air Inlet Node Name

The air-inlet node name that connects the hot air splitter to the individual zone ADU.

Field: Cold Air Inlet Node Name

The air-inlet node name that connects the cold air splitter to the individual zone ADU.

Field: Maximum Air Flow Rate

The design constant volume flow rate (m^3/sec) specified for that Multizone ADU.

The IDD specification is:

```

AirTerminal:DualDuct:ConstantVolume,
A1 , \field Name
    \required-field
A2 , \field Availability Schedule Name
    \required-field

Zone 2 Dual Duct Hot Inlet, !- Unit Hot Air Inlet Node
Zone 2 Dual Duct Cold Inlet, !- Unit Cold Air Inlet Node
0.36; !- Max Air Flow Rate {m3/s}

```

AirTerminal:DualDuct:VAV

AirTerminal:DualDuct:VAV (i.e., Dual duct variable air volume (DDVAV)) systems are used to obtain zone temperature control by mixing the cold and warm air in various volume combinations. The fan is sized for the anticipated maximum coincident hot or cold volume, not the sum of the instantaneous peaks. This system has an advantage of a true single path VAV system, except for warm port leakage. When cold air is modulated for control before mixing, it operates similar to the VAV induction when mixing occurs without hot deck reheat. It is similar to a reheat system when mixing occurs while the hot deck is using the reheat coil. It uses more energy than a true VAV system, but less than a constant volume dual duct system.

Field: Name

Unique name for the AirTerminal:DualDuct:VAV Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The outlet node from the ADU to the zone.

Field: Hot Air Inlet Node Name

The air-inlet node name that connects the hot air splitter to the individual zone ADU.

Field: Cold Air Inlet Node Name

The air-inlet node name that connects the cold air splitter to the individual zone ADU.

Field: Maximum Damper Air Flow Rate

The design maximum volume flow rate (m³/sec) specified for DDVAV ADU.

Field: Zone Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the Max Damper Air Flow Rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants.

The IDD specification is:

```

Group – Zone Forced Air Units**ZoneHVAC:IdealLoadsAirSystem**

The simplest piece of zone equipment is the ZoneHVAC:IdealLoadsAirSystem component. ZoneHVAC:IdealLoadsAirSystem is used in situations where the user wishes to study the performance of a building with an ideal system. In such a case, the Ideal Loads Air System is usually the sole conditioning component: the user does not need to specify air loops, water loops, etc. All that is needed for the ideal system are zone controls, zone equipment configurations, and the purchased air components.

This component can be operated as either a component with infinite heating and cooling capacity or as a component with finite heating and cooling capacity. For infinite capacity, the user should specify the purchased air name, the zone supply air node name, the heating supply air temp, the cooling supply air temp, the heating supply air humidity ratio and the cooling supply air humidity ratio. The program will supply, without limit, the necessary heating or cooling supply air at the specified conditions to meet the zone heating or cooling load.

For finite capacity the user should specify the aforementioned fields plus heating limit (set to **Limit**), maximum heating air flow rate, cooling limit (set to **Limit**) and maximum cooling air flow rate. The program will now limit the heating and cooling supply air flow rates to the user specified limits. These maximum flow rates are also autosizable: the user can specify

autosize as the input value and the program will calculate a value based on the design day maximums.

For either mode – infinite or limited capacity – the user can also specify on/off schedules for heating and cooling and an outdoor air flow rate (set the outdoor air field to **OutdoorAir**). The outdoor air flow rate will also accept *autosize* as an input. Then the outdoor air flow rate will be calculated based on the user's zone sizing input.

This component can be thought of as an ideal unit that mixes air at the zone return condition with the specified amount of outdoor air and then adds or removes heat & moisture at 100% efficiency in order to produce a supply air stream at the specified conditions.

Note: Every zone served by a ideal loads air system component should have a return air node, even though this node is not connected to anything.

Note: The outdoor air flow rate is never allowed to be greater than the supply air flow rate.

Field: Name

A unique user assigned name for each ideal loads air system component. Any other component that needs to use this ideal loads air system component will refer to it by this name.

Field: Zone Supply Air Node Name

The name of the outlet air node of the purchased air object. This should be the same as one of the supply air nodes for the zone the purchased air component is serving.

Field: Heating Supply Air Temperature

The constant air temperature (degrees C) of the air used for heating the zone.

Field: Cooling Supply Air Temperature

The constant air temperature (degrees C) of the air used for cooling the zone.

Field: Heating Supply Air Humidity Ratio

The constant humidity ratio (kg of water per kg of dry air) of the hot supply air.

Field: Cooling Supply Air Humidity Ratio

The constant humidity ratio (kg of water per kg of dry air) of the hot supply air.

Field: Heating Limit

The input must be either **Limit** or **NoLimit**. **Limit** means that there will be a maximum heating supply air flow rate which should be specified in the next input field. **NoLimit** (the default) means that there will not be any limit on the heating supply air flow rate and the subsequent field will be ignored.

Field: Maximum Heating Air Flow Rate

The maximum heating supply air flow rate in cubic meters per second if heating limit is set to **Limit**. This field is ignored if heating limit is set to **NoLimit**.

Field: Cooling Limit

The input must be either **Limit** or **NoLimit**. **Limit** means that there will be a maximum cooling supply air flow rate which should be specified in the next input field. **NoLimit** (the default) means that there will not be any limit on the cooling supply air flow rate and the subsequent field will be ignored.

Field: Maximum Cooling Air Flow Rate

The maximum cooling supply air flow rate in cubic meters per second if cooling limit is set to **Limit**. This field is ignored if cooling limit is set to **NoLimit**.

Field: Outdoor Air

The input must be either **OutdoorAir** or **NoOutdoorAir**. **OutdoorAir** means that there will be a fixed amount of outdoor air (specified in the next input field) mixed with zone return air to make up the heating or cooling supply air stream. **NoOutdoorAir** (the default) means that there will be no outdoor air mixed with the zone return air and the next input field will be ignored.

Cautionary Note: The Ideal Loads Air System component does not control zone humidity levels. The Ideal Loads Air System component total cooling load is simply the enthalpy change between the mixed air condition (return air plus outdoor air, if specified) and the user-specified supply air condition for the current load. The latent load is the total load less the sensible load and may be positive or negative.

Field: Outdoor Air Flow Rate

The flow rate in cubic meters per second of air at outside conditions that will be mixed with zone return air to comprise the heating or cooling supply air stream. This field is ignored if outdoor air is set to **NoOutdoorAir**. This field can be set to *autosize*, in which case the outdoor air flow rate will be based on the user's zone sizing input.

Field: Heating Availability Schedule Name

The name of a schedule (ref: Schedule) that denotes whether the heating supply air will be available for the hour. A schedule value greater than 0 (usually 1 is used) indicates that heating supply air is available during the hour. A value less than or equal to 0 (usually 0 is used) denotes that heating supply air is not available for the hour.

Field: Cooling Availability Schedule Name

The name of a schedule (ref: Schedule) that denotes whether the cooling supply air will be available for the hour. A schedule value greater than 0 (usually 1 is used) indicates that cooling supply air is available during the hour. A value less than or equal to 0 (usually 0 is used) denotes that cooling supply air is not available for the hour.

HVAC, Average, Ideal Loads Air Heating Rate[W]
 HVAC, Sum, Ideal Loads Air Sensible Cooling Energy[J]
 HVAC, Average, Ideal Loads Air Sensible Cooling Rate[W]
 HVAC, Sum, Ideal Loads Air Total Cooling Energy[J]
 HVAC, Average, Ideal Loads Air Total Cooling Rate[W]

Ideal Loads Air Heating Energy[J]

The energy needed to raise the temperature of the mixed outside and return air stream to the specified temperature of the supply air stream. Any energy needed for moisture addition or removal is ignored.

Ideal Loads Air Heating Rate[W]

The rate at which energy is added to the mixed outside and return air stream to raise its temperature to the specified temperature of the supply air stream. Any energy needed for moisture addition or removal is ignored.

Ideal Loads Air Sensible Cooling Energy[J]

The energy removed from the mixed outside and return air stream in order to lower its temperature to the specified temperature of the supply air stream. Any energy needed for moisture addition or removal is ignored.

Ideal Loads Air Sensible Cooling Rate[W]

The rate at which energy is removed from the mixed outside and return air stream in order to lower its temperature to the specified temperature of the supply air stream. Any energy needed for moisture addition or removal is ignored.

Ideal Loads Air Total Cooling Energy[J]

The total energy (sensible and latent) removed from the mixed outside and return air stream in order to bring the mixed air stream to the specified temperature and humidity ratio of the supply air stream.

Ideal Loads Air Total Cooling Rate[W]

The rate at which total energy (sensible and latent) is removed from the mixed outside and return air stream in order to bring the mixed air stream to the specified temperature and humidity ratio of the supply air stream.

ZoneHVAC:FourPipeFanCoil

The fan coil units are zone equipment units which are assembled from other components. Fan coils contain an outdoor air mixer, a fan, a simple heating coil and a cooling coil. These components are described elsewhere in this document. The fan coil input simply requires the names of these four components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, an outdoor airflow rate, and maximum and minimum hot and cold water volumetric flow rates. The unit is connected to the zone inlet and exhaust nodes and the outdoor air by specifying unit inlet, outlet, outdoor air and exhaust (relief) air node names. Note that the unit air inlet node should be the same as a zone exhaust node and the unit outlet node should be the same as a zone inlet node. The fan coil unit is connected to a hot water loop (demand side) through its hot water coil and to a chilled water loop (demand side) through its cooling coil.

The unit is controlled to meet the zone (remaining) heating or cooling demand. If there is a heating demand, the cooling coil is off and the hot water flow through the heating coil is throttled to meet the demand. The hot water control node must be specified (same as the hot water coil inlet node) as well as maximum and minimum possible hot water volumetric flow rates. If there is a cooling demand from the zone, the hot water coil is off and the chilled water flow through the cooling coil is throttled to meet the load. The cooling coil control node must be specified (same as the cooling coil inlet node) and the maximum and minimum

chilled water volumetric flow rates must be given. Finally both heating and cooling require a convergence tolerance, which denotes how closely the fan coil unit will meet the heating or cooling load. The tolerance is always relative to the zone load.

Field: Name

A unique user assigned name for an instance of a Fan Coil unit. Any reference to this Fan Coil unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan coil unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Supply Air Flow Rate

The maximum volumetric airflow rate (m^3/sec) through the fan coil unit. Since this is a constant air volume unit, this is also the design, rated airflow rate of the unit.

Field: Maximum Outdoor Air Flow Rate

If the fan coil unit uses outdoor air, this field specifies the outdoor air volumetric flow rate (m^3/sec). This flow rate should be less than or equal to the maximum airflow rate. A value of zero specifies no outdoor air. Note that the outdoor airflow rate is fixed: it cannot change during the simulation

Field: Air Inlet Node Name

The name of the HVAC system node from which the fan coil unit draws its indoor air. This should be one of zone exhaust nodes for the zone which the fan coil unit is serving.

Field: Air Outlet Node Name

The name of the HVAC system node to which the fan coil unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

Field: Outdoor Air Node Name

The name of the HVAC system node from which the fan coil unit draws its outdoor air. This should be the same node as the outdoor air node of the unit's outdoor air mixer (object: OutdoorAir:Mixer).

Field: Air Relief Node Name

The name of the HVAC system node to which the fan coil unit exhausts its relief air. This should be the same node as the relief air node of the unit's outdoor air mixer.

Field: Cold Water Inlet Node Name

The name of the HVAC system node which regulates the flow of cold water through the fan coil unit. This should be the same node as the water inlet node for the unit's cooling coil.

Field: Hot Water Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the fan coil unit. This should be the same node as the water inlet node of the unit's hot water coil.

Field: Outdoor Air Mixer Name

The name of an outdoor air mixer component (object: OutdoorAir:Mixer) which composes part of the fan coil unit. Note that some of the input for the outdoor air mixer will duplicate input fields of the fan coil unit. The outdoor air node of the outdoor air mixer should be the same as the outdoor air node of the fan coil unit. The relief air node of the outdoor air mixer should be the same as the relief air node of the fan coil unit. In addition, the return air node of

the outdoor air mixer should be the same node as the air inlet node of the fan coil unit. In addition, the outdoor air mixer's mixed air node should be the same as the inlet air node of the fan coil unit's fan.

Field: Fan Name

The name of a constant volume fan component that composes part of the fan coil unit. Note that the fan's maximum flow rate should be the same as the maximum airflow rate of the fan coil unit and the type of fan object must be Fan:ConstantVolume. The fan's inlet node should be the same as the outdoor air mixer's mixed air node. The fan's outlet node should be the same as the cooling coil's air inlet node.

Field: Cooling Coil Name

The name of the cooling coil component that composes part of the fan coil unit. The cooling coil air inlet node should be the same as the fan outlet node. The cooling coil air outlet node should be the same as the heating coil air inlet node.

Only the following coil types can be used:

```
Coil:Cooling:Water
Coil:Cooling:Water:DetailedGeometry
CoilSystem:Cooling:Water:HeatExchangerAssisted
```

Field: Maximum Cold Water Flow Rate

The maximum cold water volumetric flow rate (m³/sec) through the fan coil unit's cooling coil.

Field: Minimum Cold Water Flow Rate

The minimum cold water volumetric flow rate (m³/sec) through the fan coil unit's cooling coil.

Field: Cooling Convergence Tolerance

The convergence tolerance for the control of the unit cooling output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The cooling convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{fancoil,out} - Q_{zoneload}|}{Q_{zoneload}} \leq CoolingConvergenceTolerance$$

Field: Heating Coil Name

The name of the heating coil component that composes part of the fan coil unit. The heating coil air inlet node should be the same as the cooling coil outlet node. The heating coil air outlet node should be the same as the fan coil air outlet node.

Only the following coil type can be used:

```
Coil:Heating:Water
```

Field: Maximum Hot Water Flow Rate

The maximum hot water volumetric flow rate (m³/sec) through the fan coil unit's heating coil.

Field: Minimum Hot Water Flow Rate

The minimum hot water volumetric flow rate (m³/sec) through the fan coil unit's heating coil.

Field: Heating Convergence Tolerance

The convergence tolerance for the control of the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be

numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{fancoil,out} - Q_{zoneload}|}{Q_{zoneload}} \leq HeatingConvergenceTolerance$$

Field: Cooling Coil Object Type

This field specifies the type of chilled water cooling coil to be modeled for this fan coil unit. Only the following coil types can be used:

Coil:Cooling:Water
 Coil:Cooling:Water:DetailedGeometry
 CoilSystem:Cooling:Water:HeatExchangerAssisted

The input requirements for these chilled water coil objects are described elsewhere in this document.

The input data dictionary definition of the unit is as follows.

Fan Coil Heating Rate[W]

This field reports the dry air heating addition rate of the fan coil unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit.

Fan Coil Heating Energy[J]

This field is the dry air heat addition of the fan coil unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

Fan Coil Total Cooling Rate[W]

This field is the total (sensible and latent) heat extraction rate of the fan coil unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Fan Coil Total Cooling Energy[J]

This field is the total (sensible and latent) heat extraction of the fan coil unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

Fan Coil Sensible Cooling Rate[W]

This field reports the dry air sensible heat extraction rate of the fan coil unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Fan Coil Sensible Cooling Energy[J]

This field is the dry air sensible heat extraction of the fan coil unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions, the mass flow rate through the unit, and the timestep.

Fan Coil Electric Power[W]

This field reports the electricity consumption rate of the fan coil unit in Watts.

Fan Coil Electric Consumption[J]

This field is the electricity consumption of the fan coil unit in Joules over the timestep being reported.

ZoneHVAC:UnitVentilator

Unit ventilators are zone equipment units which are assembled from other components. They contain a built-in outdoor air mixer, a fan, a heating coil, and a cooling coil. These components are described elsewhere in this document, except the built-in outdoor air mixer which is contained within the unit ventilator statement. The unit ventilator input simply requires the names of these other three components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, outdoor air control information (control type and schedules), an outdoor airflow rate, and maximum and minimum hot and cold water mass flow rates. The unit is connected to the zone inlet and exhaust nodes and the outdoor air by specifying unit inlet, outlet, outdoor air and exhaust (relief) air node names. Note that the unit air inlet node should be the same as a zone exhaust node and the unit outlet node should be the same as a zone inlet node. In general, the unit ventilator input is very similar to the fan coil unit input, and the unit is connected to a hot water loop (demand side) through its hot water coil and to a chilled water loop (demand side) through its cooling coil.

The main difference between the fan coil and unit ventilator input is that the unit ventilator has a built-in outdoor air mixer with its own specialized controls. The outdoor air control type can be selected from one of the following options: “variable percent”, “fixed temperature” or “fixed amount”. In fixed temperature control, the amount of outdoor air is varied between the minimum outdoor air fraction (specified by a schedule) and 100% outdoor air to obtain a mixed air temperature as close as possible to the temperature schedule defined in the input. Variable percent control will also vary the amount of outdoor air between the minimum and

maximum fractions (both specified in input by the user) to meet the load without the use of a coil if possible. In fixed amount control, the outdoor air flow rate is fixed to the specified value by the user. In this control strategy, the maximum outdoor air flow rate and schedule are automatically set to be equal to the minimum outdoor air flow rate and schedule. These control types are based on the 2004 ASHRAE Systems and Equipment Handbook (pp. 31.1-31.3) description of unit ventilator systems.

The unit is controlled to meet the zone (remaining) heating or cooling demand. If there is a heating demand, the cooling coil is off and the hot water flow through the heating coil is throttled to meet the demand. The hot water control node must be specified (same as the hot water coil inlet node) as well as maximum and minimum possible hot water volumetric flow rates. If there is a cooling demand from the zone, the hot water coil is off and the chilled water flow through the cooling coil is throttled to meet the load. The cooling coil control node must be specified (same as the cooling coil inlet node) and the maximum and minimum chilled water volumetric flow rates must be given. Finally both heating and cooling require a convergence tolerance, which is the tolerance denoting how closely the fan coil unit will meet the heating or cooling load. The tolerance is always relative to the zone load.

Overall, control of the unit must consider the outdoor air. Here is a more detailed description of the overall unit control:

Off: Unit is schedule off or there is no load on it. All flow rates are set to zero and the temperatures are set to zone conditions (except for the outdoor air inlet). Outdoor air requirements will not override this condition.

Heating/No Coil/VariablePercent: The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and variable percent outdoor air control type has been specified. In this case, the variable percent outdoor air controls what happens with the outdoor air. If the outside temperature is greater than the return temperature, then the outdoor air is set to the maximum as defined by the user input. If the outdoor air temperature is less than the return temperature from the zone, then the outdoor air is set to the minimum outdoor air flow rate as defined by the user. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

Heating/No Coil/FixedTemperature: The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate.

Heating/No Coil/FixedAmount: The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

Heating /With Coil/VariablePercent: The unit is on, there is a heating load, and variable percent control is specified. The outdoor air fraction is set to the minimum outdoor air fraction (schedule based), and the heating coil is activated. The heating coil attempts to meet the remaining load on the zone being served by the unit ventilator.

Heating /With Coil/FixedAmount: The unit is on, there is a heating load, a heating coil is present and is scheduled on, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. The heating coil then attempts to meet any remaining zone heating load.

Cooling/No Coil/VariablePercent: The unit is on, there is a cooling load, no coil is present or it has been scheduled off, and variable percent outdoor air control type has been specified. In this case, the variable percent outdoor air controls what happens with the outdoor air. If the outside temperature is greater than the return temperature, then the outdoor air is set to the minimum as defined by the user input. If the outdoor air temperature is less than the return temperature from the zone, then the outdoor air is set to the maximum outdoor air flow rate as defined by the user. This may be somewhat simplistic in that it could result in overcooling of the space. However, since a temperature goal was not established, this is the best that can be done by the simulation. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

Cooling/No Coil/FixedTemperature: The unit is on, there is a cooling load, no cooling coil is present or it has been scheduled off, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate in the same fashion as the variable percent outdoor air control.

Cooling/No Coil/FixedAmount: The unit is on, there is a cooling load, no cooling coil is present or it has been scheduled off, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outside air controls.

Cooling/With Coil/VariablePercent: The unit is on, there is a cooling load, a coil is present and is scheduled on, and variable percent outdoor air control type has been specified. In this case, the percentage of outdoor air is set to the minimum flow outdoor air flow rate. The coil then attempts to meet any remaining zone load.

Cooling/With Coil/FixedTemperature: The unit is on, there is a cooling load, a cooling coil is present and is scheduled on, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate in the same fashion as the fixed temperature outdoor air control for the “no coil” conditions. The cooling coil then attempts to meet any remaining zone load.

Cooling/With Coil/FixedAmount: The unit is on, there is a cooling load, a cooling coil is present and is scheduled on, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. The cooling coil then attempts to meet any remaining zone cooling load.

Note: the unit ventilator controls are strictly temperature based and do not factor humidity into the equation (not an enthalpy economy cycle but rather a simple return air economy cycle). In addition, temperature predictions are not strict energy balances here in the control routine though in the mixing routine an energy balance is preserved.

Field: Name

This field is simply the identifying name that distinguishes one particular unit ventilator from another in the input data file. Like all other names in EnergyPlus, it is assumed that this is a unique character string and that no other unit ventilators use this same name.

Field: Availability Schedule Name

This field is a schedule name (ref: Schedule) that determines whether the unit ventilator is available to operate. The schedule is interpreted as a digital switch. If the schedule value of the unit ventilator availability schedule for a particular time frame is less than or equal to zero,

then the unit ventilator is unavailable and will not operate. For any schedule value greater than zero, the unit ventilator is considered available and may operate, if necessary.

Field: Maximum Supply Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the unit ventilator system in m^3/sec . This parameter should be some real number greater than zero.

Field: Outdoor Air Control Type

This field allows the user to control how outdoor air is used in the unit ventilator system. The unit ventilator system described by this syntax has its own outdoor air handler. The three options for outdoor air control are “**VariablePercent**”, “**FixedTemperature**” and “**FixedAmount**”. Those keys are the only allowed choices for this parameter. In general, the variable percent control will attempt to vary the amount of outdoor air between some minimum and maximum schedules of fractions (see next two fields) to best meet the current heating or cooling load. The fixed temperature control will vary the amount of outdoor air between the minimum schedule (fraction of maximum, see next field) and 100% available outdoor air to come as close as possible to a desired mixed air temperature (see 2 fields down) that can be scheduled. The fixed amount control will fix the outdoor air flow rate as minimum outdoor air flow rate and schedule specified by the user and automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate. More information on the controls and operation of the unit ventilator are given in the introductory section above.

Field: Minimum Outdoor Air Flow Rate

This field allows the user to enter the minimum volumetric flow rate of outdoor air (in m^3/sec) that will be brought in to the unit ventilator. The actual minimum outdoor air flow rate will be this number multiplied by the schedule value from the minimum outdoor air schedule. If “**FixedAmount**” type is selected as the outdoor air control strategy, the outdoor air flow rate will be fixed as this field and the unit ventilator will automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate.

Field: Minimum Outdoor Air Schedule Name

This field contains a schedule name (ref: Schedule) that should contain values for the minimum outdoor air used by the unit ventilator system for IAQ or other reasons. Note that if the unit ventilator is scheduled off or if there is no load sensed in the zone that the system will not operate even to achieve the minimum air fraction. However, if the system is operating, it will always bring in this fraction of the minimum air flow rate (see minimum air flow rate field above). If “**FixedAmount**” type is selected as the outdoor air control strategy, the actual outdoor air flow rate will be this number multiplied by the minimum outdoor air flow rate in the field above. The unit ventilator will automatically set the maximum and minimum outdoor air schedule to be equal by ignoring the maximum outdoor air schedule.

Field: Maximum Outdoor Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of outdoor air that can be brought into the unit ventilator system in m^3/sec . This parameter should be some real number greater than zero. Note that the value for this parameter may be less than the maximum air flow rate of the unit ventilator and this may affect the maximum fraction of outdoor air within the control strategy defined above. This parameter is an absolute maximum and will supercede any scheduled fraction of the unit ventilator maximum airflow rate. If “**FixedAmount**” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air flow rate specified in the field above.

Field: Maximum Outdoor Air Fraction or Temperature Schedule Name

This field can have one of two meanings depending the type of control selected in the outdoor air control type parameter above. If “VariablePercent” or “FixedAmount” was selected, then this field is a schedule name (ref: Schedule) corresponding to a maximum air fraction schedule. Furthermore, if “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air fraction specified in the field below. Note that this is a fraction of the maximum airflow rate field (see parameter above) for the unit ventilator. If “FixedTemperature” control was selected, then this field is still a schedule name (ref: Schedule), but it corresponds to a schedule of mixed air temperatures that the outdoor air control will try to attain.

Field: Air Inlet Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the unit ventilator. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit ventilator, the air inlet node to the system will typically be the same node as a zone outlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Air Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) to the unit ventilator. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit ventilator, the air outlet node from the system will typically be the same node as a zone inlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Fan Outlet Node Name

This field is a node name used to identify the node that serves as the air outlet to fan of the the unit ventilator. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit ventilator, the air outlet node from the fan is also considered the inlet node to the coils. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Outdoor Air Node Name

This field is a node name used to identify the node associated with fresh air brought into the unit ventilator from the outdoor environment. You should also have defined an OutdoorAir:Node object with the same name and assign it an optional height (above ground).

Field: Exhaust Air Node Name

This field is a node name used to identify the node associated with air exhausted out of the unit ventilator to the outdoor environment. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the unit ventilator.

Field: Mixed Air Node Name

This field is a node name used to identify the node associated with the “mixed” air of the unit ventilator. These conditions are post-“mixing box” since they are the conditions of the fraction of return air combined with the outdoor air. Since this is a simple system, this can also be viewed as the conditions of the air being sent to the coils. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the unit ventilator.

Field: Fan Name

This field is the name of a fan (ref: Fan:ConstantVolume, Fan: VariableVolume) that is part of the unit ventilator system. This name links the unit ventilator to particular fan data entered

elsewhere in the input data file. A fan name is required since it is the prime mover of air in the unit ventilator system.

Field: Coil Option

This field allows the user to specify the coil operating options as one of the following options: **None**, **Heating**, **Cooling** or **HeatingAndCooling**. If **None** is selected, the unit ventilator does not have any coils, and any other input will be ignored. If either **Heating** or **Cooling** is selected, only a heating or cooling coil, respectively, is present. Thus, only four more inputs will be expected. If **HeatingAndCooling** is selected, both heating and cooling coil input must be entered, and the unit ventilator will have both a heating and a cooling coil.

Field: Heating Coil Object Type

This field is the type of coil that is used for heating in the unit ventilator system. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system. Allowable heating coil types are:

```
Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam
```

Field: Heating Coil Name

This field is the name of the heating coil that is part of the unit ventilator system. It is assumed that there is always some sort of heating coil associated with a unit ventilator system. This name links the unit ventilator to particular heating coil data entered elsewhere in the input data file.

Field: Hot Water or Steam Inlet Node Name

This field corresponds to the water inlet node to the heating coil for a water coil. The water inlet node controls how a water heating coil operates. This field is ignored/not needed for gas and electric heating coils.

Field: Heating Convergence Tolerance

The control tolerance for the unit heating output. This field allows the user some control over how closely the heating coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point. This field is ignored for gas and electric heating coils.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{UnitVentilator,Out} - Q_{ZoneLoad}|}{Q_{ZoneLoad}} \leq HeatingConvergenceTolerance$$

Field: Cooling Coil Object Type

This field is the type of coil that is used for cooling in the unit ventilator system. It is used in conjunction with the cooling coil name (see next field) to specify the cooling coil present within the system.

Only the following coil types can be used:

Coil:Cooling:Water
 Coil:Cooling:Water:DetailedGeometry
 CoilSystem:Cooling:Water:HeatExchangerAssisted

Field: Cooling Coil Name

This field is the name of the cooling coil that is part of the unit ventilator system. This name links the unit ventilator to particular cooling coil data entered elsewhere in the input data file. Note that a cooling coil is not a required part of a unit ventilator system. If no cooling coil is present, the previous field may be followed by a semi-colon and the remaining parameters in this statement may be ignored.

Field: Cold Water Inlet Node Name

This field corresponds to the water inlet node to the cooling coil. The water inlet node controls how a water cooling coil operates and is required for the unit ventilator that has a cooling coil associated with it to function properly.

Field: Cooling Convergence Tolerance

The convergence tolerance for the unit cooling output. This field allows the user some control over how closely the cooling coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The cooling convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{UnitVentilator,Out} - Q_{ZoneLoad}|}{Q_{ZoneLoad}} \leq CoolingConvergenceTolerance$$

The input data dictionary definition of the unit ventilator is as follows:

Unit Ventilator Heating Rate[W]

This field reports the heating output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

Unit Ventilator Heating Energy[J]

This field is the heating output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

Unit Ventilator Total Cooling Rate[W]

This field reports the total cooling (sensible plus latent) output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

Unit Ventilator Total Cooling Energy[J]

This field is the total cooling (sensible plus latent) output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

Unit Ventilator Sensible Cooling Rate[W]

This field reports the sensible cooling output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

Unit Ventilator Sensible Cooling Energy[J]

This field is the sensible cooling output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

Unit Ventilator Fan Electric Power[W]

This field reports the electric power consumption rate of the fan of the unit ventilator in Watts.

Unit Ventilator Fan Electric Consumption[J]

This field reports the electric power consumed by the fan of the unit ventilator over the timestep in Joules.

ZoneHVAC:UnitHeater

Unit heaters are zone equipment units which are assembled from other components and are a simplification of unit ventilators. They contain only a fan and a heating coil. These components are described elsewhere in this document. The unit heater input simply requires the names of these components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, and maximum and minimum hot water volumetric flow rates. The unit is connected to the zone inlet and exhaust nodes by specifying unit inlet and outlet node names. Note that the unit air inlet node should be the same as a zone exhaust node and the unit outlet node should be the same as a zone inlet node.

While the control of the heating coil is similar to the fan coil units and the unit ventilator, the overall control of the unit heater is much different. There are four different modes in which a unit heat can operate based on the user input:

Off: Unit is schedule off. All flow rates are set to zero and the temperatures are set to zone conditions.

NoLoad OR Cooling/OnOff Fan Control: Unit is available, but there is no heating load. All flow rates are set to zero and the temperatures are set to zone conditions.

NoLoad OR Cooling/Continuous Fan Control: Unit is available and the fan is running (if it is scheduled to be available also). No heating is provided, only circulation via the fan running.

Heating: The unit is on/available and there is a heating load. The heating coil is modulated (constant fan speed) to meet the heating load.

Control of the heating coil and its flow rate is identical to the fan coil unit and unit ventilator.

Field: Name

This field is simply the identifying name that distinguishes one particular unit heater from another in the input data file. Like all other names in EnergyPlus, it is assumed that this is a unique character string and that no other unit heaters use this same name.

Field: Availability Schedule Name

This field is a schedule name (ref: Schedule) that determines whether the unit heater is available to operate. The schedule is interpreted as a digital switch. If the schedule value of the unit heater availability schedule for a particular time frame is less than or equal to zero, then the unit heater is unavailable and will not operate. For any schedule value greater than zero, the unit heater is considered available and may operate.

Field: Air Inlet Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the unit heater. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit heater, the air inlet node to the system will typically be the same node as a zone outlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Air Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) to the unit heater. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit heater, the air outlet node from the system will typically be the same

node as a zone inlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Fan Name

This field is the name of a fan (ref: Fan:ConstantVolume, Fan:VariableVolume) that is part of the unit heater system. This name links the unit heater to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the unit heater system.

Field: Maximum Supply Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the unit heater system in m³/s. This parameter should be some real number greater than zero.

Field: Fan Control Type

This field allows the user to define how the unit heater will operate under “no load” or cooling conditions. The user may select from two options. If the “**OnOff**” control is selected, then the fan will not run unless there is a heating load. If the fan does not run, this effectively shuts the unit heater system off (there is no option to simply run the heating coil and allow natural convection to transfer heat from the unit to the zone). If the “**Continuous**” control is selected, then the fan will always run if the unit heater is available. This will produce air movement in the zone but also add some amount of heat to the energy balance since the fan will generate some heat. For more information on controlling the operation of the unit heater, see the general description given above.

Field: Fan Outlet Node Name

This field is a node name used to identify the node that serves as the air outlet to fan of the the unit heater. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit heater, the air outlet node from the fan is also considered the inlet node to the coils. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Heating Coil Object Type

This field is the type of coil that is used for heating in the unit heater system. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system. Allowable heating coil types are:

```
Coil:Heating:Water  
Coil:Heating:Electric  
Coil:Heating:Gas  
Coil:Heating:Steam
```

Field: Heating Coil Name

This field is the name of the heating coil that is part of the unit heater system. It is assumed that there is always some sort of heating coil associated with a unit heater system. This name links the unit ventilator to particular heating coil data entered elsewhere in the input data file.

Field: Maximum Hot Water or Steam Flow Rate

This field allows the user to enter a maximum volumetric flow rate of water through a water heating coil in m³/sec. This number should be some number greater than zero and greater than the minimum hot water volumetric flow rate (see next field). Note that this parameter has no meaning for either an electric or a gas heating coil.

Field: Minimum Hot Water or Steam Flow Rate

This field allows the user to enter a minimum volumetric flow rate of water through a water heating coil in m³/sec. This number should be some number greater than zero and less than

the maximum hot water volumetric flow rate (see previous field). Note that this parameter has no meaning for either an electric or a gas heating coil.

Field: Hot Water or Steam Inlet Node Name

This field corresponds to the water inlet node to the heating coil for a water coil. The water inlet node controls how a water heating coil operates and is required for the unit ventilator to function properly. This field is ignored for gas and electric heating coils.

Field: Heating Convergence Tolerance

The convergence tolerance for the unit heating output. This field allows the user some control over how closely the heating coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point. This field is ignored for gas and electric heating coils.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{unit\ heater, out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq HeatingConvergenceTolerance$$

The IDD definition for the Unit Heater follows:

```

Unit Heater Heating Rate[W]

This field reports the heating output rate of the unit heater system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit heater.

Unit Heater Heating Energy[J]

This field is the heating output of the unit heater system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit heater, and the timestep.

Unit Heater Fan Electric Power[W]

This field reports the electric power consumption rate of the fan of the unit heater in Watts.

Unit Heater Fan Electric Consumption[J]

This field reports the electric power consumed by the fan of the unit heater over the timestep in Joules.

ZoneHVAC:WindowAirConditioner

The Window Air Conditioner is a unit of zone equipment made up of other components. Each window air conditioner consists of an outdoor air mixer, a fan, and a direct expansion (DX) cooling coil. These components are described elsewhere in this document. The input for a window air conditioner requires the names of these three pieces of equipment, which are then specified individually elsewhere in the input. The input for a window air conditioner also requires the name of an availability schedule, the maximum unit airflow rate, and the maximum outdoor airflow rate for the unit. The unit is connected to a zone by specifying an air inlet node, which must be the same as a zone exhaust node; and an air outlet node, which must be the same as a zone inlet node (ref. ZoneHVAC:EquipmentConnections). The unit is connected to the outdoor air by giving the names of the outdoor air node and the exhaust (relief) node of the unit's outdoor air mixer.

A supply air fan operating mode schedule must also be specified. The supply air fan operating mode schedule value determines if the supply air fan can run continuously with the DX coil cycling on/off to match the zone cooling demand or the fan and DX coil can cycle on/off together to meet the cooling demand. The placement of the supply air fan, in relation to the DX coil, must also be specified (blow through or draw through). The cooling convergence tolerance is required, which is the tolerance denoting how closely the window air conditioner

will meet the cooling load. The tolerance is always relative to the zone load (i.e., the unit will operate to meet the zone load to within the tolerance value times the zone load for each simulation timestep). Finally, the DX cooling coil type must be specified.

Field: Name

A unique user assigned name for an instance of a window air conditioner unit. Any reference to this window air conditioner by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the window air conditioner unit can run during a given hour. A schedule value of 1 indicates that the unit can be on during the hour. A value of 0 denotes that the unit must be off for the hour.

Field: Maximum Supply Air Flow Rate

The maximum volumetric airflow rate through the window air conditioner in cubic meters per second. Since the unit operates by cycling on/off, this is also the design, rated airflow rate of the unit.

Field: Maximum Outdoor Air Flow Rate

If the window air conditioner uses outdoor air, this field specifies the outdoor air volumetric flow rate in cubic meters per second. This flow rate should be less than or equal to the maximum airflow rate. A value of zero specifies no outdoor air. Note that the outdoor airflow rate is fixed: it cannot change during the simulation

Field: Air Inlet Node Name

The name of the HVAC system node (see Node) from which the window air conditioner draws its indoor air. This should be one of the zone exhaust nodes for the zone which the window air conditioner is cooling.

Field: Air Outlet Node Name

The name of the HVAC system node (see Node) to which the window air conditioner sends its outlet air. This should be one of the inlet air nodes for the zone which is being cooled.

Field: Outdoor Air Node Name

The name of the HVAC system node (see Node) from which the window air conditioner draws its outdoor air. This should be the same node as the outdoor air node of the unit's outdoor air mixer (object: OutdoorAir:Mixer).

Field: Air Relief Node Name

The name of the HVAC system node (see Node) to which the window air conditioner exhausts its relief air. This should be the same node as the relief air node of the unit's outdoor air mixer.

Field: Outdoor Air Mixer Name

The name of an outdoor air mixer component which composes part of the window air conditioner unit. Note that some of the input for the outdoor air mixer will duplicate input fields of the window air conditioner. The outdoor air node of the outdoor air mixer should be the same as the outdoor air node of the window air conditioner. The relief air node of the outdoor air mixer should be the same as the relief air node of the window air conditioner. The return air node of the outdoor air mixer should be the same node as the air inlet node of the window air conditioner. In addition, the outdoor air mixer's mixed air node should be the same as the window air conditioner's fan inlet air node (for blow through) or the air conditioner's DX coil inlet node (for draw through)

Field: Fan Name

The name of a constant volume fan component that composes part of the window air conditioner. Note that the fan's maximum flow rate should be the same as the maximum airflow rate of the window air conditioner. A fan of type Fan:OnOff may be used with either cycling or continuous fan, and a fan of type Fan:ConstantVolume is used only with continuous fan (see Supply Air Fan Operating Mode Schedule field below). The fan's inlet node should be the same as the outdoor air mixer's mixed air node (for blow through) or the DX coil's outlet node (for draw through). The fan's outlet node should be the same as the DX coil's air inlet node (for blow through) or the window air conditioner's air outlet node (for draw through).

Field: DX Cooling Coil Name

The name of a DX cooling coil component that composes part of the window air conditioner unit. The DX coil air inlet node should be the same as the fan outlet node (for blow through) or the outdoor air mixer's mixed air node (for draw through). The DX coil air outlet node should be the same as the window air conditioner's air outlet node (for blow through) or the fan's inlet node (for draw through).

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation. The operating mode specified here overrides the operating mode specified in the cooling coil object.

Field: Fan Placement

This input field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for "blow through fan". This means that the unit consists of an outdoor air mixer followed by a fan followed by a DX coil. The fan "blows through" the DX coil. The second choice stands for "draw through fan". This means that the unit consists of an outdoor air mixer followed by a DX coil followed by a fan. The fan "draws air through" the coil.

Field: Cooling Convergence Tolerance

This input field defines the convergence tolerance for the unit's cooling output. This field allows the user some control over how closely the air conditioner will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The window air conditioner is controlled by matching its sensible (temperature) cooling output to the zone sensible load (demand). Because the performance of the DX coil is frequently non-linear, the air conditioner model must call the DX coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The cooling convergence tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\frac{|Q_{ZoneLoad} - Q_{WindowAirConditioner,out}|}{Q_{ZoneLoad}} \leq CoolingConvergenceTolerance$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

Field: Cooling Coil Object Type

This field specifies the type of cooling coil to be modeled for this window air conditioner. The input requirements for these cooling coil objects are described elsewhere in this document. If the user wants to control the enhanced dehumidification performance of the Heat Exchanger Assisted coil type based on zone air humidity level, then the input file must include a humidistat object (ref. ZoneControl:Humidistat) for the zone being served by this air conditioner and a high humidity set point manager (ref. SetpointManager:SingleZone:Humidity:Maximum) with the high humidity set point placed on the outlet node of the heat exchanger assisted cooling coil. Only allowable coil types are:

```
Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted
```

Below is the IDD specification of the cycling window air conditioner.

```

Window AC Total Zone Cooling Rate[W]

This field is the total (sensible and latent) heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Total Zone Cooling Energy[J]

This is the total (sensible and latent) heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

Window AC Sensible Zone Cooling Rate[W]

This field reports the moist air sensible heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Sensible Zone Cooling Energy[J]

This field reports the moist air sensible heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Latent Zone Cooling Rate[W]

This output is the latent heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Latent Zone Cooling Energy[J]

This is the latent heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Electric Power[W]

This output is the electricity consumption rate of the window air conditioner unit in Watts. The consumption includes electricity used by the compressor and the fans (indoor supply air fan and the condenser fan).

Window AC Electric Consumption[J]

This output is the electricity consumption of the window air conditioner unit in Joules for the time period being reported. The consumption includes electricity used by the compressor and the fans (indoor supply air fan and the condenser fan).

Window AC Fan RunTime Fraction

This is the fraction of the report timestep during which the fan had operated.

Window AC Compressor RunTime Fraction

This is the fraction of the report timestep during which the DX unit compressor had operated.

ZoneHVAC:PackagedTerminalAirConditioner

The packaged terminal air conditioner (PTAC) is a compound object made up of other components. Each PTAC consists of an outdoor air mixer, direct expansion (DX) cooling coil, heating coil (gas, electric, hot water, or steam) and a supply air fan. While the figure below shows the PTAC with draw through fan placement, blow through fan placement can also be modeled by positioning the supply air fan between the outdoor air mixer and the DX cooling coil. The packaged terminal air conditioner coordinates the operation of these components and is modeled as a type of zone equipment (Ref. ZoneHVAC:EquipmentList and ZoneHVAC:EquipmentConnections).

Figure 87. Schematic of a packaged terminal air conditioner with draw through fan placement

Links to the PTAC's supply air fan, DX cooling coil, heating coil, and outdoor air mixer specifications are provided in the air conditioner's input syntax. Additional inputs include supply and outdoor air flow rates during cooling operation, heating operation, and when neither cooling or heating is required. A description of each input field for the packaged terminal air conditioner compound object is provided below.

Field: Name

This alpha field defines a unique user-assigned name for an instance of a packaged terminal air conditioner. Any reference to this air conditioner by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the air conditioner operates during a given time period. A schedule value equal to 0 denotes that the air conditioner must be off for that time period. A value greater than 0 denotes that the air conditioner is available to operate during that time period. This schedule may be used to completely disable the air conditioner (all of its coils and the supply air fan) as required.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the air conditioner draws its inlet air. This node name must be the name of a zone air exhaust node (Ref. ZoneHVAC:EquipmentConnections).

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the air conditioner sends its outlet air. This node name must be the name of a zone air inlet node (Ref. ZoneHVAC:EquipmentConnections).

Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component which composes part of the PTAC. The return air node of the outdoor air mixer should also be the same node as the air inlet node of the PTAC. Furthermore, the outdoor air mixer's mixed air node should be the same as the PTAC's fan inlet air node (for blow through fan placement) or the PTAC's DX cooling coil inlet node (for draw through fan placement).

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when the heating coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the air conditioner's supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation).

Field: Outdoor Air Flow Rate During Cooling Operation

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during cooling operation is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate during cooling operation cannot be greater than the air conditioner's supply air volumetric flow rate during cooling operation.

Field: Outdoor Air Flow Rate During Heating Operation

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when the heating coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during heating operation is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate during heating operation cannot be greater than the air conditioner's supply air volumetric flow rate during heating operation.

Field: Outdoor Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when neither cooling nor heating is required (i.e., cooling and heating coils are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate when no cooling/heating is needed is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate when no cooling/heating is needed cannot be greater than the air conditioner's supply air volumetric flow rate when no cooling/heating is needed. This field is only used when the air conditioner's supply air fan operating mode schedule specifies continuous fan operation. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and the field 'Supply air volumetric flow rate when no cooling or heating is needed' is set to zero or is left blank, then the model assumes that the outdoor air flow rate when no cooling/heating is needed is equal to the outdoor air flow rate when the cooling or heating coil was last operating (for cooling operation [i.e., Outdoor air Flow rate during cooling operation] or heating operation [i.e., Outdoor air flow rate during heating operation]) and this field is not used.

Field: Supply Air Fan Object Type

This alpha field defines the type of fan used by this PTAC. The only valid choices are **Fan:OnOff** and **Fan:ConstantVolume**. A fan of type Fan:OnOff is used with cycling fan operating mode, and a fan of type Fan:ConstantVolume is used with continuous fan operating mode (see Supply Air Fan Operating Mode Schedule field below). The input requirements for these fan objects are described elsewhere in this document.

Field: Supply Air Fan Name

The name of a constant volume fan component that composes part of the PTAC. Note that the fan's maximum flow rate should be greater than or equal to the maximum supply air flow rate for the PTAC. The fan's inlet node should be the same as the outdoor air mixer's mixed air node (for blow through fan placement) or the heating coil's outlet node (for draw through fan placement). The fan's outlet node should be the same as the DX cooling coil's air inlet node (for blow through fan placement) or the PTAC's air outlet node (for draw through fan placement).

Field: Heating Coil Object Type

This alpha field defines the type of heating coil to be used by this PTAC. The input requirements for this heating coil object are described elsewhere in this document. Allowable heating coil types are:

```
Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam
```

Field: Heating Coil Name

This alpha field defines the name of the heating coil used by this PTAC, and this name should match the name specified in the corresponding heating coil object.

Field: Cooling Coil Object Type

This alpha field defines the type of DX cooling coil used by this PTAC. The input requirements for these DX cooling coil objects are described elsewhere in this document. Only allowable coil types are:

```
Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted
```

Field: Cooling Coil Name

This alpha field defines the name of the cooling coil used by this PTAC, and this name should match the name specified in the corresponding DX cooling coil object.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for "blow through fan". This means that the unit consists of an outdoor air mixer followed by a fan followed by the DX cooling coil and heating coil. The fan "blows through" the DX cooling coil and the heating coil. The second choice stands for "draw through fan". This means that the unit consists of an outdoor air mixer followed by the DX cooling coil and heating coil with the fan located at the outlet of the PTAC. The fan "draws air through" the DX cooling coil and the heating coil. If this field is left blank, the default is draw through.

Note: the packaged terminal air conditioner's supply air fan, cooling coil and heating coil must be connected according to the configuration shown above (Figure 87) for the draw through fan configuration. The only other valid configuration is with a blow through fan placement, where the fan is located between the outdoor air mixer and the DX cooling coil.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

Below is the IDD specification for the packaged terminal air conditioner compound object.

A3, \field Air Inlet Node Name
  \required-field
  \type alpha
  \note Air inlet node for the PTAC must be a zone air exhaust Node.
A4, \field Air Outlet Node Name
  \required-field
  \type alpha
  \note Air outlet node for the PTAC must be a zone air inlet node.
A5, \field Outdoor Air Mixer Name
  \required-field
  \type alpha
  \note Needs to match the name of the PTAC outdoor air mixer object.
N1, \field Supply Air Flow Rate During Cooling Operation
  \required-field
  \type real
  \units m3/s
  \minimum> 0.0
  \autosizable
  \note Must be less than or equal to fan size.
N2, \field Supply Air Flow Rate During Heating Operation
  \required-field
  \type real
  \units m3/s
  \minimum> 0.0
  \autosizable
  \note Must be less than or equal to fan size.
N3, \field Supply Air Flow Rate When No Cooling or Heating is Needed
  \type real
  \units m3/s
  \minimum 0
  \autosizable
  \note Must be less than or equal to fan size.
  \note Only used when supply air fan operating mode schedule values specify continuous fan
  \note (schedule values greater than 0 specify continuous fan operation).
  \note This air flow rate is used when no heating or cooling is required and the cooling or
  \note heating coil is off. If this field is left blank or zero, the supply air flow rate
  \note from the previous on cycle (either cooling or heating) is used.
N4, \field Outdoor Air Flow Rate During Cooling Operation
  \required-field
  \type real
  \units m3/s
  \minimum 0
  \autosizable
  \note Must be less than or equal to supply air flow rate during cooling operation.

```

```

N5 , \field Outdoor Air Flow Rate During Heating Operation
    \required-field
    \type real
    \units m3/s
    \minimum 0
    \autosizable
    \note Must be less than or equal to supply air flow rate during heating operation.
N6 , \field Outdoor Air Flow Rate When No Cooling or Heating is Needed
    \type real
    \units m3/s
    \minimum 0
    \autosizable
    \note Only used when supply air fan operating mode schedule values specify continuous fan
    \note (schedule values greater than 0 specify continuous fan operation).
    \note This air flow rate is used when no heating or cooling is required and the cooling or
    \note heating coil is off. If this field is left blank or zero, the outdoor air flow rate
    \note from the previous on cycle (either cooling or heating) is used.
A6 , \field Supply Air Fan Object Type
    \required-field
    \type choice
    \key Fan:OnOff
    \key Fan:ConstantVolume
    \note Fan:ConstantVolume only works when continuous fan operation is used the entire
    \note simulation (all supply air fan operating mode schedule values are greater than 0).
    \note If any fan operating mode schedule values are 0 a Fan:OnOff object must be used.
A7 , \field Supply Air Fan Name
    \required-field
    \type object-list
    \object-list FansCVandOnOff
    \note Needs to match in the fan object.
A8 , \field Heating Coil Object Type
    \required-field
    \type choice
    \key Coil:Heating:Gas
    \key Coil:Heating:Electric
    \key Coil:Heating:Water
    \key Coil:Heating:Steam
    \note Select the type of heating coil.

    \required-field
    \type object-list
    \object-list HeatingCoilName
    \note Needs to match in the heating coil object.
A10, \field Cooling Coil Object Type
    \required-field
    \type choice
    \key Coil:Cooling:DX:SingleSpeed
    \key CoilSystem:Cooling:DX:HeatExchangerAssisted
    \note Select the type of Cooling Coil.
    \note Only works with Coil:Cooling:DX:SingleSpeed or
    \note CoilSystem:Cooling:DX:HeatExchangerAssisted.
A11, \field Cooling Coil Name
    \required-field
    \type object-list
    \object-list CoolingCoilsDXSingleSpeed
    \note Needs to match a DX cooling coil object.
A12, \field Fan Placement
    \type choice
    \key BlowThrough
    \key DrawThrough
    \default DrawThrough
    \note Select fan placement as either blow through or draw through.
A13; \field Supply Air Fan Operating Mode Schedule Name
    \type object-list
    \object-list ScheduleNames
    \note Enter the name of a schedule that controls fan operation. Schedule Name values of 0 denote
    \note cycling fan operation (fan cycles with cooling or heating coil). Schedule Name values
greater
    \note than 0 denote constant fan operation (fan runs continually regardless of coil operation).

```

As shown in the example below, correct specification of the packaged terminal air conditioner requires the following objects in addition to the compound object itself:

- 1) Fan (Fan:OnOff or Fan:ConstantVolume)
- 2) DX cooling coil (Coil:Cooling:DX:SingleSpeed or CoilSystem:Cooling:DX:HeatExchangerAssisted)
- 3) Heating coil (Coil:Heating:Gas, Coil:Heating:Electric, Coil:Heating:Water, or Coil:Heating:Steam)
- 4) OutdoorAir:Mixer

Packaged Terminal Air Conditioner Total Zone Heating Rate[W]

This output field is the total (enthalpy) heat addition rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Total Zone Heating Energy[J]

This output field is the total (enthalpy) heat addition of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Total Zone Cooling Rate[W]

This output field is the total (enthalpy) heat extraction rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Total Zone Cooling Energy[J]

This output field is the total (enthalpy) heat extraction of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Sensible Zone Heating Rate[W]

This output field is the sensible heat addition rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Sensible Zone Heating Energy[J]

This output field is the sensible heat addition of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Sensible Zone Cooling Rate[W]

This output field reports the moist air sensible heat extraction rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Sensible Zone Cooling Energy[J]

This output field reports the moist air sensible heat extraction of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Latent Zone Heating Rate[W]

This output field is the latent heat addition (humidification) rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Latent Zone Heating Energy[J]

This output field is the latent heat addition (humidification) of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Latent Zone Cooling Rate[W]

This output field is the latent heat extraction (dehumidification) rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Latent Zone Cooling Energy[J]

This output field is the latent heat extraction (dehumidification) of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Electric Power[W]

This output field is the electricity consumption rate of the packaged terminal air conditioner in Watts. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the heating coil (includes electricity consumption rate for electric heating coil or parasitic electricity consumption rate for non-electric coils). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Electric Consumption[J]

This output field is the electricity consumption of the packaged terminal air conditioner in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the heating coil (includes electricity consumption for electric heating coil or parasitic electricity consumption for non-electric coils). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported.

Packaged Terminal Air Conditioner Fan Part-Load Ratio

This output field is the part-load ratio of the fan. The fan part-load ratio is defined as the average supply air mass flow rate divided by the maximum supply air mass flow rate. The maximum supply air mass flow rate depends on whether heating, cooling, or no heating or cooling is required during the timestep. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Part-Load Ratio

This output field is the part-load ratio used by the coils (cooling and heating). Part-load ratio is defined as the total coil load divided by the coil steady-state capacity. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

ZoneHVAC:PackagedTerminalHeatPump

The packaged terminal heat pump (PTHP) is a compound object made up of other components. Each PTHP consists of an outdoor air mixer, direct expansion (DX) cooling coil, DX heating coil, supply air fan, and a supplemental heating coil as shown in the figure below. These individual components are described elsewhere in this document. The packaged terminal heat pump coordinates the operation of these components and is modeled as a type of zone equipment (Ref. ZoneHVAC:EquipmentList and ZoneHVAC:EquipmentConnections).

Figure 88. Schematic of a packaged terminal heat pump (draw through fan placement)

Links to the PTHP's supply air fan, DX coils, supplemental heating coil, and outdoor air mixer specifications are provided in the heat pump's input syntax. Additional inputs include supply and outdoor air flow rates during cooling operation, heating operation, and when neither cooling or heating is required. A description of each input field for the packaged terminal heat pump compound object is provided below.

Field: Name

This alpha field defines a unique user-assigned name for an instance of a packaged terminal heat pump. Any reference to this heat pump by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump operates during a given time period. A schedule value equal to 0 denotes that the heat pump must be off for that time period. A value greater than 0 denotes that the heat pump is available to operate during that time period. This schedule may be used to completely disable the heat pump (all of its coils and the supply air fan) as required.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the heat pump draws its inlet air. This node name must be the name of a zone air exhaust node (Ref. ZoneHVAC:EquipmentConnections).

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the heat pump sends its outlet air. This node name must be the name of a zone air inlet node (Ref. ZoneHVAC:EquipmentConnections).

Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component which composes part of the PTHP. Note that the return air node of the outdoor air mixer should also be the same node as the air inlet node of the PTHP. Furthermore, the outdoor air mixer's mixed air node should be the same as the PTHP's fan inlet air node (for blow through fan placement) or the PTHP's DX cooling coil inlet node (for draw through fan placement).

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation).

Field: Outdoor Air Flow Rate During Cooling Operation

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during cooling operation is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate during cooling operation cannot be greater than the heat pump's supply air volumetric flow rate during cooling operation.

Field: Outdoor Air Flow Rate During Heating Operation

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during heating operation is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate during heating operation cannot be greater than the heat pump's supply air volumetric flow rate during heating operation.

Field: Outdoor Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate when no cooling/heating is needed is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate when no cooling/heating is needed cannot be greater than the heat pump's supply air volumetric flow rate when no cooling/heating is needed. This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and the field 'Supply air volumetric flow rate when no cooling or heating is needed' is set to zero or is left blank, then the model assumes that the outdoor air flow rate when no cooling/heating is needed is equal to the outdoor air flow rate when the cooling or heating coil was last operating (for cooling operation [i.e., Outdoor air flow rate during cooling operation] or heating operation [i.e., Outdoor air flow rate during heating operation]) and this field is not used.

Field: Supply Air Fan Object Type

This alpha field defines the type of fan used by this PTHP. The only valid choices are Fan:OnOff and Fan:ConstantVolume. A fan of type Fan:OnOff may be used with either cycling or continuous fan operating mode, and a fan of type Fan:ConstantVolume is used only with continuous fan operating mode (see Supply Air Fan Operating Mode Schedule field below). The input requirements for these fan objects are described elsewhere in this document.

Field: Supply Air Fan Name

The name of a constant volume fan component that composes part of the PTHP. Note that the fan's maximum flow rate should be greater than or equal to the maximum supply air flow rate for the PTHP. The fan's inlet node should be the same as the outdoor air mixer's mixed air node (for blow through fan placement) or the DX heating coil's outlet node (for draw through fan placement). The fan's outlet node should be the same as the DX cooling coil's air inlet node (for blow through fan placement) or the supplemental heater's air inlet node (for draw through fan placement).

Field: Heating Coil Object Type

This alpha field defines the type of DX heating coil to be used by this PTHP. The only valid choice is **Coil:Heating:DX:SingleSpeed**. The input requirements for this DX heating coil object are described elsewhere in this document.

Field: Heating Coil Name

This alpha field defines the name of the DX heating coil used by this PTHP, and this name should match the name specified in the corresponding DX heating coil object.

Field: Heating Convergence Tolerance

This numeric field defines the convergence tolerance for the unit's heating output. This field allows the user some control over how closely the heat pump will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The heat pump is controlled by matching its sensible (temperature) heating output to the zone sensible load (demand). Because the performance of the DX heating coil is frequently non-linear, the heat pump model must call the DX heating coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The heating convergence

tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\frac{|(Q_{ZoneLoad} - Q_{HeatPump,out})|}{Q_{ZoneLoad}} \leq HeatingConvergenceTolerance$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor dry-bulb temperature in degrees Celsius for PTHP compressor operation. The compressor will not operate (for DX heating or DX cooling) when outdoor dry-bulb temperatures fall below this value. The minimum value must be greater than or equal to -20 °C. If this field is left blank, the default value is -8°C. This temperature should match the minimum compressor operating temperature specified for the heat pump's DX heating coil (if they don't match, the highest of the two temperatures will be the cut-off temperature for compressor operation).

Field: Cooling Coil Object Type

This alpha field defines the type of DX cooling coil used by this PTHP. The input requirements for these DX cooling coil objects are described elsewhere in this document. Only allowable coil types are:

```
Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted
```

Field: Cooling Coil Name

This alpha field defines the name of the cooling coil used by this PTHP, and this name should match the name specified in the corresponding DX cooling coil object.

Field: Cooling Convergence Tolerance

This numeric field defines the convergence tolerance for the unit's cooling output. This field allows the user some control over how closely the heat pump will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The heat pump is controlled by matching its sensible (temperature) cooling output to the zone sensible load (demand). Because the performance of the DX cooling coil is frequently non-linear, the heat pump model must call the DX cooling coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The cooling convergence tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\frac{|(Q_{ZoneLoad} - Q_{HeatPump,out})|}{Q_{ZoneLoad}} \leq CoolingConvergenceTolerance$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

Field: Supplemental Heating Coil Object Type

This alpha field defines the type of supplemental heating coil to be used by this PTHP. The input requirements for these heating coil objects are described elsewhere in this document. Only allowable coil types are:

Coil:Heating:Electric Coil:Heating:Gas

Field: Supplemental Heating Coil Name

This alpha field defines the name of the supplemental heating coil used by this PTHP, and this name should match the name specified in the corresponding heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum supply air temperature in degrees Celsius exiting the heat pump supplemental heater coil. The supplemental heater will be controlled so that its supply air temperature does not exceed this value. This field is autosizable.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the maximum outdoor dry-bulb temperature in degrees Celsius for PTHP supplemental heater operation. The supplemental heater will not operate when the outdoor dry-bulb temperature is above this value. The maximum value must be less than or equal to 21°C. If this field is left blank, the default value is 21°C.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of an outdoor air mixer followed by a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of an outdoor air mixer followed by the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is draw through.

Note: the packaged terminal heat pump’s supply air fan, cooling coil, heating coil and supplementary heating coil must be connected according to the configuration shown above (Figure 88) for the draw through fan configuration. The only other valid configuration is with a blow through fan placement, where the fan is located between the outdoor air mixer and the DX cooling coil.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation. The operating mode specified here overrides the operating mode specified in the cooling and heating coil objects.

Below is the IDD specification for the packaged terminal heat pump compound object.

```

ZoneHVAC:PackagedTerminalHeatPump,
  \min-fields 26
A1, \field Name
   \required-field
   \type alpha
   \note Unique name for this packaged terminal heat pump object.
A2, \field Availability Schedule Name
   \required-field
   \type object-list
   \object-list ScheduleNames
   \note Schedule values of 0 denote the unit is off.
A3, \field Air Inlet Node Name
   \required-field
   \type alpha
   \note Air inlet node for the PTHP must be a zone air exhaust node.
A4, \field Air Outlet Node Name
   \required-field
   \type alpha
   \note Air outlet node for the PTHP must be a zone air inlet node.
A5, \field Outdoor Air Mixer Name
   \required-field
   \type alpha
   \note Needs to match name of outdoor air mixer object.
N1, \field Supply Air Flow Rate During Cooling Operation
   \required-field
   \type real
   \units m3/s
   \minimum> 0.0
   \autosizable
   \note Must be less than or equal to fan size.
N2, \field Supply Air Flow Rate During Heating Operation
   \required-field
   \type real
   \units m3/s
   \minimum> 0.0
   \autosizable
   \note Must be less than or equal to fan size.
N3, \field Supply Air Flow Rate When No Cooling or Heating is Needed
   \type real
   \units m3/s
   \minimum 0
   \autosizable
   \note Must be less than or equal to fan size.
   \note Only used when heat pump fan operating mode is ContinuousFanWithCyclingCompressor. This air
flow rate
   \note is used when no heating or cooling is required and the DX coil compressor is off.
   \note If this field is left blank or zero, the supply air flow rate from the previous on cycle
   \note (either cooling or heating) is used.
N4, \field Outdoor Air Flow Rate During Cooling Operation
   \required-field
   \type real
   \units m3/s
   \minimum 0
   \autosizable
   \note Must be less than or equal to supply air flow rate during cooling operation.
N5, \field Outdoor Air Flow Rate During Heating Operation
   \required-field
   \type real
   \units m3/s
   \minimum 0
   \autosizable
   \note Must be less than or equal to supply air flow rate during heating operation.

```

```

N6 , \field Outdoor Air Flow Rate When No Cooling or Heating is Needed
    \type real
    \units m3/s
    \minimum 0
    \autosizable
    \note Only used when heat pump Fan operating mode is ContinuousFanWithCyclingCompressor. This air
flow rate
    \note is used when no heating or cooling is required and the DX coil compressor is off.
    \note If this field is left blank or zero, the outdoor air flow rate from the previous on cycle
    \note (either cooling or heating) is used.
A6 , \field Supply Air Fan Object Type
    \required-field
    \type choice
    \key Fan:OnOff
    \key Fan:ConstantVolume
    \note Fan:ConstantVolume only works with operating mode = ContinuousFanWithCyclingCompressor.
A7 , \field Supply Air Fan Name
    \required-field
    \type object-list
    \object-list FansCVandOnOff
    \note Needs to match a fan object.
A8 , \field Heating Coil Object Type
    \required-field
    \type choice
    \key Coil:Heating:DX:SingleSpeed
    \note Only works with Coil:Heating:DX:SingleSpeed.
A9 , \field Heating Coil Name
    \required-field
    \type object-list
    \object-list HeatingCoilsDXSingleSpeed
    \note Needs to match in the DX Heating Coil object.
N7 , \field Heating Convergence Tolerance
    \type real
    \minimum> 0.0
    \default 0.001
    \units dimensionless
    \note Defines Heating convergence tolerance as a fraction of Heating load to be met.
N8 , \field Minimum Outdoor Dry-Bulb Temperature for Compressor Operation
    \type real
    \minimum -20.0
    \default -8.0
    \units C
    \note Needs to match the corresponding minimum outdoor temperature defined
    \note in the DX Heating Coil object.
A10, \field Cooling Coil Object Type
    \required-field
    \type choice
    \key Coil:Cooling:DX:SingleSpeed
    \key CoilSystem:Cooling:DX:HeatExchangerAssisted
    \note Only works with Coil:Cooling:DX:SingleSpeed or
    \note CoilSystem:Cooling:DX:HeatExchangerAssisted.
A11, \field Cooling Coil Name
    \required-field
    \type object-list
    \object-list CoolingCoilsDXSingleSpeed
    \note Needs to match in the DX Cooling Coil object.
N9 , \field Cooling Convergence Tolerance
    \type real
    \minimum> 0.0
    \default 0.001
    \units dimensionless
    \note Defines Cooling convergence tolerance as a fraction of the Cooling load to be met.
A12, \field Supplemental Heating Coil Object Type
    \required-field
    \type choice
    \key Coil:Heating:Gas
    \key Coil:Heating:Electric
    \note Only works with Coil:Heating:Gas or Coil:Heating:Electric.

```

```

A13, \field Supplemental Heating Coil Name
    \required-field
    \type object-list
    \object-list HeatingCoilsGasElec
    \note Needs to match in the supplemental heating coil object.
N10, \field Maximum Supply Air Temperature from Supplemental Heater
    \required-field
    \type real
    \units C
    \autosizable
    \note Supply air temperature from the supplemental heater will not exceed this value.
N11, \field Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation
    \type real
    \maximum 21.0
    \default 21.0
    \units C
    \note Supplemental heater will not operate when outdoor temperature exceeds this value.
A14, \field Fan Placement
    \type choice
    \key BlowThrough
    \key DrawThrough
    \default DrawThrough
    \note Select fan placement as either blow through or draw through.
A15; \field Supply Air Fan Operating Mode Schedule Name
    \type object-list
    \object-list ScheduleNames
    \note Enter the name of a schedule that controls fan operation. Schedule values of 0 denote
    \note cycling fan operation (fan cycles with cooling or heating coil). Schedule Name values
greater
    \note than 0 denote constant fan operation (fan runs continually regardless of coil operation).
    \note The fan operating mode defaults to cycling fan operation if this field is left blank.

```

As shown in the example below, correct specification of the packaged terminal heat pump requires the following objects in addition to the compound object itself:

- 1) Fan (Fan:OnOff or Fan:ConstantVolume)
- 2) DX cooling coil (Coil:Cooling:DX:SingleSpeed or CoilSystem:Cooling:DX:HeatExchangerAssisted)
- 3) DX heating coil (Coil:Heating:DX:SingleSpeed)
- 4) Supplemental heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 5) OutdoorAir:Mixer

Packaged Terminal Heat Pump Total Zone Heating Rate[W]

This output field is the total (enthalpy) heat addition rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Total Zone Heating Energy[J]

This output field is the total (enthalpy) heat addition of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Total Zone Cooling Rate[W]

This output field is the total (enthalpy) heat extraction rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Total Zone Cooling Energy[J]

This output field is the total (enthalpy) heat extraction of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Sensible Zone Heating Rate[W]

This output field is the sensible heat addition rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Sensible Zone Heating Energy[J]

This output field is the sensible heat addition of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Sensible Zone Cooling Rate[W]

This output field reports the moist air sensible heat extraction rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Sensible Zone Cooling Energy[J]

This output field reports the moist air sensible heat extraction of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Latent Zone Heating Rate[W]

This output field is the latent heat addition (humidification) rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Latent Zone Heating Energy[J]

This output field is the latent heat addition (humidification) of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Latent Zone Cooling Rate[W]

This output field is the latent heat extraction (dehumidification) rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Latent Zone Cooling Energy[J]

This output field is the latent heat extraction (dehumidification) of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Electric Power[W]

This output field is the electricity consumption rate of the packaged terminal heat pump in Watts. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Heat Pump Electric Consumption[J]

This output field is the electricity consumption of the packaged terminal heat pump in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported.

Packaged Terminal Heat Pump Fan Part-Load Ratio

This output field is the part-load ratio of the fan. The fan part-load ratio is defined as the average supply air mass flow rate divided by the maximum supply air mass flow rate. The maximum supply air mass flow rate depends on whether heating, cooling, or no heating or cooling is required during the timestep. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Heat Pump Compressor Part-Load Ratio

This output field is the part-load ratio of the compressor used by the DX coils (cooling and heating). Compressor part-load ratio is defined as the total coil load divided by the coil steady-state capacity. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

ZoneHVAC:EnergyRecoveryVentilator

The ZoneHVAC:EnergyRecoveryVentilator - stand alone energy recovery ventilator (ERV) is a single-zone HVAC component used for exhaust air heat recovery (Figure 89). This compound object consists of 3 required components: a generic air-to-air heat exchanger (see object Heat Exchanger:Air to Air:Generic), a supply air fan, and an exhaust air fan (see object Fan:OnOff).

An optional controller (see object ZoneHVAC:EnergyRecoveryVentilator:Controller) may be used to simulate economizer (free cooling) operation, modify air flow rates based on high indoor humidity, or simulate a “push-button” type economizer controller.

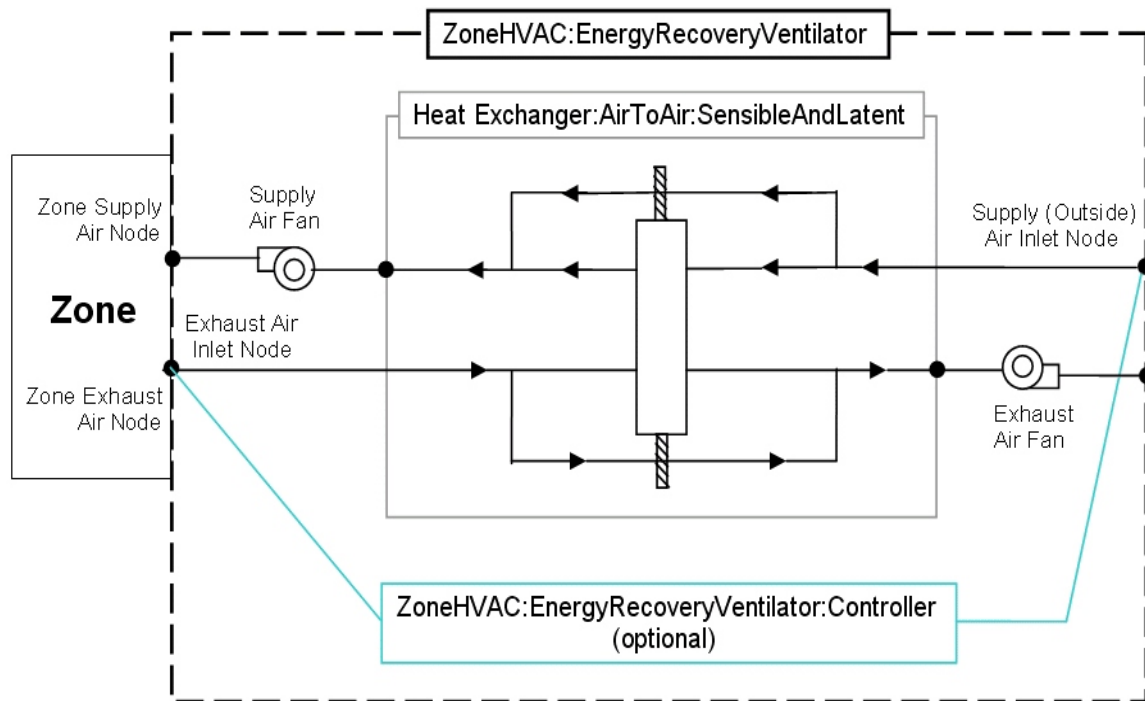

Figure 89. Schematic of the ZoneHVAC:EnergyRecoveryVentilator compound object

This compound object models the basic operation of supply and exhaust air fans and an air-to-air heat exchanger. The stand alone ERV operates whenever the unit is scheduled to be available (Availability schedule). The stand alone ERV object can be used in conjunction with an economizer feature whereby heat exchange is suspended whenever free cooling is available (i.e., air flow is fully bypassed around a fixed-plate heat exchanger or the rotation of a rotary heat exchanger is stopped). The economizer feature may also be activated based on a time-of-day schedule. Heat exchange is also suspended when air flow rates through the

heat exchanger are modified in response to a zone humidistat. When an economizer is used in conjunction with high humidity control, high humidity control has the priority.

To model a stand alone ERV connected to a single zone, the input data file should include the following objects:

- ZoneHVAC:EnergyRecoveryVentilator
- HeatExchanger:AirToAir:SensibleAndLatent
- Fan:OnOff (supply air)
- Fan:OnOff (exhaust air)
- ZoneHVAC:EnergyRecoveryVentilator:Controller (if economizer [free cooling] mode or high humidity control operation is desired)
- ZoneControl:Humidistat (required for high humidity control option)
- SetpointManager:Scheduled (if supply air outlet temperature control is used, Ref. Heat Exchanger:Air to Air:Generic for additional guidance)
- ZoneHVAC:EquipmentConnections
- ZoneHVAC:EquipmentList
- OutdoorAir:NodeList

A description of each input field for this compound object is provided below.

Field: Name

A unique user-assigned name for the stand alone ERV unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can operate during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit will not operate.

Field: Heat Exchanger Name

The user-assigned name corresponding to the air-to-air heat exchanger used in this compound object. The only allowable type is:

HeatExchanger:AirToAir:SensibleAndLatent

Field: Supply Air Flow Rate

The supply air flow rate through the ERV unit in cubic meters per second at standard temperature and pressure (dry air at 20° C drybulb). The program uses local barometric pressure to account for altitude using the equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)**5.2559$$

where p=pressure in Pa and Z=altitude in m

Note that this flow rate must be within the valid air flow range for the heat exchanger (ref: HeatExchanger:AirToAir:SensibleAndLatent in the Engineering Document). In addition, this flow rate must be less than or equal to the supply fan air flow rate (Fan:OnOff). If the supply air flow rate is less than the exhaust air flow rate, the zone infiltration (ref: ZoneInfiltration) should be specified accordingly (the infiltration induced by imbalanced air flows is not accounted for automatically). The ERV supply air flow rate may also be autosized using the ventilation rate per floor area and/or ventilation rate per occupant fields below. When autosizing, the heat exchanger and fan air flow rates should also be autosized.

Note: The supply air inlet node specified in the generic heat exchanger object must be an outdoor air node (ref: OutdoorAir:Node and OutdoorAir:NodeList). The supply air outlet node specified in the generic heat exchanger object must be a zone air inlet node (ref: ZoneHVAC:EquipmentConnections).

Field: Exhaust Air Flow Rate

The exhaust air flow rate through the ERV unit in cubic meters per second at standard temperature and pressure (dry air at 20° C drybulb). The program uses local barometric pressure to account for altitude using the equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)**5.2559$$

where p=pressure in Pa and Z=altitude in m

Note that this flow rate must be within the valid air flow range for the heat exchanger (ref: HeatExchanger:AirToAir:SensibleAndLatent in the Engineering Document). In addition, this flow rate must be less than or equal to the exhaust fan air flow rate (Fan:OnOff). If the exhaust air flow rate is greater than the supply air flow rate, the zone infiltration (ref: ZoneInfiltration) should be specified accordingly (the infiltration induced by imbalanced air flows is not accounted for automatically). The ERV exhaust air flow rate may also be autosized using the ventilation rate per floor area and/or ventilation rate per occupant fields below. When autosizing, the heat exchanger and fan air flow rates should also be autosized.

Note: The exhaust air inlet node specified in the generic heat exchanger object must be a zone air exhaust node (ref: ZoneHVAC:EquipmentConnections).

Field: Supply Air Fan Name

The name of the supply air fan used in this object. Fan type must be Fan:OnOff.

Field: Exhaust Air Fan Name

The name of the exhaust air fan used in this object. Fan type must be Fan:OnOff.

Field: Controller Name

This optional field specifies the name of the controller used by this compound component if economizer (free cooling) mode or high humidity control operation is desired. Controller type must be ZoneHVAC:EnergyRecoveryVentilator:Controller.

Field: Ventilation Rate per Unit Floor Area

This optional numeric field defines the ventilation rate per unit floor area in cubic meters per second per square meter. This field is only used when the supply and exhaust air flow rates are autosized.

Field: Ventilation Rate per Occupant

This optional numeric field defines the ventilation rate per occupant in cubic meters per second per occupant. This field is only used when the supply and exhaust air flow rates are autosized.

The full IDD specification follows:

```

ZoneHVAC:EnergyRecoveryVentilator,
  \memo This compound component models a stand-alone energy recovery ventilator (ERV)
  \memo that conditions outdoor ventilation air and supplies that air directly to a zone.
  \memo The ERV unit is modeled as a collection of components: air-to-air heat exchanger,
  \memo supply air fan, exhaust air fan and an optional controller to avoid overheating
  \memo of the supply air (economizer or free cooling operation).

Stand Alone ERV Electric Power [W]

This output field is the electric consumption rate of the stand alone energy recovery ventilator in Watts. This rate includes the electric consumption by the supply air fan, exhaust air fan and the generic air-to-air heat exchanger.

Stand Alone ERV Electric Consumption [J]

This output field is the electric consumption of the stand alone energy recovery ventilator in Joules for the timestep being reported. This value includes the electric consumption by the supply air fan, exhaust air fan and the generic air-to-air heat exchanger.

Stand Alone ERV Zone Total Cooling Rate [W]

This output field is the total (enthalpy) heat extraction rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Stand Alone ERV Zone Total Cooling Energy [J]

This output field is the total (enthalpy) heat extraction of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

Stand Alone ERV Zone Total Heating Rate [W]

This output field is the total (enthalpy) heat addition rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Stand Alone ERV Zone Total Heating Energy [J]

This output field is the total (enthalpy) heat addition of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

Stand Alone ERV Zone Sensible Cooling Rate [W]

This output is the moist air sensible heat extraction rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Stand Alone ERV Zone Sensible Cooling Energy [J]

This output is the moist air sensible heat extraction of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

Stand Alone ERV Zone Sensible Heating Rate [W]

This output is the sensible heat addition rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Stand Alone ERV Zone Sensible Heating Energy [J]

This output is the sensible heat addition of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

Stand Alone ERV Zone Latent Cooling Rate [W]

This output is the latent heat extraction (dehumidification) rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Stand Alone ERV Zone Latent Cooling Energy [J]

This output is the latent heat extraction (dehumidification) of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

Stand Alone ERV Zone Latent Heating Rate [W]

This output is the latent heat addition (humidification) rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Stand Alone ERV Zone Latent Heating Energy [J]

This output is the latent heat addition (humidification) of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

Group – Unitary Equipment

Furnace and Unitary Systems

The components

```
AirLoopHVAC:Unitary:Furnace:HeatOnly
AirLoopHVAC:Unitary:Furnace:HeatCool
AirLoopHVAC:UnitaryHeatOnly
AirLoopHVAC:UnitaryHeatCool
AirLoopHVAC:UnitaryHeatPump:AirToAir
AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed
```

are compound components usually placed in the primary air loop as the sole component. On the zone equipment side they are usually connected to one or more zones through Direct Air objects. The maximum or design air flow rate through the furnace or unitary system should usually be set equal to the sum of the maximum air flow rates through the direct air objects. However, the simulation program can account for unequal air flows if the user wishes to model this scenario.

AirLoopHVAC:Unitary:Furnace:HeatCool

The heat/cool furnace is a “virtual” component that consists of a fan component (OnOff or ConstantVolume), a Gas or Electric heating coil component, and a DX cooling coil component. The blow through furnace configuration is shown in Figure 90 below. If the dehumidification control type is specified as CoolReheat, a reheat coil component is also required. The blow through furnace’s configuration when specifying this option is shown in Figure 91. Schematic of Blow Thru Furnace with High Humidity Control below.

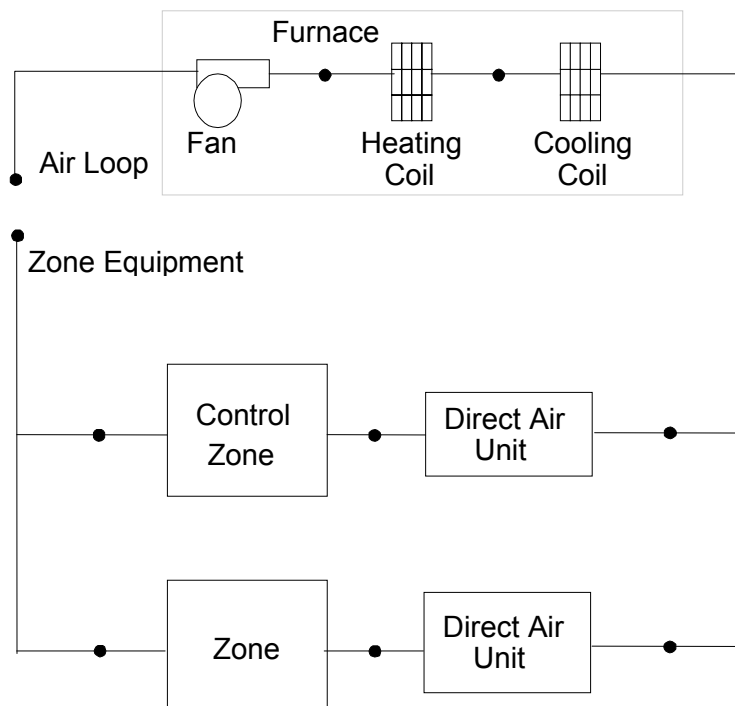

Figure 90. Schematic of EnergyPlus Heat/Cool Furnace

Links to the fan, heating coil, DX cooling coil and optional reheat coil specifications are provided in the furnace input data syntax. In addition the control zone name, the fraction of

the total furnace air flow delivered to the control zone and furnace design operating conditions are specified by the furnace syntax as shown in the Energy+.idd specification below.

```

Field: Name

This alpha field contains the identifying name for the unit.

Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the furnace to operate.

Field: Furnace Air Inlet Node Name

This alpha field contains the furnace inlet node name.

Field: Furnace Air Outlet Node Name

This alpha field contains the furnace outlet node name.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

Field: Maximum Supply Air Temperature

This numeric field contains the design operating furnace air outlet temperature in degrees C when the furnace is heating. If this input field is left blank, the default value is 80 C.

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the furnace operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the furnace operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the furnace is located.

Field: Fraction of Supply Air Flow That Goes Through the Controlling Zone

This numeric field contains the fraction (>0 to 1) of the total furnace volumetric flow rate that is supplied to the zone with the furnace thermostat.

Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the furnace. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Fan Name

This alpha field contains the identifying name given to the furnace fan.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is blow through.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the furnace. Only allowable coil types are:

Coil:Heating:Electric Coil:Heating:Gas

Field: Heating Coil Name

This alpha field contains the identifying name given to the furnace heating coil.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the furnace. Only allowable coil types are:

Coil:Cooling:DX:SingleSpeed CoilSystem:Cooling:DX:HeatExchangerAssisted
--

Field: Cooling Coil Name

This alpha field contains the identifying name given to the furnace cooling coil.

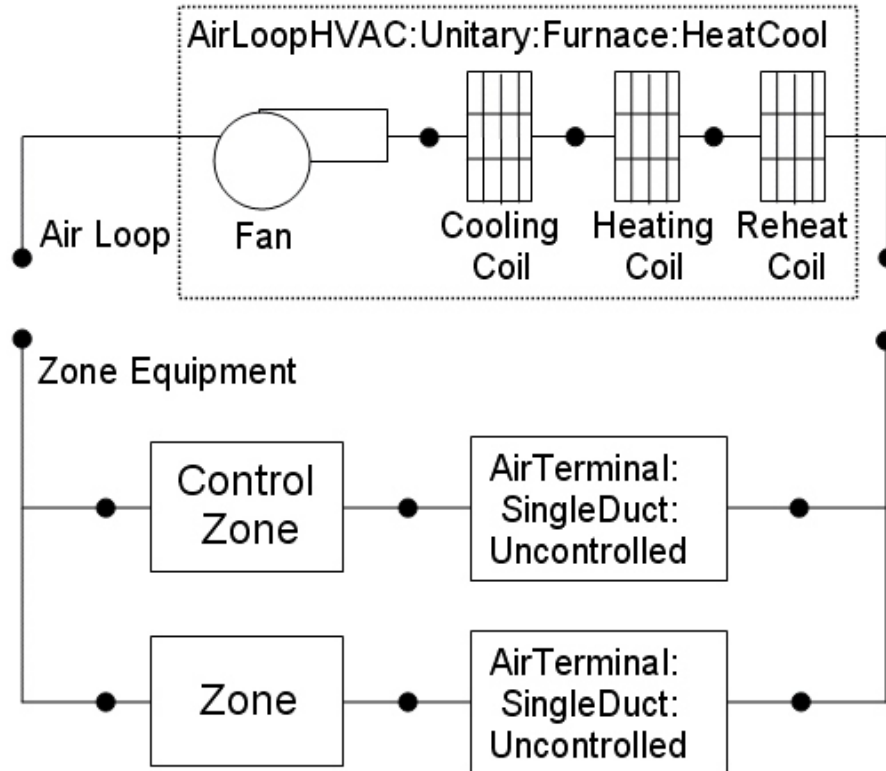

Figure 91. Schematic of Blow Thru Furnace with High Humidity Control

Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

Multimode - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted.

CoolReheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. If cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is used. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. If the dehumidification control type is specified as **CoolReheat**, then two additional inputs (reheat coil type and name) are also required as shown below.

Field: Reheat Coil Object Type

This alpha field contains the identifying type of reheat coil specified in the furnace. Reheat coil type must be one of:

```
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Desuperheater
```

Field: Reheat Coil Name

This alpha field contains the identifying name given to the furnace reheat coil.

As shown in the example below, correct specification of the heat/cool furnace requires specification of the following objects in addition to the furnace object:

- 1) fan (Fan:OnOff or Fan:ConstantVolume)
- 2) heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 3) cooling coil (Coil:Cooling:DX:SingleSpeed or CoilSystem:Cooling:DX:HeatExchangerAssisted)
- 4) reheat coil (optional, Coil:Heating:Gas, Coil:Heating:Electric, or Coil:Heating:Desuperheater)
- 5) direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the furnace

Note: the furnace's fan, heating coil, cooling coil and optional reheat coil must be connected in the air loop according to the configuration shown above (Figure 90 or Figure 91). In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the furnace object.

```

Example of Heat/Cool Furnace Specification

AirLoopHVAC:Unitary:Furnace:HeatCool Outputs

```

HVAC,Average,Furnace Fan Part-Load Ratio
HVAC,Average,Furnace Compressor Part-Load Ratio

```

Furnace Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the furnace to the furnace's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state furnace heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the furnace fan may be different from the fan part-load ratio reported here due the part-load performance of the furnace's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

Furnace Compressor Part-Load Ratio

This output variable is the ratio of the sensible cooling load to the steady-state cooling capacity of the furnace's DX cooling coil. The runtime fraction for the DX cooling coil compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

AirLoopHVAC:UnitaryHeatCool

The UnitarySystem: HeatCool is the identical model to the Furnace: HeatCool object. The heat/cool unitary system is a "virtual" component that consists of a fan component (OnOff or ConstantVolume), a Gas or Electric heating coil component and a DX cooling coil component as shown in Figure 92 below. If dehumidification control is selected, a reheat coil component is also required and the system's configuration when specifying this option is shown in Figure 93. Schematic of Blow Through Unitary System (HeatCool) with High Humidity Control below.

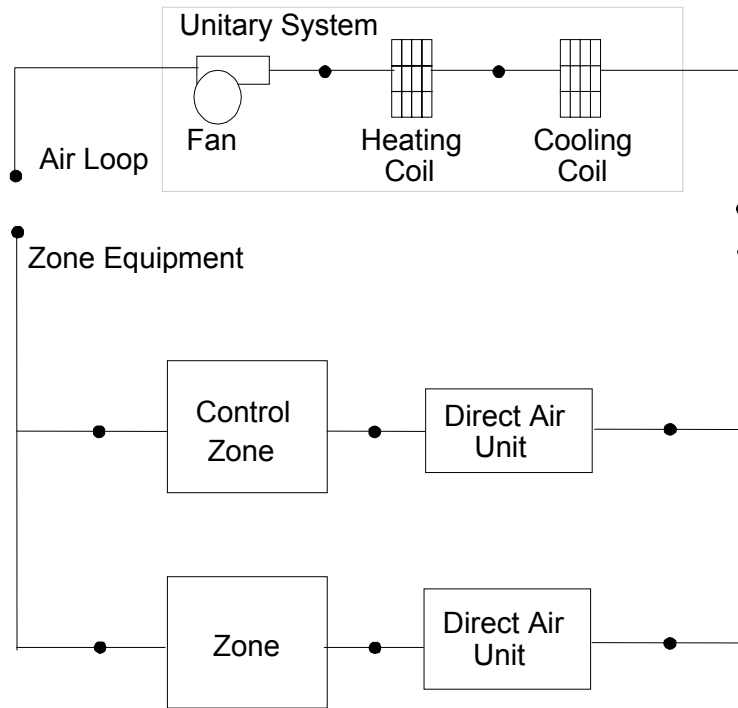

Figure 92. Schematic of Blow Through Heat/Cool Unitary System

Links to the fan, heating coil, DX cooling coil and optional reheat coil specifications are provided in the unitary system input data syntax. In addition the control zone name, the fraction of the total system air flow delivered to the control zone and system design operating conditions are specified by the unitary system syntax as shown in the Energy+.idd specification below.

```

Field: Name

This alpha field contains the identifying name for the unitary system.

Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the unitary system to operate.

Field: Unitary System Air Inlet Node Name

This alpha field contains the unitary system inlet node name.

Field: Unitary System Air Outlet Node Name

This alpha field contains the unitary system outlet node name.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

Field: Maximum Supply Air Temperature

This numeric field contains the design operating air outlet temperature in degrees C when the unitary system is heating. If this input field is left blank, the default value is 80 C.

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the unitary system operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the unitary system operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the unitary system is located.

Field: Fraction of Supply Air Flow That Goes Through the Controlling Zone

This numeric field contains the fraction (>0 to 1) of the total system volumetric flow rate that is supplied to the zone with the unitary system thermostat.

Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the unitary system. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates

continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Fan Name

This alpha field contains the identifying name given to the unitary system fan.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is blow through.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the unitary system. Only allowable coil types are:

```
Coil:Heating:Electric  
Coil:Heating:Gas
```

Field: Heating Coil Name

This alpha field contains the identifying name given to the unitary system heating coil.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the unitary system. Only allowable coil types are:

```
Coil:Cooling:DX:SingleSpeed  
CoilSystem:Cooling:DX:HeatExchangerAssisted
```

Field: Cooling Coil Name

This alpha field contains the identifying name given to the unitary system cooling coil.

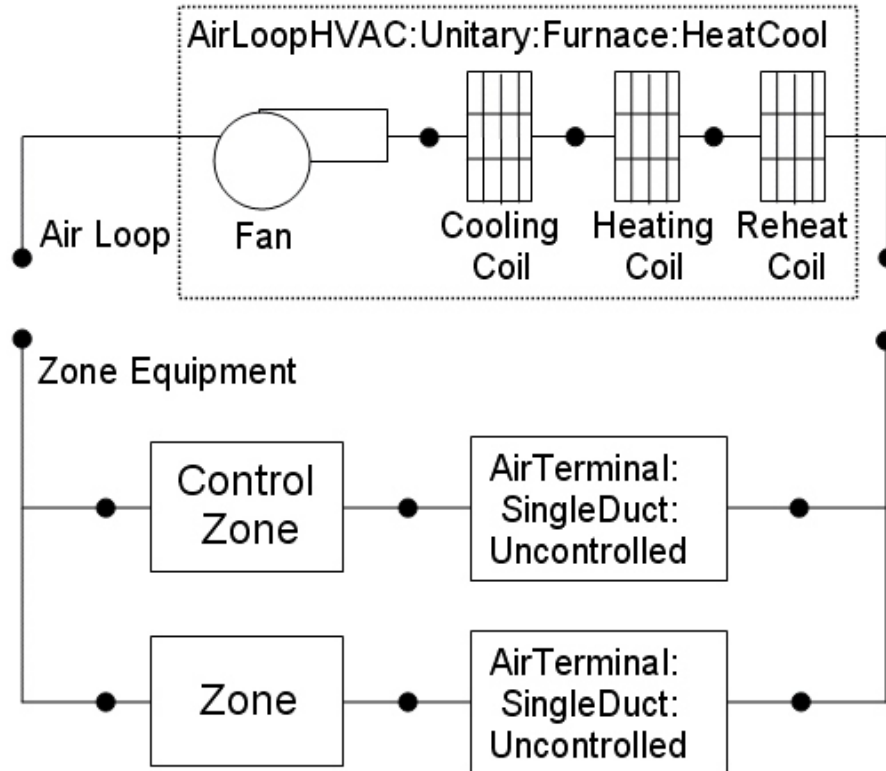

Figure 93. Schematic of Blow Through Unitary System (HeatCool) with High Humidity Control

Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

Multimode - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted.

CoolReheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. If cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is used. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. If the dehumidification control type is specified as **CoolReheat**, then two additional inputs (reheat coil type and name) are also required as shown below.

Field: Reheat Coil Object Type

This alpha field contains the identifying type of reheat coil specified in the furnace. Reheat coil type must be one of:

```
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Desuperheater
```

Field: Reheat Coil Name

This alpha field contains the identifying name given to the unitary system reheat coil.

As shown in the example below, correct specification of the heat/cool unitary system requires specification of the following objects in addition to the unitary system object:

- 1) Fan (Fan:OnOff or Fan:ConstantVolume)
- 2) Heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 3) Cooling coil (Coil:DX:Cooling:SingleSpeed or CoilSystem:Cooling:DX:HeatExchangerAssisted)
- 4) Reheat coil (optional, Coil:Heating:Gas, Coil:Heating:Electric, or Coil:Heating:Desuperheater)
- 5) Direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the unitary system

Note: the unitary system's fan, heating coil, cooling coil and optional reheat coil must be connected in the air loop according to the configuration shown above (Figure 92 or Figure 93). In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the unitary system object.

AirLoopHVAC:UnitaryHeatCool Outputs

```

HVAC,Average, Unitary System Fan Part-Load Ratio
HVAC,Average, Unitary System Compressor Part-Load Ratio

```

Unitary System Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the unitary system to the system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state unitary system heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the unitary system fan may be different from the fan part-load ratio reported here due the part-load performance of the system's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

Unitary System Compressor Part-Load Ratio

This output variable is the ratio of the sensible cooling load to the steady-state cooling capacity of the unitary system's DX cooling coil. The runtime fraction for the DX cooling coil compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

AirLoopHVAC:UnitaryHeatPump:AirToAir

The unitary air-to-air heat pump is a "virtual" component that consists of a fan component (OnOff or ConstantVolume), a DX cooling coil component, a DX heating coil component, and a Gas or Electric supplementary heating coil component as shown in the Figure below.

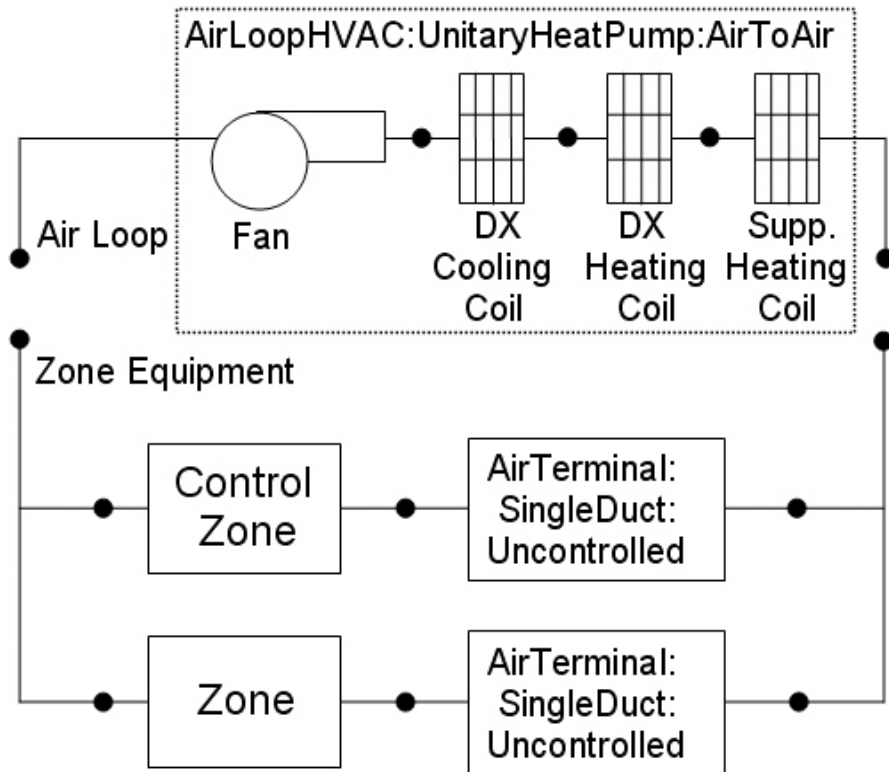

Figure 94. Schematic of EnergyPlus Unitary Air-to-Air Heat Pump (Blow Through Configuration)

Links to the fan, DX cooling coil, DX heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. In addition the control zone name, the fraction of the total system air flow delivered to the control zone and system design operating conditions are specified by the heat pump syntax as shown in the Energy+.idd specification below.

```

Field: Name

This alpha field contains the identifying name for the unitary system heat pump.

Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air.

Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air.

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the heat pump operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the heat pump is located.

Field: Fraction of Supply Air Flow That Goes Through the Controlling Zone

This numeric field contains the fraction (>0 to 1) of the total system volumetric flow rate that is supplied to the zone where the thermostat controlling the heat pump is located.

Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the heat pump. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Air Fan Name

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the heat pump. Heating coil type must be:

Coil:Heating:DX:SingleSpeed

Field: Heating Coil Name

This alpha field contains the identifying name given to the heat pump DX heating coil, and should match the name specified in the corresponding DX heating coil object.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the heat pump. There are two valid choices for this field:

```
Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted
```

Field: Cooling Coil Name

This alpha field contains the identifying name given to the heat pump cooling coil, and should match the name specified in the corresponding DX cooling coil object.

Field: Supplemental Heating Coil Object Type

This alpha field contains the identifying type of supplemental heating coil specified in the heat pump. Heating coil type must be:

```
Coil:Heating:Electric
Coil:Heating:Gas
```

Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the heat pump supplemental heating coil, and should match the name specified in the corresponding heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice represents a blow through system where the supply air fan is before the DX cooling/heating coil and the supplementary heating coil. The second choice represents a draw through system where the supply air fan is between the DX cooling/heating coil and the supplementary heating coil. If this input field is left blank, the default is blow through.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

As shown in the example below, correct specification of the air-to-air heat pump requires specification of the following objects in addition to the heat pump object:

- 6)** Fan (Fan:OnOff or Fan:ConstantVolume)
- 7)** Heating coil (Coil:Heating:DX:SingleSpeed)
- 8)** Cooling coil (Coil:DX:Cooling:SingleSpeed or CoilSystem:Cooling:DX:HeatExchangerAssisted)

- 9) Supplemental heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
 10) Direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the unitary system

Note: the air-to-air heat pump's fan, cooling coil, heating coil and supplementary heating coil must be connected in the air loop according to the configuration shown above (Figure 94) for the blow-through fan configuration. The only other valid configuration is with a draw-through fan placement, where the fan is located between the DX heating coil and the supplementary heating coil. In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the heat pump object.

AirLoopHVAC:UnitaryHeatPump:AirToAir Outputs

```

HVAC, Average, Unitary Heat Pump Fan Part-Load Ratio
HVAC, Average, Unitary Heat Pump Compressor Part-Load Ratio

```

Unitary Heat Pump Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the heat pump to the heat pump's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state heat pump heating (or cooling) capacity. For the cycling fan mode,

the runtime fraction for the heat pump fan may be different from the fan part-load ratio reported here due the part-load performance of the heat pump’s heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

Unitary Heat Pump Compressor Part-Load Ratio

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the heat pump’s DX heating or cooling coil. The runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due the part-load performance of the heating/cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed

The multispeed air-to-air heat pump is a “virtual” component that consists of a fan component (On/Off or ConstVolume), a DX multispeed cooling coil component, a DX multispeed heating coil component, and a Gas or Electric supplemental heating coil component. This system also includes the option to use available waste energy to heat water. A schematic diagram of the air-to-air multispeed heat pump is shown below. The component connection sequence for the blow through option (shown below) from inlet to outlet is fan, cooling coil, heating coil, and supplemental heater. The connection sequence for the draw through option is cooling coil, heating coil, fan, and supplemental heater.

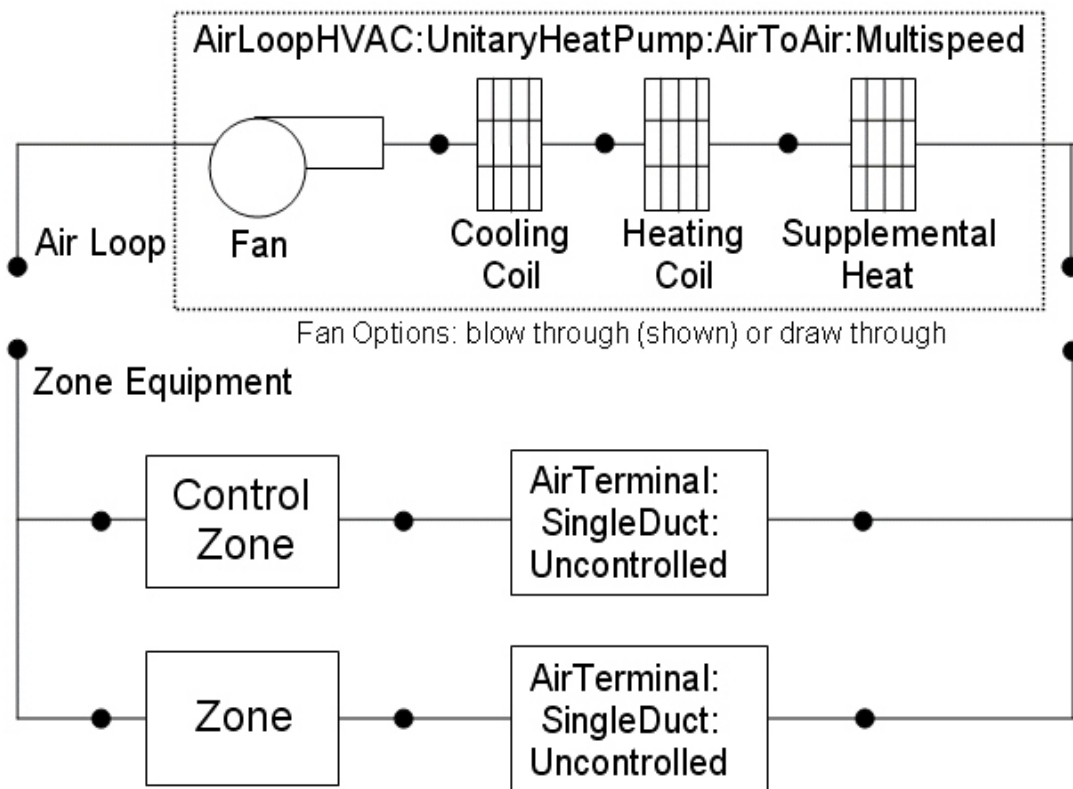

Figure 95. Schematic of EnergyPlus Unitary Air-to-Air Multi Speed Heat Pump

The main difference between this heat pump object and other EnergyPlus heat pump objects is that this object allows from two to four discrete compressor speeds for heating and cooling operation (instead of a single speed for each mode). The lowest speed is called Speed 1, and the highest speed is called Speed n (2, 3 or 4 as specified in the input syntax). This object allows a different number of speeds for cooling and heating, and each speed has an associated airflow rate. The airflow rates for the various heating speeds can be different from

the airflow rates for the cooling speeds. In addition, the airflow rate when no cooling or heating is needed can also be defined. The number of cooling and heating speeds defined by the user in this heat pump object must equal the number of speeds defined in the associated coils (child objects). For example, the number of speeds for cooling defined in this heat pump object must be equal to the number of speeds defined in the associated cooling coil object.

Links to the fan, DX multispeed cooling coil, DX multispeed heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. In addition, the control zone name, airflow rates at the corresponding compressor speeds, and the fraction of total system air flow delivered to the control zone are specified by the heat pump syntax. The object inputs are shown in the Energy+.idd specification below.

Field: Name

This alpha field contains the identifying name for the multispeed heat pump.

Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air.

Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air.

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the multispeed heat pump is located.

Field: Fraction of Supply Air Flow That Goes Through the Controlling Zone

This numeric field contains the fraction (>0 to 1) of the total system volumetric flow rate that is supplied to the zone where the thermostat controlling the multispeed heat pump is located.

Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the heat pump. Fan type must be Fan:OnOff or Fan:ConstantVolume. Fan:ConstantVolume can only be used when the supply air fan operating mode is continuous (see field 'Supply air fan operating mode schedule name').

Field: Supply Air Fan Name

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

Field: Supply Air Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by a DX multispeed cooling coil, DX multispeed heating coil, and a supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the DX cooling and heating coils followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws” air through the DX coils.

Note: the multispeed heat pump's supply air fan, cooling coil, heating coil and supplemental heating coil must be connected according to the configuration shown above (Figure 95) for the ‘blow through’ fan configuration. For the ‘draw through’ fan configuration the fan must be located between the DX heating coil and the supplemental heater, whose outlet node is the system outlet node. In addition, the DX cooling coil and DX heating coil operation mode must be specified consistently with the heat pump's supply air fan operating mode (e.g., with the heat pump's supply air fan set to cycle on and off with the cooling/heating load, the DX cooling and heating coil operation mode must be CyclingFanAndCompressor). If the operation modes in the parent (heat pump) and child (coil) objects are specified differently, the operation mode in the parent object prevails.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information to control the supply air fan. Schedule values of zero mean that the supply air fan will cycle off if there is no cooling or heating load in the control zone. Non-zero schedule values mean that the supply air fan will operate continuously even if there is no cooling or heating load in the control zone. If this field is left blank, the supply air fan will operate continuously for the entire simulation period.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the heat pump. Heating coil type must be Coil:Heating:DX:MultiSpeed.

Field: Heating Coil Name

This alpha field contains the identifying name given to the DX heating coil, and should match the name specified in the corresponding DX heating coil object.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the outdoor air dry-bulb temperature below which the DX heating coil turns off. The temperature for this input field must be greater than or equal to –20 C. If this input field is left blank, the default value is -8 C. This temperature should match the minimum compressor operating temperature specified for the multispeed heat pump's DX heating coil.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the heat pump. Cooling coil type must be Coil:Cooling:DX:MultiSpeed.

Field: Cooling Coil Name

This alpha field contains the identifying name given to the heat pump cooling coil, and should match the name specified in the corresponding DX cooling coil object.

Field: Supplemental Heating Coil Object Type

This alpha field contains the identifying type of supplemental heating coil specified in the heat pump. Heating coil type must be Coil:Gas:Heating or Coil:Electric:Heating.

Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the heat pump supplemental heating coil, and should match the name specified in the corresponding heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum allowed supply air temperature (in degrees C) exiting the heat pump supplemental heating coil. If the calculated supply air temperature exiting the supplemental heater exceeds this value, then it is reset to this maximum temperature. This field is autosizable.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Auxiliary On-Cycle Electric Power

This field defines auxiliary electrical power (W) consumed during the on-cycle period (i.e., when the cooling or heating coil is operating). The model assumes that this auxiliary power does not contribute to heating the supply air. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

Field: Auxiliary Off-Cycle Electric Power

This field defines auxiliary electrical power (W) consumed during the off-cycle period (i.e., when the cooling and heating coil are not operating). The model assumes that this auxiliary power does not contribute to heating the supply air. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

Field: Design Heat Recovery Water Flow Rate

This optional input field defines the design water flow rate used if the heat recovery option is being simulated. If this value is greater than 0.0 then a heat recovery loop must be specified and attached to the multispeed heat pump using the next 2 node fields. To determine how the heat recovery algorithm works, refer to the EnergyPlus Engineering Reference in the AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed with Heat Recovery section. The units for this input value are cubic meters per second.

Field: Maximum Temperature for Heat Recovery

This field sets the maximum temperature (in degrees C) that this heat pump can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperature leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

Field: Heat Recovery Water Inlet Node Name

This alpha field contains the identifying name for the heat recovery side inlet node.

Field: Heat Recovery Water Outlet Node Name

This alpha field contains the identifying name for the heat recovery side outlet node.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling nor heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump supply air fan is scheduled to operate continuously regardless of DX coil operation (ref. field "Supply air fan operating mode schedule). Values must be greater than or equal to zero, or this field is autosizable. If the heat pump supply air fan is scheduled to operate continuously and the input value for this field is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Field: Number of Speeds for Heating

This field defines the number of heating speeds for the heat pump, and must match the number of heating speeds defined in the associated heating coil. The value for this input field defines the number of airflow rates that must be defined for heating in the field below. The minimum value for this field is two and the maximum value is four.

Field: Number of Speeds for Cooling

This field defines the number of cooling speeds for the heat pump, and must match the number of cooling speeds defined in the associated DX cooling coil. The value for this input field defines the number of airflow rates that must be defined for cooling in the field below. The minimum value for this field is two and the maximum value is four.

Field: Speed 1 Supply Air Flow Rate During Heating Operation

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 1 (lowest speed). Values must be greater than 0 or this field is autosizable.

Field: Speed 2 Supply Air Flow Rate During Heating Operation

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 2. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for heating Speed 1.

Field: Speed 3 Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 3. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for heating Speed 2. If the 'Number of Speeds for Heating' is less than 3, then this field can be left blank.

Field: Speed 4 Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 4 (high speed). Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for heating Speed 3. If the 'Number of Speeds for Heating' is less than 4, then this field can be left blank.

Note: When autosizable is selected for any of the supply air volumetric flow rate fields, all supply air flow fields at the different speeds must be specified as autosizable. Otherwise, a fatal error will be issued and the simulation will terminate.

Field: Speed 1 Supply Air Flow Rate During Cooling Operation

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 1 (lowest speed). Values must be greater than 0 or this field is autosizable.

Field: Speed 2 Supply Air Flow Rate During Cooling Operation

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 2. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 1.

Field: Speed 3 Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 3. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 2. If the 'Number of Speeds for Cooling' is less than 3, then this field can be left blank.

Field: Speed 4 Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 4 (highest speed). Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 3. If the 'Number of Speeds for Cooling' is less than 4, then this field can be left blank.

Following is an example input for the object and its associated components.

Unitary MSHP Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the multispeed heat pump to the heat pump's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate) at Speed 1. For continuous fan operation mode, this variable is always 1.0 when the heat pump is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state heat pump heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the heat pump fan may be different from the fan part-load ratio reported here due the part-load performance of the heat pump's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff). When the speed number is greater than 1, the value is 1.0.

Unitary MSHP Compressor Part-Load Ratio

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the multispeed heat pump's DX heating or cooling coil at Speed 1. The runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due the part-load performance of the heating/cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate. When the speed number is greater than 1, the value is 1.0.

Unitary MSHP DX Coil Cycling Ratio

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the multispeed heat pump's DX heating or cooling coil (Speed 1) for the entire system timestep. The value is between 0.0 and 1.0 when the heat pump is cycling on and off its lowest speed (Speed 1) and 1.0 when the multispeed heat pump operates at speeds above 1.

Unitary MSHP DX Coil Speed Ratio

This output variable is the ratio of time in a system timestep that the compressor is at rated speed between two consecutive speed numbers ([Compressor Speed - Compressor speed at Speed i-1] / [Compressor speed at Speed i - Compressor speed at Speed i-1]). The compressor speed ratio reports (1.0 is max, 0.0 is min) and any value in between as it is averaged over the timestep. The value is 0.0 during Speed 1 operation.

The physical meaning of the speed ratio is dependent on the compressor configuration defined in the field of child coil object: Apply Part Load Fraction to Speeds greater than 1. The allowed choice is either Yes or No. When No is entered, one compressor is assumed for all speeds. The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the lower speed runs in the rest of the system timestep. When Yes is entered, multiple compressors are assumed, and each compressor has associated speed.

The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the low speed runs in a whole system timestep.

Unitary MSHP DX Coil Speed Number

This output variable reports the maximum speed needed when the heat pump operates to meet the sensible load (heating or cooling) in a system timestep. When the value is 1, the heat pump operates at Speed 1 (lowest speed). For this case the cycling ratio is between 0.0 and 1.0, while the speed ratio is 0.0. When the speed number output variable is above one, such as *i*, the heat pump operation is determined by the speed ratio through linear interpolation. For example, when the speed ratio is 0.4 and the speed number is 3, the heat pump operates at Speed 3 for 40% of a system timestep and at Speed 2 for 60% of a system timestep for a single compressor. For multiple compressors, the heat pump operates at Speed 3 in the 40% of a system timestep and at Speed 2 in the whole system timestep.

Unitary MSHP Total Heating Energy Rate [W]

This output field is the total (enthalpy) heat addition rate of the multispeed heat pump to the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Unitary MSHP Total Cooling Energy Rate [W]

This output field is the total (enthalpy) heat extraction rate of the multispeed heat pump from the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Unitary MSHP Sensible Heating Energy Rate [W]

This output field reports the sensible heat addition rate of the multispeed heat pump to the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Unitary MSHP Sensible Cooling Energy Rate [W]

This output field reports the moist air sensible heat extraction rate of the multispeed heat pump from the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Unitary MSHP Latent Heating Energy Rate [W]

This output field is the latent heat addition (humidification) rate of the multispeed heat pump in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the multispeed heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Unitary MSHP Latent Cooling Energy Rate [W]

This output field is the latent heat extraction (dehumidification) rate of the multispeed heat pump in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the multispeed heat pump. This value is calculated for

each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Unitary MSHP Electric Power [W]

This output field is the electricity consumption rate of the multispeed heat pump in Watts. The consumption includes electricity used by the DX coils (including crankcase heater if the fuel type is electricity), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), auxiliary power during on and off period, and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported. Any non-electric energy use is not reported by the heat pump object but is reported in the associated coil objects as appropriate.

Unitary MSHP Electric Consumption [J]

This output field is the electricity consumption of the multispeed heat pump in Joules for the timestep being reported. The consumption includes electricity used by the DX compressor (including crankcase heater if the fuel type is electricity), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), auxiliary power during on and off period, and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported. Any non-electric energy use is not reported by the heat pump object but is reported in the associated coil objects as appropriate.

Unitary MSHP Auxiliary Electric Power [W]

This output field is the average auxiliary electricity consumption rate (including both on-cycle and off-cycle) in Watts for the timestep being reported.

Unitary MSHP Auxiliary Electric Cooling Consumption [J]

This is the auxiliary electricity consumption in Joules for the timestep being reported. This is the auxiliary electricity consumption during periods when the heat pump is providing cooling (DX cooling coil is operating). This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Unitary MSHP Auxiliary Electric Heating Consumption [J]

This is the auxiliary electricity consumption in Joules for the timestep being reported. This is the auxiliary electricity consumption during periods when the heat pump is providing heating (DX heating coil is operating). This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter).

Unitary MSHP Waste Heat Recovery Inlet Temp [C]

Unitary MSHP Waste Heat Recovery Outlet Temp [C]

Unitary MSHP Waste Heat Recovery Mass Flow Rate [kg/s]

These outputs are the heat recovery inlet and outlet temperatures and water mass flow rate for multispeed heat pumps with heat recovery.

Unitary MSHP Waste Heat Recovery Rate [W]

Unitary MSHP Waste Heat Recovery Energy [J]

For multispeed heat pumps with heat recovery, these outputs are the recoverable energy rate (in Watts) and energy (in Joules).

AirLoopHVAC:Unitary:Furnace:HeatOnly

The EnergyPlus furnace is a “virtual” component that consists of a fan component (OnOff or ConstantVolume) and a Gas or Electric heating coil component. The blow through furnace configuration is shown in the Figure below.

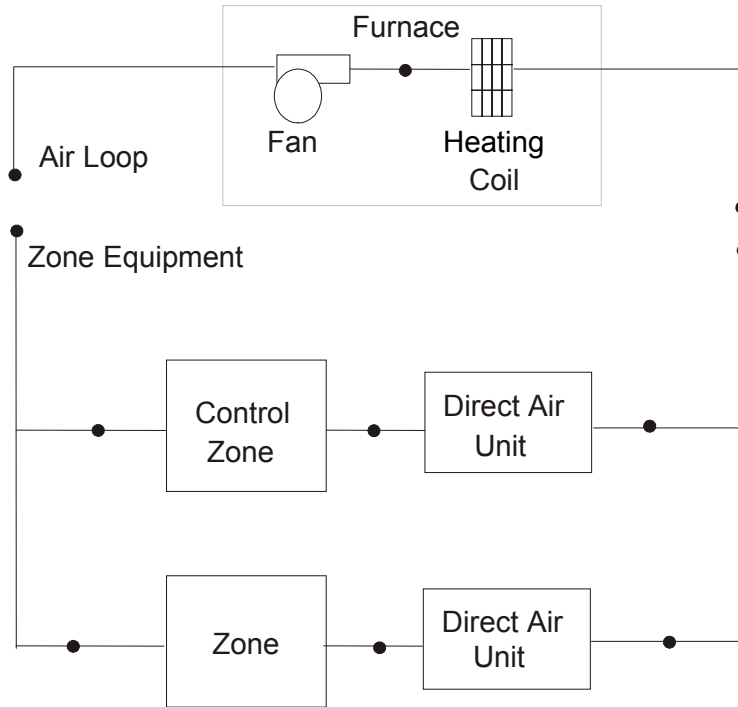

Figure 96. Schematic of Blow Through Furnace Model

Links to the fan and heating coil specifications are provided in the furnace input data syntax. In addition the control zone name, the fraction of the total furnace air flow delivered to the control zone and furnace design operating conditions are specified by the furnace syntax as shown in the Energy+.idd specification below.

```

Field: Name

This alpha field contains the identifying name for the furnace.

Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the furnace to operate.

Field: Furnace Inlet Node Name

This alpha field contains the furnace inlet node name.

Field: Furnace Outlet Node Name

This alpha field contains the furnace outlet node name.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating coil

cycle on and off together to meet the heating load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating coil cycles to meet the load.

Field: Maximum Supply Air Temperature

This numeric field contains the design operating furnace air outlet temperature in degrees C when the furnace is heating. If this input field is left blank, the default value is 80 C.

Field: Supply Air Flow Rate

This numeric field contains the design volumetric flow rate of the furnace in cubic meters per second. This volumetric flow rate should match the flow rate specified for the furnace fan.

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the furnace is located.

Field: Fraction of Supply Air Flow That Goes Through the Controlling Zone

This numeric field contains the fraction (>0 to 1) of the total furnace volumetric flow rate that is supplied to the zone with the furnace thermostat.

Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the furnace. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Fan Name

This alpha field contains the identifying name given to the furnace fan.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the heating coil. The fan “blows through” the heating coil. The second choice stands for “draw through fan”. This means that the unit consists of the heating coil followed by a fan. The fan “draws air through” the heating coil. If this field is left blank, the default is blow through.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the furnace. Heating coil type must be:

Coil:Heating:Electric
Coil:Heating:Gas

Field: Heating Coil Name

This alpha field contains the identifying name given to the furnace heating coil.

As shown in the example below, correct specification of the furnace requires specification of the following objects in addition to the furnace object:

- 1) fan (Fan:OnOff or Fan:ConstantVolume)
- 2) heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 3) direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the furnace

Note: the furnace's fan and heating coil must be connected in the air loop according to the configuration shown above (Figure 96) when a blow through fan configuration is specified. If a draw through fan is used, the fan is located down stream of the heating coil. In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the furnace object.

Example of Heat-Only Furnace Specification

AirLoopHVAC:Unitary:Furnace:HeatOnly Outputs

HVAC,Average,Furnace Fan Part-Load Ratio

Furnace Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the furnace to the furnace's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating load to the furnace heating capacity. For the cycling fan mode, the runtime fraction for the furnace fan may be different from the fan part-load ratio reported here due the part-load performance of the furnace's heating coil (delay at start-up to reach steady-state heating output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

AirLoopHVAC:UnitaryHeatOnly

The `AirLoopHVAC:UnitaryHeatOnly` is identical to the `AirLoopHVAC:Unitary:Furnace:HeatOnly` model. The heat-only unitary system is a "virtual" component that consists of a fan component (OnOff or ConstantVolume) and a Gas or Electric heating coil component. The blow through unitary system configuraion is shown in the Figure below.

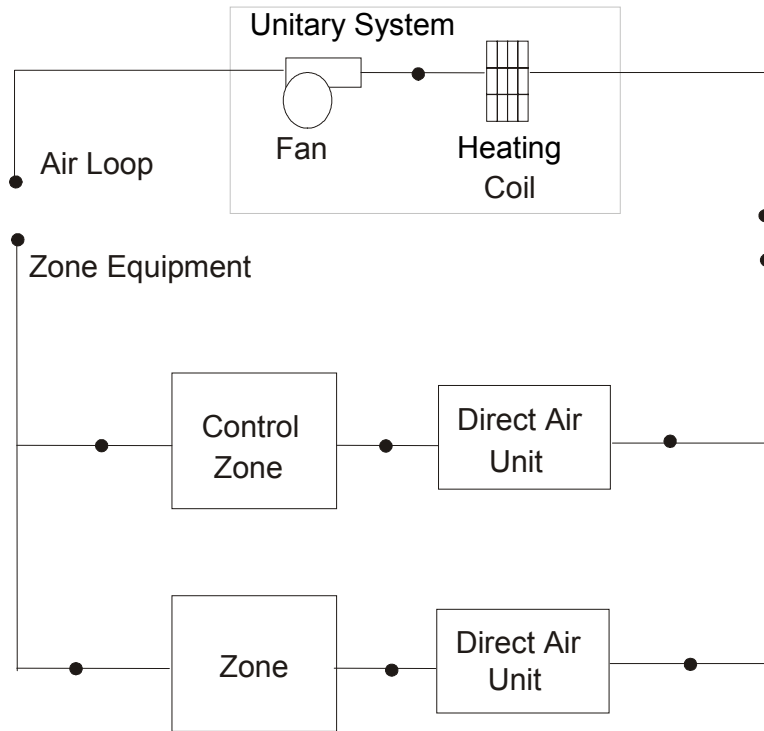

Figure 97. Schematic of Blow Through Heat-Only Unitary System

Links to the fan and heating coil specifications are provided in the unitary system input data syntax. In addition the control zone name, the fraction of the total unitary system air flow delivered to the control zone and unitary system design operating conditions are specified by the unitary system syntax as shown in the Energy+.idd specification below.

Field: Name

This alpha field contains the identifying name for the unitary system.

Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the unitary system to operate.

Field: Unitary System Air Inlet Node Name

This alpha field contains the unitary system inlet node name.

Field: Unitary System Air Outlet Node Name

This alpha field contains the unitary system outlet node name.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating coil

cycle on and off together to meet the heating load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating coil cycles to meet the load.

Field: Maximum Supply Air Temperature

This numeric field contains the design air outlet temperature in degrees C when the unitary system is heating. If this input field is left blank, the default value is 80 C.

Field: Supply Air Flow Rate

This numeric field contains the design volumetric flow rate of the unitary system in cubic meters per second. This volumetric flow rate should match the flow rate specified for the unitary system fan.

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the unitary system is located.

Field: Fraction of Supply Air Flow That Goes Through the Controlling Zone

This numeric field contains the fraction (>0 to 1) of the total system volumetric flow rate that is supplied to the zone with the unitary system thermostat.

Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the unitary system. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Fan Name

This alpha field contains the identifying name given to the unitary system fan.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the heating coil. The fan “blows through” the heating coil. The second choice stands for “draw through fan”. This means that the unit consists of the heating coil followed by a fan. The fan “draws air through” the heating coil. If this field is left blank, the default is blow through.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the unitary system. Heating coil type must be

Coil:Heating:Electric
Coil:Heating:Gas

Field: Heating Coil Name

This alpha field contains the identifying name given to the unitary system heating coil.

As shown in the example below, correct specification of the heat-only unitary system requires specification of the following objects in addition to the unitary system object:

- 4) fan (Fan:OnOff or Fan:ConstantVolume)
- 5) heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 6) direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the furnace

Note: the unitary system's fan and heating coil must be connected in the air loop according to the configuration shown above (Figure 97) when a blow through fan configuration is specified. If a draw through fan is used, the fan is located down stream of the heating coil. In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the unitary system object.

Example of Heat-Only Unitary System Specification

AirLoopHVAC:UnitaryHeatOnly Outputs

```
HVAC,Average,Unitary System Fan Part-Load Ratio
```

Unitary System Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the unitary system to the unitary system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating load to the unitary system heating capacity. For the cycling fan mode, the runtime fraction for the unitary system fan may be different from the fan part-load ratio reported here due the part-load performance of the unitary system's heating coil (delay at start-up to reach steady-state heating output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

AirLoopHVAC:UnitaryHeatPump:WaterToAir

The unitary water-to-air heat pump is relatively similar to the unitary air-to-air except water is used on the source side. Links to the fan, WaterToAirHP cooling coil, WaterToAirHP heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. The heat pump would switch back and forth between cooling and heating depending on the zone's demand. The load side(air) of the unitary water-to-air heat pump consists of an On/Off fan component, a WaterToAirHP cooling coil component, a WaterToAirHP heating coil component, and a Gas or Electric supplementary heating coil component. However, the source side (water) of the heat pump is usually connected to a ground heat exchanger through the condenser loop. The diagram below shows the setup and connection of the heat pump for the source side and load side.

There are two type of WaterToAirHP coil models available in EnergyPlus:

```

Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
Coil:Heating:WaterToAirHeatPump:ParameterEstimation
Coil:Cooling:WaterToAirHeatPump:EquationFit
Coil:Heating:WaterToAirHeatPump:EquationFit

```

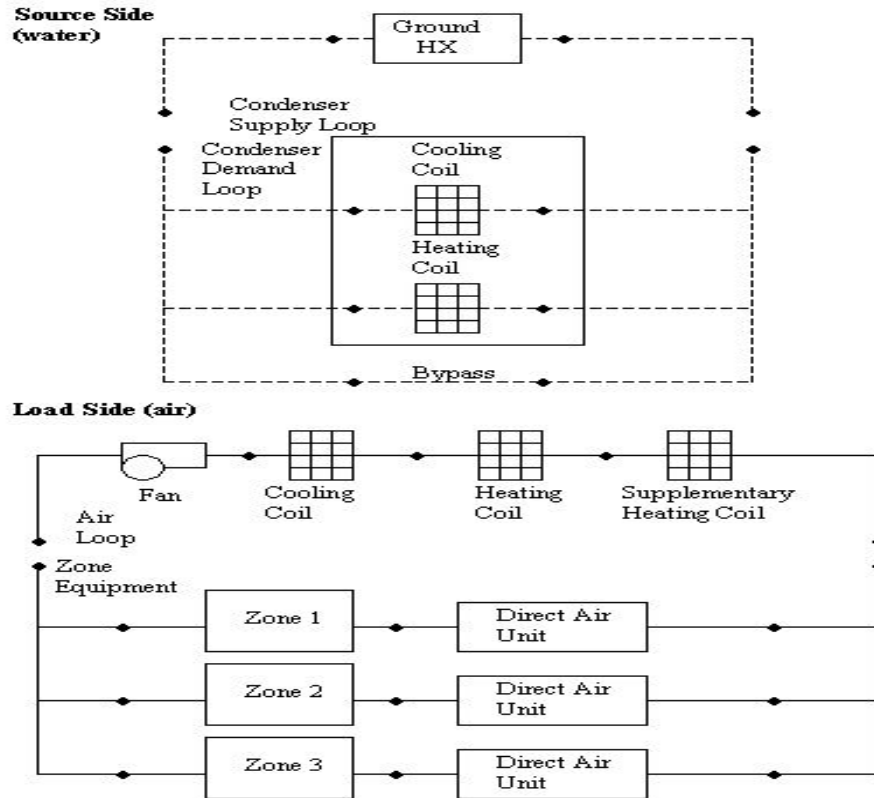

Figure 98. Layout of Water to Air Heat pump

In addition, the control zone name, the fraction of the total system air flow delivered to the control zone and system design operating conditions are specified by the heat pump syntax in the Energy+.idd specification below:

    \note The fan operating mode defaults to cycling fan operation if this field is left blank.

```

Field: Name

This alpha field contains the identifying name for the unitary system heat pump.

Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air

Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air

Field: Supply Air Flow Rate

This numeric field contains the design volumetric flow rate through the heat pump in cubic meters per second. This volumetric flow rate should match the flow rate specified for the heat pump's supply air fan, WaterToAirHP cooling coil, WaterToAirHP heating coil and supplemental heating coil.

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the heat pump is located

Field: Fraction of Supply Air Flow That Goes Through the Controlling Zone

This numeric field contains the fraction (>0 to 1) of the total system volumetric flow rate that is supplied to the zone where the thermostat controlling the heat pump is located

Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified in the heat pump. Fan type must be Fan:OnOff.

Field: Supply Air Fan Name

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the heat pump. Heating coil types are:

```
Coil:Heating:WaterToAirHeatPump:ParameterEstimation
Coil:Heating:WaterToAirHeatPump:EquationFit
```

Field: Heating Coil Name

This alpha field contains the identifying name given to the WaterToAirHP heating coil, and should match the name specified in the corresponding WaterToAirHP heating coil object.

Field: Heating Convergence

This numeric value allows the user to determine how close the air side has to be controlled. Lower the value of convergence better the control of air side conditions and less the zone temperature fluctuations. However in a poorly designed system, a lower convergence might result in warning errors which are caused due to the iteration limit for run time fraction calculation is limited to 20.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the heat pump. Cooling coil types are:

```
Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
Coil:Cooling:WaterToAirHeatPump:EquationFit
```

Field: Cooling Coil Name

This alpha field contains the identifying name given to the WaterToAirHP cooling coil, and should match the name specified in the corresponding WaterToAirHP cooling coil object.

Field: Cooling Convergence

This numeric value allows the user to determine how close the air side has to be controlled. Lower the value of convergence better the control of air side conditions and less the zone temperature fluctuations. However in a poorly designed system, a lower convergence might result in warning errors which are caused due to the iteration limit for run time fraction calculation is limited to 20.

Field: Maximum Cycling Rate

This numeric field contains the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values are shown below (Henderson et. al 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Field: Heat Pump Time Constant

This numeric field contains the time constant for the cooling coil's capacity to reach steady state after startup. Suggested values are shown below (Henderson et. al 1999):

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Field: Fraction of On-Cycle Power Use

This numeric field contains the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans, and etc. Suggested value values are below (Henderson et. al 1999):

Heat Pump Condition	Recommended Values
Typical	0.01
Good	0.01
Poor	0.03

Field: Heat Pump Fan Delay Time

This numeric field contains the time delay for heat pump fan to shut off after compressor cycle off. This field can be obtained from the manufacturer or the heat pump catalog. Enter a value of zero for heat pump operating mode "ContinuousFanWithCyclingCompressor" because field is not required. Suggested value is 60s.

Field: Supplemental Heating Coil Object Type

This is the object type of the supplemental heating coil. The only valid choices are:

Coil:Heating:Electric
Coil:Heating:Gas

Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the supplemental heating coil, and should match the name specified in the corresponding supplemental heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Outdoor Dry-Bulb Temperature Sensor Node Name

This alpha field specifies the name of the outdoor node which controls the operation of the supplemental heating coil. If this field is left blank, the outdoor temperature is based solely on the weather data. If this field is not blank, the node name specified must also be listed in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be

specified in an OutdoorAir:NodeList object where the outdoor temperature is taken directly from the weather data.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice represents a blow through system where the supply air fan is before the WatertoAirHP cooling/heating coil and the supplementary heating coil. The second choice represents a draw through system where the supply fan is between the WatertoAirHP cooling/heating coil and the supplementary heating coil. If this input field is left blank, the default is blow through.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation.

As shown in the example below, correct specifications of the water-air heat pump requires specification of the following objects in addition to the heat pump object:

- On/Off fan
- WatertoAirHP cooling coil
- WatertoAirHP heating coil
- Supplementary heating coil
- Direct air unit for each zone served by the heat pump
- Condenser demand branches

It should be noted that the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the heat pump object.

AirLoopHVAC:UnitaryHeatPump:WaterToAir Outputs

Energy use reporting for the water-to-air heat pump is documented under the heat pump coil object types:

```

Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
Coil:Heating:WaterToAirHeatPump:ParameterEstimation
Coil:Cooling:WaterToAirHeatPump:EquationFit
Coil:Heating:WaterToAirHeatPump:EquationFit

```

The heat pump *demand* as well as the compressor and fan part-load ratios may be obtained with the report variables shown below.

```

HVAC,Average, Unitary Heat Pump Sensible Cooling Demand[W]
HVAC,Average, Unitary Heat Pump Latent Cooling Demand[W]
HVAC,Average, Unitary Heat Pump Heating Demand[W]
HVAC,Average, Unitary Heat Pump Compressor Part-Load Ratio

```

HVAC, Average, Unitary Heat Pump Fan Part-Load Ratio
--

Unitary Heat Pump Sensible Cooling Demand

This output variable is the sensible cooling requested from the zone thermostat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the specific heat of the zone air, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Unitary Heat Pump Latent Cooling Demand

This output variable is the latent cooling requested from the zone humidistat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the heat of vaporization of water at the current zone conditions, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Unitary Heat Pump Heating Demand

This output variable is the sensible heating requested from the zone thermostat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the specific heat of the zone air, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Unitary Heat Pump Compressor Part-Load Ratio

This output variable is the ratio of actual load on the unitary system to the unitary system's steady state output. This ratio is based on the nominal capacity of the unit.

Unitary Heat Pump Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the unitary system to the unitary system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule).

AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass

The changeover-bypass variable air volume (CBVAV) unitary system is a compound object made up of other components. Each CBVAV system consists of an outdoor air mixer, direct expansion (DX) cooling coil, heating coil, and a supply air fan as shown in the figures below. Zone thermostats and terminal units are required in each zone served by this system. The terminal units are specific to this system type and are either `AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat` or `AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat`. A zone humidistat and single zone max humidity set point manager may also be specified to help control high humidity levels. These individual components are described elsewhere in this document. The CBVAV unitary system object coordinates the operation of these components and is modeled as a type of air loop equipment (Ref. `AirLoopHVAC`).

Figure 99. Schematic of a CBVAV unitary system (draw through fan placement)

Figure 100. Schematic of a CBVAV unitary system (blow through fan placement)

Links to the CBVAV system’s supply air fan, coils, and outdoor air mixer specifications are provided in the object’s input syntax. Additional inputs include system and outdoor air flow rates during heating and cooling operation, the priority control mode, and dehumidification

control type. A description of each input field for the CBVAV unitary system compound object is provided below.

Field: Name

This alpha field defines a unique user-assigned name for an instance of a changeover-bypass VAV system. Any reference to this system by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the system operates during a given time period. A schedule value equal to 0 denotes that the system must be off for that time period, and a schedule value greater than 0 denotes that the system is available to operate during that time period. This schedule may be used to completely disable the system (all of its coils and the supply air fan) as required.

Field: System Air Flow Rate During Cooling Operation

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0, or this field is autosizable.

Field: System Air Flow Rate During Heating Operation

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when the heating coil is operating. Values must be greater than 0, or this field is autosizable.

Field: System Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when neither cooling nor heating is required (i.e., the DX cooling coil and heating coil are off but the supply air fan operates). Values must be greater than or equal to zero, or this field is autosizable. This field is only used when the unitary system's supply air fan operating mode is specified as continuous fan operation (Ref. Field: Supply air fan operating mode schedule name). If the system's supply air fan operating mode is specified as continuous fan operation and this value is set to zero or the field is left blank, then the model assumes that the system air flow rate when no heating/cooling is needed is equal to the system air flow rate when the coils were last operating (for cooling operation or heating operation).

Field: Outdoor Air Flow Rate During Cooling Operation

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside_Air_Stream_Node) in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during cooling operating can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate multiplier schedule name). For any simulation timestep, the outdoor air flow rate during cooling operation cannot exceed the system air volumetric flow rate during cooling operation.

Field: Outdoor Air Flow Rate During Heating Operation

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside_Air_Stream_Node) in cubic meters per second when the heating coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during heating operating can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate multiplier schedule name). For any simulation timestep, the outdoor air flow rate during heating operation cannot exceed the system air volumetric flow rate during heating operation.

Field: Outdoor Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside_Air_Stream_Node) in cubic meters per second when neither cooling nor heating is required (i.e., the DX cooling coil and heating coil are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate when no cooling/heating is needed can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate multiplier schedule name). For any simulation timestep, the outdoor air flow rate when no cooling/heating is needed cannot exceed the system air volumetric flow rate when no cooling/heating is needed. This field is only used when the unitary system's supply air fan operating mode is specified as continuous fan operation (Ref. Field: Supply air fan operating mode schedule name). If the system's supply air fan operating mode is specified as continuous fan operation and this value is set to zero or the field is left blank, then the model assumes that the outdoor air flow rate when no cooling/heating is needed is equal to the outdoor air flow rate when the coils were last operating (for cooling operation [i.e. Outdoor air volumetric flow rate during cooling operation] or heating operation [i.e. Outdoor air volumetric flow rate during heating operation]) and this field is not used.

Field: Outdoor Air Flow Rate Multiplier Schedule Name

This alpha field defines the name of a schedule (ref: Schedule) that contains multipliers for the outdoor air volume flow rates (heating, cooling, no heating/cooling). Schedule values must be from zero to 1. If this field is left blank, then the model assumes that the outdoor air multiplier is 1 for the entire simulation period.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the system draws its inlet air.

Field: Bypass Duct Mixer Node Name

This alpha field defines the name of the HVAC system node where the bypass air mixes with the unitary system's inlet air. This name should match the name of the Return Air Stream Node Name for the OutdoorAir:Mixer associated with this system. This node name must be different from the system's air inlet node name.

Field: Bypass Duct Splitter Node Name

This alpha field defines the name of the HVAC system node where the conditioned air is split into bypass air and supply air leaving the system (e.g., delivered to the terminal units). This splitter air node name should match the outlet node name for the last component (furthest downstream) in this unitary system. For blow through fan placement, the splitter air node is the outlet node of the heating coil. For draw through fan placement, the splitter node is the outlet node of the supply air fan.

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the system sends its outlet air.

Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component that composes part of the CBVAV system. The name of the outdoor air mixer's Return_Air_Stream_Node should match the bypass duct mixer node name, and be different from the CBVAV system's air inlet node name. The Mixed Air Node Name of the outdoor air mixer should be the same as the CBVAV system's supply fan inlet air node (for blow through fan placement) or the system's DX cooling coil inlet node (for draw through fan placement).

Field: Supply Air Fan Object Type

This alpha field defines the type of fan used by this unitary system. The only valid choices are **Fan:OnOff** and **Fan:ConstantVolume**. The input requirements for these fan objects are described elsewhere in this document.

Field: Supply Air Fan Name

This alpha field defines the name of the fan component that composes part of this unitary system. Note that the fan component's maximum flow rate should be greater than or equal to the largest system air volumetric flow rate specified for this unitary system (heating, cooling, and no heating/cooling). In addition, the fan's inlet air node should be the same as the outdoor air mixer's Mixed Air Node (for blow through fan placement) or the heating coil's outlet node (for draw through fan placement). The fan outlet air node should be the same as the DX cooling coil's air inlet node (for blow through fan placement) or the system's bypass duct splitter node (for draw through fan placement).

Field: Supply Air Fan Placement

This alpha field defines the placement of the supply air fan within this unitary system. The only valid choices are **BlowThrough** and **DrawThrough**. With blow through placement, the supply air fan is located immediately upstream of the system's cooling coil. With draw through placement, the supply air fan is located immediately downstream of the heating coil.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field defines the name of a schedule that specifies the supply air fan operating mode during the simulation. A schedule value of 0 denotes the fan cycles off when no cooling or heating is required, and any other value denotes that the fan runs continuously regardless of the need for heating or cooling. If this field is left blank, the model assumes continuous supply air fan operation for the entire simulation period.

Field: Cooling Coil Object Type

This alpha field defines the type of cooling coil used by this unitary system. There are three valid choices for this field:

```
Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted
Coil:Cooling:DX:TwoStageWithHumidityControlMode
```

The input requirements for these cooling coil objects are described elsewhere in this document.

Field: Cooling Coil Name

This alpha field defines the name of the cooling coil used by this unitary system, and this name should match the name specified in the corresponding cooling coil object.

Field: Heating Coil Object Type

This alpha field defines the type of heating coil used by this unitary system. The only valid choices are:

```
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:DX:SingleSpeed
```

The input requirements for these heating coil objects are described elsewhere in this document.

Field: Heating Coil Name

This alpha field defines the name of the heating coil used by this unitary system, and this name should match the name specified in the corresponding heating coil object.

Field: Priority Control Mode

This choice field defines the cooling or heating priority control mode for the unitary system. Valid choices are:

CoolingPriority HeatingPriority ZonePriority
--

If CoolingPriority is selected, the system operates to meet the cooling load if any zone served by this system (air loop) requires cooling. If no zones require cooling, then the system operates in heating mode if needed. If HeatingPriority is selected, the system operates to meet the heating load if any zone requires heating. If no zones require heating, then the system operates in cooling mode if needed. If ZonePriority is selected, the system operates based on the maximum number of zones requiring either heating or cooling. If the number of zones requiring cooling is greater than the number of zones requiring heating, then the system operates in cooling mode. If the number of zones requiring heating is greater than the number of zones requiring cooling, then the system operates in heating mode. If the number of zones requiring cooling equals the number of zones requiring heating, then the largest combined load (i.e., the sum of the cooling loads for zones requiring cooling compared to the sum of the heating loads for zones that require heating) sets the cooling or heating operating mode for the system during that simulation timestep.

Field: Minimum Outlet Air Temperature During Cooling Operation

This numeric field defines the minimum outlet air temperature leaving the system when the unit is operating to provide cooling. Values are specified in degrees Celsius and must be greater than 0. The default value is 8°C. This value must be less than or equal to the maximum outlet air temperature during heating operation.

Field: Maximum Outlet Air Temperature During Heating Operation

This numeric field defines the maximum outlet air temperature leaving the system when the unit is operating to provide heating. Values are specified in degrees Celsius and must be greater than 0. The default value is 50°C. This value must be greater than or equal to the minimum outlet air temperature during cooling operation.

Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

Multimode - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = Coil:Cooling:DX:TwoStageWithHumidityControlMode.

CoolReheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. It is valid only with cooling coil type = Coil:Cooling:DX:TwoStageWithHumidityControlMode.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint on the CBVAV system's air outlet node is used. This must be set using a **ZoneControl:Humidistat** and **SetpointManager:SingleZone:Humidity:Maximum** objects. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate.

The CBVAV unitary system IDD object is shown below:

```

      \note HeatingPriority = system provides heating if any zone requires heating.
      \note ZonePriority = system controlled based on the total number of zones
      \note requiring cooling or heating (highest number of zones
      \note in cooling or heating determines the system's operating mode).
N7 , \field Minimum Outlet Air Temperature During Cooling Operation
      \type real
      \units C
      \minimum> 0.0
      \default 8.0
      \note Specify the minimum outlet air temperature allowed for this unitary system
      \note during cooling operation. This value should be less than the maximum outlet
      \note air temperature during heating operation.
N8 , \field Maximum Outlet Air Temperature During Heating Operation
      \type real
      \units C
      \minimum> 0.0
      \default 50.0
      \note Specify the maximum outlet air temperature allowed for this unitary system
      \note during heating operation. This value should be greater than the minimum outlet
      \note air temperature during cooling operation.
A18; \field Dehumidification Control Type
      \type choice
      \key None
      \key Multimode
      \key CoolReheat
      \default None
      \note None = meet sensible load only.
      \note Multimode = activate enhanced dehumidification mode
      \note as needed and meet sensible load. Valid only with
      \note Coil:Cooling:DX:TwoStageWithHumidityControlMode.
      \note CoolReheat = cool beyond the Dry-Bulb temperature setpoint
      \note as required to meet the humidity setpoint. Valid only with
      \note Coil:Cooling:DX:TwoStageWithHumidityControlMode.
      \note For all dehumidification controls, the max humidity setpoint
      \note on this unitary system's air outlet node is used.
      \note This must be set using ZoneControl:Humidistat and
      \note SetpointManager:SingleZone:Humidity:Maximum objects.

```

As shown in the example below, correct specification of the CBVAV unitary system requires specification of the following objects in addition to the UnitarySystem:VAV: ChangeoverBypass object:

- 1) outdoor air mixer (OutdoorAir:Mixer)
- 2) fan (Fan:OnOff or Fan:ConstantVolume)

- 3) cooling coil (Coil:DX:Cooling:SingleSpeed, CoilSystem:Cooling:DX:HeatExchangerAssisted, or Coil:Cooling:DX:TwoStageWithHumidityControlMode)
- 4) heating coil (Coil:Heating:Gas, Coil:Heating:Electric, or Coil:Heating:DX:SingleSpeed)
- 5) terminal unit for each zone being served by this system (AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat or AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat)

Note: The fan, heating coil, cooling coil, and outdoor air mixer must be connected in the air loop according to the configurations shown above (Figure 99 and Figure 100).

Changeover-bypass VAV Total Heating Rate[W]

This output field is the total (enthalpy) heat addition rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Changeover-bypass VAV Total Heating Energy[J]

This output field is the total (enthalpy) heat addition of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

Changeover-bypass VAV Total Cooling Rate[W]

This output field is the total (enthalpy) heat extraction rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Changeover-bypass VAV Total Cooling Energy[J]

This output field is the total (enthalpy) heat extraction of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

Changeover-bypass VAV Sensible Heating Rate[W]

This output field is the sensible heat addition rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Changeover-bypass VAV Sensible Heating Energy[J]

This output field is the sensible heat addition of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

Changeover-bypass VAV Sensible Cooling Rate[W]

This output field reports the moist air sensible heat extraction rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Changeover-bypass VAV Sensible Cooling Energy[J]

This output field reports the moist air sensible heat extraction of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

Changeover-bypass VAV Latent Heating Rate[W]

This output field is the latent heat addition (humidification) rate of the CBVAV system in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Changeover-bypass VAV Latent Heating Energy[J]

This output field is the latent heat addition (humidification) of the CBVAV system in Joules over the timestep being reported. This value is calculated as the difference between the total energy and the sensible energy delivered by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

Changeover-bypass VAV Latent Cooling Rate[W]

This output field is the latent heat extraction (dehumidification) rate of the CBVAV system in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Changeover-bypass VAV Latent Cooling Energy[J]

This output field is the latent heat extraction (dehumidification) of the CBVAV system in Joules over the timestep being reported. This value is calculated as the difference between the total energy and the sensible energy delivered by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

Changeover-bypass VAV Electric Power[W]

This output field is the electricity consumption rate of the CBVAV system in Watts. The consumption includes electricity used by the DX compressor (including crankcase heater), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), and the heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Changeover-bypass VAV Electric Consumption[J]

This output field is the electricity consumption of the CBVAV system in Joules for the time period being reported. The consumption includes electricity used by the DX compressor (including crankcase heater), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), and the heating coil (if electric). This value is calculated for each HVAC

system timestep being simulated, and the results are summed for the timestep being reported.

Changeover-bypass VAV Fan Part-Load Ratio

This output field is the part-load ratio of the supply air fan, which will be either zero or 1 for each simulation timestep. For this system, the fan will operate continuously for the simulation timestep if the system is available (ref. Field: Availability schedule name) and there is a cooling or heating load to be met (i.e., fan part-load ratio will equal 1). When the system is available but there is no cooling or heating load to be met, the fan will either be off for the entire timestep or on for the entire timestep depending on the supply air fan operating mode schedule (ref. Field: Supply air fan operating mode schedule name). This value is set for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Changeover-bypass VAV Compressor Part-Load Ratio

This output field is the part-load ratio of the compressor used by the DX coils (cooling and heating). The compressor part-load ratio is defined as the total coil load divided by the coil steady-state capacity (steady-state capacity of first stage for multi-mode coils). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Changeover-bypass VAV Bypass Mass Flow Rate[kg/s]

This output field is the mass flow rate of air, in kg/s, being bypassed from the supply air path and blended with the air entering the CBVAV system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Changeover-bypass VAV Outlet Air Set Point Temp[C]

This output field is the dry-bulb set point temperature in degrees Celsius. This set point temperature is calculated by the model based on the zone cooling/heating loads calculated by EnergyPlus, and the priority control mode and the dehumidification control type specified for this unitary system. The CBVAV system attempts to achieve the outlet air set point temperature to the extent possible.

AirLoopHVAC:UnitaryCoolOnly

The AirLoopHVAC:UnitaryCoolOnly DX System is a “virtual” component that consists of a DX cooling coil component as shown in the Figure below. The DX cooling coil specifications are provided in the input data syntax. This coil can be specified anywhere in the air loop simulation but will control the best with a blow through fan since the fan heat will be handled the most accurate.

This system does not need any plant specification and will provide the electric consumption necessary to operate the compressor and the condenser fan. The supply fan is simulated separately. This coil can be used with any system that a coil roughly meets a deck temperature and can be designed for use with all the terminal reheat, variable volume either single or multi duct systems. Any system where the deck temperature is met in the air loop and the trim control for the zone is met downstream.

For single-zone systems, using appropriate set point managers, this system can also be used to model packaged equipment as blow-thru or draw-thru, with or without humidity controls.

```

Field: Name

This alpha field contains the identifying name for the DX System.

Field: Availability Schedule Name

This alpha field contains the schedule name that contains information on the availability of the DX System to operate.

Field: DX Cooling Coil System Inlet Node Name

This alpha field contains the identifying name given to the DX cooling coil inlet node, as specified in the DX cooling coil object.

Field: DX Cooling Coil System Outlet Node Name

This alpha field contains the identifying name given to the DX cooling coil outlet node, as specified in the cooling coil object.

Field: DX Cooling Coil System Sensor Node Name

This alpha field contains the identifying name given to the DX cooling coil control node, this is the node at which the temperature set point is specified by the set point manager.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the DX system. The valid choices for this field are:

```

Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted

```

```
Coil:Cooling:DX:TwoSpeed
Coil:Cooling:DX:TwoStageWithHumidityControlMode
```

Field: Cooling Coil Name

This alpha field contains the identifying name given to the DX cooling coil.

As shown in the example below, correct specification of this system requires specification of the DX Cooling Coil object in addition to the AirLoopHVAC:UnitaryCoolOnly object.

In addition, the DX cooling coil operation mode must be specified consistently with the DX system operating mode (e.g., the DX cooling coil operation mode must be ContinuousFanWithCyclingCompressor).

Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

MultiMode - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a switchable option such as subcool reheat. It is valid only with Cooling coil type= Coil:Cooling:DX:TwoStageWithHumidityControlMode or CoilSystem:Cooling:DX:HeatExchangerAssisted.

CoolReheat - cool beyond the dry-bulb setpoint as required to meet the humidity setpoint. It is valid only with Cooling coil type=Coil:Cooling:DX:TwoStageWithHumidityControlMode.

The default is **None**. For all dehumidification controls, the max humidity setpoint on the control node is used. This must be set using a **ZoneControl:Humidistat** along with **SetpointManager:SingleZone:Humidity:Maximum** and **SetpointManager:OutdoorAirPretreat** (optional) objects. When extra dehumidification is required, the equipment may not be able to meet the humidity setpoint if its full capacity is not adequate.

Field: Run on Sensible Load

This alpha field specifies if the unit will operate to meet a sensible load as determined by the inlet node dry-bulb temperature and the dry-bulb temperature setpoint on the control node. There are two valid choices, **Yes** or **No**. If **Yes**, unit will run if there is a sensible load. If **No**, unit will not run if there is only a sensible load. The default is **Yes**.

Field: Run on Latent Load

This alpha field specifies if the unit will operate to meet a latent load as determined by the inlet node humidity ratio and the max humidity setpoint on the control node. There are two valid choices, **Yes** or **Yes**. If **Yes**, unit will run if there is a latent load. If **No**, unit will not run if there is only a latent load. The default is **No**.

Example of DX System Specification

AirLoopHVAC:UnitaryCoolOnly Outputs

```

Coil Type= Coil:Cooling:DX:TwoStageWithHumidityControlMode
HVAC,Average,DXSystem Cycling Part-Load Ratio
HVAC,Average,DXSystem Compressor Speed Ratio
Coil types=Coil:DX:Cooling:SingleSpeed &
CoilSystem:Cooling:DX:HeatExchangerAssisted
HVAC,Average,DXSystem Part-Load Ratio

```

DXSystem Cycling Part-Load Ratio

The system may operate for the entire system timestep, but to meet the load the compressor can cycle on and off. This reports the fraction of the system timestep that the compressor is operating. (1.0 is continuous, 0.0 is off).

DXSystem Compressor Speed Ratio

This is the ratio of time in a system timestep that the compressor is at rated speed. The compressor speed ratio reports (1.0 is max, 0.0 is min) and any value in between as it is averaged over the timestep.

DXSystem Part-Load Ratio

The DX system can operate with a cycling compressor or a varying speed compressor, This variable reports the fraction of the Full Load that is met during the system timestep. This can differ from the cycling part load ratio or the compressor speed ratio. (1.0 is Full Load and 0.0 is no load)

Group – Radiative / Convective Units

This section describes the radiative/convective zone equipment units. The following units are included in this section:

- ZoneHVAC:Baseboard:Convective:Electric
- ZoneHVAC:Baseboard:RadiantConvective:Water

- ZoneHVAC:Baseboard:Convective:Water
- ZoneHVAC:HighTemperatureRadiant
- ZoneHVAC:LowTemperatureRadiant:ConstantFlow
- ZoneHVAC:LowTemperatureRadiant:Electric
- ZoneHVAC:LowTemperatureRadiant:VariableFlow

ZoneHVAC:Baseboard:RadiantConvective:Water

The objective of this model is to calculate the convective and radiant heat transfer from baseboard heaters to the people and the surfaces within a zone so that surface heat balances can take into account the radiant heat transfer to the surfaces and thus enhance the accuracy of thermal comfort predictions within the space. The radiant heat gains are distributed to the surfaces by fractions defined by user input. The input data dictionary definition of the unit is as follows.

Field: Name

A unique user assigned name for an instance of a hot water baseboard heater unit. Any reference to this unit by another object will use this name.

Field: Available Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the hot water baseboard heater unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Inlet Node Name

This field is the name of the hot water inlet node for the baseboard heater.

Field: Outlet Node Name

This field is the name of the hot water outlet node for the baseboard heater.

Field: Average Water Temperature

This field is the average water temperature for the baseboard heater from manufacturer's information in degree Celsius.

Field: Standard Water Mass Flow Rate

This field is the rated standard water flow rate in kg/s which is published as part of the manufacturer's data. This flow rate is used by the manufacturer when determining the rated capacity (see next field).

Field: Rated Capacity

This field is the rated baseboard capacity in W at the rated water flow rate (see previous field).

Field: Maximum Water Flow Rate

This field is the maximum hot water volumetric flow rate in m³/sec. This field can be autosized by EnergyPlus.

Field: Convergence Tolerance

This field is the control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For hot water baseboards, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|(Q_{bb,out} - Q_{ZoneLoad})|}{Q_{ZoneLoad}} \leq \text{ConvergenceTolerance}$$

The default is 0.001.

Field: Fraction Radiant

This field specifies what fraction of the power input to the baseboard heater is actually transferred to the space as radiant heat. The fraction should be between 0 and 1. This is the portion of the total power that is modeled as radiant, the remaining energy is added to the zone as convective heat transfer. The portion that is radiant heat transfer from the baseboard heater is distributed to people and specific surfaces using the remaining fields. Note that the sum of the fractions in the remaining fields (people and surfaces) must equal 1.0 so that all the radiant power is distributed properly.

Field: Fraction of Radiant Energy Incident on People

This field specifies the fraction of radiant portion of heat transfer to the zone from the baseboard heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that although this energy is “radiant” it is actually modeled in the zone heat balance as convective energy (like an internal gain). The basic assumption here is that most radiant energy falling on people will most likely be rereleased to the zone air by convection. This is a simplification of reality, but it maintains the overall energy balance.

Field Set: Surface Name, Fraction of Radiant Energy to Surface

The following two items are repeated up to a maximum of 20 surface/fraction pairs. At least one surface/fraction pair must appear in an input file. In other words, at least one surface must be identified as a recipient of radiant energy from the baseboard heater.

Field: Surface <x> Name

This field is the name of the first surface to which radiant heat transfer from the baseboard heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

Field: Fraction of Radiant Energy to Surface <x>

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the baseboard heater that is incident on a particular surface. Users should take into account the directionality of baseboard heaters and their location when defining the value for this input field.

Note on Fraction of Radiant Energy Incident on People and to Surfaces

The radiant energy from the baseboard heater is defined by the total energy input to the baseboard heater from the water loop times the fraction radiant field shown above. This radiant energy is distributed to surfaces and people using the surface and fraction pairs and the fraction to people input by the user. These fractions to people and surfaces must add up to 1.0. In other words, in an input file, the following relation should be maintained by the user input:

$$\text{FractionIncidentOnPeople} + \sum \text{FractionToSurfaces} = 1$$

Baseboard Convective System Impact Rate [W]

This is the actual convective heat addition rate of the baseboard to the zone in Watts. This value includes the heat convected to the zone air from the baseboard unit, the heat radiated to people in the zone from the baseboard unit, and the additional convection from surfaces within the zone that have been heated by radiation from the baseboard unit. This value will be different from (and almost always less than) the next field.

Baseboard Heating Rate [W]

This is the total heat addition rate of the baseboard to the zone it is serving in Watts.

Baseboard Convective Heating Rate [W]

This field reports the rate at which convective heat addition is transferred from the baseboard to the zone in Watts.

Baseboard Radiant Heating Rate [W]

This field reports the rate at which radiant heat addition is transferred from the baseboard to the people and the surfaces within the zone in Watts.

Baseboard Convective System Impact Energy [W]

This is the actual, total convective energy transferred directly and indirectly from the baseboard to the zone it is serving in Joules. Direct convective heat transfer includes the convective portion of the baseboard unit. Indirect convective heat transfer includes heat radiated to people that is then convected to the zone air and heat that is radiated to the surfaces and then convected to the zone air.

Baseboard Heating Energy [J]

This is the total energy of the baseboard to the zone it is serving in Joules over the timestep being reported.

Baseboard Convective Heating Energy [J]

This field reports the amount of convective energy transferred from the baseboard directly to the zone air in Joules.

Baseboard Radiant Heating Energy [J]

This field reports the amount of radiant energy transferred from the baseboard to the zone in Joules.

Baseboard:EnergyTransfer [J]

This meter report variable is the sum of the baseboard heat output from all the baseboards in the HVAC systems in the simulation.

ZoneHVAC:Baseboard:Convective:Water

The hot water baseboard heater is a component of zone equipment. The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher heating priority. The control is accomplished by throttling the hot water flow. Input resembles that for the simple heating coil: there is an availability schedule, an overall UA, and a maximum hot water mass flow rate. The unit is connected to a hot water loop (demand side) with an inlet and outlet node. Finally, there is the convergence tolerance, which is the tolerance on how closely the baseboard outlet will meet the zone load. Of course, this tolerance is relative to the zone load. The input data dictionary definition of the unit is as follows.

Field: Name

A unique user assigned name for an instance of a hot water baseboard heater unit. Any reference to this unit by another object will use this name.

Field: Available Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the hot water baseboard heater unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Inlet Node Name

The name of the hot water inlet node for the baseboard heater.

Field: Outlet Node Name

The name of the hot water outlet node for the baseboard heater.

Field: U-Factor Times Area Value

The overall heat transfer coefficient for the baseboard heater in watts per degree Celsius at design conditions. The U-Factor Times Area Value (UA) is used in an NTU - effectiveness calculation. An estimate of the UA can be obtained from:

$$q = UA \times (T_{water,avg} - T_{air,avg})$$

where q is the heat transferred from water to the air in watts; $T_{water,avg}$ is the average water temperature in degrees C; and $T_{air,avg}$ is the average air temperature in degrees C. Or the LMTD temperature difference can be used.

Field: Maximum Water Flow Rate

The maximum hot water volumetric flow rate in m³/sec.

Field Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For hot water baseboards, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|(Q_{bb,out} - Q_{ZoneLoad})|}{Q_{ZoneLoad}} \leq ConvergenceTolerance$$

The default is 0.001.

Baseboard Heating Energy[J]

This is the heat addition of the convective baseboard to the zone it is serving in Joules over the timestep being reported.

Baseboard:EnergyTransfer [J]

This meter report variable is the sum of the baseboard heat output from all the baseboards in the HVAC systems in the simulation.

ZoneHVAC:Baseboard:Convective:Electric

The electric baseboard heater is a component in the zone equipment simulation. The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher heating priority. The control is accomplished by taking the remaining zone load and dividing by the efficiency of the baseboard. The input data dictionary definition of the unit is as follows.

Field: Name

A unique user assigned name for an instance of a electric baseboard heater unit. Any reference to this unit by another object will use this name.

Field: Available Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the electric baseboard heater unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Nominal Capacity

This is the nominal, or maximum capacity, of this electric baseboard unit.

Field: Efficiency

This is the overall electrical efficiency of the electric baseboard. The zone load met by this unit is divided by the electrical efficiency to obtain the total electric energy used.

HVAC, Meter, Heating:Electricity[J]

Baseboard Heating Rate[W]

This is the heat addition rate of the electric convective baseboard to the zone it is serving in Watts.

Baseboard Heating Energy[J]

This is the heat addition of the convective baseboard to the zone it is serving in Joules over the timestep being reported.

Baseboard:EnergyTransfer [J]

This meter report variable is the sum of the baseboard heat output from all the baseboards in the HVAC systems in the simulation regardless of Energy input.

Baseboard Electric Consumption [J]

This is the total electric consumption of the baseboard for the zone it is serving in Joules over the timestep being reported.

Baseboard Electric Power [W]

This is the electric power required by the baseboard to the zone it is serving in Watts.

Heating:Electricity [J]

This meter report variable is the sum of the electric output from all the electric baseboards in the HVAC systems in the simulation.

ZoneHVAC:LowTemperatureRadiant:VariableFlow

This low temperature radiant system (hydronic) is a component of zone equipment that is intended to model any “radiant system” where water is used to supply/remove energy to/from a building surface (wall, ceiling, or floor). The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher priority. The control is accomplished by throttling the hot or chilled water flow to the unit. This model covers a wide range of low temperature radiant systems: heating and/or cooling, panel or embedded pipes, etc. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model and different input syntax. Low temperature radiant systems that use electric resistance heating should also be defined using separate input syntax (ref: ZoneHVAC:LowTemperatureRadiant:Electric).

Field: Name

This field is an unique user assigned name for an instance of a hydronic low temperature radiant system. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the hydronic low temperature radiant system can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the hydronic low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: BuildingSurface) or surface list (Ref: ZoneHVAC:LowTemperatureRadiant:SurfaceGroup) in which the hydronic tubing is embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (e.g., BuildingSurface:Detailed) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Hydronic Tubing Inside Diameter

This field is the inside diameter of the tubes through which water is circulated for the system being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the water to the inside surface of the hydronic tubing.

Field: Hydronic Tubing Length

This field is the total length of pipe embedded in the surface named above in the surface name field. The length of the tube should be entered in meters and is used to determine the effectiveness of heat transfer from the fluid being circulated through the tubes and the tube/surface. Longer tubing lengths result in more heat will be transferred to/from the radiant surface to the circulating fluid.

Field: Temperature Control Type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the hydronic radiant system. The temperature denoted in the setpoint schedule can refer to one of five different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, or the outdoor wet-bulb temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

MeanAirTemperature MeanRadiantTemperature OperativeTemperature OutdoorDryBulbTemperature OutdoorWetBulbTemperature
--

Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature. If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information.

Field: Maximum Hot Water Flow

This field is the maximum flow rate of hot water through the radiant system in m³/sec. The controls for the radiant system will vary the flow rate of hot water through the surface using zero flow and the maximum flow rate specified in this field as the lower and upper bounds, respectively.

Field: Heating Water Inlet Node Name

This field contains the name of the hot water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

Field: Heating Water Outlet Node Name

This field contains the name of the hot water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

Field: Heating Control Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero flow rate up to the maximum defined by the maximum hot water flow rate field described above. The throttling range parameter is used in conjunction with the control temperature to define the response of the system to various zone conditions. The heating control temperature schedule specifies the “setpoint” temperature where the flow rate to the system is at half of the maximum flow rate. For example, if the heating control temperature setpoint is currently 15°C and the heating throttling range is 2°C, the water flow rate to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, ODB, or OWB; see control type field above) is at or above 16°C and the maximum flow rate when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the flow rate to the radiant system is varied linearly.

Field: Heating Control Temperature Schedule Name

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating control throttling range), it will define whether or not the system is running and the current flow rate. Water flow rate to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum heating flow rate parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. In addition, this schedule may be different than the thermostatic control schedule defined for overall operation of components serving the zone in which the radiant system is located. The thermostatic control determines whether or not there is a heating or cooling load in the space and thus whether the systems should be operating. This field simply controls the flow rate to the radiant system.

Field: Maximum Cold Water Flow

This field is the maximum flow rate of cold water through the radiant system in m³/sec. The controls for the radiant system will vary the flow rate of cold water through the surface using zero flow and the maximum flow rate specified in this field as the lower and upper bounds, respectively. Note that this field is optional and not required for a heating only system.

Field: Cooling Water Inlet Node Name

This field contains the name of the cold water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

Field: Cooling Water Outlet Node Name

This field contains the name of the cold water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

Field: Cooling Control Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero flow rate up to the maximum defined by the maximum cold water flow rate field described above. The throttling range parameter is used in conjunction with the control temperature to define the response of the system to various zone conditions. The

cooling control temperature schedule specifies the “setpoint” temperature where the flow rate to the system is at half of the maximum flow rate. For example, if the cooling control temperature setpoint is currently 25°C and the cooling throttling range is 2°C, the water flow rate to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, ODB, or OWB; see control type field above) is at or below 24°C and the maximum flow rate when the controlling temperature is at or above 26°C. This represents a throttling range of 2°C around the setpoint of 25°C. In between 24°C and 26°C, the flow rate to the radiant system is varied linearly.

Field: Cooling Control Temperature Schedule Name

This field specifies the cooling setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (cooling control throttling range), it will define whether or not the system is running and the current flow rate. Water flow rate to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum cooling flow rate parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for cooling. In addition, this schedule may be different that the thermostatic control schedule defined for overall operation of components serving the zone in which the radiant system is located. The thermostatic control determines whether or not there is a heating or cooling load in the space and thus whether the systems should be operating. This field simply controls the flow rate to the radiant system.

Field: Condensation Control Type

When radiant systems do cooling, there is the possibility that condensation will occur on the surface that is being cooled. This is due to the fact that the surface temperature may drop below the dew-point temperature of the space. When this occurs, condensation on the surface will occur. In EnergyPlus, users have several options for handling this situation including: Off, SimpleOff, VariableOff. When the user chooses the Off option, EnergyPlus will not do anything other than produce a warning message when condensation is predicted to occur. The program will simply continue on; no moisture will be removed from the zone air and there will be no adjustment of the surface temperature as a result of the condensation. When the user chooses the SimpleOff option, the program will predict cases where condensation will occur and shut-off the radiant system to avoid this situation. With this option, the users also have the opportunity to adjust when the system will shut down. This is specified with the next parameter (field: condensation differential parameter). Finally, when the user selects the VariableOff option, the variable flow radiant system will decrease the flow to the radiant system as much as possible to try to avoid condensation. If necessary, the radiant system will shut off flow completely. This parameter is optional and EnergyPlus will use the SimpleOff strategy when this parameter is not specified.

Field: Condensation Control Dewpoint Offset

This optional parameter is only valid with the SimpleOff condensation handling algorithm (see previous input parameter). It establishes the difference between the calculated dew-point temperature of the space and the allowed surface temperature to which the surface can drop before the radiant system shuts down in degrees Celsius. This parameter can be any positive, negative, or zero value. When this parameter is zero, the radiant system will shut down when the surface temperature drops to the dew-point temperature or below. When this parameter is positive, the radiant system will shut down when the surface is the number of degrees Celsius above the dew-point temperature. This allows some extra safety to avoid condensation. When this parameter is negative, the radiant system will shut down when the surface temperature is the number of degrees Celsius below the dew-point temperature. While not recommended, this strategy allows the user to simulate a situation where small amounts of condensation are tolerable.

Hydronic Low Temp Radiant Heating Rate[W]

This field reports the heating input rate to the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

Hydronic Low Temp Radiant Heating Energy[J]

This field reports the heating input to the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Hydronic Low Temp Radiant Cooling Rate[W]

This field reports the cooling input rate to the low temperature radiant system in Watts. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

Hydronic Low Temp Radiant Cooling Energy[J]

This field reports the cooling input to the low temperature radiant system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Hydronic Low Temp Radiant Water Mass Flow Rate[kg/s]

This field reports the mass flow rate of water through the low temperature radiant system in kilograms per second.

Hydronic Low Temp Radiant Water Inlet Temp[C]

This field reports the temperature of water entering the low temperature radiant system in Celsius.

Hydronic Low Temp Radiant Water Outlet Temp[C]

This field reports the temperature of water leaving the low temperature radiant system in Celsius.

Hydronic Low Temp Radiant Time Condensation Occurring[s]

This field reports the amount of time when condensation is occurring. When using the Off condensation control, this simply reports the amount of time when condensation occurs. When using the SimpleOff condensation control, this indicates the amount of time when the system has been shut off because of the potential danger of condensation.

ZoneHVAC:LowTemperatureRadiant:ConstantFlow

This low temperature radiant system (hydronic) is a component of zone equipment that is intended to model any “radiant system” where water is used to supply/remove energy to/from a building surface (wall, ceiling, or floor). The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher priority. The constant flow system differs from the hydronic system describe above in what it controls. The hydronic system varies the flow rate through the radiant system based on some control temperature. The constant flow system keeps flow rate constant via a local circulation pump and varies the water temperature that is sent to the radiant system. This is accomplished with a mixing valve that is controlled by a sensor. This model covers a wide range of low temperature radiant systems: heating and/or cooling, panel or embedded pipes, etc. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model and different input syntax. Low temperature radiant systems that use electric resistance heating should also be defined using separate input syntax (ref: ZoneHVAC:LowTemperatureRadiant:Electric). Low temperature radiant systems that vary the flow rate through the radiant system should also be defined using separate input syntax (ref: ZoneHVAC:LowTemperatureRadiant:VariableFlow)

One of the other differences between this model and the variable flow hydronic radiant system is that the constant flow radiant system has a built-in local secondary loop. It will recirculate flow coming out of the system and mix this with flow from the loop to arrive at the desired inlet temperature to the radiant system (note that this model has the temperature sensor AFTER the pump to insure proper inlet temperature to the radiant system). The local loop also contains a pump which is assumed to be upstream of the radiant system and after the mixing valve. So, the local loop can have some recirculation. The flow from the main loop may also bypass the radiant system if more than enough flow is available and the main loop is also a constant flow system.

Field: Name

This field is an unique user assigned name for an instance of a constant flow low temperature radiant system. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the constant flow low temperature radiant system can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the constant flow low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: BuildingSurface:Detailed) or surface list (Ref: ZoneHVAC:LowTemperatureRadiant:SurfaceGroup) in which the hydronic tubing is embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (BuildingSurface:Detailed) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Hydronic Tubing Inside Diameter

This field is the inside diameter of the tubes through which water is circulated for the system being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the water to the inside surface of the hydronic tubing.

Field: Hydronic Tubing Length

This field is the total length of pipe embedded in the surface named above in the surface name field. The length of the tube should be entered in meters and is used to determine the effectiveness of heat transfer from the fluid being circulated through the tubes and the tube/surface. Longer tubing lengths result in more heat being transferred to/from the radiant surface to the circulating fluid.

Field: Temperature Control Type

This field specifies along with setpoint (control) and water schedules how the user wishes to control the constant flow radiant system. The temperature denoted in the setpoint schedule can refer to one of five different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, or the outdoor wet-bulb temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

MeanAirTemperature MeanRadiantTemperature OperativeTemperature OutdoorDryBulbTemperature OutdoorWetBulbTemperature
--

Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature. If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information.

Field: Rated Flow Rate

This field is the maximum flow rate of water through the radiant system in m³/sec. This flow rate is held constant by the local component pump, but the user has the option of varying this flow rate via a schedule (see next input field). The constant flow system will accept this flow rate and control the inlet temperature based on the control and water temperature schedules defined below.

Field: Pump Flow Rate Schedule Name

This field modifies the maximum flow rate of water through the radiant system in m³/sec. This input is “optional”. If the user does not enter a schedule, the flow rate through the radiant system is assumed to be constant during all hours that it is operating based on the value entered in the previous input field. Note that the values for this schedule must be between zero and one.

Field: Rated Pump Head

This numeric field contains the pump’s rated head in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump’s rated power consumption in Watts.

Field: Motor Efficiency

This numeric field contains the pump’s efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump’s fraction of power loss to the fluid.

Field: Heating Water Inlet Node Name

This field contains the name of the hot water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

Field: Heating Water Outlet Node Name

This field contains the name of the hot water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

Field: Heating High Water Temperature Schedule Name

This field specifies the high water temperature in degrees Celsius for the temperature control of a constant flow radiant heating system. Water and control temperatures for heating work together to provide a linear function that determines the water temperature sent to the radiant system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet water temperature is set to the low water temperature. If the control temperature is below the low temperature, then the inlet water temperature is set to the high water temperature. If the control temperature is between the high and low value, then the inlet water temperature is linearly interpolated between the low and high water temperature values.

Field: Heating Low Water Temperature Schedule Name

This field specifies the low water temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

Field: Heating High Control Temperature Schedule Name

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

Field: Heating Low Control Temperature Schedule Name

This field specifies the low control temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

Field: Cooling Water Inlet Node Name

This field contains the name of the cold water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

Field: Cooling Water Outlet Node Name

This field contains the name of the cold water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

Field: Cooling High Water Temperature Schedule Name

This field specifies the high water temperature in degrees Celsius for the temperature control of a constant flow radiant cooling system. Water and control temperatures for heating work together to provide a linear function that determines the water temperature sent to the radiant system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet water temperature is set to the low water temperature. If the control temperature is below the low temperature, then the inlet water temperature is set to the high water temperature. If the control temperature is between the high and low value, then the inlet water temperature is linearly interpolated between the low and high water temperature values.

Field: Cooling Low Water Temperature Schedule Name

This field specifies the low water temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

Field: Cooling High Control Temperature Schedule Name

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

Field: Cooling Low Control Temperature Schedule Name

This field specifies the low control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

Field: Condensation Control Type

When radiant systems do cooling, there is the possibility that condensation will occur on the surface that is being cooled. This is due to the fact that the surface temperature may drop below the dew-point temperature of the space. When this occurs, condensation on the surface will occur. In EnergyPlus, users have several options for handling this situation including: Off, SimpleOff, VariableOff. When the user chooses the Off option, EnergyPlus will not do anything other than produce a warning message when condensation is predicted to occur. The program will simply continue on; no moisture will be removed from the zone air and there will be no adjustment of the surface temperature as a result of the condensation. When the user chooses the SimpleOff option, the program will predict cases where condensation will occur and shut-off the radiant system to avoid this situation. With this

option, the users also have the opportunity to adjust when the system will shut down. This is specified with the next parameter (field: condensation differential parameter). Finally, when the user selects the VariableOff option, the variable flow radiant system will decrease the flow to the radiant system as much as possible to try to avoid condensation. If necessary, the radiant system will shut off flow completely. This parameter is optional and EnergyPlus will use the SimpleOff strategy when this parameter is not specified.

Field: Condensation Control Dewpoint Offset

This optional parameter is only valid with the SimpleOff condensation handling algorithm (see previous input parameter). It establishes the difference between the calculated dew-point temperature of the space and the allowed surface temperature to which the surface can drop before the radiant system shuts down in degrees Celsius. This parameter can be any positive, negative, or zero value. When this parameter is zero, the radiant system will shut down when the surface temperature drops to the dew-point temperature or below. When this parameter is positive, the radiant system will shut down when the surface is the number of degrees Celsius above the dew-point temperature. This allows some extra safety to avoid condensation. When this parameter is negative, the radiant system will shut down when the surface temperature is the number of degrees Celsius below the dew-point temperature. While not recommended, this strategy allows the user to simulate a situation where small amounts of condensation are tolerable.

Constant Flow Low Temp Radiant Heating Rate[W]

This field reports the heating input rate to the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

Constant Flow Low Temp Radiant Heating Energy[J]

This field reports the heating input to the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Constant Flow Low Temp Radiant Cooling Rate[W]

This field reports the cooling input rate to the low temperature radiant system in Watts. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

Constant Flow Low Temp Radiant Cooling Energy[J]

This field reports the cooling input to the low temperature radiant system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Constant Flow Low Temp Radiant Water Mass Flow Rate[kg/s]

This field reports the mass flow rate of water through the low temperature radiant system in kilograms per second. This should be identical to the pump flow rate for the system.

Constant Flow Low Temp Radiant Injection Mass Flow Rate[kg/s]

This field reports the mass flow rate of water that is injected into the radiant system from the main loop. A valve will control the injection and recirculation mass flow rates (see next field) to match the temperature controls specified by the user and dictated by the current simulation conditions.

Constant Flow Low Temp Radiant Recirculation Mass Flow Rate[kg/s]

This field reports the mass flow rate of water that is recirculated from the radiant system outlet and mixed with the injection flow from the main loop. A valve will control the injection and recirculation mass flow rates (see next field) to match the temperature controls specified by the user and dictated by the current simulation conditions.

Constant Flow Low Temp Radiant Water Inlet Temp[C]

This field reports the temperature of water entering the low temperature radiant system in Celsius. This may differ from the inlet node temperature for the component since this component has its own local secondary loop.

Constant Flow Low Temp Radiant Water Outlet Temp[C]

This field reports the temperature of water leaving the low temperature radiant system in Celsius. This may differ from the outlet node temperature for the component since this component has its own local secondary loop.

Constant Flow Low Temp Pump Water Inlet Temp[C]

This field reports the temperature of water entering the low temperature radiant system pump in Celsius. This may differ from the inlet node temperature for the component since this component has its own local secondary loop. It is assumed that the pump is upstream of the radiant system.

Constant Flow Low Temp Pump Electric Power[W]

This field reports the rate of electric power consumption for the pump which supplies flow to the constant flow radiant system in Watts.

Constant Flow Low Temp Pump Electric Consumption[J]

This field reports the electric power consumption for the pump which supplies flow to the constant flow radiant system in Joules.

Constant Flow Low Temp Radiant Pump Water Mass Flow[kg/s]

This field reports the mass flow rate of water through the low temperature radiant system pump in kilograms per second. This should be identical to the flow rate for the system.

Constant Flow Low Temp Pump Heat to Fluid[W]

This field reports the rate at which heat is added to the fluid stream as it passes through the pump in Watts. This heat is reflected in the radiant system inlet temperature which will be different from the pump inlet temperature if this field has a non-zero value.

Constant Flow Low Temp Pump Heat to Fluid Energy[J]

This field reports the amount of heat energy added to the fluid stream as it passes through the pump in Joules. This heat is reflected in the radiant system inlet temperature which will be different from the pump inlet temperature if this field has a non-zero value.

Constant Flow Low Temp Radiant Time Condensation Occurring[s]

This field reports the amount of time when condensation is occurring. When using the Off condensation control, this simply reports the amount of time when condensation occurs. When using the SimpleOff condensation control, this indicates the amount of time when the system has been shut off because of the potential danger of condensation.

ZoneHVAC:LowTemperatureRadiant:Electric

This low temperature radiant system (electric) is a component of zone equipment that is intended to model any “radiant system” where electric resistance heating is used to supply energy (heat) to a building surface (wall, ceiling, or floor). The component is controlled to meet any remaining zone heating load not met by other equipment in the zone that have higher heating priority. The control is accomplished by varying the electrical power supplied to the unit. This model covers either a radiant panel system or wires embedded in entire walls, floors, or ceilings. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model and different input syntax. Low temperature radiant systems that use water flowing through tubes to provide heat to the system should also be defined using separate input syntax (ref: Low Temp Radiant System:Hydronic).

Field: Name

This field is a unique user assigned name for an instance of an electric low temperature radiant system. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the electric low temperature radiant system can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the electric low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: BuildingSurface) or surface list (Ref: ZoneHVAC:LowTemperatureRadiant:SurfaceGroup) in which the hydronic tubing is embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (e.g. BuildingSurface:Detailed) are valid.

Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Maximum Electrical Power to Panel

This field is the maximum amount of electrical energy that can be converted to heat in this particular radiant system in Watts. The controls for the radiant system will vary the amount of power supplied to the surface between zero input and the maximum power specified in this field as the lower and upper bounds, respectively.

Field: Temperature Control Type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the low temperature electric radiant system. The temperature denoted in the setpoint schedule can refer to one of three different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, or the outdoor wet-bulb temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

MeanAirTemperature MeanRadiantTemperature OperativeTemperature OutdoorDryBulbTemperature OutdoorWetBulbTemperature
--

Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature. If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information.

Field: Heating Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero heat input via the electric resistance wires up to the maximum defined by the maximum electrical power field described above. The throttling range parameter is used in conjunction with the control temperature (see below) to define the response of the system to various zone conditions. The heating control temperature schedule specifies the “setpoint” temperature where the power input to the system is at half of the maximum power input. For example, if the heating control temperature setpoint is currently 15°C and the heating throttling range is 2°C, the electrical power supplied to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, ODB, or OWB; see control type field above) is at or above 16°C and the maximum power input when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the power input to the radiant system is varied linearly.

Field: Heating Setpoint Temperature Schedule Name

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating throttling range), it will define whether or not the system is running and the current power input to the radiant surface. Power input to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum electrical power parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. In addition, this schedule may be different that the thermostatic control schedule defined for overall operation of components serving the zone in which the radiant system is located. The thermostatic control determines whether or not there is a heating or cooling load in the space and thus whether the systems should be operating. This field simply controls the flow rate to the radiant system.

Electric Low Temp Radiant Electric Power [W]

This field reports the rate at which electric energy is “burned” in the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

Electric Low Temp Radiant Electric Consumption [J]

This field reports the amount of electric energy “burned” in the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

ZoneHVAC:LowTemperatureRadiant:SurfaceGroup

A low temperature radiant system (hydronic or electric) may consist of multiple active surfaces that are serving to condition the space. Surfaces that act serially can be specified as multiple radiant systems using the standard radiant system input described above. However, if the multiple surfaces act in parallel, the Radiant System Surface Group input line is used to specify which surfaces are acting in a coordinated fashion and how flow rate is split between the surfaces. This list of surfaces (the name it is assigned) replaces the name of a single surface in the radiant system input described above. Note that all of the surfaces within a single list must be a part of the same zone and that the zone of these surfaces must also match the zone the radiant system is attempting to condition.

Field: Name

This field is an unique user assigned name for the list of surfaces that are acting in coordination with one another. Any reference to this list by a radiant system will use this name.

Field Set: Surface Name, Flow Fraction to Surface

The pairs of Surface Name, Flow Fraction to Surface are used in several objects. There can be up to 10 specified. The object is extensible so more can be added.

Field: Surface <x> Name

This field is the name of a surface in the zone being conditioned by the radiant system. Only base surfaces (walls, roofs, floors) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Flow Fraction for Surface <x>

This field is the fraction of the total radiant system flow rate that is being sent to this particular surface. Note that the Surface Name/Surface Flow Fraction pair can be repeated up to 10 times. Flow rate fractions must sum to unity, otherwise the program will not accept the input as valid.

```

ZoneHVAC:HighTemperatureRadiant

The high temperature radiant system (gas-fired or electric) is a component of zone equipment that is intended to model any “high temperature” or “high intensity” radiant system where electric resistance or gas-fired combustion heating is used to supply energy (heat) to a building occupants directly as well as the building surfaces (wall, ceiling, or floor). The component is controlled to meet any remaining zone heating load not met by other equipment in the zone that have higher heating priority. The control is accomplished by varying the electrical power supplied to or gas consumed by the unit. It is not intended to simulate low temperature electric or hydronic radiant systems. Those devices will be handled by a separate model and different input syntax (ref: the low temperature systems described elsewhere).

Field: Name

This field is an unique user assigned name for an instance of the high temperature radiant system. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the high temperature radiant system can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the high temperature radiant system is principally located and intended to affect.

Field: Maximum Power Input

This field is the maximum amount of energy (rate) that can be converted to heat in this particular radiant system in Watts. The controls for the radiant system will vary the amount of power supplied to the surface between zero input and the maximum power specified in this field as the lower and upper bounds, respectively.

Field: Fuel Type

This field denotes the type of high temperature radiant heater: gas or electric. The user must specify this by inputting either the keyword “Gas” or “Electric” for this field.

Field: Combustion Efficiency

This field is the combustion efficiency for a gas high temperature radiant heater. This value should be greater than 0 and less than or equal to 1. It is intended to take into account any potential inefficiencies in the combustion process inside the radiant heater. The heater gas consumption is the ratio of heater output over the combustion efficiency. This parameter has no meaning for an electric high temperature radiant heater and is ignored when the previous field is equal to “Electric”.

Field: Fraction of Input Converted to Radiant Energy

This field specifies what fraction of the power input to the high temperature radiant heater is actually radiant heat transfer. The fraction should be between 0 and 1. In conjunction with the next two parameters, it defines the breakdown of how the power input to the heater is

distributed to the rest of the zone. The sum of these fractions must be less than or equal to 1. If the fractions are less than one, the remaining energy is added to the zone as convective heat transfer. The radiant heat transfer from the heat is distributed to people and surfaces using the distribution fractions listed below.

Field: Fraction of Input Converted to Latent Energy

This field specifies the fraction of the power input to the high temperature radiant heater that is converted to a latent heat gain within the space. This may be appropriate when a combustion process produces moisture that is transferred into the space. The latent heat addition from a high temperature radiant heater is handled as any other latent heat gain within the space, affecting the moisture balance on the zone air.

Field: Fraction of Input that Is Lost

This field specifies the fraction of power input to the high temperature radiant heater that is “lost”. This energy is a loss term, and this fraction of the input power has no effect on the zone heat balances.

Field: Temperature control type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the high temperature radiant system. The temperature denoted in the setpoint schedule can refer to one of three different temperatures: a mean air temperature, a mean radiant temperature, or an operative temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

```
MeanAirTemperature
MeanRadiantTemperature
OperativeTemperature
MeanAirTemperatureSetpoint
MeanRadiantTemperatureSetpoint
OperativeTemperatureSetpoint
```

If the user does not select a control type, OperativeTemperature control is assumed by EnergyPlus. For the setpoint control strategies (those ending in Setpoint above), EnergyPlus will attempt to find the correct heater output to meet the heating setpoint temperature (see below) through iteration and interpolation. This will more closely match the operation of an actual thermostat, but it will require significantly longer execution times. For more information on the standard piecewise linear control algorithm used by the Mean Air Temperature, Mean Radiant Temperature, and Operative Temperature control types (the “non-Setpoint” controls), see the throttling range and control temperature schedule fields below for more information.

Field: Heating Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero heat input via the electric resistance wires up to the maximum defined by the maximum electrical power field described above. The throttling range parameter is used in conjunction with the control temperature (see below) to define the response of the system to various zone conditions. The heating control temperature schedule specifies the “setpoint” temperature where the power input to the system is at half of the maximum power input. For example, if the heating control temperature setpoint is currently 15°C and the heating throttling range is 2°C, the electrical power supplied to the radiant system will be zero when the controlling temperature (Mean Air Temperature, Mean Radiant Temperature, and Operative Temperature; see control type field above) is at or above 16°C and the maximum power input when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the power input to the radiant system is varied linearly.

Field: Heating Setpoint Temperature Schedule Name

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating throttling range), it will define whether or not the system is running and the current power input to the radiant surface. Power input to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum electrical power parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. In addition, this schedule may be different than the thermostatic control schedule defined for overall operation of components serving the zone in which the radiant system is located. The thermostatic control determines whether or not there is a heating or cooling load in the space and thus whether the systems should be operating. This field simply controls the flow rate to the radiant system.

Field: Fraction of Radiant Energy Incident on People

This field specifies the fraction of radiant heat transfer to the zone from the radiant heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that since the thermal comfort models only use the results of the zone heat balances this energy is accounted for within the heat balance as convective energy, directly affecting the zone air heat balance. The basic assumption here is that most radiant energy falling on people will most likely be convected to the surroundings. This is a simplification of reality, but it maintains the overall energy balance.

Field Set: Surface Name, Fraction of radiant energy to Surface

The pairs of Surface Name, Fraction of Radiant Energy to Surface are used in several objects. There can be up to 20 specified.

Field: Surface <x> Name

This field is the name of the first surface to which radiant heat transfer from the high temperature radiant heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

Field: Fraction of Radiant Energy to Surface <x>

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the high temperature radiant system that is incident on a particular surface. Users should take into account the directionality of high temperature radiant heaters and their location when defining the value for this input field. Note that the sum of all fractions plus the fraction of radiant energy incident on people must add up to less than or equal to 1.

High Temperature Radiant Heating Rate[W]

This field reports the rate at which energy is transferred from the high temperature radiant system to the zone in Watts. This rate is determined by the zone conditions and the control scheme defined in the user input. Note that this amount takes into account any combustion inefficiency and thus could be different that the gas consumption rate in a high temperature gas radiant system.

High Temperature Radiant Heating Energy[J]

This field reports the amount of energy transferred from the high temperature gas radiant system to the zone in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep. Note that this amount takes into account any combustion inefficiency and thus could be different that the gas consumption in a high temperature gas radiant system.

High Temperature Radiant Gas Consumption Rate[W]

This field reports the rate at which gas is “burned” in a high temperature gas radiant system in Watts. This rate is determined by the zone conditions and the control scheme defined in the user input.

High Temperature Radiant Gas Consumption[J]

This field reports the amount of gas “burned” in a high temperature gas radiant system in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

High Temperature Radiant Electric Power[W]

This field reports the rate at which electric energy is “burned” in a high temperature electric radiant system in Watts. This rate is determined by the zone conditions and the control scheme defined in the user input.

High Temperature Radiant Electric Consumption[J]

This field reports the amount of electric energy “burned” in a high temperature electric radiant system in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

ZoneHVAC:VentilatedSlab

Ventilated slab systems in general use outdoor air to “precool” slabs with colder nighttime air. This method of precooling the thermal mass of a space can be very effective when nighttime temperatures are low and the mass of the system is high enough to provide a significant amount of cooling potential during the day to counteract internal heat gains within a zone. Nearly all ventilated slabs are simple systems such as that shown in the right side of Figure 102. The fan is shown in a blow through position, but the model will allow either a blow or draw through configuration.

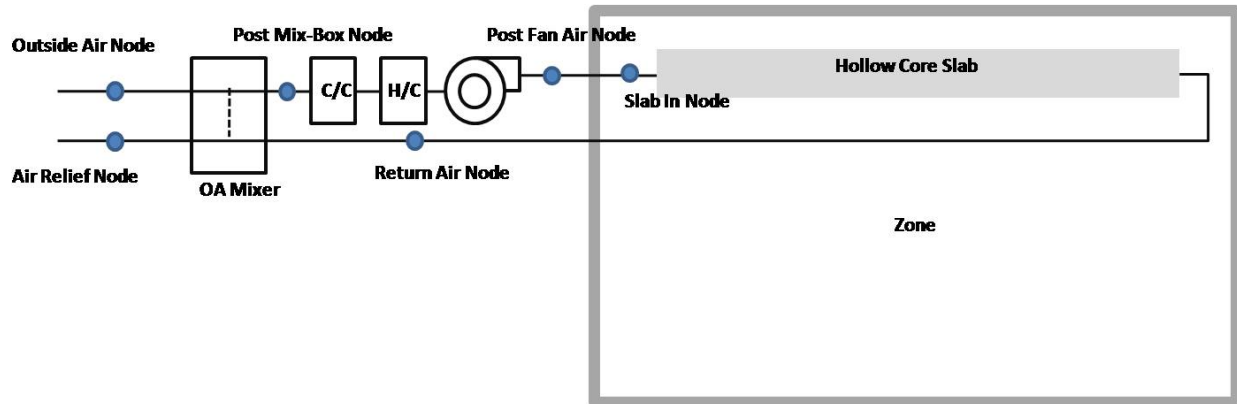

Figure 102. Ventilated Slab model - basic system

It should be noted that in this figure the use of “unit ventilator” and “low temperature radiant system” do not imply that the user must also specify these elements in the input file. In fact, the ventilated slab model combines aspects of these two existing EnergyPlus features into a single model that the user specifies through the input shown below and does not require any additional radiant system or unit ventilator input.

Field: Name

This field is a unique user assigned name for an instance of a ventilated slab system. Any reference to this unit by another object will use this name. Other objects that use this ventilated slab system will reference it by this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the ventilated slab system can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

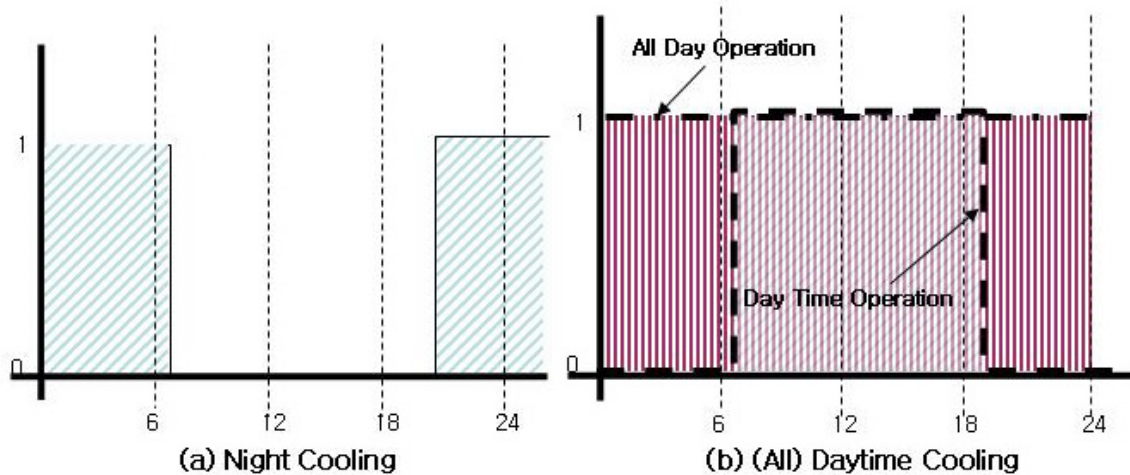

Figure 103. Example operating schedule for Ventilated Slab

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the ventilated slab system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the system response.

Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: Surface) or surface list (Ref: ZoneHVAC:VentilatedSlab:SlabGroup) in which the hollow cores are embedded/contained. This specification attaches the source or sinks from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (Walls, Roofs, Floors) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Maximum Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the ventilated slab system in m^3/sec . This parameter should be some real number greater than zero.

Field: Outdoor Air Control Type

This field allows the user to control how outdoor air is used in the ventilated slab system. The ventilated slab system described by this syntax has its own outdoor air handler. The three options for outdoor air control are “**VariablePercent**”, “**FixedTemperature**” and “**FixedAmount**”. Those keywords are the only allowed choices for this parameter. In general, the variable percent control will attempt to vary the amount of outdoor air between some minimum and maximum schedules of fractions (see next two fields) to best meet the current heating or cooling load. The fixed temperature control will vary the amount of outdoor air between the minimum schedule (fraction of maximum, see next field) and 100% available outdoor air to come as close as possible to a desired mixed air temperature (see two fields down) that can be scheduled. The fixed amount control will fix the outdoor air flow rate as minimum outdoor air flow rate and schedule specified by the user and automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate. More information on the controls and operation of the ventilated slab are given in the section above (preceding the IDD/IDF description).

Field: Minimum Outdoor Air Flow Rate

This field allows the user to enter the minimum volumetric flow rate of outdoor air (in m³/sec) that will be brought in to the ventilated slab. The actual minimum outdoor air flow rate will be this number multiplied by the schedule value from the minimum outdoor air schedule. If “FixedAmount” type is selected as the outdoor air control strategy, the outdoor air flow rate will be fixed at the value of this field and the ventilated slab will automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate.

Field: Minimum Outdoor Air Schedule Name

This field contains a schedule name (ref: Schedule) that should contain values for the minimum outdoor air used by the ventilated slab system for IAQ or other reasons. Note that if the ventilated slab is scheduled off or if there is no load sensed in the zone that the system will not operate even to achieve the minimum air fraction. However, if the system is operating, it will always bring in at least this fraction of the minimum air flow rate (see minimum air flow rate field above). If “FixedAmount” type is selected as the outdoor air control strategy, the actual outdoor air flow rate will be this number multiplied by the minimum outdoor air flow rate in the field above. The ventilated slab will automatically set the maximum and minimum outdoor air schedule to be equal by ignoring the maximum outdoor air schedule.

Field: Maximum Outdoor Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of outdoor air that can be brought into the ventilated slab in m³/sec. This parameter should be some real number greater than zero. Note that the value for this parameter may be less than the maximum air flow rate of the ventilated slab and this may affect the maximum fraction of outdoor air within the control strategy defined above. This parameter is an absolute maximum and will supercede any scheduled fraction of the ventilated slab maximum airflow rate. If “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air flow rate specified in the field above.

Field: Maximum Outdoor Air Fraction or Temperature Schedule Name

This field can have one of two meanings depending the type of control selected in the outdoor air control type parameter above. If “VariablePercent” or “FixedAmount” was selected, then this field is a schedule name (ref: Schedule) corresponding to a maximum air fraction schedule. Furthermore, if “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air fraction specified in the field below. Note that this is a fraction of the maximum airflow rate field (see parameter above) for the ventilated slab. If “FixedTemperature” control was selected, then this field is still a schedule name (ref: Schedule), but it corresponds to a schedule of mixed air temperatures that the outdoor air control will try to attain.

Field: System Configuration Type

This field allows the user to control how the air is circulated using the ventilated slab system. The options for system configuration are

SlabOnly SlabAndZone SeriesSlabs
--

In the **SlabOnly**, the ventilation air is sent to the slab only and does not enter the zone. In the **SlabAndZone**, the air first enters the slab and then is delivered to the zone before returning to the system. With the **SeriesSlabs** option, the user specifies a list of slabs (ZoneHVAC:VentilatedSlab:SlabGroup). This list determines the order of slabs through which the air passes. In this option, air is not delivered to any zone.

Field: Hollow Core Inside Diameter

This field is the inside diameter of the cores through which air is circulated for the system being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the circulated air to the inside surface of the ventilated slab.

Field: Hollow Core Length

This field is the length of core embedded in the surface named above in the surface name field. In other words, this should be the distance that air travels as it through the slab. The length of the hollow core in the slab should be entered in meters and is used to determine the effectiveness of heat transfer from the air being circulated through the cores and the core inside surface. Longer core lengths result in more heat transferred to/from the radiant surface to the circulating fluid.

Field: Number of Cores

This field allows the user to specify how many cores there are in the ventilated slab. Air flow will be divided equally among the different cores.

Field: Temperature Control Type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the ventilated slab system. The temperature denoted in the set temperature schedule can refer to one of seven different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the surface temperature of the ventilated slab, the outdoor dry-bulb temperature, the outdoor wet-bulb temperature, or the dewpoint temperature of zone mean air temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

```
MeanAirTemperature
MeanRadiantTemperature
OperativeTemperature
OutdoorDryBulbTemperature
OutdoorWetBulbTemperature
SurfaceTemperature
ZoneAirDewPointTemperature
```

If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the control temperature schedule fields below for more information.

Field: Heating High Air Temperature Schedule Name

This field specifies the high air temperature in degrees Celsius for the temperature control of a ventilated slab system. Air and control temperatures for heating work together to provide a linear function that determines the air temperature sent to the ventilated slab. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet air temperature is set to the low air temperature. If the control temperature is below the low temperature, then the inlet air temperature is set to the high air temperature. If the control temperature is between the high and low value, then the inlet air temperature is linearly interpolated between the low and high air temperature values.

Field: Heating Low Air Temperature Schedule Name

This field specifies the low air temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

Field: Heating High Control Temperature Schedule Name

This field specifies the high control temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

Field: Heating Low Control Temperature Schedule Name

This field specifies the low control temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

Field: Cooling High Air Temperature Schedule Name

This field specifies the high air temperature in degrees Celsius for the temperature control of a ventilated slab system. Air and control temperatures for cooling work together to provide a linear function that determines the air temperature sent to the ventilated slab system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet air temperature is set to the low air temperature. If the control temperature is below the low temperature, then the inlet air temperature is set to the high air temperature. If the control temperature is between the high and low value, then the inlet air temperature is linearly interpolated between the low and high air temperature values.

Field: Cooling Low Air Temperature Schedule Name

This field specifies the low air temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

Field: Cooling High Control Temperature Schedule Name

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

Field: Cooling Low Control Temperature Schedule Name

This field specifies the low control temperature in degrees Celsius for the temperature control of a ventilated slab system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

Field: Return Air Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the ventilated slab. In EnergyPlus, nodes represent points between components or at various points in the loops. In a ventilated slab, the air inlet node to the system will typically be the same node as a zone outlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Slab In Node Name

This field is a node name used to identify the node that serves as the outlet (air side) of the ventilated slab. In EnergyPlus, nodes represent points between components or at various points in the loops. In a ventilated slab, the air outlet node from the system will typically be the same node as a zone inlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Zone Supply Air Node Name

This field is a node name used to identify the node that serves as the outlet from the system to zone. In EnergyPlus, nodes represent points between components or at various points in the loops. In a ventilated slab, the air outlet node from the system will typically be the same node as a zone inlet node. In the case of “SlabOnly” configuration, it should be left BLANK.

Although it has data in this field, it will be ignored for “SlabOnly” configuration. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Outdoor Air Node Name

This field is a node name used to identify the node associated with fresh air brought into the ventilated slab from the outdoor environment. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the ventilated slab.

Field: Relief Air Node Name

This field is a node name used to identify the node associated with air exhausted out of the ventilated slab to the outdoor environment. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the ventilated slab.

Field: Outdoor Air Mixer Outlet Node Name

This field is a node name used to identify the node associated with the “mixed” air of the ventilated slab. These conditions are post-“mixing box” since they are the conditions of the fraction of return air combined with the outdoor air. Since this is a simple system, this can also be viewed as the conditions of the air being sent to the coils. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the ventilated slab.

Field: Fan Outlet Node Name

This field is a node name used to identify the node that serves as the air outlet to fan before the ventilated slab. In EnergyPlus, nodes represent points between components or at various points in the loops. In a ventilated slab, the air outlet node from the fan is also considered the inlet node to the coils. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Fan Name

This field is the name of a fan (ref: Fan:ConstantVolume) that is part of the ventilated slab system. This name links the ventilated slab to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the ventilated slab system.

Field: Coil Option Type

This field allows the user to specify the coil operating options as one of the following options:

None Heating Cooling HeatingAndCooling

If **None** is selected, the ventilated slab does not have any coils, and any other input will be ignored. If either **Heating** or **Cooling** is selected, only a heating or cooling coil, respectively, is present. Thus, only four more inputs will be expected. If **HeatingAndCooling** is selected, both heating and cooling coil input must be entered, and the ventilated slab will have both a heating and a cooling coil.

Field: Heating Coil Object Type

This field is the type of coil (ref: Coil:Heating:Water, Coil:Heating:Electric, Coil:Heating:Gas, Coil:Heating:Steam) that is used for heating in the ventilated slab system. This field must be one of the following keywords: Coil:Heating:Water, Coil:Heating:Electric, Coil:Heating:Gas,

Coil:Heating:Steam. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system.

Field: Heating Coil Name

This field is the name of the heating coil that is part of the ventilated slab system. It is assumed that there is always some sort of heating coil associated with a ventilated slab system. This name links the ventilated slab to particular heating coil data entered elsewhere in the input data file.

Field: Hot Water or Steam Inlet Node Name

This field corresponds to the water inlet node to the heating coil for a water coil. The water inlet node controls how a water heating coil operates. This field is ignored/not needed for gas and electric heating coils.

Field: Cooling Coil Object Type

This field is the name of the cooling coil (ref: Coil:Cooling:Water, Coil:Cooling:Water:DetailedGeometry, CoilSystem:Cooling:Water:HeatExchangerAssisted) that is part of the ventilated slab system. This name links the ventilated slab system to particular cooling coil data entered elsewhere in the input data file. If no cooling coil is present, the previous field may be followed by a semi-colon and the remaining parameters in this statement may be ignored.

Field: Cooling Coil Name

This field is the name of the cooling coil that is part of the ventilated slab system. It is assumed that there is always some sort of cooling coil associated with a ventilated slab system. This name links the ventilated slab to particular cooling coil data entered elsewhere in the input data file.

Field: Cold Water Inlet Node Name

This field corresponds to the water inlet node to the cooling coil. The water inlet node controls how a water cooling coil operates and is required for the ventilated slab system that has a cooling coil associated with it to function properly.

The IDD definition for the ventilated slab system module is shown below.

Ventilated Slab Radiant Heating Rate [W]

This field reports the radiant heating input rate of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilated slab system.

Ventilated Slab Radiant Heating Energy [J]

This field is the heating radiant input of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilated slab system, and the timestep.

Ventilated Slab Radiant Cooling Rate [W]

This field reports the radiant cooling input rate to the ventilated slab system in Watts. This is the heat sink to the surface that is defined as the ventilated slab system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

Ventilated Slab Radiant Cooling Energy [J]

This field reports the radiant cooling input to the ventilated slab system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Ventilated Slab Coil Heating Rate [W]

This field reports the heating input rate of the heating coil of ventilated slab system the zone it is serving in Watts. This is determined by return air and zone air conditions and the mass flow rate through the ventilation slab system.

Ventilated Slab Coil Heating Energy [J]

This field is the heating output of the heating coil of the ventilated slab system the zone it is serving in Joules over the timestep being reported. This is determined by return air and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

Ventilated Slab Total Coil Cooling Rate [W]

This field reports the total cooling (sensible plus latent) output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

Ventilated Slab Total Coil Cooling Energy [J]

This field is the total cooling (sensible plus latent) output of the cooling coil of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

Ventilated Slab Sensible Coil Cooling Rate [W]

This field reports the sensible cooling output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

Ventilated Slab Sensible Coil Cooling Energy [J]

This field is the sensible cooling output of the cooling coil of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

Ventilated Slab Latent Coil Cooling Rate [W]

This field reports the latent cooling output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

Ventilated Slab Latent Coil Cooling Energy [J]

This field is the latent cooling output of the cooling coil of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

Ventilated Slab Air Mass Flow Rate [kg/s]

This field reports the mass flow rate of air through the ventilated slab system in kilograms per second.

Ventilated Slab Fan Electric Power [W]

This field reports the electric power consumption rate of the fan of the ventilated slab system in Watts.

Ventilated Slab Fan Electric Consumption [J]

This field reports the electric power consumed by the fan of the ventilated slab system over the timestep in Joules.

Ventilated Slab Slab Inlet Air Temperature [C]

This field reports the temperature of air entering the ventilated slab system in Celsius.

Ventilated Slab Slab Outlet Air Temperature [C]

This field reports the temperature of air leaving the ventilated slab system in Celsius.

Ventilated Slab Zone Inlet Air Temperature [C]

This field reports the temperature of air entering the zone in Celsius.

Ventilated Slab Return Air Temperature [C]

This field reports the temperature of air leaving the zone in Celsius. When system does not circulate air to zone ("SlabOnly" Configuration), the slab outlet temperature and return air temperature will be the same.

Ventilated Slab Fan Outlet Air Temperature [C]

This field reports the fan outlet air temperature for the ventilated slab system in Celsius.

ZoneHVAC:VentilatedSlab:SlabGroup

A ventilated slab system may consist of multiple active slabs that are serving to condition the zone. Slabs that act serially can be specified as multiple radiant systems using the standard ventilated slab input described above. This list of surfaces (the name it is assigned) replaces the name of a single surface in the ventilated slab system input described above.

Field : Name of Ventilated Slab Surface Group

This field is a unique user assigned name for the list of surfaces that are acting in coordination with one another. Any reference to this list by a ventilated slab system will use this name.

Field: Zone Name

This field is the name of the zone in which the surface is principally located and intended to affect.

Field: Surface Name

This field is the name of a surface in the zone being conditioned by the ventilated slab system. Only base surfaces like walls, floors and roofs are valid. Door/Window Surface and Internal Mass are not valid surface types for the ventilated slab system.

Field: Core Diameter

This field is the inside diameter of the cores through which air is circulated for the surface being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the circulated air to the inside surface of the ventilated slab.

Field: Core length

This field is the length of core embedded in the surface named above in the surface name field. In other words, this should be the distance that air travels as it through the slab. The length of the hollow core in the surface should be entered in meters and is used to determine the effectiveness of heat transfer from the air being circulated through the cores and the core inside surface. Longer core lengths result in more heat transferred to/from the radiant surface to the circulating fluid.

Field: Number of Cores

This field allows the user to specify how many cores there are in the ventilated slab. Air flow will be divided equally among the different cores.

Field: Slab Inlet Node Name

This field is a node name (character string) used to identify the node that serves as the inlet (air side) to the surface. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Slab Outlet Node Name

This field is a node name (character string) used to identify the node that serves as the outlet (air side) of the surface. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Group – Refrigeration

There are two ways to model a supermarket refrigeration system. The first uses one or more Refrigeration Case objects with a refrigeration compressor rack object (Ref. Refrigeration:Case and Refrigeration:CompressorRack). The second uses one or more Refrigeration Case objects with a refrigeration system (Ref. Refrigeration:Case and Refrigeration:System). The refrigeration system requires the use of a case list object, a compressor list object, one or more compressor objects, and one condenser object, which

may be either air-cooled, evaporative-cooled, or water-cooled (Ref. Refrigeration:CaseList, Refrigeration:CompressorList, Refrigeration:Compressor, Refrigeration:Condenser:AirCooled, Refrigeration:Condenser:EvaporativeCooled, or Refrigeration:Condenser:WaterCooled). The system may optionally use subcoolers (Ref. Refrigeration:Subcooler).

Refrigeration:CompressorRack

The refrigeration compressor rack object works in conjunction with the refrigeration case object (Ref. Refrigeration:Case) to simulate the performance of a refrigerated case system. This object models the electric consumption of the rack compressors and the condenser fans. Heat removed from the refrigerated cases and compressor/condenser fan heat can be rejected either outdoors or to a zone. Compressor rack waste heat can also be reclaimed for use by an optional air- or water-heating coil (Ref. Coil:Heating:Desuperheater and Coil:WaterHeating:Desuperheater).

If heat is rejected outdoors, condenser cooling can either be accomplished by direct air flow, evaporative water cooling, or a by water-cooled condenser with appropriate plant loop piping. With evaporative cooling, water is sprayed through the air stream to effectively lower the air temperature experienced by the condenser coil as a result of water evaporation. The use of a water-cooled condenser requires the definition of a plant loop to supply cooling to the condenser. Waste heat can be reclaimed and stored using a water storage device.

The inputs for the compressor rack object include a name, the heat rejection location, the compressor rack coefficient of performance (COP) at design conditions, the design condenser fan power, and the type of condenser cooling. The model requires two curve objects to describe performance at off-design conditions. If the condenser is water-cooled, the inlet and outlet node names as well as the water outlet temperature schedule name are required. If the condenser has evaporative cooling, additional inputs for evaporative condenser effectiveness, condenser air flow rate, basin heater parameters, water pump power, water source, and an evaporative cooling availability schedule are available. The names of refrigerated cases connected to the compressor rack are the final inputs to the model. Currently, up to six refrigerated cases can be connected to a single rack; however these fields are extensible.

Field: Name

A unique user-assigned name for an instance of a refrigeration compressor rack. Any reference to this compressor rack by another object will use this name.

Field: Heat Rejection Location

The location of the compressor rack's condenser. The compressor rack condenser heat can be directed "Outdoors" to model an outdoor air or water-cooled condenser or "Zone" to model a condenser located in a zone (e.g., a stand-alone packaged refrigerated case with integral condenser located in a conditioned zone). If the heat rejection location is "Zone", then all refrigerated cases connected to this compressor rack must be located in the same zone. The default for this field is "Outdoors".

NOTE: When modeling a heat reclaim coil, the heat rejection location must be "Outdoors". If the heat rejection location is "Zone", the total amount of waste heat available for reclaim (e.g., by a desuperheater heating coil) is set to zero by this compressor rack object and the simulation proceeds.

Field: Design Compressor Rack COP

The coefficient of performance (COP) for the compressor rack at design conditions (compressors only, excluding condenser fan power). This value must be greater than zero, with a default value of 2.0 if this field is left blank. This value should represent the compressor

rack COP corresponding to the lowest evaporating temperature of any case served by the rack.

Field: Compressor Rack COP Function of Temperature Curve Name

The name of the curve object defining the change in compressor rack COP as a function of the temperature of air entering the condenser. The curve object will be evaluated using the zone air dry-bulb temperature when rack heat rejection location equals “Zone” and the outdoor air dry-bulb temperature when rack heat rejection location equals “Outdoors” and the condenser type is air-cooled. As explained below, if the condenser is cooled by evaporative or water loop cooling, the curve object is evaluated using an effective temperature. The output from this curve is multiplied by the design compressor rack COP to yield the actual COP at the specific air temperature entering the condenser. This curve must be cubic or quadratic (Curve:Cubic or Curve:Quadratic), and should be normalized to 1.0 at the condenser entering air temperature at which the design compressor rack COP occurs. This curve should represent the compressor rack COP corresponding to the lowest evaporating temperature of any case served by the rack.

Field: Design Condenser Fan Power

This field defines the design power for the condenser fan(s) in Watts. This field is applicable for air or evaporative cooling only. If the condenser is water-cooled, the fan power is captured in the cooling object (e.g., cooling tower). If applicable, this value must be greater than 0.0, with a default value of 250 Watts if this field is left blank.

Field: Condenser Fan Power Function of Temperature Curve Name

This field is the name of the curve object defining the change in condenser fan power as a function of the temperature of air entering the condenser. This curve is used to simulate the modulation of air flow by the condenser fans (e.g., staging, multi-speed, or variable speed) as a function of temperature. The curve object will be evaluated using the zone air dry-bulb temperature when rack heat rejection location equals “Zone” and the outdoor air dry-bulb temperature when rack heat rejection location equals “Outdoors” and the condenser type is air-cooled. As explained below, if the condenser is cooled by evaporative cooling, the curve object is evaluated using an effective temperature. The output from this curve is multiplied by the design condenser fan power to yield the actual fan power at the specific air temperature entering the condenser. This curve must be cubic or quadratic (Curve:Cubic or Curve:Quadratic), and should be normalized to 1.0 at the condenser entering air temperature at which the design condenser fan power occurs. The actual condenser fan power is not allowed to exceed the design condenser fan power defined in the previous input field or go below zero (i.e., the output of the curve object is limited to values from 0.0 to 1.0). If this field is left blank, then the model assumes the condenser fan power is at the design power level when any of the refrigerated cases connected to this rack are operating.

Field: Condenser Type

When the heat rejection location is “Outdoors”, the condenser may be either cooled by dry air by specifying “AirCooled”, by wet evaporative cooling by specifying “EvaporativelyCooled”, or by a water loop by specifying “WaterCooled”. If the condenser type is “WaterCooled”, then a plant cooling loop will need to be defined using other EnergyPlus objects, e.g., plant loop, pump, cooling tower, etc. The default value is “AirCooled”.

Field: Water-cooled Condenser Inlet Node Name

When the condenser type is “WaterCooled”, a node name for the water-side condenser inlet must be provided.

Field: Water-cooled Condenser Outlet Node Name

When the condenser type is “WaterCooled”, a node name for the water-side condenser outlet must be provided.

Field: Water-cooled Loop Flow Type

When the condenser type is “WaterCooled”, the type of flow loop should be specified. The two choices are **VariableFlow**, in which a Pump:VariableSpeed needs to be included in the plant loop, or **ConstantFlow**, in which the loop circuit has a constant flow rate, typically associated with a Pump:ConstantSpeed object. If the flow type is VariableFlow, the flow needed to remove the condenser heat energy will be calculated and requested of the pump. If the flow type is Constant Flow, the outlet water temperature will be determined based on the fixed loop flow rate and heat energy to be removed. The default type is **VariableFlow**. Refer to additional discussion in the Engineering Reference.

Field: Water-cooled Condenser Outlet Temperature Schedule Name

When the water-cooled loop flow type is “Variable Flow”, the name of a schedule (Ref: Schedule) that defines the desired condenser water outlet temperature must be provided. The schedule may define an outlet temperature that varies through time.

Field: Water-cooled Condenser Design Volumetric Flow Rate

When the water-cooled loop flow type is “Constant Flow”, this is the design water flow rate in m^3/s that will be requested initially. This requested flow will be passed to the loop simulation, and resulting actual flow will be dependent upon supply system capabilities (e.g., pump capability). The design flow rate must always be less than the maximum flow rate, defined below.

Field: Water-cooled Condenser Maximum Volumetric Flow Rate

When the condenser type is “Water Cooled”, this is the maximum water flow rate in m^3/s that will be allowed through the condenser. When the loop flow type is Variable Flow, if the calculated flow rate is higher than the maximum flow rate, an error message will be generated, and the flow rate will be reset to the maximum flow rate.

Field: Water-cooled Condenser Maximum Water Outlet Temperature

This field specifies the maximum allowed water temperature in degrees C leaving the compressor rack condenser. The default value is 55 degrees C.

Field: Water-cooled Condenser Minimum Water Inlet Temperature

This field specifies the minimum allowed water temperature in degrees C entering the compressor rack condenser. The default value is 10 degrees C. Refer to additional discussion in the Engineering Reference.

Field: Evaporative Condenser Availability Schedule Name

For evaporative cooled condensers, the name of the optional schedule (Ref: Schedule) that specifies the time periods that evaporative cooling is available/unavailable. In some colder climates, evaporative cooling is periodically discontinued and the basin sumps drained to avoid freezing. In these times, the condenser runs as a typical dry air cooled condenser, and related evaporative cooling systems (e.g., water pump, basin heaters) do not operate. Use of this optional schedule permits modeling of planned, seasonal interruptions of evaporative cooling. All schedule values must be greater than or equal to zero. Typically, an ON/OFF schedule type is used with values being either 0 or 1. A schedule value of 1 indicates that evaporative cooling is available during the defined time period, and a value of 0 denotes that evaporative cooling is not available during the defined time period. If the schedule name is omitted (blank) and Condenser Type = “Evap Cooled”, then the model assumes that evaporative cooling of the condenser is available for the entire simulation period.

Field: Evaporative Condenser Effectiveness

This field specifies the effectiveness of the evaporative system in modifying the temperature of the air entering the condenser coil. The resulting effective temperature is determined as

$$T_{effective} = T_{owb} + (1 - \varepsilon) * [T_{odb} - T_{owb}]$$

where:

- $T_{effective}$ = effective dry-bulb temperature of air entering the condenser cooling coil (°C)
- T_{owb} = outdoor air wet-bulb temperature (°C)
- T_{odb} = outdoor air dry-bulb temperature (°C)
- ε = evaporative condenser effectiveness.

The resulting condenser inlet air temperature is used by the Compressor Rack COP as a Function of Temperature Curve and the Condenser Fan Power as a Function of Temperature Curve. The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = AirCooled. If the user wants to model an air-cooled condenser, they should simply specify "AirCooled" in the field Condenser Type.

If the two function-of-temperature curves (i.e., Compressor Rack COP as a Function of Temperature Curve and Condenser Fan Power as a Function of Temperature Curve) are based on wet-bulb temperature rather than dry-bulb temperature, the evaporative condenser effectiveness should be set to 1.0 for consistency.

Field: Evaporative Condenser Air Flow Rate

The air volume flow rate, in m³ per second, entering the evaporative condenser. This value is used to calculate the amount of water evaporated when evaporatively cooling the condenser inlet air. The value for this field must be greater than zero. This input field is also autocalculatable, equivalent to 0.000144 m³/s per watt of total cooling capacity [850 cfm/ton] where the total cooling capacity is the sum of the rated total cooling capacities for the refrigerated cases connected to this compressor rack (Ref. Refrigeration:Case). This field is not used when Condenser Type = AirCooled.

Field: Basin Heater Capacity

This field defines the power level of the basin heater, if applicable, used to avoid water freezing in an outdoor evaporative cooler basin. This numeric field contains the capacity of the electric basin heater in watts per degree Kelvin. This field is used in conjunction with the Basin Heater Set Point Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the dry-bulb temperature of the condenser coil inlet air. The basin heater only operates when the condenser fan is off (i.e., no compressor heat rejection). The basin heater capacity must be greater than or equal to zero, with a default value of 200 W/K if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this set point temperature, as long as the condenser fan is off. The default value is 2°C if this field is left blank.

Field: Design Evaporative Condenser Water Pump Power

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The value for this field must be greater than or equal to 0, with a default value of 1000 Watts if this field is left blank. This input field is also autocalculatable, equivalent to 0.004266 W per watt [15 W/ton] of total cooling capacity where the total cooling capacity is the sum of the rated total cooling capacities for the refrigerated cases connected to this

compressor rack (Ref. Refrigeration:Case). This field is not used when Condenser Type = AirCooled.

Field: *Evaporative Water Supply Tank Name*

This field is used to define where the compressor rack obtains water used for evaporative cooling of its condenser. If this field is left blank, the unit will obtain water directly from the mains (Ref. Water Mains Temperatures). If the name of a Water Storage Tank object is used here, then the unit will obtain its water from that tank. This field is not used when Condenser Type = Air Cooled.

Field: *Condenser Air Inlet Node Name*

This optional alpha field contains the name of the node from which the outdoor compressor rack condenser draws its outdoor air. This field is applicable only when the heat rejection location is "Outdoors" (if the heat rejection location is "Zone", this field is disregarded). If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, this node name must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: *End-Use Subcategory*

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: *Refrigeration:Case Name or CaseList Name*

This alpha field is the name of a single refrigerated case or the name of a caselist for multiple refrigerated cases connected to this compressor rack. This field is required.

Below is the input data dictionary definition for the Refrigeration Compressor Rack object.

Refrigeration Compressor Rack Electric Power [W]

This output is the electric power input to the rack compressor(s) in Watts.

Refrigeration Compressor Rack Electric Consumption [J]

This is the electricity consumption of the rack compressor(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Compressor Rack Condenser Fan Electric Power [W]

This output is the electric input to the rack condenser fan(s) in Watts.

Refrigeration Compressor Rack Condenser Fan Electric Consumption [J]

This is the electricity consumption of the rack condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Compressor Rack Total Heat Transfer Rate [W]

This output is the total heat transfer rate of the refrigeration compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases that are connected to this rack. This value does not include compressor or condenser fan heat.

Refrigeration Compressor Rack Total Heat Transfer [J]

This is the total heat transfer of the refrigeration compressor rack in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Compressor Rack COP [W/W]

This field is the refrigeration compressor rack coefficient of performance. It is the actual compressor rack COP for the timestep being reported, accounting for the COP variation as a function of temperature. It is calculated as the Design Compressor Rack COP times the Compressor Rack COP as a Function of Temperature Curve evaluated at the effective condenser entering air temperature for the timestep being reported.

Refrigeration Compressor Rack Evap Condenser Pump Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the compressor rack condenser.

Refrigeration Compressor Rack Evap Condenser Pump Elec Consumption [J]

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration Compressor Rack Evap Cond Basin Heater Elec Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the compressor rack condenser.

Refrigeration Compressor Rack Evap Cond Basin Heater Elec Consumption [J]

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the compressor rack condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End

Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter).

Refrigeration Compressor Rack Evap Condenser Water Consumption Rate [m³/s]

The volumetric flow rate in m³/s of water consumed while providing evaporative cooling of the compressor rack condenser.

Refrigeration Compressor Rack Evap Condenser Water Consumption [m³]

This is the water consumed by evaporation in m³ while providing evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Compressor Rack Condenser Mass Flow Rate [kg/s]

When condenser type is Water Cooled, this is the mass flow rate of water flowing through the water cooled condenser.

Compressor Rack Condenser Heat Transfer Rate [W]

When condenser type is Water Cooled, this is the total heat transfer across the condenser (i.e., compressor energy and case cooling).

Compressor Rack Condenser Heat Transfer Energy [J]

When condenser type is Water Cooled, this is the total heat energy flowing across the condenser for the timestep being reported.

Rack Sensible Heating Rate To Zone [W]

This field is the rate of sensible heating in Watts provided to the zone by condenser waste heat rejection, which impacts the zone air heat balance.

Rack Sensible Heating Energy To Zone [J]

This field is the sensible heating energy in Joules provided to the zone by condenser waste heat rejection for the timestep being reported.

Rack Sensible Heating Rate To HVAC Return Air [W]

This field is the rate of sensible heating in Watts provided by condenser waste heat rejection to the HVAC return air (zone return air path outlet node), which impacts the HVAC return air temperature. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

Rack Sensible Heating Energy To HVAC Return Air [J]

This field is the sensible heating energy in Joules provided by condenser waste heat rejection to the HVAC return air (zone return air path outlet node) for the timestep being reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigeration:Case

The Refrigeration Case object works in conjunction with a compressor rack or a refrigeration system object (Refrigeration:CompressorRack or Refrigeration:System) to simulate the performance of a refrigerated case system. The refrigerated case model uses performance information at rated conditions along with performance curves for latent case credits and defrost heat load to determine performance at off-rated conditions. Energy use for lights, fans and anti-sweat heaters is modeled based on inputs for nominal power, schedules, and control

type. The refrigerated case model accounts for the sensible and latent heat exchange with the surrounding environment (termed "case credits") which impacts the temperature and humidity in the zone where the case is located.

The Refrigeration Case object inputs include a case name, an availability schedule name, the zone name for the location of the case, and the temperature and relative humidity of the ambient (zone) air surrounding the refrigerated case at the rating conditions for case performance. Additional inputs include the total cooling capacity, latent heat ratio, and run time fraction of the refrigerated case at rated conditions. The case length and operating temperature (average temperature of air/products within the case) must also be specified.

The refrigerated case model requires two curves to describe performance at off-rated conditions (i.e., at different zone humidity levels): the latent case credit curve and the defrost energy correction curve. The user must enter cubic performance curves with the independent variable being user selectable (case temperature, zone relative humidity, or zone dewpoint temperature).

The user can select from six case defrost types, with additional inputs being required depending on the type selected. The user must enter a defrost schedule (unless Case Defrost Type = None), and an optional defrost drip-down schedule can be specified to allow additional time for melted frost to drain from the cooling coil following the regular defrost period.

Inputs are required for case fans, lights, and anti-sweat heaters. Case lighting can be controlled by the user through entering a schedule. The case fans operate whenever the cooling coil is operating and during defrost periods for certain case defrost types. Anti-sweat heater power can be controlled by several methods which are user selectable. The model assumes that the fans are contained within the thermal envelope of the case and provide a direct heat load on the case cooling coil. For lighting and anti-sweat heaters, the user can specify the fraction of their respective heat loads that directly impact the case cooling coil (with the remainder of their heat load impacting the surrounding zone air).

The user has the option of specifying a case restocking schedule and a schedule for modifying the case credits if needed. Finally, the user can specify the under case HVAC return air fraction which determines the portion of the case credits that directly impact the HVAC return air conditions (with the remainder of the case credits impacting the zone sensible and latent loads).

Field: Name

A unique user-assigned name for an instance of a refrigerated case. Any reference to this case by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the case will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the refrigerated case will operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, cases require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired.

Field: Zone Name

The name of the zone where the refrigerated case is located. The refrigerated case will impact the air heat balance in this zone. When modeling multiple refrigerated cases connected to a single compressor rack where the condenser heat is rejected to the zone (ref: Refrigeration:CompressorRack), **all** of the refrigerated cases connected to that compressor rack must be located in the same zone.

Field: Rated Ambient Temperature

Dry-bulb temperature of the ambient (zone) air surrounding the refrigerated case at the rating conditions for refrigerated case performance. The default value for this field is 23.9°C (75°F). This temperature must be greater than 0°C and greater than the case operating temperature.

Field: Rated Ambient Relative Humidity

Relative humidity of the ambient (zone) air surrounding the refrigerated case at the rating conditions for refrigerated case performance. The default value for this field is 55% RH.

Field: Rated Total Cooling Capacity per Unit Length

The total, full load cooling capacity (sensible plus latent) in watts per unit length of refrigerated case (W/m) at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, and Case Operating Temperature). The value entered for this field must be greater than zero, with a default value of 1900 W/m if the field is blank.

Field: Rated Latent Heat Ratio

The latent heat ratio (LHR=latent capacity divided by total cooling capacity) of the refrigerated case at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, and Case Operating Temperature). The value for this field can range from zero to 1.0, with a default value of 0.3 if the field is blank.

Field: Rated Runtime Fraction

The runtime fraction of the refrigerated case at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, and Case Operating Temperature). Even at rated conditions, refrigerated cases typically include additional cooling capacity to account for product stocking and recovery from defrost. The rated runtime fraction for refrigerated cases typically ranges from 0.8 to 0.9. The entered value for this field must be greater than 0.0 and less than or equal to 1.0, and the default value is 0.85 if the field is blank.

Field: Case Length

The length of the refrigerated case in meters. The entered value for this field must be greater than 0.0, and the default value is 3 meters if the field is blank.

Field: Case Operating Temperature

The average temperature of the air and products within the refrigerated case in °C. The refrigerated case manufacturer typically provides this information in the product literature. Typical operating temperatures for medium temperature cases are 1.6°C to 7.2°C (35°F to 45°F). Typical operating temperatures for low temperature cases are -28.9°C to -17.8°C (-20°F to 0°F). The entered value for this field must be less than 20°C and lower than the Rated Ambient Temperature. The default value is 1.1°C if the field is blank.

Field: Latent Case Credit Curve Type

This alpha field defines the form of the curve used to modify the latent case credits (latent heat removed from the zone where the refrigerated case is located) at off-rated conditions. The valid choices for this field are:

- CaseTemperatureMethod

This method defines the variation in latent case credits as a cubic function of Case Operating Temperature. The result from the cubic curve is multiplied by the difference between the rated ambient relative humidity and the actual zone relative humidity, and one minus this value is multiplied by the Rated LHR to give the operating LHR at the actual zone humidity condition.

- RelativeHumidityMethod

This method defines the variation in latent case credits as a cubic function of ambient (zone) air relative humidity.

- DewpointMethod

This method defines the variation in latent case credits as a cubic function of ambient (zone) air dewpoint temperature.

The default curve type is the Case Temperature Method. Refer to the Engineering Reference for further information on how latent case credits are modeled.

Field: Latent Case Credit Curve Name

The name of a **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the latent case credits at off-rated conditions. The curve should be normalized to have a value of 1.0 at the rated ambient air conditions defined above.

Field: Standard Case Fan Power per Unit Length

The total standard fan power in watts per unit length of refrigerated case (W/m). This value is representative of refrigerated cases with standard fans and is used to determine the sensible case credits. The entered value for this field must be greater than or equal to zero, and the default value is 75.0 W/m if the field is blank.

Field: Operating Case Fan Power per Unit Length

The total operating fan power in watts per unit length of refrigerated case (W/m). Enter the actual power for the installed fans. High efficiency fans may be modeled by inserting the high efficiency fan power in this field with the standard efficiency fan power inserted in the previous field (i.e., Standard Case Fan Power per Unit Length). The entered value for this field must be greater than or equal to zero, and the default value is 75.0 W/m if the field is blank.

Field: Standard Case Lighting Power per Unit Length

The total lighting power in watts per unit length of refrigerated case (W/m). This value should represent the standard lighting provided by the case manufacturer. If energy-efficient lights are being modeled, then use the next field (i.e. Case Lighting Schedule Name) to specify the name of a schedule that contains the fraction of the Standard Case Lighting Power per Unit Length to be modeled for each timestep of the simulation period. The entered value for this field must be greater than or equal to zero, and the default value is 90.0 W/m if the field is blank.

Field: Case Lighting Schedule Name

The name of the schedule (ref: Schedule) that denotes the fraction of refrigerated case lights that operate during a given time period. A schedule value greater than 0 indicates that the lights will operate during that time period (maximum schedule value of 1.0 means lights are fully on at the Standard Case Lighting Power per Unit Length level). A schedule value of zero denotes that the lights are off. The refrigerated case lights will typically operate only when the store is open for business and can be scheduled off as desired via this schedule. The user should enter the nominal lighting power for “standard” lights for the refrigerated case in the field Standard Case Lighting Power per Unit Length. If energy-efficient lights are used, the maximum case lighting schedule values may be 0.7 – 0.8 to account for the improved lighting efficiency.

Field: Fraction of Lighting Energy To Case

The fraction of the lighting energy that directly contributes to the case heat load. The remainder of the lighting energy (1 – fraction) is a heating load to the zone where the case is located. This field can be used to model lighting ballasts and bulbs located outside the air curtain of the refrigerated case. The value for this field can range from zero to 1.0, with a default value of 1.0 if the field is blank.

Field: Case Anti-Sweat Heater Power per Unit Length

The electric anti-sweat heater power in watts per unit length of refrigerated case (W/m). The entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

Field: Minimum Anti-Sweat Heater Power per Unit Length

The minimum electric anti-sweat heater power in watts per unit length of refrigerated case (W/m). Anti-sweat heater power will remain at or above this value for anti-sweat heater control types linear, dewpoint method, or heat balance method. Other anti-sweat heater control types disregard this field. The entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

Field: Anti-Sweat Heater Control Type

The type of anti-sweat heater control used for this refrigerated case. Valid choices are None, Constant, Linear, DewpointMethod, or HeatBalanceMethod. The default is None if the field is blank. Refer to the Engineering Reference for further information on how the different anti-sweat heater controls are modeled.

Field: Humidity at Zero Anti-Sweat Heater Energy

The value of this numeric field is only used when the Linear anti-sweat heater control type is selected. Enter the zone relative humidity where anti-sweat heater energy use is zero. Negative values for relative humidity may be entered. Other anti-sweat heater control types disregard this field. The value entered for this field must be less than the Rated Ambient Relative Humidity specified above. The default for this field is -10.0.

Field: Case Height

The value of this numeric field is used when Heat Balance Method anti-sweat heater control is selected. Enter the case height in meters. Other anti-sweat heater control types disregard this field. The entered value for this field must be greater than zero when Heat Balance Method anti-sweat heater control is selected, and the default value is 1.5 meters if the field is blank.

Field: Fraction of Anti-Sweat Heater Energy To Case

This value denotes the fraction of anti-sweat heater energy that results in a direct heat load to the refrigerated case. The remainder of the anti-sweat heater energy (1-fraction) is a heating load to the zone where the refrigerated case is located. The value for this field can range from zero to 1.0, with a default value of 1.0 if the field is blank.

Field: Case Defrost Power per Unit Length

The defrost power in watts per unit length of refrigerated case (W/m). This input is required for hot-gas or electric defrost types. Refrigerated case manufacturers do not typically provide information on the heat input for hot-gas defrost. Information provided for electric defrost power can be substituted here for refrigerated cases using hot-gas defrost if other information is not available. Only electric Case Defrost Types consume electricity during the defrost period. The entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

Field: Case Defrost Type

The type of defrost used for this refrigerated case. Valid choices are None, Off-Cycle, Hot-Gas, Hot-Gas with Temperature Termination, Electric, and Electric with Temperature Termination. The default defrost type is Off-Cycle if the field is blank. Refer to the Engineering Reference for further information on how the different case defrost types are modeled.

Field: Case Defrost Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case requires defrosting. A schedule value greater than 0 (maximum schedule value of 1.0 is usually used) indicates that defrost can be on during a given time period. A value equal to 0 denotes that the defrost is off. Defrost schedules normally repeat the duration and number of defrost cycles for each day of the year. The refrigerated case manufacturer typically provides this information with the product literature. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

Field: Case Defrost Drip-Down Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case requires additional time for draining condensate after the defrost period. A schedule value greater than 0 (maximum schedule value of 1.0 is usually used) indicates that the defrost drip-down period is on during a given time period. A value equal to 0 denotes that the defrost drip-down period is over. The refrigerated case manufacturer typically provides this information with the product literature.

Each defrost drip-down period specified in this schedule should start at the same time as the corresponding defrost period specified in the schedule for Case Defrost Schedule, and the drip-down schedule defrost period should always be longer than or equal to the length of the defrost schedule time period. For example, if the case defrost schedule contains a defrost period from 7:00 to 7:15, you would specify a case defrost drip-down period from 7:00 to 7:20 if you wanted to model a 5 minute condensate drip-down period after the regular defrost period. If no drip-down schedule is entered, then the case defrost schedule (specified for the previous input field) will be used. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

Field: Defrost Energy Correction Curve Type

This alpha field defines the form of the correction curve used to modify the defrost energy use (and the associated load on the case cooling coil) at off-rated conditions. The valid choices for this field are:

- None
This choice specifies that a defrost energy correction curve will not be used.
- CaseTemperatureMethod
This method defines the variation in defrost energy as a cubic function of Case Operating Temperature. The result from the cubic curve is multiplied by the difference between the rated ambient relative humidity and the actual zone relative humidity, and one minus this value is multiplied by the Case Defrost Power to give the (average) operating defrost power at the actual zone humidity condition.
- RelativeHumidityMethod
This method defines the variation in defrost energy as a cubic function of ambient (zone) air relative humidity.
- DewpointMethod
This method defines the variation in defrost energy as a cubic function of ambient (zone) air dewpoint temperature.

The default curve type is None. The methods described here (e.g. Case Temperature, Relative Humidity, and Dewpoint) are applicable only to Electric with Temperature Termination and Hot-Gas with Temperature Termination case defrost types. Refer to the Engineering Reference for further information on how the defrost energy correction types are modeled.

Field: Defrost Energy Correction Curve Name

The name of a **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the defrost energy (and the associated load on the case cooling coil) at off-rated conditions. The curve should be normalized to have the value of 1.0 at the rated ambient air conditions defined above. The defrost energy correction curve name is used only for the Electric with Temperature Termination and Hot-Gas with Temperature Termination case defrost types.

Field: Under Case HVAC Return Air Fraction

This field denotes the fraction of HVAC system (air loop) return air that passes beneath the refrigerated case, if any. At times it is necessary to design HVAC systems with under case returns to avoid overcooling the area around the refrigerated case, thus providing a more comfortable environment for the zone occupants. This return air fraction affects the portion of the case credits (sensible and latent) that are applied to the air returning to the HVAC system, while the remainder of the case credits directly impacts the zone air heat balance. Refer to the Engineering Reference for further information on how this is modeled. The sum of the Under Case HVAC Return Air Fractions for all refrigerated cases located in a single zone must be less than or equal to 1.0. The value for this field can range from zero to 1.0, with a default value of 0 if the field is blank.

Field: Refrigerated Case Restocking Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case is being restocked with product. The schedule should contain values in units of Watts per unit length of refrigerated case (W/m). This field can be used to denote the additional load imposed on the refrigerated case from stocking the case with product that is warmer than the refrigerated case temperature. This information is difficult to find and may require additional research for proper modeling; however, this schedule is available for this purpose if desired. If restocking of the refrigerated case will not be simulated, enter a schedule with values of zero for all time periods or leave this field blank.

Field: Case Credit Fraction Schedule Name

The name of the schedule (ref: Schedule) that denotes a fraction of both the sensible and latent case credits to be applied to the zone and/or the HVAC system return air. Schedule values must be from 0 to 1. This allows correction of the case credits for various refrigerated case types. For instance, if glass door refrigerated display cases are installed in a store that is operated 12 hours per day, then the doors will remain closed during the unoccupied times and would therefore reduce the sensible and latent case credits during the unoccupied time. Leaving this field blank will result in no case credit fraction being applied during the simulation.

Field: Design Evaporator Temperature

The value of this numeric field is used only with the refrigeration system and is not read for the compressor-rack system. For the refrigeration system, it is used to evaluate compressor performance and is also used when the evaporator pressure and temperature are allowed to float at load less than the design load. The minimum value is -70C and the maximum value is 40C. The default value is 5C less than the case temperature.

Field: Average Refrigerant Charge Inventory

The value of this optional field is the refrigerant inventory present in the refrigerated case during ordinary operation. The value is used to produce an estimate of the total refrigerant present in the refrigeration system. The value is entered in kg/m.

Below is the input data dictionary description for the Refrigeration:Case object.

Refrigerated Case Evaporator Total Heat Transfer Rate [W]

This field is the total (sensible plus latent) cooling rate of the refrigerated case evaporator coil in Watts.

Refrigerated Case Evaporator Total Heat Transfer [J]

This field is the total (sensible plus latent) cooling of the refrigerated case evaporator coil in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Refrigerated Case Evaporator Sensible Heat Transfer Rate [W]

This field is the sensible cooling rate of the refrigerated case evaporator coil in Watts.

Refrigerated Case Evaporator Sensible Heat Transfer [J]

This field is the sensible cooling of the refrigerated case evaporator coil in Joules over the timestep being reported.

Refrigerated Case Evaporator Latent Heat Transfer Rate [W]

This field is the latent cooling (dehumidification) rate of the refrigerated case evaporator coil in Watts.

Refrigerated Case Evaporator Latent Heat Transfer [J]

This field is the latent cooling (dehumidification) of the refrigerated case evaporator coil in Joules over the timestep being reported.

Refrigerated Case Sensible Cooling Zone Credit Rate [W]

This field is the rate of sensible cooling case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

Refrigerated Case Sensible Cooling Zone Credit Energy [J]

This field is the amount of sensible cooling case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

Refrigerated Case Sensible Heating Zone Credit Rate [W]

This field is the rate of sensible heating case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

Refrigerated Case Sensible Heating Zone Credit Energy [J]

This field is the amount of sensible heating case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

Refrigerated Case Latent Zone Credit Rate [W]

This field is the rate of latent cooling (dehumidification) case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the latent case credits are applied to the zone. A negative value (or zero) will be reported since the refrigerated case provides dehumidification (thereby reducing the zone latent load).

Refrigerated Case Latent Zone Credit Energy [J]

This field is the amount of latent cooling (dehumidification) case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the latent case credits are applied to the zone. A negative value (or zero) will be reported since the refrigerated case provides dehumidification (thereby reducing the zone latent load).

Refrigerated Case Sensible Cooling HVAC RA Credit Rate [W]

This field is the rate of sensible cooling case credits delivered to the return air duct (zone return air node) in Watts. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is cooled by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible cooling is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Sensible Cooling HVAC RA Credit Energy [J]

This field is the amount of sensible cooling case credit energy delivered to the return air duct (zone return air node) in Joules. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is cooled by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible cooling is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Sensible Heating HVAC RA Credit Rate [W]

This field is the rate of sensible heating case credits delivered to the return air duct (zone return air node) in Watts. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is heated by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Sensible Heating HVAC RA Credit Energy [J]

This field is the amount of sensible heating case credit energy delivered to the return air duct (zone return air node) in Joules. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is heated by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Latent HVAC RA Credit Rate [W]

This field is the rate of latent cooling (dehumidification) case credits delivered to the return air duct (zone return air node) in Watts. If an under case return duct is simulated, a portion of the latent case credits are applied to the HVAC (zone) return air. A negative value (or zero) will be reported in all cases since the refrigerated case provides dehumidification (thereby reducing the zone latent load). If the HVAC system is off for a simulation timestep (no return air mass flow), then this latent energy is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Latent HVAC RA Credit Energy [J]

This field is the amount of latent cooling (dehumidification) case credit energy delivered to the return air duct (zone return air node) in Joules. If an under case return duct is simulated, only a portion of the latent case credits are applied to the HVAC (zone) return air. A negative value (or zero) will be reported since the refrigerated case provides dehumidification (thereby reducing the zone latent load). If the HVAC system is off for a simulation timestep (no return air mass flow), then this latent energy is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Evaporator Fan Electric Power [W]

This field is the electric power input to the refrigerated case fan(s) in Watts.

Refrigerated Case Evaporator Fan Electric Consumption [J]

This field is the electricity consumption of the refrigerated case fan(s) in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Refrigerated Case Lighting Electric Power [W]

This field is the electric power input to the refrigerated case lights in Watts.

Refrigerated Case Lighting Electric Consumption [J]

This field is the electricity consumption of the refrigerated case lights in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Refrigerated Case Defrost Energy Correction Curve Value

This field is the output of the Defrost Energy Correction Curve which denotes the variation in defrost energy at off-rated conditions. The output of the defrost energy correction curve directly impacts the energy used during the defrost time period. It does not, however, impact

the duration of the defrost period. This output is available only for Electric with Temperature Termination or Hot-Gas with Temperature Termination case defrost types.

Refrigerated Case Latent Case Credit Curve Value

This field is the output of the Latent Case Credit Curve which denotes the variation in latent case credits at off-rated conditions. The output of the latent case credit curve directly impacts the amount of frost formation on the refrigerated case evaporator coil and the requirement for defrost.

Refrigerated Case Anti-Sweat Heater Electric Power [W]

This field is the electric power input to the refrigerated case anti-sweat heater in Watts. This output is available unless anti-sweat heater control type is specified as NONE.

Refrigerated Case Anti-Sweat Heater Electric Consumption [J]

This field is the total electricity consumption of the refrigerated case anti-sweat heater in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter). This output is available unless anti-sweat heater control type is specified as NONE.

Refrigerated Case Defrost Electric Power [W]

This field is the electric power input to the refrigerated case electric defrost heater(s) in Watts. This output is available if case defrost type is Electric or Electric with Temperature Termination.

Refrigerated Case Defrost Electric Consumption [J]

This field is the total electricity consumption of the refrigerated case electric defrost heater(s) in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter). This output is available if case defrost type is Electric or Electric with Temperature Termination.

Refrigeration:System

The refrigeration system works in conjunction with the case list object, the Refrigeration Case object, the compressor list object, the compressor object, and an optional subcooler object (Ref. Refrigeration:System, Refrigeration:CaseList, Refrigeration:Case, Refrigeration:CompressorList, Refrigeration:Compressor, and Refrigeration:Subcooler) to simulate the performance of a supermarket refrigeration system. Heat is rejected outdoors in a condenser by direct air flow, evaporative water cooling, or by a water-cooled condenser with appropriate plant loop piping. With evaporative cooling, water is sprayed through the air stream to effectively lower the air temperature experienced by the condenser coil as a result of water evaporation. The use of a water-cooled condenser requires the definition of a plant loop to supply cooling to the condenser (ref: Refrigeration:Condenser:AirCooled, Refrigeration:Condenser:EvaporativeCooled, Refrigeration:Condenser:WaterCooled). The system object coordinates the energy flows between the other refrigeration objects and is used to set system parameters. Compressor waste heat can also be reclaimed for use by an optional air- or water-heating coil (Ref. Coil:Heating:Desuperheater and Coil:WaterHeating:Desuperheater).

The inputs for the refrigeration system object include a name, the name of a single refrigerated case or a list of refrigerated cases, the name of the condenser, the name of a single compressor or a list of compressors, the minimum condensing temperature, the refrigeration system working fluid, the names of any subcoolers, and the type of suction temperature control.

Field: Name

A unique user-assigned name for an instance of a refrigeration system. Any reference to this refrigeration system by another object will use this name.

Field: Refrigeration Case or Case List Name

Identifies a single case, or a particular list of refrigerated cases, that are cooled by this refrigeration system. The name will be validated against the case or caselist names (ref: List:Refrigeration:Cases) in the input file.

Field: Refrigeration Condenser Name

The name of the condenser that is used to reject heat from this refrigeration system. The name will be validated against the condenser names (ref: Refrigeration:Condenser:AirCooled, Refrigeration:Condenser:WaterCooled, and Refrigeration:Condenser:EvapCooled) in the input file.

Field: Compressor or Compressor List Name

Identifies a single compressor, or a particular list of compressors, that provide cooling energy to this refrigeration system. The name will be validated against the compressor list names (ref: List:Refrigeration:Compressors) in the input file.

Field: Minimum Condensing Temperature

This numeric field specifies the minimum condensing temperature (C), which is usually determined by the temperature required to maintain acceptable thermal expansion valve performance.

Field: Refrigeration System Working Fluid Type

The type of refrigerant used by the system. Valid choices are R11, R123, R134A, R12, R22, R404A, R507A, or R410A. This name will be validated against Fluid Names (ref: Fluid Properties section) in the input file. Note that the corresponding property data, available in FluidPropertiesRefData.idf, must be supplied in the input file.

Field: Suction Temperature Control Type

The type of suction temperature control used by the system. Valid choices are **FloatSuctionTemperature** and **ConstantSuctionTemperature**. If the field is blank, the default will be **ConstantSuctionTemperature**. See the Engineering Reference section, Variable Evaporator Temperature, for a discussion of this option.

Field: Mechanical Subcooler Name

This optional field identifies a particular mechanical subcooler that provides cooling to this refrigeration system. The name will be validated against the subcooler names (ref: Refrigeration:Subcooler) in the input file.

Field: Liquid Suction Heat Exchanger Subcooler Name

This optional field identifies a particular liquid suction heat exchanger (LSHX) subcooler present in this refrigeration system. The name will be validated against the subcooler names (ref: Refrigeration:Subcooler) in the input file.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Refrigeration System Total Compressor Electric Power [W]

This output is the total electric power input to the systems compressor(s) in Watts.

Refrigeration System Total Compressor Electric Consumption [J]

This is the electricity consumption of the system’s compressor(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration System Average Compressor COP [W/W]

This output is the system average compressor COP, the total refrigeration effect divided by the total power to the compressors

Refrigeration System Total Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the Refrigeration Compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and subcoolers that are connected to this system. This value does not include compressor or condenser fan heat.

Refrigeration System Total Compressor Heat Transfer Energy [J]

This is the total heat transfer of the Refrigeration Compressor rack in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration System Total Cases Heat Transfer Rate [W]

This output is the total heat transfer rate of the from the refrigerated cases served by this system in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases that are connected to this rack. This value does not include compressor or condenser fan heat.

Refrigeration System Estimated Refrigerant Inventory [kg]

This output is the sum of the input inventory values for the condenser, receiver, cases, and liquid pipes that are a part of this system.

Refrigeration System Estimated Refrigerant Mass Flow [kg/s]

This output is the calculated refrigerant mass flow through the compressors for this system.

Refrigeration System Condensing Temperature [C]

This is the saturated condensing temperature.

Refrigeration System Evaporating Temperature [C]

This is the saturated evaporating temperature.

Refrigeration System Suction Temperature [C]

This is the temperature at the compressor inlet including superheat after the cases and superheat from any liquid suction heat exchangers.

Refrigeration System Liquid Temperature to TXV [C]

This is the temperature entering the thermal expansion valve before the cases, equal to the condensing temperature minus any subcooling included in the condenser or provided by mechanical or liquid suction heat exchanger subcoolers.

Refrigeration:CompressorList

This object provides a list of all the compressors included within a single refrigeration system (Ref: Refrigeration:System). Each list must contain at least one compressor. The order in which the individual compressors are listed here will be the order in which the compressors are dispatched to meet the system load. That is, at very low loads, only compressor #1 will be operating. As the load increases, the first two compressors will be operating, and so on. This list is extensible.

Field: Name

A unique user-assigned name for an instance of a compressor list. Any reference to this compressor list by another object will use this name.

Field: Refrigeration Compressor <x> Name

Identifies a particular compressor that works in conjunction with the other compressors on this list to provides cooling to a single refrigeration system. The name will be validated against the compressor names (ref: Refrigeration:Compressor) in the input file. Up to 20 are available in the IDD; this object is extensible.

Below is the input data dictionary description for the List:Refrigeration:Compressors object.

```
Refrigeration:CompressorList,

  CompressorC;              !- Refrigeration Compressor Name #3
```

Refrigeration:CaseList

This object provides a list of all the refrigerated cases cooled by a single refrigeration system (ref: Refrigeration:System). This list is extensible.

Field: Name

A unique user-assigned name for an instance of a case list. Any reference to this case list by another object will use this name.

Field: Case <x> Name

Identifies a particular refrigerated case. The name will be validated against the Refrigeration Case names (ref: Refrigeration:Case) in the input file. Up to 20 are provided in the IDD; this object is extensible.

Below is the input data dictionary description for the List:Refrigeration:Cases object.

```

```

Refrigeration:Compressor

The compressors are described here using manufacturer's data for curves that provide the efficiency, cooling capacity, and power consumption. The corresponding rated values for cycle superheat and subcooling are also required. A dataset has been provided containing the compressor rating data, including the performance curve inputs, for a large number of compressors. See RefrigerationCompressorCurves.idf.

Field: Refrigeration Compressor Name

A unique user-assigned name for an instance of a compressor. Any reference to this compressor by another object will use this name.

Field: Refrigeration Compressor Power Curve Name

This required field provides the name of the curve object that describes the compressor power as a function of the evaporating and condensing temperatures, as specified in ARI 540. The curve is of the bicubic form(ref: Curve:Bicubic). However, the input order for the Energy Plus bicubic curve does not match the ARI 540 standard order. When this curve is entered, the user should use the following assignments:

N1 is ARI C1 and N2 is ARI C2.
N3 is ARI C4 and N4 is ARI C3.
N5 is ARI C6 and N6 is ARI C5,
N7 is ARI C7.
N8 is ARI C10, N9 is ARI C8, and N10 is ARI C9.
N11 is the Minimum evaporating temperature and N12 is the Maximum evaporating temperature.
N13 is the the Minimum condensing temperature and N14 is the Maximum condensing temperature

Field: Refrigeration Compressor Capacity Curve Name

This required field provides the name of the curve object that describes the compressor cooling capacity as a function of the evaporating and condensing temperatures, as specified in ARI 540. The curve is of the bicubic form(ref: Curve:Bicubic). However, the input order for the Energy Plus bicubic curve does not match the ARI 540 standard order. When this curve is entered, the user should use the following assignments:

N1 is ARI C1 and N2 is ARI C2.
N3 is ARI C4 and N4 is ARI C3.
N5 is ARI C6 and N6 is ARI C5,
N7 is ARI C7.
N8 is ARI C10, N9 is ARI C8, and N10 is ARI C9.
N11 is the Minimum evaporating temperature and N12 is Maximum evaporating temperature.
N13 is the Minimum condensing temperature and N14 is the Maximum condensing temperature

Field: Superheat Rating Type

The type of rating information provided by the compressor manufacture consistent with the curves input for capacity, mass flow, and power consumption. Valid choices are RatedSuperheat and RatedReturnGasTemperature. Some manufacturers specify a constant return gas temperature. This corresponds to the type, RatedReturnGasTemperature. Some manufacturers specify a constant superheat (the difference between the saturated evaporating temperature and the actual return gas temperature). This corresponds to the RatedSuperheat choice.

Field: Compressor Rated Suction Temperature

This numeric field is the either the rated return gas temperature, or the rated superheat (C) as stated by the compressor manufacturer corresponding to the rating curves and as identified by the Superheat Rating Type.

Field: Subcooling Rating Type

The type of rating information provided by the compressor manufacture consistent with the curves input for capacity, mass flow, and power consumption. Valid choices are RatedSubcooling and RatedLiquidTemperature. Some manufacturers specify a constant liquid temperature. This corresponds to the type, RatedLiquidTemperature. Some manufacturers specify a constant subcooling (the difference between the saturated condensing temperature and the actual liquid temperature). This corresponds to the RatedSubcooling choice.

Field: Compressor Rated Subcooling

This numeric field is either the rated liquid temperature or the rated subcooling (C) as stated by the compressor manufacturer corresponding to the rating curves and consistent with the Subcooling Rating Type.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature System"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Refrigeration:Compressor Outputs

Zone,Average,Refrigeration Compressor Electric Power [W]
Zone,Sum,Refrigeration Compressor Electric Energy [J]
Zone,Average,Refrigeration Compressor Heat Transfer Rate [W]
Zone,Sum,Refrigeration Compressor Heat Transfer Energy [J]

Refrigeration Compressor Electric Power [W]

This output is the electric power input to the compressor in Watts.

Refrigeration Compressor Electric Energy [J]

This is the electric energy consumed by the compressor in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Compressor Heat Transfer Rate [W]

This output is the heat removed from the refrigerated cases by the compressor in Watts.

Refrigeration Compressor Heat Transfer Energy [J]

This is the heat removed from the refrigerated cases by the compressor in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration:Subcooler

Two types of subcoolers are modeled by the detailed refrigeration system. As described in the Engineering Reference, the liquid suction heat exchanger uses cool suction gas to subcool the hot condensate after it leaves the condenser and before it reaches the thermal expansion valve. For the liquid suction heat exchanger, both the source and sink of energy are located within the same refrigeration system. In contrast, a mechanical subcooler is used to transfer cooling capacity from one refrigeration system to another. The mechanical subcooler is listed as a part of the system for which the condensate is cooled. However, the input data for the mechanical subcooler includes a field that identifies the system that provides the cooling capacity.

Field: Name

A unique user-assigned name for an instance of a subcooler. Any reference to this subcooler by another object will use this name.

Field: Subcooler Type

The type of subcooler. Valid choices are Mechanical and LiquidSuction. If the field is blank, the default will be LiquidSuction.

Field: Liquid Suction Design Subcooling Temperature

This numeric field is the design subcooling (C) for a liquid suction heat exchanger and should be blank for a mechanical subcooler.

Field: Design Liquid Inlet Temperature

This numeric field is the design inlet temperature for the hot liquid entering a liquid suction heat exchanger and should be blank for a mechanical subcooler.

Field: Design Vapor Inlet Temperature

This numeric field is the design inlet temperature for the cool vapor entering a liquid suction heat exchanger and should be blank for a mechanical subcooler.

Field: Capacity-Providing System

This field is the name of the refrigeration system object that provides the cooling capacity for the mechanical subcooler (ref: Refrigeration:System Name). This field should be blank for a liquid suction heat exchanger.

Field: Outlet Control Temperature

This numeric field is the controlled outlet temperature (C) for subcooled liquid exiting a mechanical subcooler. This field should be blank for a liquid suction heat exchanger.

Below is the input data dictionary description for the Refrigeration:Subcooler object.

Refrigeration:Subcooler Outputs

```

Zone,Average, Refrigeration Liquid Suction Subcooler Load Transfer Rate [W]
Zone,Average, Refrigeration Mechanical Subcooler Load Transfer Rate [W]

```

Refrigeration Liquid Suction Subcooler Load Transfer Rate [W]

This output is the energy transferred from the refrigerant before it enters the thermal expansion valve to the refrigerant leaving the refrigerated cases in Watts.

Refrigeration Mechanical Subcooler Load Transfer Rate [W]

This output is the cooling energy transferred from one system's compressor group to the refrigerant leaving the condenser for another refrigeration system in Watts.

Refrigeration:Condenser:AirCooled

The refrigeration system requires a single condenser. The air cooled condenser object is one of three options for this condenser. In an air-cooled condenser, the total heat of rejection is characterized by a linear relationship between the difference between the outside drybulb and condensing temperatures. This curve is commonly found in the condenser manufacturers' literature. This rating curve, which corresponds to ARI 460 standards, also has an associated rated value for subcooling that should be entered. The rated condenser fan power and fan speed control type must be specified. If the condenser is not at ground level, the user may specify an air inlet node name (ref: OutdoorAir:Node name). Optional input is provided to help the user compare refrigerant inventories for different systems. These inputs represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

Field: Name

Identifies a particular condenser that rejects heat for a single refrigeration system. The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser) in the input file, including names used for evaporative- and water-cooled condensers.

Field: Rated Effective Total Heat Rejection Rate Curve Name

This field is the name of a curve object defining the condenser heat rejection as a function of the difference between the condensing and entering air temperatures. The curve should be linear (Curve:Linear). See the Engineering Reference for more discussion on the curve coefficients.

Field: Rated Subcooling Temperature

This numeric field specifies the rated subcooling (C) specified by the manufacturer, consistent with the heat rejection curve rating data.

Field: Condenser Fan Speed Control Type

The type of fan speed control used by the condenser fan. Valid choices are **Fixed**, **VariableSpeed**, and **TwoSpeed**. If the field is blank, **Fixed** will be used. See the Engineering Reference for a discussion of this option's effect on fan energy consumption.

Field: Rated Fan Power

This numeric field specifies the rated fan power (W) specified by the manufacturer, under standard rating conditions.

Field: Air Inlet Node Name

This optional alpha field contains the name of the node from which the condenser draws its outdoor air. If this field is left blank, the outdoor air drybulb temperature entering the condenser is taken directly from the weather data. If this field is not blank, this node name must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

Field: Condensate Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

```

Refrigeration System Condenser Fan Electric Power [W]

This output is the electric input to the system's condenser fan(s) in Watts.

Refrigeration System Condenser Fan Electric Energy [J]

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration System Condenser Heat Transfer Rate [W]

This is the total heat transfer across the condenser (i.e., compressor energy and case cooling).

Refrigeration System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported.

Refrigeration:Condenser:EvaporativeCooled

Each refrigeration system requires a single condenser. The evaporative cooled condenser object is one of three options for this condenser. In an evaporative-cooled condenser, the total heat of rejection is characterized by a four-factor relationship between the difference between the outside wetbulb and condensing temperatures. This curve must be developed by regression from the condenser manufacturers' literature. This rating curve, which is based upon rated data taken according to ARI 460 standards, also has an associated rated value for subcooling that should be entered. The rated condenser fan power and fan speed control type must be specified. If the condenser is not at ground level, the user may specify an air inlet node name (ref: OutdoorAir:Node name). Optional input is provided to help the user compare refrigerant inventories for different systems. These input represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

Additional inputs are needed for basin heater parameters, water pump power, water source, and an evaporative cooling availability schedule are available.

Field: Name

Identifies a particular condenser that rejects heat for a single refrigeration system. The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser) in the input file, including names used for air- and water-cooled condensers.

Field: Rated Effective Total Heat Rejection Rate

This numeric field should be the rated heat rejection effect (W) at standard rating conditions per ARI 490. Be sure the rating corresponds to the correct refrigerant.

Field: Rated Subcooling Temperature

This numeric field specifies the rated subcooling (C) specified by the manufacturer, consistent with the rated value for total heat rejection.

Field: Fan Speed Control Type

The type of fan speed control used by the condenser fan. Valid choices are **Fixed**, **VariableSpeed**, and **TwoSpeed**. If the field is blank, **Fixed** will be used. See the Engineering Reference for a discussion of this option's effect on fan energy consumption.

Field: Rated Fan Power

This numeric field specifies the rated fan power (W) specified by the manufacturer, under standard rating conditions.

Field: Approach Temperature Constant Term

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$(T_{\text{condense}} - T_{\text{wetbulb}}) = A1 + A2(\text{hrCF}) + A3/(\text{hrCF}) + A4(T_{\text{wb}})$$

This numeric field is the value for A1 and has a default value of 6.63, a minimum of 0. and a maximum of 20. (C)

Field: Approach Temperature Coefficient 2

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$(T_{\text{condense}} - T_{\text{wetbulb}}) = A1 + A2(\text{hrCF}) + A3/(\text{hrCF}) + A4(T_{\text{wb}})$$

This numeric field is the value for A2 and has a default value of 0.468, a minimum of 0, and a maximum of 20 (C).

Field: Approach Temperature Coefficient 3

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$(T_{\text{condense}} - T_{\text{wetbulb}}) = A1 + A2(\text{hrCF}) + A3/(\text{hrCF}) + A4(T_{\text{wb}})$$

This numeric field is the value for A3 and has a default value of 17.93, a minimum of 0, and a maximum of 30 (C).

Field: Approach Temperature Coefficient 4

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$(T_{\text{condense}} - T_{\text{wetbulb}}) = A1 + A2(\text{hrCF}) + A3/(\text{hrCF}) + A4(T_{\text{wb}})$$

This numeric field is the value for A4 and has a default value of -0.322, a minimum of -20., and a maximum of 20 (dimensionless).

Field: Minimum Capacity Factor

This numeric field is the minimum heat rejection capacity factor in the manufacturer's data used to develop the equation described in the preceding four fields. The default value is 0.5.

Field: Maximum Capacity Factor

This numeric field is the maximum heat rejection capacity factor in the manufacturer's data used to develop the equation described in the preceding four fields. The default value is 5.0.

Field: Air Inlet Node Name

This optional alpha field contains the name of the node from which the condenser draws its outdoor air.. If this field is left blank, the outdoor air drybulb temperature entering the condenser is taken directly from the weather data. If this field is not blank, this node name must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Rated Air Flow Rate

The air volume flow rate, in m³ per second, entering the evaporative condenser. This value is used to calculate the amount of water evaporated when evaporatively cooling the condenser inlet air. The value for this field must be greater than zero. This input field is also

autocalculatable, equivalent to 0.000144 m³/s per watt of total cooling capacity [850 cfm/ton] where the total cooling capacity is the total heat of rejection.

Field: Basin Heater Capacity

This field defines the power level of the basin heater, if applicable, used to avoid water freezing in an outdoor evaporative cooler basin. This numeric field contains the capacity of the electric basin heater in Watts per degree C. This field is used in conjunction with the Basin Heater Set Point Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the dry-bulb temperature of the condenser coil inlet air. The basin heater only operates when the condenser fan is off (i.e., no compressor heat rejection). The basin heater capacity must be greater than or equal to zero, with a default value of 200 W/C if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this set point temperature, as long as the condenser fan is off. The default value is 2°C if this field is left blank.

Field: Rated Water Pump Power

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The value for this field must be greater than or equal to 0, with a default value of 1000 Watts if this field is left blank. This input field is also autocalculatable, equivalent to 0.004266 W per Watt [15 W/ton] of total cooling capacity.

Field: Evaporative Water Supply Tank Name

This field is used to define where the condenser obtains water used for evaporative cooling. If this field is left blank, the unit will obtain water directly from the mains (Ref. Water Mains Temperatures). If the name of a Water Storage Tank object is used here, then the unit will obtain its water from that tank.

Field: Evaporative Condenser Availability Schedule Name

For evaporative cooled condensers, the name of the optional schedule (Ref: Schedule) that specifies the time periods that evaporative cooling is available/unavailable. In some colder climates, evaporative cooling is periodically discontinued and the basin sumps drained to avoid freezing and to avoid ice formation on the condenser. In these times, the condenser runs as a typical dry air cooled condenser, and related evaporative cooling systems (e.g., water pump, basin heaters) do not operate. Use of this optional schedule permits modeling of planned, seasonal interruptions of evaporative cooling. All schedule values must be greater than or equal to zero. Typically, an ON/OFF schedule type is used with values being either 0 or 1. A schedule value of 1 indicates that evaporative cooling is available during the defined time period, and a value of 0 denotes that evaporative cooling is not available during the defined time period. If the schedule name is omitted (blank), then the model assumes that evaporative cooling of the condenser is available for the entire simulation period. Note: the use of this schedule is the correct way to model an evaporative condenser in a climate subject to freezing weather. However, because some users will take a single model description and run it for a multiple climates, the code also includes an automatic switch from wet to dry operation, as described in the Engineering Reference.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref:

Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

Field: Condensate Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

Below is the input data dictionary description for the object.

Refrigeration System Condenser Fan Electric Power [W]

This output is the electric input to the system’s condenser fan(s) in Watts.

Refrigeration System Condenser Fan Electric Energy [J]

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration System Condenser Heat Transfer Rate [W]

This is the total heat transfer across the condenser (i.e., compressor energy and case cooling) in Watts.

Refrigeration System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported.

Refrigeration System Condenser Pump Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the condenser.

Refrigeration System Condenser Pump Electric Energy [J]

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration System Condenser Basin Heater Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the condenser.

Refrigeration System Condenser Basin Heater Electric Energy [J]

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration System Condenser Water Consumption Rate [m³/s]

The volumetric flow rate in m³/s of water consumed while providing evaporative cooling of the condenser.

Refrigeration System Condenser Water Consumption [m³]

This is the water consumed by evaporation in m³ while providing evaporative cooling of the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration:Condenser:WaterCooled

The refrigeration system requires a single condenser. The water cooled condenser object is one of three options for this condenser. Manufacturer's data is required for the rated total heat rejection, the rated condensing temperature, and the rated leaving liquid refrigerant temperature, all per ARI 450. These values are used to calculate the subcooling included in the rated capacity. The inlet and outlet node names as well as the water outlet temperature schedule name are required. Optional input is provided to help the user compare refrigerant inventories for different systems. These input represent the design values for the refrigerant

inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

Field: Name

Identifies a particular condenser that rejects heat for a single refrigeration system. The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser) in the input file, including names used for air- and evaporative-cooled condensers.

Field: Rated Effective Total Heat Rejection Rate

This numeric field should be the rated heat rejection effect (W) at standard rating conditions per ARI 450. Be sure the rating corresponds to the correct refrigerant.

Field: Rated Condensing Temperature

This numeric field provides the rated condensing temperature (C) corresponding to the rated heat rejection capacity.

Field: Rated Subcooling Temperature

This numeric field provides the rated liquid refrigerant subcooling (C) corresponding to the rated heat rejection capacity. Note this is equal to the difference between the saturated condensing temperature and the leaving liquid refrigerant temperature.

Field: Rated Water Inlet Temperature

This numeric field provides the rated water inlet temperature (C) corresponding to the rated heat rejection capacity at the rated condensing temperature.

Field: Water Inlet Node Name

A node name for the water-side condenser inlet must be provided.

Field: Water Outlet Node Name

A node name for the water-side condenser outlet must be provided.

Field: Water-Cooled Loop Flow Type

The type of flow loop should be specified. The two choices are **VariableFlow**, in which a Pump:VariableSpeed must be included in the plant loop, or **ConstantFlow**, in which the loop circuit has a constant flow rate, typically associated with a Pump:ConstantSpeed object. If the flow type is VariableFlow, the flow needed to remove the condenser heat energy will be calculated and requested of the pump. If the flow type is ConstantFlow, the outlet water temperature will be determined based on the fixed loop flow rate and heat energy to be removed. The default type is VariableFlow. Refer to additional discussion in the Engineering Reference.

Field: Water Outlet Temperature Schedule Name

When the water-cooled loop flow type is "VariableFlow", the name of a schedule (Ref: Schedule) that defines the desired condenser water outlet temperature must be provided. The schedule may define an outlet temperature that varies through time.

Field: Water Design Flow Rate

When the water-cooled loop flow type is "ConstantFlow", this is the design water flow rate in m³/s that will be requested initially. This requested flow will be passed to the loop simulation, and resulting actual flow will be dependent upon supply system capabilities (e.g., pump capability). The design flow rate must always be less than the maximum flow rate, defined below.

Field: Water Maximum Flow Rate

This numeric field is the maximum water flow rate in m³/s that will be allowed through the condenser. When the loop flow type is Variable Flow, if the calculated flow rate is higher than the maximum flow rate, an error message will be generated, and the flow rate will be reset to the maximum flow rate.

Field: Water Maximum Water Outlet Temperature

This numeric field specifies the maximum allowed water temperature in degrees C leaving the condenser. The default value is 55 degrees C.

Field: Water Minimum Water Inlet Temperature

This numeric field specifies the minimum allowed water temperature in degrees C entering the compressor rack condenser. The default value is 10 degrees C. Refer to additional discussion in the Engineering Reference.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature System"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

Field: Condensate Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

Below is the input data dictionary description for the object.

Zone,Average, Refrigeration System Condenser Heat Transfer Rate [W]
Zone, Sum, Refrigeration System Condenser Heat Transfer Energy [J]
Zone,Average, Refrigeration System Condenser Water Mass Flow Rate [kg/s]

```

Refrigeration System Condenser Heat Transfer Rate [W]

This is the total heat transfer across the condenser (i.e., compressor energy and case cooling) in Watts.

Refrigeration System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported.

Refrigeration System Condenser Water Mass Flow Rate [kg/s]

This is the mass flow rate of the water used to cool the condenser in kg/s.

Group – Zone Controls – Thermostats and Humidistats

Zone Control objects are used to control zone conditions to a specific setpoint. The four types of zone control are described in this section. They are, by name, ZoneControl:<name>.. These types are:

Thermostat – The object provides the traditional approach to space control using air temperatures. Each controlled zone contains a thermostat object.

Humidistat – The object is used to control a zone to a specified relative humidity.

Thermostat:ThermalComfort – The object provides a method to control a zone to a dry-bulb temperature setpoint based on a thermal comfort model (e.g. Fanger) and a user-specified thermal comfort setpoint schedule.

Thermostat:OperativeTemperature – The operative temperature control is formulated to reuse all of the traditional thermostat objects. One input object will be used for each thermal zone to indicate if that zone's thermostat control mode should be overridden to effect operative temperature control rather than traditional air temperature control. The user will still have to input all the traditional ZoneControl:Thermostat and setpoint objects.

ZoneControl:Thermostat

The thermostatic zone control object is used to control a zone to a specified temperature. ZoneControl:Thermostat references a control type schedule and one or more control type objects which in turn reference one or more setpoint schedules. The example at the end of

this section illustrates a complete zone thermostat specification including the control type and setpoint schedules.

The control type schedule and the list of control type/name pairs are directly related. The schedule defines the type of control that is to be used throughout the simulation. Valid Control Types are:

- 0 - Uncontrolled (No specification or default)
- 1 - Single Heating Setpoint
- 2 - Single Cooling SetPoint
- 3 - Single Heating/Cooling Setpoint
- 4 - Dual Setpoint (Heating and Cooling) with deadband

Thus, if the schedule referenced in the ZoneControl:Thermostat statement has a control type of 4 for a particular time period, this indicates that during that time period "Dual Setpoint with deadband" control is to be used. The specific "Dual Setpoint (Heating and Cooling) with deadband" control object to be used is specified in the list of control type/name pairs. Then the specific control type objects reference the thermostat setpoint temperature schedule to be used. Because only one control can be specified for each control type in a ZoneControl:Thermostat statement, there are only four pairs possible in a particular ZoneControl:Thermostat type/name list. This is because individual controls can be defined throughout the simulation, thus giving the user a full range of flexibility. Since putting in the name of the control type directly in the schedule would be very cumbersome, the control types are assigned a number which is used in the schedule profile.

Field: Name

Unique identifying name for the thermostat.

Field: Zone Name

Name of the zone that is being controlled.

Field: Control Type Schedule Name

Schedule which defines what type of control is active during the simulation. Valid Control Types are:

- 0 - Uncontrolled (No specification or default)
- 1 - Single Heating Setpoint
- 2 - Single Cooling SetPoint
- 3 - Single Heating Cooling Setpoint
- 4 - Dual Setpoint with Deadband (Heating and Cooling)

Each non-zero control type which is used in this schedule must appear in the following fields which list the specific thermostat control objects to be used for this zone.

Field Set (Control Object Type, Control Name)

Up to four pairs of Control Object Type and Control Name may be listed to specify which control objects are used for this zone. This list is not order-dependent, and the position in this list has no impact on the control type schedule. In the control type schedule, a value of 1 always means "Single Heating Setpoint", even if that control type is not first in this list.

Field: Control Object <x>Type

This field specifies the control type to be used for this zone. Available control types are:

```
ThermostatSetpoint:SingleHeating
ThermostatSetpoint:SingleCooling
ThermostatSetpoint:SingleHeatingOrCooling
ThermostatSetpoint:DualSetpoint
```

Field: Control <x> Name

The corresponding control type name. The name is used in an object with the name of the control type and specifies the schedule.

The input data dictionary description for the thermostat object is shown below:

```

Zone, Average, Zone/Sys Thermostat Control Type
Zone, Average, Zone/Sys Thermostat Heating Setpoint [C]
Zone, Average, Zone/Sys Thermostat Cooling Setpoint [C]
```

Zone/Sys Sensible Load Predicted[W]

This is the predicted sensible load in W required to meet the current zone thermostat setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active heating and/or cooling setpoints, determines if the zone requires heating or cooling or is in the deadband, and then passes this single load to the equipment. This value is not multiplied by zone or group multipliers.

Zone/Sys Sensible Load to Heating Setpoint Predicted[W]

This is the predicted sensible load in W required to meet the current zone thermostat heating setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. This value is not multiplied by zone or group multipliers.

Zone/Sys Sensible Load to Cooling Setpoint Predicted[W]

This is the predicted sensible load in W required to meet the current zone thermostat cooling setpoint. A positive value indicates a heating load, a negative value indicates a cooling load.

This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. This value is not multiplied by zone or group multipliers.

Zone/Sys Thermostat Control Type

This is the current zone thermostat control type (0 through 4). This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermostat Heating Setpoint [C]

This is the current zone thermostat heating setpoint in degrees C. If there is no heating thermostat active, then the value will be 0. This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermostat Cooling Setpoint [C]

This is the current zone thermostat cooling setpoint in degrees C. If there is no cooling thermostat active, then the value will be 0. This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Time Heating Setpoint Not Met[hr]

Hours when the zone temperature is lower than 0.2 degrees C below the heating setpoint.

Time Heating Setpoint Not Met While Occupied[hr]

Hours when the zone temperature is lower than 0.2 degrees C below the heating setpoint and when people are present in the zone.

Time Cooling Setpoint Not Met[hr]

Hours when the zone temperature is greater than 0.2 degrees C above the cooling setpoint.

Time Cooling Setpoint Not Met While Occupied[hr]

Hours when the zone temperature is greater than 0.2 degrees C above the cooling setpoint and when people are present in the zone.

Time Zone Temperature Oscillating[hr]

Hours when the temperature in the zone is oscillating back and forth. Oscillation is defined as times when the three differences between zone temperatures during successive timesteps are greater in magnitude than 0.15 degrees C and the sign of the differences changes from positive to negative to positive or from negative to positive to negative.

This may indicate a simulation with reduced reliability during the oscillation. Some oscillating hours should be expected in all simulations but excessive oscillations call into question the overall validity of the results. If excessive oscillations are occurring, try reducing the minimum system timestep (see ConvergenceLimits object) and the zone timestep (see the TimeStep object). Reducing these timestep lengths does increase the total computer time needed to complete the simulation. Having the zone timestep and the minimum system timestep the same length of time can also cause more oscillations. What amount of oscillations is considered “excessive” is difficult to quantify. One approach is comparing the number of oscillations to the case with 15 minute zone timesteps (4 per hour) and 1 minute minimum system timesteps. Often this variable is used as an indicator of the validity of the results when trying to decrease the time needed to perform the simulation.

Time Any Zone Temperature Oscillating[hr]

Hours when any zone in the building has oscillations. See Time Zone Temperature Oscillating definition above.

Zone Thermostat Setpoints

The syntax for the current set of four zone thermostat setpoint objects is given below. In each case, the keyword is accompanied by an identifying name and either one or two schedule names (depending on whether the control is a single or dual setpoint control). The schedule defines a temperature setpoint for the control type. The schedule would be defined through the standard schedule syntax described earlier in this document. For an uncontrolled zone no thermostat is specified or necessary.

ThermostatSetpoint:SingleHeating

This would be for a heating only thermostat. The setpoint can be scheduled and varied throughout the simulation but only heating is allowed with this control type.

Field: Name

Unique name for this control type.

Field: Setpoint Temperature Schedule Name

The name of the associated schedule. Values in the schedule are temperatures {C}.

ThermostatSetpoint:SingleCooling

This would be for a cooling only thermostat. The setpoint can be scheduled and varied throughout the simulation but only cooling is allowed.

Field: Name

Unique name for this control type.

Field: Setpoint Temperature Schedule Name

The name of the associated schedule. Values in the schedule are temperatures {C}.

ThermostatSetpoint:SingleHeatingOrCooling

This would be for heating and cooling thermostat but only heating or cooling can be scheduled at any given time period. The setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

Field: Name

Unique name for this control type.

Field: Setpoint Temperature Schedule Name

The name of the associated schedule. Values in the schedule are temperatures {C}.

ThermostatSetpoint:DualSetpoint

This would be for heating and cooling thermostat where both a heating and cooling setpoint can be scheduled for any given time period. The setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

Field: Name

Unique name for this control type.

Field: Heating Setpoint Temperature Schedule Name

The heating temperature schedule. Values in the schedule are temperatures {C}.

Field: Cooling Setpoint Temperature Schedule Name

The cooling temperature schedule. Values in the schedule are temperatures {C}.

The input data dictionary description for the thermostat control objects is shown below:

```

ThermostatSetpoint:SingleHeating,

```

Examples of these statements in an IDF are:

```

ThermostatSetpoint:SingleHeating, Heating Setpoint with SB, Heating Setpoints;
ThermostatSetpoint:SingleCooling, Cooling Setpoint with SB, Cooling Setpoints;
ThermostatSetpoint:SingleHeatingOrCooling, Heating Cooling Setpoint Sched, Heating Cooling Setpoints;
ThermostatSetpoint:DualSetpoint, VAV Setpoints, Heating Setpoints, Cooling Setpoints;

```

ZoneControl:Thermostat:OperativeTemperature

This object is used to modify the program's behavior for ZoneControl:Thermostat objects. One input object is used for each thermal zone to indicate if that zone's thermostat control mode should be overridden to effect operative temperature control rather than traditional air temperature control. Zone Control:Thermostatic and related set point objects also need to be included in the input file. When this object is used, the zone can be controlled by a weighted mixture of radiant and air temperatures (rather than just air temperatures).

This thermostatic operative temperature, T_{OP} , is defined as:

$$T_{OP} = \gamma T_{MRT} + (1 - \gamma) T_{drybulb}$$

where,

γ is the radiative fraction,

T_{MRT} is the mean radiant temperature for the thermal zone, and

$T_{drybulb}$ is the mean zone air temperature.

The radiative fraction γ is selected by the user and can be scheduled to vary during the simulation. A typical value is 0.5. The maximum value needs to be less than 0.9 and the minimum is 0.0. A value of 0.0 is the same as controlling on only zone air temperature. If air velocities are higher than 0.2 m/s, then lower values for radiative fraction might apply. Niu and Burnett (1998) cite International Standard ISO 77300 in recommending the values for this fraction listed in the following table.

Table 25. Radiative Fraction vs Air Velocity (Operative Temperature Control)

Air Velocity (m/s)	< 0.2	0.2 to 0.6	0.6 to 1.0
γ	0.5	0.4	0.3

Reference: J. Niu and J. Burnett. 1998. Integrating Radiant/Operative Temperature Controls into Building Energy Simulations. ASHRAE Transactions Vol. 104. Part 2. page 210. ASHRAE. Atlanta, GA.

Field: Thermostat Name

Name of ZoneControl:Thermostat object defined elsewhere in the input file whose operation is to be modified to effect control based on operative temperature.

Field: Radiative Fraction Input Mode

This field controls whether the input for radiative fraction is a constant value or if it is entered using a schedule. Enter “**Constant**” here to use a fixed radiative fraction defined in the following field. Enter “**Scheduled**” to vary the radiative fraction according to the schedule named in the second field below.

Field: Fixed Radiative Fraction

This is the fraction, γ , of the operative temperature that is due to the mean radiant temperature in the zone. This field is used by the program if the previous field is set to **Constant**.

Field: Radiative Fraction Schedule Name

This field contains the name of a schedule, defined elsewhere, that determines the value for radiative fraction γ during the simulation period. This schedule should have fractional values from 0.0 to 0.9. When the value of this schedule is 0.0, the controlling will be equivalent to control based only on zone air temperature. This field is used by the program if the Input Mode field is set to **Scheduled**.

Note that by setting the values in this schedule separately for design days, the user can control how operative temperature control is applied during autosizing. (Operative temperature control tends to increase the equipment capacities calculated during sizing.)

The input data dictionary for this object follows.

```

Zone Control Thermostatic Operative Temperature Outputs

Zone, Average, Zone Thermostat Operative Temperature [C]

Zone Thermostat Operative Temperature [C]

Operative temperature (OT) is a weighted mixture of Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT), using the current value of Radiative Fraction (RF): $OT = (1-RF)*MAT + RF*MAT$. This report variable does not include the direct effect of high temperature radiant systems. See also Zone Operative Temperature.

ZoneControl:Humidistat

The humidistat zone control object is used to control a zone to a single relative humidity setpoint schedule, or to dual humidity setpoint schedules (humidifying/ dehumidifying setpoints with deadband). The single setpoint humidistat requires single setpoint input only, and the dual-setpoint humidistat requires inputs of both humidifying and dehumidifying setpoints. The schedules consist of relative humidities, expressed as a percentage (0-100), to be used during the simulation for that zone's moisture prediction calculation. Only one humidistat control statement can be specified for each zone. For a single setpoint humidistat, if the zone relative humidity is below the control relative humidity setpoint and the equipment specified can humidify then that equipment will try and meet the zone's humidification load. The opposite is true if the zone relative humidity is above the control relative humidity setpoint and the equipment can dehumidify. For a dual setpoint humidistat, if the zone relative humidity is below the **humidifying** relative humidity setpoint and the equipment specified can humidify then that equipment will try and meet the zone's humidification load. The opposite is true if the zone relative humidity is above the **dehumidifying** relative humidity setpoint and the equipment can dehumidify.

If the ZoneControl:Humidistat is used by a furnace or unitary system (Ref. Furnace and Unitary Systems) no other objects are required. The signal from the humidistat is used directly by that component. If the Zone Control:Humidistat object is used to control a Humidifier or used in conjunction with a Controller:WaterCoil object with control variable **TemperatureAndHumidityRatio**, then either the "SetpointManager:SingleZone:Humidity:Minimum" or "SetpointManager:SingleZone:Humidity:Minimum" objects are required to determine a

setpoint for those components for a single setpoint humidistat. For a dual setpoint humidistat, both the “SetpointManager:SingleZone:Humidity:Maximum” and “SetpointManager:SingleZone:Humidity:Minimum” objects are required to determine the setpoints for the corresponding humidification and dehumidification components.

Field: Name

Unique identifying name for the humidistat.

Field: Zone Name

Name of the zone that is being controlled.

Field: Humidifying Relative Humidity Setpoint Schedule Name

Name of a schedule that defines the humidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation.

Note: If only a single setpoint humidistat is desired, then input the single schedule name in the Humidifying Setpoint Schedule Name field (and leave the Dehumidifying Setpoint Schedule Name blank).

Field: Dehumidifying Relative Humidity Setpoint Schedule Name

Name of a schedule that defines the dehumidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation. This field is optional, only used if a dual setpoint humidistat is to be modeled.

The input data dictionary description for the humidistat object is shown below:

```

ZoneControl:Humidistat Outputs

Outputs available from the ZoneControl:Humidistat:

```

HVAC, Average, Zone/Sys Moisture Load Rate Predicted[kgWater/sec]
HVAC, Average, Zone/Sys Moisture Load Rate Predicted to Humidifying Setpoint[kgWater/sec]
HVAC, Average, Zone/Sys Moisture Load Rate Predicted to Dehumidifying Setpoint[kgWater/sec]

```

Zone/Sys Moisture Load Rate Predicted[kgWater/sec]

This is the predicted latent (moisture) load in $\text{kg}_{\text{water}}/\text{s}$ required to meet the current zone humidistat setpoint. A positive value indicates a humidification load, a negative value indicates a dehumidification load. For a dual setpoint humidistat, the value is zero when the controlled zone's relative humidity is between the defined humidifying and dehumidifying setpoints. This moisture load rate is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat setpoints, determines if the zone requires humidification or dehumidification, and then passes this single load to the equipment for the single setpoint humidistat case. This value is not multiplied by zone or group multipliers.

Zone/Sys Moisture Load Rate Predicted to Humidifying Setpoint [kgWater/sec]

This is the predicted latent (moisture) load in $\text{kg}_{\text{water}}/\text{s}$ required to meet the current zone humidistat **humidifying** setpoint. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat humidifying setpoints, determines if the zone requires humidification or not, and then passes this load to the equipment for the case of a dual setpoint humidistat (see Zone/Sys Moisture Load Rate Predicted, above, for single setpoint humidistat case). This value is multiplied by zone or group multipliers.

Zone/Sys Moisture Load Rate Predicted to Dehumidifying Setpoint [kgWater/sec]

This is the predicted latent (moisture) load in $\text{kg}_{\text{water}}/\text{s}$ required to meet the current zone humidistat **dehumidifying** setpoint. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat humidifying setpoints, determines if the zone requires dehumidification or not, and then passes this load to the equipment for a dual setpoint humidistat (see Zone/Sys Moisture Load Rate Predicted, above, for single setpoint humidistat case). This value is multiplied by zone or group multipliers.

ZoneControl:Thermostat:ThermalComfort

The thermal comfort zone control provides a method to control a zone to a dry-bulb temperature setpoint based on a thermal comfort model (e.g. Fanger) and a user-specified thermal comfort setpoint schedule.

This object references a control type schedule and one or more thermal comfort control type objects which in turn reference one or more setpoint schedules. The example at the end of this section illustrates a complete zone thermal comfort control specification including the control type and setpoint schedules. The control type schedule and the list of control type/name pairs are directly related. The schedule defines the type of control that is to be used during for each hour. Valid Control Types are

- 0 – Uncontrolled (No thermal comfort control)
- 1 - Single Thermal Comfort Heating Setpoint:Fanger
- 2 - Single Thermal Comfort Cooling Setpoint:Fanger
- 3 - Single Thermal Comfort Heating Cooling Setpoint:Fanger
- 4 - Dual Thermal Comfort Setpoint with Deadband:Fanger

Thus, if the schedule referenced in the ZoneControl:Thermostat:ThermalComfort statement has a value of 4 for a particular hour, this indicates that during that hour "Dual Thermal Comfort Setpoint with Deadband:Fanger" is to be used. The specific "Dual Thermal Comfort Setpoint with Deadband:Fanger " control object to be used is specified in the list of control type/name pairs. Then the specific control type objects reference the thermal comfort control setpoint schedule to be used. Because only one control can be specified for each control type in a ZoneControl:Thermostat:ThermalComfort statement, there are only four pairs possible in a particular ZoneControl:Thermostat:ThermalComfort type/name list. This is because individual controls can be defined hourly, thus giving the user a full range of flexibility. Since putting in the name of the control type directly in the schedule would be very cumbersome, the control types are assigned a number which is used in the hourly schedule profile.

The ZoneControl:Thermostat:ThermalComfort object can be used alone, or with a ZoneControl:Thermostat object. When both control objects co-exist for a specific zone and the thermal comfort control type value in the thermal comfort control type schedule is non-zero the thermal comfort object will override the value from the zone thermostat object. If the thermal comfort control is specified as "Uncontrolled" (thermal comfort control type value of 0) for a particular period, then control will revert to thermostat control if specified. If the thermal comfort control is specified as "Uncontrolled" for a particular period and thermostat control is not specified in the input, then conditions will float,

This object currently allows only Fanger comfort control (Ref. Thermal Comfort in Engineering Reference). It requires one or more people objects in a specific zone. It also requires inputs of Fields *Activity Level Schedule Name*, *Work Efficiency Schedule Name*, *Clothing Insulation Schedule Name* and *Air Velocity Schedule Name* in the people object(s). When thermal comfort control is used in a zone, the air velocity entered in the Air Velocity Schedule (Ref. People) should be greater than or equal to 0.1 and less than or equal to 0.5 m/s. A warning message will be issued if thermal comfort control is active and the air velocity is outside this range.

This object reads input PMV values from a given PMV setpoint schedule to calculate a dry-bulb temperature setpoint based on the selected thermal comfort model. The dry-bulb temperature setpoint calculation uses zone air humidity ratio at the previous system timestep and surface temperatures at the previous zone timestep, along with other conditions at the current timestep (e.g., activity level, clothing level and air velocity from the PEOPLE object).

Field: Name

Unique identifying name for this thermal comfort control object.

Field: Zone Name

Name of the zone that is being controlled.

Field: Averaging Method

This choice field specifies the method for calculating the thermal comfort dry-bulb temperature setpoint for a zone with multiple People objects defined. The available choices

are: **SpecificObject**, **ObjectAverage**, and **PeopleAverage**. This field is only used when multiple people objects are defined for this zone. If this field is specified as **PeopleAverage** and the total number of people for all people objects is zero for a particular timestep, the PeopleAverage method can not be applied and the program automatically uses the ObjectAverage method for this timestep. The default input is **PeopleAverage**.

Field: Object Name for Specific Object Averaging Method

This choice field specifies the name of the specific People object to be used for calculating comfort control when multiple People objects are defined. Only used if the Averaging Method is specified as "SpecificObject."

Field: Minimum Dry-Bulb Temperature Setpoint

This field specifies the minimum dry-bulb temperature setpoint allowed for this zone. If the dry-bulb temperature calculated by the thermal comfort setpoint model is below this value, then the temperature setpoint will be set to this value. The default value is 0 °C.

Field: Maximum Dry-Bulb Temperature Setpoint

This field specifies the maximum dry-bulb temperature setpoint allowed for this zone. If the dry-bulb temperature calculated by the thermal comfort setpoint model exceeds this value, then the temperature setpoint will be set to this value. The default value is 50 °C.

Note the minimum and maximum temperature setpoint fields are provided to allow the user to bound the temperature control in a specific zone if necessary. These fields are used to provide boundaries for the dry-bulb temperature setpoint calculated at each system timestep when unrealistic inputs have been specified.

Field: Thermal Comfort Control Type Schedule Name

Schedule which defines what type of thermal comfort control is active during each simulation timestep.

Valid Control Types are

- 0 – No thermal comfort control
- 1 - Single Thermal Comfort Heating Setpoint:Fanger
- 2 - Single Thermal Comfort Cooling Setpoint:Fanger
- 3 - Single Thermal Comfort Heating Cooling Setpoint:Fanger
- 4 - Dual Thermal Comfort Setpoint with Deadband:Fanger

Each non-zero control type used in this schedule must appear in the following fields which list the specific thermal comfort control objects to be used for this zone.

Field Set (Thermal Comfort Control Object Type, Thermal Comfort Control Name)

Up to four pairs of Thermal Comfort Control Type and Thermal Comfort Control Type Name fields may be listed to specify which thermal comfort control type objects are used for this zone. This list is not order-dependent, and the position in this list has no impact on the control type schedule. In the control type schedule, a value of 1 always means "Single Thermal Comfort Heating Setpoint:Fanger", even if that control type is not first in this list.

Field: Thermal Comfort Control <x> Object Type

This field specifies the first control type name to be used for this zone. Available control types are:

```
ThermostatSetpoint:ThermalComfort:Fanger:SingleHeating
ThermostatSetpoint:ThermalComfort:Fanger:SingleCooling
ThermostatSetpoint:ThermalComfort:Fanger:SingleHeatingOrCooling
ThermostatSetpoint:ThermalComfort:Fanger:DualSetpoint
```

Field: Thermal Comfort Control <x> Name

The unique name for the corresponding thermal comfort control type.

The input data dictionary description for the thermal comfort object is shown below:

```

ZoneControl:Thermostat:ThermalComfort Outputs

Three outputs are available from the ZoneControl:Thermostat:ThermalComfort object. Two report variables used primarily for the ZoneControl:Thermost object are also described here to explain their meaning when using thermal comfort control.

ZONE CONTROL:THERMAL COMFORT

```

Zone,Average,Zone/Sys Thermal Comfort Control Type
Zone,Average,Zone/Sys Thermal Comfort Control Fanger Low PMV
Zone,Average,Zone/Sys Thermal Comfort Control Fanger High PMV

```

ZoneControl:Thermostat

```

Zone,Average,Zone/Sys Thermostat Heating Setpoint [C]
Zone,Average,Zone/Sys Thermostat Cooling Setpoint [C]

```

Zone/Sys Thermal Comfort Control Type

This is the current zone thermal comfort control type (0 through 4). This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermal Comfort Control Fanger Low PMV

This is the current zone thermal comfort low PMV value. Values range between -3 and +3. If there is no heating thermal comfort active, then the value reported will be -999. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermal Comfort Control Fanger High PMV

This is the current zone thermal comfort high PMV value. Values range between -3 and +3. If there is no cooling thermal comfort active, then the value reported will be 999. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermostat Heating Setpoint [C]

The Zone Control:Thermal Comfort object shares the same output variable and overwrites the thermal setpoints defined in object Zone Control:Thermostatic when both objects of Zone Control:Thermostatic and Zone Control:Thermal Comfort co-exist. It outputs the current zone thermal comfort heating setpoint in degrees C when thermal comfort control is active, otherwise this output variable will report the thermostat heating setpoint (Ref. Zone Control:Thermostatic Outputs). If there is no heating thermal comfort active and no thermostat heating setpoint is defined for this zone, this value will be 0. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for

longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermostat Cooling Setpoint [C]

This output variable defined in object Zone Control:Thermostatic. The Thermal Comfort object shares the same output variable and overwrites the thermal setpoints defined in object Zone Control:Thermostatic when both objects of Zone Control:Thermostatic and Zone Control:Thermal Comfort co-exist. It outputs the current zone thermal comfort cooling setpoint in degrees C when thermal comfort control is active, otherwise this output variable will report the thermostat cooling setpoint (Ref. Zone Control:Thermostatic Outputs). If there is no cooling thermal comfort active and no thermostat cooling setpoint is defined for this zone, this value will be 0. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Thermal Comfort Setpoints

The syntax for the current set (4) of zone thermal comfort control types is given below. In each case, the keyword is accompanied by an identifying name and either one or two schedule names (depending on whether the control type is a single or dual setpoint control). The schedule defines a Predicted Mean Vote (PMV) setpoint for the control type. The schedule would be defined through the standard schedule syntax described earlier in this document. For an uncontrolled thermal comfort zone, no Fanger thermal comfort object is specified or necessary.

ThermostatSetpoint:ThermalComfort:Fanger:SingleHeating

This would be used for heating only thermal comfort control. The PMV setpoint can be scheduled and varied throughout the simulation but only heating is allowed with this control type.

Field: Name

Unique name for this control type.

Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule containing FANGER PMV values.

ThermostatSetpoint:ThermalComfort:Fanger:SingleCooling

This would be used for cooling only thermal comfort control. The PMV setpoint can be scheduled and varied throughout the simulation but only cooling is allowed with this control type.

Field: Name

Unique name for this control type.

Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule, containing FANGER PMV values.

ThermostatSetpoint:ThermalComfort:Fanger:SingleHeatingOrCooling

This would be used for heating and cooling thermal comfort control but only heating or cooling can be scheduled at any given time period. The PMV setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

Field: Name

Unique name for this control type.

Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule containing FANGER PMV values.

ThermostatSetpoint:ThermalComfort:Fanger:DualSetpoint

This would be used for heating and cooling thermal comfort control where both a heating and cooling PMV setpoint can be scheduled for any given time period. The PMV setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

Field: Name

Unique name for this control type.

Field: Fanger Thermal Comfort Heating Schedule Name

The name of the associated schedule containing heating setpoint FANGER PMV values.

Field: Fanger Thermal Comfort Cooling Schedule Name

The name of the associated schedule containing cooling setpoint FANGER PMV values.

Group – Air Path

AirLoopHVAC:SupplyPath, AirLoopHVAC:ReturnPath

The zone supply and return air paths are used to describe the configuration of the flow path that the supply air takes in moving from the main air handler to the zone terminal units and that the return air takes on leaving the zones and returning to the central return air duct. The air paths consist of a group of components – AirLoopHVAC:ZoneSplitters and AirLoopHVAC:SupplyPlenums for the supply path and AirLoopHVAC:ReturnPlenums and AirLoopHVAC:ZoneMixers for the return path. The connectivity of the paths is established by the components' node connections. There are no branches defined in the zone air path constructs.

For a typical single duct air system there will be one AirLoopHVAC:SupplyPath and one AirLoopHVAC:ReturnPath. A typical dual duct system would have 2 AirLoopHVAC:SupplyPaths – one for the hot air and one for the cold air – and 1 AirLoopHVAC:ReturnPath.

The AirLoopHVAC:SupplyPlenum component provides the capability to have supply air be distributed to the conditioned zones through one or more plenum zones such as would occur in an underfloor air distribution system (UFAD). The AirLoopHVAC:ReturnPlenum component allows the program to model return air plenums. Of course plenums are always optional. The simplest AirLoopHVAC:SupplyPath would consist of only a AirLoopHVAC:ZoneSplitter; similarly the simplest return air path consists of a single AirLoopHVAC:ZoneMixer. A UFAD system supply air path might consist of a single AirLoopHVAC:ZoneSplitter connecting to multiple AirLoopHVAC:SupplyPlenums which in turn could each supply one or more conditioned zones. A system with return plenums would have a AirLoopHVAC:ReturnPath in which the conditioned zones connect to the return plenum inlets and the return plenums outlets connect to a single AirLoopHVAC:ZoneMixer.

Both the zone supply and return plenums are solved in the heat balance as thermal zones which couple through heat conduction with adjacent zones. Since they are solved as thermal zones the solution scheme involves the zone predictor-corrector technique which will lag the temperature at the system timestep in every zone. See Summary of Predictor-Corrector Procedure in the EnergyPlus Engineering Document.

Below are the descriptions of the zone supply and return path statements. Note that each statement type has an identifying name, a single inlet/outlet node number, and a list of component type/name pairs. For a single zone being served by an air loop, the inlet to its air distribution unit and the zone outlet can be the zone equipment inlet and outlet nodes directly, thus eliminating the need to specify a `AirLoopHVAC:SupplyPath` and a `AirLoopHVAC:ReturnPath`.

AirLoopHVAC:SupplyPath

The `AirLoopHVAC:SupplyPath` lists the `AirLoopHVAC:ZoneSplitter` and `AirLoopHVAC:SupplyPlenum` components comprising the path. The components are listed in flow order: upstream to downstream. Connectivity is established by means of the individual component inlet and outlet nodes.

Field: Name

Unique name to identify the supply air path, i.e. Main Hot Air Inlet.

Field: Supply Air Path Inlet Node Name

The name of an inlet node for the zone equipment half of the air loop. This should be one of the nodes named in the `AirLoopHVAC` field: Demand Side Inlet Node Names.

Field Set Component Type and Name

The remaining fields are sets of two repeated times: a component type and a name. These pairs of fields define the components on the supply air path.

Field: Component <#> Object Type

Start of the component list for the `AirLoopHVAC:SupplyPath`. This field should contain either `AirLoopHVAC:SupplyPlenum` or `AirLoopHVAC:ZoneSplitter`.

Field: Component <#> Name

Unique name of the `AirLoopHVAC:SupplyPlenum` or `AirLoopHVAC:ZoneSplitter` component.

AirLoopHVAC:ReturnPath

The `AirLoopHVAC:ReturnPath` lists the `AirLoopHVAC:ZoneMixer` and `AirLoopHVAC:ReturnPlenum` components comprising the path. The components are listed in flow order: upstream to downstream. Connectivity is established by means of the individual component inlet and outlet nodes. At this time there can only be 1 `AirLoopHVAC:ZoneMixer` in a `AirLoopHVAC:ReturnPath`.

Field: Name

Unique name to identify the return air path.

Field: Return Air Path Outlet Node Name

The name of the node that is the outlet to the air loop from the `AirLoopHVAC:ReturnPath`. This should be the same node named in the `AirLoopHVAC` field: Demand Side Outlet Node Name.

Field Set Component Type and Name

The remaining fields are sets of two repeated times: a component type and a name. These pairs of fields define the components on the return air path.

Field: Component <#> Object Type

Start of the component list for the AirLoopHVAC:ReturnPath. This field should contain either *AirLoopHVAC:ReturnPlenum* or *AirLoopHVAC:ZoneMixer*.

Field: Component <#> Name

Unique name of the AirLoopHVAC:ReturnPlenum or AirLoopHVAC:ZoneMixer.

AirLoopHVAC:ReturnPlenum

The simple building shown in the figure below, consists of a controlled zone and a return plenum zone that are used for the return air. This simple configuration contains a ground floor controlled zone with a window and a return plenum zone which handles the roof load. The return air plenum is a special type of component since there is both a heat balance connection and building description and a system airflow connection that transfers the airflow directly from the controlled zone to the return plenum zone in the system air simulation. The input described in this section is mainly just for the system airflow connections in the HVAC algorithms. In addition the return plenum zone must be fully input as a zone object for the heat balance calculation. The zone description needs to contain the wall descriptions - the interzone ceiling and floor, and for this simple case the roof. All the other attributes of a zone that can be specified in the building description can be used with a return plenum zone if necessary: scheduled loads, windows, etc.

Figure 104. Illustration of Zone Return Plenum

After all the building zone attributes are specified, the AirLoopHVAC:ReturnPlenum object is specified and included as one of the named components in a AirLoopHVAC:ReturnPath.

Field: Name

A unique identifying name identifying the AirLoopHVAC:ReturnPlenum system component.

Field: Zone Name

The zone name specified in the heat balance portion of the input. This piece of input connects the zone return plenum system component to the heat balance data structure.

Field: Zone Node Name

The name of the zone node. The zone node name connects the heat balance data structure to the system airflow data structure through this node. This node name is defined by the user in the field "Zone Air Node Name" in the ZoneHVAC:EquipmentConnections object for the zone named in the previous field.

Field: Outlet Node Name

The name of the zone outlet node. For the zone return plenum there is only one outlet node that can be specified.

Field: Inlet <#> Node Name

The name of one of the plenum inlet nodes. The zone return plenum component can collect air from many different zones, therefore multiple zone inlet nodes can be listed. Currently the limit is 30 per air loop but this can easily be extended by adding more inlet nodes in the Energy+.idd. There can be no duplicate names in the different inlet node name fields.

The IDD entry for this object follows.

```
AirLoopHVAC:ReturnPlenum,
  \extensible:1 Just duplicate last field and \ comments (changing numbering, please)
  \memo Connects N zone inlet air streams, through zone return plenum, to outlet
  \memo Node names cannot be duplicated within a single list.

  Zone Return Air Mixer;   ! Component 2 Name
```

AirLoopHVAC:SupplyPlenum

The building shown in the figure below consists of three controlled zones served by a AirLoopHVAC:SupplyPlenum beneath the floor.

Figure 105. Illustration of AirLoopHVAC:SupplyPlenum

The AirLoopHVAC:SupplyPlenum has a heat balance connection and building description, and a system airflow connection which transfers the airflow from the supply plenum zone to the controlled zones in the system simulation. The input described in this section is mainly just for the system airflow connections in the HVAC algorithms. In addition the supply plenum zone must be fully input in the building zone description. The supply plenum zone description needs to contain the wall descriptions, the interzone ceiling and floor, and the ground connection. All the other attributes of a zone that can be specified in the building description can be utilized with a supply plenum zone if necessary, i.e. scheduled loads, windows, etc.

After all the building zone attributes are specified, the AirLoopHVAC:SupplyPlenum object is specified and included as one of the named components in a AirLoopHVAC:SupplyPath.

Field: Name

A unique identifying name identifying the AirLoopHVAC:SupplyPlenum system component.

Field: Zone Name

The zone name specified in the heat balance portion of the input. This piece of input connects the AirLoopHVAC:SupplyPlenum system component to the heat balance data structure.

Field: Zone Node Name

The name of the zone node. The zone node name connects the heat balance data structure to the system airflow data structure through this node. This node name is defined by the user in the field "Zone Air Node Name" in the ZoneHVAC:EquipmentConnections object for the zone named in the previous field.

Field: Inlet Node Name

The name of the inlet node to the zone supply air path. The AirLoopHVAC:SupplyPlenum component can send air to many outlets but there is only one inlet.

Field: Outlet <#> Node Name

The name of an outlet node. The AirLoopHVAC:SupplyPlenum component can send air to many outlets or zones, therefore multiple outlet nodes can be named and this field can be repeated for as many zones as needed. Currently this value is 30 per air loop but this can

easily be extended by adding more outlet nodes in the Energy+.idd (or rely on automatic extension). There can be no duplicate names in the different outlet node name fields.

The IDD entry for this object follows.

```
AirLoopHVAC:SupplyPlenum,
  \extensible:1 Just duplicate last field and \ comments (changing numbering, please)
  \memo Connects 1 zone inlet air stream, through zone supply plenum, to one or more outlets.
  \memo Node names cannot be duplicated within a single supply plenum list.

  Supply Plenum 1,          ! Component 1 Name
  AirLoopHVAC:ZoneSplitter, ! Component 2 Object Type
  Zone Supply Air Splitter; ! Component 2 Name
```

AirLoopHVAC:ZoneSplitter

The AirLoopHVAC:ZoneSplitter is a component that splits airflow from a single inlet to multiple outlets. It is one of the components included in a AirLoopHVAC:SupplyPath. The input contains only node connection information.

Field: Name

Unique name for this zone splitter.

Field: Inlet Node Name

The name of the single inlet node going into the splitter.

Field: Outlet <#> Node Name

These are all of the outlet node names from the splitter leading to downstream supply air path components. The AirLoopHVAC:ZoneSplitter component can send air to many outlets or zones, therefore multiple outlet nodes can be named and this field can be repeated for as many zones as needed. There can be no duplicate names in the different outlet node name fields.

The IDD entry for this object follows.

```

AirLoopHVAC:ZoneSplitter,
  \extensible:1 Just duplicate last field and \ comments (changing numbering, please)
  \memo Split one air stream into N outlet streams (currently 50 per air loop, but extensible). Node
names
  \memo cannot be duplicated within a single zone splitter list.
  A1, \field Name
      \required-field

      \required-field

  A52; \field Outlet 50 Node Name

```

An example is shown below.

```

AirLoopHVAC:ZoneSplitter,
  Zone Supply Air Splitter, ! Name
  Zone Equipment Inlet Node, ! Inlet Node Name
  Zone 1 Damper Inlet Node, ! Outlet 1 Node Name
  Zone 2 Damper Inlet Node, ! Outlet 2 Node Name
  Zone 3 Damper Inlet Node; ! Outlet 3 Node Name

```

AirLoopHVAC:ZoneMixer

The AirLoopHVAC:ZoneMixer takes the air from multiple inlets from various zones and mixes the streams together to be sent out of a single outlet node on the return air path. This is a simple process of summing flows and averaging the air properties.

Field: Name

Unique name for this zone mixer.

Field: Outlet Node Name

The name of the single outlet node leaving the mixer.

Field: Inlet <#> Node Name

These are all the inlet node names that are coming from zones or plenums on the return air side and going into the mixer. The AirLoopHVAC:ZoneMixer component can collect air from many outlets or zones, therefore multiple inlet nodes can be named and this field can be repeated for as many zones as needed. There can be no duplicate names in the different inlet node name fields.

The IDD entry for this object follows.

```

AirLoopHVAC:ZoneMixer,
  \extensible:1 Just duplicate last field and \ comments (changing numbering, please)
  \memo Mix N inlet air streams into one (currently 50 per air loop, but extensible). Node names
cannot
  \memo be duplicated within a single zone mixer list.

```

Group – Non-Zone Equipment

The non-zone equipment group consists of plant objects that connect to the demand side of the plant loop but are not associated with a specific Zone (and do not have their own group). There is currently one non-zone equipment object called LoadProfile:Plant. This object places a scheduled demand load on the plant.

Non-zone equipment allows the option of performing a plant-only EnergyPlus simulation, i.e. without any zones. This can be useful for comparing the performance of various plant configurations or components without the added complexity of a full building description.

LoadProfile:Plant

The LoadProfile:Plant object is used to simulate a scheduled demand profile. This can be useful when the building loads are already known. Demanded load and flow rate are schedules specified in the object definition. The load profile can specify heating and cooling loads. Cooling loads are entered as negative numbers. The actual load met is dependent on the performance of the supply loop components.

The LoadProfile:Plant object must be connected on the demand side of the plant loop. It should be located on a Branch with its control type set to “Active.” If desired, multiple LoadProfile:Plant objects can be combined in series and/or parallel.

Field: Name

The unique name of the LoadProfile:Plant object.

Field: Inlet Node Name

The name of the inlet node connection to the plant loop.

This node should be on the demand side.

Field: Outlet Node Name

The name of the outlet node connection to the plant loop.

Field: Load Schedule Name

Reference to the schedule object specifying the load profile [W].

Field: Peak Flow Rate

The peak demanded water flow rate [m^3/s]. This value is multiplied by the flow rate fraction schedule values (below) to determine the actual volumetric flow rate.

Field: Flow Rate Fraction Schedule Name

Reference to the schedule object specifying the flow rate fraction relative to the value in the field Peak Flow Rate (above).

The IDD entry for this object follows.

  Demand Load Profile 1 Outlet Node, !- Outlet Node Name
  Load Profile 1 Load Schedule,    !- Load Schedule Name {W}
  0.003,                          !- Peak Flow Rate {m3/s}
  Load Profile 1 Flow Frac Schedule; !- Flow Rate Fraction Schedule Name

```

LoadProfile:Plant Output

The following output variables and meters are reported for the LoadProfile:Plant object:

```

HVAC,Average,Plant Load Profile Mass Flow Rate [kg/s]
HVAC,Average,Plant Load Profile Heat Transfer Rate [W]
HVAC,Sum,Plant Load Profile Heat Transfer Energy [J]
Zone,Meter,EnergyTransfer:Facility [J]
Zone,Meter,EnergyTransfer:Plant [J]
Zone,Meter,Miscellaneous:EnergyTransfer [J]

```

The inlet and outlet node temperatures and mass flow rates can be monitored using the system node output variables:

```

HVAC,Average,System Node Temp [C]
HVAC,Average,System Node MassFlowRate [kg/s]

```

Group – Solar Collectors

Solar collectors are thermal devices that convert solar energy into thermal energy by raising the temperature of a circulating heat transfer fluid. The fluid can then be used to heat water for domestic hot water usage or space heating.

In EnergyPlus solar collectors are components that are connected to the plant loop. A solar heating system can be constructed with a combination of solar collectors, pumps, and hot water tanks.

Solar collectors are defined using two objects: SolarCollector:FlatPlate:Water and SolarCollectorPerformance:FlatPlate. The SolarCollector:FlatPlate:Water object describes the plant component connections. The object also references a SolarCollectorPerformance:FlatPlate object which contains the thermal and optical

performance test data for a specific make and model of collector. Parameters are defined separately so that these values can be organized into a reference data set and need only be entered once if for an array of the same type of collectors.

SolarCollector:FlatPlate:Water

The flat-plate solar collector model simulates glazed, unglazed, and tubular (i.e. evacuated tube) collectors. The SolarCollector:FlatPlate:Water object represents a single collector module connected to the plant loop. The thermal and optical properties of the collector module are taken from the referenced SolarCollectorPerformance:FlatPlate object. A surface or shading object defines the collector tilt, azimuth, and gross area. The collector surface participates normally in all shading calculations if the "FullExterior," "FullInteriorAndExterior," "FullExteriorWithReflections", or "FullInteriorAndExteriorWithReflections" flags are set in the Solar Distribution field of the Building object. Inlet and outlet nodes are specified for plant connections on the demand side of the plant loop.

Field: Name

The unique name of the SolarCollector:FlatPlate:Water object.

Field: Solar Collector Performance Name

Reference name of a SolarCollectorPerformance:FlatPlate object that defines the thermal and optical properties of the collector.

Field: Surface Name

Reference to one of the many different types of surfaces such as the BuildingSurface:Detailed or the Shading:Zone:Detailed objects. The surface named here is used to define the solar collector tilt, azimuth, and gross area.

Field: Inlet Node Name

The name of the inlet node connection to the plant loop.

Field: Outlet Node Name

The name of the outlet node connection to the plant loop.

Field: Maximum Flow Rate

The maximum flow rate [m³/s] allowed through the collector. This field is optional. If not specified, the collector will allow as much flow as the rest of the plant can deliver.

The IDD entry for this object follows.

```

0.00005,                   !- Maximum Flow Rate (m3/s)
```

SolarCollector:FlatPlate:Water Output

The following output variables are reported for the SolarCollector:FlatPlate:Water object:

```
HVAC,Average,Solar Collector Incident Angle Modifier []
HVAC,Average,Solar Collector Efficiency []
HVAC,Average,Solar Collector Heat Transfer Rate [W]
HVAC,Average,Solar Collector Heat Gain Rate [W]
HVAC,Average,Solar Collector Heat Loss Rate [W]
HVAC,Sum,Solar Collector Heat Transfer Energy [J]
```

In addition, several surface variables are also relevant for the collector's surface object (BuildingSurface:Detailed or Shading:Zone:Detailed):

```
Zone,Average,Surface Ext Sunlit Area [m2]
Zone,Average,Surface Ext Sunlit Fraction []
Zone,Average,Surface Ext Solar Incident [W/m2]
Zone,Average,Surface Ext Solar Beam Incident [W/m2]
Zone,Average,Surface Ext Solar Sky Diffuse Incident [W/m2]
Zone,Average,Surface Ext Solar Ground Diffuse Incident [W/m2]
Zone,Average,Surface Ext Solar Beam Cosine Of Incidence Angle []
```

The temperatures at the inlet and outlet nodes and the collector mass flow rate can be monitored using the system node output variables:

```
HVAC,Average,System Node Temp[C]
HVAC,Average,System Node MassFlowRate[kg/s]
```

SolarCollectorPerformance:FlatPlate

The SolarCollectorPerformance:FlatPlate object contains the thermal and optical performance parameters for a single collector module. These parameters are based on the testing methodologies described in ASHRAE Standards 93 and 96. The Solar Rating and Certification Corporation (SRCC) applies these standards in their rating procedures of solar collectors. The ratings for commercially available collectors in North America are published in the *Directory of SRCC Certified Solar Collector Ratings*. The SRCC database has also been converted into an EnergyPlus data set of SolarCollectorPerformance:FlatPlate objects that is included with the program (see SolarCollectors.idf in the DataSets folder).

The coefficients for the energy conversion efficiency and incident angle modifier allow first order (linear) or second order (quadratic) correlations. To use a first order correlation, the second order coefficient must be left blank or set to zero.

In order for the model to work correctly, the test conditions for which the performance coefficients were measured must be specified in the fields: *Test Fluid*, *Test Volumetric Flow Rate*, and *Test Correlation Type*. Currently, only water is allowed as the *Test Fluid*.

For more detailed information about the performance coefficients, see the *EnergyPlus Engineering Reference Document*.

Field: Name

The unique name of the SolarCollectorPerformance:FlatPlate object.

Field: Gross Area

The gross area of the collector module [m²]. This value is mainly for reference. The area of the associated collector surface object is used in all calculations.

Field: Test Fluid

The fluid that was used in the testing procedure that resulted in the thermal and optical performance coefficients below. Currently only “Water” is allowed. This is the fluid during the collector testing, not the fluid used during a particular EnergyPlus run.

Field: Test Flow Rate

The volumetric flow rate during testing [m³/s]. If the value is available as flow rate per unit area, it is recommended to multiply by the *Gross Area* of the collector module, not the net aperture area.

Field: Test Correlation Type

This field specifies type of temperature used to develop the correlation equations. The testing procedure is based on an experimental correlation using either “Inlet,” “Average,” or “Outlet” temperature. Enter one of these choices. The ASHRAE Standards 93 and 96 always use Inlet temperature.

Field: Coefficient 1 of Efficiency Equation

First coefficient of efficiency equation for energy conversion [dimensionless]. This is the Y-intercept term.

Field: Coefficient 2 of Efficiency Equation

Second coefficient of efficiency equation for energy conversion [W/m²-deltaC]. This is the first-order term.

Field: Coefficient 3 of Efficiency Equation

Third coefficient of efficiency equation for energy conversion [W/m²-deltaC²]. This field is optional. This is the second-order term. If left blank or set to zero, a first-order linear correlation is used.

Field: Coefficient 2 of Incident Angle Modifier

Second coefficient of the incident angle modifier equation. This the first-order term. (There is no *Coefficient 1 of Incident Angle Modifier* because that number is always 1.0.)

Field: Coefficient 3 of Incident Angle Modifier

Third coefficient of the incident angle modifier equation. This is the second-order term. This field is optional. If left blank or set to zero, a first order linear correlation is used.

SolarCollectorPerformance:FlatPlate Output

This object does not generate any output; see SolarCollector:FlatPlate:Water Output

SolarCollector:FlatPlate:PhotovoltaicThermal

This object is used to model hybrid photovoltaic-thermal (PVT) solar collectors that convert incident solar energy into both electricity and useful thermal energy. This object describes the PVT solar collector by referencing other objects that provide more detail or connections to other parts of the EnergyPlus model.

The PVT solar collectors need to be connected to either an HVAC air system or a plant loop for collected thermal energy to be utilized. The input field for the type of thermal working fluid informs the program how the PVT collector is expected to be connected. If the the working fluid is air, then the PVT collectors are modeled as a ventilation air pretreatment component and connected to an outdoor air system. If the working fluid is water, then the PVT collectors are modeled as a hot water solar collector and are connected to a plant loop with a water thermal storage tank.

Field: Name

This field should contain a unique name chosen by the user to identify a specific PVT collector in the building model.

Field: Surface Name

This field is the user-defined name of a surface object (defined elsewhere) to which the PVT module is attached. These can be any type of building surface that is exposed to the exterior environment. The model uses the named surface's geometry for the PVT solar collector.

Field: Photovoltaic-Thermal Model Performance Name

This field is the user-defined name of an object (defined elsewhere) that provides the performance details of the PVT module. This should be the name of a SolarCollectorPerformance:PhotovoltaicThermal:Simple object. Multiple different SolarCollector:FlatPlate:PhotovoltaicThermal objects can reference the same object that provides performance details.

Field: Photovoltaic Generator Name

This field is the user-defined name of a Generator:Photovoltaic object (defined elsewhere) that will be used to model the solar electric portion of the PVT solar collector. The PVT models make any adjustments needed to model PV performance in the context of the PVT collector.

Field: Thermal Working Fluid Type

This field is the user's choice for the type of fluid used to collect thermal energy. PVT solar collectors can capture thermal energy in either air or water streams. The choices available for this field are "Water" or "Air." If the choice is "Air" then the PVT collector needs to be connected to an HVAC air system loop. The PVT collector should be situated as the first

component on an outdoor air inlet stream. If the choice is “Water” then the PVT collector needs to be connected to a Plant water system loop. The connections are made via node names which are defined in the following fields, depending on the working fluid type.

Field: Water Inlet Node Name

This field is the name of Plant loop node that serves as the inlet to the PVT collector. This field is only used if the Thermal Working Fluid Type is set to “Plant/Water.”

Field: Water Outlet Node Name

This field is the name of a plant loop node that serves as the outlet from the PVT collector. This field is only used if the Thermal Working Fluid Type is set to “Plant/Water.”

Field: Air Inlet Node Name

This field is the name of HVAC air loop node that serves as the inlet to the PVT collector. This field is only used if the Thermal Working Fluid Type is set to “HVAC/Air.”

Field: Air Outlet Node Name

This field is the name of HVAC air loop node that serves as the outlet from the PVT collector. This field is only used if the Thermal Working Fluid Type is set to “HVAC/Air.”

Field: Design Flow Rate

This field is used to describe the nominal volume flow rate of the thermal working fluid. The units are m3/s. The volume flow rate is autosizable.

SolarCollector:FlatPlate:PhotovoltaicThermal Outputs

The output variables that are available for flat plate PVT include the following.

```

HVAC,Average,Generator Thermal Power Produced [W]
HVAC,Sum,Generator Thermal Energy Produced [J]
HVAC,Average,PVT Bypass Status [ ]
HVAC,Average,PVT Working Fluid Inlet Temperature [C]
HVAC,Average,PVT Working Fluid Outlet Temperature [C]
HVAC,Average,PVT Working Fluid Mass Flow Rate [kg/s]

```

Generator Thermal Power Produced [W]

Generator Thermal Energy Produced [J]

These outputs are the thermal energy and power produced by the PVT collector. PVT collectors are a type of cogenerator, producing both electrical and thermal power and these variables report the thermal portion in the same manner as other fuel-based cogenerators. The thermal energy is placed on “HeatProduced” meter and is attributed to ‘SolarWater’ or ‘SolarAir’ depending on the type of working fluid. The generator thermal production is also reported at the load center level.

PVT Bypass Status []

This report variable indicates the status a bypass damper. It is only available for air-based PVT. There are no dimensions and the range is between 0.0 and 1.0. If the value is 0.0, then there is no bypassing and all the working fluid goes through the collector. If the value is 1.0, then there is complete bypassing and all the working fluid goes around the collector. If the value is between 0.0 and 1.0, then the model is effectively mixing bypass and collector streams to target a temperature setpoint placed on the outlet node.

PVT Working Fluid Inlet Temperature [C]

This report is the inlet temperature of the working fluid that enters the PVT collector

PVT Working Fluid Outlet Temperature [C]

This report is the outlet temperature of the working fluid that leaves the PVT collector

PVT Working Fluid Mass Flow Rate [kg/s]

This report is the mass flow rate of the working fluid through the PVT collector. This is the overall mass flow rate, portions of the flow may be internally bypassed around the collector itself for control modulation.

SolarCollectorPerformance:PhotovoltaicThermal:Simple

This object is used to provide performance details for the simple PVT model. This is a simple user-defined efficiency model. Thermal conversion efficiency is a constant or scheduled value. There are no output variable for this object, reporting is done by the parent PVT object.

Field: Name

This field is the unique name for this object.

Field: Fraction of Surface Area with Active Thermal Collector

This field is the fraction of the surface area that is active. It should be a decimal fraction between 0.0 and 1.0. The area of the PVT's surface will be multiplied by this fraction to determine the active area of the PVT collector(s).

Field: Thermal Conversion Efficiency Input Mode Type

This field is used to determine how the thermal efficiency is input. There are two choices, "Fixed" or "Scheduled." If this field is set to Fixed, then a constant value for thermal efficiency will be used (set in next field). If this field is set to Scheduled, then the thermal efficiency values are defined in a schedule.

Field: Value for Thermal Conversion Efficiency if Fixed

This field is used to provide a value for the efficiency with which solar energy is collected in the working fluid. This field is only used if the input mode is set to "Fixed" in the previous field. Efficiency is defined as the thermal energy collected divided by the incident solar radiation. The value should be between 0.0 and 1.0. The user should be careful that the thermal efficiency and the electrical efficiency be consistent with each other because the overall efficiency of the PVT collector is the combination of both thermal and electrical.

Field: Name of Schedule for Thermal Conversion Efficiency

This field is used for the name of a schedule that provides values for the efficiency with which solar energy is collected in the working fluid. This field is only used if the input mode is set to "Scheduled" in the field above. Efficiency is defined as the thermal energy collected divided by the incident solar radiation. The values in the named schedule should be between 0.0 and 1.0. The user should be careful that the thermal efficiency and the electrical efficiency be consistent with each other because the overall efficiency of the PVT collector is the combination of both thermal and electrical.

Field: Front Surface Emittance

This field is used to describe an average value for the total hemispherical emittance of the collector's front face exposed to the sky. This is used to model cooling applications where the PVT collectors are operated at night to cool the working fluid.

Solar Collector Heating System Plant Connections

This section provides an overview of how to model solar heating systems. A solar heating system can be constructed using a combination of solar collectors, pumps, water tanks and water heaters. The solar collector must be connected on the demand side of the plant loop. Multiple collector modules can be combined in series and parallel using the normal plant connection rules. The supply side of the plant loop should contain a water heater with the solar collector loop connecting to the *Source Side Inlet* and *Source Side Outlet* nodes. As usual, the pump must be the first component on the supply side.

If the solar heating system is for domestic hot water (or service water heating) usage only, the field *Use Flow Rate Fraction Schedule Name* of the WaterHeater:Mixed object can be used to avoid additional plant connections. If the system has more complicated hot water requirements or if the system is for space heating, the *Use Side Inlet* and *Use Side Outlet* nodes must be connected to another plant loop to serve zone and non-zone equipment. (See the WaterHeater:Mixed object documentation for more information.)

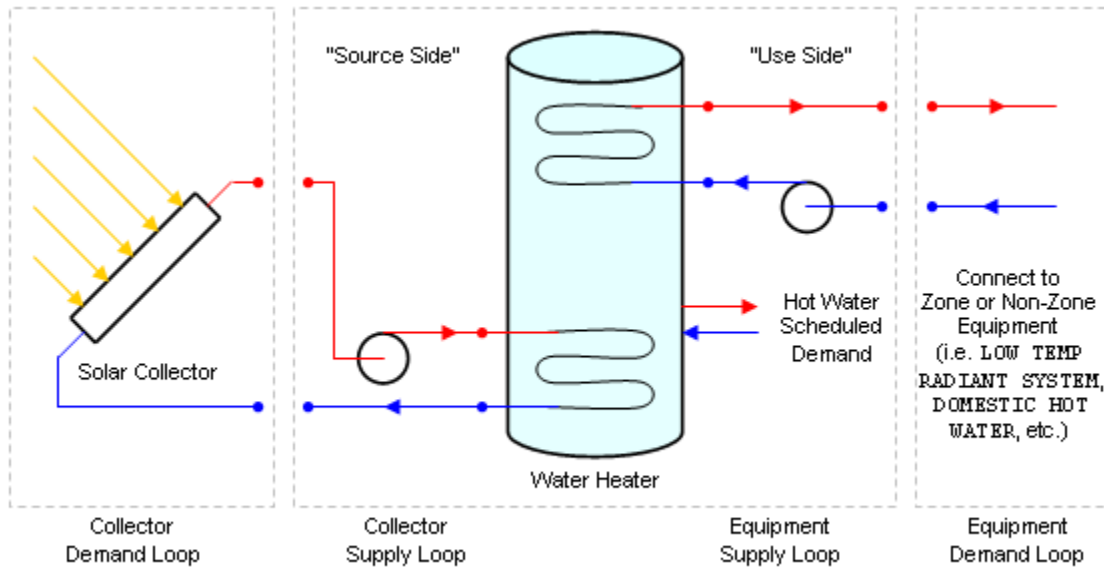

Figure 106. Solar Collector Plant Loop Connection Diagram

NOTE: The EnergyPlus plant simulation requires the pump to be the first component on the supply side. This may be different from the way the solar heating system is actually configured. This should not affect the validity of the simulation results.

In order to realize energy savings with a solar heating system, it is best to use a two-tank system with a storage tank and auxiliary water heater. The storage tank gathers heat directly from the solar collectors and stores it for later use. The storage tank is modeled using a `WaterHeater:Mixed` object with the *Heater Maximum Capacity* set to zero. The auxiliary water heater is positioned downstream of the storage tank on the supply side of the main plant loop. The auxiliary water heater, or booster water heater, provides additional heat if the storage tank water is not hot enough. The auxiliary water heater can be modeled as an instantaneous/tankless water heater or as a standard tanked water heater with heating source (see `WaterHeater:Mixed`).

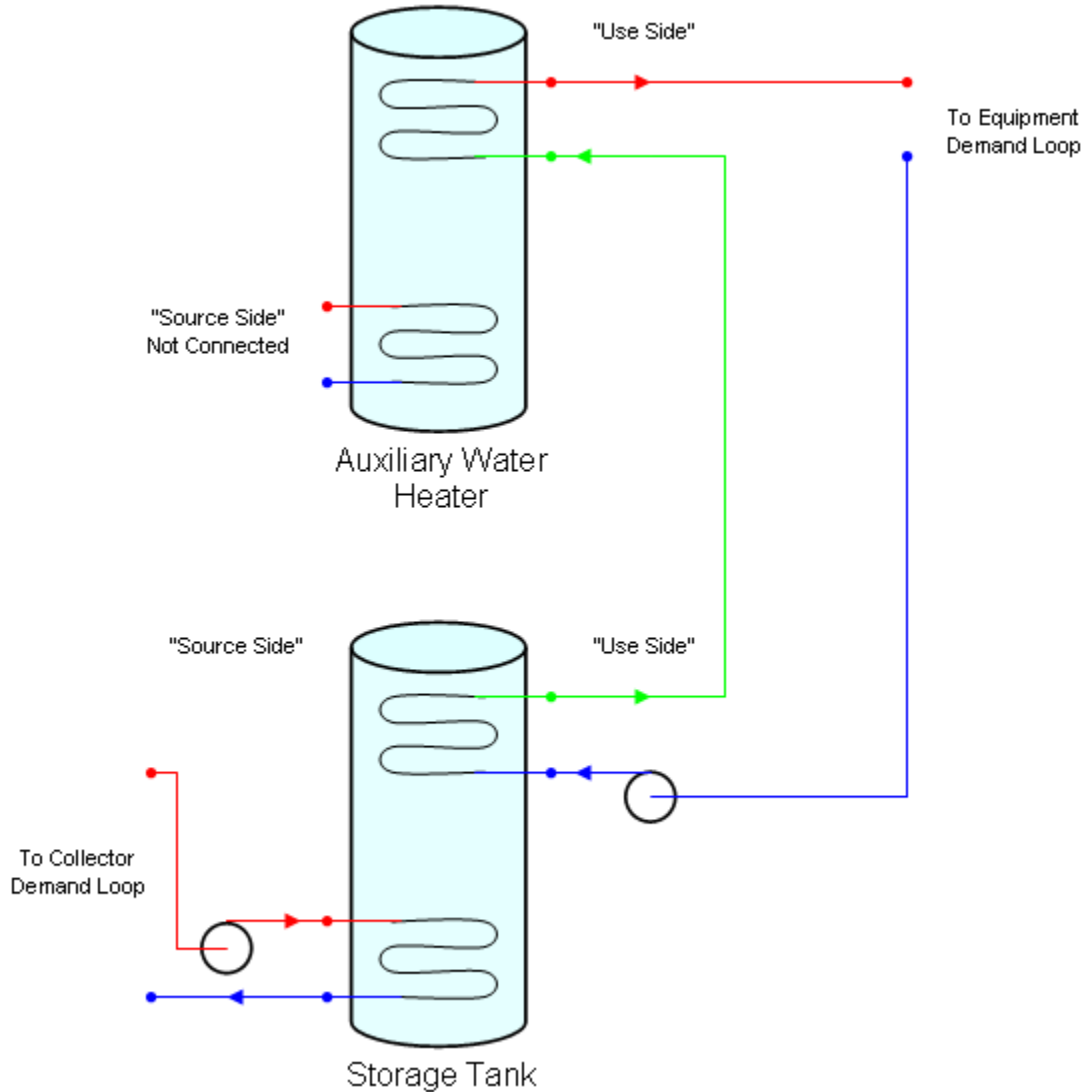

Figure 107. Two-Tank Solar Heating System Connection Diagram

Another strategy to consider for solar heating systems is to allow the storage tank to reach a much higher temperature than necessary for the end use. This allows the tank to store more energy from the solar collectors, when it is available. However, for applications such as domestic hot water, it is undesirable and unsafe to supply excessive hot water temperatures at the point of demand. To take advantage of higher storage temperatures, yet still avoid scalding temperatures at the faucet, the hot water leaving the storage tank can be tempered with cold water using a three-way valve to achieve the target temperature. See the TemperingValve object documentation for more details.

A complete two-tank solar heating system with tempering valve is shown below.

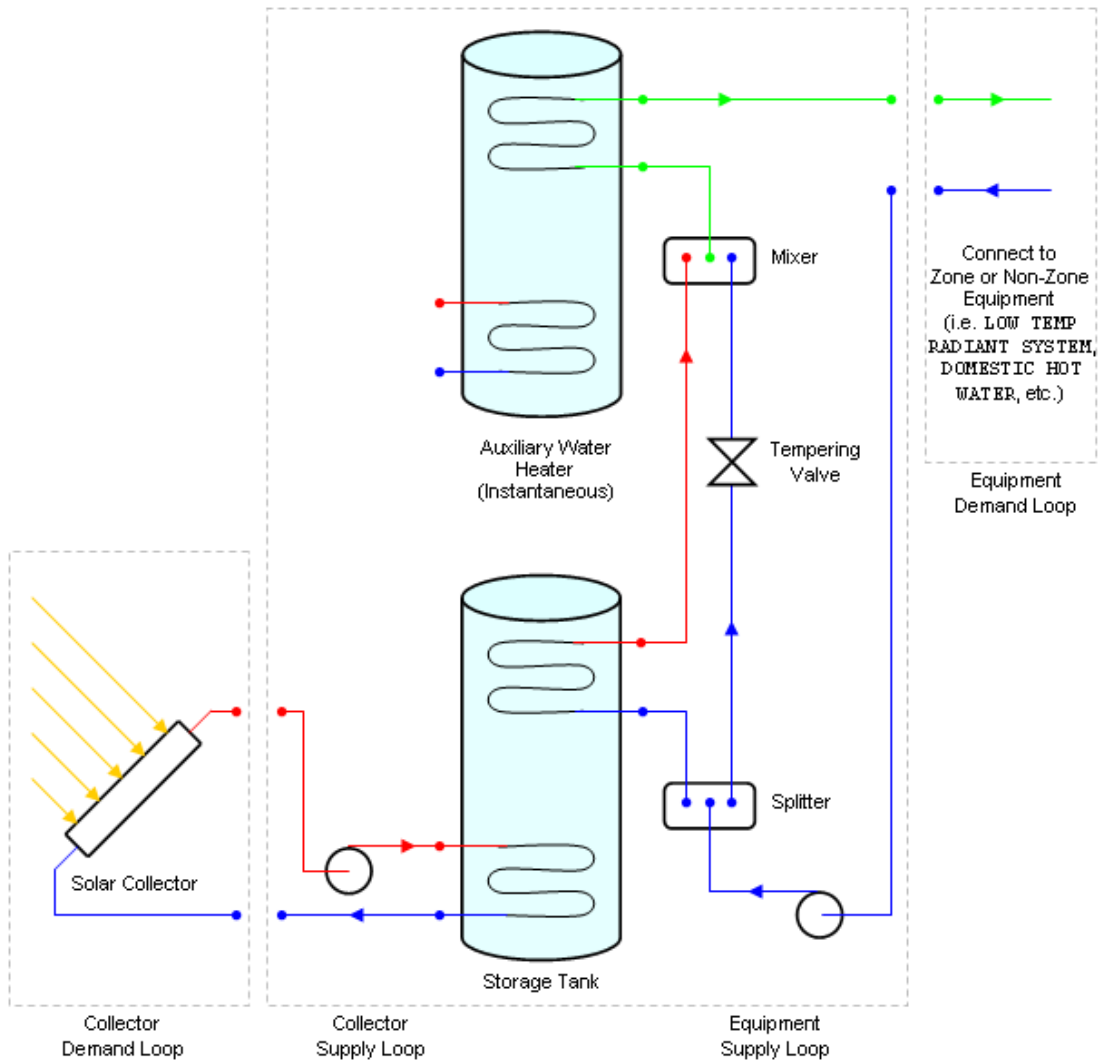

Figure 108. Two-Tank Solar Heating System with Tempering Valve

Solar Heating System Control

There are several options for controlling a solar heating system in EnergyPlus. Since the solar collectors request a constant flow demand based on their *Maximum Flow Rate*, the limiting factor is actually the flow rate determined by the loop pump. Therefore the entire system can be controlled using the *Pump Flow Rate Schedule* of the pump. If the schedule is omitted, the pump and system will run all the time (without any other controls specified). This is usually not the best way to operate a solar heating system.

To better control the collector loop, a differential thermostat can be used to compare the temperature in the water heater to the temperature in the collector so that the pump is only turned on when there is a useful heat gain. The differential thermostat is simulated using the *AvailabilityManager:DifferentialThermostat* object. For a typical system, the *Hot Node Name* field refers to an outlet node of one of the collector modules. The *Cold Node Name* field refers to the *Source Side Outlet* node, i.e. the cold storage water leaving the water heater. The fields *Temperature Difference On Limit* and *Temperature Difference Off Limit* are usually 8 – 12 C and 1 – 3 C respectively. If the two temperature differences are too close, it is possible for the system to turn on and off rapidly without much useful heat gain. This can also

occur if the flow rate through the collector is too high. Without flow the fluid in the collector heats up more quickly; when high flow is turned on, all of the hot fluid is removed and the temperature drops, forcing the system off again.

Another control method is to use a photovoltaic panel to power the pump. The system begins pumping when there is enough solar radiation to operate the pump. This is not yet implemented in EnergyPlus.

Freeze Prevention

In climates with a cold season, the solar heating system must be designed to avoid the risk of fluid freezing in the solar collector or exposed pipes and causing damage. This is not a problem if air is the heat transfer fluid. With water, however, there are several strategies that can minimize the risk.

Seasonal schedule. The simplest strategy is to not use the system during the cold season. This is a hassle because it requires the collector to be manually drained of all fluid. The benefits of the solar heating system are also lost during this time. This can be simulated in EnergyPlus with the appropriate pump schedule for the collector system.

Antifreeze. The freezing point of the liquid is decreased by adding antifreeze to the water or using a different heat transfer liquid with a lower freezing point. This cannot yet be simulated in EnergyPlus because only pure water is currently allowed in plant loops.

Drain-back system. This strategy automatically empties the collector when the pump is not running. This scenario is modeled by default in EnergyPlus, although the extra pump energy required to start the system is not taken into account.

Recirculation system. This strategy automatically recirculates warm liquid from the storage tank back through the collector to maintain the system above the freezing point. There are system losses using this method. This can be simulated in EnergyPlus by using AvailabilityManager:LowTemperatureTurnOn to force the system to turn on when the outdoor air temperature or collector outlet temperature falls below a specified minimum.

Additional Controls

In addition to freeze prevention, it is also necessary to prevent the system from becoming too hot. This is usually a safety issue for the water heater. For this case it is important to have a high temperature cutoff to stop the pump before damaging the water heater. This is accomplished with a AvailabilityManager:HighTemperatureTurnOff.

System Availability Manager List Example

To use the availability managers for the control cases described above, a AvailabilityManagerAssignmentList must be defined and referenced in the PlantLoop object of the collector loop. An example of a differential thermostat, recirculation for freeze prevention, and high temperature cutoff is shown below:

```

AvailabilityManagerAssignmentList,
Collector Loop Availability Manager List,      !- Name
AvailabilityManager:HighTemperatureTurnOff,   !- Availability Manager 1 Object Type
High Temperature Turn Off Availability Manager, !- Availability Manager 1 Name
AvailabilityManager:HighTemperatureTurnOn,    !- Availability Manager 2 Object Type
Low Temperature Turn On Availability Manager,  !- Availability Manager 2 Name
AvailabilityManager:DifferentialThermostat,   !- Availability Manager 3 Object Type
Differential Thermostat Availability Manager;  !- Availability Manager 3 Name

AvailabilityManager:HighTemperatureTurnOff,    ! For water heater safety
High Temperature Turn Off Availability Manager, !- Name
Water Heater Use Outlet Node,                 !- Sensor Node Name
60.0;                                          !- Temperature (C)

AvailabilityManager:HighTemperatureTurnOn,     ! For freeze prevention by recirculation
Low Temperature Turn On Availability Manager,  !- Name
Collector Outlet Node,                        !- Sensor Node Name
0.0;                                          !- Temperature (C)

AvailabilityManager:DifferentialThermostat,    ! For useful heat gain from collector to tank
Differential Thermostat Availability Manager,  !- Name
Collector Outlet Node,                        !- Hot Node Name
Water Heater Source Outlet Node,             !- Cold Node Name
10.0,                                         !- Temperature Difference On Limit (delta C)
2.0;                                          !- Temperature Difference Off Limit (delta C)

```

The AvailabilityManager:DifferentialThermostat object must always be the last manager in the availability manager list. See the AvailabilityManagerAssignmentList object documentation for more information.

SolarCollector:UnglazedTranspired

This object is used to model unglazed transpired solar collectors (UTSC) used to condition outdoor air. These collectors are generally used to heat air drawn through perforated absorbers that are heated by the sun and also recover heat conducted out through the underlying wall. The SolarCollector:UnglazedTranspired object represents a single collector attached to one or more BuildingSurface:Detailed objects and to one or more outdoor air systems. Therefore the transpired collector is part of both the thermal envelope and the HVAC system. An example file is provided called TranspiredCollectors.idf.

The area and orientation of the collector is obtained from BuildingSurface:Detailed objects, which are referenced by name. Although the collector surface itself is slightly detached from the underlying building wall (or roof), no additional surface object is needed to represent the collector itself. When modeling transpired collectors, it is important to consider the size of the collector when developing the building model's BuildingSurface:Detailed objects because the underlying surfaces must match the collector. For example, if the collector covers only part of the wall, then that wall should be split into separate surfaces where one matches the size of the collector. A single collector can be associated with as many BuildingSurface:Detailed objects as desired (although if you need to use more than 10 surfaces, then the IDD will need to be extended). The collector can be arranged at any tilt angle by describing the surfaces appropriately. The surfaces need not be contiguous nor have the same orientation, but the program will issue warnings if surfaces have widely ranging tilts and azimuths.

The collector conditions outdoor air and is connected to the outdoor air system using the usual method of specifying node names. Using the UTSC model requires specifying a relatively complete HVAC air system that includes an outdoor air path. This will typically require using a set of objects that, at a minimum, will include: AirLoopHVAC:ControllerList, AirLoopHVAC:OutdoorAirSystem:EquipmentList, AirLoopHVAC:OutdoorAirSystem, OutdoorAir:NodeList, OutdoorAir:Mixer, SetpointManager:MixedAir, and Controller:OutdoorAir. A single UTSC can serve more than one outdoor air system but requires also using a separate object, called SolarCollector:UnglazedTranspired:MultiSystem to specify node connections.

Controls for the UTSC involve setting the rate of air flow and the status of a bypass damper. If the bypass damper is open, then all the ventilation air goes straight into the outdoor air mixer; if it closed, then all the air first passes through the UTSC. The bypass damper is modeled as completely open or completely closed. The UTSC bypass damper control is determined by an availability manager, the airflow set by the outdoor air mixer controls, and thermostatic type controls that decide if heating is useful. An availability schedule is used to bypass the collector for certain times of the year, eg. summer cooling season. The air flow rates are set by controls associated with the outdoor air mixer (see `SetpointManager:MixedAir`, and `Controller:OutdoorAir`). Thermostatic type control decides if the collector will provide useful heating based on either of two types of setpoints. The first type of temperature setpoint is managed by `SetpointManager:MixedAir`, where the UTSC model looks at a control node, usually the mixed air node. The second type is an extra setpoint especially for free heating that is managed within this object where the UTSC model looks at the zone air node.

Field: Name

This field contains a unique name for the unglazed transpired solar collector.

Field: Boundary Conditions Model Name

This field contains the name of a `SurfaceProperty:OtherSideConditionsModel` object declared elsewhere in the input file. This will connect the collector to the exterior boundary conditions for the underlying heat transfer surface.

Field: Availability Schedule Name

This field contains the name of a schedule that determines whether or not the UTSC is available. When the schedule value is zero, the UTSC is always bypassed. When the schedule value is greater than zero, the UTSC is available and will be used when other conditions are met, such as outdoor air requested by mixer and preheating has been determined to be beneficial based on thermostatic control.

Field: Inlet Node Name

This field contains the name of an air node that provides air into the UTSC. This node name should also be assigned to be an outdoor air node using the `OutdoorAir:NodeList` or `OutdoorAir:Node` objects. This node should also be named as the actuated node in a `Controller:OutdoorAir` object. If the UTSC is connected to more than one air system, then this field can be left blank and the `SolarCollector:UnglazedTranspired:MultiSystem` object should be used to define the nodes.

Field: Outlet Node Name

This field contains the name of an air node that is the outlet of the UTSC. This node name will typically be the inlet to the `OutdoorAir:Mixer` (if there is no other equipment on the outdoor air path). If the UTSC is connected to more than one air system, then this field can be left blank and the `SolarCollector:UnglazedTranspired:MultiSystem` object should be used to define the nodes.

Field: Setpoint Node Name

This field contains the name of an air node that has a setpoint manager controlling its temperature setpoint. This node name will typically be named as the control node in a `Controller:OutdoorAir` object. If the UTSC is connected to more than one air system, then this field can be left blank and the `SolarCollector:UnglazedTranspired:MultiSystem` object should be used to define the nodes.

Field: Zone Node Name

This field contains the name of an air node for a thermal zone that is ultimately connected to the air system. This node is used with the setpoint schedule, defined in the following field, to

provide an added layer of thermostatic control for the UTSC without affecting the control of auxiliary heating. If there is a single air system that is connected to more than one zone, then a single zone should be selected based on where the thermostat might be located. If the UTSC is connected to more than one air system, then this field can be left blank and the SolarCollector:UnglazedTranspired:MultiSystem object should be used to define the nodes.

Field: Free Heating Setpoint Schedule Name

This field contains the name of a temperature schedule defined elsewhere in the input file. This schedule should define temperatures *desired* in the zone, but not necessarily *required*. This secondary setpoint schedule is used to allow the UTSC to operate as if it has its own thermostat that is separate from the primary control mechanism. When the UTSC is used with auxiliary heating, the usual setpoint managers and temperature controllers will determine how the auxiliary heaters are controlled. This allows using a higher zone air temperature setpoint for controlling UTSC bypass than for the auxiliary heating system.

Field: Diameter of Perforations in Collector

This field is used to enter the effective diameter of the perforations in the collector surface. The diameter should be entered in meters. For perforations other than round, use an equivalent diameter for a round hole that would have the same area.

Field: Distance Between Perforations in Collector

This field is used to enter the pitch, or average, shortest distance between perforations.

Field: Thermal Emissivity of Collector Surface

This field is used to enter the thermal emissivity of the collector. This surface property is for longwave infrared radiation. The property is used for both sides of collector. Most painted materials have an emissivity of 0.9.

Field: Solar Absorbtivity of Collector Surface

This field is used to enter the solar absorbtivity of the collector. This surface property is for shortwave, solar radiation. The property is used for the front side of the collector that faces the environment. Darker colors have a higher absorbtivity. While black is the highest performance, other colors might be used to match the color scheme of the rest of the facade. The following table provides sample solar absorbtivities for different colors (source: Conserval Engineering Inc., Toronto, Ontario, Canada).

Color Name of Kynar®⁸ Paint	Solar Absorptivity
Black	0.94
Classic Bronze	0.91
Chocolate Brown	0.90
Hartford Green	0.90
Med. Bronze	0.89

Field: Effective Overall Height of Collector

This field is used to enter a nominal height for the collector. This value is used in the program to determine a length scale in the vertical direction for the buoyancy-driven portion of natural ventilation that occurs when the collector is inactive. (Note that most of the geometry information is obtained from the underlying surfaces.) The value entered here is adjusted inside the program to account for tilt of the collector. While the value here would generally correspond to the actual distance/height, its value is not critical and it can be used to adjust modeling the air exchange rates in passive mode. If the collector is horizontal, then the length scale is obtained from the following field.

Field: Effective Gap Thickness of Plenum Behind Collector

This field is used to enter a nominal gap thickness for the collector. This distance value is only used when the collector is near horizontal to determine a length scale in the vertical direction for buoyancy calculations. For example, if the collector is mounted on a flat roof, its tilt-adjusted height is zero and the program will use this gap thickness as a length scale rather than the height from the previous field.

Field: Effective Cross Section Area of Plenum Behind Collector

This field is used to enter the nominal cross sectional area of the gap behind the collector. This area is used to determine a velocity scale for surface convection heat transfer correlations when the collector is active. This value is generally the average gap thickness times the average width of the collector.

Field: Hole Layout Pattern for Pitch

This field is used to describe the pattern of perforations in the collector surface. There are currently two choices available: Square and Triangle. Note that the hole layout pattern should be consistent with how the value for pitch was determined.

Field: Heat Exchange Effectiveness Correlation

This field is used to select which correlation is used to model heat transfer from the collector surface to the incoming air when the collector is active. There are two choices available: Kutscher1994, and VanDeckerHollandsBrunger2001. See the Engineering Reference for details and references.

Field: Ratio of Actual Collector Surface Area to Projected Surface Area

This field is used to enter a factor that accounts for the extra surface area resulting from corrugations in the collector surface. Corrugations help stiffen the collector. The projected surface area is obtained by the program from the (flat) underlying surfaces. If the collector is flat then this ratio is 1.0. If the collector is corrugated, then this ratio will be greater than one. A typical value might be 1.165.

Field: Roughness of Collector

This field is used to describe the relative roughness of the collector material. This field is similar to one in the Material object. This parameter only influences the convection coefficients, more specifically the outside convection coefficient. A special keyword is expected in this field with the options being "VeryRough", "Rough", "MediumRough", "MediumSmooth", "Smooth", and "VerySmooth" in order of roughest to smoothest options.

Field: Collector Thickness

This field is used to enter the thickness of the collector material. This value is only needed for the Van Decker Hollands Brunger 2001 correlation. The material thickness should be entered in meters.

Field: Effectiveness for Perforations with Respect to Wind

This field is used to enter a value for the coefficient used to determine natural air exchanges from wind, or Cv. When the collector is inactive, wind will cause exterior air to move in and out of the collector. Cv is an arbitrary coefficient used to model the effectiveness of openings and depends on opening geometry and the orientation with respect to the wind. Cv should probably be in the range 0.25 to 0.65. Increasing Cv will increase the amount of natural ventilation.

Field: Discharge Coefficient for Openings with Respect to Buoyancy Driven Flow

This field is used to enter a value for the coefficient used to determine natural air exchanges from buoyancy, or Cd. When the collector is inactive, stack or buoyancy effects will cause exterior air to move in and out of the collector. Cd is an arbitrary discharge coefficient that depends on the geometry of the opening. Cd should probably be in the range 0.4 to 1.0. Increasing Cd will increase the amount of natural ventilation.

Field: Surface <#> Name

The remaining fields are used to name the BuildingSurface:Detailed objects that are associated with the UTSC. These are the underlying heat transfer surfaces and are defined elsewhere in the input file. These other surfaces should all specify OtherSideConditionsModel as their exterior environment. The input object can currently accommodate up to ten surfaces, but it is extensible.

The IDD entry for this object follows.

HVAC,Average,UTSC Collector Efficiency []
```

UTSC Heat Exchanger Effectiveness []

The results from UTSC correlations defined by $\epsilon_{HX} = \frac{T_{a,HX} - T_{amb}}{T_{s, coll} - T_{amb}}$.

UTSC Leaving Air Drybulb from Collector [C]

The temperature of air entering the plenum after being heated by the collector.

UTSC Average Suction Face Velocity [m/s]

The bulk velocity of air approaching the collector.

UTSC Collector Temperature [C]

The surface temperature of the collector itself.

UTSC Plenum Drybulb Temperature [C]

The temperature of air inside, and leaving, the plenum behind the collector.

UTSC Sensible Heating Rate [W]

The overall rate at which heat is being added to the outdoor air stream.

SolarAir:Facility [J]

A meter that includes the heating energy provided by the UTSC.

SolarAir:HVAC [J]

A meter that includes the heating energy provided by the UTSC.

HeatProduced:SolarAir [J]

A meter that includes the heating energy provided by the UTSC.

UTSC Sensible Heating Energy [J]

The overall sum of energy added to the outdoor air stream.

UTSC Air Changes per Hour Passive [ACH]

The rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive in Air Changes per Hour.

UTSC Total Natural Vent Mass Flow [kg/s]

The mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive.

UTSC Total Natural Vent Mass Flow from Wind [kg/s]

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to wind-driven forces.

UTSC Total Natural Vent Mass Flow from Bouyancy [kg/s]

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to bouyancy-driven forces.

UTSC Incident Solar Radiation [W/m2]

The intensity of solar radiation incident on the UTSC collector from all sources.

UTSC Overall Efficiency []

The efficiency of the UTSC system including collected solar energy and heat recovered from the underlying surface.

UTSC Collector Efficiency []

The efficiency of the UTSC solar collector.

SolarCollector:UnglazedTranspired:MultiSystem

This object is used to model unglazed transpired solar collectors (UTSC) that are connected to multiple outdoor air systems. This object supplements the SolarCollector:UnglazedTranspired object and is only necessary if more than one air system is connected to a single transpired collector. After the name field, there are sets of four node names used to define the connections of each air system. Each set contains node names for inlet, outlet, control, and zone. If more than five air systems are needed, this object is extensible.

Field: Solar Collector Name

This field is used to identify the name of the SolarCollector:UnglazedTranspired object that needs to be connected to more than one air system. This field must match the name.

Field Set: Inlet Node, Outlet Node, Mixed Air Node, Zone Node

The following four fields form a repeating set of four fields. One set is used for each outdoor air system that is connected to the collector.

Field: Outdoor Air System <#> Collector Inlet Node

This field contains the name of an air node that provides air into the UTSC. This node name should also be assigned to be an outdoor air node using the OutdoorAir:NodeList and OutdoorAir:Node objects. This node is also be named as the actuator node in a Controller:OutdoorAir object.

Field: Outdoor Air System <#> Collector Outlet Node

This field contains the name of an air node that is the outlet of the UTSC. This node name will typically be the Outdoor Air Stream Node Name in the OutdoorAir:Mixer (if there is no other equipment on the outdoor air path).

Field: Outdoor Air System <#> Mixed Air Node

This field contains the name of an air node that has a setpoint manager controlling its temperature setpoint. This node name will typically be named as the mixed air node in a Controller:OutdoorAir object.

Field: Outdoor Air System <#> Zone Node

This field contains the name of an air node for a thermal zone that is ultimately connected to the air system. This node is used with the setpoint schedule, defined in the following field, to provide an added layer of thermostatic control for the UTSC without affecting the control of auxiliary heating. If there is a single air system that is connected to more than one zone, then a single zone should be selected based on where the thermostat might be located.

The IDD entry for this object follows.

Group – Pumps

EnergyPlus plant and condenser loops need pump components to drive liquid flow around the loop. There are various types of pump models available.

Pump:VariableSpeed

Pumps are needed in both plant and condenser loops. The syntax for a variable speed pump is given below.

Field: Name

This alpha field contains the identifying a unique name for the pump.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump outlet node.

Field: Rated Flow Rate

This numeric field contains the pump's rated volumetric flow rate in cubic meters per second.

Field: Rated Pump Head

This numeric field contains the pump's rated head pressure in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump's rated power consumption in Watts.

Field: Motor Efficiency

This numeric field contains the pump's efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump's fraction of power loss to the fluid.

Field: Coefficient 1 of the Part Load Performance Curve

This numeric field contains the first coefficient in the part load ratio curve. The fraction of full load power is determined by the cubic equation:

$$\text{FractionFullLoadPower} = C_1 + C_2\text{PLR} + C_3\text{PLR}^2 + C_4\text{PLR}^3$$

where $C_1, C_2, C_3,$ and C_4 are Coefficients 1 – 4 (below) and PLR is the Part Load Ratio.

Field: Coefficient 2 of the Part Load Performance Curve

This numeric field contains the second coefficient in the part load ratio curve.

Field: Coefficient 3 of the Part Load Performance Curve

This numeric field contains the third coefficient in the part load ratio curve.

Field: Coefficient 4 of the Part Load Performance Curve

This numeric field contains the fourth coefficient in the part load ratio curve.

Field: Minimum Flow Rate

This field contains the minimum volumetric flow rate while operating in variable flow capacity rate in cubic meters per second.

Field: Pump Control Type

This is a choice field of Continuous or Intermittent. A variable speed pump is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump is operating intermittently, then the pump can shutdown. For any other condition such as the loop having a load and the pump is operating intermittently or the pump is continuously operating (regardless of the loading condition), the pump will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump is running, it will try to meet the flow request made by demand side components.

Field: Pump Flow Rate Schedule Name

The schedule values modify the value for Rated Flow Rate of the pump on a time basis. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations.

The IDD entry for this object follows.

Pump:VariableSpeed Outputs

```

HVAC,Average,Pump Electric Power [W]
HVAC,Sum,Pump Electric Consumption [J]
HVAC,Average,Pump Shaft Power [W]
HVAC,Average,Pump Heat To Fluid [W]
HVAC,Sum,Pump Heat To Fluid Energy [J]
HVAC,Average,Pump Outlet Temp [C]
HVAC,Average,Pump Mass Flow Rate [kg/s]

```

Pump Electric Power [W]

Pump Electric Consumption [J]

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

Pump Heat To Fluid [W]

Pump Heat To Fluid Energy [J]

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

Pump Outlet Temp [C]

Pump Mass Flow Rate [kg/s]

These outputs are the water outlet temperature and mass flow rate.

Pump:ConstantSpeed

Pumps may be found in both plant and condenser loops. The syntax for a constant speed pump is given below.

Field: Name

This alpha field contains the identifying name for the pump.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump outlet node.

Field: Rated Flow Rate

This numeric field contains the pump's rated volumetric flow rate in cubic meters per second.

Field: Rated Pump Head

This numeric field contains the pump's rated head pressure in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump's rated power consumption in Watts.

Field: Motor Efficiency

This numeric field contains the pump's efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump's fraction of power loss to the fluid.

Field: Pump Control Type

This is a choice field of Continuous or Intermittent. The operation of a constant speed pump is fairly straightforward. If the user designates a constant speed pump that is operating continuously, the pump will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump is constant speed and operates intermittently, the pump will run at its capacity if a load is sensed and will shut off if there is no load on the loop.

Field: Pump Flow Rate Schedule Name

The schedule values modify the Rated Flow Rate of the pump on a time basis. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations.

The IDD entry for this object follows.

HVAC,Average,Pump Heat To Fluid [W]
HVAC,Sum,Pump Heat To Fluid Energy [J]
HVAC,Average,Pump Outlet Temp [C]
HVAC,Average,Pump Mass Flow Rate [kg/s]

```

Pump Electric Power [W]

Pump Electric Consumption [J]

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

Pump Heat To Fluid [W]

Pump Heat To Fluid Energy [J]

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

Pump Outlet Temp [C]

Pump Mass Flow Rate [kg/s]

These outputs are the water outlet temperature and mass flow rate.

HeaderedPumps:ConstantSpeed

Headered pumps are components with more than one identical pumps connected in parallel. The syntax for HeaderedPumps:ConstantSpeed is as follows.

Field: Name

This alpha field contains the identifying name for the pump bank.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump bank inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump bank outlet node.

Field: Total Rated Flow Rate

This numeric field contains the pump bank's rated volumetric flow rate in cubic meters per second. This is equal to the product of number of pumps and the flow rate of each individual pump. The field can be autosized.

Field: Number of Pumps in Bank

The numeric field specifies the number of pumps present in the pump bank. All these pumps are connected in parallel internally.

Field: Flow Sequencing Control Scheme

The alpha field specifies the scheme for sequencing flow. Currently the only choice is Sequential, where a pump in the pump bank will be turned ON only after fully loading the previous pump.

Field: Rated Pump Head

This numeric field contains the pump's rated head pressure in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump bank's total power consumption in Watts. This field is equal to the product of number of pumps and the rated power consumption of each individual pump.

Field: Motor Efficiency

This numeric field contains the pump's efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump's fraction of power loss to the fluid.

Field: Pump Control Type

This is a choice field of Continuous or Intermittent. The operation of a constant speed pump bank is fairly straightforward. If the user designates a constant speed pump bank that is operating continuously, the pump bank will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump bank is constant speed and operates intermittently, the pump bank will run at its capacity if a load is sensed and will shut off if there is no load on the loop.

Field: Pump Flow Rate Schedule Name

The schedule values modify the Total Rated Flow Rate of the pump on a time basis. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations.

The IDD entry for this object follows.

This output tells the number of pumps in the pump bank operating at any reporting frequency.

HeaderedPumps:VariableSpeed

Headered pumps are components with more than one identical pumps connected in parallel. Currently this object may be found only in plant loops. The syntax for a HeaderedPumps:VariableSpeed pump is given below.

Field: Name

This alpha field contains the identifying unique name for the pump bank.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump bank inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump bank outlet node.

Field: Total Rated Flow Rate

This numeric field contains the pump bank's rated volumetric flow rate in cubic meters per second. This is equal to the product of number of pumps and the flow rate of each individual pump. The field can be autosized.

Field: Number of Pumps in Bank

The numeric field specifies the number of pumps present in the pump bank. All these pumps are connected in parallel internally.

Field: Flow Sequencing Control Scheme

The alpha field specifies the scheme for sequencing flow. Currently the only choice is Sequential, where a pump in the pump bank will be turned ON only after fully loading the previous pump.

Field: Rated Pump Head

This numeric field contains the pump's rated head in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump bank's total power consumption in Watts. This field is equal to the product of number of pumps and the rated power consumption of each individual pump.

Field: Motor Efficiency

This numeric field contains the efficiency of the individual pump (which will be equivalent to pump bank efficiency) in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the individual pump's fraction of power loss to the fluid.

Field: Coefficient 1 of the Part Load Performance Curve

This numeric field contains the first coefficient (C_1) in the part load ratio curve. The fraction of full load power is determined by the cubic equation:

$$\text{FractionFullLoadPower} = C_1 + C_2\text{PLR} + C_3\text{PLR}^2 + C_4\text{PLR}^3$$

where $C_1, C_2, C_3,$ and C_4 are Coefficients 1 – 4 (below) and PLR is the Part Load Ratio.

Field: Coefficient 2 of the Part Load Performance Curve

This numeric field contains the second coefficient (C_2) in the part load ratio curve.

Field: Coefficient 3 of the Part Load Performance Curve

This numeric field contains the third coefficient (C_3) in the part load ratio curve.

Field: Coefficient 4 of the Part Load Performance Curve

This numeric field contains the fourth coefficient (C_4) in the part load ratio curve.

Field: Minimum Flow Rate

The numeric field specifies the minimum flow allowed for the pump bank as a fraction of the nominal flow. If the requested flow is less than minimum flow pump bank runs at minimum flow.

Field: Pump Control Type

This is a choice field of Continuous or Intermittent. A variable speed pump bank is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump bank is operating intermittently, then the bank can shutdown. For any other condition such as the loop having a load and the pump bank is operating intermittently or the pump bank is continuously operating (regardless of the loading condition), the bank will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump bank is running, it will try to meet the flow request made by demand side components.

Field: Pump Flow Rate Schedule Name

Modifies the Rated Volumetric Flow Rate of the pump on a time basis. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations.

Pump Electric Power [W]

Pump Electric Consumption [J]

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

Pump Heat To Fluid [W]

Pump Heat To Fluid Energy [J]

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

Pump Outlet Temp [C]

Pump Mass Flow Rate [kg/s]

These outputs are the water outlet temperature and mass flow rate.

Number of Pumps Operating []

This output tells the number of pumps in the pump bank operating at any reporting frequency.

Duct

The Duct object is a component for air systems that is a direct analogue for Pipe:Adiabatic in the fluid loops. It is used when it is necessary (due to the HVAC system configuration) to have a branch that has no functional components. This case most often arises for a bypass branch. Since every branch must have at least one component, the Duct component is used

for this situation. The duct is an adiabatic, pass-through component; all of its inlet conditions are passed through unchanged to its outlet.

Field: Name

This is the unique name for this component. Any reference to this component (in a BranchList, for instance) will refer to it by this name.

Field: Inlet Node Name

The name of the component's air inlet node.

Field: Outlet Node Name

The name of the component's air outlet node.

Below is the IDD definition of the Duct component.

```
Duct,
  \memo Passes inlet node state variables to outlet node state variables

```

Duct Outputs

There are no outputs for Duct.

Group – Heating and Cooling Coils

Several different coils may be added to zone equipment and air loops. This includes simple heating (gas, electric, and hot water) and a simple water-cooling coil as well as a more detailed flat fin water-cooling coil model. In general, the heating coil description can be used for a heating coil, a reheat coil, or a preheat coil in the air loop simulation or for zone equipment. Figure 109 is an example of a heating and cooling coil in the air loop simulation in a dual duct system. This does show the basic node structure that will be referenced in the input description. The figure does show water coils since they are the most complex to input in the simulation compared to the Electric and Gas coils which only have air connections.

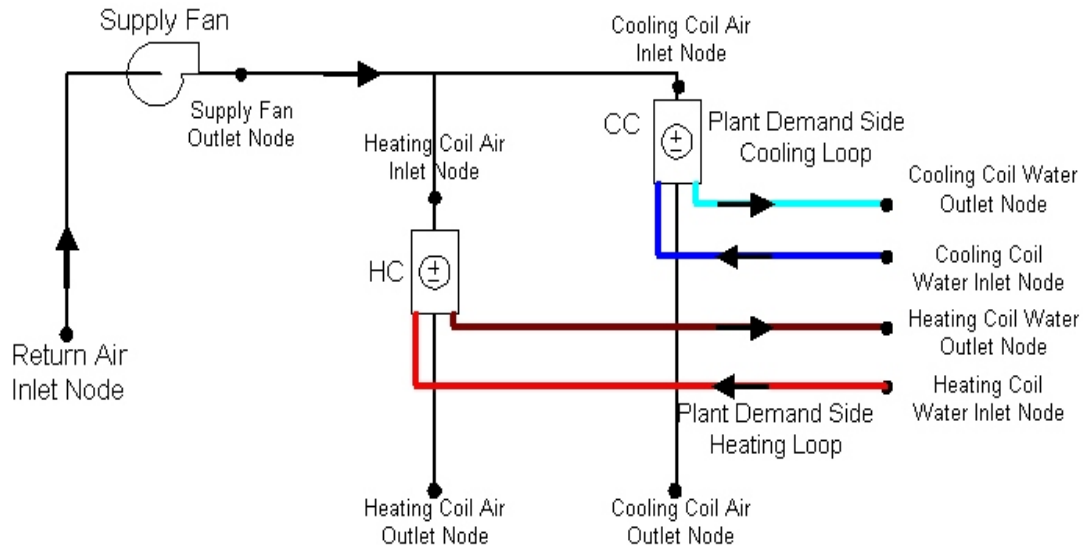

Figure 109. Example Air Loop Heating & Cooling Coil

Coil:Cooling:Water

The water cooling coil (Coil:Cooling:Water) has the ability to give detailed output with simplified inputs, inputting complicated coil geometry is not required by the user for this model instead the coil is sized in terms of auto-sizeable thermodynamic inputs. The coil requires thermodynamic inputs such as temperatures, mass flow rates and humidity ratios.

The coil is sized using auto-sized/user design input conditions and the UA values are calculated from the design conditions. A rough estimate of the coil area is provided along with percentage of surface wet and/or dry. This model uses the NTU-effectiveness approach to model heat transfer and has two types of flow arrangements cross-flow or counter-flow.

The basic underlying idea is - use auto sizeable thermodynamic design inputs, calculate the coil UA's, use these UA values and operating conditions from the nodes connections, calculate the outlet stream conditions, and calculate the heat transfer rates.

See section "Cooling Coil Model" in the EnergyPlus Engineering Document for further details regarding this model.

Field: Name

A unique user-assigned name for an instance of a cooling coil. Any reference to this cooling coil by another object will use this name.

Field: Available Schedule Name

Schedule that defines when the coil is available. The name of the schedule (ref: Schedule) that denotes whether the cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off.

Field: Design Water Flow Rate

The maximum possible water volume flow rate (m^3/sec) through the coil. This is an auto sizeable design input.

Field: Design Air Flow Rate

The maximum possible air volume flow rate (m^3/sec) through the coil. This is an auto sizeable design input.

Field: Design Inlet Water Temperature

The inlet water temperature for the design flow (deg C). This is an auto sizable design input.

Field: Design Inlet Air Temperature

The inlet air temperature for the design flow (deg C). This is an auto sizable design input.

Field: Design Outlet Air Temperature

The outlet air condition desired for design flow (deg C). This is an auto sizable design input.

Field: Design Inlet Air Humidity Ratio

The highest value of humidity ratio possible for the Design inlet air stream. This is an auto sizable input.

Field: Design Outlet Air Humidity Ratio

The value of humidity ratio for the Design outlet air stream, it is an auto sizable input.

Field: Water Inlet Node Name

The name of the water coil inlet from the chilled water loop, i.e. Cooling Coil Water Inlet Node. It is from this node the operating inputs for water are transferred to the coil.

Field: Water Outlet Node Name

The name of the water coil outlet from the chilled water loop, i.e. Cooling Coil Water Outlet Node. It is from this node the operating output for water are reported to the coil.

Field: Air Inlet Node Name

The name of the air inlet to the water coil, i.e. Cooling Coil Air Inlet Node. It is from this node the operating inputs for air are transferred to the coil.

Field: Air Outlet Node Name

The name of the air outlet from the water coil, i.e. Cooling Coil Air Outlet Node. It is from this node the operating output for airside is reported to the coil.

Field: Type of Analysis

The coil has two modes of operation, termed as **SimpleAnalysis** and **DetailedAnalysis**. The difference between the two modes being, the simple mode reports the value of surface area fraction wet of the coil as dry or wet. The detailed mode give the exact value, however the execution time in detailed mode is noticeably higher.

Field: Heat Exchanger Configuration

The coil is operable in two modes, Cross Flow for general A/C applications and Counter flow mode. Air-conditioning systems generally use cross flow heat exchangers, hence the default is set to cross flow.

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Below is the input data dictionary description for the Cooling coil:

Coil:Cooling:Water Outputs

Following are the list of possible output report variables from this coil model:

```

HVAC,Sum,Total Water Cooling Coil Energy[J]
HVAC,Sum,Sensible Water Cooling Coil Energy[J]
HVAC,Average,Total Water Cooling Coil Rate[W]
HVAC,Average,Sensible Water Cooling Coil Rate[W]
HVAC,Average,Cooling Coil Area Wet Fraction
HVAC,Average,Cooling Coil Condensate Volumetric Flow Rate [m3/s]
Zone,Meter,OnSiteWater:Facility [m3]
Zone,Meter,OnSiteWater:HVAC [m3]
Zone,Meter,Condensate:OnSiteWater [m3]
HVAC,Sum,Cooling Coil Condensate Volume [m3]

```

Total Water Cooling Coil Energy (J)

Total Water Cooling Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Sensible Water Cooling Coil Energy (J)

Sensible Water Cooling Coil Energy is the total amount of Sensible heat transfer taking place in the coil at the operating conditions. It only takes into account temperature difference in the inlet and outlet air streams at operating conditions.

Total Water Cooling Coil Rate (W)

Total Water Cooling Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

Sensible Water Cooling Coil Rate (W)

Sensible Water Cooling Coil Rate is the Rate of Sensible heat transfer taking place in the coil at the operating conditions.

Cooling Coil Area Wet Fraction

It defines the fraction of total surface area of coil which is wet due to moisture condensation on the surface of the coil. Value varies between 0.0 and 1.0.

In addition, if a Water Storage Tank is used to collect coil condensate, then the following outputs will be available.

Cooling Coil Condensate Volumetric Flow Rate [m3/s]

Cooling Coil Condensate Volume [m3]

These reports provide the rate and amount of condensate from the coil. Condensate is water condensed out of the air as a result of cooling. The condensate volume is also reported on the meter for "OnSiteWater."

Coil:Heating:Water

This simple heating coil model only does sensible heating of the air. The simple heating coil uses the Effectiveness-NTU algorithm and assumes a cross-flow heat exchanger.

Field: Name

A unique identifying name for each coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: U-Factor Times Area Value

The UA value for the coil needed for the Effectiveness-NTU heat exchanger model. An estimate of the UA can be obtained from:

$$q = UA \times (T_{\text{water, avg}} - T_{\text{air, avg}})$$

where q is the heat transferred from water to the air in watts; $T_{\text{water, avg}}$ is the average water temperature in degrees C; and $T_{\text{air, avg}}$ is the average air temperature in degrees C. Or the LMTD temperature difference can be used. This field is used when *Performance Input Method = UFactorTimesAreaAndDesignWaterFlowRate*. This field is autosizable.

Field: Maximum Water Flow Rate

The maximum possible water flow rate (m^3/sec) through the coil. This field is used when *Coil Performance Input Method = UFactorTimesAreaAndDesignWaterFlowRate*. This field is autosizable.

Field: Water Inlet Node Name

The name of the coil's water inlet node from the hot water loop.

Field: Water Outlet Node Name

The name of the coil's water outlet node from the hot water loop.

Field: Air Inlet Node Name

The name of the air inlet node to the water coil.

Field: Air Outlet Node Name

The name of the air outlet node from the water coil.

Field: Performance Input Method

The user can choose either *UFactorTimesAreaAndDesignWaterFlowRate* or *NominalCapacity*. If *UFactorTimesAreaAndDesignWaterFlowRate* is selected, the user must input values for UA of the Coil and Max Water FlowRate of the Coil (and Rated Capacity is ignored). If *NominalCapacity* is chosen, the user must input a Rated Capacity for the coil; UA of the Coil and Max Water FlowRate of the Coil will be ignored. Rated capacity is defined as the heating capacity in watts of the coil at the rating points (i.e., the rated inlet and outlet water/air temperatures defined in the input fields below). The rated capacity is used to calculate a water mass flow rate and a UA for the coil. The default is *NominalCapacity*.

To autosize the capacity, choose *UfactorTimesAreaAndDesignWaterFlowRate* and put autosize as the inputs for *U-Factor Times Area Value*, *Maximum Water Flow Rate*, and *Rated Capacity*. The program will use the Sizing inputs to size the coil. The rated temperatures (see below) are ignored in autosizing. These are used only when the user is specifying coil performance using the *NominalCapacity* input method.

Field: Rated Capacity

The heating capacity of the coil in watts at the rated inlet and outlet air and water temperatures. This field is used when the *Performance Input Method = Nominal Capacity*. This field is autosizable. The rating points are given in the four subsequent input fields.

Field: Rated Inlet Water Temperature

The inlet water temperature (degrees C) corresponding to the rated heating capacity. The default is 82.2 degrees C (180 degrees F).

Field: Rated Inlet Air Temperature

The inlet air temperature (degrees C) corresponding to the rated heating capacity. The default is 16.6 degrees C (60 degrees F).

Field: Rated Outlet Water Temperature

The outlet water temperature (degrees C) corresponding to the rated heating capacity. The default is 71.1 degrees C (160 degrees F).

Field: Rated Outlet Air Temperature

The outlet air temperature (degrees C) corresponding to the nominal heating capacity. The default is 32.2 degrees C (90 degrees F).

Field: Name

A unique identifying name for each steam coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: Maximum Steam Flow Rate

The maximum possible steam flow rate (m³/sec) through the coil. This field is autosizable.

Field: Degree of SubCooling

Ideally the steam trap located at the outlet of steam coil should remove all the condensate immediately, however there is a delay in this process in actual systems which causes the condensate to SubCool by certain degree in the coil before leaving the coil, this SubCool occurs in the steam coil and this SubCool-heat is added to the zone. The minimum value is 2 °Celsius and default is 5 °Celsius.

Field: Degree of Loop SubCooling

This essentially represents the heat loss to the atmosphere due to uninsulated condensate return piping to the boiler. Condensate return piping operates at atmospheric pressure and is not insulated. The condensate sub cools to certain degree before it is pumped back to the boiler. The minimum value is 10 °Celsius and default is 20 °Celsius.

Field: Water Inlet Node Name

The name of the steam coil inlet from the steam loop, i.e. Steam Coil steam inlet node.

Field: Water Outlet Node Name

The name of the steam coil outlet to the condensate loop, i.e. Steam Coil condensate outlet node.

Field: Air Inlet Node Name

The name of the air inlet to the steam coil, i.e. Steam Coil Air Inlet Node.

Field: Air Outlet Node Name

The name of the air outlet from the steam coil, i.e. Steam Coil Air Outlet Node.

Field: Coil Control Type

Choice of either **ZoneLoadControl** steam coil or **TemperatureSetpointControl** steam coil. A zone coil is load controlled and an air loop steam coil is temperature controlled.

An example of a Steam Coil input statement (Temperature Controlled) from an IDF is given below:

```
Coil:Heating:Steam,
  VAV SYS 1 Heating Coil,      !- Coil Name

Coil:Heating:Steam Outputs:

```
HVAC,Sum, Total Steam Coil Heating Energy[J]
HVAC,Average,Total Steam Coil Heating Rate[W]
HVAC,Average,Loop Losses[W]
HVAC, Average, Steam Coil Inlet Temp[C]
HVAC, Average, Steam Coil Outlet Temp [C]
HVAC, Average, Steam Coil Mass Flow Rate [kg/s]
```

Total Steam Heating Coil Energy (J)

Total Steam Heating Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Total Steam Heating Coil Rate (W)

Total Steam Heating Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

HVAC,Average,Loop Losses[W]

Loop losses represent the unavoidable loss due to degree of sub cooling in the condensate return piping back to the boiler and the loss occurring due to flashing of steam across the steam trap due to pressure differential between the steam and the condensate side.

Steam Coil Inlet Temp [C]**Steam Coil Outlet Temp [C]****Steam Coil Mass Flow Rate [kg/s]**

These outputs are the Steam inlet and condensate outlet temperatures and steam flow rate for the boiler.

Coil:Heating:Electric

The electric heating coil is a simple capacity model with a user-inputted efficiency. In many cases, this efficiency for the electric coil will be 100%. This coil will be simpler than shown in Figure 109 since it will only have air nodes to connect it in the system. The coil can be used in the air loop simulation or in the zone equipment as a reheat coil. Depending on where it is used determines if this coil is temperature or capacity controlled. If used in the air loop simulation it will be controlled to a specified temperature scheduled from the SetPoint Manager. If it is used in zone equipment, it will be controlled from the zone thermostat by meeting the zone demand.

Field: Name

A unique identifying name for each coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: Efficiency

This is user-inputted efficiency (decimal units, not percent) and can account for any loss. In most cases for the electric coil, this will be 100%.

Field: Nominal Capacity

This is the maximum capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

Field: Air Inlet Node Name

The name of the air inlet to the electric coil, i.e. Heating Coil Air Inlet Node.

Field: Air Outlet Node Name

The name of the air outlet from the electric coil, i.e. Heating Coil Air Outlet Node.

```

Coil:Heating:Electric Outputs

```

HVAC,Sum,Heating Coil Energy[J]
HVAC,Average,Heating Coil Rate[W]
HVAC,Sum,Heating Coil Electric Consumption [J]
HVAC,Average,Heating Coil Electric Power [W]

```

Heating Coil Energy (J)

Heating Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Heating Coil Rate[W]

Heating Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

Heating Coil Electric Consumption [J]

Heating Coil electric consumption after the efficiency of the coil has been taken into account in Joules for the timestep reported.

Heating Coil Electric Power [W]

This field is the average Heating Coil electric power after the efficiency of the coil has been taken into account in Watts for the timestep reported.

Coil:Heating:Desuperheater

A simplified approach is used to determine the performance of this air heating coil. The model assumes that the heating energy provided by this coil is reclaimed from the superheated refrigerant gas leaving a compressor (i.e., a desuperheating refrigerant-to-air heating coil) and does not impact the performance of the compressor. This coil can be used in air loop simulations but can't be used by certain compound objects (e.g., UnitarySystem: AirToAir:HeatPump, UnitarySystem:WaterToAir:HeatPump, or Desiccant Dehumidifier:Solid) or any air distribution equipment (e.g., Single Duct:Const Volume:Reheat, Single Duct:VAV:Reheat, or Single Duct:Series PIU:Reheat).

The desuperheater heating coil input requires a coil name, an availability schedule, and a heat reclaim recovery efficiency. The reclaim recovery efficiency determines the amount of heat available for use by this heating coil. Approximately 25-30% of the energy rejected by typical refrigeration system condensers is to reduce the superheated refrigerant vapor temperature to the condensing temperature. Recovery efficiencies higher than 30% may

cause the refrigerant gas to condense which in turn impacts the performance of the refrigeration system. For this reason, the maximum heat reclaim recovery efficiency for this coil is 30% for most sources of waste heat, including refrigeration compressor racks. The one exception to this 30% limit is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 0.9.

The next two input items for the desuperheater heating coil are the node names for the inlet and outlet air streams. The following two input fields define the source of heating energy for the coil. This desuperheater heating coil may only be used with direct expansion (DX) cooling or refrigeration equipment. The first of these two inputs is the heating source object type while the second defines the name of the heating source. For proper modeling, the desuperheater heating coil must be placed downstream of a DX cooling coil when reclaiming heat from that cooling coil. Desuperheating heating coil placement is unrestricted when reclaiming heat from a Refrigeration:CompressorRack or Refrigeration:Condenser.

The next input field is optional and defines the set point node name if the desuperheater heating coil is to be controlled based on temperature. When a load-based control scheme is used, this field is left blank. A final optional input is used to model parasitic electric energy use of auxiliary equipment associated with the desuperheater heating coil (e.g., solenoid valve).

Field: Name

This alpha field defines a unique user-assigned name for an instance of a desuperheater heating coil. Any reference to this desuperheater heating coil by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the desuperheater heating coil can run during a given time period. Schedule values must range from 0 to 1. A schedule value greater than 0 indicates that the coil can operate during the time period. A value equal to 0 denotes that the coil must be off for that time period.

Field: Heat Reclaim Recovery Efficiency

This numeric field defines the ratio of recovered waste heat from the superheated refrigerant gas to the total rejected waste heat from the heating source (as if no heat reclaim occurred). Values can range from 0.0 up to a maximum of 0.9 if the source is a refrigeration condenser and 0.3 for all other waste heat sources. If this input field is left blank, the default value is 0.8 for a refrigeration condenser source type and 0.25 for all other sources.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the desuperheater heating coil draws its inlet air.

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the desuperheater heating coil sends its outlet air.

Field: Heating Source Object Type

This alpha field defines the source of superheated refrigerant gas from which the desuperheater heating coil recovers energy. Valid choices are:

Coil:Cooling:DX:SingleSpeed Coil:Cooling:DX:TwoSpeed Coil:Cooling:DX:TwoStageWithHumidityControlMode Refrigeration:CompressorRack
--

Refrigeration:Condenser

When the heating coil source is a DX Coil, the air loop's supply air fan control mode may be auto fan (cycling fan cycling coil), constant fan, or variable volume. When the heating source is a compressor rack for refrigerated cases or a refrigeration condenser, the supply air fan control mode should be either variable volume or constant fan.

NOTE: Use of the desuperheater heating coil in variable air volume systems should be done with caution since the model assumption of a fixed heat reclaim recovery efficiency may not be valid if the air flow rate over the coil varies significantly.

Field: Heating Source Name

This alpha field defines the name of the desuperheater heating coil source (e.g., the name of a specific valid coil (as mentioned in the previous field) which provides waste heat to this desuperheater heating coil).

NOTE: When the heating source is a Refrigeration Compressor rack, the heat rejection location in the Refrigeration:CompressorRack object must be "Outdoors". If the compressor rack heat rejection location is "Zone", the total amount of heat rejection available for reclaim (e.g., by this desuperheater heating coil) is set to zero by the compressor rack object and the simulation proceeds.

Field: Temperature Setpoint Node Name

This optional alpha field defines the name of the HVAC system node used for temperature-based control (e.g., controlling the heating coil's outlet air dry-bulb temperature to a setpoint). If the desuperheater heating coil is temperature controlled through the use of a Set Point Manager, then the control node specified in the Set Point Manager will be entered here. If the desuperheater heating coil is controlled based on a certain heating load to be met (e.g., using this heating coil as part of UnitarySystem:BlowThru:HeatCool for high humidity control), this field should be left blank.

Field: Parasitic Electric Load

This optional numeric field defines the parasitic electric load (in Watts) due to control valves or other devices specific to the desuperheater heating coil. The load is applied whenever the coil is heating the air. The model assumes that this electric load is small and does not contribute to heating the air.

Below is the IDD Definition for the desuperheater heating coil.

HVAC,Sum,Heating Coil Energy [J]
HVAC,Average,Heating Coil Electric Power [W]
HVAC,Sum,Heating Coil Electric Consumption [J]
HVAC,Average,Heating Coil Runtime Fraction
    
```

Heating Coil Rate [W]

This output is the average heating rate of the desuperheater heating coil in Watts over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

Heating Coil Energy [J]

This output is the total heating output of the desuperheater heating coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Report Meter).

Heating Coil Electric Power [W]

This output is the average electric consumption rate for the parasitic load associated with the desuperheater heating coil in Watts.

Heating Coil Electric Consumption [J]

This output is the electric consumption of the desuperheater heating coil parasitic load in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter).

Heating Coil Runtime Fraction

This is the runtime fraction of the desuperheater heating coil for the timestep being reported. Since the desuperheater heating coil can only provide heat when the heat source object is active, the runtime fraction of the desuperheater heating coil will always be less than or equal to the runtime fraction of the heat source object.

Coil:WaterHeating:Desuperheater

A simplified approach is used to determine the performance of this water heating coil. The model assumes that the heating energy provided by this coil is reclaimed from the superheated refrigerant gas leaving a compressor (i.e., a desuperheating refrigerant-to-water heating coil) and does not impact the performance of the compressor. This coil must be used with a water heater tank (e.g., Water Heater:Mixed) which can supply heated potable water and/or hot water for use in a plant loop (e.g., hydronic air reheat coils).

Except for detailed refrigeration system models, the amount of available superheat is simply a percentage of the total heat being rejected by the DX system's condenser. Approximately 25-30% of the energy rejected by typical refrigeration system condensers is to reduce the superheated refrigerant vapor temperature to the condensing temperature. Recovery efficiencies higher than 30% may cause the refrigerant gas to condense which in turn impacts the performance of the refrigeration system. For this reason, the maximum heat reclaim recovery efficiency for this coil is 30% for most sources of waste heat, including refrigeration compressor racks. The one exception to this 30% limit is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 90%.

The model includes the ability to modify the heat reclaim recovery efficiency based on variations in inlet water temperature and outdoor air dry-bulb temperature.

This coil model performs the following major functions:

- calculates the amount of heat delivered to the water tank
- calculates the electricity consumption of the integral water pump and on/off-cycle parasitic loads

The input fields for this object are described below in detail:

Field: Name

This alpha field contains a unique user-assigned name for an instance of a desuperheater water heating coil. Any reference to this desuperheater coil by another object will use this name.

Field: Availability Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that denotes whether the desuperheater coil is available to operate during a given time period. A schedule value equal to 0 denotes that the desuperheater coil is off for that time period. A value other than 0 denotes that the desuperheater coil is available to operate during that time period. During times when the desuperheater coil is scheduled off, the heater (element or burner) in the water tank object operates based on its tank set point temperature schedule and the desuperheater coil's parasitic electric power is also off for that time period.

Field: Setpoint Temperature Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that specifies the set point (or "cut-out") temperature for the desuperheater coil. Temperature values used in this schedule should be in degrees Celsius. The desuperheater coil turns off when the tank water reaches this set point temperature. Once the desuperheater coil is off, the tank water temperature floats downward until it falls below the set point temperature minus the dead band temperature difference defined below (i.e., the "cut-in" temperature). At this point, the desuperheater coil turns on and remains on until the desuperheater coil set point temperature is reached.

Field: Dead Band Temperature Difference

This numeric field contains the dead band temperature difference in degrees Celsius. The desuperheater coil "cut-in" temperature is defined as the desuperheater coil set point temperature defined above minus this dead band temperature difference. The desuperheater coil turns on when the water temperature in the tank falls below the "cut-in" temperature. The desuperheater coil remains on until the water temperature in the tank rises above the desuperheater coil set point ("cut-out") temperature defined above. The dead band temperature difference must be greater than 0°C and less than or equal to 20°C. If this field is left blank, the default value is 5°C.

Desuperheater water heating coils are typically used to offset energy consumption by the water tank's heater (element or burner). Therefore, the cut-in temperature for the desuperheater coil (set point minus dead band temperature difference) is usually higher than the set point temperature for the heater (element or burner) in the associated water heater tank object. At times when the water heater tank set point temperature is greater than the cut-in temperature of the desuperheater coil, the model disables the desuperheater coil and the tank's heater is used to heat the water.

Field: Rated Heat Reclaim Recovery Efficiency

This numeric field defines the ratio of recovered waste heat from the superheated refrigerant gas to the total rejected waste heat from the heating source (as if no heat reclaim occurred). Input values must be greater than 0 up to a maximum value is 0.3 (with a defaults of 0.25) for most sources of waste heat, including refrigeration compressor racks. The one exception to this 0.3 limit is a source that is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 0.9. with a default value is 0.8.

Field: Rated Inlet Water Temperature

This numeric field defines the coil inlet water temperature, in degrees Celsius, that corresponds to the rated heat reclaim recovery efficiency. Also see field “Heat Reclaim Efficiency Modifier Curve Name (function of temperature)” below.

Field: Rated Outdoor Air Temperature

This numeric field defines the outdoor air dry-bulb temperature, in degrees Celsius, that corresponds to the rated heat reclaim recovery efficiency. The outdoor air dry-bulb temperature impacts the desuperheater coil refrigerant temperature and the amount of heat available for reclaim. Also see field “Heat Reclaim Efficiency Modifier Curve Name(function of temperature)” below.

Field: Maximum Inlet Water Temperature for Heat Reclaim

This numeric field defines the maximum coil inlet water temperature in degrees Celsius. Any time the inlet water temperature to the desuperheater coil is above this maximum allowed temperature, heat reclaim is restricted so that the tank water does not exceed this temperature.

Field: Heat Reclaim Efficiency Function of Temperature Curve Name

This alpha field specifies the name of a bi-quadratic curve object (ref: Performance Curves) that defines the variation in heat reclaim efficiency as a function of inlet fluid (air and water) temperatures. The bi-quadratic curve uses the coil inlet water temperature and outdoor air dry-bulb temperature (entering the DX coil condenser) as the independent variables. The output of this curve is multiplied by the rated heat reclaim recovery efficiency to give the heat reclaim efficiency at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heat reclaim efficiency remains constant (curve value assumed to be 1.0 for all conditions). The model restricts the product of the output of this curve and the rated heat reclaim recovery efficiency to a maximum of 0.9 for refrigeration condenser sources and 0.3 for all other sources..

Field: Water Inlet Node Name

This alpha field defines the name of the water node from which the desuperheater heating coil draws its inlet water. This node name must also match the source side outlet node name for the water heater tank used with this coil (ref. Water Heaters).

Field: Water Outlet Node Name

This alpha field defines the name of the water node to which the desuperheater heating coil sends its outlet water. This node name must also match the source side inlet node name for the water heater tank used with this coil (ref. Water Heaters).

Field: Tank Object Type

This alpha (choice) field contains the type of water heater tank used by this desuperheater heating coil. Currently, the only valid choice is Water Heater:Mixed.

Field: Tank Name

This alpha field contains the name of the specific water heater tank (Water Heater:Mixed object) used by this desuperheater heating coil.

Field: Heating Source Object Type

This alpha (choice) field defines the source of superheated refrigerant gas from which the desuperheater water heating coil recovers energy through heat reclaim. Valid choices are:

Coil:Cooling:DX:SingleSpeed
Coil:Cooling:DX:TwoSpeed

Coil:Cooling:DX:TwoStageWithHumidityControlMode Refrigeration:CompressorRack Refrigeration:Condenser
--

Field: Heating Source Name

This alpha field defines the name of the desuperheater coil's heat source (e.g., the name of a specific coil of the type mentioned in the previous field which provides waste heat to this desuperheater water heating coil).

Field: Water Flow Rate

This numeric field defines the desuperheater coil's water flow rate in cubic meters per second. The model assumes that this flow rate is constant (throughout the simulation period) when the desuperheater coil operates, and that it corresponds to the heat reclaim recovery efficiency performance specified by the user. This water flow rate must be greater than zero.

Field: Water Pump Power

This numeric field defines the coil's water circulation pump power in Watts. This is the operating pump power as installed. Values must be greater than or equal to 0. If this field is left blank, the default value is 0. A warning message will be issued if the ratio of water pump power to desuperheater water volumetric flow rate exceeds $7.9264E6$ W/m³/s, but the simulation will continue using the user-defined values. The model assumes that this integral pump (i.e., no need to define a separate pump object) cycles on and off with the desuperheater heating coil.

Field: Fraction of Pump Heat to Water

This numeric field defines the fraction of water circulation pump heat that is transferred to the water. The pump is assumed to be downstream of the desuperheater water heating coil, and this field is used to determine the desuperheater water outlet temperature. Values must be greater than or equal to 0 and less than or equal to 1. If this field is left blank, the default value is 0.2.

Field: On-Cycle Parasitic Electric Load

This optional numeric field contains the on-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the desuperheater water heating coil. This parasitic electric load is consumed whenever the desuperheater coil is operating, and the model assumes that this parasitic power does not contribute to heating the water nor does it affect the zone air heat balance. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Field: Off-Cycle Parasitic Electric Load

This optional numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the desuperheater water heating coil. This parasitic electric load is consumed whenever the desuperheater coil is available but is not operating, and the model assumes that this parasitic power does not contribute to heating the water nor does it affect the zone air heat balance. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Below is the IDD definition for the object:

```

Coil:WaterHeating:Desuperheater,
  \min-fields 18
A1 , \field Name
  \required-field
  \type alpha
  \reference WaterHeatingCoilsDesuperheater
  \note Unique name for this instance of a desuperheater water heating coil.
A2 , \field Availability Schedule Name
  \type alpha
  \note Schedule values of 0 denote the desuperheater heating coil is off and the parasitic electric
  \note energy is also off.
A3 , \field Setpoint Temperature Schedule Name
  \required-field
  \type alpha
  \note Defines the cut-out temperature where the desuperheater water heating coil turns off.
  \note The desuperheater heating coil setpoint temperature should always be greater
  \note than the water tank's heater (element or burner) setpoint temperature. Temperature
  \note schedule values should be in degrees C.
N1 , \field Dead Band Temperature Difference
  \type real
  \units deltaC
  \minimum> 0
  \maximum 20
  \default 5
  \note Setpoint temperature minus the dead band temperature difference defines
  \note the cut-in temperature where the desuperheater water heating coil turns on.
  \note The water tank's heater (element or burner) setpoint temperature
  \note should always be less than the desuperheater heating coil cut-in temperature.
N2 , \field Rated Heat Reclaim Recovery Efficiency
  \type real
  \minimum> 0.0
  \maximum 0.3
  \default 0.25
  \note Enter the fraction of waste heat reclaimed by the desuperheater water heating coil.
N3 , \field Rated Inlet Water Temperature
  \required-field
  \type real
  \units C
  \note The inlet water temperature corresponding to the rated heat reclaim recovery efficiency.
N4 , \field Rated Outdoor Air Temperature
  \required-field
  \type real
  \units C
  \note The outdoor air dry-bulb temperature corresponding to the
  \note rated heat reclaim recovery efficiency.
N5 , \field Maximum Inlet Water Temperature for Heat Reclaim
  \required-field
  \type real
  \units C
  \note The desuperheater water heating coil is off when the inlet water temperature is above
  \note the maximum inlet water temperature for heat reclaim.
A4 , \field Heat Reclaim Efficiency Function of Temperature Curve Name
  \type object-list
  \object-list CubicCurves
  \note A biquadratic curve defining the performance of the desuperheater heating coil.
  \note Performance can be specified as a function of inlet water temperature, outdoor air
  \note dry-bulb temperature, or both.
  \note Curve = a + b*Tw + c*Tw**2 + d*odb + e*odb**2 + f*Tw*odb.
  \note Tw = desuperheater heating coil entering water temperature (C).
  \note Odb = outdoor dry-bulb temperature at DX system condenser (C).
A5 , \field Water Inlet Node Name
  \required-field
  \type alpha
  \note The node from which the desuperheater heating coil draws its inlet water.
  \note This name should match the source side outlet node name in the associated
  \note water heater tank object.

```

```

A6 , \field Water Outlet Node Name
    \required-field
    \type alpha
    \note The node to which the desuperheater heating coil sends its outlet water.
    \note This name should match the source side inlet node name in the associated
    \note water heater tank object.
A7 , \field Tank Object Type
    \required-field
    \type choice
    \key WaterHeater:Mixed
    \default WaterHeater:Mixed
    \note Specify the type of water heater tank used by this desuperheater water heating coil.
A8 , \field Tank Name
    \required-field
    \type alpha
    \note The name of the water heater tank used by this desuperheater water heating coil.
    \note Needs to match the name used in the corresponding water heater object.
A9 , \field Heating Source Object Type
    \required-field
    \type choice
    \key Coil:Cooling:DX:SingleSpeed
    \key Coil:Cooling:DX:TwoSpeed
    \key Coil:Cooling:DX:TwoStageWithHumidityControlMode
    \key Refrigeration:CompressorRack
    \key Refrigeration:Condenser
    \note The type of DX system that is providing waste heat for reclaim.
A10, \field Heating Source Name
    \required-field
    \type object-list
    \object-list DesuperHeatingCoilSources
    \note The name of the DX system used for heat reclaim.
N6 , \field Water Flow Rate
    \required-field
    \type real
    \units m3/s
    \minimum > 0
    \note The operating water flow rate.
N7 , \field Water Pump Power
    \type real
    \units W
    \minimum 0.0
    \default 0.0
    \note The water circulation pump electric power.
N8 , \field Fraction of Pump Heat to Water
    \type real
    \minimum 0
    \maximum 1
    \default 0.2
    \note The fraction of pump heat transferred to the water. The pump is assumed to be downstream of
    \note the desuperheater water heating coil.
N9 , \field On-Cycle Parasitic Electric Load
    \type real
    \units W
    \minimum 0
    \default 0
    \note Parasitic electric power consumed when the desuperheater water heating coil operates.
    \note Parasitic electric load does not contribute to water heating or the zone air heat balance.
    \ip-units W
N10; \field Off-Cycle Parasitic Electric Load
    \type real
    \units W
    \minimum 0
    \default 0
    \note Parasitic electric load consumed when the desuperheater water heating coil is off.
    \note Parasitic electric load does not contribute to water heating or the zone air heat balance.
    \note Off-cycle parasitic power is 0 when the availability schedule is 0.
    \ip-units W

Desuperheater Part Load Ratio

This output field contains the part load ratio of the desuperheater heating coil for the timestep being reported. This ratio represents the fraction of the timestep that the desuperheater heating coil is operating.

Desuperheater Water Heating Rate [W]

This output field contains the average heating rate output of the desuperheater heating coil in Watts for the timestep being reported. This value includes the portion of circulation pump heat attributed to heating the water.

Desuperheater Water Heating Energy [J]

This output field contains the total heating output of the desuperheater heating coil in Joules for the timestep being reported. This value includes the portion of circulation pump heat attributed to heating the water.

Desuperheater Pump Electric Power [W]

This output field contains the average electricity consumption rate for the water circulation pump in Watts for the timestep being reported.

Desuperheater Pump Electric Consumption [J]

This output field contains the electricity consumption of the water circulation pump in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key= DHW, Group Key= Plant (ref. Report Meter).

Desuperheater Heat Reclaim Efficiency Modifier Curve Output

This output field contains the average output of the Heat Reclaim Efficiency Modifier Curve (function of temperature) for the timestep being reported.

Desuperheater On-Cycle Parasitic Electric Power [W]***Desuperheater On-Cycle Parasitic Electric Consumption [J]******Desuperheater Off-Cycle Parasitic Electric Power [W]******Desuperheater Off-Cycle Parasitic Electric Consumption [J]***

These outputs are the parasitic electric power and consumption associated with the desuperheater water heating coil. Specific outputs represent parasitic electrical usage during the coil on and off cycles. These outputs represent electronic controls or other electric component. The model assumes that the parasitic power does not contribute to heating the water nor does it impact the zone air heat balance. The parasitic electric consumption outputs are also added to a report meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Report Meter).

Coil:Heating:Gas

The gas heating coil is a simple capacity model with a user inputted gas burner efficiency. The default for the gas burner efficiency is 80%. This coil will be simpler than shown in Figure 109 since it will only have air nodes to connect it in the system. The coil can be used in the air loop simulation or in the zone equipment as a reheat coil. Depending on where it is used determines if this coil is temperature or capacity controlled. If used in the air loop simulation it will be controlled to a specified temperature scheduled from the Setpoint Manager. If it is used in zone equipment, it will be controlled from the zone thermostat by meeting the zone demand.

Field: Name

A unique identifying name for each coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: Gas Burner Efficiency

This is user inputted gas burner efficiency (decimal, not percent) and is defaulted to 80%.

Field: Nominal Capacity

This is the maximum capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

Field: Air Inlet Node Name

The name of the air inlet to the gas coil, i.e. Heating Coil Air Inlet Node.

Field: Air Outlet Node Name

The name of the air outlet from the gas coil, i.e. Heating Coil Air Outlet Node.

Field: Temperature Setpoint Node Name

If the coil is used in the air loop simulation and is temperature controlled by the Set Point Manager then the node that is the control node needs to be specified here.

Field: Parasitic Electric Load

This is the parasitic electric load associated with the gas coil operation, such as an inducer fan, etc.. This will be modified by the PLR (or coil runtime fraction if a part-load fraction correlation is provided in the next input field) to reflect the time of operation in a simulation timestep.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of gas consumption rate by the heating coil as a function of the part load ratio (PLR, sensible heating load/nominal capacity of the heating coil). For any simulation timestep, the nominal gas consumption rate (heating load/burner efficiency) is divided by the part-load fraction (PLF) if a part-load curve has been defined. The part-load curve accounts for efficiency losses due to transient coil operation.

The part-load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the heating coil runs continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$$\text{PLF} \geq 0.7 \quad \text{and} \quad \text{PLF} \geq \text{PLR}$$

If $\text{PLF} < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the heating coil is defined a PLR/PLF . If $\text{PLF} < \text{PLR}$, then a warning message is issues and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional gas heating coil (e.g., residential furnace) would be:

$$\text{PLF} = 0.8 + 0.2(\text{PLR})$$

Field: Parasitic Gas Load

This numeric field is the parasitic gas load associated with the gas coil's operation (Watts), such as a standing pilot light. The model assumes that this parasitic load is consumed only for the portion of the simulation timestep where the gas heating coil is not operating.

Heating Coil Energy [J]

This field is the total heating output of the coil in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Report Meter).

Heating Coil Rate [W]

This field is the average heating rate output of the coil in Watts over the timestep being reported.

Heating Coil Gas Consumption [J]

This field is the gas consumption of the heating coil in Joules over the timestep being reported, including the impacts of part-load performance if a part load fraction correlation is specified. This output is also added to a report meter with Resource Type = Gas, End Use Key = Heating, Group Key = System (ref. Report Meter).

Heating Coil Gas Consumption Rate [W]

This field is the average gas consumption rate of the coil in Watts over the timestep being reported, including the impacts of part-load performance if a part load fraction correlation is specified.

Heating Coil Electric Consumption [J]

This field is the electric consumption of the heating coil auxiliaries in Joules over the timestep being reported (e.g., inducer fan). This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter).

Heating Coil Electric Power [W]

This field is the average electric consumption rate of the heating coil auxiliaries (e.g., inducer fan) in Watts over the timestep being reported.

Heating Coil Parasitic Gas Consumption [J]

This field is the parasitic gas consumption of the heating coil in Joules over the timestep being reported (e.g., standing pilot light). The model assumes that the parasitic load is accumulated only for the portion of the simulation timestep where the gas heating coil is not operating. This output is also added to a report meter with Resource Type = Gas, End Use Key = Heating, Group Key = System (ref. Report Meter).

Heating Coil Parasitic Gas Consumption Rate [W]

This field is the average parasitic gas consumption rate of the heating coil (e.g., standing pilot light) in Watts over the timestep being reported. The model assumes that the parasitic load is present only for the portion of the simulation timestep where the gas heating coil is not operating.

Coil:Cooling:Water:DetailedGeometry

This detailed flat fin coil model is for continuous plate fins. First, found in Type 12 from MODSIM, but now programmed directly from Elmahdy, A.H. and Mitalas, G.P. Then there was a discontinuity in their original model that was fixed in the EnergyPlus implementation. Now this model can be used in an interval halving solution technique for controlling this coil without the problems of non-convergence.

"A Model for Cooling and Dehumidifying Coils for Use in Energy Requirements for Buildings" ASHRAE Transactions, Vol. 83, Part 2, pp. 103-117 (1977). For fin efficiency see K.A. Gardner, "Efficiency of Extended ," Transactions ASME, Vol. 67, pp. 621-631, 1945.

The following figures illustrate the geometry and circuits in a cooling coil.

Figure 110. Geometry of a Cooling Coil (CC)

Half Circuiting - 2 passes per vertical row
 (Note: Rows are perpendicular to air flow)

Figure 111. Number of Coolant Circuits (CCNCC)

Field: Name

A unique identifying name for each coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: Maximum Water Flow Rate

The maximum possible water flow rate (m³/sec) through the coil.

Field: Tube Outside Surface Area

The outside surface area (m²) of the tubes that is exposed to air (i.e. the outside area of the unfinned tubes minus the area of tubes covered by the fins).

Field: Total Tube Inside Area

The total surface area (m²) inside the tubes (water side).

Field: Fin Surface Area

The total surface area (m²) of the fins attached to the coil.

Field: Minimum Air Flow Area

The minimum cross sectional area (m²) available for air passage. Frequently calculated as

$$A_{\min} = (A_{\min}/A_{\text{fr}}) * A_{\text{fr}}$$

where A_{fr} is the frontal area of the heat exchanger, and (A_{\min}/A_{fr}) is the ratio of the minimum airflow area to frontal area.

Field: Coil Depth

The distance (m) from the front of the coil to the back of the coil in the airflow direction. Also called the fin depth. Illustrated in the figure (Figure 110. Geometry of a Cooling Coil (CC)).

Field: Fin Diameter

The outside diameter (m) of the fins. Used instead of COIL HEIGHT

Field: Fin Thickness

Thickness (m) of the air side fins.

Field: Tube Inside Diameter

The inside diameter (m) of the tubes.

Field: Tube Outside Diameter

The outside diameter (m) of the tubes.

Field: Tube Thermal Conductivity

The thermal conductivity (W/m-K) of the tube material.

Field: Fin Thermal Conductivity

The thermal conductivity (W/m-K) of the fin material.

Field: Fin Spacing

The spacing (m) of the fins, centerline to centerline.

Field: Tube Depth Spacing

The spacing (m) of the tube rows, centerline to centerline. Also called tube longitudinal spacing.

Field: Number of Tube Rows

The number of tube rows in the direction of the airflow.

Field: Number of Tubes per Row

The number of tubes per row. (NTPR in the above diagram)

Field: Water Inlet Node Name

The name of the water coil inlet from the chilled water loop, i.e. Cooling Coil Water Inlet Node.

Field: Water Outlet Node Name

The name of the water coil outlet from the chilled water loop, i.e. Cooling Coil Water Outlet Node.

Field: Air Inlet Node Name

The name of the air inlet to the water coil, i.e. Cooling Coil Air Inlet Node.

Field: Air Outlet Node Name

The name of the air outlet from the water coil, i.e. Cooling Coil Air Outlet Node.

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

The IDD specification for this object:

Total Water Cooling Coil Energy (J)

Total Water Cooling Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Sensible Water Cooling Coil Energy (J)

Sensible Water Cooling Coil Energy is the total amount of Sensible heat transfer taking place in the coil at the operating conditions. It only takes into account temperature difference in the inlet and outlet air streams at operating conditions.

Total Water Cooling Coil Rate (W)

Total Water Cooling Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

Sensible Water Cooling Coil Rate (W)

Sensible Water Cooling Coil Rate is the Rate of Sensible heat transfer taking place in the coil at the operating conditions.

In addition, if a Water Storage Tank is used to collect coil condensate, then the following outputs will be available.

Cooling Coil Condensate Volumetric Flow Rate [m3/s]

Cooling Coil Condensate Volume [m3]

These reports provide the rate and amount of condensate from the coil. Condensate is water condensed out of the air as a result of cooling. The condensate volume is also reported on the meter for "OnSiteWater."

Coil:Cooling:DX:SingleSpeed

This DX cooling coil model and input are quite different from that for the heating and cooling water coils. The simple water coils use an NTU-effectiveness heat exchanger model. The single speed DX coil model uses performance information at rated conditions along with curve fits for variations in total capacity, energy input ratio and part-load fraction to determine performance at part-load conditions. Sensible/latent capacity splits are determined by the rated sensible heat ratio (SHR) and the apparatus dewpoint/bypass factor (ADP/BF) approach. This approach is analogous to the NTU-effectiveness calculations used for sensible-only heat exchanger calculations, extended to a cooling and dehumidifying coil.

This DX cooling coil input requires an availability schedule, the rated total cooling capacity, the rated SHR, the rated COP, and the rated air volume flow rate. The latter 4 inputs determine the coil performance at the rating point (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb and air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb). The rated air volume flow rate should be between .00004027 m³/s and .00006041 m³/s per watt of rated total cooling capacity (300 to 450 cfm/ton).

This model requires 5 curves as follows:

1. The total cooling capacity modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
2. The total cooling capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating.
3. The energy input ratio (EIR) modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
4. The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.
5. The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible cooling load / steady-state sensible cooling capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The curve should be normalized to a value of 1.0 when the part-load ratio equals 1.0 (i.e., the compressor(s) run continuously for the simulation timestep).

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (see Performance Curves in this document).

The next input item for this DX cooling coil object is the supply air fan operation mode. Either the supply air fan runs continuously while the DX coil cycles on/off

(ContinuousFanWithCyclingCompressor), or the fan and coil cycle on/off together (CyclingFanAndCompressor). When this DX cooling coil is used in a parent object that has a fan operating mode schedule (e.g. Furnace:HeatCool), this input is not used.

The next four input fields are optional and relate to the degradation of latent cooling capacity when the supply air fan operates continuously while the cooling coil/compressor cycle on and off to meet the cooling load. The field Supply Air Fan Operation Mode must be “ContinuousFanWithCyclingCompressor” (i.e. either in the field above or the fan operating mode schedule specified in the parent object must be greater than 0 to calculate degradation of latent cooling capacity. At times when the parent object’s supply air fan operating mode schedule is 0, latent degradation will be ignored.) and these next four input fields must have positive values in order to model latent capacity degradation.

The next input specifies the outdoor air node used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor temperature entering the condenser is taken directly from the weather data. If this field is not blank, the node name specified must be listed in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an OutdoorAir:NodeList object where the outdoor temperature entering the condenser is taken directly from the weather data.

The next input describes the type of outdoor condenser coil used with the DX cooling coil (Air Cooled or Evap Cooled). The following three inputs are required when modeling an evaporative-cooled condenser: evaporative condenser effectiveness, evaporative condenser air volume flow rate, and the power consumed by the evaporative condenser pump. Crankcase heater capacity and cutout temperature are entered in the next two input fields. The final two fields for this object define the name of the water storage tank for supply and condensate collection. See section “DX Cooling Coil Model” in the EnergyPlus Engineering Document for further details regarding this model.

Field: Name

A unique user-assigned name for an instance of a DX cooling coil. Any reference to this DX coil by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

Field: Rated Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb⁹, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated Sensible Heat Ratio

The sensible heat ratio (SHR=sensible capacity divided by total cooling capacity) of the DX cooling coil at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

⁹ The 23.9°C wet-bulb temperature condition is not applicable for air-cooled condensers which do not evaporate condensate.

Field: Rated COP

The coefficient of performance (cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity (gross)”. If this input field is left blank, the default value is 3.0.

Field: Rated Air Flow Rate

The air volume flow rate, in m³ per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total cooling capacity (300 to 450 cfm/ton). The rated total cooling capacity, rated SHR and rated COP should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

Field: Air Inlet Node Name

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

Field: Air Outlet Node Name

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

Field: Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

Field: Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point.

Field: Energy Input Ratio Function of Flow Fraction Curve Name

The name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$$\text{PLF} \geq 0.7 \quad \text{and} \quad \text{PLF} \geq \text{PLR}$$

If $\text{PLF} < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $\text{PLF} < \text{PLR}$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

Field: Supply Air Fan Operation Mode

This input field has two choices: **CyclingFanAndCompressor** or **ContinuousFanWithCyclingCompressor**. The first choice stands for “cycling fan cycling compressor”. This means that the unit unloads by cycling both the fan and compressor; that is, both the supply air fan and the DX coil unit compressor cycle on and off together to meet the load. The second choice stands for “continuous fan cycling compressor”. The supply air fan runs continuously while the DX coil unit compressor cycles. When this DX cooling coil is used in a parent object that has a fan operating mode schedule (e.g. Furnace:HeatCool), this input is not used.

Field: Nominal Time for Condensate Removal to Begin

The nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The field Supply Air Fan Operation Mode must be “ContinuousFanWithCyclingCompressor”, and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

Ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The field Supply Air Fan Operation Mode must be "ContinuousFanWithCyclingCompressor"; and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation.

Field: Maximum Cycling Rate

The maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The field Supply Air Fan Operation Mode must be "ContinuousFanWithCyclingCompressor"; and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation.

Field: Latent Capacity Time Constant

Time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45; zero value means latent degradation model is disabled. The default value for this field is zero. The field Supply Air Fan Operation Mode must be "ContinuousFanWithCyclingCompressor", and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation.

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is AirCooled.

Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of

temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: *Evaporative Condenser Air Flow Rate*

The air volume flow rate, in m³ per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m³/s per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: *Evaporative Condenser Pump Rated Power Consumption*

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = Air Cooled.

Field: *Crankcase Heater Capacity*

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field "Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation" (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump (Ref. UnitarySystem:HeatPump:AirToAir or PackageTerminal:HeatPump:AirToAir), the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. Coil:DX:HeatingEmpirical) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

Field: *Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation*

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C, and the default value is 10°C.

Field: *Supply Water Storage Tank Name*

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling of its condenser. If blank or omitted, then the unit will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the unit will obtain its

water from that tank. If a tank is specified, the unit will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the condenser needs, then the unit will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Below is the input data dictionary description for the CoolingBypassFactorEmpirical DX coil.

Coil:Cooling:DX:TwoSpeed

This component models a DX cooling unit with a two speed or variable speed compressor and fan. The method is based on that used for the cycling, single speed DX unit. The single speed unit is described by single full load capacity, SHR, COP, and air flow rate at rated conditions. Off rated full load performance is obtained by the use of 4 modifier curves. At partial load the unit cycles on/off and the cycling losses are described by a part load fraction curve.

The multispeed unit is described by specifying the performance at two states: high speed compressor, high speed fan; and low speed compressor, low speed fan. When the unit load is above the high speed capacity, the unit runs with high speed compressor and fan. When the load on the unit is below the high speed capacity but above the low speed capacity, the unit will run with performance intermediate between high speed and low speed. When the load is less than the low speed capacity, the unit will cycle on/off just like the single speed unit.

The multispeed unit model requires 2 full sets of performance data. There must be a high and low speed capacity, SHR, COP, and evaporator air flow rate; as well as high and low speed performance curves – total cooling capacity modifier curve (function of temperature) and energy input ratio modifier curve (function of temperature).

The multispeed DX component should be used for all cases in which a DX VAV system is being simulated. Obviously this model – in which performance is obtained by interpolating between 2 specified states - is an oversimplification of how real multi-speed and variable speed DX cooling units are controlled. But detailed descriptions of how actual units perform and are controlled are not available. This model should give a good average prediction of multispeed and variable speed DX cooling unit performance.

Field: Name

A unique user-assigned name for an instance of a multispeed DX cooling coil. Any reference to this DX coil by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit

can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Rated High Speed Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated High Speed Sensible Heat Ratio

The sensible heat ratio (sensible capacity divided by total cooling capacity) of the DX cooling coil for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb¹⁰, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated High Speed COP

The coefficient of performance (cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity (gross)”. If this input field is left blank, the default value is 3.0.

Field: Rated High Speed Air Flow Rate

The high speed air volume flow rate, in m³ per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total cooling capacity. The rated total cooling capacity, rated SHR and rated COP should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

Field: Air Inlet Node

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

Field: Air Outlet Node

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

Field: Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point. This curve is used for performance at the high speed compressor, high speed fan operating point.

¹⁰ The 23.9°C wet-bulb temperature condition is not applicable for air-cooled condensers which do not evaporate condensate.

Field: Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. This curve is applied only at the high speed compressor, high speed fan operating point. There is no corresponding curve for the low speed operating point.

Field: Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering the cooling coil and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point. This curve is used for performance at the high speed compressor, high speed fan operating point.

Field: Energy Input Ratio Function of Flow Fraction Curve Name

The name of a quadratic performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This curve is applied only at the high speed compressor, high speed fan operating point. There is no corresponding curve for the low speed operating point.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$$\text{PLF} \geq 0.7 \quad \text{and} \quad \text{PLF} \geq \text{PLR}$$

If $\text{PLF} < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $\text{PLF} < \text{PLR}$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Field: Supply Air Fan Operating Mode

This input field is currently not used. The unit operates as a variable speed fan, variable speed compressor when above the low speed limit. Below the low speed limit, the unit cycles on / off.

Field: Rated Low Speed Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate, low speed” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated Low Speed Sensible Heat Ratio

The sensible heat ratio (SHR=sensible capacity divided by total cooling capacity) of the DX cooling coil for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate, low speed” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated Low Speed COP

The coefficient of performance (COP=cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate, low speed” below). The input power includes power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity (gross)”. If this input field is left blank, the default value is 3.0.

Field: Rated Low Speed Air Flow Rate

The low speed volume air flow rate, in m³ per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total cooling capacity. The rated total cooling capacity, rated SHR and rated COP should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

Field: Low Speed Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point. This curve is used for performance at the low speed compressor, low speed fan operating point.

Field: Low Speed Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wetbulb temperature of the air

entering the cooling coil and the drybulb temperature of the air entering the air-cooled condenser (wetbulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point. This curve is used for performance at the low speed compressor, low speed fan operating point.

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the multi-speed DX cooling coil. Valid choices for this input field are Air Cooled or Evap Cooled. The default for this field is Air Cooled.

Field: High Speed Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at high compressor/fan speed, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb, o}) + (1 - EvapCondEffectiveness_{HighSpeed})(T_{db, o} - T_{wb, o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb, o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db, o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature)

and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: High Speed Evaporative Condenser Air Flow Rate

The air volume flow rate, in m³ per second, entering the evaporative condenser at high compressor/fan speed. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m³/s per watt of rated high-speed total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: High Speed Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts at high compressor/fan speed. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated high-speed total cooling capacity). This field is not used when Condenser Type = Air Cooled.

Field: Low Speed Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at low compressor/fan speed, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness_{LowSpeed})(T_{db,o} - T_{wb,o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve, low speed (function of temperature) and the Energy Input Ratio Modifier Curve, low speed (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled. See field “Evaporative Condenser Effectiveness, High Speed” above for further information.

Field: Low Speed Evaporative Condenser Air Flow Rate

The air volume flow rate, in m³ per second, entering the evaporative condenser at low compressor/fan speed. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000048 m³/s per watt of rated high-speed total cooling capacity [280 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: Low Speed Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts at low compressor/fan speed. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.001422 W per watt [5 W/ton] of rated high-speed total capacity). This field is not used when Condenser Type = Air Cooled.

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Below is the input data dictionary description for the object.

Coil:Cooling:DX:TwoStageWithHumidityControlMode

The multimode DX coil is functionally equivalent to Coil:DX:Cooling:SingleSpeed but with multiple performance modes. It is capable of modeling two-stage DX units and units with an enhanced dehumidification mode such as coil bypass or subcool reheat. This object contains one-time specifications for the DX unit such as node names and crankcase heater specifications. It references one or more CoilPerformance:DX:CoolingBypassFactorEmpirical objects which define the performance for each mode of operation. It can have up to 4 performance modes to accommodate a 2-stage 2-mode unit. The multimode DX coil can be used only as a component of DXSystem:Airloop or UnitarySystem:VAV:ChangeoverBypass (parent object). These parent objects pass a load and dehumidification mode to this coil. If the coil has 2 capacity stages, the multimode coil model determines the stage sequencing.

Field: Name

A unique user-assigned name for an instance of a DX cooling coil. Any reference to this DX coil by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

Field: Air Inlet Node Name

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

Field: Air Outlet Node Name

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field “Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation” (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump (Ref. AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass), the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. Coil:Heating:DX:SingleSpeed) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C, and the default value is 10°C.

Field: Number of Capacity Stages

This integer field defines the number of capacity stages. The value for this input field must be greater 1 or 2, and the default value is 1. Larger DX units often have two capacity stages, which are often two completely independent compressor/coil circuits with the evaporator coils arranged in parallel in the supply air stream. 2-stage operation affects cycling losses and latent degradation due to re-evaporation of moisture with continuous fan operation.

Field: Number of Enhanced Dehumidification Modes

This integer field defines the number of enhanced dehumidification modes available. The value for this input field must be 0 or 1, and the default value is 0. If the DX unit can switch operating modes to increase dehumidification based on a humidistat signal, then set this to 1. This field just specified the availability of enhanced dehumidification. Actual control of the operating mode is handled by the coil's parent component.

Field: Normal Mode Stage 1 Coil Performance Object Type**Field: Normal Mode Stage 1 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1 operation without enhanced dehumidification (normal mode). The only valid performance object type is CoilPerformance:DX:Cooling.

Field: Normal Mode Stage 1+2 Coil Performance Object Type**Field: Normal Mode Stage 1+2 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1+2 operation (both stages active) without enhanced dehumidification (normal mode). The only valid performance object type is CoilPerformance:DX:Cooling.

Field: Dehumidification Mode 1 Stage 1 Coil Performance Object Type**Field: Dehumidification Mode 1 Stage 1 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1 operation with enhanced dehumidification active. The only valid performance object type is CoilPerformance:DX:Cooling.

Field: Dehumidification Mode 1 Stage 1+2 Coil Performance Object Type**Field: Dehumidification Mode 1 Stage 1+2 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1+2 operation (both stages active) with enhanced dehumidification active. The only valid performance object type is CoilPerformance:DX:Cooling.

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Below is the input data dictionary description for the object.

CoilPerformance:DX:Cooling

This coil performance object is used to specify DX coil performance for one mode of operation for a Coil:Cooling:DX:TwoStageWithHumidityControlMode. A single Coil:Cooling:DX:TwoStageWithHumidityControlMode object will reference one to four CoilPerformance:DX:Cooling objects depending on the number of available stages and dehumidification modes as specified in the two stage DX object. For example, a standard 2-stage DX system will use two of these performance objects, one to defined the capacity and performance for stage 1 operation, and a second one for stage 1+2 (both stages active) operation. In nearly all cases, the Rated Air Volume Flow Rate will be the same for all performance objects associated with a given multimode DX coil. If bypass is specified, the Rated Air Volume Flow Rate includes both the bypassed flow and the flow through the active coil.

This DX coil model is identical to Coil:DX:Cooling:SingleSpeed with addition of bypass and multi-stage capabilities. This DX cooling coil model and input are quite different from that for the heating and cooling water coils. The simple water coils use an NTU-effectiveness heat exchanger model. The single speed DX coil model uses performance information at rated conditions along with curve fits for variations in total capacity, energy input ratio and part-load fraction to determine performance at part-load conditions. Sensible/latent capacity splits are determined by the rated sensible heat ratio (SHR) and the apparatus dewpoint/bypass factor (ADP/BF) approach. This approach is analogous to the NTU-effectiveness calculations used for sensible-only heat exchanger calculations, extended to a cooling and dehumidifying coil.

The DX cooling coil input requires the rated total cooling capacity, the rated SHR, the rated COP, the rated air volume flow rate, and the fraction of air flow which is bypassed around the coil. The first 4 inputs determine the coil performance at the rating point (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb and air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb). The rated air volume flow rate (less any bypassed fraction) should be between .00004027 m³/s and .00006041 m³/s per watt of rated total cooling capacity (300 to 450 cfm/ton).

This model requires 5 curves as follows:

1. The total cooling capacity modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
2. The total cooling capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating.
3. The energy input ratio (EIR) modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
4. The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.
5. The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible cooling load / steady-state sensible cooling capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The curve should be normalized to a value of 1.0 when the part-load ratio equals 1.0 (i.e., the compressor(s) run continuously for the simulation timestep).

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (see Performance Curves in this document).

The next input item for this DX cooling coil object is the supply air fan operation mode. Either the supply air fan runs continuously while the DX coil cycles on/off (ContinuousFanWithCyclingCompressor), or the fan and coil cycle on/off together (CyclingFanAndCompressor).

The next four input fields are optional and relate to the degradation of latent cooling capacity when the supply air fan operates continuously while the cooling coil/compressor cycle on and off to meet the cooling load. The field Supply Air Fan Operation Mode must be “ContinuousFanWithCyclingCompressor” and these next four input fields must have positive values in order to model latent capacity degradation.

The next input specifies the outdoor air node used to define the conditions of the air entering the outdoor condenser. If this field is not blank, the node name specified must be listed in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an OutdoorAir:NodeList object where the outdoor temperature entering the condenser is taken directly from the weather data. This field may also be left blank, if this is the case then the outdoor temperature entering the condenser is taken directly from the weather data.

The next input describes the type of outdoor condenser coil used with the DX cooling coil (Air Cooled or Evap Cooled). The following three inputs are required when modeling an evaporative-cooled condenser: evaporative condenser effectiveness, evaporative condenser air volume flow rate, and the power consumed by the evaporative condenser pump. See section “DX Cooling Coil Model” in the EnergyPlus Engineering Document for further details regarding this model.

Field: Name

This alpha field is a unique user-assigned name for an instance of DX cooling coil performance. Any reference to this DX coil performance object by another object will use this name.

Field: Rated Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb¹¹, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated Sensible Heat Ratio

The sensible heat ratio (SHR=sensible capacity divided by total cooling capacity) of the DX cooling coil at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated COP

The coefficient of performance (COP=cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/ 23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity (gross)”. If this input field is left blank, the default value is 3.0.

Field: Rated Air Flow Rate

The air volume flow rate, in m³ per second, across the DX cooling coil at rated conditions. The rated total cooling capacity, rated SHR and rated COP should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

¹¹ The 23.9°C wet-bulb temperature condition is not applicable for air-cooled condensers which do not evaporate condensate.

Field: Fraction of Air Flow Bypassed Around Coil

This numeric field specifies the fraction of the Rated Air Volume Flow Rate which bypasses the active cooling coil for this performance mode. The remaining portion of the flow should be between 0.00004027 m³/s and .00006041 m³/s per watt of rated total cooling capacity (300 to 450 cfm/ton) for this performance mode. This is used to model face-split coils on multi-stage units or bypass dampers. If total flow rate varies during simulation, the same fraction is bypassed. This input may range from 0.0 to <1.0. The default is 0.0. For a multi-stage face-split coil in which stage 1 is 60% of total capacity, this field would be set to 0.4 for the Stage 1 performance and set to 0.0 for the Stage 1+2 performance. For a DX system which activates a bypass damper for improved dehumidification, this field would be set to 0.0 for normal mode performance and set to something greater than zero for enhanced dehumidification mode performance.

Field: Total Cooling Capacity Function of Temperature Curve Name

The name of a **biquadratic** performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

Field: Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a **quadratic** or **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Energy Input Ratio Function of Temperature Curve Name

The name of a **biquadratic** performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point.

Field: Energy Input Ratio Function of Flow Fraction Curve Name

The name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling

capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$$\text{PLF} \geq 0.7 \quad \text{and} \quad \text{PLF} \geq \text{PLR}$$

If $\text{PLF} < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $\text{PLF} < \text{PLR}$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

Field: Supply Air Fan Operation Mode

This input field has two choices: `CyclingFanAndCompressor` or `ContinuousFanWithCyclingCompressor`. The first choice stands for “cycling fan cycling compressor”. This means that the unit unloads by cycling both the fan and compressor; that is, both the supply air fan and the DX coil unit compressor cycle on and off together to meet the load. The second choice stands for “continuous fan cycling compressor”. The supply air fan runs continuously while the DX coil unit compressor cycles.

Field: Nominal Time for Condensate Removal to Begin

The nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The field `Supply Air Fan Operation Mode` must be “`ContinuousFanWithCyclingCompressor`”, and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

Ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The field `Supply Air Fan Operation Mode` must be “`ContinuousFanWithCyclingCompressor`”; and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation.

Field: Maximum Cycling Rate

The maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The field `Supply Air Fan Operation Mode` must be “`ContinuousFanWithCyclingCompressor`”; and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation.

Field: Latent Capacity Time Constant

Time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45; zero value means latent degradation model is disabled. The

default value for this field is zero. The field Supply Air Fan Operation Mode must be “ContinuousFanWithCyclingCompressor”, and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation.

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb, o}) + (1 - EvapCondEffectiveness)(T_{db, o} - T_{wb, o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb, o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db, o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air

entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: Evaporative Condenser Air Flow Rate

The air volume flow rate, in m³ per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m³/s per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = AirCooled.

Below is the input data dictionary description for the object.

```

DX Coil Total Cooling Rate [W]

This field is the total (sensible and latent) cooling rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Cooling Energy [J]

This is the total (sensible plus latent) cooling output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (Ref. Report Meter).

DX Coil Sensible Cooling Rate [W]

This output is the moist air sensible cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Sensible Cooling Energy [J]

This is the moist air sensible cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Rate [W]

This is the latent cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Energy [J]

This is the latent cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Cooling Coil Electric Power [W]

This output is the electricity consumption rate of the DX coil compressor and condenser fan(s) in Watts.

DX Cooling Coil Electric Consumption [J]

This is the electricity consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Report Meter).

DX Cooling Coil Runtime Fraction

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the timestep being reported.

DX Cooling Coil Crankcase Heater Power[W]

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported.

DX Cooling Coil Crankcase Heater Consumption[J]

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Cooling Coil Condenser Inlet Temp [C]

This is the inlet air temperature to the condenser coil in degrees C. This value can represent the outdoor air dry-bulb temperature, wet-bulb temperature, or somewhere in between from the weather data being used, depending on the value used in the input field "Evaporative

Condenser Effectiveness”. The temperature reported here is used in the various modifier curves related to temperature (e.g., Total Cooling Capacity Modifier Curve [function of temperature]).

DX Cooling Coil Evap Condenser Water Consumption [m3]

This output is the amount of water used to evaporatively cool the condenser coil inlet air, in cubic meters. This output is also added to a report meter with Resource Type = Water, End Use Key = Cooling, Group Key = System (ref. Report Meter).

DX Cooling Coil Evap Condenser Pump Electric Power [W]

This is the average electricity consumption rate of the evaporative condenser water pump in Watts for the timestep being reported.

DX Cooling Coil Evap Condenser Pump Electric Consumption [J]

This is the electricity consumption rate of the evaporative condenser water pump in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

DX Cooling Coil Stage 2 Runtime Fraction

This is the runtime fraction of the stage 2 DX coil compressor and condenser fan(s) for the timestep being reported. Applicable only for COIL Coil:Cooling:DX:TwoStageWithHumidityControlMode when 2 capacity stages are specified. For 2-stage systems, DX Cooling Coil Runtime Fraction is the stage 1 runtime fraction. These runtime fractions overlap, because stage 2 will not run unless stage 1 is already running. For example, a system where stage 1 is 60% of total capacity is passed a load of 70%. The DX Cooling Coil Runtime Fraction (stage 1) will be 1.0, and the DX Cooling Coil Stage 2 Runtime Fraction will be 0.25 $[(70\%-60\%)/(100\%-60\%)]$.

DX Cooling Coil Dehumidification Mode

This is the dehumidification mode for the timestep being reported. Applicable only for Coil:Cooling:DX:TwoStageWithHumidityControlMode when enhanced dehumidification mode is available. A value of 0 indicates normal mode (extra dehumidification not active). A value of 1 indicates dehumidification mode 1 is active. Note that this is an averaged variable, so fractional values are likely to be reported for reporting frequencies longer than "detailed".

DX Cooling Coil Condensate Volumetric Flow Rate [m3/s]

DX Cooling Coil Condensate Volume [m3]

These outputs are the rate and volume of water collected as condensate from the coil. These reports only appear if a water storage tank is named in the input object.

Coil:Cooling:DX:MultiSpeed

This component models a DX cooling unit with multiple discrete levels of cooling capacity. Depending on input choices, the user can model a single compressor with multiple operating speeds, or a unit with a single cooling coil fed by multiple compressors (e.g., row split or intertwined coil circuiting). Currently, this cooling coil can only be referenced by a AirLoopHVAC:UnitaryHeatPump:AirToAir compound object. Refer to Coil:Cooling:DX:TwoStageWithHumidityControlMode if the user wishes to model a cooling coil with discrete levels of cooling and the possibility of air bypass during low speed operation (e.g. face-split coil circuiting), or if cooling coil operation based on dehumidification requirements is desired.

The multispeed DX cooling coil can have from two to four operating speeds. When the coil operates at Speed 1 (the lowest speed), its performance is very similar to the single speed DX coil where the impacts of part-load ratio and latent capacity degradation can be included. When the coil operates at higher speeds (above Speed 1), the linear approximation

methodology is applied. The coil outputs at two consecutive speeds are linearly interpolated to meet the required cooling capacity during an HVAC system timestep. When the coil performs above the lowest speed, the user can choose if they want to include part-load ratio and latent capacity degradation impacts at the higher speeds.

The multispeed unit is described by specifying the performance at different operating speeds. Each speed has its own set of input specifications: full load capacity, SHR, COP and air flow rate at rated conditions, along with modifier curves to determine performance when actual operating conditions are different from the rated conditions.

The coil operates to meet the sensible capacity being requested. When this requested capacity is above the sensible capacity of the highest operating speed, the coil runs continuously at the highest speed. When the requested capacity is between the sensible capacities of two consecutive speeds, the unit will operate a portion of the time at each speed to meet the request. When the requested capacity is less than the low speed (Speed 1) capacity, the unit will cycle on/off as needed.

Field: Name

A unique user-assigned name for an instance of a multispeed DX cooling coil. Any reference to this DX coil by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

Field: Air Outlet Node Name

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

Field: Supply Air Fan Operating Mode

This input field has 2 choices: `CyclingFanAndCompressor` and `ContinuousFanWithCyclingCompressor`. The parent object `UnitarySystem:MultiSpeedHeatPump:AirToAir` also has an input field that defines a schedule for the supply fan operation mode. Currently, the mode defined in the parent object schedule overrides the fan operation mode defined in this field.

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an `OutdoorAir:Node` object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an `OutdoorAir:NodeList` object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the multispeed DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the evaporative cooler will obtain water directly from the

mains. If the name of a Water Storage Tank object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Field: Apply Part Load Fraction to Speeds Greater than 1

This field determines whether part-load impacts on coil energy use are applied when the coil is operating at speeds greater than speed 1. The allowed choices are Yes or No, with the default being No if this field is left blank. Other input fields in this object allow the user to specify a part-load fraction correlation for each speed to account for compressor start up losses (cycle on/off). For the case of a single multi-speed compressor, the part load losses may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify NO for this input field to neglect part-load impacts on energy use at higher operating speeds. If part-load impacts on coil energy use are thought to be significant (e.g., intertwined cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify YES and the part-load fraction correlations specified for speeds 2 through 4 will be applied as appropriate. The selection for this input field does not affect part-load impacts when the compressor cycles between speed 1 and off (i.e., the part-load fraction correlation for speed 1 is always applied).

Field: Apply Latent Degradation to Speeds Greater than 1

This field determines whether latent capacity degradation is applied when the coil is operating at speeds greater than speed 1. The allowed choices are Yes or No, with the default being No if this field is left blank. Other input fields in this object allow the user to specify latent capacity degradation at each speed.

The latent capacity degradation model only applies when the ContinuousFanWithCyclingCompressor supply air fan operating mode is specified, to account for moisture evaporation from the wet cooling coil when the compressor cycles off but the supply air fan continues to operate. For the case of a single multi-speed compressor, latent capacity degradation may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify NO for this input field to neglect latent capacity degradation impacts at higher operating speeds. If latent capacity degradation is thought to be significant (e.g., intertwined or row-split cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify YES and the latent capacity degradation model will be applied for speeds 2 through 4 as appropriate. The selection for this input field does not affect latent capacity degradation between speed 1 and off.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field "Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation" (described below), the crankcase heater is enabled during the time that the compressor is not running. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C. If this input field is left blank, the default value is 10°C.

Field: Fuel Type

This alpha field determines the type of fuel that this cooling coil uses. This field has seven choices: Electricity, NaturalGas, PropaneGas, Diesel, Gasoline, FuelOil#1, and FuelOil#2. The default is NaturalGas.

Field: Number of Speeds

This field specifies the number of sets of data being entered for rated specifications, performance curves, evaporative condenser data, latent degradation data, and waste heat specifications for each cooling speed. The rated specifications consist of rated capacity, rated SHR, rated COP, and rated air flow rate. The performance curves consist of a total capacity modifier curve as a function of temperature, total capacity modifier curve as a function of flow fraction, energy input ratio modifier curve as a function of temperature, energy input ratio modifier curve as a function of flow fraction, and part load fraction correlation as a function of part load ratio. The evaporative condenser data consists of effectiveness, condenser air volume flow rate, and rated pump power consumption. The latent degradation data consists of nominal time for condensate removal to begin, ratio of initial moisture evaporation rate and steady-state latent capacity, maximum On/Off cycling rate, and latent capacity time constant. The latent degradation data are only applied if the supply air fan operation mode is specified as ContinuousFanWithCyclingCompressor. The waste heat specifications include the fraction of energy input to the cooling coil at the fully loaded and rated conditions, and a temperature modifier. The minimum number of speeds for cooling is 2 and the maximum number is 4. The number of speeds should be the same as the number of speeds for cooling defined in its parent object (UnitarySystem:MultiSpeedHeatPump: AirToAir). The first set of performance inputs is for Speed 1 and should be for low speed, and the last set of performance inputs should be for high speed. For example, if only three cooling speeds are defined, the first set should be for low speed (Speed 1), the second set should be for medium speed (Speed 2), and the third set should be for high speed (Speed 3). In this example, any performance inputs for Speed 4 would be neglected (since this input field specifies that the coil only has three cooling speeds).

Field Group: rated specification, performance curves, latent capacity degradation inputs, and evaporative cooled condenser data

The performance for each cooling speed must be specified as shown below. All inputs for Speed 1 are required first, followed by the inputs for Speed 2, Speed 3 and Speed 4.

Field: Speed <x> Rated Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb¹², and a cooling coil air flow rate defined by field "Rated Air Volume Flow Rate, Speed <x>" below). Capacity should be "gross" (i.e., supply air fan heat is NOT included).

Field: Speed <x> Rated Sensible Heat Ratio

The sensible heat ratio (SHR=sensible capacity divided by total cooling capacity) of the DX cooling coil for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field "Rated Air Volume Flow Rate, Speed

¹² The 23.9°C wet-bulb temperature condition is not applicable for air-cooled condensers which do not evaporate condensate.

<x>” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Speed <x> Rated COP

The coefficient of performance (COP=cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “Rated Air Volume Flow Rate, Speed <x>” below). The input power includes power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity, Speed <x> (gross)”. If this input field is left blank, the default value is 3.0.

Field: Speed <x> Rated Air Flow Rate

The volumetric air flow rate for Speed <x>, in m³ per second, across the DX cooling coil at rated conditions. The rated air volume flow rate for Speed <x> should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total cooling capacity for Speed <x>. The rated total cooling capacity, rated SHR and rated COP for Speed <x> should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

Field: Speed <x> Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity for Speed <x> as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity for Speed <x> to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed <x> Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity for Speed <x> as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate for Speed <x> (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity for Speed <x> at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate for Speed <x>.

Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) for Speed <x> as a function of the wetbulb temperature of the air entering the cooling coil and the drybulb temperature of the air entering the air-cooled condenser (wetbulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR for Speed <x> (inverse of rated COP for Speed <x>) to give the EIR for Speed <x> at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point.

Field: Speed <x> Energy Input Ratio Function of Flow Fraction Curve Name

The name of a quadratic performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) for Speed <x> as a function of the ratio of actual

air flow rate across the cooling coil to the rated air flow rate for Speed <x> (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR for Speed <x> at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate for Speed <x>.

Field: Speed <x> Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity for Speed <x>). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep for Speed <x>. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$$\text{PLF} \geq 0.7 \text{ and } \text{PLF} \geq \text{PLR}$$

If $\text{PLF} < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $\text{PLF} < \text{PLR}$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional DX cooling coil (Speed <x>) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

Field: Speed <x> Nominal Time for Condensate Removal to Begin

For Speed <x>, the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The field Supply Air Fan Operation Mode must be “ContinuousFanWithCyclingCompressor”, and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation for Speed <x>.

Field: Speed <x> Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

For Speed <x>, the ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) for Speed <x> at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The field Supply Air Fan Operation Mode must be “ContinuousFanWithCyclingCompressor”; and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation for Speed <x>.

Field: Speed <x> Maximum Cycling Rate

For Speed <x>, the maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation

model is disabled. The default value for this field is zero. The field Supply Air Fan Operation Mode must be “ContinuousFanWithCyclingCompressor”; and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation for Speed <x>.

Field: Speed <x> Latent Capacity Time Constant

For Speed <x>, the time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45; zero value means latent degradation model is disabled. The default value for this field is zero. The field Supply Air Fan Operation Mode must be “ContinuousFanWithCyclingCompressor”, and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation for Speed <x>.

Field: Speed <x> Rated Waste Heat Fraction of Power Input

The fraction of energy input to the cooling coil that is available as recoverable waste heat at full load and rated conditions for Speed <x>.

Field: Speed <x> Waste Heat Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of outdoor dry-bulb temperature and the entering coil dry-bulb temperature at Speed <x>. The output of this curve is multiplied by the rated waste heat fraction at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point. When the fuel type is electricity, this field can remain blank since it is ignored by the program in this instance.

Field: Speed <x> Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at Speed <x>, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb, o}) + (1 - EvapCondEffectiveness_{Speed1})(T_{db, o} - T_{wb, o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb, o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db, o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference

performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves for Speed <x> must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: Speed <x> Evaporative Condenser Air Flow Rate

The air volume flow rate, in m^3 per second, entering the evaporative condenser at Speed <x>. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to $0.000114 \text{ m}^3/\text{s}$ per watt of rated total cooling capacity for Speed <x> [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: Speed <x> Rated Evaporative Condenser Pump Power Consumption

The rated power of the evaporative condenser water pump in Watts at Speed <x>. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total capacity for Speed <x>). This field is not used when Condenser Type = Air Cooled.

Below is the input data dictionary description for the Coil:DX:MultiSpeed:Cooling object.

DX Coil Total Cooling Rate [W]

This field is the total (sensible and latent) cooling rate output of the multispeed DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Cooling Energy [J]

This is the total (sensible plus latent) cooling output of the multispeed DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (Ref. Report Meter).

DX Coil Sensible Cooling Rate [W]

This output is the moist air sensible cooling rate output of the multispeed DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Sensible Cooling Energy [J]

This is the moist air sensible cooling output of the multispeed DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Rate [W]

This is the latent cooling rate output of the multispeed DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Energy [J]

This is the latent cooling output of the multispeed DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Cooling Coil <FuelType> Power [W]

This output variable is the input fuel type power for the cooling coil in Watts, averaged during the timestep being reported.

DX Cooling Coil <FuelType> Consumption [J]

This output variable is the input fuel consumption for the multispeed cooling coil in the unit of Joules, summed for the timestep being reported. This output is added to a report meter with Resource Type = <FuelType>, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Note: <FuelType> in the above two output variables depends on the user specified input for the Fuel Type field. In addition to Electricity, valid fuel types are NaturalGas, Propane, FuelOil#1, FuelOil#2, Coal, Diesel, and Gasoline.

DX Cooling Coil Runtime Fraction

This output variable is the cooling coil run time fraction (PLR/PLF), averaged for the timestep being reported. When the cooling speed is above 1, this output is the run time fraction for the higher speed.

Cooling Coil Condenser Inlet Temp [C]

This is the inlet air temperature to the condenser coil in degrees C. This value can represent the outdoor air dry-bulb temperature, wet-bulb temperature, or somewhere in between from the weather data being used, depending on the value used in the input field “Evaporative Condenser Effectiveness”. The temperature reported here is used in the various modifier curves related to temperature (e.g., Total Cooling Capacity Modifier Curve [function of temperature]).

DX Cooling Coil Evap Condenser Water Consumption [m3]

This output is the amount of water used to evaporatively cool the condenser coil inlet air, in cubic meters. This output is also added to a report meter with Resource Type = Water, End Use Key = Cooling, Group Key = System (ref. Report Meter).

DX Cooling Coil Evap Condenser Pump Electric Power [W]

This is the average electricity consumption rate of the evaporative condenser water pump in Watts for the timestep being reported.

DX Cooling Coil Evap Condenser Pump Electric Consumption [J]

This is the electricity consumption rate of the evaporative condenser water pump in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Coil:Heating:DX:SingleSpeed

The single speed heating DX coil model uses performance information at rated conditions along with curve fits for variations in total capacity, energy input ratio and part load fraction to determine performance at part-load conditions. The impacts of various defrost strategies (reverse cycle, resistive, timed or on-demand) are modeled based on a combination of user inputs and empirical models taken from the air-to-air heat pump algorithms in DOE-2.1E.

The single speed heating DX coil input requires an availability schedule, the rated total heating capacity, the rated COP and the rated air volume flow rate. The latter 3 inputs determine the coil performance at the rating point (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, coil entering air dry-bulb temperature of 21.11 C, coil entering air wet-bulb temperature of 15.55 C). The rated air volume flow rate should be between .00004027 m³/s and .00006041 m³/s per watt of rated total heating capacity.

Up to 6 curves are required depending on the defrost strategy selected.

- 1) The total heating capacity modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 2) The total heating capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate

across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating.

- 3) The energy input ratio (EIR) modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 4) The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.
- 5) The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible heating load / steady-state heating capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the “effective” EIR for a given simulation timestep. The part load fraction correlation accounts for efficiency losses due to compressor cycling.
- 6) The defrost energy input ratio (EIR) modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: outdoor air dry-bulb temperature and the heating coil entering air wet-bulb temperature. The output of this curve is multiplied by the heating coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the coil is operating. This curve is only required when a reverse-cycle defrost strategy is specified.

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (ref. Performance Curves).

The next input item for the HeatingEmpirical DX coil is the supply air fan operation mode. Either the supply air fan runs continuously while the DX coil cycles on/off, or the fan and coil cycle on/off together. The next two inputs define the minimum outdoor dry-bulb temperature that the heat pump compressor will operate and the maximum outdoor dry-bulb temperature for defrost operation. Crankcase heater capacity and cutout temperature are entered in the following two inputs. The final four inputs cover the type of defrost strategy (reverse-cycle or resistive), defrost control (timed or on-demand), the fractional defrost time period (timed defrost control only), and the resistive defrost heater capacity if a resistive defrost strategy is selected.

Field: Name

This alpha field defines a unique user-assigned name for an instance of a DX heating coil. Any reference to this DX heating coil by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the DX heating coil can run during a given hour. A schedule value greater than 0 (usually 1 is

used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Rated Total Heating Capacity

This numeric field defines the total, full load heating capacity in watts of the DX coil unit at rated conditions (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and a heating coil air flow rate defined by field “rated air flow volume” below). The value entered here must be greater than 0. Capacity should not include supply air fan heat.

Field: Rated COP

This numeric field defines the coefficient of performance (COP=heating power output in watts divided by electrical power input in watts) of the DX heating coil unit at rated conditions (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, coil entering air dry-bulb temperature of 21.11 C, coil entering air wet-bulb temperature of 15.55 C, and a heating coil air flow rate defined by field “rated air flow volume rate” below). The value entered here must be greater than 0. The input power includes power for the compressor(s) and outdoor fan(s) but does not include the power consumption of the indoor supply air fan. The heating power output is the value entered above in the field “Rated Total Heating Capacity”.

Field: Rated Air Flow Rate

This numeric field defines the volume air flow rate, in m³ per second, across the DX heating coil at rated conditions. The value entered here must be greater than 0. The rated air volume flow rate should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total heating capacity. The rated total heating capacity and rated COP should be performance information for the unit with outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and the rated air volume flow rate defined here.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

Field: Total Heating Capacity Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Total Heating Capacity Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of total heating capacity as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction

of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Energy Input Ratio Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$$\text{PLF} \geq 0.7 \quad \text{and} \quad \text{PLF} \geq \text{PLR}$$

If $\text{PLF} < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $\text{PLF} < \text{PLR}$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

Field: Defrost Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the outdoor air dry-bulb temperature and the wet-bulb

temperature of the air entering the indoor coil. The EIR is the inverse of the COP. The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. This curve is only required when a reverse-cycle defrost strategy is selected. The curve is normalized to a value of 1.0 at the rating point conditions.

Field: Supply Air Fan Operating Mode

This alpha field has two choices: CyclingFanAndCompressor or ContinuousFanWithCyclingCompressor. The first choice stands for “cycling fan cycling compressor”. This means that the unit unloads by cycling both the fan and compressor; that is, both the supply fan and the heating coil compressor cycle on and off together to meet the load. The second choice stands for “continuous fan cycling compressor”. The supply fan runs continuously while the heating coil compressor cycles.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the heating coil compressor turns off. The temperature for this input field must be greater than or equal to -20 C. If this input field is left blank, the default value is -8 C.

Field: Maximum Outdoor Dry-Bulb Temperature for Defrost Operation

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 C and less than or equal to 7.22 C. If this input field is left blank, the default value is 5 C.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field “Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation” (described below), the crankcase heater is enabled during the time that the compressor is not running. If this heating coil is used as part of an air-to-air heat pump (Ref. UnitarySystem:HeatPump:AirToAir or PackageTerminal:HeatPump:AirToAir), the crankcase heater defined for this DX heating coil is enabled during the time that the compressor is not running for either heating or cooling (and the crankcase heater power defined in the DX cooling coil object is disregarded in this case). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor’s crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 C. If this input field is left blank, the default value is 10 C.

Field: Defrost Strategy

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle.

Field: Defrost Control

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor

weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

Field: Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to “timed” defrost (see Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter $3.5/60 = 0.058333$. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

Field: Resistive Defrost Heater Capacity

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

Below is the input data dictionary description of the DX heating coil.

DX Coil Total Heating Rate [W]

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Heating Energy[J]

This is the total heating output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (ref. Report Meter).

DX Heating Coil Electric Power[W]

This output is the electricity consumption rate of the DX coil compressor and outdoor fan(s) in Watts. This rate is applicable when the unit is providing heating to the conditioned zone(s), and excludes periods when the unit is in reverse-cycle defrost mode.

DX Heating Coil Electric Consumption[J]

This is the electricity consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This consumption is applicable when the unit is providing heating to the conditioned zone(s), and excludes periods when the unit is in reverse-cycle defrost mode. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

DX Heating Coil Electric Defrost Power[W]

This is the electricity consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle or resistive).

DX Heating Coil Electric Defrost Consumption[J]

This is the electricity consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle or resistive).

DX Heating Coil Crankcase Heater Power[W]

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported.

DX Heating Coil Crankcase Heater Consumption[J]

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Miscellaneous, Group Key = System (ref. Report Meter).

DX Heating Coil Runtime Fraction

This is the runtime fraction of the DX heating coil compressor and outdoor fan(s) for the timestep being reported.

Coil:Heating:DX:MultiSpeed

This component models a DX heating unit with multiple discrete levels of heating capacity. Currently, this heating coil can only be referenced by a `AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed` compound object. The multispeed DX heating coil can have from two to four operating speeds. When the coil operates at Speed 1 (the lowest speed), its performance is very similar to the `Coil:Heating:DX:SingleSpeed` object where the impacts of part-load ratio can be included. When the coil operates at higher speeds (above Speed 1), the linear approximation methodology is applied. The coil outputs at two consecutive speeds are linearly interpolated to meet the required heating capacity during an HVAC system timestep. When the coil performs above the lowest speed, the user can choose if they want to include part-load ratio impacts at the higher speeds.

The multispeed unit is described by specifying the performance at different operating speeds. Each speed has its own set of input specifications: full load capacity, COP and air flow rate at rated conditions, along with modifier curves to determine performance when actual operating conditions are different from the rated conditions.

The coil operates to meet the sensible capacity being requested. When this requested capacity is above the sensible capacity of the highest operating speed, the coil runs continuously at the highest speed. When the requested capacity is between the sensible capacities of two consecutive speeds, the unit will operate a portion of the time at each speed to meet the request. When the requested capacity is less than the low speed (Speed 1) capacity, the unit will cycle on/off as needed.

After inputting the coil name, available schedule, and inlet and outlet air node names, the next input item for the multiSpeed DX heating coil is the supply air fan operation mode. Either the supply air fan runs continuously while the DX coil cycles on/off, or the fan and coil cycle on/off together. The next input defines the minimum outdoor dry-bulb temperature where the compressor will operate. The following two inputs are related to crankcase heater operation: capacity and maximum outdoor dry-bulb temperature for crankcase heater operation. The next six inputs cover defrost operation: defrost EIR modifier curve, the maximum outdoor dry-bulb temperature for defrost operation, the type of defrost strategy (reverse-cycle or resistive), defrost control (timed or on-demand), the fractional defrost time period (timed defrost control only), and the resistive defrost heater capacity if a resistive defrost strategy is selected. The activation of defrost is dependent on outdoor conditions. The capacity reduction and energy use modification are independent of speed. The defrost EIR modifier is described below:

The defrost energy input ratio (EIR) modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: outdoor air dry-bulb temperature and the heating coil entering air wet-bulb temperature. The output of this curve is multiplied by the heating coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the coil is operating. This curve is only required when a reverse-cycle defrost strategy is specified.

The next input allows the user to choose whether to apply the part load fraction correlation to speeds greater than 1 or not. The following input is the type of fuel.

Then the number of speed for heating is entered. The rest of inputs are speed dependent. Each set of data consists of rated heating capacity, rated COP, and the rated air volume flow rate. These three inputs determine the coil performance at the rating point (outdoor air dry-bulb temperature of 8.33°C, outdoor air wet-bulb temperature of 6.11°C, coil entering air dry-bulb temperature of 21.11°C, coil entering air wet-bulb temperature of 15.55°C). The rated air volume flow rate should be between .00004027 m³/s and .00006041 m³/s per watt of rated total heating capacity. The rated waste heat fraction is needed to calculate how much waste

heat is available at the rated conditions. In addition, up to 6 modifier curves are required per speed.

- 1) The total heating capacity modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 2) The total heating capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating.
- 3) The energy input ratio (EIR) modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 4) The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.
- 5) The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible heating load / steady-state heating capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the “effective” EIR for a given simulation timestep. The part load fraction correlation accounts for efficiency losses due to compressor cycling.
- 6) The waste heat modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: outdoor air dry-bulb temperature and the heating coil entering air dry-bulb temperature. The output of this curve is multiplied by the heating input energy, the waste heat fraction of heat input to give the recoverable waste heat.

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (ref. Performance Curves).

Field: Name

This alpha field defines a unique user-assigned name for an instance of a multispeed DX heating coil. Any reference to this DX heating coil by another object will use this name. The only allowed parent is UnitarySystem:MultiSpeedHeatPump:AirToAir.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the multispeed DX heating coil can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node name

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

Field: Supply Air Fan Operation Mode

This alpha field has two choices: `CyclingFanAndCompressor` or `ContinuousFanWithCyclingCompressor`. The first choice stands for “cycling fan cycling compressor”. This means that the unit unloads by cycling both the fan and compressor; that is, both the supply fan and the heating coil compressor cycle on and off together to meet the load. The second choice stands for “continuous fan cycling compressor”. The supply fan runs continuously while the heating coil compressor cycles. The parent object of `UnitarySystem:MultiSpeedHeatPump:AirToAir` has a field as a schedule to define fan operation mode at a given time. The value defined in the parent schedule will override the fan operation mode defined in this field.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the heating coil compressor turns off. The temperature for this input field must be greater than or equal to -20°C . If this input field is left blank, the default value is -8°C .

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field “Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation” (described below), the crankcase heater is enabled during the time that the compressor is not running. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor’s crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C . If this input field is left blank, the default value is 10°C .

Field: Defrost Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the outdoor air dry-bulb temperature and the wet-bulb temperature of the air entering the indoor coil. The EIR is the inverse of the COP. The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. This curve is only required when a reverse-cycle defrost strategy is selected. The curve is normalized to a value of 1.0 at the rating point conditions.

Field: Maximum Outdoor Dry-Bulb Temperature for Defrost Operation

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0°C and less than or equal to 7.22°C. If this input field is left blank, the default value is 5°C.

Field: Defrost Strategy

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle.

Field: Defrost Control

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

Field: Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to “timed” defrost (see Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter $3.5/60 = 0.058333$. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

Field: Resistive Defrost Heater Capacity

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

Field: Apply Part Load Fraction to Speeds Greater than 1

This field determines whether part-load impacts on coil energy use are applied when the coil is operating at speeds greater than speed 1. The allowed choices are Yes or No, with the default being No if this field is left blank. Other input fields in this object allow the user to specify a part-load fraction correlation for each speed to account for compressor start up losses (cycle on/off). For the case of a single multi-speed compressor, the part load losses may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify **No** for this input field to neglect part-load impacts on energy use at higher operating speeds. If part-load impacts on coil energy use are thought to be significant (e.g., intertwined cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify **Yes** and the part-load fraction correlations specified for speeds 2 through 4 will be applied as appropriate. The selection for this input field does not affect part-load impacts when the compressor cycles between speed 1 and off (i.e., the part-load fraction correlation for speed 1 is always applied).

Field: Fuel Type

This alpha field determines the type of fuel that the chiller uses. This field has seven choices: Electricity, NaturalGas, PropaneGas, Diesel, Gasoline, FuelOil#1, and FuelOil#2. The default is NaturalGas.

Field: Number of Speeds

This field specifies the number of sets of data being entered for rated specifications, performance curves, and waste heat specifications for each cooling speed. The rated specifications consist of rated capacity, rated COP, and rated air flow rate. The performance curves consist of a total capacity modifier curve as a function of temperature, total capacity modifier curve as a function of flow fraction, energy input ratio modifier curve as a function of temperature, energy input ratio modifier curve as a function of flow fraction, and part load fraction correlation as a function of part load ratio. The waste heat specifications include the fraction of energy input to the heating coil at the fully loaded and rated conditions, and a temperature modifier. The minimum number of speeds for heating is 2 and the maximum number is 4. The number of speeds should be the same as the number of speeds for heating defined in its parent object (UnitarySystem:MultiSpeedHeatPump: AirToAir). The first set of performance inputs is for Speed 1 and should be for low speed, and the last set of performance inputs should be for high speed. For example, if only three heating speeds are defined, the first set should be for low speed (Speed 1), the second set should be for medium speed (Speed 2), and the third set should be for high speed (Speed 3). In this example, any performance inputs for Speed 4 would be neglected (since this input field specifies that the coil only has three heating speeds).

Field Group: rated specification, performance curves, and waste heat data

The performance for each heating speed must be specified as shown below. All inputs for Speed 1 are required first, followed by the inputs for Speed 2, Speed 3 and Speed 4.

Field: Speed <x> Rated Total Heating Capacity

This numeric field defines the total, full load heating capacity in watts of the DX coil unit at rated conditions for Speed <x> operation (outdoor air dry-bulb temperature of 8.33°C, outdoor air wet-bulb temperature of 6.11°C, heating coil entering air dry-bulb temperature of 21.11°C, heating coil entering air wet-bulb temperature of 15.55°C, and a heating coil air flow rate defined by field “Rated Air Volume Flow Rate, Speed <x>” below). The value entered here must be greater than 0. Capacity should not include supply air fan heat.

Field: Speed <x> Rated COP

This numeric field defines the coefficient of performance (COP=heating power output in watts divided by electrical power input in watts) of the DX heating coil unit at rated conditions for Speed <x> operation (outdoor air dry-bulb temperature of 8.33°C, outdoor air wet-bulb temperature of 6.11°C, coil entering air dry-bulb temperature of 21.11°C, coil entering air wet-bulb temperature of 15.55°C, and a heating coil air flow rate defined by field “Speed <x> Rated Air Flow Rate” below). The value entered here must be greater than 0. The input power includes power for the compressor(s) and outdoor fan(s) but does not include the power consumption of the indoor supply air fan. The heating power output is the value entered above in the field “Rated Total Heating Capacity”.

Field: Speed <x> Rated Air Flow Rate

This numeric field defines the volume air flow rate, in m³ per second, across the DX heating coil at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The rated air volume flow rate should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total heating capacity. The rated total heating capacity and rated COP should be performance information for the unit with outdoor air dry-bulb temperature of 8.33°C, outdoor air wet-bulb temperature of 6.11°C, heating coil entering air dry-bulb

temperature of 21.11°C, heating coil entering air wet-bulb temperature of 15.55°C, and the rated air volume flow rate defined here.

Field: Speed <x> Total Heating Capacity Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed <x> Total Heating Capacity Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of total heating capacity as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed <x> Energy Input Ratio Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Speed <x> Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$$\text{PLF} \geq 0.7 \text{ and } \text{PLF} \geq \text{PLR}$$

If $\text{PLF} < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $\text{PLF} < \text{PLR}$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional DX heating coil (Speed <x>) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

Field: Speed <x> Rated Waste Heat Fraction of Power Input

The fraction of heat input to heating that is available as recoverable waste heat at full load and rated conditions for Speed <x> operation.

Field: Speed <x> Waste Heat Function of Temperature Curve Name

The name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of outdoor dry-bulb temperature and the entering coil dry-bulb temperature for Speed <x>. The output of this curve is multiplied by the rated recoverable waste heat at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point. When the fuel type is electricity, the field is either left blank or ignored by the program.

Below is the input data dictionary description of the DX heating coil.

DX Coil Total Heating Rate [W]

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Heating Energy[J]

This is the total heating output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoil, Group Key = System (ref. Report Meter).

DX Heating Coil <FuelType> Power [W]

This output variable is the input fuel type power for the heating coil in the unit of Watts, averaged during the report period.

DX Cooling Coil <FuelType> Consumption [J]

This output variable is the input fuel type consumption for the multispeed heating coil in the unit of Joules, summed during the report period. This output is also added to a report meter with Resource Type = <FuelType>, End Use Key = Heating, Group Key = System (ref. Report Meter).

Note: The FuelType defined in the above two output variables depends on the input in the fuel type filed. In addition to Electricity, Valid fuel types are NaturalGas, Propane, FuelOil#1, FuelOil#2, Coal, Diesel, and Gasoline.

DX Heating Coil Electric Defrost Power [W]

This is the electricity consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle or resistive). The variable is available when the defrost mode is resistive or the fuel type is electricity.

DX Heating Coil Electric Defrost Consumption [J]

This is the electricity consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle or resistive). The variable is available when the defrost mode is resistive or the fuel type is electricity.

DX Heating Coil <FuelType> Defrost Power [W]

This is the fuel consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle). The variable is available when the defrost mode is reverse-cycle and the fuel type is non-electricity.

DX Heating Coil <FuelType> Defrost Consumption[J]

This is the fuel consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle). The variable is available when the defrost mode is reverse-cycle and the fuel type is non-electricity.

DX Heating Coil Crankcase Heater Power [W]

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. When a companion cooling coil exits, the crankcase heater power of the companion cool coil is also reported in this variable.

DX Heating Coil Crankcase Heater Consumption [J]

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter). When a companion cooling coil exits, the crankcase heater power of the companion cool coil is also reported in this variable.

DX Heating Coil Runtime Fraction

This is the runtime fraction of the DX heating coil compressor and outdoor fan(s) for the timestep being reported. When the heating speed is above 1, this output is the run time fraction for the higher speed.

CoilSystem:Cooling:DX:HeatExchangerAssisted

The heat exchanger-assisted DX cooling coil is a "virtual" component consisting of a direct expansion (DX) cooling coil and an air-to-air heat exchanger as shown in Figure 112 below. The air-to-air heat exchanger pre-conditions the air entering the cooling coil, and reuses this

energy to post-condition the supply air leaving the cooling coil. This heat exchange process improves the latent removal performance of the cooling coil by allowing it to dedicate more of its cooling capacity toward dehumidification (lower sensible heat ratio).

This compound object models the basic operation of an air-to-air heat exchanger in conjunction with a cooling coil. The heat exchanger-assisted DX cooling coil does not have an operating schedule of its own; its operating schedule is governed by the availability schedules for the DX cooling coil and the air-to-air heat exchanger. This compound object is used in place of where a DX cooling coil object would normally be used by itself.

To model a heat exchanger-assisted DX cooling coil, the input data file should include the following objects:

- CoilSystem:Cooling:DX:HeatExchangerAssisted object
- Air-to-air heat exchanger object (HeatExchanger:AirToAir:FlatPlate, HeatExchanger:AirToAir:SensibleAndLatent, or HeatExchanger:Desiccant:BalancedFlow)
- DX cooling coil object (Coil:DX:Cooling:SingleSpeed)

In terms of controlling the operation of the heat exchanger, the heat exchanger is assumed to always provide its heat transfer when the associated DX cooling coil is operating and no high humidity control mechanism is specified. However, the heat exchanger's energy transfer may be controlled (i.e., turned on and off) based on a zone air humidity level using either a humidistat (ref. AirLoopHVAC:Unitary:Furnace:HeatCool or AirLoopHVAC:UnitaryHeatCool) or a humidistat and a maximum humidity set point manager to place a humidity ratio set point on the appropriate control node (ref. AirLoopHVAC:UnitaryCoolOnly). This model may also be used with the unitary changeover bypass system and the unitary air-to-air heat pump system (ref. AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass and AirLoopHVAC:UnitaryHeatPump:AirToAir); however, the heat exchanger is assumed to always provide its heat transfer when the cooling coil operates and can not be turned on and off based on a zone air humidity set point. Two zone air conditioners may also use this model for improved dehumidification. The first type is the packaged terminal heat pump (ref. ZoneHVAC:PackagedTerminalHeatPump) where the heat exchanger's heat transfer is always active whenever the cooling coil operates. The second type is the window air conditioner (ref. ZoneHVAC:WindowAirConditioner) where the heat exchanger's heat transfer is always active when the cooling coil operates and no high humidity control mechanism is specified, OR the heat exchanger's heat transfer may be controlled based on zone air humidity level if a humidistat and high humidity set point manager are specified (maximum humidity ratio set point placed on the heat exchanger's exhaust air outlet node, ref. Figure 112).

Links to the cooling coil and air-to-air heat exchanger specifications are provided in the input data syntax for this compound object. A description of each input field for this compound object is provided below.

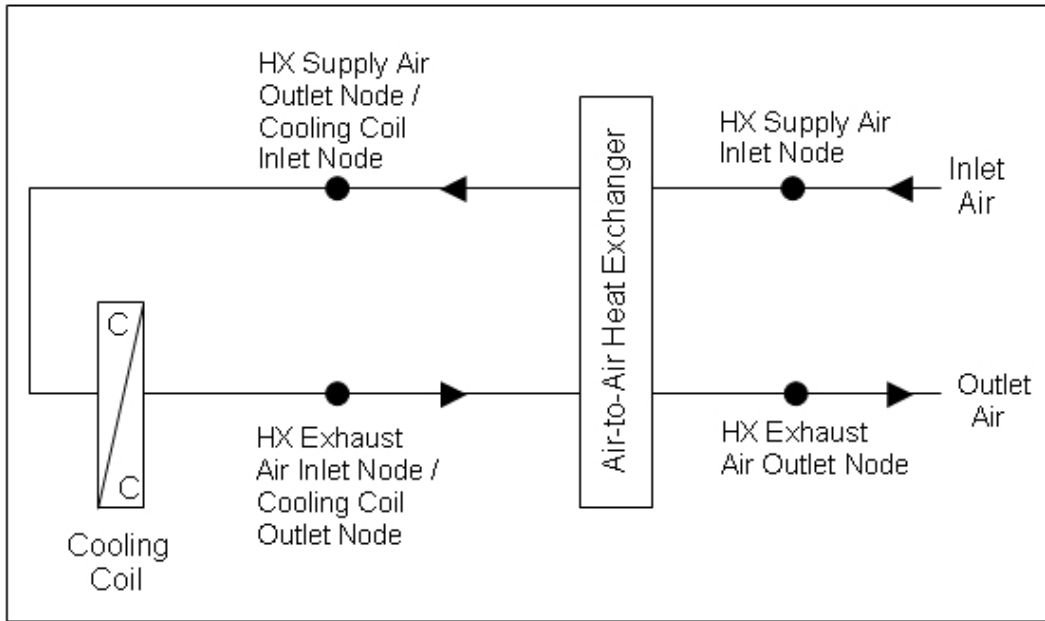

Figure 112. Schematic of the CoilSystem:Cooling:DX:HeatExchangerAssisted compound object

NOTE: Node naming shown in Figure 112 is representative for HeatExchanger:AirToAir:SensibleAndLatent. For HeatExchanger:AirToAir:FlatPlate, the exhaust air nodes are referred to as 'secondary air' nodes. For HeatExchanger:Desiccant:BalancedFlow, the supply air nodes are referred to as 'regeneration air' nodes and the exhaust air nodes as 'process air' nodes.

Field: Name

A unique user-assigned name for the heat exchanger-assisted DX cooling coil. Any reference to this compound component by another object will use this name.

Field: Heat Exchanger Object Type

This alpha field denotes the type of heat exchanger being modeled. Valid choices are:

```
HeatExchanger:AirToAir:FlatPlate
HeatExchanger:AirToAir:SensibleAndLatent
HeatExchanger:Desiccant:BalancedFlow
```

Field: Heat Exchanger Name

This alpha field denotes the name of the air-to-air heat exchanger being modeled.

Field: Cooling Coil Object Type

This alpha field denotes the type of DX cooling coil being modeled. The only valid choice is Coil:Cooling:DX:SingleSpeed.

Field: Cooling Coil Name

This alpha field denotes the name of the DX cooling coil being modeled.

The full IDD specification follows:

CoilSystem:Cooling:DX:HeatExchangerAssisted Outputs

No variables are reported for this compound object. However, outputs are provided by the cooling coil and heat exchanger that are specified.

Coil:Water:CoolingHeatExchangerAssisted

The heat exchanger-assisted water cooling coil is a “virtual” component consisting of a chilled-water cooling coil and an air-to-air heat exchanger as shown in Figure 113 below. The air-to-air heat exchanger precools the air entering the cooling coil, and reuses this energy to reheat the supply air leaving the cooling coil. This heat exchange process improves the latent removal performance of the cooling coil by allowing it to dedicate more of its cooling capacity toward dehumidification (lower sensible heat ratio).

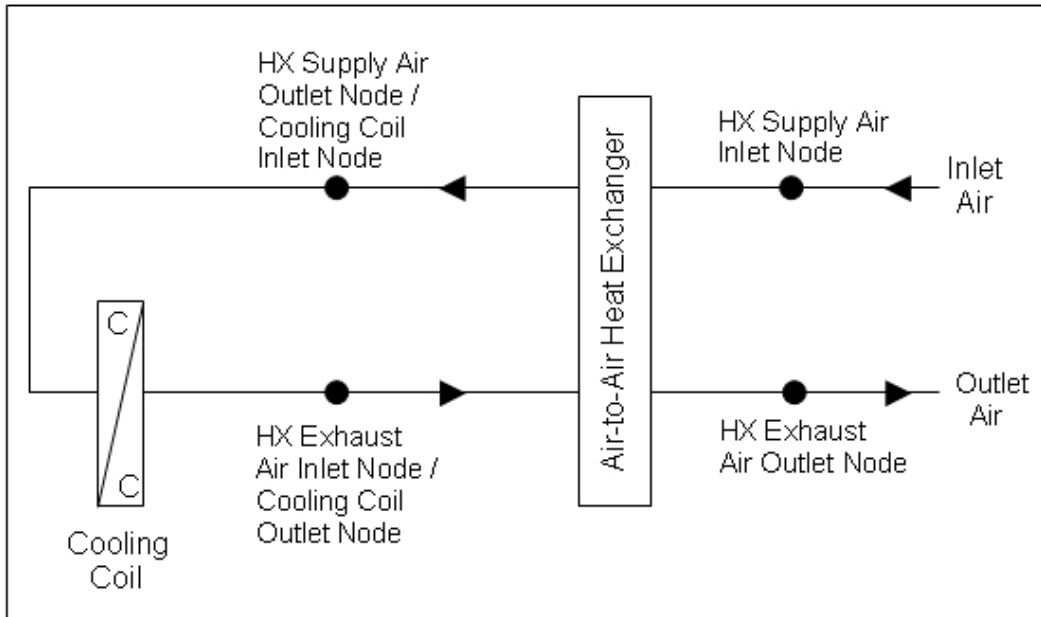

Figure 113. Schematic of the CoilSystem:Cooling:Water:HeatExchangerAssisted compound object

Note: Node naming shown in Figure 113 is representative for HeatExchanger:AirToAir:SensibleAndLatent. For HeatExchanger:AirToAir:FlatPlate, the exhaust air nodes are referred to as ‘secondary air’ nodes.

This compound object models the basic operation of an air-to-air heat exchanger in conjunction with a chilled-water cooling coil. The heat exchanger-assisted water cooling coil does not have an operating schedule of its own; its operating schedule is governed by the

availability schedules for the chilled-water cooling coil and the air-to-air heat exchanger. Heat exchange will occur whenever the heat exchanger is available to operate (via its availability schedule) and a temperature difference exists between the two air streams -- there is currently no method to enable or disable heat exchange based on zone air humidity level. This compound object is used in place of where a chilled-water cooling coil object would normally be used by itself.

To model a heat exchanger-assisted water cooling coil, the input data file should include the following objects:

- CoilSystem:Cooling:Water:HeatExchangerAssisted compound object
- Air-to-air heat exchanger object (HeatExchanger:AirToAir:FlatPlate or HeatExchanger:AirToAir:SensibleAndLatent)
- Chilled-water cooling coil object (Coil:Cooling:Water or Coil:Cooling:Water:DetailedGeometry)

Links to the cooling coil and air-to-air heat exchanger specifications are provided in the input data syntax for this compound object. A description of each input field for this compound object is provided below.

Field: Name

A unique user-assigned name for the heat exchanger-assisted water cooling coil. Any reference to this compound component by another object (e.g., ZoneHVAC:UnitVentilator, ZoneHVAC:FourPipeFanCoil, component in an air loop Branch object) will use this name.

Field: Heat Exchanger Object Type

This alpha field denotes the type of heat exchanger being modeled. Valid choices are:

```
HeatExchanger:AirToAir:FlatPlate
HeatExchanger:AirToAir:SensibleAndLatent
```

Field: Heat Exchanger Name

This alpha field denotes the name of the air-to-air heat exchanger being modeled.

Field: Cooling Coil Object Type

This alpha field denotes the type of chilled-water cooling coil being modeled. Valid choices are:

```
Coil:Cooling:Water
Coil:Cooling:Water:DetailedGeometry
```

Field: Cooling Coil Name

This alpha field denotes the name of the chilled-water cooling coil being modeled.

CoilSystem:Cooling:Water:HeatExchangerAssisted Outputs

No variables are reported for this compound object. However, outputs are provided by the cooling coil and heat exchanger that are specified.

Coil:WaterHeating:AirToWaterHeatPump

EnergyPlus can model a heat pump water heater (HPWH) consisting of a water heater tank (e.g., WaterHeater:Mixed), a direct expansion (DX) “coil” (i.e., an air-to-water DX compression system which includes a water heating coil, air coil, compressor, and water pump), and a fan to provide air flow across the air coil associated with the DX compression system. These objects work together to model a system which heats water using zone air, outdoor air, or a combination of zone and outdoor air as the primary heat source.

The WaterHeater:HeatPump compound object, water heater tank object (e.g., WaterHeater:Mixed), and fan object (e.g., Fan:OnOff) are defined elsewhere in this reference document. Coil:WaterHeating:AirToWaterHeatPump object described here models an air-to-water DX compression system to determine its air-side and water-side performance. This DX coil object calculates the air-side sensible and latent cooling capacity at the specific operating conditions for each simulation timestep, as well as the condenser’s water-side temperature difference at a given condenser water flow rate.

The heat pump water heater DX coil model performs the following major functions:

- calculates the electric consumption of the DX compressor and water pump
- calculates the amount of heat delivered to the water tank
- calculates the electric consumption of the compressor’s crankcase heater
- calculates the air-side performance of the DX coil

The input fields for this object are described below in detail:

Field: Name

This alpha field defines a unique user-assigned name for an instance of a heat pump water heater DX coil. Any reference to this coil by another object (e.g., Heat Pump:Water Heater) will use this name.

Field: Rated Heating Capacity

This numeric field defines the DX coil heating capacity in Watts at the rated evaporator inlet air temperatures, rated condenser inlet water temperature, rated evaporator air flow rate, and rated condenser water flow rate specified below. Values must be greater than 0. This value

represents water heating capacity, and it may or may not include the impact of condenser pump heat (see field Condenser Pump Heat Included in Rated Heating Capacity below).

Field: Rated COP

This numeric field defines the DX coil's water heating coefficient of performance (COP=water heating capacity in watts divided by electrical power input in watts) at rated conditions (rated inlet temperatures and flow rates specified below). This input not only determines the electric energy use of the heat pump DX coil, but also the amount of total air cooling provided by the evaporator. The rated COP includes compressor power, and may or may not include condenser pump power or evaporator fan power (see field Evaporator Fan Power Included in Rated COP and field Condenser Pump Power Included in Rated COP). Values must be greater than 0. If this field is left blank, the default value is 3.2.

Field: Rated Sensible Heat Ratio

This numeric field defines the air-side sensible heat ratio (SHR=sensible cooling capacity divided by total cooling capacity) of the DX coil at rated conditions (rated inlet temperatures and flow rates specified below). This value should not include the effect of evaporator fan heat. Values must be greater than or equal to 0.5, and less than or equal to 1.0. The default value is 0.85.

Field: Rated Evaporator Inlet Air Dry-Bulb Temperature

This numeric field defines the evaporator inlet air dry-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5°C. If this field is left blank, the default value is 19.7°C.

Field: Rated Evaporator Inlet Air Wet-Bulb Temperature

This numeric field defines the evaporator inlet air wet-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5°C. If this field is left blank, the default value is 13.5°C.

Field: Rated Condenser Inlet Water Temperature

This numeric field defines the condenser inlet water temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 25°C. If this field is left blank, the default value is 57.5°C.

Field: Rated Evaporator Air Flow Rate

This numeric field defines the evaporator air volume flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = **autocalculate**), the default value is 5.035E-5 m³/s/W (31.25 cfm/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated evaporator air volumetric flow rate, a zone sizing object is not required.

Field: Rated Condenser Water Flow Rate

This numeric field defines the condenser water volumetric flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = **autocalculate**), the default value is 4.487E-8 m³/s/W (0.208 gpm/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated condenser water volumetric flow rate, a zone sizing object is not required. A warning message will be issued if the ratio of Rated Condenser Water Volumetric Flow Rate to Rated Heating Capacity is less than 1.79405E-8 m³/s/W (0.083 gpm/MBH) or greater than 8.97024E-8 m³/s/W (0.417 gpm/MBH), but the simulation will continue.

Field: Evaporator Fan Power Included in Rated COP

This choice field specifies if evaporator fan power is included in the rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling

provided by the evaporator for each simulation timestep. If Yes is selected, the evaporator fan power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. If No is selected, it is assumed that the total heating power does not include evaporator fan power. If this field is left blank, the default is Yes. See the Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Field: Condenser Pump Power Included in Rated COP

This choice field specifies if condenser pump power is included in the rated COP defined above. This input impacts the calculation of compressor electric power which then impacts the total air cooling provided by the evaporator for each simulation timestep. If Yes is selected, the condenser pump power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. If No is selected, it is assumed that the total heating power does not include the condenser pump. If this field is left blank, the default is No. See Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Field: Condenser Pump Heat Included in Rated Heating Capacity and Rated COP

This choice field specifies if condenser pump heat is included in the rated heating capacity and rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep. If Yes is selected, the condenser pump heat is already included in the rated heating capacity and rated COP. If No is selected, it is assumed that the rated heating capacity and rated COP do not include the condenser pump heat, and pump heat is added to the total water heating capacity based on the Condenser Water Pump Power and Fraction of Condenser Pump Heat to Water fields below. If this field is left blank, the default is No. See Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Field: Condenser Water Pump Power

This numeric field defines the DX coil's condenser pump power in Watts. This is the operating pump power as installed. Values must be greater than or equal to 0. If this field is left blank, the default value is 0. A warning message will be issued if the ratio of Condenser Water Pump Power to Rated Heating Capacity exceeds 0.1422 W/W (41.67 Watts/MBH), but the simulation will continue.

Field: Fraction of Condenser Pump Heat to Water

This numeric field defines the fraction of condenser pump heat that is transferred to the condenser water. The pump is assumed to be downstream of the condenser water coil, and this field is used to determine the water temperature at the condenser outlet node when the field Condenser Pump Power Included in Rated Heating Capacity is set to No. Values must be greater than or equal to 0 and less than or equal to 1. If this field is left blank, the default value is 0.2.

Field: Evaporator Air Inlet Node Name

This alpha field defines the name of the air node from which the evaporator coil draws its inlet air.

Field: Evaporator Air Outlet Node Name

This alpha field defines the name of the air node to which the evaporator coil sends its outlet air.

Field: Condenser Water Inlet Node Name

This alpha field defines the name of the node from which the DX coil condenser draws its inlet water. This node name must also match the source side outlet node name for the water heater tank connected to this DX coil (ref: Water Heaters).

Field: Condenser Water Outlet Node Name

This alpha field defines the name of the node to which the heat pump condenser sends its outlet water. This node name must also match the source side inlet node name for the water heater tank connected to this DX coil (ref: Water Heaters).

Field: Crankcase Heater Capacity

This numeric field defines the compressor's crankcase heater capacity in Watts. The crankcase heater only operates when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation specified below.

Field: Maximum Ambient Temperature for Crankcase Heater Operation

This numeric field defines the maximum ambient temperature for crankcase heater operation in degree Celsius. The crankcase heater only operates when the air surrounding the compressor is below this maximum temperature value and the compressor is off. The ambient temperature surrounding the compressor is set by the Heat Pump:Water Heater parent object (field Compressor Location).

Field: Evaporator Air Temperature Type for Curve Objects

This choice field specifies the air temperature type used for the heating capacity and COP modifier curve objects below. The valid selections are Dry-bulb Temperature and Wet-bulb Temperature. If dry-bulb temperature is selected, the inlet air dry-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If wet-bulb temperature is selected, the inlet air wet-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If this field is left blank and the following curve names are defined, the default value is wet-bulb temperature. If the following curve names are not defined, this field is not used.

Field: Heating Capacity Function of Temperature Curve Name

This alpha field specifies the name of a **biquadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated heating capacity to give the heating capacity at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all conditions).

Field: Heating Capacity Function of Air Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated heating capacity and the heating capacity modifier curve (function of temperature) to give the DX coil heating capacity at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all air flow rates).

Field: Heating Capacity Function of Water Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of

the ratio of actual water flow rate through the condenser to the rated condenser water flow rate. The output of this curve is multiplied by the rated heating capacity and the output from the two other heating capacity modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating capacity at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all water flow rates).

Field: Heating COP Function of Temperature Curve Name

This alpha field specifies the name of a **biquadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated COP to give the heating COP at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the COP remains constant (curve value assumed to be 1.0 for all conditions).

Field: Heating COP Function of Air Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated COP and the heating COP modifier curve (function of temperature) to give the heating COP at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all air flow rates).

Field: Heating COP Function of Water Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual water flow rate through the condenser to the rated condenser water flow rate.. The output of this curve is multiplied by the rated COP and the output from the two other heating COP modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating COP at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all water flow rates).

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$$\text{PLF} \geq 0.7 \quad \text{and} \quad \text{PLF} \geq \text{PLR}$$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $PLF < PLR$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$PLF = 0.85 + 0.15(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Below is the IDD Definition for the Heat Pump Water Heater DX Coil.

    \units W
    \minimum 0
    \default 0
    \note A warning message will be issued if the ratio of Condenser Water Pump Power to Rated
    \note Heating Capacity exceeds 0.1422 W/W (41.67 Watts/MBH), but the simulation will continue.
N10, \field Fraction of Condenser Pump Heat to Water
    \type real
    \minimum 0
    \maximum 1
    \default 0.2
    \note Fraction of pump heat transferred to the condenser water. The pump is assumed
    \note to be located downstream of the condenser.
A5 , \field Evaporator Air Inlet Node Name
    \required-field
    \type alpha
    \note The node from which the DX coil draws its inlet air.
A6 , \field Evaporator Air Outlet Node Name
    \required-field
    \type alpha
    \note The node to which the DX coil sends its outlet air.
A7 , \field Condenser Water Inlet Node Name
    \required-field
    \type alpha
    \note The node from which the DX coil condenser draws its inlet water.
    \note This name should match the source side outlet node name in the associated
    \note water heater tank object.

```

```

A8 , \field Condenser Water Outlet Node Name
    \required-field
    \type alpha
    \note The node to which the DX coil condenser sends its outlet water.
    \note This name should match the source side inlet node name in the associated
    \note water heater tank object.
N11, \field Crankcase Heater Capacity
    \type real
    \minimum 0
    \default 0
    \units W
    \note The compressor crankcase heater only operates when the dry-bulb temperature of air
    \note surrounding the compressor is below the Maximum Ambient Temperature for Crankcase
    \note Heater Operation and the DX coil is off. The ambient temperature surrounding the
    \note compressor is set by the Heat Pump:Water Heater parent object (field Compressor Location).
N12, \field Maximum Ambient Temperature for Crankcase Heater Operation
    \type real
    \minimum 0
    \default 10
    \units C
    \note The compressor crankcase heater only operates when the dry-bulb temperature of air
    \note surrounding the compressor is below the Maximum Outdoor Temperature for Crankcase
    \note Heater Operation and the unit is off. The ambient temperature surrounding the
    \note compressor is set by the WaterHeater:HeatPump parent object (field Compressor Location).
A9 , \field Evaporator Air Temperature Type for Curve Objects
    \type choice
    \key DryBulbTemperature
    \key WetBulbTemperature
    \default WetBulbTemperature
    \note Determines temperature type for heating capacity curves and
    \note heating COP curves. This input determines whether
    \note the inlet air dry-bulb or wet-bulb temperature is used to evaluate these curves.
A10, \field Heating Capacity Function of Temperature Curve Name
    \type object-list
    \object-list BiQuadraticCubicCurves
    \note Heating capacity modifier curve (function of temperature) should be biquadratic or cubic.
    \note Biquadratic curve =  $a + b(ta) + c(ta)^2 + d(tw) + e(tw)^2 + f(ta)(tw)$ .
    \note Cubic curve =  $a + b(ta) + c(ta)^2 + d(ta)^3$ .
    \note  $ta$  = evaporator inlet air [dry-bulb or wet-bulb] temperature (C).
    \note  $tw$  = condenser inlet water temperature (C).
    \note The field Evaporator Air Temperature Type for Curve Objects determines if dry-bulb or wet-
bulb
    \note is used as the evaporator inlet air temperature ( $ta$ ).
A11, \field Heating Capacity Function of Air Flow Fraction Curve Name
    \type object-list
    \object-list QuadraticCubicCurves
    \note Heating capacity modifier curve (function of air flow fraction) should be quadratic or cubic.
    \note Quadratic curve =  $a + b(ff) + c(ff)^2$ .
    \note Cubic curve =  $a + b(ff) + c(ff)^2 + d(ff)^3$ .
    \note  $ff$  = fraction of the rated evaporator air flow rate.
    \note Use curve coefficients of 1,0,0 or leave this field blank when neglecting performance impacts
    \note due to variations in air flow rate fraction.
A12, \field Heating Capacity Function of Water Flow Fraction Curve Name
    \type object-list
    \object-list QuadraticCubicCurves
    \note Heating capacity modifier curve (function of water flow fraction) should be quadratic or
cubic.
    \note Quadratic curve =  $a + b(ff) + c(ff)^2$ .
    \note Cubic curve =  $a + b(ff) + c(ff)^2 + d(ff)^3$ .
    \note  $ff$  = fraction of the rated condenser water flow rate.
    \note Use curve coefficients of 1,0,0 or leave this field blank when neglecting performance impacts
    \note due to variations in water flow rate fraction.

```

```

A13, \field Heating COP Function of Temperature Curve Name
\type object-list
\object-list BiQuadraticCubicCurves
\note Heating COP modifier curve (function of temperature) should be biquadratic or cubic.
\note Biquadratic curve =  $a + b(ta) + c(ta)^2 + d(tw) + e(tw)^2 + f(ta)(tw)$ .
\note Cubic curve =  $a + b(ta) + c(ta)^2 + d(ta)^3$ .
\note ta = evaporator inlet air [dry-bulb or wet-bulb] temperature (C).
\note tw = condenser inlet water temperature (C).
\note The field Evaporator Air Temperature Type for Curve Objects determines if dry-bulb or wet-
bulb
\note is used as the evaporator inlet air temperature (ta).
A14, \field Heating COP Function of Air Flow Fraction Curve Name
\type object-list
\object-list QuadraticCubicCurves
\note Heating COP modifier curve (function of air flow fraction) should be quadratic or cubic.
\note Quadratic curve =  $a + b(ff) + c(ff)^2$ .
\note Cubic curve =  $a + b(ff) + c(ff)^2 + d(ff)^3$ .
\note ff = fraction of the rated evaporator air flow rate.
\note Use curve coefficients of 1,0,0 or leave this field blank when neglecting performance impacts
\note due to variations in air flow rate fraction.
A15, \field Heating COP Function of Water Flow Fraction Curve Name
\type object-list
\object-list QuadraticCubicCurves
\note Heating COP modifier curve (function of water flow fraction) should be quadratic or cubic.
\note Quadratic curve =  $a + b(ff) + c(ff)^2$ .
\note Cubic curve =  $a + b(ff) + c(ff)^2 + d(ff)^3$ .
\note ff = fraction of the rated condenser water flow rate.
\note Use curve coefficients of 1,0,0 or leave this field blank when neglecting performance impacts
\note due to variations in water flow rate fraction.
A16; \field Part Load Fraction Correlation Curve Name
\type object-list
\object-list QuadraticCubicCurves
\note Part Load Fraction Correlation (function of part load ratio) should be quadratic or cubic.
\note Quadratic curve =  $a + b(PLR) + c(PLR)^2$ .
\note Cubic curve =  $a + b(PLR) + c(PLR)^2 + d(PLR)^3$ .
\note PLR = part load ratio (heating delivered/steady-state heating capacity).
\note Use curve coefficients of 1,0,0 or leave this field blank when neglecting performance impacts
\note due to variations in part load ratio.

HVAC,Sum,DX Cooling Coil Crankcase Heater Consumption[J]
HVAC,Average,DX Coil Total Water Heating Rate[W]
HVAC,Sum,DX Coil Total Water Heating Energy[J]
HVAC,Average,DX Coil Water Heating Electric Power[W]
HVAC,Sum,DX Coil Water Heating Electric Consumption[J]

DX Coil Total Cooling Rate[W]

This output field is the average total (sensible and latent) cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Cooling Energy[J]

This output field is the total (sensible plus latent) cooling output of the DX coil in Joules for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Sensible Cooling Rate[W]

This output field is the average moist air sensible cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Sensible Cooling Energy[J]

This output field is the moist air sensible cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Rate[W]

This output field is the average latent cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Energy[J]

This output field is the latent cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Runtime Fraction

This output field is the average runtime fraction of the DX coil compressor for the timestep being reported. This also represents the runtime fraction of the condenser water pump.

DX Coil Crankcase Heater Power[W]

This output field is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. The crankcase heater operates only when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation, otherwise this report variable is set equal to 0.

DX Coil Crankcase Heater Consumption[J]

This output field is the total electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Report Meter).

DX Coil Total Water Heating Rate[W]

This output field is the average water heating rate output of the DX coil (condenser coil plus condenser water pump) in Watts for the timestep being reported. This is determined using the inlet and outlet water temperatures and the water mass flow rate through the condenser coil.

DX Coil Total Water Heating Energy[J]

This output field is the total water heating output of the DX coil (condenser coil plus condenser water pump) in Joules for the timestep being reported. This is determined using the inlet and outlet water temperatures and the water mass flow rate through the condenser coil.

DX Coil Water Heating Electric Power[W]

This output field is the average electricity consumption rate of the DX coil compressor and condenser pump in Watts for the timestep being reported.

DX Coil Water Heating Electric Consumption[J]

This output field is the electricity consumption of the DX coil compressor and condenser pump in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Report Meter).

Coil:Cooling:WaterToAirHeatPump:ParameterEstimation

The **Coil:Cooling:WaterToAirHeatPump:ParameterEstimation** coil is a deterministic model that requires parameters to describe the operating conditions of the heat pump's components. The parameters are generated from the manufacturer catalog data using multi-variable optimization method. In addition, the cooling coil model can be used for 3 type of compressors: **reciprocating**, **rotary** and **scroll**. Descriptions and strength of each respective model is available in the following references:

Jin, Hui. 2002. Parameter Estimation Based Models of Water Source Heat Pumps. Phd. Thesis, Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Tang,C. C. 2005. Modeling Packaged Heat Pumps in Quasi-Steady State Energy Simulation Program. M.S. Thesis. Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Field: Name

This alpha field contains the identifying name for the water-to-air heat pump

Field: Compressor Type

Type of compressor mode used for the heat pump. Choices available are reciprocating, rotary and scroll compressor. Note that the parameters vary for different compressor.

Field: Source Side Fluid Name

This alpha field contains the name of fluid used at the source side.

Field: Refrigerant Type

This alpha field contains the type of refrigerant used by the heat pump.

Field: Design Source Side Flow Rate

This numeric field defines the water flow rate though the coil in m³/sec

Field: Nominal Cooling Coil Capacity

This numeric field defines the nominal cooling capacity for the WatertoAirHP cooling coil in Watts.

Field: Nominal Time for Condensate Removal to Begin

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: High Pressure Cutoff

This numeric field defines the compressor's maximum allowable pressure in Pascal (N/m²)

Field: Low Pressure Cutoff

This numeric field defines the compressor's minimum allowable pressure in Pascal (N/m²)

Field: Water Inlet Node Name

This alpha field contains the cooling coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the cooling coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the cooling coil air inlet node name.

Field: Air Outlet Node Name

This alpha field contains the cooling coil air outlet node name.

Cooling Coil Parameters

Depending on the type of compressor and the source side fluid specified, the type of parameters and values also differs. An Excel Spreadsheet is developed to estimate the parameters based on the manufacturer data. The general parameters (1-5) are listed first followed by specific parameters (6-8) required by the respective compressor model. Lastly, parameters (9-10) are listed based on the type of source side fluid used.

Field: Parameter 1

This numeric field defines the estimated parameter **load side total heat transfer coefficient** in W/K.

Field: Parameter 2

This numeric field defines the estimated parameter **load side outside surface heat transfer coefficient** in W/K.

Field: Parameter 3

This numeric field defines the estimated parameter **superheat temperature** at the evaporator outlet in °C.

Field: Parameter 4

This numeric field defines the estimated parameter **compressor power losses**, which accounts for the loss of work due to mechanical and electrical losses in the compressor in Watts.

Field: Parameter 5

This numeric field defines the estimated parameter of the **compressor's efficiency**. The compressor efficiency is formulated as the equation below:

$$\eta = \frac{\dot{W}_{Theoretical}}{\dot{W}_{CompInput} - \dot{W}_{Loss}}$$

Reciprocating Compressor:**Field: Parameter 6**

This numeric field defines the estimated parameter **piston displacement of the compressor** in m³/s.

Field: Parameter 7

This numeric field defines the estimated parameter **pressure drop** at the compressor suction and discharge in Pascals (N/m²)

Field: Parameter 8

This numeric field defines the estimated parameter **clearance factor of the compressor**. This parameter is dimensionless.

Rotary Compressor:**Field: Parameter 6**

This numeric field defines the estimated parameter **piston displacement** of the compressor in m³/s.

Field: Parameter 7)

This numeric field defines the estimated parameter **pressure drop** at the compressor suction and discharge in Pascal (N/m²)

Field: Parameter 8)

Only 7 parameters are needed for Rotary Compressor.

Scroll Compressor:**Field: Parameter 6**

This numeric field defines the **refrigerant volume flow rate** at the beginning of the compression [m³/s]

Field: Parameter 7

This numeric field defines the built-in-**volume ratio**.

Field: Parameter 8

This numeric field defines the **leak rate coefficient** for the relationship between pressure ratio and leakage rate.

If pure water is used as the source side fluid:**Field: Parameter 9**

This numeric field defines the estimated parameter **source side heat transfer coefficient** in W/K.

Field: Parameter 10

Not Required

If antifreeze is used as the source side fluid:**Field: Parameter 9**

This numeric field defines the estimated parameter **source side heat transfer resistance 1**. Unit is dimensionless

Field: Parameter 10

This numeric field defines the estimated parameter **source side heat transfer resistance 2**. Unit is W/K.

Coil:Cooling:WaterToAirHeatPump:EquationFit

The Coil:Cooling:WaterToAirHeatPump:EquationFit is a simple curve-fit model that requires coefficients generated from the heat pump catalog data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. The performance of the heat pump is modeled using curves fitted from the catalog data. Description of the equation-fit model is available in the following reference:

Tang,C. C. 2005. Modeling Packaged Heat Pumps in Quasi-Steady State Energy Simulation Program. M.S. Thesis. Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Field: Name

This alpha field contains the identifying name for the Coil:WatertoAirHPSimple:Cooling

Field: Water Inlet Node Name

This alpha field contains the cooling coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the cooling coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the cooling coil air inlet node name.

Field: Air Outlet Node Name

This alpha field contains the cooling coil air outlet node name.

Field: Rated Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump in m3/s.

Field: Rated Water Flow Rate

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump in m3/s.

Field: Rated Total Cooling Capacity

This numeric field contains the rated total cooling capacity of the heat pump in W.

Field: Rated Sensible Cooling Capacity

This numeric field contains the rated sensible capacity of the heat pump in W.

Field: Rated Cooling Power Consumption

This numeric field contains the rated heating power consumption of the heat pump in W.

Field: Total Cooling Capacity Coefficient 1 to 5

These numeric fields contain the first to fifth coefficient for the heat pump total cooling capacity.

Field: Sensible Cooling Capacity Coefficient 1 to 6

These numeric fields contain the first to sixth coefficient for the heat pump sensible cooling capacity.

Field: Cooling Power Consumption Coefficient 1 to 5

These numeric fields contain the first to fifth coefficient for the heat pump power consumption.

Field: Nominal Time for Condensate Removal to Begin

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

HVAC, Sum, WatertoAirHP Source Side Cooling Energy [J]
```

WatertoAirHP Power [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

WatertoAirHP Load Side Total Heat Transfer Rate [W]

The output variable is the average total cooling load provide by the heat pump which includes the sensible and latent load in Watts over the timestep being reported.

WatertoAirHP Load Side Sensible Heat Transfer Rate [W]

The output variable is the average sensible cooling load provide by the heat pump in Watts over the timestep being reported.

WatertoAirHP Source Side Total Heat Transfer Rate [W]

The output variable is the average heat rejected to the water at the heat pump condenser in Watts over the timestep being reported.

WatertoAirHP Part-Load Ratio

This output variable is the ratio of the part-load capacity to the steady state capacity of the WatertoAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the WatertoAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

WatertoAirHP Duty Factor

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

WatertoAirHP Load Side Mass Flow Rate [kg/s]

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

WatertoAirHP Load Side Inlet Dry Bulb Temperature [C]

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

WatertoAirHP Load Side Inlet Humidity Ratio [kg/kg]

The output variable is the average entering air dry humidity ratio over the timestep being reported.

WatertoAirHP Load Side Outlet Dry Bulb Temperature [C]

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

WatertoAirHP Load Side Outlet Humidity Ratio [kg/kg]

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

WatertoAirHP Source Side Mass Flow Rate [kg/s]

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

WatertoAirHP Source Side Inlet Temperature [C]

The output variable is the average entering water temperature over the timestep being reported.

WatertoAirHP Source Side Outlet Temperature [C]

The output variable is the average leaving water temperature over the timestep being reported.

WatertoAirHP Cooling Electric Consumption [J]

The output variable is the electric consumption of the heat pump in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

WatertoAirHP Load Side Total Cooling Energy [J]

The output variable is the total cooling output of the coil in Joules over the timestep being reported. Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (ref. Report Meter).

WatertoAirHP Load Side Sensible Cooling Energy [J]

The output variable is the total sensible cooling output of the coil in Joules over the timestep being reported

WatertoAirHP Load Side Latent Cooling Energy [J]

The output variable is the total latent cooling output of the coil in Joules over the timestep being reported.

WatertoAirHP Source Side Cooling Energy [J]

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported

Coil:Heating:WaterToAirHeatPump:ParameterEstimation

The Water to Air heat pump heating coil is a deterministic model that requires parameters to describe the operating conditions of the heat pump's components. The parameters are generated from the manufacturer catalog data using multi-variable optimization method. However, the parameters required for WatertoAirHP heating coil is similar to WatertoAirHP cooling except (source side outside heat transfer coefficient) parameter is not required for heating. In addition, the heating coil model can be used for 3 type of compressors which are **reciprocating**, **rotary** and **scroll**.

Field: Name

This alpha field contains the identifying name for the water-to-air heat pump

Field: Compressor Type

Type of compressor mode used for the heat pump. Choices available are reciprocating, rotary and scroll compressor. Note that the parameters vary for different compressor.

Field: Source Side Fluid Name

This alpha field contains the name of fluid used at the source side.

Field: Refrigerant Type

This alpha field contains the type of refrigerant used by the heat pump.

Field: Design Source Side Flow Rate

This numeric field defines the water flow rate though the coil in m3/sec

Field: Nominal Heating Coil Capacity

This numeric field defines the nominal heating capacity for the WatertoAirHP heating coil in Watts.

Field: High Pressure Cutoff

This numeric field defines the compressor's maximum allowable pressure in Pascal (N/m²)

Field: Low Pressure Cutoff

This numeric field defines the compressor's minimum allowable pressure in Pascal (N/m²)

Field: Water Inlet Node Name

This alpha field contains the heating coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the heating coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the heating coil air inlet node name.

Field: Air Outlet Node Name

This alpha field contains the heating coil air outlet node name.

Heating Coil Parameters

Depending on the type of compressor specified, the type of parameters and values also differs. An Excel Spreadsheet is in the final stage of development that is capable of estimating the parameters based on the manufacturer data. The general parameters (1-4) are listed first followed by specific parameters (5-7) required by the respective compressor model. Lastly, parameters (8-9) are listed based on the type of source side fluid used.

Field: Parameter 1

This numeric field defines the estimated parameter **load side total heat transfer coefficient** in W/K.

Field: Parameter 2

This numeric field defines the estimated parameter **superheat temperature** at the evaporator outlet in °C.

Field: Parameter 3

This numeric field defines the estimated parameter **compressor power losses**, which accounts for the loss of work due to mechanical and electrical losses in the compressor in Watts.

Field: Parameter 4

This numeric field defines the estimated parameter of the **compressor's efficiency**. The compressor efficiency is formulated as the equation below:

$$\eta = \frac{\dot{W}_{Theoretical}}{\dot{W}_{CompInput} - \dot{W}_{Loss}}$$

Reciprocating Compressor:**Field: Parameter 5**

This numeric field defines the estimated parameter **piston displacement of the compressor** in m³/s.

Field: Parameter 6

This numeric field defines the estimated parameter **pressure drop at the compressor suction** and discharge in Pascals (N/m²)

Field: Parameter 7)

This numeric field defines the estimated parameter **clearance factor of the compressor**. This parameter is dimensionless.

Rotary Compressor:**Field: Parameter 5**

This numeric field defines the estimated parameter **piston displacement of the compressor** in m³/s.

Field: Parameter 6

This numeric field defines the estimated parameter **pressure drop at the compressor suction** and discharge in Pascal (N/m²)

Field: Parameter 7

Only 6 parameters are needed for Rotary Compressor.

Scroll Compressor:**Field: Parameter 5**

This numeric field defines the **refrigerant volume flow rate** at the beginning of the compression [m³/s]

Field: Parameter 6

This numeric field defines the **built-in-volume ratio**.

Field: Parameter 7 (Leak Rate Coefficient)

This numeric field defines the coefficient for the relationship between **pressure ratio and leakage rate**.

If pure water is used as the source side fluid:**Field: Parameter 8**

This numeric field defines the estimated parameter **source side heat transfer coefficient** in W/K.

Field: Parameter 9

Not Required

If antifreeze is used as the source side fluid:**Field: Parameter 8**

This numeric field defines the estimated parameter **source side heat transfer resistance 1**. Unit is dimensionless

Field: Parameter 9)

This numeric field defines the estimated **parameter source side heat transfer resistance 2**. Unit is W/K.

Coil:Heating:WaterToAirHeatPump:EquationFit

The Water to Air Heating Equation Fit Coil is a simple curve-fit model that requires coefficients generated from the heat pump catalog data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. The performance of the heat pump is modeled using curves fitted from the catalog data.

Field: Name

This alpha field contains the identifying name for the Coil:WatertoAirHP:EquationFit:Heating

Field: Water Inlet Node Name

This alpha field contains the heating coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the heating coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the heating coil air inlet node name.

Field: Air Outlet Node Name

This alpha field contains the heating coil air outlet node name.

Field: Rated Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump in m³/s.

Field: Rated Water Flow Rate

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump in m³/s.

Field: Rated Heating Capacity

This numeric field contains the rated heating capacity of the heat pump in W.

Field: Rated Heating Power Consumption

This numeric field contains the rated heating power consumption of the heat pump in W.

Field: Heating Capacity Coefficient 1-5

These numeric fields contain the first to fifth coefficient for the heat pump capacity.

Field: Heating Power Consumption Coefficient 1-5

These numeric fields contain the first to fifth coefficient for the heat pump power consumption.

**Water to Air Heat Pump Heating Coil (parameter Estimation and Equation Fit)
Outputs**

Coil:Heating:WaterToAirHeatPump:ParameterEstimation and
 Coil:Heating:WaterToAirHeatPump:EquationFit have the same output variables listed as follows;

```

HVAC, Average, WatertoAirHP Power [W]
HVAC, Average, WatertoAirHP Load Side Total Heat Transfer Rate [W]
HVAC, Average, WatertoAirHP Load Side Sensible Heat Transfer Rate [W]
HVAC, Average, WatertoAirHP Source Side Heat Transfer Rate [W]
HVAC, Average, WatertoAirHP Part Load Ratio
HVAC, Average, WatertoAirHP Duty Factor

HVAC, Average, WatertoAirHP Load Side Mass Flow Rate[kg/s]
HVAC, Average, WatertoAirHP Load Side Inlet Dry Bulb Temperature [C]
HVAC, Average, WatertoAirHP Load Side Inlet Humidity Ratio [kg/kg]
HVAC, Average, WatertoAirHP Load Side Outlet Dry Bulb Temperature [C]
HVAC, Average, WatertoAirHP Load Side Outlet Humidity Ratio [kg/kg]

HVAC, Average, WatertoAirHP Source Side Mass Flow Rate[kg/s]
HVAC, Average, WatertoAirHP Source Side Inlet Temperature [C]
HVAC, Average, WatertoAirHP Source Side Outlet Temperature [C]

HVAC, Sum, WatertoAirHP Heating Electric Consumption [J]
HVAC, Sum, WatertoAirHP Load Side Total Heating Energy [J]
HVAC, Sum, WatertoAirHP Source Side Heating Energy [J]
  
```

WatertoAirHP Power [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

WatertoAirHP Load Side Total Heat Transfer Rate [W]

The output variable is the average total heating capacity provide by the heat pump which includes the sensible and latent capacity in Watts over the timestep being reported.

WatertoAirHP Load Side Sensible Heat Transfer Rate [W]

The output variable is the average sensible heating capacity provide by the heat pump in Watts over the timestep being reported. For heating mode, the sensible capacity is equal to the total capacity.

WatertoAirHP Source Side Total Heat Transfer Rate [W]

The output variable is the average heat absorbed at the heat pump evaporator in Watts over the timestep being reported.

WatertoAirHP Part-Load Ratio

This output variable is the ratio of the part-load capacity to the steady state capacity of the WatertoAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the WatertoAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

WatertoAirHP Duty Factor

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

WatertoAirHP Load Side Mass Flow Rate [kg/s]

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

WatertoAirHP Load Side Inlet Dry Bulb Temperature [C]

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

WatertoAirHP Load Side Inlet Humidity Ratio [kg/kg]

The output variable is the average entering air dry humidity ratio over the timestep being reported.

WatertoAirHP Load Side Outlet Dry Bulb Temperature [C]

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

WatertoAirHP Load Side Outlet Humidity Ratio [kg/kg]

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

WatertoAirHP Source Side Mass Flow Rate [kg/s]

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

WatertoAirHP Source Side Inlet Temperature [C]

The output variable is the average entering water temperature over the timestep being reported.

WatertoAirHP Source Side Outlet Temperature [C]

The output variable is the average leaving water temperature over the timestep being reported.

WatertoAirHP Heating Electric Consumption [J]

The output variable is the total electric consumption of the heat pump in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter).

WatertoAirHP Load Side Total Heating Energy [J]

The output variable is the total cooling output of the coil in Joules over the timestep being reported. Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Report Meter).

WatertoAirHP Source Side Heating Energy [J]

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported

Coil:WaterHeating:Desuperheater

A simplified approach is used to determine the performance of this water heating coil. The model assumes that the heating energy provided by this coil is reclaimed from the superheated refrigerant gas leaving a compressor (i.e., a desuperheating refrigerant-to-water heating coil) and does not impact the performance of the compressor. This coil must be used with a water heater tank (e.g., WaterHeater:Mixed) which can supply heated potable water and/or hot water for use in a plant loop (e.g., hydronic air reheat coils).

Since detailed refrigeration system models do not currently exist in EnergyPlus, the amount of available superheat is simply a percentage of the total heat being rejected by the DX system's condenser. Approximately 25-30% of the energy rejected by typical refrigeration system condensers is to reduce the superheated refrigerant vapor temperature to the condensing temperature. Recovery efficiencies higher than 30% may cause the refrigerant gas to condense which in turn impacts the performance of the refrigeration system. For this reason, the maximum heat reclaim recovery efficiency for this coil is 30%. The model includes the ability to modify the heat reclaim recovery efficiency based on variations in inlet water temperature and outdoor air dry-bulb temperature.

This coil model performs the following major functions:

- calculates the amount of heat delivered to the water tank
- calculates the electricity consumption of the integral water pump and on/off-cycle parasitic loads

The input fields for this object are described below in detail:

Field: Name

This alpha field contains a unique user-assigned name for an instance of a desuperheater water heating coil. Any reference to this desuperheater coil by another object will use this name.

Field: Availability Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that denotes whether the desuperheater coil is available to operate during a given time period. A schedule value equal to 0 denotes that the desuperheater coil is off for that time period. A value other than 0 denotes that the desuperheater coil is available to operate during that time period. During times when the desuperheater coil is scheduled off, the heater (element or burner) in the water tank object operates based on its tank set point temperature schedule and the desuperheater coil's parasitic electric power is also off for that time period.

Field: Setpoint Temperature Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that specifies the set point (or "cut-out") temperature for the desuperheater coil. Temperature values used in this schedule should be in degrees Celsius. The desuperheater coil turns off when the tank water reaches this set point temperature. Once the desuperheater coil is off, the tank water temperature floats downward until it falls below the set point temperature minus the dead band temperature difference defined below (i.e., the "cut-in" temperature). At this point, the desuperheater coil turns on and remains on until the desuperheater coil set point temperature is reached.

Field: Dead Band Temperature Difference

This numeric field contains the dead band temperature difference in degrees Celsius. The desuperheater coil "cut-in" temperature is defined as the desuperheater coil set point temperature defined above minus this dead band temperature difference. The desuperheater coil turns on when the water temperature in the tank falls below the "cut-in" temperature. The desuperheater coil remains on until the water temperature in the tank rises above the desuperheater coil set point ("cut-out") temperature defined above. The dead band temperature difference must be greater than 0°C and less than or equal to 20°C. If this field is left blank, the default value is 5°C.

Desuperheater water heating coils are typically used to offset energy consumption by the water tank's heater (element or burner). Therefore, the cut-in temperature for the desuperheater coil (set point minus dead band temperature difference) is usually higher than the set point temperature for the heater (element or burner) in the associated water heater tank object. At times when the water heater tank set point

temperature is greater than the cut-in temperature of the desuperheater coil, the model disables the desuperheater coil and the tank's heater is used to heat the water.

Field: Rated Heat Reclaim Recovery Efficiency

This numeric field defines the ratio of recovered waste heat from the superheated refrigerant gas to the total rejected waste heat from the heating source (as if no heat reclaim occurred). Input values must be greater than 0 up to a maximum of 0.3. If this input field is left blank, the default value is 0.25.

Field: Rated Inlet Water Temperature

This numeric field defines the coil inlet water temperature, in degrees Celsius, that corresponds to the rated heat reclaim recovery efficiency. Also see field "Heat Reclaim Efficiency Modifier Curve Name (function of temperature)" below.

Field: Rated Outdoor Air Temperature

This numeric field defines the outdoor air dry-bulb temperature, in degrees Celsius, that corresponds to the rated heat reclaim recovery efficiency. The outdoor air dry-bulb temperature impacts the desuperheater coil refrigerant temperature and the amount of heat available for reclaim. Also see field "Heat Reclaim Efficiency Modifier Curve Name(function of temperature)" below.

Field: Maximum Inlet Water Temperature for Heat Reclaim

This numeric field defines the maximum coil inlet water temperature in degrees Celsius. Any time the inlet water temperature to the desuperheater coil is above this maximum allowed temperature, heat reclaim is restricted so that the tank water does not exceed this temperature.

Field: Heat Reclaim Efficiency Function of Temperature Curve Name

This alpha field specifies the name of a **biquadratic** curve object (ref: Performance Curves) that defines the variation in heat reclaim efficiency as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses the coil inlet water temperature and outdoor air dry-bulb temperature (entering the DX coil condenser) as the independent variables. The output of this curve is multiplied by the rated heat reclaim recovery efficiency to give the heat reclaim efficiency at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heat reclaim efficiency remains constant (curve value assumed to be 1.0 for all conditions). The model restricts the product of the output of this curve and the rated heat reclaim recovery efficiency to a maximum of 0.3.

Field: Water Inlet Node Name

This alpha field defines the name of the water node from which the desuperheater heating coil draws its inlet water. This node name must also match the source side outlet node name for the water heater tank used with this coil (ref. Water Heaters).

Field: Water Outlet Node Name

This alpha field defines the name of the water node to which the desuperheater heating coil sends its outlet water. This node name must also match the source side inlet node name for the water heater tank used with this coil (ref. Water Heaters).

Field: Tank Object Type

This alpha (choice) field contains the type of water heater tank used by this desuperheater heating coil. Currently, the only valid choice is WaterHeater:Mixed.

Field: Tank Name

This alpha field contains the name of the specific water heater tank (WaterHeater:Mixed object) used by this desuperheater heating coil.

Field: Heating Source Object Type

This alpha (choice) field defines the source of superheated refrigerant gas from which the desuperheater water heating coil recovers energy through heat reclaim. Valid choices are:

Coil:Cooling:DX:SingleSpeed Coil:Cooling:DX:TwoSpeed Coil:Cooling:DX:TwoStageWithHumidityControlMode Refrigeration:CompressorRack Refrigeration:Condenser

Field: Heating Source Name

This alpha field defines the name of the desuperheater coil's heat source which provides waste heat to this desuperheater water heating coil.

Field: Water Flow Rate

This numeric field defines the desuperheater coil's water flow rate in cubic meters per second. The model assumes that this flow rate is constant (throughout the simulation period) when the desuperheater coil operates, and that it corresponds to the heat reclaim recovery efficiency performance specified by the user. This water flow rate must be greater than zero.

Field: Water Pump Power

This numeric field defines the coil's water circulation pump power in Watts. This is the operating pump power as installed. Values must be greater than or equal to 0. If this field is left blank, the default value is 0. A warning message will be issued if the ratio of water pump power to desuperheater water volumetric flow rate exceeds $7.9264E6 \text{ W/m}^3/\text{s}$, but the simulation will continue using the user-defined values. The model assumes that this integral pump (i.e., no need to define a separate pump object) cycles on and off with the desuperheater heating coil.

Field: Fraction of Pump Heat to Water

This numeric field defines the fraction of water circulation pump heat that is transferred to the water. The pump is assumed to be downstream of the desuperheater water heating coil, and this field is used to determine the desuperheater water outlet temperature. Values must be greater than or equal to 0 and less than or equal to 1. If this field is left blank, the default value is 0.2.

Field: On-Cycle Parasitic Electric Load

This optional numeric field contains the on-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the desuperheater water heating coil. This parasitic electric load is consumed whenever the desuperheater coil is operating, and the model assumes that this parasitic power does not contribute to heating the water nor does it affect the zone air heat balance. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Field: Off-Cycle Parasitic Electric Load

This optional numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the desuperheater water heating coil. This parasitic electric load is consumed whenever the desuperheater coil is available but is not operating, and the model assumes that this parasitic power does not contribute to heating the water nor does it affect the zone air heat balance. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Below is the IDD definition for the Coil:Water:DesuperheaterHeating object:

```

Coil:WaterHeating:Desuperheater,
  \min-fields 18
A1 , \field Name
  \required-field
  \type alpha
  \reference WaterHeatingCoilsDesuperheater
  \note Unique name for this instance of a desuperheater water heating coil.
A2 , \field Availability Schedule Name
  \type alpha
  \note Schedule values of 0 denote the desuperheater heating coil is off and the parasitic electric
  \note energy is also off.
A3 , \field Setpoint Temperature Schedule Name
  \required-field
  \type alpha
  \note Defines the cut-out temperature where the desuperheater water heating coil turns off.
  \note The desuperheater heating coil setpoint temperature should always be greater
  \note than the water tank's heater (element or burner) setpoint temperature. Temperature
  \note schedule values should be in degrees C.
N1 , \field Dead Band Temperature Difference
  \type real
  \units deltaC
  \minimum> 0
  \maximum 20
  \default 5
  \note Setpoint temperature minus the dead band temperature difference defines
  \note the cut-in temperature where the desuperheater water heating coil turns on.
  \note The water tank's heater (element or burner) setpoint temperature
  \note should always be less than the desuperheater heating coil cut-in temperature.
N2 , \field Rated Heat Reclaim Recovery Efficiency
  \type real
  \minimum> 0.0
  \maximum 0.3
  \default 0.25
  \note Enter the fraction of waste heat reclaimed by the desuperheater water heating coil.
N3 , \field Rated Inlet Water Temperature
  \required-field
  \type real
  \units C
  \note The inlet water temperature corresponding to the rated heat reclaim recovery efficiency.
N4 , \field Rated Outdoor Air Temperature
  \required-field
  \type real
  \units C
  \note The outdoor air dry-bulb temperature corresponding to the
  \note rated heat reclaim recovery efficiency.
N5 , \field Maximum Inlet Water Temperature for Heat Reclaim
  \required-field
  \type real
  \units C
  \note The desuperheater water heating coil is off when the inlet water temperature is above
  \note the maximum inlet water temperature for heat reclaim.
A4 , \field Heat Reclaim Efficiency Function of Temperature Curve Name
  \type object-list
  \object-list CubicCurves
  \note A biquadratic curve defining the performance of the desuperheater heating coil.
  \note Performance can be specified as a function of inlet water temperature, outdoor air
  \note dry-bulb temperature, or both.
  \note Curve = a + b*Tw + c*Tw**2 + d*odb + e*odb**2 + f*Tw*odb.
  \note Tw = desuperheater heating coil entering water temperature (C).
  \note Odb = outdoor dry-bulb temperature at DX system condenser (C).

```

```

A5 , \field Water Inlet Node Name
    \required-field
    \type alpha
    \note The node from which the desuperheater heating coil draws its inlet water.
    \note This name should match the source side outlet node name in the associated
    \note water heater tank object.
A6 , \field Water Outlet Node Name
    \required-field
    \type alpha
    \note The node to which the desuperheater heating coil sends its outlet water.
    \note This name should match the source side inlet node name in the associated
    \note water heater tank object.
A7 , \field Tank Object Type
    \required-field
    \type choice
    \key WaterHeater:Mixed
    \default WaterHeater:Mixed
    \note Specify the type of water heater tank used by this desuperheater water heating coil.
A8 , \field Tank Name
    \required-field
    \type alpha
    \note The name of the water heater tank used by this desuperheater water heating coil.
    \note Needs to match the name used in the corresponding water heater object.
A9 , \field Heating Source Object Type
    \required-field
    \type choice
    \key Coil:Cooling:DX:SingleSpeed
    \key Coil:Cooling:DX:TwoSpeed
    \key Coil:Cooling:DX:TwoStageWithHumidityControlMode
    \key Refrigeration:CompressorRack
    \key Refrigeration:Condenser
    \note The type of DX system that is providing waste heat for reclaim.
A10, \field Heating Source Name
    \required-field
    \type object-list
    \object-list DesuperHeatingCoilSources
    \note The name of the DX system used for heat reclaim.
N6 , \field Water Flow Rate
    \required-field
    \type real
    \units m3/s
    \minimum > 0
    \note The operating water flow rate.
N7 , \field Water Pump Power
    \type real
    \units W
    \minimum 0.0
    \default 0.0
    \note The water circulation pump electric power.
N8 , \field Fraction of Pump Heat to Water
    \type real
    \minimum 0
    \maximum 1
    \default 0.2
    \note The fraction of pump heat transferred to the water. The pump is assumed to be downstream of
    \note the desuperheater water heating coil.
N9 , \field On-Cycle Parasitic Electric Load
    \type real
    \units W
    \minimum 0
    \default 0
    \note Parasitic electric power consumed when the desuperheater water heating coil operates.
    \note Parasitic electric load does not contribute to water heating or the zone air heat balance.
    \ip-units W

```

```

N10; \field Off-Cycle Parasitic Electric Load
      \type real
      \units W
      \minimum 0
      \default 0
      \note Parasitic electric load consumed when the desuperheater water heating coil is off.
      \note Parasitic electric load does not contribute to water heating or the zone air heat balance.
      \note Off-cycle parasitic power is 0 when the availability schedule is 0.
      \ip-units W

```

Desuperheater Part Load Ratio

This output field contains the part load ratio of the desuperheater heating coil for the timestep being reported. This ratio represents the fraction of the timestep that the desuperheater heating coil is operating.

Desuperheater Water Heating Rate [W]

This output field contains the average heating rate output of the desuperheater heating coil in Watts for the timestep being reported. This value includes the portion of circulation pump heat attributed to heating the water.

Desuperheater Water Heating Energy [J]

This output field contains the total heating output of the desuperheater heating coil in Joules for the timestep being reported. This value includes the portion of circulation pump heat attributed to heating the water.

Desuperheater Pump Electric Power [W]

This output field contains the average electricity consumption rate for the water circulation pump in Watts for the timestep being reported.

Desuperheater Pump Electric Consumption [J]

This output field contains the electricity consumption of the water circulation pump in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key= DHW, Group Key= Plant (ref. Report Meter).

Desuperheater Heat Reclaim Efficiency Modifier Curve Output

This output field contains the average output of the Heat Reclaim Efficiency Modifier Curve (function of temperature) for the timestep being reported.

Desuperheater On-Cycle Parasitic Electric Power [W]***Desuperheater On-Cycle Parasitic Electric Consumption [J]******Desuperheater Off-Cycle Parasitic Electric Power [W]******Desuperheater Off-Cycle Parasitic Electric Consumption [J]***

These outputs are the parasitic electric power and consumption associated with the desuperheater water heating coil. Specific outputs represent parasitic electrical usage during the coil on and off cycles. These outputs represent electronic controls or other electric component. The model assumes that the parasitic power does not contribute to heating the water nor does it impact the zone air heat balance. The parasitic electric consumption outputs are also added to a report meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Report Meter).

Group – Fans

A fan may be defined either in the air loop or as a zone equipment component. The data that is common to the fan types shown below include an identifying name, an availability schedule name, a total efficiency rating, a rated pressure rise, and inlet and outlet air node names. In the case of a variable volume fan, additional input includes parameters for modeling fan performance over a range of speeds. See the engineering documentation for the variable speed fan for a further description of what these coefficients represent. Suggested values for different variable volume systems are shown in the following table.

Table 26. Fan Coefficient Values

Type of Fan	Fan Coeff. 1	Fan Coeff. 2	Fan Coeff. 3	Fan Coeff. 4	Fan Coeff. 5
Inlet Vane Dampers	0.35071223	0.30850535	-0.54137364	0.87198823	0.000
Discharge Dampers	0.37073425	0.97250253	-0.34240761	0.000	0.000
Var. Speed Motor	0.0015302446	0.0052080574	1.1086242	-0.11635563	0.000

Fan:ConstantVolume

This object models a constant air volume fan that is intended to operate continuously based on a time schedule. This fan will not cycle on and off based on cooling/heating load or other control signals (Ref: Fan:OnOff).

Field: Name

A unique user-assigned name for an instance of a Fan:ConstantVolume. Any reference to this fan by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the fan can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the fan must be off for the hour.

Field: Fan Efficiency

The ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the fan efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be between 0 and 1.

Field: Pressure Rise

The pressure rise in Pascals at full flow and standard (sea level) conditions (20°C and 101325 Pa).

Field: Maximum Flow Rate

The full load air volumetric flow rate (m³/sec) at standard temperature and pressure (dry air at 20°C drybulb). The program does use local barometric pressure to account for altitude using equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)**5.2559$$

where p=pressure in Pa and Z=altitude in m

Field: Motor Efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1.

Field: Motor In Airstream Fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Field: Air Inlet Node Name

The name of the HVAC system node which supplies the inlet air conditions to the fan.

Field: Air Outlet Node Name

The name of the HVAC system node to which the fan sends its outlet air.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Central System", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the fan will be assigned to the "General" end-use subcategory.

```

Constant Volume Fan Outputs

```

HVAC,Average,Fan Electric Power[W]
HVAC,Average,Fan Delta Temp[C]
HVAC,Sum,Fan Electric Consumption[J]

```

Fan Electric Power [W]

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

Fan Delta Temp [C]

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) in degrees Celsius for the timestep being reported.

Fan Electric Consumption [J]

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key= Fans, Group Key= System (ref. Report Meter).

Fan:OnOff

This object models a constant air volume fan that is intended to cycle on and off in tandem with a cooling or heating system (i.e., AUTO fan control mode). The fan can also operate continuously like Fan:ConstantVolume. If modeling continuous operation and this object is used as part of a system that utilizes Coil:Heating:Gas, Coil:Cooling:DX:SingleSpeed or Coil:Heating:DX:SingleSpeed, the user should confirm proper air flow rates (coil and fan max

flows are equal) and that the coil part-load fraction correlation(s) are appropriate (e.g., part-load fraction is less than or equal to 1 for all values of coil part-load ratio). If modeling multi-speed fan operation, this object must be used as part of a compound object that allows multiple fan speeds (e.g., AirLoopHVAC:Unitary:Furnace:HeatCool, ZoneHVAC:PackagedTerminalAirConditioner, etc.). In this case, the ratio of the compound object air flow rate to the fan's maximum air flow rate is used to determine the power at alternate fan speeds. The optional input for Fan Power Ratio Function of Speed Ratio Curve Name must be entered to model multi-speed fan operation. An optional fan total efficiency ratio curve is also available to model efficiency differences at alternate fan speeds.

Field: Name

A unique user-assigned name for an instance of a Fan:OnOff. Any reference to this fan by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the fan can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the fan must be off for the hour.

Field: Fan Efficiency

The ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the fan efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be between 0 and 1.

Field: Pressure Rise

The pressure rise in Pascals at full flow and standard (sea level) conditions (20°C and 101325 Pa).

Field: Maximum Flow Rate

The full load air volumetric flow rate (m³/sec) at standard temperature and pressure (dry air at 20°C drybulb). The program does use local barometric pressure to account for altitude using equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)**5.2559$$

where p=pressure in Pa and Z=altitude in m

Field: Motor Efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1.

Field: Motor In Airstream Fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Field: Air Inlet Node Name

The name of the HVAC system node which supplies the inlet air conditions to the fan.

Field: Air Outlet Node Name

The name of the HVAC system node to which the fan sends its outlet air.

Field: Fan Power Ratio Function of Speed Ratio Curve Name

Enter the name of an exponent performance curve. This optional alpha field must be used to simulate multi-speed fan motors. This curve represents the ratio of actual fan power to rated fan power when a change in fan speed occurs. Leave this field blank when simulating constant-speed fan motors.

Field: Fan Efficiency Ratio Function of Speed Ratio Curve Name

Enter the name of a quadratic or cubic performance curve. This optional alpha field is used to simulate multi-speed fan motors. This curve represents the ratio of actual fan total efficiency to rated fan total efficiency when a change in fan speed occurs. Leave this field blank when simulating constant-speed fan motors.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Main Fans", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the fan will be assigned to the "General" end-use subcategory.

Below is the input data dictionary description for the OnOff fan:

```

OnOff Fan Outputs

```

HVAC,Average,Fan Electric Power[W]
HVAC,Average,Fan Delta Temp[C]
HVAC,Sum,Fan Electric Consumption[J]
HVAC,Average,On/Off Fan Runtime Fraction

```

Fan Electric Power [W]

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

Fan Delta Temp [C]

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) in degrees Celsius for the timestep being reported.

Fan Electric Consumption [J]

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key= Fans, Group Key= System (ref. Report Meter).

On/Off Fan Runtime Fraction

This output field contains the fraction of time that this fan operated for the timestep being reported.

Fan:VariableVolume

Field: Name

A unique user-assigned name for an instance of a Fan:VariableVolume. Any reference to this fan by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the fan can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the fan must be off for the hour.

Field: Fan Efficiency

The ratio of the power delivered to the fluid to the electrical input power at maximum flow. It is the product of the motor efficiency and the fan efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be between 0 and 1.

Field: Pressure Rise

The pressure rise in Pascals at full flow and standard (sea level) conditions (20°C and 101325 Pa).

Field: Maximum Flow Rate

The full load air volumetric flow rate (m³/sec) at standard temperature and pressure (dry air at 20°C drybulb). The program does use local barometric pressure to account for altitude using equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)**5.2559$$

where p=pressure in Pa and Z=altitude in m

Field: Minimum Flow Rate

The minimum air volumetric flow rate (m³/sec) for the fan at standard temperature and pressure (see Maximum Flow Rate field above for details).

Field: Motor Efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1.

Field: Motor In Airstream Fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Field: Fan Coefficient 1

The constant coefficient (C₁) in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

Field: Fan Coefficient 2

The linear coefficient (C₂) in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

Field: Fan Coefficient 3

The quadratic coefficient (C₃) in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

Field: Fan Coefficient 4

The cubic coefficient (C₄) in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

Field: Fan Coefficient 5

The coefficient C₅ in a fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate. The curve is:

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

Field: Air Inlet Node Name

The name of the HVAC system node which supplies the inlet air conditions to the fan.

Field: Air Outlet Node Name

The name of the HVAC system node to which the fan sends its outlet air.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Central System", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the fan will be assigned to the "General" end-use subcategory.

FanPerformance:NightVentilation

This object is used for specifying an alternate set of performance parameters for a fan. These alternate parameters are used when a system manager (such as *AvailabilityManager:NightVentilation*) sets a specified flow rate for a central forced air system. The fan model checks whether a fixed flow rate has been set; if it has the fan model will use these alternate performance parameters. Note that it is assumed that the fan will run at a fixed speed in the alternate mode. The inputs needed by this object are the fan name, fan total efficiency, pressure rise, flow rate, motor efficiency, and motor in airstream fraction.

Field: Fan Name

This is the name of a fan defined elsewhere in the input file. The night vent performance parameters will be applied to the named fan when a system manager has set the air system flow rate.

Field: Fan Efficiency

The power delivered to the fluid divided by the electrical input power. It is the product of the motor efficiency and the fan efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be between 0 and 1.

Field: Pressure Rise

The pressure rise in Pascals at full flow and standard (sea level) conditions (20°C and 101325 Pa).

Field: Maximum Flow Rate

The design volumetric flow rate of the fan (m³/sec) at standard conditions. This input is not currently used by the night ventilation manager.

Field: Motor Efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1.

Field: Motor in Airstream Fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Group – Humidifiers

Humidifier:Steam:Electric

The electric steam humidifier is a component that represents an electrically heated, self contained steam humidifier. The component uses electrical energy to convert ordinary tap water to steam which it then injects into the supply air stream by means of a blower fan. The actual unit might be an electrode-type humidifier or a resistance-type humidifier.

The humidifier model includes local control of the humidifier unit to meet a humidity ratio setpoint on its air outlet node. A set point manager is needed to put a setpoint on the exit node but no other local controllers are needed. The humidifier will add moisture to meet the humidity ratio setpoint.

Field: Name

A unique user assigned name for a particular humidifier unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Rated Capacity

The nominal full output water addition rate of the unit in m³/sec of water at 5.05 C.

Field: Rated Power

The nominal full output power consumption of the unit in watts, exclusive of the blower fan power consumption and any standby power.

Field: Rated Fan Power

The nominal full output power consumption of the blower fan in watts.

Field: Standby Power

The standby power consumption in watts. This amount of power will be consumed whenever the unit is available (as defined by the availability schedule).

Field: Air Inlet Node Name

The name of the HVAC system node from which the unit draws inlet air.

Field: Air Outlet Node Name

The name of the HVAC system node to which the unit sends its outlet air.

Field: Water Storage Tank Name

This field is optional. If left blank or omitted, then the humidifier obtains its water directly from the mains water. If the name of a Water Storage Tank is specified, then the humidifier will try to obtain its water from that tank. If the tank can't provide all the water then the rest will be drawn from the mains and the humidifier will still operate.

Humidifier Water Consumption Rate[m3/s]

This field reports the water consumption rate of the steam humidifier in cubic meters of water per second.

Humidifier Water Consumption[m3]

This output is the cubic meters of water consumed by the steam humidifier over the timestep being reported.

Humidifier Electric Power[W]

This output is the electricity consumption rate in Watts of the steam humidifier.

Humidifier Electric Consumption[J]

This is the electricity consumption in Joules of the steam humidifier over the timestep being reported.

Humidifier:Water [m3]

This meter output contains the sum of the water consumed (in cubic meters of water during the report timestep) by all the steam humidifiers at the HVAC level in the simulation.

Humidifier:Electricity [J]

This meter output contains the sum of the electricity consumed (in Joules during the report timestep) by all the steam humidifiers at the HVAC level in the simulation.

Humidifier Water From Storage Tank Rate [m3/s]

Humidifier Water From Storage Tank [m3]

These outputs contain the rate and volume of water obtained from water storage tank. These are only present if the humidifier is connected to a Water Storage Tank for its water supply.

Humidifier Water Starved By Storage Tank Rate [m3/s]

Humidifier Water Starved By Storage Tank [m3]

These outputs contain the rate and volume of water that could not be obtained from the water storage tank. The component will still operate as if it did get all the water with the balance obtained directly from the mains

Humidifier Water Mains Draw [m3]

This output contains the volume of water obtained from the mains.

Group – Desiccant Dehumidifiers**Dehumidifier:Desiccant:NoFans**

This object models a solid desiccant dehumidifier (excluding associated fans). The process air stream is the air which is dehumidified. The regen air stream is the air which is heated to regenerate the desiccant. This object determines the process air outlet conditions, the load on the regeneration heating coil, the electric power consumption for the wheel rotor motor, and the regeneration air fan mass flow rate. All other heat exchangers are modeled as separate objects connected to the inlet and outlet nodes of the dehumidifier. The solid desiccant dehumidifier is typically used in an AirLoopHVAC:OutdoorAirSystem object, but can also be specified in any AirLoopHVAC.

Field: Name

This alpha field contains the identifying name for the desiccant dehumidifier.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the desiccant unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Process Air Inlet Node Name

The name of the node entering the process side of the desiccant wheel.

Field: Process Air Outlet Node Name

The name of the node leaving the process side of the desiccant wheel.

Field: Regeneration Air inlet Node Name

The name of the node entering the regeneration side of the desiccant wheel after the regeneration coil.

Field: Regeneration Fan Inlet Node Name

Node name for air entering the regeneration fan, mass flow is set by this desiccant dehumidifier model.

Field: Control Type

Type of setpoint control. Options are LeavingMaximumHumidityRatioSetpoint and SystemNodeMaximumHumidityRatioSetpoint.

LeavingMaximumHumidityRatioSetpoint means that the unit is controlled to deliver air at the *Leaving Maximum Humidity Ratio Setpoint*, using bypass dampers to prevent overdrying.

SystemNodeMaximumHumidityRatioSetpoint means that the unit is controlled to deliver air at the maximum humidity ratio setpoint (System Node Humidity Ratio Max) on the *Process Air outlet node*, using bypass dampers to prevent overdrying. This setpoint must be established using a set point manager which sets the MaximumHumidityRatio control variable, such as SetpointManager:SingleZone:Humidity:Maximum which also requires the use of a ZoneControl:Humidistat object. If the dehumidifier is located in the outdoor air stream, it may also be necessary to use SetpointManager:OutdoorAirPretreat.

Field: Leaving Maximum Humidity Ratio Setpoint

Fixed setpoint for maximum process air leaving humidity ratio. Applicable only when Control Type = LeavingMaximumHumidityRatioSetpoint.

Field: Nominal Process Air Flow Rate

Process air flow rate in m³/s at nominal conditions.

Field: Nominal Process Air Velocity

Process air velocity in m/s at nominal flow.

Field: Rotor Power

Power input to wheel rotor motor in W.

Field: Regeneration Coil Object Type

Type of heating coil object for regeneration air. Must be one of Coil:Heating:Electric or Coil:Heating:Gas.

Field: Regeneration Coil Name

Name of heating coil object for regeneration air.

Field: Regeneration Fan Object Type

Type of fan object for regeneration air. For UserCurves performance (see below) Fan:VariableVolume and Fan:ConstantVolume are valid. For Default performance (see below) only Fan:VariableVolume is valid.

Field: Regeneration Fan Name

Name of fan object for regeneration air.

Field: Performance Model Type

Specifies whether the Default performance model or UserCurves curves should be used to model the performance. The default model is a generic solid desiccant wheel using performance curves of the form:

$$\begin{aligned} \text{curve} = & C1 + C2*\text{edb} + C3*\text{edb}^2 + C4*\text{ew} + C5*\text{ew}^2 + \\ & C6*\text{vel} + C7*\text{vel}^2 + C8*\text{edb}*\text{ew} + C9*\text{edb}^2*\text{ew}^2 + \\ & C10*\text{edb}*\text{vel} + C11*\text{edb}^2*\text{vel}^2 + C12*\text{ew}*\text{vel} + C13*\text{ew}^2*\text{vel}^2 + \\ & C14*\text{ALOG}(\text{edb}) + C15*\text{ALOG}(\text{ew}) + C16*\text{ALOG}(\text{vel}) \end{aligned}$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kg/kg]

vel = process air velocity [m/s]

The Default curves are valid for the following range of process inlet conditions: dry-bulb temperatures of 1.67C (35F) to 48.9C (120F) and humidity ratios of 0.002857 kg/kg (20 gr/lb) to 0.02857 kg/kg (200 gr/lb). If the process inlet conditions are outside this range, the dehumidifier will not operate.

If UserCurves are specified, then performance is calculated as follows:

Leaving Dry-bulb = (Leaving Dry-Bulb Function of Entering Dry-Bulb and Humidity Ratio Curve) * (Leaving Dry-Bulb Function of Air Velocity Curve)

Leaving Humidity Ratio = (Leaving Humidity Ratio Function of Entering Dry-Bulb and Humidity Ratio Curve) * (Leaving Humidity Ratio Function of Air Velocity Curve)

Regeneration Energy = (Regeneration Energy Function of Entering Dry-Bulb and Humidity Ratio Curve) * (Regeneration Energy Function of Air Velocity Curve)

Regeneration Velocity = (Regeneration Velocity Function of Entering Dry-Bulb and Humidity Ratio Curve) * (Regeneration Velocity Function of Air Velocity Curve)

The UserCurves are limited to the following range of process inlet conditions (essentially not limited): dry-bulb temperatures of -73.3C (-100F) to 65.6C (150F) and humidity ratios of 0.0 kg/kg (0 gr/lb) to 0.21273 kg/kg (1490 gr/lb). If the process inlet conditions are outside this range, the dehumidifier will not operate.

When the Default performance model is selected, the remaining fields are ignored.

Field: Leaving Dry-Bulb Function of Entering Dry-Bulb and Humidity Ratio Curve Name

This field is applicable only when UserCurves performance model type is specified.

Leaving dry-bulb of process air as a function of entering dry-bulb and entering humidity ratio, biquadratic curve.

$$\text{curve} = C1 + C2*\text{edb} + C3*\text{edb}^2 + C4*\text{ew} + C5*\text{ew}^2 + C6*\text{edb}*\text{ew}$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kg/kg]

Field: Leaving Dry-Bulb Function of Air Velocity Curve Name

This field is applicable only when UserCurves performance model type is specified.

Leaving dry-bulb of process air as a function of air velocity, quadratic curve.

$$\text{curve} = C1 + C2*v + C3*v^2$$

v = process air velocity [m/s]

Field: Leaving Humidity Ratio Function of Entering Dry-Bulb and Humidity Ratio Curve Name

This field is applicable only when UserCurves performance model type is specified.

Leaving humidity ratio of process air as a function of entering dry-bulb and entering humidity ratio, biquadratic curve

$$\text{curve} = C1 + C2*\text{edb} + C3*\text{edb}^2 + C4*\text{ew} + C5*\text{ew}^2 + C6*\text{edb}*\text{ew}$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kg/kg]

Field: Leaving Humidity Ratio Function of Air Velocity Curve Name

This field is applicable only when UserCurves performance model type is specified.

Leaving humidity ratio of process air as a function of process air velocity, quadratic curve.

$$\text{curve} = C1 + C2*v + C3*v^2$$

v = process air velocity [m/s]

Field: Regeneration Energy Function of Entering Dry-Bulb and Humidity Ratio Curve Name

This field is applicable only when UserCurves performance model type is specified.

Regeneration energy [J/kg of water removed] as a function of entering dry-bulb and entering humidity ratio, biquadratic curve

$$\text{curve} = C1 + C2*\text{edb} + C3*\text{edb}^2 + C4*\text{ew} + C5*\text{ew}^2 + C6*\text{edb}*\text{ew}$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kg/kg]

Field: Regeneration Energy Function of Air Velocity Curve Name

This field is applicable only when UserCurves performance model type is specified.

Regeneration energy [J/kg of water removed] as a function of process air velocity, quadratic curve.

$$\text{curve} = C1 + C2*v + C3*v^2$$

v = process air velocity [m/s]

Field: Regeneration Velocity Function of Entering Dry-Bulb and Humidity Ratio Curve Name

This field is applicable only when UserCurves performance model type is specified.

Regeneration velocity [m/s] as a function of entering dry-bulb and entering humidity ratio, biquadratic curve

$$\text{curve} = C1 + C2*\text{edb} + C3*\text{edb}^2 + C4*\text{ew} + C5*\text{ew}^2 + C6*\text{edb}*\text{ew}$$

edb = process entering drybulb temperature [C]

ew = process entering humidity ratio [kg/kg]

Field: Regeneration Velocity Function of Air Velocity Curve Name

This field is applicable only when UserCurves performance model type is specified.

Regeneration velocity [m/s] as a function of process air velocity, quadratic curve.

$$\text{curve} = C1 + C2*v + C3*v^2$$

v = process air velocity [m/s]

Field: Nominal Regeneration Temperature

This field is applicable only when UserCurves performance model type is specified.

Nominal regeneration temperature upon which the regeneration energy modifier curve is based. This input is ignored when Performance Model Type = Default, which assume a regeneration temperature of 121C.

Desiccant Dehumidifier Water Removed [kg]

Mass of water removed from process air stream.

Desiccant Dehumidifier Water Removal Rate[kg/s]

Rate of water removal from process air stream.

Desiccant Dehumidifier Part Load Ratio[]

Dehumidifier water removal rate divided by full-load water removal rate.

Desiccant Dehumidifier Electric Power [W]

Dehumidifier rotor electric power.

Desiccant Dehumidifier Electric Consumption [W]

Dehumidifier rotor electric energy.

Desiccant Dehumidifier Specific Regen Energy [J/kg H2O]

Regeneration heating coil energy divided by water removed.

Desiccant Dehumidifier Regen Energy Rate[W]

Regeneration heating coil output rate.

Desiccant Dehumidifier Regen Energy [J]

Regeneration heating coil output energy.

Desiccant Dehumidifier Regen Air Velocity[m/s]

Regeneration air velocity.

Desiccant Dehumidifier Regen Air Mass Flow Rate[kg/s]

Regeneration air mass flow rate.

Desiccant Dehumidifier Process Air Mass Flow Rate[kg/s]

Process air mass flow rate.

Dehumidifier:Desiccant:System

The Dehumidifier:Desiccant:System object models the dehumidification of an air stream, normally called the process air stream. A second heated air stream, called the regeneration air stream, is used to remove the collected moisture from the desiccant heat exchanger and this moisture-laden air is then usually exhausted from the building. This Dehumidifier:Desiccant:System object is similar to the Dehumidifier:Desiccant:NoFans object but has some additional modeling capabilities.

The Dehumidifier:Desiccant:System object in EnergyPlus is a compound object that can be placed anywhere in an air loop (AirLoopHVAC). Common locations for this object are in an AirLoopHVAC:OutdoorAirSystem or in the main air loop (AirLoopHVAC) downstream of a cooling coil (postcooling desiccant dehumidifier). This compound object coordinates the operation of several 'children' objects: a desiccant heat exchanger, a regeneration air fan, and an optional regeneration air heater. If this dehumidifier is placed in the main air loop immediately downstream of a direct expansion (DX) cooling coil, then the dehumidifier's operation can be coordinated with the operation of the companion DX coil and it is also possible to specify that the DX system's condenser waste heat can be used to help regenerate the desiccant heat exchanger. For the case of condenser waste heat regeneration, an optional exhaust fan can also be modeled by this desiccant dehumidifier compound object to help maintain a set point temperature for air entering the regeneration side of the desiccant heat exchanger.

It is important to note that the optional exhaust air fan is modeled internal to the Dehumidifier:Desiccant:System and a separate fan object should not be added to the input data file (idf) for this fan. On the other hand, a separate fan object is required in the input data file for the regeneration air fan.

Figure 114. Schematic of Dehumidifier:Desiccant:System with Draw Through Regeneration Fan Placement

A schematic of the compound object Dehumidifier:Desiccant:System is shown in Figure 114 with the draw through regeneration air fan placement. Figure 115 shows the Dehumidifier:Desiccant:System object configured with the blow through regeneration air fan placement.

NOTE: As with any air loop compound object, the Dehumidifier:Desiccant:System object itself is specified on the AirLoopHVAC Branch or in the AirLoopHVAC:OutdoorAirSystem:EquipmentList for an AirLoopHVAC:OutdoorAirSystem. The children objects (e.g., desiccant heat exchanger, regeneration air fan, and optional regeneration air heater) must be specified separately in the input data file and their inlet/outlet connections must be as shown in Figure 114 or Figure 115.

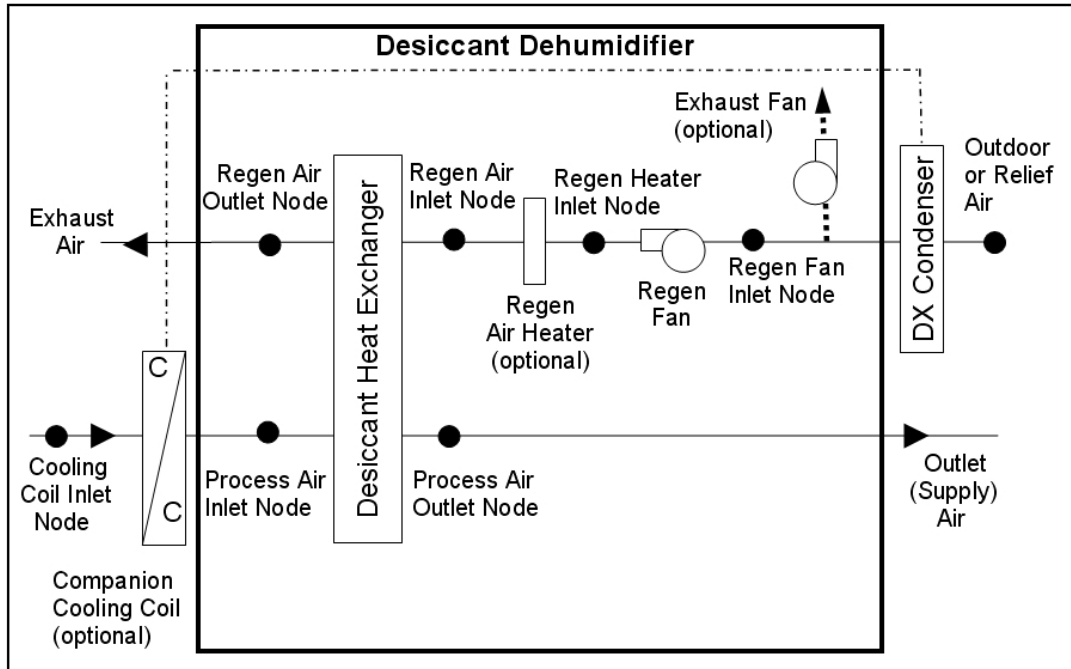

Figure 115. Schematic of Dehumidifier:Desiccant:System with Blow Through Regeneration Fan Placement

Currently the only heat exchanger choice for this object is HeatExchanger:Desiccant:BalancedFlow. So to model a Dehumidifier:Desiccant:System located in an air loop, the input data file should include the following objects:

- Dehumidifier:Desiccant:System (in an air loop (AirLoopHVAC) Branch or AirLoopHVAC:OutdoorAirSystem:EquipmentList for an AirLoopHVAC:OutdoorAirSystem)
- HeatExchanger:Desiccant:BalancedFlow (desiccant heat exchanger child object)
- HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1 (desiccant heat exchanger data object)
- ZoneControl:Humidistat, and SetpointManager:SingleZone:Humidity:Maximum (when in an air loop (AirLoopHVAC) Branch) or SetpointManager:OutdoorAirPretreat (when in an AirLoopHVAC:OutdoorAirSystem) to place a maximum humidity ratio set point on the sensor node, typically the process air outlet node
- Fan:OnOff or Fan:ConstantVolume (regeneration air fan)
- Coil:Heating:Electric or Coil:Heating:Gas (optional regeneration air heater)
- Coil:Cooling:DX:SingleSpeed or Coil:Cooling:DX:TwoStageWithHumidityControlMode (optional companion cooling coil)

If the user wants to model the Dehumidifier:Desiccant:System in an AirLoopHVAC:OutdoorAirSystem, then the process air path of the dehumidifier should be located in the outdoor air stream and the regeneration air path may be placed in the relief air stream or modeled by the desiccant dehumidifier itself where the first node for the regeneration inlet air stream must be an outdoor air node. If the user wants to model the Dehumidifier:Desiccant:System in an air loop (AirLoopHVAC) Branch, then the process air path of the dehumidifier should be located in the air loop Branch object. For this case, the regeneration air stream is modeled by the desiccant dehumidifier object itself (i.e., not part of an air loop Branch statement) and the first node for the regeneration inlet air stream must be an outdoor air node (ref. Figure 114 or Figure 115).

A description of each input field for this object is provided below:

Field: Name

A unique, user-assigned name for a particular Dehumidifier:Desiccant:System. Any reference to this dehumidifier by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the dehumidifier can operate during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the dehumidifier can operate. A value less than or equal to 0 (usually 0 is used) denotes that the dehumidifier will not operate (i.e., no heat exchange will take place and the regeneration air fan does not operate). For the case where companion cooling coil regeneration air heating has been specified, the desiccant dehumidifier's exhaust fan serves as the condenser air fan for the cooling coil system so this availability schedule will not disable exhaust fan operation.

Field: Desiccant Heat Exchanger Object Type

This alpha field contains the type of desiccant heat exchanger used with this dehumidifier. Currently, the only valid choice is HeatExchanger:Desiccant:BalancedFlow.

Field: Desiccant Heat Exchanger Name

This alpha field contains the name of the desiccant heat exchanger used with this dehumidifier.

Field: Sensor Node Name

This alpha field specifies the name of the air loop node used to control desiccant heat exchanger operation. A set point manager must be used to place a maximum humidity ratio set point on this node (e.g., SetpointManager:SingleZone:Humidity:Maximum or SetpointManager:OutdoorAirPretreat).

Field: Regeneration Air Fan Object Type

This alpha field contains the type of regeneration air fan used. Available fan types are Fan:OnOff and Fan:ConstantVolume.

Field: Regeneration Air Fan Name

This alpha field contains the name of the regeneration air fan used with this dehumidifier.

Field: Regeneration Air Fan Placement

This alpha field specifies the fan configuration used in the desiccant dehumidifier. Valid choices are 'BlowThrough' and 'DrawThrough', with a default of 'DrawThrough' if this field is left blank.

Field: Regeneration Air Heater Object Type

This alpha field contains the type of heating coil used to heat the regeneration air stream. Valid choices are Coil:Heating:Electric and Coil:Heating:Gas. This field may be left blank when no regeneration air heater is required.

Field: Regeneration Air Heater Name

This alpha field contains the name of the heating coil used to heat the regeneration air stream. This field may be left blank when no regeneration air heater is required.

Field: Regeneration Inlet Air Setpoint Temperature

This optional numeric field specifies the regeneration air inlet temperature setpoint in Celsius. The regeneration air heater and/or the companion coil regeneration air heating will be controlled to this temperature to the extent possible. This field may be left blank when no

regeneration air heater is required or when control of the exhaust fan used with the companion coil regeneration air heating option is not required.

Field: Companion Cooling Coil Object Type

This optional alpha field contains the type of companion cooling coil used with this desiccant dehumidifier. The only valid choices are Coil:Cooling:DX:SingleSpeed and Coil:Cooling:DX:TwoStageWithHumidityControlMode.

Field: Companion Cooling Coil Name

This optional alpha field contains the name of the companion cooling coil used with this desiccant dehumidifier. This field may be left blank when no companion cooling coil is being modeled.

Field: Companion Cooling Coil Upstream of Dehumidifier Process Inlet

This choice field specifies if the companion cooling coil is located immediately upstream of the dehumidifier's process inlet. Valid choices are Yes and No. If Yes is selected, then the outlet air node for the companion cooling coil must be the same as the dehumidifier's process air inlet node (i.e., the process air inlet node name for the desiccant heat exchanger specified for this desiccant dehumidifier). For this case, the companion cooling coil and the desiccant dehumidifier are assumed to operate "in tandem"; that is, if the simulation determines that the companion cooling coil is unable to meet the humidity set point specified on the sensor node based on its own operation, then the desiccant dehumidifier operates at the same time and for the same duration as the cooling coil to provide improved dehumidification. If No is selected, then the dehumidifier will control to the humidity set point specified on the sensor node to the extent possible. The default value is No if this field is left blank.

Field: Companion Coil Regeneration Air Heating

This choice field determines if the companion cooling coil's condenser waste heat is used to heat the regeneration inlet air. Valid choices are Yes and No. The default value is No if this field is left blank.

Field: Exhaust Fan Maximum Flow Rate

This optional numeric field contains the maximum fan volumetric flow rate for the exhaust fan in cubic meters per second. As noted previously, this exhaust fan is modeled internally by the Dehumidifier:Desiccant:System object and a separate fan object should NOT be specified in the input data file for this fan. This field is used only when a companion cooling coil is specified and the 'Companion Coil Regeneration Air Heating' field is set to 'Yes'. This field must be used in conjunction with the 'Exhaust Fan Maximum Power' and the 'Exhaust Fan Power Curve Name' input fields. The model assumes that the exhaust fan will operate as needed to maintain the 'Regeneration Inlet Air Setpoint Temperature', up to the maximum flow rate specified in this input field. If the desiccant dehumidifier is OFF for a simulation timestep but its companion cooling coil is operating and is specified to provide regeneration air heating, then the exhaust fan operates at this maximum air flow rate (i.e., this fan serves as the condenser fan for the companion cooling coil system when regeneration air heating is specified, so the inputs to the companion cooling coil object should not include the condenser fan energy since the condenser fan energy is modeled by the Dehumidifier:Desiccant:System object).

Field: Exhaust Fan Maximum Power

This optional numeric field contains the maximum power for the exhaust fan in Watts (i.e., at the Exhaust Fan Maximum Flow Rate). This field is used only when a companion cooling coil is used and the 'Companion Coil Regeneration Air Heating' field is set to 'Yes'. This field must be used in conjunction with the 'Exhaust Fan Maximum Flow Rate' and the 'Exhaust Fan Power Curve Name' input fields.

Field: Exhaust Fan Power Curve Name

This optional alpha field contains the name of the exhaust fan power modifier curve. This field is used only when a companion cooling coil is used and the 'Companion Coil Regeneration Air Heating' field is set to 'Yes'. This field must be used in conjunction with the 'Exhaust Fan Maximum Flow Rate' and the 'Exhaust Fan Maximum Power' input fields. If this field is blank, the exhaust fan operates (when required) at the maximum power specified in the field above. The curve object type for this Exhaust Fan Power Curve Name must be Curve:Cubic or Curve:Quadratic. The curve object (Curve:Cubic or Curve:Quadratic) defines the change in exhaust fan power as a function of the ratio of the actual exhaust air flow rate divided by the maximum flow rate.

Dehumidifier:Desiccant:System,

```

\memo This compound object models a desiccant heat exchanger, an optional
\memo heater, and associated fans. The process air stream is the air which
\memo is dehumidified. The regeneration air stream is the air which is
\memo heated to regenerate the desiccant. The desiccant heat exchanger
\memo transfers both sensible and latent energy between the process and
\memo regeneration air streams. The desiccant dehumidifier is typically used
\memo in an AirLoopHVAC:OutdoorAirSystem, but can also be specified in any AirLoopHVAC.

HVAC,Sum,Desiccant Dehumidifier Exhaust Fan Electric Consumption [J]

```

Desiccant Dehumidifier Water Removed [kg]

This output is the mass of water removed from the process air stream in kilograms for the timestep being reported.

Desiccant Dehumidifier Water Removal Rate [kg/s]

This output is the average rate of water removal from the process air stream in kilograms per second for the timestep being reported.

Desiccant Dehumidifier Part Load Ratio []

This output is the fraction of time that the desiccant heat exchanger (and associated regeneration air heater and fans, if appropriate) operate for the timestep being reported.

Desiccant Dehumidifier Exhaust Fan Electric Power [W]

This output is the average electric consumption rate for the exhaust fan in Watts for the timestep being reported.

Desiccant Dehumidifier Exhaust Fan Electric Consumption [J]

This output is the electric consumption for the exhaust fan in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, EndUseKey = Cooling, GroupKey = System (ref. Report Meter).

Group – System Availability Managers

System Availability Managers are one of the high-level control constructs in EnergyPlus. An System Availability Manager is able to access data from any of the HVAC system nodes and use this data to to make a decision on whether an entire AirLoopHVAC or PlantLoop should be on or off.

System Availability Managers are executed at the start of each HVAC timestep. They reside outside the HVAC system iteration loops. Thus, the System Availability Managers are executed once per HVAC timestep, and they use previous timestep information (except for zone load) to calculate their set points.

Some of the managers monitor the temperature at an air or plant node to determine whether the system should be on or off. If the system is to be controlled on the outdoor dry-bulb temperature, an OutdoorAir:NodeList object can be used to define a node which will have the current outdoor air conditions.

The output from each System Availability Manager is an availability status flag. This flag can have the values *NoAction*, *ForceOff*, *CycleOn*, or *CycleOnZoneFansOnly*. The availability status flags for the System Availability Managers referenced by an air or plant loop are used to set the availability status flag for each loop. For the air loops, *ForceOff* takes precedence: if any of the loop's availability managers are showing status *ForceOff*, the loop status will be *ForceOff*. Next in precedence is *CycleOnZoneFansOnly*, followed by *CycleOn*, and *NoAction*. For the plant loops, there is no precedence among the System Availability Manager status flag values. Instead, the first availability manager giving a status flag value other than *NoAction* sets the status for the loop. The System Availability Managers are executed in AvailabilityManagerAssignmentList order.

The actual action of turning on or off a loop is taken by the loop prime movers: fans for AirLoopHVACs and pumps for plant loops. For instance when a fan is deciding whether it is on or off, it checks its on/off schedule and whether the loop availability status flag is *CycleOn* or *ForceOff*. If the schedule is on and the status flag is *ForceOff*, the fan will be off. If the fan schedule says off and the status flag is *CycleOn*, the fan will be on. Thus the availability managers overrule the fan on/off schedule. The availability managers, air loops, and plant loops all have report variables which may be used to verify the action of the loop.

Availability managers for AirLoopHVAC systems also control the availability of zone exhaust fans (Ref. Fan:ZoneExhaust) and terminal unit fans (Ref. AirTerminal:SingleDuct:SeriesPIU:Reheat, AirTerminal:SingleDuct: ParallelPIU:Reheat, and AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan) in the zones served by the AirLoopHVAC system.

AvailabilityManager:Scheduled

The simplest System Availability Manager is when the availability is determined by an on/off schedule. The syntax for implementing such an availability manager is shown below. The identifying name refers back to the name recorded in the AvailabilityManagerAssignmentList statement described in the **Group – Air Distribution** section. The schedule must be the name of a schedule defined elsewhere in the input.

Field: Name

The unique, user-assigned name of an instance of a scheduled availability manager. Other objects that use this scheduled availability manager will reference it by this name.

Field: Schedule Name

The name of a schedule defined elsewhere in the input. Schedule values greater than zero (usually 1 is used) indicate that the system is on. Schedule values less than or equal to zero (usually 0 is used) denote that the system is off. This schedule overrides the central fan schedule for determining whether the fan is on.

The IDD specification for this object is:

```
AvailabilityManager:Scheduled,
  \min-fields 2
  \memo Determines the availability of a loop or system: whether it is on or off.
  \memo Schedule overrides fan/pump schedule.
A1 , \field Name
  \required-field
  \type alpha
  \reference SystemAvailabilityManagers
A2 ; \field Schedule Name
  \required-field

  \object-list ScheduleNames
```

An example of this statement in an IDF is:

```
AvailabilityManager:Scheduled,
  VAV Sys 1 Avail, !- Name
  FanAvailSched; !- Schedule Name
```

AvailabilityManager:ScheduledOn

The Schedule On Availability Manager is used when equipment must be turned on during a given time period. This availability manager will not turn the equipment off, a separate availability manager must be used to disable the equipment as necessary. The scheduled on availability is determined by an on schedule. Schedule values other than 0 set a *CycleOn* availability status. Schedule values equal to 0 set a *NoAction* availability status. The syntax for implementing such an availability manager is shown below. The identifying name refers back to the name recorded in the *AvailabilityManagerAssignmentList* statement described in the **Group – Air Distribution** section. The schedule must be the name of a schedule defined elsewhere in the input.

Field: Name

The unique, user-assigned name of an instance of a scheduled on availability manager. Other objects that use this scheduled on availability manager will reference it by this name.

Field: Schedule Name

The name of a schedule defined elsewhere in the input. Schedule values greater than zero (usually 1 is used) indicate that the system is on. Schedule values less than or equal to zero (usually 0 is used) denote that *NoAction* is desired. This schedule overrides the central fan schedule for determining whether the fan is on.

The IDD specification for this object is:

```

AvailabilityManager:ScheduledOn,
  \min-fields 2
  \memo Determines the availability of a loop or system: only controls the turn on action.
  \memo Schedule overrides fan/pump schedule.
A1 , \field Name
  \required-field

```

An example of this statement in an IDF is:

```

AvailabilityManager:ScheduledOn,
  VAV Sys 1 Avail On,  !- Name
  FanAvailSched;      !- Schedule Name

```

AvailabilityManager:ScheduledOff

The Schedule Off Availability Manager is used when equipment must be turned off during a given time period. This availability manager will not turn the equipment on, a separate availability manager must be used to enable the equipment as necessary. The scheduled off availability is determined by an off schedule. Schedule values equal to 0 set a *ForceOff* availability status. Schedule values other than 0 (usually a 1 is used) set a *NoAction* availability status. The syntax for implementing such an availability manager is shown below. The identifying name refers back to the name recorded in the *AvailabilityManagerAssignmentList* statement described in the **Group – Air Distribution** section. The schedule must be the name of a schedule defined elsewhere in the input.

Field: Name

The unique, user-assigned name of an instance of a scheduled off availability manager. Other objects that use this scheduled off availability manager will reference it by this name.

Field: Schedule Name

The name of a schedule defined elsewhere in the input. Schedule values equal to zero indicate that the system is off. Schedule values other than (usually 0 is used) denote that *NoAction* is desired.

The IDD specification for this object is:

```

AvailabilityManager:ScheduledOff,
  \min-fields 2
  \memo Determines the availability of a loop or system: only controls the turn off action.
  \memo Schedule overrides fan/pump schedule.

  \required-field
  \type object-list
  \object-list ScheduleNames

```

An example of this statement in an IDF is:

```
AvailabilityManager:ScheduledOff,
VAV Sys 1 Avail Off,      !- Name
FanAvailSched;           !- Schedule Name
```

AvailabilityManager:NightCycle

This manager is used for cycling on an air system when one or more zones become too hot or too cold. The usual situation is that the central air handler is turned off at night. However if the building gets too cold there might be condensation on the walls and other damage. Thus the control system is usually programmed to turn the system on if 1 control thermostat or any thermostat shows a zone temperature of less than a night time set point. Similarly there might be a concern about a building getting too hot. Again the control system is programmed to turn the air handler back on if one or any zone temperature exceeds a night time cooling set point.

This object gives the user considerable flexibility in determining how the night time on/off decision will be made. The manager can look at the temperature in 1 zone or it can sample all the zones connected to the air handler. The user can specify a temperature tolerance and a run time for the system once it switches on. There is also an applicability schedule – the user can schedule whether or not this availability manager itself is being applied.

Field: Name

A unique, user-assigned name for an instance of a night cycle availability manager. Other objects that use this availability manager will reference it by this name.

Field: Applicability Schedule Name

The name of a schedule defined elsewhere in the input file. This schedule determines whether or not for a given time period this availability manager is to be applied. Schedule values greater than zero (usually 1 is used) indicate the availability manager is to be applied. Schedule values less than or equal to zero (usually 0 is used) denote that the availability manager is not used for this time period.

Field: Fan Schedule Name

The name of the central fan on/off schedule for the air system that this availability manager will affect.

Field: Control Type

The possible inputs are *StayOff*, *CycleOnAny*, *CycleOnControlZone*, *CycleOnAnyZoneFansOnly*. *StayOff* means the availability manager will have no effect – air handler on/off will be determined by the fan schedule. *CycleOnAny* means that if any zone served by a system whose *AvailabilityManagerAssignmentList* references this system availability manager has an air temperature outside the cooling or heating set points the central fan will turn on even though the fan schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only one zone. *CycleOnAnyZoneFansOnly* is the same as *CycleOnAny* except that only the zone fans are cycled on and the central air handler fan is left off. The default is *StayOff*.

Field: Thermostat Tolerance

This is the amount in degrees Celsius by which the zone temperature must exceed the cooling set point or fall below the heating set point in order for the availability manager to signal that the system should turn on. The default is 1 degree C.

Field: Cycling Run Time

The time in seconds for which the system will run after it has cycled on. The default is 3600 seconds (1 hour).

Field: Control Zone Name

For the option *CycleOnControlZone* this is the name of the control zone.

The IDD specification for this object is:

```
AvailabilityManager:NightCycle,
  \min-fields 6
  \memo Determines the availability of a loop or system: whether it is on or off.
  \memo Depending on zone temperatures, overrides Schedules and forces system Fans on.

7200.;               ! Cycle Run Time {s}
```

AvailabilityManager:DifferentialThermostat

The differential thermostat compares the temperatures at two different system nodes. If the temperature difference (ΔT) is above the *Temperature Difference On Limit*, the system is turned on. If the ΔT is below the *Temperature Difference Off Limit*, the system is turned off. Between the *On Limit* and *Off Limit* the system is either on or off depending on the previous state of the thermostat. Unlike other availability managers, the differential thermostat is always either "On" or "Off"; it does not use the "No Action" state. Therefore, the differential thermostat must be the last manager in the *AvailabilityManagerAssignmentList*. Any availability managers after the differential thermostat manager will never be simulated.

One application of the differential thermostat is to ensure a useful heat gain for solar heating systems, i.e. the system is only turned on when there is a significant temperature difference between the solar collector outlet node and the storage tank outlet node.

Field: Name

The name of the object. This is referenced in the *AvailabilityManagerAssignmentList*.

Field: Hot Node Name

The sensor node with the higher temperature.

Field: Cold Node Name

The sensor node with the colder temperature.

Field: Temperature Difference On Limit

Temperature difference [deltaC] between hot and cold nodes necessary to turn the system on.

Field: Temperature Difference Off Limit

Temperature difference [deltaC] between hot and cold nodes necessary to turn the system off. This field defaults to the *Temperature Difference On Limit*.

The IDD specification for this object is:

```
AvailabilityManager:DifferentialThermostat,
  \memo Overrides fan/pump schedules depending on temperature difference between two nodes.

High Temperature Turn On Availability Manager, !- Name
Outside Air Inlet Node, !- Sensor Node
30.0; !- Temperature {C}
```

AvailabilityManager:LowTemperatureTurnOff

This manager turns the system off if the temperature at the sensor node is below the specified setpoint temperature.

Field: Name

The name of the object. This is referenced in the AvailabilityManagerAssignmentList.

Field: Sensor Node Name

The air or plant node where the temperature is monitored.

Field: Temperature

The setpoint temperature [C] at which the system is turned off.

Field: Applicability Schedule Name

The name of a schedule defined elsewhere in the input file. This schedule determines whether or not for a given time period this availability manager is to be applied. Schedule values greater than zero (usually 1 is used) indicate the availability manager is to be applied. Schedule values less than or equal to zero (usually 0 is used) denote that the availability manager is not used for this time period. If this field is left blank, this availability manager is always active.

The IDD specification for this object is:

```
AvailabilityManager:LowTemperatureTurnOff,
  \memo Overrides fan/pump schedules depending on temperature at sensor node.

```

AvailabilityManager:LowTemperatureTurnOn,
  Low Temperature Turn On Availability Manager,  !- Name
  Collector Outlet Node,  !- Sensor Node Name
  0.0;  !- Temperature {C}

```

System Availability Manager:Night Ventilation

This manager allows the user to implement a strategy for precooling a building at night using outdoor air. This strategy can consist of running the system fans with the outdoor air dampers open when outdoor conditions are favorable for a precooling strategy. The zone terminal unit air dampers may also be held at their fully open position to minimize fan energy consumption while precooling. Fan energy consumption is the critical parameter in deciding whether a precooling strategy will save energy.

The inputs for the night ventilation manager consist of an applicability schedule name (determining when the manager is active), a fan schedule name (for the fan(s) that the manager can switch on), a ventilation temperature schedule name (one zone must be above this temperature for night venting to be active), a ventilation temperature difference (indoor – outdoor temperature difference for night venting), a low limit temperature (no conditioned zone may fall below this temperature during night venting), a night venting flow fraction (fraction of the design flow rate at which the fans run during night venting), and the zone name of a control zone.

The night ventilation manager is used in conjunction with another object: *FanPerformance:NightVentilation*. The performance of the fan during night venting may be very different than during normal operation (a different fan might even be used). The *FanPerformance:NightVentilation* object allows the user to specify alternate fan performance parameters for use during night ventilation.

Field: Name

A unique, user-assigned name for an instance of a night ventilation availability manager. Other objects that use this availability manager will reference it by this name.

Field: Applicability Schedule Name

The name of a schedule defined elsewhere in the input file. This schedule determines whether or not for a given time period this availability manager is to be applied. Schedule values greater than zero (usually 1 is used) indicate the availability manager is to be applied. Schedule values less than or equal to zero (usually 0 is used) denote that the availability manager is not used for this time period.

Field: Fan Schedule Name

The name of the central fan on/off schedule for the air system that this availability manager will affect.

Field: Ventilation Temperature Schedule Name

The name of a temperature schedule defined elsewhere in the input file. At least one conditioned zone in the forced air system using this availability manager must be above the current temperature specified in this schedule for night ventilation to occur or to continue occurring.

Field: Ventilation Temperature Difference

This field specifies an indoor / outdoor temperature difference (in degrees C). The control zone temperature minus the outdoor air temperature must be greater than the Ventilation Temperature Difference for night ventilation to occur or to continue occurring. The default is 2 degrees C.

Field: Ventilation Temperature Low Limit

This field specifies a lower limit (in degrees C) on zone temperatures for night ventilation. If any conditioned zone served by the air system using this availability manager is below the ventilation temperature low limit, night ventilation will not occur or will switch off. The default is 15 degrees C.

Field: Night Venting Flow Fraction

The fraction (could be greater than 1) of the design flow rate at which the night ventilation will be done. The default is 1.

Field: Control Zone Name

The name of the control zone used in the ventilation temperature difference check.

The IDD specification for this object is:

```

AvailabilityManager:HybridVentilation

This availability manager is executed at the start of each HVAC system timestep, before EnergyPlus calculates airflows defined in the objects ZoneInfiltration, ZoneVentilation, ZoneMixing, and ZoneCrossMixing, and before the AirflowNetwork model calculates multizone airflows. It serves two purposes: 1) prevents simultaneous natural ventilation and HVAC system operation, and 2) allows users to examine various ventilation strategies to maximize natural ventilation in order to reduce heating/cooling loads. The natural ventilation objects controlled by this availability manager have two groups: simple airflow group and AirflowNetwork group. The simple airflow group consists of the ZoneVentilation and ZoneMixing objects. The AirflowNetwork group consists of AirflowNetwork:MultiZone:Component:DetailedOpening and AirflowNetwork:MultiZone:Component:SimpleOpening objects used in the AirflowNetwork model. These two groups are not allowed to work simultaneously (see restrictions in the

Airflow Network model section). Basically, this object overrides the controls for these opening objects or ZoneVentilation and ZoneMixing objects, closing the “openings” or shutting off ventilation/mixing airflows under certain conditions and allowing the HVAC system (AirLoopHVAC) to operate. If the availability manager determines that conditions are favorable for natural ventilation, then the HVAC system (AirLoopHVAC) is disabled and the “opening” objects or ventilation/mixing objects are able to operate based on the controls specified for those objects.

Each AirLoopHVAC can have a corresponding hybrid ventilation availability manager. Each hybrid ventilation manager can control natural ventilation in the zones served by the AirLoopHVAC. The hybrid ventilation availability manager is triggered by zone air conditions for the controlled zone specified in an object input field. Presently, this availability manager must be used either with the ZoneVentilation and ZoneMixing objects or with the AirflowNetwork model.

The inputs for this availability manager consist of the name for the air loop (AirLoopHVAC) being controlled, the controlled zone name to determine which zone air conditions are used to determine system availability, a ventilation control mode schedule, maximum wind speed and rain indicator to determine whether natural ventilation is allowed or not, a low limit and high limit for dry-bulb temperature, enthalpy and dewpoint temperature to determine the hybrid ventilation control, and a minimum outdoor air ventilation schedule. The last control allows user to use a wind speed modifier to adjust openness when the AirflowNetwork opening objects are selected. The other inputs include how to control simple airflow objects and AirflowNetwork opening objects.

The hybrid ventilation availability manager works independently of all other system availability manager objects, so this manager is not a valid system availability manager type in the AvailabilityManagerAssignmentList object.

Field: Name

A unique, user-assigned name for an instance of a hybrid ventilation availability manager. Other objects that use this availability manager will reference it by this name.

Field: HVAC Air Loop Name

The name of the air loop (AirLoopHVAC object) to be controlled by this system availability manager.

Field: Controlled Zone Name

The name of a controlled zone served by the air loop defined in the previous field. The air conditions in this zone are used to determine if natural ventilation should be provided.

Field: Ventilation Control Mode Schedule Name

The name of a schedule defined elsewhere in the input file. This schedule determines whether or not for a given time the hybrid ventilation control mode is to be applied. Schedule values equal to zero indicate no ventilation control, resulting in natural ventilation and HVAC system operation being performed based on their own controls. Schedule values equal to one denote temperature control for either cooling or heating, which is determined internally based on thermostat set point and temperature control type. The temperature control is restricted between the minimum and maximum outdoor temperatures provided in two additional input fields (below). Schedule values equal to two denote enthalpy control, which is restricted between minimum and maximum outdoor enthalpy values given in two additional input fields (below). Schedule values equal to three denote dewpoint control for either dehumidification or humidification. Schedule values equal to four represent outdoor ventilation air control. The outdoor ventilation air control works with AirflowNetwork opening objects only, and is not allowed to work with ZoneVentilation and ZoneMixing objects.

The detailed control logic is given in the EnergyPlus Engineering Reference.

Field: Use Weather File Rain Indicators

This logical alpha field indicates whether or not the rain indicator is used to shut off natural ventilation or not. The valid choices for Rain Indicator are Yes and No, with the default being Yes. This can help simulate conditions where one would normally close windows to avoid rain penetration in a space. Any possible rain getting into a space will not be counted as a zone load.

Field: Maximum Wind Speed

This is the wind speed (m/s) above which hybrid ventilation is shut off. This can help simulate conditions where one would normally close windows to avoid wind problems in a space (papers blowing around, etc).

Field: Minimum Outdoor Temperature

This is the outdoor temperature (in Celsius) below which hybrid ventilation is shut off when the ventilation control mode = 1 (Temperature). This lower temperature limit is intended to avoid overcooling a space, which could result in a heating load.

Field: Maximum Outdoor Temperature

This is the outdoor temperature (in Celsius) above which hybrid ventilation is shut off when the ventilation control mode = 1 (Temperature). This upper temperature limit is intended to avoid overheating a space, which could result in a cooling load.

Field: Minimum Outdoor Enthalpy

This is the outdoor enthalpy (in J/kg) below which hybrid ventilation is shut off when the ventilation control mode = 2 (Enthalpy).

Field: Maximum Outdoor Enthalpy

This is the outdoor enthalpy (in J/kg) above which hybrid ventilation is shut off when the ventilation control mode = 2 (Enthalpy).

Field: Minimum Outdoor Dewpoint

This is the outdoor dewpoint (in Celsius) below which hybrid ventilation is shut off when the ventilation control mode = 3 (Dewpoint). This lower dewpoint temperature limit is intended to avoid dehumidifying a space.

Field: Maximum Outdoor Dewpoint

This is the outdoor dewpoint temperature (in Celsius) above which hybrid ventilation is shut off when the ventilation control mode = 3 (Dewpoint). This upper dewpoint temperature limit is intended to avoid humidifying a space.

Field: Minimum Outdoor Ventilation Air Schedule Name

The name of a schedule defined elsewhere in the input file. This field applies only if Ventilation Control Mode = 4 (Outdoor Ventilation Air Control). This schedule determines the minimum outdoor ventilation air for a given time in the units of air change per hour (ACH). The program calculates the natural (outdoor) ventilation in the controlled zone first and compares the amount of outdoor air introduced by opening windows or doors and other small openings to this minimum value. If the amount of outdoor air from natural ventilation is less than the minimum value, the natural ventilation is shut off (i.e., the window or door openings are closed) and the HVAC system may operate if needed. Otherwise, the natural ventilation is on and the HVAC system is shut off. The amount of outdoor ventilation air entering the controlled zone is determined as air from outdoors and not from other adjacent zones. Therefore, this option is only applied to a zone having a window or door exposed to outdoors.

Field: Opening Factor Function of Wind Speed Curve Name

The name of a linear or quadratic performance curve (ref: Performance Curves) that parameterizes the variation of opening factor as a function of outdoor wind speed. The output of this curve is multiplied by the opening factor of opening objects to give the final openness. This field only works with the AirflowNetwork opening objects.

Field: AirflowNetwork Control Type Schedule Name

The name of a schedule defined elsewhere in the input file. This field works with the AirflowNetwork opening objects only. This schedule determines for a given simulation timestep how the opening objects respond to the hybrid ventilation control when the hybrid ventilation control allows the objects to operate.

Schedule values equal to zero indicate individual ventilation control based on the control requirements specified for each individual AirflowNetwork opening object. Schedule values equal to one denote "group" control. The opening objects exposed to outdoors in the controlled zone served by the primary air loop (Ref. Field "HVAC Air Loop Name") will be considered as a master to provide group control.

Field: Simple Airflow Control Type Schedule Name

The name of a schedule defined elsewhere in the input file. This field works with ZoneVentilation and ZoneMixing objects only. This schedule determines for a given simulation timestep how the ZoneVentilation and ZoneMixing objects respond to the hybrid ventilation control when the hybrid ventilation control allows the objects to operate.

Schedule values equal to zero indicate the individual ventilation control based on the control requirements from their own objects. Schedule values equal to one denote group control. The ZoneVentilation and ZoneMixing objects in the zones served by the primary air loop defined in a previous input field (Ref. Field "HVAC Air Loop Name") are controlled by a single object, whose name is provided in the following input field.

Field: ZoneVentilation Object Name

The name of a ZoneVentilation object whose zone name is the controlled zone name defined in a previous input field for this availability manager object (Ref. Field "Controlled Zone Name"). The controls defined for this specific ZoneVentilation object to enable ventilation air will be applied to other ZoneVentilation and ZoneMixing objects served by the air loop controlled by this availability manager, regardless of the controls defined for the other ZoneVentilation and ZoneMixing objects. In other words, when ventilation is enabled by this specific ZoneVentilation object, the other ZoneVentilation and ZoneMixing objects in the zones served by the primary air loop are also enabled.

Below is the input data dictionary description for the AvailabilityManager:HybridVentilation object.

AvailabilityManager:HybridVentilation Outputs

The hybrid ventilation availability manager has two output variables.

HVAC,Average,Hybrid Ventilation Control Mode HVAC,Average,Hybrid Ventilation Control Status
--

Hybrid Ventilation Control Mode

This is the hybrid ventilation control mode given in the Ventilation Control Mode Schedule.

Hybrid Ventilation Control Status

This is the hybrid ventilation control status, which can have three integer values: 0, 1, and 2. A zero value indicates no hybrid ventilation control, corresponding to zero value defined in the previous output variable. A value of one indicates that natural ventilation is allowed. A value of two denotes that the natural ventilation is not allowed, so all window/door openings are closed.

Group – Setpoint Managers

Setpoint Managers are one of the high-level control constructs in EnergyPlus. A Setpoint Manager is able to access data from any of the HVAC system nodes and use this data to calculate a setpoint (usually a temperature setpoint) for one or more other HVAC system nodes. Setpoints are then used by Controllers or Plant or Condenser Loops as a goal for their control actions.

Setpoint Managers are executed at the start of each HVAC timestep, and they reside outside the HVAC system iteration loops. Thus, the Setpoint Managers are executed once per HVAC timestep, and they use previous timestep information (except for zone load) to calculate their setpoints.

The following situations require the use of a Setpoint Manager:

- 1) any use of Controller:WaterCoil; either in "Temperature" control only or 2 Setpoint Managers for the " TemperatureAndHumidityRatio " control variable option.
- 2) use of Controller:OutdoorAir with *Economizer Control Type* set to anything but *NoEconomizer*;
- 3) use of Coil:Heating:Gas or Coil: Heating: Electric with the field *Temperature Setpoint Node Name* set to a node name;
- 4) any use of AirLoopHVAC:UnitaryCoolOnly;
- 5) any use of Humidifier:Steam:Electric.
- 6) Any use of PlantLoop or CondenserLoop

Setpoint managers will place a calculated or scheduled setpoint value on the setpoint node and overwrite any previous value. This value may represent one of several control types (e.g., Temperature, HumidityRatio, MassFlowRate, etc.). No two setpoint managers should use the same setpoint node for like control types.

For the case when two setpoint managers place a setpoint on the same setpoint node (e.g., a temperature setpoint placed on the same node by two different setpoint managers), the setpoint value on the node is calculated by the last setpoint manager simulated. Within a specific type of setpoint manager (e.g., Scheduled), the setpoint managers are simulated in the order found in the input data file (idf) when viewed using a text editor. It is also possible for two different types of setpoint managers to place setpoints of like control variable on the same node. In this case, the order of simulation for the type of setpoint manager determines which setpoint manager is the last to write a setpoint value to the node. This conflict in setpoint node data is most likely to cause inaccurate simulation results. For this reason, a conflicting setpoint node name warning message is issued so that the conflict can be resolved. Duplicate setpoint node names found within a specific node list will not typically cause problems with the simulation (the same value is written twice to the same node). In this case a duplicate setpoint node name warning is issued, however, this could be an error in the spelling of the node name and should be corrected.

Simulation order for setpoint managers:

- SetpointManager:Scheduled
- SetpointManager:Scheduled:DualSetpoint
- SetpointManager:OutdoorAirReset
- SetpointManager:SingleZone:Reheat
- SetpointManager:SingleZone:Heating
- SetpointManager:SingleZone:Cooling
- SetpointManager:SingleZone:Humidity:Minimum
- SetpointManager:SingleZone:Humidity:Maximum
- SetpointManager:Warmest
- SetpointManager:Coldest
- SetpointManager:WarmestTemperatureFlow
- SetpointManager:ReturnAirBypassFlow
- SetpointManager:MixedAir
- SetpointManager:OutdoorAirPretreat

SetpointManager:Scheduled

The simplest Setpoint Manager simply uses a schedule to determine one or more setpoints. No node data is used as input. The input consists of the Setpoint Manager name, the control variable, the schedule name, and the name of a node list. The node list contains the name of those nodes at which the setpoint is to be applied. Of course, a node list name can always be simply the name of a single node.

Note that although this object provides a very general method of setting the values of many different control variables on nodes, the component models and system solvers may or may not be able to use them. Therefore, it is important to understand that simply setting a control variable using this object will not necessarily always produce the desired behavior.

Field: Name

A unique, user-assigned name for an instance of a scheduled setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. There are several choices for this type of set point manager. The most common control variable is Temperature but other major choices include: HumidityRatio and MassFlowRate. The versatility of control variables available here (probably) exceeds what is actually available in the component and systems models. However, a large number of possible control variables are made available here for maximum flexibility and because some (but not all) component models will be able to use them. The complete list of key words and the units required in the associated schedules follow.

- Temperature Temperature of fluid at node (°C)
- MaximumTemperature Maximum temperature of fluid at node (°C)
- MinimumTemperature Minimum temperature of fluid at node (°C)
- HumidityRatio Humidity ratio of fluid at node (kg water/ kg dry air)
- MaximumHumidityRatio Maximum humidity ratio of fluid at node (kg water/kg dry air)
- MinimumHumidityRatio Minimum humidity ratio of fluid at node (kg water/kg dry air)
- MassFlowRate Mass flow rate of fluid at node (kg/s)
- MaximumMassFlowRate Maximum mass flow rate of fluid at node (kg/s)
- MinimumMassFlowRate Minimum mass flow rate of fluid at node (kg/s)

Field: Schedule Name

The name of a schedule whose values are to be used as setpoints on the node or node list. The schedule value for each time period is the setpoint for this type of setpoint manager. The schedule must have values that are in the appropriate units as defined in the previous field.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which setpoints will be established by this setpoint manager.

Below is the Input Data Dictionary definition of a Scheduled Setpoint Manager.

```
SetpointManager:Scheduled,
  A1 , \field Name
      \required-field
      \reference SetpointManagers
  A2 , \field Control Variable
      \type choice
      \key Temperature
      \key MaximumTemperature
      \key MinimumTemperature
      \key HumidityRatio
      \key MaximumHumidityRatio
      \key MinimumHumidityRatio
      \key MassFlowRate
      \key MaximumMassFlowRate
      \key MinimumMassFlowRate
      \required-field
  A3 , \field Schedule Name
      \type object-list
      \object-list ScheduleNames
      \required-field
  A4 ; \field Setpoint Node or NodeList Name
      \note Node(s) at which temperature will be set
      \required-field
```

Following is an example of the input for a Scheduled Setpoint Manager.

```
SetpointManager:Scheduled,
  Supply Air Temp Manager 1,  !- Name
  Temperature,                !- Control Variable
  Seasonal Reset Supply Air Temp Sch,  !- Schedule Name
  VAV Sys 1 Outlet Node;      !- Setpoint Node or NodeList Name
```

SetpointManager:Scheduled:DualSetpoint

This setpoint manager places a high and low schedule value on one or more nodes. The input consists of the Setpoint Manager name, the control variable, the high and low set point schedule names, and the name of a node list. The node list contains the name of those nodes at which the setpoint is to be applied. Of course, a node list name can simply be the name of a single node. Currently the DualSetpoint Manager will be used with PlantLoop when the Plant Loop Demand Calculation Scheme is set to “DualSetpointDeadband”.

Field: Name

A unique, user-assigned name for an instance of this scheduled setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

Field: High Setpoint Schedule Name

The name of a schedule that contains the high setpoint values. The schedule value for each time period is the high setpoint for this type of setpoint manager.

Field: Low Setpoint Schedule Name

The name of a schedule that contains the low setpoint values. The schedule value for each time period is the low setpoint for this type of setpoint manager.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Below is the Input Data Dictionary definition for SetpointManager:Scheduled:DualSetpoint.

```
SetpointManager:Scheduled:DualSetpoint,
  A1 , \field Name
      \required-field
      \reference SetpointManagers
  A2 , \field Control Variable
      \type choice
      \key Temperature
      \default Temperature
  A3 , \field High Setpoint Schedule Name
      \type object-list
      \object-list ScheduleNames
      \required-field
  A4 , \field Low Setpoint Schedule Name
      \type object-list
      \object-list ScheduleNames
      \required-field
  A5 ; \field Setpoint Node or NodeList Name
      \note Node(s) at which temperature will be set
      \required-field
```

Following is an example of the input for a SetpointManager:Scheduled:DualSetpoint object.

```
SetpointManager:Scheduled:DualSetpoint,
  Water Loop Setpoint Manager,    !- Name
  Temperature,                   !- Control Variable
  Plant Loop High Temp Schedule,  !- High Setpoint Schedule Name
  Plant Loop Low Temp Schedule,   !- Low Setpoint Schedule Name
  Plant Supply Outlet Node;       !- Setpoint Node or NodeList Name
```

SetpointManager:OutdoorAirReset

The Outdoor Air Reset Setpoint Manager sets the supply air temperature according to the outdoor air temperature using a reset rule. The reset rule is determined by 2 points: the supply air setpoint temperature at the outdoor high temperature (SATOH) and the supply air setpoint temperature at the outdoor low temperature (SATOL). If the outdoor temperature is above the outdoor high temperature, the supply air temperature is set to SATOH. If the outdoor temperature is below the outdoor low temperature, the supply air temperature is set to SATOL. If the outdoor temperature is between the outdoor high and outdoor low temperatures, the supply air temperature is linearly interpolated between SATOH and SATOL.

The input consists of the setpoint manager name, the type of control variable, a node list name of the nodes affected by the setpoint, and the data for the reset rule: the supply air setpoint temperature at the outdoor low temperature, the outdoor low temperature, the supply air setpoint temperature at the outdoor high temperature, and the outdoor high temperature.

There are optional inputs for a second reset rule. First there is the name of a schedule that indicates which rule to use: a schedule value of 1 means use the first rule; a schedule value of 2 means use the second rule. Next, there are the 4 inputs specifying the second reset rule.

Field: Name

A unique, user-assigned name for an instance of an outdoor air reset setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

Field: Setpoint at Outdoor Low Temperature

The supply air temperature setpoint in °C at the outdoor low temperature for the first reset rule.

Field: Outdoor Low Temperature

The outdoor air low temperature in °C for the first supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its maximum.

Field: Setpoint at Outdoor High Temperature

The supply air temperature setpoint in °C at the outdoor high temperature for the first reset rule.

Field: Outdoor High Temperature

The outdoor air high temperature in °C for the first supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its minimum.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Field: Schedule Name

The name of a schedule whose values indicate which reset rule to use. Schedule values of 1 indicate that the first reset rule will be used. Schedule values of 2 select the second reset rule.

Field: Setpoint at Outdoor Low Temperature 2

The supply air temperature setpoint in °C at the outdoor low temperature for the second reset rule.

Field: Outdoor Low Temperature 2

The outdoor air low temperature in °C for the second supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its maximum.

Field: Setpoint at Outdoor High Temperature 2

The supply air temperature setpoint in °C at the outdoor high temperature for the second reset rule.

Field: Outdoor High Temperature 2

The outdoor air high temperature in °C for the second supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its minimum.

Following is the Input Data Dictionary description of the Outdoor Air Reset Setpoint Manager:

  Temperature, !- Control Variable
  16.7, !- Setpoint at Outdoor Low Temperature {C}
  0.0, !- Outdoor Low Temperature {C}
  12.8, !- Setpoint at Outdoor High Temperature {C}
  32.0, !- Outdoor High Temperature {C}
  Supply Air Temp Nodes; !- Setpoint Node or NodeList Name

NodeList,
  Supply Air Temp Nodes, !- Name
  Air Loop Outlet Node; !- Node 1 Name

```

SetpointManager:SingleZone:Reheat

The Single Zone Reheat Setpoint Manager allows the simulation of a single zone reheat system. This setpoint manager detects the control zone load, zone inlet node flow rate, and zone node temperature and calculates a setpoint temperature for the supply air that will satisfy the zone load for the control zone. This setpoint manager creates a variable temperature system. The input consists of the setpoint manager name, the control variable type, the minimum and maximum supply air temperatures, the name of the control zone, the name of the control zone node, the name of the control zone inlet node, and the name of a node or node list containing the nodes whose setpoint temperatures are to be set by this manager.

Field: Name

A unique, user-assigned name for an instance of this setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

Field: Minimum Supply Air Temperature

The minimum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager).

Field: Maximum Supply Air Temperature

The maximum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager)

Field: Control Zone Name

The name of the control zone for this single zone reheat system. The heating or cooling load for this zone determines the supply air temperature setpoint.

Field: Zone Node Name

The name of the zone node for the control zone.

Field: Zone Inlet Node Name

The name of the zone inlet node that is supplying air to the control zone.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

The following shows the Input Data Dictionary description of the SetpointManager:SingleZone:Reheat object.

```
SetpointManager:SingleZone:Reheat,

```

SetpointManager:SingleZone:Heating

The Single Zone Heating Setpoint Manager allows a component to be controlled based on the load required to meet the zone heating setpoint. This setpoint manager detects the control zone load to meet the current heating setpoint, zone inlet node flow rate, and zone node temperature, and calculates a setpoint temperature for the supply air that will satisfy the zone heating load for the control zone. This setpoint manager creates a variable temperature system. The input consists of the setpoint manager name, the controlled variable type, the minimum and maximum supply air temperatures, the name of the control zone, the name of the control zone node, the name of the control zone inlet node, and the name of a node or node list containing the nodes whose setpoint temperatures are to be set by this manager.

Field: Name

A unique, user-assigned name for an instance of a single zone heating setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

Field: Minimum Supply Air Temperature

The minimum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager).

Field: Maximum Supply Air Temperature

The maximum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager)

Field: Control Zone Name

The name of the control zone for this setpoint manager. The heating load for this zone (to meet the zone heating setpoint) determines the supply air temperature setpoint.

Field: Zone Node Name

The name of the zone node for the control zone.

Field: Zone Inlet Node Name

The name of the zone inlet node that is supplying air to the control zone.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

The following shows the Input Data Dictionary description of the Single Zone Heating Setpoint Manager.

```
SetpointManager:SingleZone:Heating,

  Zone 1 Heating Coil Outlet;               !- Setpoint Node or NodeList Name
```

SetpointManager:SingleZone:Cooling

The Single Zone Cooling Setpoint Manager allows a component to be controlled based on the load required to meet the zone cooling setpoint. This setpoint manager detects the control zone load to meet the current cooling setpoint, zone inlet node flow rate, and zone node temperature, and calculates a setpoint temperature for the supply air that will satisfy the zone cooling load for the control zone. This setpoint manager creates a variable temperature system. The input consists of the setpoint manager name, the controlled variable type, the minimum and maximum supply air temperatures, the name of the control zone, the name of the control zone node, the name of the control zone inlet node, and the name of a node or node list containing the nodes whose setpoint temperatures are to be set by this manager.

Field: Name

A unique, user-assigned name for an instance of a single zone cooling setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

Field: Minimum Supply Air Temperature

The minimum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager).

Field: Maximum Supply Air Temperature

The maximum supply air temperature (in °C) that is allowed for this system (as set by this setpoint manager)

Field: Control Zone Name

The name of the control zone for this setpoint manager. The cooling load of this zone (to meet the zone cooling set point) determines the supply air temperature setpoint.

Field: Zone Node Name

The name of the zone node for the control zone.

Field: Zone Inlet Node Name

The name of the zone inlet node that is supplying air to the control zone.

Field: Setpoint Node or NodeList Name

The name of a Node List object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

The following shows the Input Data Dictionary description of the SetpointManager:SingleZone:Cooling object.

```
SetpointManager:SingleZone:Cooling,
  \min-fields 8
A1 , \field Name
  \required-field
  \reference SetpointManagers
A2 , \field Control Variable
  \type choice
  \key Temperature

Zone 1 Supply Inlet, !- Zone Inlet Node Name
Zone 1 Cooling Coil Outlet; !- Setpoint Node or NodeList Name
```

SetpointManager:SingleZone:Humidity:Minimum

The Single Zone Minimum Humidity Setpoint Manager allows the control of a single zone minimum humidity level. This setpoint manager detects the humidity level in a control zone and, using air and moisture mass balance, calculates the supply air humidity ratio needed to maintain the zone relative humidity at or above a given setpoint. The calculated supply air humidity ratio is then used as the setpoint for the designated setpoint node. A humidifier component placed upstream of the setpoint node can then use the humidity ratio setpoint to control its moisture addition rate.

The use of this object requires that a “ZoneControl:Humidistat” object be specified with a humidifying relative humidity schedule for the controlling zone. The humidistat’s controlling zone must correspond with the control zone air node name specified in this setpoint manager.

Field: Name

A unique, user-assigned name for an instance of a single zone minimum humidity setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

Deprecated Field. This field is not used and will be deleted in a future release.

Field: Schedule Name

Deprecated Field. This field is not used and will be deleted in a future release.

Field: Setpoint Node or NodeList Name

The name of the HVAC system node where the calculated humidity ratio setpoint is set. If the setpoint is being placed on more than one node, this input should be the name of a NodeList.

Field: Control Zone Air Node Name

The name of the zone node for the humidity control zone (as specified in the object ZoneHVAC:EquipmentConnections).

The IDD description for the setpoint manager is shown below:

```
SetpointManager:SingleZone:Humidity:Minimum,
A1 , \field Name
    \required-field
    \reference SetpointManagers
A2 , \field Control Variable
    \note Deprecated Field. This field is not used
A3 , \field Schedule Name
    \note Deprecated Field. This field is not used
A4 , \field Setpoint Node or NodeList Name
    \required-field
    \note Node(s) at which humidity ratio setpoint will be set
A5 ; \field Control Zone Air Node Name
    \required-field
    \note Name of the zone air node for the humidity control zone
```

An IDF example for this setpoint manager is shown below with the required humidistat:

```

SetpointManager:SingleZone:Humidity:Minimum,
  Zone Min Set Point Manager,  !- Name
  ,  !- Control Variable
  ,  !- Schedule Name
  Air Loop Outlet Node,  !- Setpoint Node or NodeList Name
  Zone 2 Node;  !- Control Zone Air Node Name

ZoneControl:Humidistat,
  Zone 2 Humidistat,  !- Name
  ZONE 2,  !- Zone Name
  Min rel Hum Set Sch2;  !- Humidifying Relative Humidity Setpoint Schedule Name

```

SetpointManager:SingleZone:Humidity:Maximum

The Single Zone Maximum Humidity Setpoint Manager allows the control of a single zone maximum humidity level. This setpoint manager, used in conjunction with object ZoneControl:Humidistat, detects the air humidity level in a single control zone and uses air/moisture mass balances to calculate the supply air humidity ratio needed to maintain the zone relative humidity at or below a given setpoint. The calculated supply air humidity ratio is then used as the setpoint for the designated setpoint node. A dehumidification component placed upstream of this node can then use the humidity ratio setpoint to control its moisture removal rate (e.g., desiccant dehumidifiers).

In the case of a chilled water coil which is used for both temperature and high humidity control, this setpoint manager works in conjunction with a Controller:WaterCoil object to determine the minimum supply air temperature required to meet both the temperature (sensible) and humidity (latent) load in the control zone. See object Controller:WaterCoil in the EnergyPlus Engineering Reference for a detailed discussion of how this is achieved.

The use of this object requires that a “ZoneControl:Humidistat” object be specified with a relative humidity setpoint schedule for the controlling zone. The humidistat’s controlling zone must correspond with the control zone air node name specified in this setpoint manager..

Field: Name

A unique, user-assigned name for an instance of a single zone maximum humidity setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

Deprecated Field. This field is not used and will be deleted in a future release.

Field: Schedule Name

Deprecated Field. This field is not used and will be deleted in a future release.

Field: Setpoint Node or NodeList Name

The name of the HVAC system node where the calculated humidity ratio setpoint is set. If the setpoint is being placed on more than one node, this input should be the name of a NodeList.

Field: Control Zone Air Node Name

The name of the zone air node for the humidity control zone (as specified in the object ZoneHVAC:EquipmentConnections).

The IDD description for this object is shown below:

```

SetpointManager:SingleZone:Humidity:Maximum,
  \min-fields 5
A1 , \field Name
    \required-field
    \reference SetpointManagers
A2 , \field Control Variable
    \note Deprecated Field. This field is not used

  0.0;                           !- Minimum Actuated Flow {m3/s}

```

SetpointManager:MixedAir

The Mixed Air Setpoint Manager is meant to be used in conjunction with a Controller:OutdoorAir object. This setpoint manager is used to establish a temperature setpoint at the mixed air node. The Controller:OutdoorAir then operates the outdoor air damper to attempt to meet this setpoint.

In EnergyPlus the relief and outdoor air dampers, the economizer, and any outdoor air conditioning equipment form a separate subsystem of an air loop system (ref. AirLoopHVAC). The outdoor air controller operates within the subsystem. Consequently the mixed air temperature setpoint must take into account any downstream system fan heat if it is to meet a desired system supply air leaving temperature. The Mixed Air Setpoint Manager accomplishes this by referencing a supply air setpoint set by another setpoint manager (most likely at the AirLoopHVAC outlet node). The supply fan inlet and outlet nodes are also inputs to the Mixed Air Setpoint Manager. From this information the Mixed Air Setpoint Manager calculates the supply fan air temperature rise, subtracts it from the reference setpoint temperature, and sets the result as the mixed air node setpoint temperature.

Of course any type of setpoint manager can be used to establish a temperature setpoint at the mixed air node. But the Mixed Air Setpoint Manager is likely to be the most useful.

Field: Name

A unique, user-assigned name for an instance of a mixed air setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: Temperature.

Field: Reference Setpoint Node Name

The name of an HVAC system node where the system supply air temperature is set. Normally this would be the AirLoopHVAC outlet node. The temperature setpoint at this reference node is set by a different setpoint manager.

Field: Fan Inlet Node Name

The name of the supply fan inlet node.

Field: Fan Outlet Node Name

The name of the supply fan outlet node.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name where temperature setpoints will be established by this setpoint manager.

The Input Data Dictionary description for the SetpointManager:MixedAir object is.

```
SetpointManager:MixedAir,
A1 , \field Name
    \required-field
    \reference SetpointManagers
A2 , \field Control Variable

```

SetpointManager:OutdoorAirPretreat

The Outdoor air Pretreat Setpoint Manager is meant to be used in conjunction with an OutdoorAir:Mixer object. The Outdoor air Pretreat Setpoint Manager is used to establish a temperature or humidity ratio setpoint in the outdoor air stream flowing into the "Outdoor Air Stream Node" of an OutdoorAir:Mixer object. This setpoint manager determines the required setpoint in the outdoor air stream to produce the reference setpoint in the mixed air stream after mixing with return air. For example, if the temperature setpoint at the mixed air node is 15°C, the return air temperature is 20°C, and the outdoor air flow fraction is 0.5, the Outdoor Air Pretreat setpoint would be set to 10°C.

Of course any type of setpoint manager can be used to establish setpoints in the outdoor air stream, but this setpoint manager is likely to be the most useful for systems which precondition outdoor air with equipment such as a DX cooling coil or desiccant dehumidifier.

Field: Name

A unique, user-assigned name for an instance of an outdoor air pretreat setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. The choices are:

- Temperature – references and sets the "System Node Setpoint Temp" property. This single temperature setpoint is set and used by all temperature setpoint managers and equipment controls except dual-setpoint equipment.
- MaximumHumidityRatio – references and sets the "System Node Humidity Ratio Max" property. This type of reference setpoint may be set using SetpointManager:SingleZone:Humidity:Maximum and is used by equipment such as Controller:WaterCoil (with control variable "TemperatureAndHumidityRatio") and Dehumidifier:Desiccant:NoFans.
- MinimumHumidityRatio – references and sets the "System Node Humidity Ratio Min" property. This type of reference setpoint may be set using SetpointManager:SingleZone:Humidity:Minimum and is used by equipment such as Humidifier:Steam:Electric.
- HumidityRatio – references and sets the "System Node Setpoint Humidity Ratio" property. This type of reference setpoint may be set using (no applicable setpoint

managers at this time) and is used by equipment such as Controller:WaterCoil (with control variable "HumidityRatio").

The system node properties listed above are all available as an Output:Variable to facilitate tracking these setpoints both at the reference node and the setpoint nodes.

Field: Minimum Setpoint Temperature

The minimum temperature (in °C) that is allowed by this setpoint manager. Applicable only if Control variable is Temperature.

Field: Maximum Setpoint Temperature

The maximum temperature (in °C) that is allowed by this setpoint manager. Applicable only if Control variable is Temperature.

Field: Minimum Setpoint Humidity Ratio

The minimum humidity ratio (in kg/kg) that is allowed by this setpoint manager. Applicable only if Control variable is MaximumHumidityRatio, MinimumHumidityRatio, or HumidityRatio. Note that zero is not allowed as the computed setpoint humidity ratio, because zero is used as a special value to indicate that no humidification or dehumidification is needed. If the reference humidity ratio setpoint value is zero, the zero value will be passed directly to the Set Point Node(s).

Field: Maximum Setpoint Humidity Ratio

The maximum humidity ratio (in kg/kg) that is allowed by this set point manager. Applicable only if Control variable is MaximumHumidityRatio, MinimumHumidityRatio, or HumidityRatio.

Field: Reference Setpoint Node Name

The name of an HVAC system node where the desired mixed air condition has been set. Normally this would be the mixed air node leaving the OutdoorAir:Mixer. The temperature or humidity setpoint at this reference node must be set by a different setpoint manager of the appropriate type (see Control Variable above).

Field: Mixed Air Stream Node Name

The name of the mixed air node. This node is used to obtain the flow rate of the combined air stream. This node is usually the same node at the Reference Setpoint Node Name, but does not have to be.

Field: Outdoor Air Stream Node Name

The name of a node in the outdoor air stream. This node is used to obtain the flow rate of the outdoor air stream.

Field: Return Air Stream Node Name

The name of a node in the return air stream. This node is used to obtain the flow rate of the return air stream.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature or humidity ratio setpoints will be established by this setpoint manager.

The following shows the Input Data Dictionary description of the Outdoor Air Pretreat Setpoint Manager.

```

SetpointManager:OutdoorAirPretreat,

SetpointManager:Warmest

The Warmest Setpoint Manager resets the cooling supply air temperature of a central forced air HVAC system according to the cooling demand of the warmest zone. For each zone in the system at each system timestep, the manager calculates a supply air temperature that will meet the zone cooling load at the maximum zone supply air flow rate. The lowest of the possible supply air temperatures becomes the new supply air temperature setpoint, subject to minimum and maximum supply air temperature constraints. The resulting temperature setpoint is the highest supply air temperature that will meet the cooling requirements of all the zones. When compared to a fixed cooling supply air temperature setpoint, this strategy minimizes zone reheat coil energy (or overcooling) and central chiller energy consumption (if the chilled water temperature is also reset) at the cost of possible increased fan energy.

Field: Name

A unique, user-assigned name for an instance of a warmest setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. Currently there is only one choice: Temperature.

Field: HVAC Air Loop Name

The name of the AirLoopHVAC object (the central air system) which will use this setpoint manager to set its cooling supply air temperature.

Field: Minimum Setpoint Temperature

The minimum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum.

Field: Maximum Setpoint Temperature

The maximum allowed setpoint temperature in degrees C. If the calculated setpoint is greater than this value the setpoint is set to the maximum. This value is also used as the setpoint temperature when none of the zones have a cooling load.

Field: Strategy

Currently, the only choice for this field is MaximumTemperature.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

The following shows the Input Data Dictionary description of the Warmest Setpoint Manager.

```

Set Point Manager:Coldest

The Coldest Setpoint Manager is used in dual duct systems to reset the setpoint temperature of the air in the heating supply duct. Usually it is used in conjunction with a Warmest Setpoint Manager resetting the temperature of the air in the cooling supply duct. For each zone in the system at each system timestep, the manager calculates a supply air temperature that will meet the zone heating load at the maximum zone supply air flow rate. The highest of the possible supply air temperatures becomes the new supply air temperature setpoint, subject to minimum and maximum supply air temperature constraints. The resulting temperature setpoint is the lowest supply air temperature that will meet the heating requirements of all the zones. When compared to a fixed heating supply air temperature setpoint, this strategy minimizes central boiler energy consumption (if the hot water temperature is also reset or there are variable speed pumps) at the cost of possible increased fan energy (if there is variable volume control in the air system).

Field: Name

A unique, user-assigned name for an instance of a coldest setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. Currently there is only one choice: Temperature.

Field: HVAC Air Loop Name

The name of the AirLoopHVAC object (the central air system) which will use this setpoint manager to set its heating supply air temperature.

Field: Minimum Setpoint Temperature

The minimum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum. This value is also used as the setpoint temperature when none of the zones have a heating load.

Field: Maximum Setpoint Temperature

The maximum allowed setpoint temperature in degrees C. If the calculated setpoint is greater than this value the setpoint is set to the maximum.

Field: Strategy

Currently, the only choice for this field is MinimumTemperature.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

The following shows the Input Data Dictionary description of the Coldest Setpoint Manager.

Set Point Manager:Return Air Bypass Flow

This manager is user in conjunction with a return air bypass configuration. This type of air system is basically a standard single duct system with the addition of a bypass duct that bypasses return air around the main system components – in particular, the central cooling coil. This allows the central cooling coil to sufficiently dehumidify the mixed air; the bypassed air is then added to the supply air stream to bring the supply air temperature up to the desired temperature set point. This scheme is very useful in situations where an higher than normal supply air temperature is used – for instance, in underfloor air distribution systems.

This manager relies on the program to figure out the system configuration and to extract the needed data from the system nodes. All the user needs to input is the name of the air system and a schedule giving the desired supply air temperature setpoint. No node names are required. The manager will establish a bypass air flow rate that upon mixing with the non-bypassed air will yield the temperature given in the schedule.

Field: Name

A unique, user-assigned name for an instance of an Return Air Bypass Flow setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. Currently there is only one choice: Flow.

Field: HVAC Air Loop Name

The name of the AirLoopHVAC object (the central air system) which will use this setpoint manager to set its return air bypass flow rate.

Field: Temperature Setpoint Schedule Name

The name of a schedule whose values are temperatures in °C. The schedule value for the time period is the setpoint for this type of setpoint manager. The setpoint is assumed to be at the air handler outlet.

Below is the IDD definition for the SetpointManager:ReturnAirBypassFlow object.

```

SetpointManager:WarmestTemperatureFlow

The Warmest Temperature Flow Setpoint Manager resets the cooling supply air temperature of a central forced air HVAC system according to the cooling demand of the warmest zone. The user can select on of two strategies: 'Temperature First' or 'Flow First'. For each zone in the system at each system timestep, the manager calculates a supply air temperature that will meet the zone cooling load at the minimum zone supply air flow rate ('Temperature First') or at the maximum zone supply air flow rate ('Flow First'). The lowest of the possible supply air temperatures becomes the new supply air temperature setpoint, subject to minimum and maximum supply air temperature constraints. The resulting temperature setpoint is the highest supply air temperature that will meet the cooling requirements of all the zones. When compared to a fixed cooling supply air temperature setpoint, the 'Temperature First' strategy minimizes fan energy at the cost of possible increased zone reheat coil energy (or overcooling) and central chiller energy consumption, whereas the 'Flow First' strategy

minimizes zone reheat coil energy (or overcooling) and central chiller energy consumption at the cost of possible increased fan energy.

Field: Name

A unique, user-assigned name for an instance of this setpoint manager. Anywhere in the input that this setpoint manager is used, it is referred to by this name.

Field: Control Variable

The type of variable that will be controlled. For this setpoint manager, this input should be Temperature.

Field: HVAC Air Loop Name

The name of the AirLoopHVAC object (the central air system) which will use this setpoint manager to set its cooling supply air temperature.

Field: Minimum Setpoint Temperature

The minimum allowed setpoint temperature in degrees C. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum.

Field: Maximum Setpoint Temperature

The maximum allowed setpoint temperature in degrees C. If the calculated setpoint is greater than this value the setpoint is set to the maximum. This value is also used as the setpoint temperature when none of the zones have a cooling load.

Field: Strategy

The choices for this field are *TemperatureFirst* and *FlowFirst*.

Field: Setpoint Node or NodeList Name

The name of a NodeList object containing the names of the HVAC system nodes or the HVAC System Node Name for which temperature setpoints will be established by this setpoint manager.

Field: Minimum Turndown

The minimum value of the ratio of the actual air flow rate to the maximum air flow rate, either for the supply fan if there are no VAV terminal boxes, or for the VAV boxes if present. If there are VAV boxes, it is assumed that the same value of minimum turndown applies to all boxes.

Group – Controllers

Controls (Air Loop and Zone Equipment)

A controller mimics the function of an actual physical controller in a somewhat rudimentary way. It can sense one node variable, compare it with its setpoint, and determine the desired value for another node variable. It should be noted that a controller cannot span a loop manager boundary (but a Setpoint Manager can). Thus, in an air loop (AirLoopHVAC), the

sensed node and the controlled device must be in the air loop simulation. This means that a single zone system cannot be modeled with a simple controller sensing zone temperature and controlling coil water flow. Instead this must be modeled as a Setpoint Manager sensing a zone temperature and resetting the supply air temperature setpoint each timestep. This is artificial but should simplify the control modeling task. It should also be noted that there are various types of controllers and that each controller might hook into loops in a slightly different way. As a result, each controller type is described separately below.

Controller:WaterCoil

This controller is really a solution inverter. For a water coil the simulation cannot be inverted where the mass flow rate of the water through the coil can be solved directly given an air temperature. Thus, this “controller” will numerically step through all of the water flow possibilities by an interval-halving technique until the mass flow rate is determined to meet the specified outlet air temperature within a specified user tolerance.

As the reader probably noted when reading the descriptions of the coil syntax shown earlier in this section, there were no controls attached directly to a particular component. This is because the input can be simplified somewhat by entering node names to be controlled. This avoids having to search through multiple lists of component types for the sake of simply controlling components. The Controller:WaterCoil shown below is a way of controlling variables at one node based on conditions at another node. After the identifying name for the controller, the user must define which control variable the controller is managing. These options include Temperature, Humidity Ratio, TemperatureAndHumidityRatio, or Flow.

The next parameter in the input syntax is the Action of the control, which determines how the controlled variable (e.g., mass flow rate through a water coil) is changed based on the control signal. The following input parameter is the actuator variable, which is currently limited to mass flow through a water coil.

The next two parameters in the input syntax are node names corresponding to the node that is being sensed and the actuated node which controls the water mass flow through the coil. For example, in the case of a cooling coil the control variable might be the outlet air temperature of the coil while the actuated variable might be the water flow rate through the coil. These two parameters are followed by the controller convergence tolerance. Finally, the last two input parameters represent the maximum and minimum values allowed for the actuated variable at the actuated node.

Field: Name

This is the unique name of the controller.

Field: Control Variable

This was setup to be generic but to date has only been used for temperature control, or temperature and humidity ratio control, of a water coil in the air loop simulation. The keyword Temperature is used for air temperature control and is normally specified for the coil’s outlet air node. The keyword TemperatureAndHumidityRatio is used for controlling both air temperature and high humidity levels, and is normally specified for a cooling coil’s outlet air node. The keyword HumidityRatio is used for humidity control and would normally be specified for a dehumidifier outlet node. The keyword Flow is used to control flow for pumps or fans and would typically be specified at the equipment’s outlet node.

Field: Action

The next input refers to the “action” of the control. This can be best described by an example. In a coil where water mass flow rate is to be controlled, a coil will increase the mass flow rate through the coil when more heating or cooling is requested. In a heating coil, this increases the value of heat transfer from the water to the air stream. As a result, this is considered a “Normal” action controller. In a cooling coil, an increase in water mass flow rate through the coil decreases the value of heat transfer from the water to the air stream (absolute value increases, but since cooling is traditionally described as a negative number, an increase in

absolute value results in a decrease in the actual heat transfer value). Thus, the cooling coil controller has “Reverse” action since an increase in flow rate results in a decrease in heat transfer.

Field: Actuator Variable

This was again meant to be more generic but currently has only been used to control the water mass flow rate of a heating or cooling coil. This actuator variable must be set to the keyword Flow to control the water mass flow rate.

Field: Sensor Node Name

Name of the node where the temperature, humidity ratio or flow is sensed.

Field: Actuator Node Name

Name of the actuated node that controls the water mass flow rate through the coil.

Field: Controller Convergence Tolerance

The coil is controlled by knowing the outlet temperature and/or humidity ratio specified by the setpoint managers, and setting the outlet conditions from the coil to meet these setpoints. The hot and chilled water coils use complex models that cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot or cold water the models are inverted numerically using an iterative procedure. The iterative solution uses an interval-halving routine and needs a termination criteria that is set with the Controller Convergence Tolerance parameter. The convergence tolerance is the maximum difference between the actual temperature at the setpoint node and the setpoint temperature. This control offset is set to a small temperature difference, such as 0.01 to denote 1/100 degree C. The default is 0.1 degree C.

Field: Maximum Actuated Flow

This is the maximum water flow (m^3/sec) through the coil. Set to the maximum design water flow for the coil.

Field: Minimum Actuated Flow

Set to the minimum design water flow (m^3/sec) for the water coil, normally a shut off valve that is set to zero.

Controller:OutdoorAir

A mixed air box has its own controller type called Controller:OutdoorAir. The purpose of the outdoor air controller is to provide outdoor air for ventilation and also provide free cooling (through additional outdoor air and/or bypassing an air-to-air heat exchanger) whenever possible. The outdoor air controller includes a number of user-selectable limit controls. If any of the selected limits are exceeded, the outdoor airflow rate is set to the minimum.

If all the limits are satisfied, the outdoor air controller does the following for continuous air flow systems: if the outdoor air temperature is greater than or equal to the mixed air temperature setpoint, the outdoor air flow rate is set to the maximum; if the outdoor air temperature is less than the mixed air temperature setpoint, the outdoor air controller will modulate the outdoor air flow so that the mixed air temperature will match the mixed air setpoint temperature.

A time-of-day schedule may also be used to simulate an increase in outdoor air flow rate for “push-button” type economizer applications. When the schedule permits (i.e., schedule values are greater than 0), the outdoor air flow rate is increased to the user-specified maximum outdoor air flow rate.

The outdoor air controller can also account for changes in the outdoor air flow rate during times when indoor humidity levels are high. A zone humidistat must be used with this control option. During high indoor humidity, the outdoor air flow rate is modified in response to a high indoor humidity condition. If high humidity control is based on the outdoor air humidity ratio and the outdoor humidity ratio is greater than the indoor humidity ratio, high humidity control is terminated. When the economizer is used in conjunction with the high humidity control option, high humidity control has priority and controls the change in air flow rates. The Night Cycle Availability Manager has priority over high humidity control and will use the controller’s maximum outdoor air flow rate when this Availability Manager cycles the fan on (Ref. System Availability Managers)

The mixed air box connections are defined separately in the **OutdoorAir:Mixer** object.

Although the mixer will commonly be connected directly to the outdoor air, other components may be placed on the outdoor air path upstream of the mixer. When this is the case, any modulation will be determined by the conditions at the inlet node of the mixer rather than the outdoor air. This means that the controller will account for any heat recovery or other preheating/precooling components that may modify the condition of outdoor air before it reaches the mixer.

If all the limits are satisfied, the outdoor air controller does the following for cycling fan systems: the outdoor air flow rate is set to the maximum when the fan cycles on. If the limits are not satisfied, the outdoor air flow rate is at the minimum when the fan cycles on.

Field: Name

The unique user-assigned name for an instance of an outdoor air controller. Any other object referencing this outdoor air controller will use this name.

Field: Relief Air Outlet Node Name

The name of the relief air node of the outdoor air mixer associated with this outdoor air controller.

Field: Return Air Node Name

The name of the return air node of the outdoor air mixer associated with this outdoor air controller.

Field: Mixed Air Node Name

Name of the node where the mixed air setpoint is set. The outdoor air controller senses the temperature at this node and attempts to control that temperature to the node setpoint.

Field: Actuator Node Name

The name of the node that is associated with the outdoor air damper. This should be the outermost air node on the outdoor air path connected to the outdoor air stream for the mixer associated with this outdoor air controller.

Field: Minimum Outdoor Air Flow Rate

Input for this field is the minimum outdoor air flow rate for the system in cubic meters per second.

Field: Maximum Outdoor Air Flow Rate

Input for this field is the maximum outdoor air flow rate for the system in cubic meters per second.

Field: Economizer Control Type

The options for this field are

- FixedDryBulb
- DifferentialDryBulb
- FixedEnthalpy
- DifferentialEnthalpy
- ElectronicEnthalpy
- FixedDewPointAndDryBulb
- DifferentialDryBulbAndEnthalpy
- NoEconomizer

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

FixedEnthalpy checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

DifferentialEnthalpy does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the DifferentialDryBulb and DifferentialEnthalpy economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

Field: Economizer Control Action Type

There are two choices for this field: **MinimumFlowWithBypass** and **ModulateFlow**, with the default being **ModuleFlow** if this input field is left blank.

ModulateFlow means the outdoor air flow rate will be increased to meet the mixed air setpoint temperature, subject to the limits imposed via other inputs for this object (e.g., Economizer Maximum Limit Dry-Bulb Temperature, Maximum Outdoor Air Flow Rate, etc.).

MinimumFlowWithBypass is used exclusively in conjunction with air-to-air heat exchanger:objects (Ref. HeatExchanger:*) for providing free cooling operation in the absence of a conventional air-side economizer (i.e., when outdoor air flow rate is not increased during economizer mode). The MinimumFlowWithBypass choice forces the outdoor air flow rate to always remain at the minimum. However, when high humidity control is used, the outdoor air flow rate is set to the product of the maximum outdoor air flow rate multiplied by the high humidity outdoor air flow ratio. The heat exchanger uses the limit checking in the outdoor air controller to decide whether or not to bypass the outdoor air around the heat exchanger – or turn off the wheel motor in the case of a rotary heat exchanger. Heat exchange is also suspended when high humidity control is active.

The **ModulateFlow** option can also be used with the HeatExchanger:AirToAir:FlatPlate or HeatExchanger:AirToAir:SensibleAndLatent objects.

Field: Economizer Maximum Limit Dry-Bulb Temperature

Input for this field is the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor airflow rate will be set to the minimum. This field is required if Economizer Control Type 'FixedDryBulb' or 'FixedDewPointAndDryBulb' has been specified.

No input (blank) in this field means that there is no outdoor air temperature high limit control. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Field: Economizer Maximum Limit Enthalpy

Input for this field is the outdoor air enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor airflow rate will be set to the minimum. This field is required if Economizer Control Type 'FixedEnthalpy' has been specified.

No input (blank) in this field means that there is no outdoor air enthalpy limit control. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Field: Economizer Maximum Limit Dewpoint Temperature

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type 'FixedDewPointAndDryBulb' has been specified.

No input (blank) in this field means that there is no outdoor air dewpoint limit control. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Field: Electronic Enthalpy Limit Curve Name

Input for this field is the name of a quadratic or cubic curve which provides the maximum outdoor air humidity ratio (function of outdoor air dry-bulb temperature) for economizer operation. If the outdoor air humidity ratio is greater than the curve's maximum humidity ratio (evaluated at the outdoor air dry-bulb temperature), the outdoor air flow rate will be set to the minimum. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer. No input (blank) in this field means that there is no electronic enthalpy limit control.

Field: Economizer Minimum Limit Dry-Bulb Temperature

Input for this field is the outdoor air temperature low limit (°C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor airflow rate will be set to the minimum.

No input (blank) in this field means that there is no outdoor air temperature low limit control. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Field: Lockout Type

Choices for this field are NoLockout, LockoutWithHeating, and LockoutWithCompressor. This field is used for packaged systems with DX coils. LockoutWithHeating means that if the packaged unit is in heating mode, the economizer is locked out – i.e., the economizer dampers are closed and there is minimum outdoor air flow. LockoutWithCompressor means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is operating to provide cooling. In other words, the economizer must meet the entire cooling load – it isn't allowed to operate in conjunction with the DX cooling coil. This option (LockoutWithCompressor) is sometimes called a “nonintegrated” economizer.

The default is NoLockout.

Field: Minimum Limit Type

Choices for this field are FixedMinimum or ProportionalMinimum. FixedMinimum means that the minimum outdoor airflow rate is fixed no matter what the actual system flow rate is. ProportionalMinimum means the minimum outdoor airflow rate varies in proportion to the total system air flow rate. The default is ProportionalMinimum.

Field: Minimum Outdoor Air Schedule Name

The name of a schedule whose values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air fraction. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours. If this field is not input, the minimum outdoor air flow rate remains constant during the simulation period.

Field: Minimum Fraction of Outdoor Air Schedule Name

This is an optional field with the schedule values in decimal fractions (0.0-1.0). This field enables the user to limit the minimum amount of outdoor air permissible and thus also helps in getting at least the minimum amount of air in.

Field: Maximum Fraction of Outdoor Air Schedule Name

This is an optional field with the schedule values in decimal fractions (0.0-1.0). This field enables the user to limit the maximum of amount of outdoor air permissible and thus also limits the permissible maximum outdoor air into the system.

If both the above schedules are given values of 1.0, the system works at 100% outdoor air, so in a system if 100% outdoor air is required regardless of any other condition, these fields are helpful.

Field: Mechanical Ventilation Controller Name

This optional field is the name of the mechanical ventilation controller object to be used in conjunction with this outdoor air controller. The Controller:MechanicalVentilation object allows the user to define the minimum outdoor air flow rate based on air flow per unit floor area and air flow per person (occupant) for the zones being served by the air loop that utilizes this controller.

This feature allows the user to perform a first-order evaluation of carbon dioxide(CO₂)-based demand controlled ventilation (outdoor ventilation varied according to occupancy levels).

If a valid name for a Controller:MechanicalVentilation object is entered in this field, the minimum outdoor air flow rate delivered will be the greater of:

- the minimum outdoor air flow rate calculated by the fields Minimum Outdoor Air Flow Rate, Minimum Limit Type, and Minimum Outdoor Air Schedule Name as defined for this outdoor air controller, or
- the outdoor air flow rate calculated using the Controller:MechanicalVentilation object named in this input field.

Leaving this input field blank will bypass the Controller:MechanicalVentilation object calculations and the minimum outdoor air flow rate will be based on the other inputs associated with this outdoor air controller object. Actual outdoor air flow rates may be higher than the minimum if free cooling is available and the object inputs are properly selected. Regardless, the maximum outdoor air flow rate is limited by the field Maximum Outdoor Air Flow Rate.

Field: Time of Day Economizer Control Schedule Name

This alpha field is the name of a schedule which controls the outdoor air flow rate based on a time-of-day economizer. Schedule values equal to 0 disable this feature. Schedule values greater than 0 cause the outdoor air flow rate to increase to the maximum. When an economizer is used in conjunction with the high humidity control option, high humidity control has priority.

Field: High Humidity Control

This choice field establishes whether or not the outdoor air flow rate is modified in response to high indoor relative humidity. Valid choices are Yes and No. If Yes is selected, the outdoor air flow rate may be modified when the indoor relative humidity is above the humidstat setpoint. If No is selected, this option is disabled and the following three fields are not used.

Field: Humidistat Control Zone Name

This input defines the zone name where the humidistat is located. This is the same name used in the ZoneControl:Humidistat object. This field is required when the input field High Humidity Control is specified as Yes.

Field: High Humidity Outdoor Air Flow Ratio

This input is the ratio of the modified outdoor air flow rate to the maximum outdoor air flow rate. When the high humidity control algorithm determines that the outdoor air flow rate will be changed (i.e., increased or decreased), the operating outdoor air flow rate is equal to the maximum outdoor air flow rate multiplied by this ratio. The minimum value for this field is 0. If this field is blank, the default value is 1. This field is used only when the input field High Humidity Control is specified as Yes. When an economizer is used in conjunction with the high humidity control option, high humidity control has priority.

Field: Control High Indoor Humidity Based on Outdoor Humidity Ratio

This choice field determines if high humidity control is activated based on high indoor relative humidity alone or is activated only when the indoor relative humidity is above the humidstat setpoint *and* the indoor humidity ratio is greater than the outdoor humidity ratio. Valid choices are Yes and No. If No is selected, high humidity control is active any time the zone humidistat senses a moisture load. If Yes is selected, the model also verifies that the outdoor humidity ratio is less than the humidistat's zone air humidity ratio. This field is used only when the input field High Humidity Control is specified as Yes.

The default value is Yes.

Field: AirLoopHVAC Outdoor Air Economizer Status

Reports the average operating status of an air economizer over the reporting interval. The economizer status is set to 1 when the conditions are favorable for the economizer to operate (i.e., none of the control limits have been exceeded). While conditions may be favorable for economizer operation, it does not guarantee that the air-side economizer has increased outdoor air flow above the minimum level since the actual outdoor air flow rate is also governed by other controls (e.g., mixed air set point temperature, time of day economizer control, maximum humidity setpoint, etc.). This variable is set to 0 if conditions disable economizer operation or NoEconomizer (Economizer Control Type) is specified.

Field: AirLoopHVAC Outdoor Air High Humidity Control Status

Reports the average operating status of the controller's high humidity control over the reporting interval. The high humidity control status is set to 1 when the controller determines that a zone high humidity condition exists *according to the settings specified in the controller*.

This variable is set to 0 if conditions disable high humidity control operation or High Humidity Control is specified as No.

Field: AirLoopHVAC Actual Outdoor Air Fraction

Reports the average actual outdoor air fraction for the outdoor air controller over the reporting interval.

Field: AirLoopHVAC Minimum Outdoor Air Fraction

Reports the average minimum limit of the outdoor air fraction for the outdoor air controller over the reporting interval.

Field: AirLoopHVAC Outdoor Air Mass Flow Rate [kg/s]

Reports the average outdoor air mass flow rate introduced by the outdoor air controller over the reporting interval.

Field: AirLoopHVAC Mixed Air Mass Flow Rate [kg/s]

Reports the average mixed air mass flow rate of the HVAC air loop associated with this outdoor air controller over the reporting interval.

Controller:MechanicalVentilation

This object is used in conjunction with an outdoor air controller (Ref. Controller:OutdoorAir, Field: Mechanical Ventilation Controller Name) to establish the minimum outdoor air flow rate provided by a mixed air box.

Ventilation standards provide guidance on appropriate levels of outdoor ventilation air required for acceptable indoor air quality. The Ventilation Rate Procedure (VRP) of ASHRAE Standard 62.1-2007 (www.ashrae.org) requires outdoor ventilation rates to be determined based on the floor area of each occupied zone plus the number of people in each zone and considers the zone air distribution effectiveness and system ventilation efficiency. The outdoor air ventilation rate can be reset dynamically as operating conditions change (e.g., variations in occupancy). The Controller:MechanicalVentilation object implements the VRP for calculating these outdoor air ventilation requirements and resetting them based on varying occupancy levels and zone diversification. This is particularly useful for large air distribution systems that serve a number of different zone types with varying occupancy levels.

The first four inputs for this object are the name, the availability schedule, the zone outdoor air method, and the system outdoor air method. The next six input fields define the zone name (or zone list name), the ventilation rate per unit floor area, the ventilation rate per occupant, zone air distribution effectiveness in cooling mode, zone air distribution effectiveness in heating mode, and zone air distribution effectiveness schedule name to be applied to this zone (or zone list). The last six fields are extensible. If the zone air distribution effectiveness schedule is specified, the other two filed inputs will be ignored - zone air distribution effectiveness in cooling mode, and zone air distribution effectiveness in heating mode.

Field: Name

The unique user assigned name for an instance of mechanical ventilation. Any other object referencing this mechanical ventilation object will use this name.

Field: Availability Schedule Name

The name of a schedule whose values are greater than 0 when mechanical ventilation, as calculated by this object, is desired. If this field is left blank, outdoor ventilation occurs according to the parameters specified in the Controller:OutdoorAir object as if the Controller:MechanicalVentilation object has not been specified. This schedule is useful for purging the building of contaminants prior to occupancy (i.e., ventilation rate per unit floor area will be provided even if the occupancy is zero).

Field: Zone Outdoor Air Method

The method used to calculate the zone minimum outdoor air flow. Two choices are Sum and Maximum of the occupant based outdoor air flow and the floor area based outdoor air flow.

Field: System Outdoor Air Method

The method used to calculate the system minimum outdoor air flow. Two choices are ZoneSum and VRP. ZoneSum sums the outdoor air flows across all zones served by the system, which is the method used in EnergyPlus 3.0. VRP uses the multi-zone equations defined in 62.1-2007 to calculate the system outdoor air flow. VRP considers zone air distribution effectiveness and zone diversification of outdoor air fractions.

Field Set (Zone Name, Ventilation Rate per Unit Floor Area, Ventilation Rate Per Occupant, Zone Air Distribution Effectiveness in Cooling Mode, Zone Air Distribution Effectiveness in Heating Mode, and Zone Air Distribution Effectiveness Schedule Name)

The following six fields are needed to define the parameters for the ventilation. This object is extensible by duplicating these six fields.

Field: Zone<x> Name

The zone name or zone list to apply the ventilation rates specified in the next two input fields.

Field: Ventilation Rate per Unit Floor Area <x>

The numeric input for this field is the volumetric air flow rate ($\text{m}^3/\text{s}\cdot\text{m}^2$) of outdoor air to be delivered per square meter of floor area for the zone specified in the previous field. This field helps determine the minimum outdoor air flow that is provided by the air loop that utilizes this mechanical ventilation object in conjunction with an outdoor air controller. The model automatically determines the total zone floor area based on the Zone object(s), the zone and zone list multipliers (Zone and ZoneGroup objects), and the air loop connections to the occupied zones.

Field: Ventilation Rate per Occupant <x>

The numeric input for this field is the volumetric air flow rate ($\text{m}^3/\text{sec}\cdot\text{person}$) of outdoor air to be delivered per occupant. This field helps establish the minimum outdoor air flow that is provided by the air loop that utilizes this mechanical ventilation object in conjunction with an outdoor air controller. The model automatically determines the total number of occupants based on the People object(s), the zone and zone list multipliers (Zone and ZoneGroup objects), and the air loop connections to the occupied zones.

Field: Zone Air Distribution Effectiveness in Cooling Mode <x>

The positive numeric input for this field is the zone air distribution effectiveness when the zone is in cooling mode. ASHRAE Standard 62.1-2007 provides typical values.

Field: Zone Air Distribution Effectiveness in Heating Mode <x>

The positive numeric input for this field is the zone air distribution effectiveness when the zone is in heating mode. ASHRAE Standard 62.1-2007 provides typical values as follows:

Zone Air Distribution Effectiveness

Air Distribution Configuration	E_z
Ceiling supply of cool air	1.0
Ceiling supply of warm air and floor return	1.0
Ceiling supply of warm air 15°F (8°C) or more above space temperature and ceiling return.	0.8
Ceiling supply of warm air less than 15°F (8°C) above space temperature and ceiling return provided that the 150 fpm (0.8 m/s) supply air jet reaches to within 4.5 ft (1.4 m) of floor level. Note: For lower velocity supply air, $E_z = 0.8$.	1.0
Floor supply of cool air and ceiling return provided that the 150 fpm (0.8 m/s) supply jet reaches 4.5 ft (1.4 m) or more above the floor. Note: Most underfloor air distribution systems comply with this proviso.	1.0
Floor supply of cool air and ceiling return, provided low-velocity displacement ventilation achieves unidirectional flow and thermal stratification	1.2
Floor supply of warm air and floor return	1.0
Floor supply of warm air and ceiling return	0.7

Figure 116. Controller:MechanicalVentilation Zone Air Distribution Effectiveness (Source: ASHRAE Standard 62.1-2007)

Field: Zone Air Distribution Effectiveness Schedule Name <x>

This optional field input points to a schedule with values of zone air distribution effectiveness. It provides a more flexible way of specifying zone air distribution effectiveness if it changes with time and/or system operating status and controls. If the schedule is specified, the zone air distribution effectiveness in cooling mode and heating mode will be ignored.

As described previously, the Controller:MechanicalVentilation object works in conjunction with Controller:OutdoorAir. As such, the minimum quantity of outdoor air delivered via the mixed air box will be the greater of:

- the minimum outdoor air flow rate calculated by the fields Minimum Outdoor Air Flow Rate, Minimum Limit and Minimum Outdoor Air Schedule Name in the associated Controller:OutdoorAir object, or
- the outdoor air flow rate calculated by the VRP (details in the Engineering Reference) with inputs specified in this object.

The actual outdoor air flow rate may be higher than the minimum if free cooling is available. Regardless, the outdoor air flow rate will not exceed the Maximum Outdoor Air Flow Rate specified in the associated Controller:OutdoorAir object.

The full IDD specification follows:

Controller:MechanicalVentilation,

```

\memo This object is used in conjunction with Controller:OutdoorAir to specify outdoor
\memo ventilation air based on flow rate per unit floor area and flow rate per person.
\memo The Controller:OutdoorAir object is associated with a specific air loop, so the
\memo outdoor air flow rates specified in Controller:MechanicalVentilation correspond to the zones
\memo attached to that specific air loop.

ZoneHVAC:EnergyRecoveryVentilator:Controller

This controller object is used exclusively by the stand alone energy recovery ventilator (ZoneHVAC:EnergyRecoveryVentilator, see Figure 117). The purpose of this controller is to simulate economizer operation for the stand alone ERV and provide free cooling whenever possible or modify the outdoor air flow rate during high indoor humidity conditions. During economizer operation, if all of the limits are satisfied, the controller activates economizer mode (fully bypassing the fixed-plate air-to-air heat exchanger or stopping the rotation of a rotary heat exchanger). If any of the selected limits are exceeded, economizer operation is terminated. A time-of-day schedule may also be used to simulate a “push-button” type economizer controller.

In addition, the outdoor air flow rate may be modified and heat exchange suspended in response to high indoor relative humidities. When the indoor relative humidity exceeds the zone humidistat’s relative humidity set point, high humidity control is activated. When activated, if high humidity control is based on the outdoor air humidity ratio and the outdoor humidity ratio is greater than the indoor humidity ratio, high humidity control is terminated.

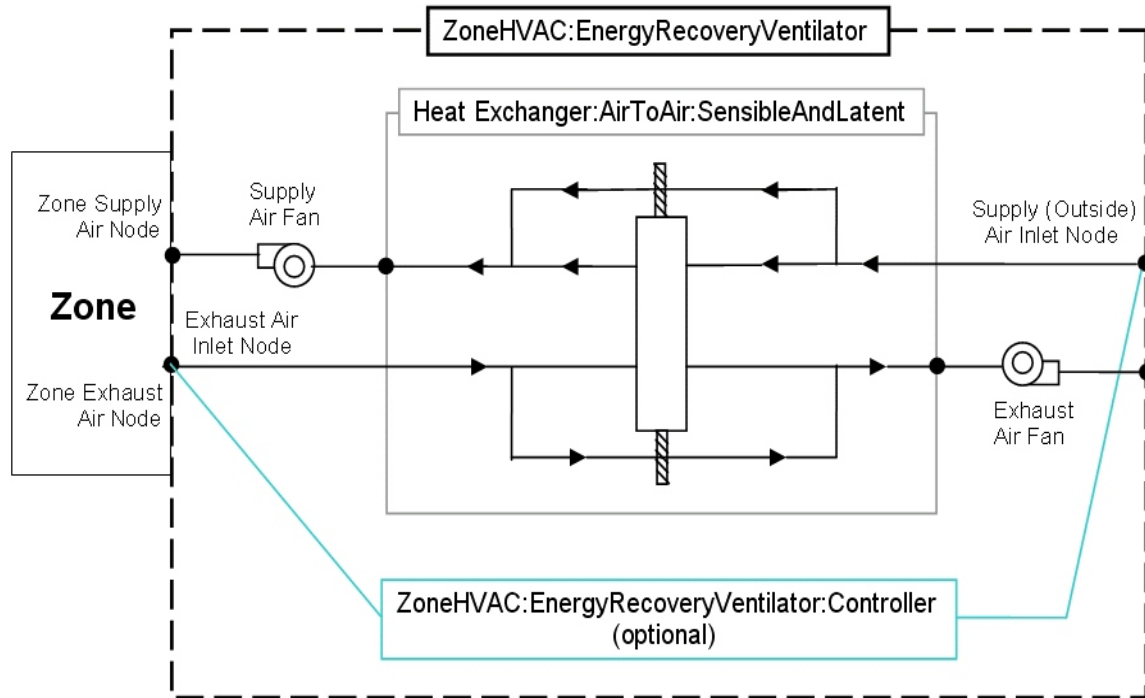

Figure 117. Schematic of the ZoneHVAC:EnergyRecoveryVentilator compound object

Field: Name

A unique user-assigned name for the stand alone ERV controller. Any reference to this controller by another object will use this name.

Field: Temperature High Limit

The input for this field is the outdoor air temperature high limit ($^{\circ}\text{C}$) for economizer operation. If the outdoor air temperature is above this limit, economizer (free cooling) operation is terminated. No input (blank) in this field means that there is no outdoor air temperature high limit control.

Field: Temperature Low Limit

The input for this field is the outdoor air temperature low limit ($^{\circ}\text{C}$) for economizer operation. If the outdoor air temperature is below this limit, economizer (free cooling) operation is terminated. No input (blank) in this field means that there is no outdoor air temperature low limit control.

Field: Enthalpy High Limit

The input for this field is the outdoor air enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, economizer (free cooling) operation is terminated. No input (blank) in this field means that there is no outdoor air economizer limit control.

Field: Dewpoint Temperature Limit

Input for this field is the outdoor air dewpoint limit ($^{\circ}\text{C}$) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. No input (blank) in this field means that there is no outdoor air dewpoint limit control. This limit applies to the conditions at the Actuated Node regardless of whether or not there are any other components on the outdoor air path upstream of the mixer.

Field: Electronic Enthalpy Limit Curve Name

Input for this field is the name of a quadratic or cubic curve which provides the maximum outdoor air humidity ratio (function of outdoor air dry-bulb temperature) for economizer operation. If the outdoor air humidity ratio is greater than the curve's maximum humidity ratio (evaluated at the outdoor air dry-bulb temperature), the outdoor air flow rate will be set to the minimum. This limit applies to the conditions at the Actuated Node regardless of whether or not there are any other components on the outdoor air path upstream of the mixer. No input (blank) in this field means that there is no electronic enthalpy limit control.

Field: Exhaust Air Temperature Limit

This input establishes whether or not there is a limit control on the exhaust air temperature. The choices are **ExhaustAirTemperatureLimit** or **NoExhaustAirTemperatureLimit**. If **ExhaustAirTemperatureLimit** is chosen, the controller deactivates economizer mode whenever the outdoor air temperature is greater than the exhaust air temperature. If **NoExhaustAirTemperatureLimit** is chosen, no limit check on the exhaust air temperature is performed.

Field: Exhaust Air Enthalpy Limit

This input establishes whether or not there is a limit control on the exhaust air enthalpy. The choices are **ExhaustAirEnthalpyLimit** or **NoExhaustAirEnthalpyLimit**. If **ExhaustAirEnthalpyLimit** is chosen, the controller deactivates economizer mode whenever the outdoor air enthalpy is greater than the exhaust air enthalpy. If **NoExhaustAirEnthalpyLimit** is chosen, no limit check on the exhaust air enthalpy is performed.

Field: Time of Day Economizer Flow Control Schedule Name

This alpha field is the name of a schedule which controls the change in air flow rate based on time-of-day. Schedule values equal to 0 disable this feature. Schedule values greater than 0 activate the economizer. Note that heat exchange between the air streams is suspended when the economizer is active. This schedule can be used with or without the high humidity control option. When an economizer is used in conjunction with the high humidity control option, high humidity control has priority.

Field: High Humidity Control Flag

This optional choice field establishes whether or not the supply and exhaust air flow rates are modified in response to high indoor relative humidity. Valid choices are Yes and No. If Yes is selected, the supply and exhaust air flow rates may be modified when the indoor relative humidity is above the humidstat set point. If No is selected, this option is disabled and the following three fields are not used. Note that heat exchange between the air streams is suspended during times when high humidity control is active. The default value is No.

Field: Humidistat Control Zone Name

This optional input defines the zone name where the humidistat is located. This is the same zone name used in the Zone Control:Humidistat object. This field is required when the High Humidity Control Flag is specified as Yes.

Field: High Humidity Outdoor Air Flow Ratio

This optional input is the ratio of the modified supply (outdoor) air flow rate to the supply air flow rate specified in the Energy Recovery Ventilator:Stand Alone ERV object. When the high humidity control algorithm determines that the supply air flow rate will be changed (i.e. increased or decreased), the operating supply air flow rate is equal to the supply air flow rate specified in the Energy Recovery Ventilator:Stand Alone ERV object multiplied by this ratio. The minimum value for this field is 0. This field is used to modify both the supply and exhasut air flow rates when high humidity control is active. The supply and exhasut air fan volumetric

flow rates must be able to account for the increase in air flow when this input is greater than 1. The default value is 1.

Field: Control High Indoor Humidity based on Outdoor Humidity Ratio

This optional choice field determines if high humidity control is activated based on high indoor relative humidity alone or is activated only when the indoor relative humidity is above the humidstat set point *and* the outdoor humidity ratio is less than the indoor humidity ratio. Valid choices are Yes and No. If No is selected, high humidity control is active any time the zone humidstat senses a moisture load. If yes is selected, the model also verifies that the outdoor humidity ratio is less than the humidstat's zone air humidity ratio. This field is used only when the High Humidity Control Flag is specified as Yes. The default value is Yes.

The full IDD specification follows:

Group – Evaporative Coolers

This group of objects describes the properties and configuration for the evaporative coolers models for the HVAC section.

EvaporativeCooler:Direct:CelDekPad

The direct stage, shown in the figure below, consists of a rigid media evaporative pad, with water recirculated from a reservoir. The water is pumped from the reservoir to a water distribution header, for water feed by gravity from above the media. The evaporative pad

provides the area for the adiabatic saturation of the air. While the process provides a lower dry-bulb temperature, the moisture content of the leaving air is higher than the entering condition. The direct stage is used for comfort cooling in a building where adding humidity to the air can be tolerated.

Figure 118. Direct Stage Evaporative Cooler

The thermodynamic process is a simultaneous heat and mass transfer, or adiabatic cooling, and follows a constant enthalpy line on the psychrometric chart, it is shown in the figure below as a process from A to B. Since the deviation of the constant wet-bulb line and the constant enthalpy line is small, it is assumed that the wet-bulb temperature is constant across the direct evaporative stage.

Figure 119. Psychrometric Chart -- Constant Enthalpy

If the direct evaporative process were 100% efficient, the leaving dry-bulb temperature would equal the entering wet-bulb temperature. The efficiency of the direct evaporative process is less than 100% and by defining saturation efficiency (ϵ_{se}) for the direct stage or evaporative pad, the leaving dry-bulb temperature can be expressed by the following equation.

$$T_{db\,supout} = T_{db\,supin} - \epsilon_{se} \cdot (T_{db\,supin} - T_{wb\,supin})$$

Field: Name

A unique identifying name for each evaporative cooler.

Field: Availability Schedule Name

The name of a schedule which defines when the evaporative cooler is available.

Field: Direct Pad Area

The face area of the evaporative pad in m². With the area and mass flow rate, the air velocity is calculated and is used to determine the saturation efficiency.

Field: Direct Pad Depth

The depth of the evaporative pad in meters. The pad depth is used to determine the saturation efficiency.

Field: Recirculating Water Pump Power Consumption

This field is used to specify the power consumed by the evaporative cooler recirculating pump in Watts.

Field: Air Inlet Node Name

The name of the evaporative cooler air inlet node from the Air Loop Simulation.

Field: Air Outlet Node Name

The name of the evaporative cooler air outlet node from the Air Loop Simulation.

Field: Control Type

This input field is currently unused and can be left blank.

Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a WaterUse:Storage object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

```

EvaporativeCooler:Direct:CeIDekPad Outputs

The output variables that are available for this direct evaporative cooler are shown below:

```

HVAC,Average, Direct Evap Saturation Efficiency
HVAC,Average, Evap Cooler Electric Power[W]
HVAC,Sum, Evap Cooler Electric Energy[J]
HVAC,Sum, Evap Cooler Water Consumption[m3]
HVAC,Sum,Evap Cooler Mains Water Mains Draw [m3]
HVAC,Sum,Evap Cooler Tank Water Consumption [m3]
HVAC,Sum,Evap Cooler Starved Water Consumption [m3]
HVAC,Sum,Evap Cooler Starved Water Mains Draw [m3]

```

Direct Evap Saturation Efficiency

The saturation efficiency is the temperature change of the supply air divided by the difference between the inlet air dry-bulb and wet-bulb temperatures. In other words, it is a measure of the approach to the inlet air wet-bulb temperature.

Evap Cooler Electric Power[W]

Evap Cooler Electric Energy[J]

These output variables report the electric power and electric energy required to operate the water pump.

Evap Cooler Water Consumption [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Mains Water Mains Draw [m3]

This is the source of the water consumed. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Tank Water Consumption [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Consumption [m3]

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Mains Draw [m3]

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

EvaporativeCooler:Direct:ResearchSpecial

This cooler is similar in principal to the EvaporativeCooler:Direct:CelDekPad. The model differs in that it gives the user a simple way of specify the cooler effectiveness. Using the ResearchSpecial input object also allows the cooler to control the amount of cooling based on node setpoints (controlled by SetpointManagers). This avoid problems from over cooling when conditions are such that loads are low and cooling power is high. Water pump power is assumed to vary linearly when the cooler is operating at less than full capacity.

Field: Name

A unique identifying name for each cooler.

Field: Availability Schedule Name

The name of a schedule that defines when the evaporative cooler is available.

Field: Cooler Effectiveness

This field specifies the effectiveness that is applied to the wetbulb depression to determine the conditions leaving the cooler. This model assumes that the effectiveness is constant.

Field: Recirculating Water Pump Power Consumption

This field is used to specify the power consumed by the water pump that circulates water in Watts.

Field: Air Inlet Node Name

The name of the air inlet node for the primary air flow path through the cooler.

Field: Air Outlet Node Name

The name of the air outlet node for the primary air flow path through the cooler.

Field: Sensor Node Name

This field specifies the name of a node that will provide system air temperature setpoint information. A separate SetpointManager object should be setup to update this node.

Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a WaterUse:Storage object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

Field: Drift Loss Fraction

This field is optional and can be used to model additional water consumed by the cooler from drift. Drift is water that leaves the cooling media as droplets and does not evaporate into the process air stream. For example, water may get blown off the evaporative media by winds and escape the air system. The value entered here is a simple fraction of the water consumed by the cooler for normal process evaporation. The amount of drift is this fraction times the water evaporated for the normal cooling process. This field can be left blank and then there will be no added water consumption from drift.

Field: Blowdown Concentration Ratio

This field is optional and can be used to model additional water consumed by the cooler from blowdown. Blowdown is water that is intentionally drained from the cooler's sump to offset the build up of solids in the water that would otherwise occur because of evaporation. The

value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values are 3 to 5. The default is 3.0.

The IDD entry for this model is.

Evap Cooler Electric Power[W]

Evap Cooler Electric Energy[J]

These output variables report the electric power and electric energy required to operate the water pump.

Evap Cooler Water Consumption [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Mains Water Mains Draw [m3]

This is the source of the water consumed. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Tank Water Consumption [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Consumption [m3]

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Mains Draw [m3]

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

EvaporativeCooler:Indirect:CelDekPad

The dry coil indirect evaporative cooler, shown in the figure below, has a rigid media pad, similar to the direct evaporative stage, where the adiabatic cooling takes place. The secondary air leaves the rigid media pad and enters an air to air heat exchanger where it cools the supply air flowing through the heat exchanger tubes. The moist secondary air is then exhausted to the environment. The secondary air stream has its own fan and consists of a rigid media evaporative pad, with water recirculated from a reservoir. The water is pumped from the reservoir to a water distribution header, for water feed by gravity from above the media. The evaporative pad provides the area for the adiabatic saturation of the air.

Figure 120. Evaporative Cooler -- Indirect Dry Coil

The process that the secondary air goes through, A to C to D, is shown by the dashed lines in the following figure. Process A to C is adiabatic cooling in the rigid media pad. Then the air enters the shell side of the heat exchanger and is sensibly heated from C to D by the warm supply air passing through the tube side. The secondary air inlet is modeled as a separate stream of outdoor air and the user has the option of defining the name of an outdoor air node.

Figure 121. Secondary Air Process -- Indirect Dry Coil Evap Cooler

The advantage of the dry coil heat exchanger is that the heat exchanger does not have the evaporation taking place on the outside of the tubes, thus no mineral deposits are left on the heat exchange surface to reduce the efficiency of the heat exchanger. The rigid media pads are designed to flush the mineral deposits to the sump, so the saturation efficiency of the pad stays relatively constant.

Field: Name

A unique identifying name for each evaporative cooler.

Field: Availability Schedule Name

The name of a schedule which defines when the evaporative cooler is available.

Field: Direct Pad Area

The face area of the evaporative pad in m². With the area and mass flow rate, the air velocity is calculated and is used to determine the saturation efficiency on the secondary side of the evaporative cooler.

Field: Direct Pad Depth

The depth of the evaporative pad in meters. The pad depth is used to determine the saturation efficiency on the secondary side of the evaporative cooler.

Field: Recirculating Water Pump Power Consumption

This field is used to specify the power consumed by the evaporative cooler recirculating pump in Watts.

Field: Secondary Fan Flow Rate

This field is used to specify the secondary fan flow rate and is specified in m³/sec.

Field: Secondary Fan Efficiency

This field is used to specify the efficiency of the fan and is used to calculate the power consumed by the evaporative cooler secondary fan. Input values should be > 0.0 and <= 1.0.

Field: Secondary Fan Delta Pressure

This field is used to specify the delta pressure across the secondary stage of the evaporative cooler in Pascals.

Field: Indirect Heat Exchanger Effectiveness

This field is used to specify the effectiveness of the indirect heat exchanger between the primary and secondary air flow.

Field: Primary Air Inlet Node Name

The name of the evaporative cooler's primary air inlet node from the Air Loop Simulation. This is the air flow being cooled indirectly.

Field: Primary Air Outlet Node Name

The name of the evaporative cooler's primary air outlet node from the Air Loop Simulation.

Field: Control Type

This input field is currently unused and can be left blank.

Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a WaterUse:Storage object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

Field: Secondary Air Inlet Node Name

This field is optional. It is used to explicitly define an outdoor air node for the inlet for secondary air stream. Defining an outdoor air node here allows using the height-dependent model for outdoor air conditions.

EvaporativeCooler:Indirect:CelDekPad Outputs

The output variables that are available for the indirect dry evaporative cooler are shown below:

HVAC,Average, Indirect Dry Evap Saturation Efficiency
HVAC,Average, Indirect Dry Evap Total Stage Efficiency
HVAC,Average, Evap Cooler Electric Power[W]
HVAC,Sum, Evap Cooler Electric Energy[J]
HVAC,Sum, Evap Cooler Water Consumption[m3]
HVAC,Sum,Evap Cooler Mains Water Mains Draw [m3]
HVAC,Sum,Evap Cooler Tank Water Consumption [m3]
HVAC,Sum,Evap Cooler Starved Water Consumption [m3]
HVAC,Sum,Evap Cooler Starved Water Mains Draw [m3]

Indirect Dry Evap Saturation Efficiency

The dry evaporation saturation efficiency is the saturation efficiency of the secondary or wet side air stream defined as the temperature change of the supply air divided by the difference between the outdoor dry-bulb and wet-bulb temperatures. In other words, it is a measure of the approach to the outdoor wet-bulb temperature.

Indirect Dry Evap Total Stage Efficiency

The total stage efficiency includes the sensible heat exchanger effectiveness of the heat exchanger in the supply air stream. It is the saturation efficiency multiplied by the heat exchanger effectiveness.

Evap Cooler Electric Power[W]

Evap Cooler Electric Energy[J]

These output variables report the electric power and energy consumed by the secondary air fan and the sump pump.

Evap Cooler Water Consumption[m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Mains Water Mains Draw [m3]

This is the source of the water consumed. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Tank Water Consumption [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Consumption [m3]

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Mains Draw [m3]

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

EvaporativeCooler:Indirect:WetCoil

The wetted coil evaporative cooler shown in the figure below, has water sprayed directly on the tubes of the heat exchanger where latent cooling takes place. The vaporization of the water on the outside of the heat exchanger tubes allows the simultaneous heat and mass

transfer which removes heat from the supply air on the tube side. Then the moist secondary air is exhausted. The secondary air stream has its own fan.

Figure 122. Evaporative Cooler – Indirect Wet Coil

The process that the secondary air goes through, A to C on the following figure, is a path of simultaneous heat and mass transfer, but it does not follow a line of constant enthalpy as in the direct stage. The process is not adiabatic due to the heat gain from the supply air flowing through the tubes of the heat exchanger.

Figure 123. Secondary Air Process – Indirect Wet Coil Evap Cooler

The wet coil heat exchanger can have a higher stage efficiency than the dry coil due to a higher heat transfer rate on the outside of the heat exchanger tubes. Over the operating lifetime of the heat exchanger, the vaporization taking place on the heat exchange surface can leave mineral deposits which will decrease the effectiveness of the heat exchanger.

Field: Name

A unique identifying name for each evaporative cooler.

Field: Availability Schedule Name

The name of a schedule which defines when the evaporative cooler is available.

Field: Coil Maximum Efficiency

The maximum efficiency of the stage is a combination of the efficiency due to the simultaneous heat and mass transfer on the outside of the tube and the efficiency of the heat

exchanger. This value can be higher than the dry coil overall efficiency since the convective coefficients on the outside of the tube are larger.

Field: Coil Flow Ratio

The Coil Flow Ratio is determined from performance data. The Coil Flow Ratio tells how quickly the efficiency of the stage would decrease with a mismatch of the supply and secondary flows.

Field: Recirculating Water Pump Power Consumption

This field is used to specify the power consumed by the evaporative cooler recirculating pump in Watts.

Field: Secondary Fan Flow Rate

This field is used to specify the secondary fan flow rate and is specified in m³/sec.

Field: Secondary Fan Efficiency

This field is used to specify the efficiency of the fan and is used to calculate the power consumed by the evaporative cooler secondary fan. Input values should be > 0.0 and <= 1.0.

Field: Secondary Fan Delta Pressure

This field is used to specify the delta pressure across the secondary stage of the evaporative cooler in Pascals.

Field: Primary Air Inlet Node Name

The name of the evaporative cooler air inlet from the Air Loop Simulation.

Field: Primary Air Outlet Node Name

The name of the evaporative cooler air outlet from the Air Loop Simulation.

Field: Control Type

This input field is currently unused and can be left blank.

Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a WaterUse:Storage object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

Field: Secondary Air Inlet Node Name

This field is optional. It is used to explicitly define an outdoor air node for the inlet for secondary air stream. Defining an outdoor air node here allows using the height-dependent model for outdoor air conditions.

Field: Drift Loss Fraction

This field is optional and can be used to model additional water consumed by the cooler from drift. Drift is water that leaves the cooling media as droplets and does not evaporate into the process air stream. For example, water may get blown off the evaporative media by winds and escape the air system. The value entered here is a simple fraction of the water consumed by the cooler for normal process evaporation. The amount of drift is this fraction times the water evaporated for the normal cooling process. This field can be left blank and then there will be no added water consumption from drift.

Field: Blowdown Concentration Ratio

This field is optional and can be used to model additional water consumed by the cooler from blowdown. Blowdown is water that is intentionally drained from the cooler's sump to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values are 3 to 5. The default is 3.0.

EvaporativeCooler:Indirect:WetCoil Outputs

The output variables that are available for the wet indirect evaporative cooler are shown below:

```

HVAC,Average, Indirect Wet Evap Total Stage Efficiency
HVAC,Average, Evap Cooler Electric Power[W]
HVAC,Sum, Evap Cooler Electric Energy[J]
HVAC,Sum, Evap Cooler Water Consumption[m3]
HVAC,Sum,Evap Cooler Mains Water Mains Draw [m3]
HVAC,Sum,Evap Cooler Tank Water Consumption [m3]
HVAC,Sum,Evap Cooler Starved Water Consumption [m3]
HVAC,Sum,Evap Cooler Starved Water Mains Draw [m3]

```

Indirect Wet Evap Total Stage Efficiency

The Total Stage Efficiency is defined as the temperature change of the supply air divided by the difference between the outdoor dry-bulb and wet-bulb temperatures, including the effect of the reduction in flow because of the secondary air stream. In other words, it is a measure of the approach to the outdoor wet-bulb temperature.

Evap Cooler Electric Power[W]

Evap Cooler Electric Energy[J]

These output variables report the electric power and energy that are consumed by the secondary air fan and the sump pump.

Evap Cooler Water Consumption[m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Mains Water Mains Draw [m3]

This is the source of the water consumed. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Tank Water Consumption [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Consumption [m3]

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Mains Draw [m3]

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

EvaporativeCooler:Indirect:ResearchSpecial

This cooler is similar in principal to the EvaporativeCooler:Indirect:CelDekPad and EvaporativeCooler:Indirect:WetCoil (see Figure 121, Figure 122, and Figure 123). The model differs in that it gives the user more flexibility to specify the source of secondary air. The cooler effectiveness with respect to wetbulb depression is allowed to go beyond 1.0. Using the ResearchSpecial input object also allows the cooler to control the amount of cooling based on node setpoints (controlled by SetpointManagers). This avoids problems from over cooling when conditions are such that loads are low and cooling power is high. Fan power is assumed to vary linearly when the cooler is operating at less than full capacity.

Field: Name

A unique identifying name for each cooler.

Field: Availability Schedule Name

The name of a schedule that defines when the evaporative cooler is available.

Field: Cooler Maximum Effectiveness

This field specifies the maximum effectiveness that is applied to the wetbulb depression to determine the conditions leaving the cooler. This effectiveness is a complicated function of the efficiency with which heat and mass are transferred on the secondary side and the efficiency of heat exchange between the secondary and primary flows. The model assumes that the effectiveness is constant.

Field: Cooler Flow Ratio

Not used in this model.

Field: Recirculating Water Pump Power Consumption

This field is used to specify the power consumed by the water pump that circulates water in Watts. The pump power and energy consumption is reduced by cycling when the amount of cooling needs to be restricted for control purposes.

Field: Secondary Fan Flow Rate

This field is used to specify the secondary fan flow rate and is specified in m^3/s . This flow rate would typically be similar in magnitude to the flow through the primary side. This field can be autosized. When it is autosized, the program detects if the component is in the main air loop or on an outdoor air path. If it is on the main air loop, then the flow rate is set to the AirLoopHVAC system's design supply air flow rate (which is the maximum required for heating and cooling). If it is on the outdoor air path, then the flow rate is set to the larger of either the design minimum outdoor air flow rate or one-half of the main air loop design flow rate. The flow rate is used to determine parasitic fan energy and does not impact the modeling of cooler effectiveness. The flow rate (and fan power) is effectively reduced by cycling when the amount of cooling needs to be restricted for control purposes.

Field: Secondary Fan Efficiency

This field is used to specify the total efficiency for the secondary fan. This efficiency is used to calculate the energy use for the secondary fan and should be a value >0.0 and ≤ 1.0 .

Field: Secondary Fan Delta Pressure

This field is used to specify the pressure difference in Pascals experienced by the secondary fan as it moves air through the wet side of the cooler.

Field: Primary Air Inlet Node Name

The name of the air inlet node for the primary air flow path through the cooler.

Field: Primary Air Outlet Node Name

The name of the air outlet node for the primary air flow path through the cooler.

Field: Control Type

This input field is not used by this model. But using this model does implement controlling of the primary outlet temperature.

Field: Dewpoint Effectiveness Factor

This field specifies an effectiveness that is applied to the dewpoint depression to determine a bound for the conditions leaving the cooler. The model uses the warmer of the two temperatures determined from wetbulb depression and dewpoint depression.

Field: Secondary Air Inlet Node Name

This field specifies the name of the node providing air to the secondary/wet side of the cooler. Typically this node could appear in an outdoor air node list or be part of an air system loop.

Field: Sensor Node Name

This field specifies the name of a node that will provide system air temperature setpoint information. A separate SetpointManager object should be setup to update this node.

Field: Relief Air Inlet Node Name

This field is optional, but can be used to feed two sources of secondary air into the wet side of the cooler. Typical use is to run the air system relief air into the system. The model first uses all of the air flow available from this node and then adds the air flow from the secondary air inlet node to make up the total defined by Secondary Fan Flow Rate.

Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooler obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a WaterUse:Storage object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the cooler will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains.

Field: Drift Loss Fraction

This field is optional and can be used to model additional water consumed by the cooler from drift. Drift is water that leaves the cooling media as droplets and does not evaporate into the process air stream. For example, water may get blown off the evaporative media by winds and escape the air system. The value entered here is a simple fraction of the water consumed by the cooler for normal process evaporation. The amount of drift is this fraction times the water evaporated for the normal cooling process. This field can be left blank and then there will be no added water consumption from drift.

Field: Blowdown Concentration Ratio

This field is optional and can be used to model additional water consumed by the cooler from blowdown. Blowdown is water that is intentionally drained from the cooler's sump to offset the build up of solids in the water that would otherwise occur because of evaporation. The

value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values are 3 to 5. The default is 3.0.

Indirect Wet Evap Total Stage Efficiency

The Total Stage Efficiency is defined as the temperature change of the supply air divided by the difference between the outdoor dry-bulb and wet-bulb temperatures, including the effect of the reduction in flow because of the secondary air stream. In other words, it is a measure of the approach to the outdoor wet-bulb temperature.

Indirect Wet Evap Part Load Fract

This report variable provides the part load fraction of the indirect cooler. The ResearchSpecial cooler model is able to modulate to meet a temperature set point to avoid over cooling. This report variable is the fraction formed by the ratio of the capacity needed over the maximum cooling capacity available. A value of 1.0 corresponds to full capacity cooling.

IEC RDDSpecial Dewpoint Bound

This report variable is a flag that indicates if the modeling was based on dewpoint effectiveness rather than wetbulb effectiveness. The ResearchSpecial model is usually based on wet-bulb approach, but since values in excess of 1.0 are allowed, there is a secondary constraint imposed by dewpoint. If the dewpoint effectiveness was applied, then this flag variable will have the value 1.0, otherwise it is 0.0.

Evap Cooler Electric Power[W]

Evap Cooler Electric Energy[J]

These output variables report the electric power and energy that are consumed by the secondary air fan and the sump pump.

Evap Cooler Water Consumption[m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources

of consumption such as drift or concentration blow down. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Mains Water Mains Draw [m3]

This is the source of the water consumed. This report variable appears when mains water is supplied to the cooler.

Evap Cooler Tank Water Consumption [m3]

The water consumption is the water evaporated from the pad. This water consumption is only from the direct thermodynamics of water evaporation and does not include other sources of consumption such as drift or concentration blow down. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Consumption [m3]

This is the water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

Evap Cooler Starved Water Mains Draw [m3]

This is the source (mains) of water consumed by the evaporative cooler that could not actually be met by the storage tank. This report variable appears when storage tank water is supplied to the cooler.

Group – Heat Recovery

HeatExchanger:AirToAir:FlatPlate

The air-to-air flat plate heat exchanger is an HVAC component typically used for exhaust or relief air heat recovery. The user can choose the flow arrangement type: counter flow, parallel flow, or cross flow with both streams unmixed. The input requires no geometric data. Performance is defined by specifying primary outlet air temperature at nominal (user specified) inlet conditions. In addition, the ratio $(hA)_p / (hA)_s$ at nominal flow needs to be input, where h is the convective heat transfer coefficient, A is the surface area, p stands for primary side, s for secondary side.

If the heat exchanger is operated in conjunction with an outdoor air economizer (economizer lockout set to Yes), the nominal supply air flow rate should be set equal to the minimum outdoor air flow rate specified in the Controller:OutdoorAir. The heat exchanger detects that the economizer is operating by the fact that its inlet air flow rate is greater than its nominal supply air flow rate.

Field: Name

A unique user-assigned name for a particular air-to-air flat plate heat exchanger unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Flow Arrangement Type

The user specified flow arrangement of the heat exchanger. The possible inputs are *CounterFlow*, *ParallelFlow*, or *CrossFlowBothUnmixed*.

Field: Economizer Lockout

This input denotes whether the heat exchanger unit is locked out (bypassed) when the air-side economizer is operating. Both the economizer and high humidity control (Ref. Controller:OutdoorAir) activate the heat exchanger lockout as specified by this input. The input choices are *Yes* (meaning locked out) or *No*. The default input for this field is *Yes*.

Field: Ratio of Supply to Secondary hA Values

The ratio $(hA)_p / (hA)_s$ at nominal flow. h is the surface convective heat transfer coefficient, A is the heat transfer area, and p and s stand for primary side and secondary side respectively. A typical value for this ratio is 1.0.

Field: Nominal Supply Air Flow Rate

The nominal primary side air flow rate in cubic meters per second. If the unit is operated in conjunction with an outdoor air economizer this should be equal to the minimum outdoor air flow rate.

Field: Nominal Supply Air Inlet Temperature

The nominal primary side air inlet temperature in Celsius.

Field: Nominal Supply Air Outlet Temperature

The nominal primary side air outlet temperature in Celsius.

Field: Nominal Secondary Air Flow Rate

The nominal secondary side air flow rate in cubic meters per second.

Field: Nominal Secondary Air Inlet Temperature

The nominal secondary side air inlet temperature in Celsius.

Field: Nominal Electric Power

The electric consumption rate of the unit in watts. Electric power is considered constant whenever the unit operates. This input can be used to model electric power consumption by controls (transformers, relays, etc.) and/or a motor for a rotary heat exchanger. None of this electric power contributes thermal load to the supply or exhaust air streams. The default value for this field is 0.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary inlet air.

Field: Supply Air Outlet Node Name

The name of the HVAC system node to which the unit sends its primary outlet air.

Field: Secondary Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary inlet air.

Field: Secondary Air Outlet Node Name

The name of the HVAC system node to which the unit sends its secondary outlet air.

Heat Exchanger Sensible Heating Rate [W]

This output is the sensible heating rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, the supply air inlet and outlet conditions, and the specific heat of the inlet supply air. A positive value is reported if the supply air is heated by the heat exchanger, else the rate is set to zero.

Heat Exchanger Sensible Heating Energy [J]

This output is the sensible heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Latent Heating Rate [W]

This output is the latent heating rate (humidification) of the supply air by the heat exchanger in Watts. This rate is determined by taking the difference between the Heat Exchanger Total Heating Rate and the Heat Exchanger Sensible Heating Rate. A positive value is reported if the supply air is humidified by the heat exchanger, else the rate is set to zero.

Heat Exchanger Latent Heating Energy [J]

This output is the latent heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Total Heating Rate [W]

This output is the total heating rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, and the enthalpy of the supply air entering and leaving the unit. A positive value is reported if the enthalpy of the supply air is increased by the heat exchanger, else the rate is set to zero.

Heat Exchanger Total Heating Energy [J]

This output is the total heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported. This output is also added to a report meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforHeating, GroupKey = System (ref. Report Meter).

Heat Exchanger Sensible Cooling Rate [W]

This output is the sensible cooling rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, the supply air inlet and outlet conditions, and the specific heat of the inlet supply air. A positive value is reported if the supply air is cooled by the heat exchanger, else the rate is set to zero.

Heat Exchanger Sensible Cooling Energy [J]

This output is the sensible cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Latent Cooling Rate [W]

This output is the latent cooling rate (dehumidification) of the supply air by the heat exchanger in Watts. This rate is determined by taking the difference between the Heat Exchanger Total Cooling Rate and the Heat Exchanger Sensible Cooling Rate. A positive value is reported if the supply air is dehumidified by the heat exchanger, else the rate is set to zero.

Heat Exchanger Latent Cooling Energy [J]

This output is the latent cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Total Cooling Rate [W]

This output is the total cooling rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, and the enthalpy of the supply air entering and leaving the unit. A positive value is reported if the enthalpy of the supply air is decreased by the heat exchanger, else the rate is set to zero.

Heat Exchanger Total Cooling Energy [J]

This output is the total cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported. This output is also added to a report meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforCooling, GroupKey = System (ref. Report Meter).

Heat Recovery Electric Power [W]

This output is the electric consumption rate of the unit in Watts. This rate is applicable whenever the unit operates (i.e., whenever the unit is scheduled to be available and supply and exhaust air flows exist).

Heat Recovery Electric Consumption [J]

This output is the electric consumption of the unit in Joules for the timestep being reported. This output is also added to a report meter with ResourceType = Electricity, EndUseKey = HeatRecovery, GroupKey = System (ref. Report Meter).

HeatExchanger:AirToAir:SensibleAndLatent

The sensible and latent air-to-air heat exchanger is an HVAC component typically used for exhaust or relief air heat recovery (Figure 124). Heat exchanger performance can be specified to transfer sensible energy, latent energy or both between the supply and exhaust air streams. The input requires no geometric data. Performance is defined by specifying sensible and/or latent effectiveness at 75% and 100% of the nominal (rated) supply air flow rate at two operating conditions as shown in Table 27.

Figure 124. Schematic of the Sensible and Latent Air-to-Air Heat Exchanger

Table 27. Operating Conditions for Defining Heat Exchanger Performance

Parameter	Conditions	
	Heating	Cooling
Entering supply air temperature:		
Dry-bulb	1.7°C (35°F)	35°C (95°F)
Wet-bulb	0.6°C (33°F)	26°C (78°F)
Entering exhaust air temperature:		
Dry-bulb	21°C (70°F)	24°C (75°F)
Wet-bulb	14°C (58°F)	17°C (63°F)

Note: Conditions consistent with the Air-Conditioning and Refrigeration Institute’s (ARI) Standard 1060-2001.

This object models the basic operation of an air-to-air heat exchanger. Heat exchange between the supply and exhaust air streams occurs whenever the unit is scheduled to be available (Availability schedule) and supply/exhaust air flow is present. This heat exchanger object can be used in conjunction with a conventional air-side economizer (i.e., specify `ModulateFlow` in the `Controller:OutdoorAir` object), whereby heat exchange is suspended whenever the air-side economizer (or high humidity control) is active (i.e., air flow is fully bypassed around a fixed-plate heat exchanger or the rotation of a rotary heat exchanger is stopped). This object is also able to suspend heat exchange for the purpose of providing free cooling operation in the absence of a conventional air-side economizer (i.e., specify `MinimumFlowWithBypass` in the `Controller:OutdoorAir` object).

During winter weather, humid exhaust air entering the heat exchanger can form frost on the cold heat exchanger surfaces, which can reduce air flow and the amount of energy recovery. Several methods are used to control or eliminate frost formation, and the following types can be modeled for this heat exchanger object: supply air preheat, minimum exhaust air temperature, exhaust air recirculation and exhaust only. For preheat frost control, a separate heating coil object must be placed in the supply inlet air stream to keep the air temperature above the frost threshold temperature. The other frost control types are modeled within this object itself (i.e., do not require a separate object to be defined) based on alpha and numeric inputs to this heat exchanger object.

Air-to-air heat exchangers are sometimes controlled to maintain a fixed supply air outlet temperature to avoid overheating. To model this control in EnergyPlus, a set point manager object is used to establish a temperature set point at the supply air outlet node of the heat exchanger. Wheel speed modulation or plate supply air bypass is used to control the supply air exiting conditions to this set point. The set point for supply air temperature control should be set at the minimum economizer temperature set point if an air-side economizer is also being used by the air system. If frost control and supply air outlet temperature control are used, frost control takes precedence over supply air temperature control (e.g., frost control defrost time fraction is determined as if wheel speed modulation or plate supply air bypass is not used).

To model a sensible and latent air-to-air heat exchanger located in an air loop, the input data file should include the following objects:

- AirLoopHVAC:OutdoorAirSystem
- Controller:OutdoorAir
- OutdoorAir:Mixer
- HeatExchanger:AirToAir:SensibleAndLatent
- Coil:Heating:Water, Coil:Heating:Electric or Coil:Heating:Gas (if preheat frost control is to be modeled)
- SetpointManager:Scheduled (if supply air outlet temperature control is used)

The sensible and latent air-to-air heat exchanger can also be used in a number of other applications, including conditioning outdoor ventilation air and supplying it directly to a zone without an air loop. See object ZoneHVAC:EnergyRecoveryVentilator for further details on this specific application.

A description of each input field for this object is provided below.

Field: Name

A unique user-assigned name for a particular sensible/latent air-to-air heat exchanger. Any reference to this heat exchanger by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can operate during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit will not operate (i.e., no heat exchange will take place).

Field: Nominal Supply Air Flow Rate

The nominal primary side (supply) air flow rate in cubic meters per second. The actual supply and exhaust air flow rates must be between 50% and 130% of this value or a warning will be issued.

Field: Sensible Effectiveness at 100% Heating Air Flow

The sensible heat exchange effectiveness at the *heating* condition defined in Table 27 above with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate specified in the previous input field. The default value for this field is 0.

Field: Latent Effectiveness at 100% Heating Air Flow

The latent heat exchange effectiveness at the *heating* condition defined in Table 27 with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

Field: Sensible Effectiveness at 75% Heating Air Flow

The sensible heat exchange effectiveness at the *heating* condition defined in Table 27 with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. The default value for this field is 0.

Field: Latent Effectiveness at 75% Heating Air Flow

The latent heat exchange effectiveness at the *heating* condition defined in Table 27 with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

Field: Sensible Effectiveness at 100% Cooling Air Flow

The sensible heat exchange effectiveness at the *cooling* condition defined in Table 27 with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. The default value for this field is 0.

Field: Latent Effectiveness at 100% Cooling Air Flow

The latent heat exchange effectiveness at the *cooling* condition defined in Table 27 with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

Field: Sensible Effectiveness at 75% Cooling Air Flow

The sensible heat exchange effectiveness at the *cooling* condition defined in Table 27 with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. The default value for this field is 0.

Field: Latent Effectiveness at 75% Cooling Air Flow

The latent heat exchange effectiveness at the *cooling* condition defined in Table 27 with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its supply (primary) inlet air.

Field: Supply Air Outlet Node Name

The name of the HVAC system node to which the unit sends its supply (primary) outlet air.

Field: Exhaust Air Inlet Node Name

The name of the HVAC system node from which the unit draws its exhaust (secondary) inlet air.

Field: Exhaust Air Outlet Node Name

The name of the HVAC system node to which the unit sends its exhaust (secondary) outlet air.

Field: Nominal Electric Power

The electric consumption rate of the unit in watts. Electric power is considered constant whenever the unit operates. This numeric input can be used to model electric power consumption by controls (transformers, relays, etc.) and/or a motor for a rotary heat exchanger. None of this electric power contributes thermal load to the supply or exhaust air streams. The default value for this field is 0.

Field: Supply Air Outlet Temperature Control

This alpha field determines if the heat exchanger's supply air outlet is controlled to a temperature set point. The choices for this input field are "Yes" or "No", with the default being "No". When supply air outlet temperature control is used, the wheel rotational speed modulates or supply air is bypassed around the plate heat exchanger to maintain the desired setpoint temperature. A setpoint manager object is required to establish the desired set point at the supply air outlet node (reference: SetpointManager:Scheduled). When an air-side economizer is also being modeled for this air system, the set point for the supply air outlet temperature control should be equal to the economizer outdoor air temperature lower limit (reference: Controller:OutdoorAir, field Economizer Minimum Limit Dry-Bulb Temperature).

Field: Heat Exchanger Type

This alpha field denotes the type of heat exchanger being modeled: Plate (e.g., fixed plate) or Rotary (e.g., rotating cylinder or wheel). The default choice for this field is "Plate". The heat exchanger type affects the modeling of frost control options and supply air outlet temperature control. For rotary heat exchangers, rotational speed is varied to control frost formation or the supply air outlet temperature. For plate exchangers, air bypass around the heat exchanger is used to obtain the desired effect.

Field: Frost Control Type

This alpha field has four choices: None, ExhaustAirRecirculation, ExhaustOnly and MinimumExhaustTemperature. If this field is left blank, the default frost control type is "None". For modeling preheat frost control, specify "None" for this input field and insert a separate heating coil object in the supply inlet air stream to keep the air temperature above the desired frost threshold temperature.

ExhaustAirRecirculation: dampers are used to direct exhaust air back into the zone through the supply side of the heat exchanger when the supply (outdoor) air inlet temperature falls below a threshold temperature (defined in the next input field). The fraction of time that exhaust air is circulated through the supply side of the heat exchanger is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time fraction (see *Field: Rate of Defrost Time Fraction Increase*). When exhaust air is being recirculated, no supply (outdoor ventilation) air is being provided through the heat exchanger unit (which may or may not be acceptable regarding ventilation for occupants).

ExhaustOnly (supply air bypass): this control cycles off the supply air flow through the heat exchanger for a certain period of time while the exhaust air continues to flow through the exhaust side of the heat exchanger. The fraction of time that the supply flow through the heat exchanger is cycled off is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time fraction (see *Field: Rate of Defrost Time Fraction Increase*). When implemented in real applications, provisions are usually made to avoid building depressurization when this frost control is operating (automatic or pressure-operated dampers, or a bypass air damper around the supply side of the heat exchanger). For this frost control type, it is assumed that the supply air is bypassed around the heat exchanger during frost control operation (i.e., the total supply flow is not reduced during defrost, but merely bypassed around the heat exchanger).

MinimumExhaustTemperature: the temperature of the exhaust air leaving the heat exchanger is monitored and the heat exchanger effectiveness is decreased (by slowing heat exchanger rotation or bypassing supply air around the plate exchanger) to keep the exhaust air from falling below the threshold temperature.

Field: Threshold Temperature

This numeric field defines the dry-bulb temperature of air which is used to initiate frost control. The default value is 1.7°C. For ExhaustAirRecirculation and ExhaustOnly frost control, the threshold temperature defines the supply (outdoor) air inlet temperature below which frost control is active. For MinimumExhaustTemperature frost control, heat exchanger effectiveness is controlled to keep the exhaust air outlet temperature from falling below this threshold temperature value.

The appropriate threshold temperature varies with exhaust (inlet) air temperature and humidity, frost control type, heat exchanger type, and whether the heat exchanger transfers sensible energy alone or both sensible and latent energy (enthalpy). Typical threshold temperatures are provided in Table 28 below. However, it is recommended that the user consult manufacturer’s information for the specific air-to-air heat exchanger being modeled.

Table 28. Typical threshold temperatures

Frost control type	Heat exchanger type	Energy exchange	Threshold temperature
Exhaust air recirculation	Plate	Sensible-only	-1.1°C (30°F)
		Sensible + latent	-12.2°C (10°F)
	Rotary	Sensible-only	-12.2°C (10°F)
		Sensible + latent	-23.3°C (-10°F)
Exhaust only	Plate	Sensible-only	-1.1°C (30°F)
		Sensible + latent	-12.2°C (10°F)
	Rotary	Sensible-only	-12.2°C (10°F)
		Sensible + latent	-23.3°C (-10°F)
Minimum exhaust temperature	Plate	Sensible-only	1.7°C (35°F)
		Sensible + latent	1.7°C (35°F)
	Rotary	Sensible-only	1.7°C (35°F)
		Sensible + latent	1.7°C (35°F)
Preheat**	Plate	Sensible-only	-1.1°C (30°F)
		Sensible + latent	-12.2°C (10°F)
	Rotary	Sensible-only	-12.2°C (10°F)
		Sensible + latent	-23.3°C (-10°F)

Source: Indoor Humidity Assessment Tool, U.S. Environmental Protection Agency, <http://www.epa.gov/iaq/schooldesign/saves.html>

** To model preheat frost control, specify frost control type as “None” and place a heating coil in the supply inlet air stream controlled to the keep the air temperature above the frost threshold temperature.

Field: Initial Defrost Time Fraction

This numeric field defines the fraction of the simulation timestep when frost control will be invoked when the threshold temperature is reached. This field is only used for the ExhaustAirRecirculation and ExhaustOnly frost control types. The value for this field must be ≥ 0 and ≤ 1 . The default time fraction is 0.083 (e.g., 5 min / 60 min) which is typical for ExhaustAirRecirculation frost control. Higher initial defrost time fractions (e.g., 0.167 = 10 min / 60 min) are typically required for ExhaustOnly frost control. For best results, the user should obtain this information from the manufacturer.

Field: Rate of Defrost Time Fraction Increase

This numeric field defines the rate of increase in the defrost time fraction as the supply (outdoor) air inlet temperature falls below the threshold temperature. This field is only used for the ExhaustAirRecirculation and ExhaustOnly frost control types. The value for this field must be ≥ 0 . The default value is 0.012 (e.g., 0.72 min / 60 min per degree C temperature difference) which is typical for ExhaustAirRecirculation frost control. Higher values (e.g., 0.024 = 1.44 min / 60 min per degree C temperature difference) are typically required for ExhaustOnly frost control. For best results, the user should obtain this information from the manufacturer.

This value is used to determine the total defrost time fraction as follows:

Total defrost time fraction = Initial Defrost Time Fraction +

$$\text{Rate of Defrost Time Fraction Increase} * (T_{\text{threshold}} - T_{\text{supply air inlet}})$$

The model does not allow the total defrost time fraction to exceed 1.0 or be less than 0.

Field: Economizer Lockout

This input denotes whether the heat exchanger unit is locked out (bypassed for plate type heat exchangers or the rotation is suspended for rotoray type heat exchangers) when the air-side economizer is operating. Both the economizer and high humidity control (Ref. Controller:OutdoorAir) activate the heat exchanger lockout as specified by this input. The input choices are Yes (meaning locked out) or No. The default input for this field is Yes.

Heat Exchanger Sensible Heating Rate [W]

This output is the sensible heating rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, the supply air inlet and outlet conditions, and the specific heat of the inlet supply air. A positive value is reported if the supply air is heated by the heat exchanger, else the rate is set to zero.

Heat Exchanger Sensible Heating Energy [J]

This output is the sensible heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Latent Heating Rate [W]

This output is the latent heating rate (humidification) of the supply air by the heat exchanger in Watts. This rate is determined by taking the difference between the Heat Exchanger Total Heating Rate and the Heat Exchanger Sensible Heating Rate. A positive value is reported if the supply air is humidified by the heat exchanger, else the rate is set to zero.

Heat Exchanger Latent Heating Energy [J]

This output is the latent heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Total Heating Rate [W]

This output is the total heating rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, and the enthalpy of the supply air entering and leaving the unit. A positive value is reported if the enthalpy of the supply air is increased by the heat exchanger, else the rate is set to zero.

Heat Exchanger Total Heating Energy [J]

This output is the total heating energy added to the supply air by the heat exchanger in Joules over the timestep being reported. This output is also added to a report meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforHeating, GroupKey = System (ref. Report Meter).

Heat Exchanger Sensible Cooling Rate [W]

This output is the sensible cooling rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, the supply air inlet and outlet conditions, and the specific heat of the inlet supply air. A positive value is reported if the supply air is cooled by the heat exchanger, else the rate is set to zero.

Heat Exchanger Sensible Cooling Energy [J]

This output is the sensible cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Latent Cooling Rate [W]

This output is the latent cooling rate (dehumidification) of the supply air by the heat exchanger in Watts. This rate is determined by taking the difference between the Heat Exchanger Total Cooling Rate and the Heat Exchanger Sensible Cooling Rate. A positive value is reported if the supply air is dehumidified by the heat exchanger, else the rate is set to zero.

Heat Exchanger Latent Cooling Energy [J]

This output is the latent cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Total Cooling Rate [W]

This output is the total cooling rate of the supply air by the heat exchanger in Watts. This rate is determined using the supply air mass flow rate through the heat exchanger unit, and the enthalpy of the supply air entering and leaving the unit. A positive value is reported if the enthalpy of the supply air is decreased by the heat exchanger, else the rate is set to zero.

Heat Exchanger Total Cooling Energy [J]

This output is the total cooling energy added to the supply air by the heat exchanger in Joules over the timestep being reported. This output is also added to a report meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforCooling, GroupKey = System (ref. Report Meter).

Heat Recovery Electric Power [W]

This output is the electric consumption rate of the unit in Watts. This rate is applicable whenever the unit operates (i.e., whenever the unit is scheduled to be available and supply and exhaust air flows exist).

Heat Recovery Electric Consumption [J]

This output is the electric consumption of the unit in Joules for the timestep being reported. This output is also added to a report meter with ResourceType = Electricity, EndUseKey = HeatRecovery, GroupKey = System (ref. Report Meter).

Heat Recovery Sensible Effectiveness [-]

This output is the average sensible effectiveness of the heat exchanger (excluding bypass air, if any) over the timestep being reported.

Heat Recovery Latent Effectiveness [-]

This output is the average latent effectiveness of the heat exchanger (excluding bypass air, if any) over the timestep being reported.

Heat Recovery Supply Air Bypass Mass Flow [kg/s]

This output is the average mass flow rate in kg/second of the supply (primary) air stream that is bypassing the heat exchanger over the timestep being reported. This flow rate is equal to

the total supply mass flow rate through the heat exchanger **unit** minus the amount passing through the supply side of the heat exchanger **core**.

Heat Recovery Exhaust Air Bypass Mass Flow [kg/s]

This output is the average mass flow rate in kg/second of the exhaust (secondary) air stream that is bypassing the heat exchanger over the timestep being reported. This flow rate is equal to the total exhaust mass flow rate through the heat exchanger **unit** minus the amount passing through the exhaust side of the heat exchanger **core**.

Heat Recovery Defrost Time Fraction [-]

This output is the average fraction of the reporting timestep when frost control is being implemented.

HeatExchanger:Desiccant:BalancedFlow

This desiccant heat exchanger object is an HVAC component used to model both temperature (sensible) and moisture (latent) heat exchange between two air streams (Figure 125). The model assumes balanced air flow through the regeneration and process sides of the heat exchanger (i.e., regeneration and process air volume flow rates and face velocities are the same). Heat exchanger performance is specified through a performance data type object (e.g., HeatExchanger:Desiccant:BalancedFlow:PerformanceData1).

Figure 125. Schematic of the Balanced Flow Desiccant Heat Exchanger

Currently, this desiccant heat exchanger model can be referenced by two compound objects: CoilSystem:Cooling:DX:HeatExchangerAssisted and Dehumidifier:Desiccant:System, both of which are used to provide enhanced dehumidification over conventional systems. If this heat exchanger is referenced by a compound object, the compound object will control heat exchanger operation (i.e., tell the heat exchanger if heat exchange is needed or not for each simulation timestep).

This desiccant heat exchanger object may also be specified directly in an AirLoopHVAC (air loop BranchList) or in an AirLoopHVAC:OutdoorAirSystem (AirLoopHVAC:OutdoorAirSystem:EquipmentList) without being referenced by a compound object. If specified directly in an AirLoopHVAC or AirLoopHVAC:OutdoorAirSystem, then the heat exchanger can be controlled to provide heat exchange based on a maximum and/or minimum humidity set point placed on the process air outlet node (ref. Setpoint Managers). If no humidity set points are provided on this node, then heat exchange will be provided

whenever the heat exchanger is available to operate (via its availability schedule) and there is a temperature and/or humidity ratio difference between the two air streams.

Inputs to this model include an availability schedule name, inlet and outlet air node names, and the type and name of the heat exchanger performance data object. A description of each input field for this object is provided below.

Field: Name

A unique, user-assigned name for a particular balanced flow desiccant heat exchanger. Any reference to this heat exchanger by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the heat exchanger can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the heat exchanger can operate during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the heat exchanger will not operate (i.e., no heat exchange will take place).

Field: Regeneration Air Inlet Node Name

The name of the HVAC system node from which the unit draws its regeneration inlet air.

Field: Regeneration Air Outlet Node Name

The name of the HVAC system node to which the unit sends its regeneration outlet air.

Field: Process Air Inlet Node Name

The name of the HVAC system node from which the unit draws its process inlet air.

Field: Process Air Outlet Node Name

The name of the HVAC system node to which the unit sends its process outlet air.

Field: Heat Exchanger Performance Object Type

This alpha field contains the type of model used to simulate the desiccant heat exchanger's thermal performance and electrical energy use. Currently, the only valid choice is HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1.

Field: Heat Exchanger Performance Name

This alpha field contains the identifying name of the specific heat exchanger performance type object (e.g., HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1) that defines the performance for this heat exchanger. A single heat exchanger performance type object may be used to define performance for many HeatExchanger:Desiccant:BalancedFlow objects (i.e., the same name may be used in this input field for more than one balanced flow desiccant heat exchanger).

Field: Economizer Lockout

This input denotes whether the heat exchanger unit is locked out (heat exchanger rotation is suspended) when the air-side economizer is operating. Both the economizer and high humidity control (Ref. Controller:OutdoorAir) activate the heat exchanger lockout as specified by this input. The input choices are *Yes* (meaning locked out) or *No*. Economizer lockout is typically *not* used for this type of heat exchanger. For this reason, the default input for this field is *No*.

The full IDD specification follows:

```

HeatExchanger:Desiccant:BalancedFlow,
  \memo This object models a balanced desiccant heat exchanger.
  \memo The heat exchanger transfers both sensible and latent energy between the
  \memo process and regeneration air streams. The air flow rate and face velocity
  \memo are assumed to be the same on both the process and regeneration sides of the
  \memo heat exchanger.

Heat Exchanger Sensible Heating Rate [W]

This output is the sensible heating rate of the process air by the heat exchanger in Watts. This rate is determined using the process air mass flow rate through the heat exchanger unit, the process air inlet and outlet temperatures, and the specific heat of the inlet process air. A positive value is reported if the process air is heated by the heat exchanger, else the rate is set to zero.

Heat Exchanger Sensible Heating Energy [J]

This output is the sensible heating energy added to the process air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Latent Heating Rate [W]

This output is the latent heating rate (humidification) of the process air by the heat exchanger in Watts. This rate is determined by taking the difference between the heat exchanger's total heat recovery rate and the sensible heat recovery rate. A positive value is reported if the process air is humidified by the heat exchanger, else the rate is set to zero.

Heat Exchanger Latent Heating Energy [J]

This output is the latent heating energy added to the process air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Total Heating Rate [W]

This output is the total heating rate of the process air by the heat exchanger in Watts. This rate is determined using the process air mass flow rate through the heat exchanger unit and the enthalpy of the air entering and leaving the process side of the unit. A positive value is reported if the enthalpy of the process air is increased by the heat exchanger, else the rate is set to zero.

Heat Exchanger Total Heating Energy [J]

This output is the total heating energy added to the process air by the heat exchanger in Joules over the timestep being reported. This output is also added to a report meter with

ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforHeating, GroupKey = System (ref. Report Meter).

Heat Exchanger Sensible Cooling Rate [W]

This output is the sensible cooling rate of the process air by the heat exchanger in Watts. This rate is determined using the process air mass flow rate through the heat exchanger unit, the process air inlet and outlet temperatures, and the specific heat of the inlet process air. A positive value is reported if the process air is cooled by the heat exchanger, else the rate is set to zero.

Heat Exchanger Sensible Cooling Energy [J]

This output is the sensible cooling energy added to the process air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Latent Cooling Rate [W]

This output is the latent cooling rate (dehumidification) of the process air by the heat exchanger in Watts. This rate is determined by taking the difference between the heat exchanger's total heat recovery rate and the sensible heat recovery rate. A positive value is reported if the process air is dehumidified by the heat exchanger, else the rate is set to zero.

Heat Exchanger Latent Cooling Energy [J]

This output is the latent cooling energy added to the process air by the heat exchanger in Joules over the timestep being reported.

Heat Exchanger Total Cooling Rate [W]

This output is the total cooling rate of the process air by the heat exchanger in Watts. This rate is determined using the process air mass flow rate through the heat exchanger unit and the enthalpy of the air entering and leaving the process side of the unit. A positive value is reported if the enthalpy of the process air is decreased by the heat exchanger, else the rate is set to zero.

Heat Exchanger Total Cooling Energy [J]

This output is the total cooling energy added to the process air by the heat exchanger in Joules over the timestep being reported. This output is also added to a report meter with ResourceType = EnergyTransfer, EndUseKey = HeatRecoveryforCooling, GroupKey = System (ref. Report Meter).

Heat Recovery Electric Power [W]

This output is the average electric consumption rate of the unit in Watts. This average rate includes portions of the simulation timestep when the heat exchanger may be cycled off (i.e., average of on and off periods, as appropriate).

Heat Recovery Electric Consumption [J]

This output is the electric consumption of the unit in Joules for the timestep being reported. This output is also added to a report meter with ResourceType = Electricity, EndUseKey = HeatRecovery, GroupKey = System (ref. Report Meter).

HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1

This object specifies a performance model and model coefficients for a balanced flow desiccant heat exchanger. A HeatExchanger:Desiccant:BalancedFlow object will reference a HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1 object. This performance data object is used to specify the thermal performance and electric consumption of the heat exchanger. Some representative inputs for this object are provided in the EnergyPlus Reference DataSets (PerfCurves.idf and AllDataSets.idf).

This model predicts the regeneration air stream outlet temperature and humidity ratio values based on the entering regeneration and process air stream temperature, humidity ratio and face velocity. The process air stream outlet humidity ratio and temperatures are calculated based on a simple heat and moisture balance. The model requires that the user enter the nominal volumetric flow rate and a nominal face velocity, electric power consumption, empirical model coefficients for the regeneration outlet air temperature and humidity ratio equations, and the applicable minimum and maximum values for both the independent and dependent variables for the empirical model coefficients provided. This model is based on the following equations:

- The dry-bulb temperature of the regeneration outlet air is defined using the following equation:

$$RTO = B1 + B2 * RWI + B3 * RTI + B4 * \left(\frac{RWI}{RTI} \right) + B5 * PWI + B6 * PTI + B7 * \left(\frac{PWI}{PTI} \right) + B8 * RFV$$

where,

RTO = Regeneration outlet air dry-bulb temperature (C)

RWI = Regeneration inlet air humidity ratio (kg/kg)

RTI = Regeneration inlet air dry-bulb temperature (C)

PWI = Process inlet air humidity ratio (kg/kg)

PTI = Process inlet air dry-bulb temperature (C)

RFV = Regeneration (and process) face velocity (m/s)

- The humidity ratio of the regeneration outlet air is defined using the same empirical equation form; however, different coefficients are used as follows:

$$RWO = C1 + C2 * RWI + C3 * RTI + C4 * \left(\frac{RWI}{RTI} \right) + C5 * PWI + C6 * PTI + C7 * \left(\frac{PWI}{PTI} \right) + C8 * RFV$$

where,

RWO = Regeneration outlet air humidity ratio (kg/kg)

- The process outlet air conditions are then calculated based on the regeneration outlet air conditions (temperature or humidity ratio) calculated above, the actual regeneration inlet air conditions entering the heat exchanger, and assuming the same amount of sensible and total energy transfer across both the process and regeneration sides of the heat exchanger. The difference between the actual inlet air conditions and *RTI/RWI/PTI/PWI* is made here because user-defined limits for *RTI/RWI/PTI/PWI* may result in a difference between the actual conditions and those used in the equations shown above (see the EnergyPlus Engineering Reference for further discussion).

A description of each input field for this object is provided below.

Field: Name

This alpha field contains the identifying name for this set of desiccant heat exchanger performance data. Any reference to this performance data set by another object (e.g., HeatExchanger:Desiccant:BalancedFlow) will use this name.

Field: Nominal Air Flow Rate

The nominal air volume flow rate in cubic meters per second. This model assumes balanced air flow (i.e., the same air volume flow rate across the process and regeneration sides of the heat exchanger). The minimum value should be greater than 0.

Field: Nominal Air Face Velocity

This numeric field contains the nominal air velocity across the heat exchanger face area in meters per second. It is assumed that this air velocity is the same for both sides of the heat exchanger. This value, along with the Nominal Air Flow Rate sets the heat exchanger face area. With this fixed face area, the air face velocity is calculated every simulation timestep based on the actual air volume flow rate for the timestep. The minimum value should be greater than 0 and less than or equal to 6.

Field: Nominal Electric Power

This numeric field contains the nominal electric consumption rate of the heat exchanger in watts. This electric power is considered constant and is consumed only when the heat exchanger operates (e.g., for all or a portion of the simulation timestep, as appropriate). This numeric input can be used to model electric power consumption by controls (transformers, relays, etc.) and/or a motor for a rotary heat exchanger. None of this electric power contributes thermal load to the process or regeneration air streams. The minimum value should be greater than or equal to 0. The default value for this field is also 0.

The coefficients for the regeneration air outlet temperature equation described above are defined in the following eight fields:

Field: Temperature Equation Coefficient 1

The constant coefficient (B_1) in the temperature equation shown above (RTO).

Field: Temperature Equation Coefficient 2

The coefficient (B_2) in the temperature equation shown above (RTO).

Field: Temperature Equation Coefficient 3

The coefficient (B_3) in the temperature equation shown above (RTO).

Field: Temperature Equation Coefficient 4

The coefficient (B_4) in the temperature equation shown above (RTO).

Field: Temperature Equation Coefficient 5

The coefficient (B_5) in the temperature equation shown above (RTO).

Field: Temperature Equation Coefficient 6

The coefficient (B_6) in the temperature equation shown above (RTO).

Field: Temperature Equation Coefficient 7

The coefficient (B_7) in the temperature equation shown above (RTO).

Field: Temperature Equation Coefficient 8

The coefficient (B_8) in the temperature equation shown above (RTO).

The following 16 fields are used to establish the valid range for the dependent and independent variables associated with the coefficients defined above (B_1 through B_8) for the regeneration outlet air temperature equation.

Field: Minimum Regeneration Inlet Air Humidity Ratio for Temperature Equation

The minimum allowable value of RWI in the temperature equation shown above (kg/kg). Values of RWI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Maximum Regeneration Inlet Air Humidity Ratio for Temperature Equation

The maximum allowable value of RWI in the temperature equation shown above (kg/kg). Values of RWI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air temperature and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Minimum Regeneration Inlet Air Temperature for Temperature Equation

The minimum allowable value of RTI in the temperature equation shown above (C). Values of RTI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued.

Field: Maximum Regeneration Inlet Air Temperature for Temperature Equation

The maximum allowable value of RTI in the temperature equation shown above (C). Values of RTI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air temperature and a warning message will be issued.

Field: Minimum Process Inlet Air Humidity Ratio for Temperature Equation

The minimum allowable value of PWI in the temperature equation shown above (kg/kg). Values of PWI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Maximum Process Inlet Air Humidity Ratio for Temperature Equation

The maximum allowable value of PWI in the temperature equation shown above (kg/kg). Values of PWI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air temperature and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Minimum Process Inlet Air Temperature for Temperature Equation

The minimum allowable value of PTI in the temperature equation shown above (C). Values of PTI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued.

Field: Maximum Process Inlet Air Temperature for Temperature Equation

The maximum allowable value of PTI in the temperature equation shown above (C). Values of PTI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air temperature and a warning message will be issued.

Field: Minimum Regeneration Air Velocity for Temperature Equation

The minimum allowable value of RFV in the temperature equation shown above (m/s). Values of RFV less than the minimum will be replaced by this minimum when calculating the regeneration outlet air temperature and a warning message will be issued. The minimum value for this input field should be greater than 0.

Field: Maximum Regeneration Air Velocity for Temperature Equation

The maximum allowable value of RFV in the temperature equation shown above (m/s). Values of RFV greater than the maximum will be replaced by this maximum value when calculating the regeneration outlet air temperature and a warning message will be issued. The minimum value for this input field should be greater than 0.

Field: Minimum Regeneration Outlet Air Temperature for Temperature Equation

The minimum value of RTO resulting from the temperature equation shown above (C). If RTO is less than this value, RTO will be replaced by this minimum value and a warning message will be issued.

Field: Maximum Regeneration Outlet Air Temperature for Temperature Equation

The maximum value of RTO resulting from the temperature equation shown above (C). If RTO is greater than this value, RTO will be replaced by this maximum value and a warning message will be issued.

Field: Minimum Regeneration Inlet Air Relative Humidity for Temperature Equation

The minimum relative humidity of the regeneration inlet air for the temperature equation shown above (percent). If the relative humidity of the regeneration inlet air is below this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

Field: Maximum Regeneration Inlet Air Relative Humidity for Temperature Equation

The maximum relative humidity of the regeneration inlet air for the temperature equation shown above (percent). If the relative humidity of the regeneration inlet air is above this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

Field: Minimum Process Inlet Air Relative Humidity for Temperature Equation

The minimum relative humidity of the process inlet air for the temperature equation shown above (percent). If the relative humidity of the process inlet air is below this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

Field: Maximum Process Inlet Air Relative Humidity for Temperature Equation

The maximum relative humidity of the process inlet air for the temperature equation shown above (percent). If the relative humidity of the process inlet air is above this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

The coefficients for the regeneration outlet air humidity ratio equation are defined in the following eight fields:

Field: Humidity Ratio Equation Coefficient 1

The constant coefficient (C_1) in the humidity ratio equation shown above (RWO).

Field: Humidity Ratio Equation Coefficient 2

The coefficient (C_2) in the humidity ratio equation shown above (RWO).

Field: Humidity Ratio Equation Coefficient 3

The coefficient (C_3) in the humidity ratio equation shown above (RWO).

Field: Humidity Ratio Equation Coefficient 4

The coefficient (C_4) in the humidity ratio equation shown above (RWO).

Field: Humidity Ratio Equation Coefficient 5

The coefficient (C_5) in the humidity ratio equation shown above (RWO).

Field: Humidity Ratio Equation Coefficient 6

The coefficient (C_6) in the humidity ratio equation shown above (RWO).

Field: Humidity Ratio Equation Coefficient 7

The coefficient (C_7) in the humidity ratio equation shown above (RWO).

Field: Humidity Ratio Equation Coefficient 8

The coefficient (C_8) in the humidity ratio equation shown above (RWO).

The following 16 fields are used to establish the valid range for the dependent and independent variables associated with the coefficients defined above (C_1 through C_8) for the regeneration outlet air humidity ratio equation.

Field: Minimum Regeneration Inlet Air Humidity Ratio for Humidity Ratio Equation

The minimum allowable value of RWI in the humidity ratio equation shown above (kg/kg). Values of RWI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Maximum Regeneration Inlet Air Humidity Ratio for Humidity Ratio Equation

The maximum allowable value of RWI in the humidity ratio equation shown above (kg/kg). Values of RWI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Minimum Regeneration Inlet Air Temperature for Humidity Ratio Equation

The minimum allowable value of RTI in the humidity ratio equation shown above (C). Values of RTI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued.

Field: Maximum Regeneration Inlet Air Temperature for Humidity Ratio Equation

The maximum allowable value of RTI in the humidity ratio equation shown above (C). Values of RTI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued.

Field: Minimum Process Inlet Air Humidity Ratio for Humidity Ratio Equation

The minimum allowable value of PWI in the humidity ratio equation shown above (kg/kg). Values of PWI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Maximum Process Inlet Air Humidity Ratio for Humidity Ratio Equation

The maximum allowable value of PWI in the humidity ratio equation shown above (kg/kg). Values of PWI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Minimum Process Inlet Air Temperature for Humidity Ratio Equation

The minimum allowable value of PTI in the humidity ratio equation shown above (C). Values of PTI less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued.

Field: Maximum Process Inlet Air Temperature for Humidity Ratio Equation

The maximum allowable value of PTI in the humidity ratio equation shown above (C). Values of PTI greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued.

Field: Minimum Regeneration Air Velocity for Humidity Ratio Equation

The minimum allowable value of RFV in the humidity ratio equation shown above (m/s). Values of RFV less than the minimum will be replaced by this minimum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The minimum value for this input field should be greater than 0.

Field: Maximum Regeneration Air Velocity for Humidity Ratio Equation

The maximum allowable value of RFV in the humidity ratio equation shown above (m/s). Values of RFV greater than the maximum will be replaced by this maximum when calculating the regeneration outlet air humidity ratio and a warning message will be issued. The minimum value for this input field should be greater than 0.

Field: Minimum Regeneration Outlet Air Humidity Ratio for Humidity Ratio Equation

The minimum value of RWO resulting from the humidity ratio equation shown above (kg/kg). If RWO is less than this value, RWO will be replaced by this minimum value and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Maximum Regeneration Outlet Air Humidity Ratio for Humidity Ratio Equation

The maximum value of RWO resulting from the humidity ratio equation shown above (kg/kg). If RWO is greater than this value, RWO will be replaced by this maximum value and a warning message will be issued. The valid range for this input field is 0.0 to 1.0.

Field: Minimum Regeneration Inlet Air Relative Humidity for Humidity Ratio Equation

The minimum relative humidity of the regeneration inlet air for the humidity ratio equation shown above (percent). If the relative humidity of the regeneration inlet air is below this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

Field: Maximum Regeneration Inlet Air Relative Humidity for Humidity Ratio Equation

The maximum relative humidity of the regeneration inlet air for the humidity ratio equation shown above (percent). If the relative humidity of the regeneration inlet air is above this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

Field: Minimum Process Inlet Air Relative Humidity for Humidity Ratio Equation

The minimum relative humidity of the process inlet air for the humidity ratio equation shown above (percent). If the relative humidity of the process inlet air is below this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

Field: Maximum Process Inlet Air Relative Humidity for Humidity Ratio Equation

The maximum relative humidity of the process inlet air for the humidity ratio equation shown above (percent). If the relative humidity of the process inlet air is above this value, a warning message will be issued. The valid range for this input field is 0.0 to 100.0.

The full IDD specification follows:

```
HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1,
  \memo RTO = B1 + B2*RWI + B3*RTI + B4*(RWI/RTI) + B5*PWI + B6*PTI + B7*(PWI/PTI)

HeatExchanger:Desiccant:BalancedFlow:PerformanceDataType1 Outputs

No variables are reported for this object. However, outputs are provided by the HeatExchanger:Desiccant:BalancedFlow object that references this PerformanceDataType1 object.

Group – Demand Limiting Controls

Demand limiting, or demand management, is a strategy for reducing a building's demand for utilities, e.g., electricity. Utility companies typically charge a monthly fee for "demand charges" that is based on the peak demand during a certain time period. Often the peak demand charge is set by one exceptional day that is much higher than the peak demand for an average day during the month. Therefore, to save utility costs, it is in the interest of building owners to find ways to manage the demand on peak days. While demand management is generally concerned with the demand for electricity, the future will likely see demand management of other utilities, such as natural gas or water.

Demand limiting controls shut off or reduce the power to non-essential loads in order to reduce the overall building demand. Some typical controls:

- shut off or dim electric lights, equipment, or HVAC systems
- reset the thermostatic set points on HVAC systems
- reduce the load of a set of similar components by rotating one or more components "off" for a short time interval
- turn on generators to meet some or all of the building's demand.

The demand limiting controls implemented in EnergyPlus are intended to allow some of the more common demand limiting strategies. Currently, only Exterior:Lights, Lights, ElectricEquipment, and ZoneControl:Thermostat objects can be demand limited. Additional components will be demand limited in future releases.

DemandManagerAssignmentList

The DemandManagerAssignmentList object is a high level control that makes demand limiting decisions based on a list of possible demand limiting strategies. Each demand limiting strategy is described in a separate DemandManager object. (This is structured like the relationship between the AvailabilityManagerAssignmentList and the AvailabilityManager objects.)

Each DemandManagerAssignmentList monitors and demand limits one meter. Only electricity meters are currently allowed. In many cases, the meter will be *Electricity:Facility*. A schedule and safety factor are used to set the demand limit above which the DemandManagers become activated. The billing month schedule and demand window are also taken into account when calculating the demand limit.

DemandManagers in the list are activated based on the *Demand Manager Priority*. If the **Sequential** option is used, each manager in the list is activated in sequence from first to last until demand is reduced below the limit or until all managers are activated. If the **All** option is used, all managers are activated simultaneously to achieve the maximum demand reduction.

A DemandManager is skipped if it cannot reduce the demand. Possible reasons that a manager cannot reduce demand include:

- not enough load to limit
- not available because of its *Availability Schedule*
- already activated; load limited during a previous timestep.

```

Field: Name

The name of the DemandManagerAssignmentList object.

Field: Meter Name

This field references the meter that is to be monitored and demand limited. Only electricity meters are currently allowed.

Field: Demand Limit Schedule Name

The reference to the schedule object specifying the target demand limits [schedule values should be in Watts].

Field: Demand Limit Safety Fraction

This field is a multiplier that is applied to the target demand limit (above). When the metered demand exceeds (target demand limit * safety fraction), the DemandManagers begin to limit the demand. This helps to ensure that the target limit is not exceeded.

Field: Billing Period Schedule Name

The reference to the schedule object that defines the monthly billing periods. The peak demand during the peak period of the billing period typically determines the demand charge. This should reference the same schedule that is used in the *Month Schedule Name* field of the UtilityCost:Tariff object. If left blank, it defaults to the regular divisions between months.

Field: Peak Period Schedule Name

The reference to the schedule object that defines the peak/off-peak time-of-use periods. The peak demand during the peak period of the billing period typically determines the demand charge. This should reference the same schedule that is used in the *Time of Use Period Schedule Name* field of the UtilityCost:Tariff object. A value of 1 indicates the peak period; any other value is off-peak. If left blank, it defaults to always on the peak period. The DemandManagerAssignmentList only attempts to demand limit during peak periods.

Field: Demand Window Length

This field is similar to the field of the same name in the UtilityCost:Tariff object. However, the user may not want to limit using the same demand window as the utility company. This field allows the user to input the number of minutes over which to calculate the current demand. The minutes are rounded to match the nearest multiple of time steps.

Field: Demand Manager Priority

This field indicates what logic should be used to activate the individual DemandManagers in the list. **Sequential** treats the list of DemandManagers as a sequential priority list, i.e., the first DemandManager in the list is activated first, then the second, etc., until the demand falls below the limit. **All** activates all demand managers to achieve the maximum demand reduction.

Field: Demand Manager Type 1

The key word defining the type of DemandManager.

Field: Demand Manager Name 1

The name of a DemandManager object defined elsewhere in the input file.

DemandManagers are listed by pairs of data items: *Demand Manager Type* and *Demand Manager Name*. Ten managers are accommodated in the list by default. The IDD specification, however, is extensible and additional pairs may be added by directly editing the IDD.

An example IDF showing how this object is used is provided below:

```

DemandManagerAssignmentList,
Demand Manager,           !- Name
Electricity:Facility,     !- Meter Name

DemandManagerAssignmentList Outputs

The following output variables are reported for the DemandManagerAssignmentList object:

```

Zone,Average,Demand Manager Meter Demand [W]
Zone,Average,Demand Manager Average Demand [W]
Zone,Average,Demand Manager Peak Demand [W]
Zone,Average,Demand Manager Scheduled Limit [W]
Zone,Average,Demand Manager Demand Limit [W]
Zone,Average,Demand Manager Avoided Demand [W]
Zone,Average,Demand Manager Over Limit [W]
Zone,Sum,Demand Manager Over Limit Duration [hr]
Zone,Sum,Demand Manager Exterior Energy Iterations []
Zone,Sum,Demand Manager Heat Balance Iterations []
Zone,Sum,Demand Manager HVAC Iterations []

```

Demand Manager Meter Demand [W]

The current demand for the designated meter.

Demand Manager Average Demand [W]

The current demand for the designated meter averaged over the *Demand Window Length*.

Demand Manager Peak Demand [W]

The peak demand in the billing month so far.

Demand Manager Scheduled Limit [W]

The scheduled target demand limit from the *Demand Limit Schedule*.

Demand Manager Demand Limit [W]

The actual demand limit after multiplication by the *Demand Limit Safety Fraction*.

Demand Manager Avoided Demand [W]

The demand that was avoided by the active DemandManagers.

Demand Manager Over Limit [W]

The difference between the demand limit and the average demand.

Demand Manager Over Limit Duration [hr]

The number of hours that the demand limit was exceeded.

Demand Manager Exterior Energy Iterations []

The number times that the exterior energy use was resimulated for demand limiting.

Demand Manager Heat Balance Iterations []

The number times that the zone heat balance was resimulated for demand limiting.

Demand Manager HVAC Iterations []

The number times that the HVAC system was resimulated for demand limiting.

DemandManager:ExteriorLights

The DemandManager:ExteriorLights object is used for demand limiting Exterior:Lights objects.

Field: Name

The name of the DemandManager:ExteriorLights object.

Field: Availability Schedule Name

The reference to the schedule object specifying the availability of this DemandManager.

Field: Limit Control

This field specifies the type of limiting control. The **Fixed** option reduces the power to the controlled loads by a fixed amount determined by the *Maximum Limit Fraction* field. The **Off** option disables the DemandManager in the simulation.

Field: Minimum Limit Duration

The minimum amount of time [minutes] that the DemandManager will continue to demand limit after being activated. This prevents loads from turning on and off every time step.

Field: Maximum Limit Fraction

This field specifies a fraction of the *Design Level* power for the load that determines the lowest allowable power level. With *Limit Control* set to **Fixed**, the power is reduced to $Maximum\ Limit\ Fraction * Design\ Level$ whenever the manager is activated. For example, if the *Maximum Limit Fraction* is 0.8, then a 100 W design level load is reduced to 80 W when limiting. A *Maximum Limit Fraction* of zero means that the load can be shut off entirely.

Field: Limit Step Change

NOT YET IMPLEMENTED.

Field: Selection Control

This field specifies which loads are selected to be limited. The **All** option simultaneously limits all of the loads listed in this DemandManager. The **RotateMany** option limits all loads except for one which rotates sequentially through the loads listed. The **RotateOne** limits only one load which rotates sequentially through the loads listed. The time interval between rotations is set by the *Rotation Duration* field.

Field: Rotation Duration

If the **RotateOne** or **RotateMany** option is used for *Selection Control*, this field sets the time interval [minutes] between rotations.

Field: Exterior Lights 1-10 Name

The names of Exterior:Lights objects defined elsewhere in the input file. These are the loads to be limited by this DemandManager.

Ten objects are accommodated in the list by default. The IDD specification, however, is extensible and additional fields may be added by directly editing the IDD.

An example IDF showing how this object is used is provided below:

```
DemandManager:ExteriorLights,

<reduced for brevity>

```

Field: Name

The name of the DemandManager:Thermostats object.

Field: Availability Schedule Name

The reference to the schedule object specifying the availability of the DemandManager.

Field: Reset Control

This field specifies the type of limiting control. The **Fixed** option resets the thermostats to a fixed temperature determined by the *Maximum Heating Setpoint Reset* and *Maximum Cooling Setpoint Reset* fields. The **Off** option disables the DemandManager in the simulation.

Field: Minimum Reset Duration

The minimum amount of time [minutes] that the DemandManager will continue to demand limit after being activated. This prevents thermostats from resetting on and off every time step.

Field: Maximum Heating Setpoint Reset

This field specifies the thermostat heating setpoint temperature [C] that represents the largest allowable temperature reset or setback. With *Reset Control* set to **Fixed**, the setpoint temperature is reset to the *Maximum Heating Setpoint Reset* whenever the manager is activated. For example, if the heating setpoint is normally 22 C and the *Maximum Heating Setpoint Reset* is 20 C, then the setpoint is reset to 20 C when limiting.

Field: Maximum Cooling Setpoint Reset

This field specifies the thermostat cooling setpoint temperature [C] that represents the largest allowable temperature reset or setback. With *Reset Control* set to **Fixed**, the setpoint temperature is reset to the *Maximum Cooling Setpoint Reset* whenever the manager is activated. For example, if the cooling setpoint is normally 22 C and the *Maximum Cooling Setpoint Reset* is 24 C, then the setpoint is reset to 24 C when limiting.

Field: Reset Step Change

NOT YET IMPLEMENTED.

Field: Selection Control

This field specifies which loads are selected to be limited. The **All** option simultaneously limits all of the loads listed in this DemandManager. The **RotateMany** option limits all loads except for one which rotates sequentially through the loads listed. The **RotateOne** limits only one load which rotates sequentially through the loads listed. The time interval between rotations is set by the *Rotation Duration* field.

Field: Rotation Duration

If the **RotateOne** or **RotateMany** option is used for *Selection Control*, this field sets the time interval [minutes] between rotations.

Field: Thermostat 1-10 Name

The names of ZoneControl:Thermostat objects defined elsewhere in the input file. These are the loads to be limited by this DemandManager.

Ten objects are accommodated in the list by default. The IDD specification, however, is extensible and additional fields may be added by directly editing the IDD.

An example IDF showing how this object is used is provided below:

```

```

DemandManager:Thermostats Outputs

There are no output variables reported for the DemandManager:Thermostats object.

Group – Electric Load Center-Generator Specifications**ElectricLoadCenter:Distribution**

ElectricLoadCenter:Distribution objects are used to include on-site electricity generators in a simulation. The electric load center dispatches generators according to operation schemes and tracks and reports the amount of electricity generated and purchased. When using on-site generators, the program provides a “net” report where the total electricity used is reduced by the amount generated on site. Electrical demand tracking is done by the internal or custom meters used by EnergyPlus for reporting. The thermal demand tracking uses internal load calculations from the plant simulation. The dispatching of different generators is based on expectations based on their nominal generating capacities. If the current conditions are such that the generator model determines that generation was higher or lower, then the results of the dispatch may differ from expectations.

Multiple different ElectricLoadCenter:Distribution objects can be included in an input file. A great deal of flexibility is available by mixing different load centers and operating schemes. If multiple load centers are used, the supervisory control will dispatch generators sequentially across the load centers. Therefore, the order of these input objects in the IDF file becomes important with the generators associated with first load center in the file being the first to be managed. A certain amount of caution is needed to avoid conflicting operating schemes.

The electricity produced from photovoltaic arrays will be reported in the electricity produced report variable and will reduce the demand that the generators will try to meet for that timestep.

Field: Name

This alpha field contains the identifying name for the electric load center.

Field: Generator List Name

This alpha field contains the identifying name for the list of generators in the set.

Field: Generator Operation Scheme Type

This alpha field specifies the type of operating scheme for the generator set. The available operating schemes are “Baseload,” “DemandLimit,” “TrackElectrical,” “TrackSchedule,” “TrackMeter,” “FollowThermal,” and “FollowThermalLimitElectrical.” The Baseload scheme operates the generators at their rated capacity when the generator is scheduled ON. The DemandLimit scheme limits the amount of purchased electrical from the utility to the amount specified in the input object. The DemandLimit scheme tries to have the generators meet all of the demand above the purchased electric limit set by the user in the next field. The TrackElectrical scheme tries to have the generators meet all of the electrical demand for the building. The TrackSchedule scheme tries to have the generators meet all of the electrical demand determined in a user-defined schedule. The TrackMeter scheme tries to have the generators meet all the electrical demand from a meter, which could also be a user-defined custom meter.

The DemandLimit, TrackElectrical, TrackSchedule, and TrackMeter schemes will sequentially load the available generators. All demand not met by available generator capacity will be met by purchased electrical. Therefore, if DemandLimit, TrackElectrical, TrackSchedule, or TrackMeter is utilized and the available generators are not enough to meet demand, then purchased electrical will offset the difference. If a generator is needed in the simulation for a small load and it is less than the minimum part load ratio the generator will operate at the

minimum part load ratio and the excess will either reduce demand or the excess energy will be available for returning to the electric grid.

The FollowThermal and FollowThermalLimitElectrical schemes are for heat following cogeneration and run the generators to meet the thermal demand. The FollowThermal schemes allow excess electrical generation to be exported to the grid, while the FollowThermalLimitElectrical scheme restricts generator output to a maximum of the building's current electrical demand (so that no electricity is exported). The thermal demand is determined from the plant modeling and depends on the flow requested by other components on the demand side of the plant loop, the loop temperatures, and the loop temperature set point. The electric load center converts the thermal load to an electrical load using a nominal ratio of the thermal to electrical power production for each generator. For these schemes, the generator needs to be connected to the supply side of a plant loop and supply components that request hot water need to be on the demand side of the plant loop. This is different than the usual configuration for electrical following schemes where the generator is put on the demand side and request flow for the purposes of cooling the generator. Therefore a switch from one of the electrical-based operating schemes to one of the thermal-based operating schemes requires a substantial change in plant topology.

If the load center includes electrical storage, then the choice of operating schemes will also affect how storage is managed.

Field: Demand Limit Scheme Purchased Electric Demand Limit

This numerical field is the user input for the demand limit above which the generators will try and meet the entire electrical load on the building minus the photovoltaic array if available.

Field: Track Schedule Name Scheme Schedule Name

This alpha field is the user input for the name of a schedule defined elsewhere in the input file that contains values for the "demand" loads placed on the generator(s). The schedule values should be in Watts.

Field: Track Meter Scheme Meter Name

This alpha field is the user input for the name of a meter. Any valid meter name can be used here to control the loads that the generator(s) will try to meet. Many different meters are automatically generated by the program and will depend on the objects used throughout the input file. The typical process of determining the exact name to enter in this field involves doing an initial run of EnergyPlus and then examining the *.rdd file which will list the meters and their resulting names. The *.mtd file will also be useful to understand what exactly is included in a meter. The user can also use the Output:CustomMeter objects to redefine meter names and to control what electrical loads are included on them in a flexible manner.

Field: Electrical Buss Type

This alpha field is used to describe how the electric load center is configured with respect to any power conditioning and/or storage equipment. There are five configurations for load centers available by using one of these keywords:

- AlternatingCurrent
- AlternatingCurrentWithStorage
- DirectCurrentWithInverter
- DirectCurrentWithInverterDCStorage
- DirectCurrentWithInverterACStorage

AlternatingCurrent is the default. All the generators connected to a specific load center need to be of the same type (all AC or all DC). If the generators are DC, then an inverter is needed to convert the DC to AC. If there are DC generators and a DC electrical storage device on the buss along with an inverter, then use DirectCurrentWithInverterDCStorage in this field.

See the Engineering Reference for more information including diagrams of the load center configurations.

Field: Inverter Object Name

This field is used to identify the inverter connected to this load center (if any). This field is only used if the Electrical Buss Type is set to DirectCurrentWithInverter and should contain the user-defined name of an inverter object. There are three types of inverter models available—see ElectricLoadCenter:Inverter:Simple, ElectricLoadCenter:Inverter:LookUpTable, or ElectricLoadCenter:Inverter:FunctionOfPower. Enter the name of one of these types of inverter objects defined elsewhere in the input file.

Field: Electrical Storage Object Name

This field is used to identify the electrical storage connected to this load center (if any). This field is only used if the Electrical Buss Type is set to DirectCurrentWithInverterDCStorage or DirectCurrentWithInverterACStorage. Enter the name of an ElectricLoadCenter:Storage:Simple object defined elsewhere in the input file.

The IDD entry for this object is:

```

ElectricLoadCenter Outputs

There are three levels of results reporting related to electric load centers and generators. The top level of reporting provides results across the whole building and all the different electric load centers and generators. The second level of reporting provides results for individual load centers. The third level is for each type of generator (see individual generator descriptions). This section discusses the first two levels.

The whole-building summary report variables are:

```

HVAC,Average,Total Electric Power Produced [W]
HVAC,Sum,Total Electric Energy Produced [J]
HVAC,Average,Total Electric Power Purchased [W]
HVAC,Sum,Total Electric Energy Purchased [J]
HVAC,Average,Total Building Electric Demand [W]
HVAC,Average,Total HVAC Electric Demand [W]
HVAC,Average,Total Electric Demand [W]

```

These report variables all use a default keyword "Whole Building."

These report variables can also be accessed without specifying generation equipment by including the syntax shown below:

```

ElectricLoadCenter:Distribution,
  Electric Load Center; !- Name

```

Even if no ElectricLoadCenter:Distribution object is included, these report variables are also available for all simulations that have any electricity consuming equipment with the default keyword name "Electrical Service."

Total Electric Power Produced [W]

Total Electric Energy Produced [J]

These outputs are the total generator and photovoltaic electricity produced for the entire model, and they are both in Power and Energy units.

Total Electric Power Purchased [W]

Total Electric Energy Purchased [J]

These outputs are the total of electricity purchased for the entire model in both Power and Energy units. This value is always positive and indicates the amount of energy is purchased from the utility.

Total Electric Energy Surplus [J]

This output is the excess electricity produced and sent out to the electrical grid. This value is always positive and indicates the surplus electricity from generation that exceeds whole-building demand and fed into the grid.

Total Building Electric Demand [W]

This report variable includes all of the electric demand from the building (non-HVAC) portion of the simulation, which would contain lights, electrical equipment, exterior lights and equipment, etc.

Total HVAC Electric Demand [W]

This report variable includes all of the electric demand from the HVAC portion of the simulation, which would contain fans, electric coils, pumps, chillers, cooling towers, etc.

Total Electric Demand [W]

This is the total of the whole Building and HVAC electric demands.

Net Electric Power Purchased [W]**Net Electric Energy Purchased [J]**

These outputs are the net electricity purchased in both Power and Energy units. This value can be either positive or negative. Positive values are defined as electricity purchased from the utility. Negative values are defined as surplus electricity fed back into the grid.

Each ElectricLoadCenter also collects results from the individual generators that are connected to that load center. The report variables available at the ElectricLoadCenter level are:

```
HVAC,Average,Load Center Electric Power Produced [W]
HVAC,Sum,Load Center Electric Energy Produced [J]
HVAC,Average,Load Center Thermal Power Produced [W]
HVAC,Sum,Load Center Thermal Energy Produced [J]
```

Load Center Electric Power Produced [W]**Load Center Electric Energy Produced [J]**

These outputs are the sum of electrical energy and power produced by the generators attached to a particular load center. The keywords for these reports are the unique names of ElectricLoadCenter:Distribution objects.

Load Center Thermal Power Produced [W]**Load Center Thermal Energy Produced [J]**

These outputs are the sum of the thermal energy and power produced by the generators attached to a particular load center. The keywords for these reports are the unique names of ElectricLoadCenter:Distribution objects.

ElectricLoadCenter:Generators

The ElectricLoadCenter:Generators object is used to provide a list of the generators to include in the simulation. The list includes the names and types of all the generators along with separate availability schedules, the rated power output, and thermal-to-electrical power ratio for each. Sets of five input fields are repeated for each generator. If more than 30 generators are needed the user will need to extend the associated entry in the Energy+.idd file.

Field: Name

This alpha field contains the identifying name for the generators in the set.

FieldSet: Name, Object Type, Rated Power Output, Availability, Thermal Ratio up to 30

Each generator is specified by a set of 5 input fields that contain an identifying name, a keyword that indicates the type of generator, the rated output of the generator, the availability schedule of the generator, and the thermal to electrical power production ratio.

Field: Generator 1 Name

This alpha field contains the identifying name for the first generator in the list.

Field: Generator 1 Object Type

This alpha field contains the keyword for the type of generator. The available types include:

- Generator:InternalCombustionEngine
- Generator:CombustionTurbine
- Generator:Photovoltaic
- Generator:FuelCell
- Generator:MicroCHP
- Generator:MicroTurbine

These keywords are the names of the input objects for the type of generator.

Field: Generator 1 Rated Electric Power Output

This numeric field contains the nominal rated electric output of the generator in Watts. This value is used only for supervisory control and dispatch; the actual power is determined by the generator models.

Field: Generator 1 Availability Schedule

This alpha field is used as an identifying field for the generator availability Schedule. This field should contain the name of Schedule defined elsewhere in the input file. A value of 0.0 indicate the generator is not available.

Field: Generator 1 Rated Thermal to Electrical Power Ratio

This numeric field contains the ratio of the rated thermal output to the rated electric output. It is only needed and used if the operation scheme is set to **FollowThermal** or **FollowThermalLimitElectrical**. This nominal ratio is only used for control and dispatch decisions. This value should be generally consistent with the more detailed performance input for the individual generator component models but it is not used in those component models.

ElectricLoadCenter:Inverter:Simple

This input object is used to model conversion from Direct Current (DC) to Alternating Current (AC) in an electric load center that contains photovoltaic modules. Such a load center has an array of photovoltaic modules that feed an inverter DC power and the inverter produces AC power. This input object is for the simplest inverter model and uses a fixed efficiency. There are two other types of inverters with more complex models described below.

Field: Name

This field contains a unique name for the inverter. The name entered must also be unique across all other types of inverters that may also be in the input file.

Field: Availability Schedule Name

This field contains the name of a schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by scheduling a value of 0, then it cannot produce AC power and will not consume ancillary power during standby. Any non-zero schedule value means the inverter is available to produce AC power and consume ancillary power during standby. If the Inverter is schedule to be unavailable but it is being supplied with DC power anyway, then the energy is dissipated as heat.

Field: Zone Name

This field contains the name of the thermal zone where the inverter is located. Entering a valid name of zone here will direct EnergyPlus to include the inverter's losses as heat gains to the named thermal zone. If the inverter is not within a thermal zone, then this field can be left blank (and the thermal energy associated with inverter losses is removed from the building model).

Field: Radiative Fraction

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

Field: Inverter Efficiency

This field contains the value for inverter efficiency. In the simple model, efficiency is a constant. This is the so-called 1-term model. Input data for different types of inverters is available at http://www.gosolarcalifornia.org/equipment/inverter_tests/summaries where the "CEC Efficiency" would be the value to enter here.

```

ElectricLoadCenter:Inverter:FunctionOfPower

This input object is used to model conversion from Direct Current (DC) to Alternating Current (AC) in an electric load center that contains photovoltaic modules. Such a load center has an array of photovoltaic modules that feed an inverter DC power and the inverter produces AC power. This input object is for an inverter model where efficiency is a function of normalized power.

Field: Name

This field contains a unique name for the inverter. The name entered must also be unique across all other types of inverters that may also be in the input file.

Field: Availability Schedule Name

This field contains the name of a schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by scheduling a value of 0, then it cannot produce AC power, nor contribute heat gains to the zone, and will not consume ancillary power during standby. Any non-zero schedule value means the inverter is available to

produce AC power, contribute heat gains to the zone and consume ancillary power during standby.

Field: Zone Name

This field contains the name of the thermal zone where the inverter is located. Entering a valid name of zone here will direct EnergyPlus to include the inverter's losses as heat gains to the named thermal zone. If the inverter is not within a thermal zone, then this field can be left blank (and the thermal energy associated with inverter losses is removed from the building model).

Field: Radiative Fraction

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

Field: Efficiency Function of Power Curve Name

This field contains the name of curve representing the relationship between DC power input into the inverter and the efficiency with which that power is converted to AC. The curve can be either a Curve:Linear, Curve:Quadratic, or Curve:Cubic. The curve's "x" value is DC power input normalized by the following field. The result of the curve should be power conversion efficiency expressed as a fraction between 0.0 and 1.0.

Field: Rated Maximum Continuous Input Power

This field contains the rated power input in watts. This is value used to normalize input power for use with the curve named in the previous field. This is DC power from the PV arrays going into the inverter.

Field: Minimum Efficiency

This field contains a minimum bound on the inverter efficiency. This value will be used as a limit on the curve's result.

Field: Maximum Efficiency

This field contains a maximum bound on the inverter efficiency. This value will be used as a limit on the curve's result.

Field: Minimum Power Output

This field contains a lower limit on the AC power produced by the inverter. If the resulting power output would be below this level, then the inverter is assumed to not produce any power and is in stand by mode. All DC power input is lost (unless it is going into storage).

Field: Maximum Power

This field contains an upper limit on the AC power produced by the inverter. If the resulting power output would be above this level, then the power produced is capped at this level with the rest of input power converted to losses (unless it is going into storage).

Field: Ancillary Power Consumed In Standby

This field contains the ancillary power in watts used by the inverter when not producing AC power. This is AC electricity consumed in standby mode. Standby mode occurs when the inverter is scheduled to be available but the incoming DC power is too low.

ElectricLoadCenter:Inverter:LookUpTable

This input object is used to model conversion from Direct Current (DC) to Alternating Current (AC) in an electric load center that contains photovoltaic modules. Such a load center has an array of photovoltaic modules that feed an inverter DC power and the inverter produces AC power. This input object is for an inverter model where efficiency is interpolated using a look up table.

This object was designed for use with data contained in the Inverter Performance Test Summaries available at http://www.gosolarcalifornia.org/equipment/inverter_tests/summaries. All of the data needed for this object can be found there by make and model of inverter. The core of the data set is a 3x6 matrix of efficiency at different voltage and power levels. These form the look up table used in the model. Note that EnergyPlus' PV models currently model only power and not the voltage and current situation. Therefore, only the nominal voltage data are used. This is the middle row of data in the Go Solar summaries.

Field: Name

This field contains a unique name for the inverter. The name entered must also be unique across all other types of inverters that may also be in the input file.

Field: Availability Schedule Name

This field contains the name of a schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by setting a value of 0, then it cannot produce AC power, nor contribute heat gains to the zone, and will not consume ancillary power during

standby. Any non-zero schedule value means the inverter is available to produce AC power, contribute heat gains to the zone and consume ancillary power during standby.

Field: Zone Name

This field contains the name of the thermal zone where the inverter is located. Entering a valid name of zone here will direct EnergyPlus to include the inverter's losses as heat gains to the named thermal zone. If the inverter is not within a thermal zone, then this field can be left blank (and the thermal energy associated with inverter losses is removed from the building model).

Field: Radiative Fraction

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This field is not used if the previous field for zone name is left blank.

Field: Rated Maximum Continuous Output Power

This field contains the rated maximum continuous output power in watts.

Field: Night Tare Loss Power

This field contains the "night tare loss" in watts. This is modeled as ancillary power consumed during standby.

Field: Nominal Voltage Input

This field contains the nominal DC input voltage in volts. This is "Vnom" in the Go Solar test summaries.

Field: Efficiency at 10% Power and Nominal Voltage

This field contains the fractional efficiency at nominal voltage and 10% power.

Field: Efficiency at 20% Power and Nominal Voltage

This field contains the fractional efficiency at nominal voltage and 20% power.

Field: Efficiency at 30% Power and Nominal Voltage

This field contains the fractional efficiency at nominal voltage and 30% power.

Field: Efficiency at 50% Power and Nominal Voltage

This field contains the fractional efficiency at nominal voltage and 50% power.

Field: Efficiency at 75% Power and Nominal Voltage

This field contains the fractional efficiency at nominal voltage and 75% power.

Field: Efficiency at 100% Power and Nominal Voltage

This field contains the fractional efficiency at nominal voltage and 100% power.

Inverter Outputs

Each inverter can report the following seven output variables.

```

HVAC,Average,Inverter DC to AC Efficiency [ ]
HVAC,Average,Inverter DC Power Input [W]
HVAC,Sum,Inverter DC Energy Input [J]
HVAC,Average,Inverter AC Power Output [W]
HVAC,Sum,Inverter AC Energy Output [J]
HVAC,Average,Inverter Thermal Loss Rate [W]
HVAC,Sum,Inverter Thermal Loss Energy [J]

```

Inverter DC to AC Efficiency []

This is the efficiency with which DC power is converted to AC power by the inverter.

Inverter DC Power Input [W]***Inverter DC Energy Input [J]***

These outputs are total electricity power or energy fed into the inverter. This is Direct Current from photovoltaics (or DC-based electrical storage) going into the inverter.

Inverter AC Power Output [W]***Inverter AC Energy Output [J]***

These outputs are the total electricity power or energy produced by the inverter. This is Alternating Current going out of the inverter.

Inverter Thermal Loss Rate [W]***Inverter Thermal Loss Energy [J]***

These outputs are the thermal power or energy losses in the inverter that stem from converting from DC to AC.

Inverter Ancillary AC Consumed Rate [W]***Inverter Ancillary AC Consumed Energy [J]***

These outputs are the Alternating Current electricity consumed by the inverter. These are ancillary, or night tare loss, power uses by the inverter and modeled as if powered by the building's grid connection. These ancillary power draws generally occur when the inverter is not generating power but waiting in a standby mode ready to begin generating power.

ElectricLoadCenter:Storage:Simple

This input object is used to model storage of electricity in an electric load center. This is a simple model that does not attempt to represent any of the characteristics of a real storage device such as a battery. The type of power, AC or DC, depends on the configuration chosen as the Electrical Buss Type in the ElectricLoadCenter:Distribution object.

Field: Name

This field contains a unique name for the electric storage device.

Field: Availability Schedule Name

This field contains the name of a schedule that describes when the storage device is available. If storage is not available, by scheduling a value of 0, then no electrical energy can be stored or drawn from the device. Any non-zero schedule value means the devices is available.

Field: Zone Name

This field contains the name of the thermal zone where the storage device is located. Entering a valid name of a zone here will direct EnergyPlus to include the storage losses as heat gains to the name thermal zone. If the storage is not within a thermal zone, then this field can be left blank.

Field: Radiative Fraction for Zone Heat Gains

This field contains the fraction of storage losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses are convective. This field is not used if the previous field for zone name is left blank.

Field: Nominal Energetic Efficiency for Charging

This field contains the charging efficiency. This is the energetic efficiency of storing electrical energy in the storage device. A value of 1.0 means the device does not lose any energy when charging.

Field: Nominal Discharging Energetic Efficiency

This field contains the discharging efficiency. This is the energetic efficiency of drawing electrical energy from the storage device. A value of 1.0 means the device does not lose any energy when drawing power.

Field: Maximum Storage Capacity

This field describes the maximum amount of energy that can be stored in the device in Joules. Once the storage device is full, no additional energy can be stored in it.

Field: Maximum Power for Discharging

This field describes the maximum rate at which electrical power can be discharged from the storage device in watts.

Field: Maximum Power for Charging

This field describes the maximum rate at which electrical power can be stored in the device in watts.

Field: Initial State of Charge

This field describes the value for the initial state of charge in Joules. This is used to model the storage device as having some amount of stored energy at the beginning of the simulation period.

ElectricLoadCenter:Storage:Simple Outputs

Each electrical storage device can report the following seven output variables.

```

HVAC,Average,Electrical Storage State of Charge [J]
HVAC,Average,Electrical Storage Power Into Storage [W]
HVAC,Sum,Electrical Storage Energy Into Storage [J]
HVAC,Average,Electrical Storage Power From Storage [W]
HVAC,Sum,Electrical Storage Energy From Storage [J]
HVAC,Average,Electrical Storage Thermal Loss Rate [W]
HVAC,Sum,Electrical Storage Thermal Loss Energy [J]

```

Electrical Storage State of Charge [J]

This output is the state of charge of the storage device. State of charge is the amount of electrical energy stored in the device at a point of time. The amount of energy stored is tracked in Joules.

Electrical Storage Power Into Storage [W]

Electrical Storage Energy Into Storage [J]

These outputs are total electricity power or energy fed into the storage device. This is the rate or amount of charging.

Electrical Storage Power From Storage [W]

Electrical Storage Energy From Storage [J]

These outputs are total electricity power or energy drawn from the storage device. This is the rate or amount of discharging.

Electrical Storage Thermal Loss Rate [W]

Electrical Storage Thermal Loss Energy [J]

These outputs are the thermal power or energy losses from both charging and drawing electrical power in or out of the storage device.

Generator:InternalCombustionEngine

The Internal Combustion (IC) Engine generator uses a modified Otto cycle. This generator model uses the electrical load and rated engine generator size to compute part-load ratios (PLR). Fuel energy input and recoverable jacket and lube oil heat are then computed. Finally, the recoverable exhaust heat is calculated.

Manufacturer's curves or tables must be obtained for IC engine generators to derive the equipment performance parameters that are specified in the quadratic curve fits. Note that simple transformation of the form of the manufacturer's curves may be required. Electric energy output/fuel energy input is related to the part-load ratio (i.e., electric/load generator capacity) with a polynomial. Recoverable jacket heat/fuel energy equipment, recoverable lube oil heat/fuel energy input equipment performance, total exhaust heat/fuel energy input equipment, exhaust gas temperature/fuel energy input equipment performance parameters are all specified with a quadratic curve fit.

When the heat recovery curve fits = 0.0, this means that no heat recovery is done on the IC engine generator exhaust gas; and no heat recovery is specified.

Field: Name

This alpha field contains the identifying name for the IC engine generator.

Field: Rated Power Output

The design nominal capacity of the generator in Watts [W].

Field: Electric Circuit Node Name

This named node contains where the electric power is put in the program simulation for use by the electric equipment in the Load Center.

Field: Minimum Part Load Ratio

This field contains the minimum allowed operating fraction of full load.

Field: Maximum Part Load Ratio

This field contains the maximum allowed operating fraction of full load.

Field: Optimum Part Load Ratio

This alpha field contains the optimal operating fraction of full load. This is the part load ratio that gives the optimal production of electric power with the least amount of fuel usage.

Field: Shaft Power Curve Name

This alpha field contains the name of the shaft power curve. The curve itself is specified separately using a curve object (see **Curve:Quadratic**). The Shaft Power Curve is a quadratic equation that determines the electric output versus the fuel used. Used to calculate the electric energy output divided by the fuel energy consumption as a function of part-load ratio. The defining equation is:

$$\text{ShaftPowerToFuelRatio} = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Rated Power Output.

Field: Jacket Heat Recovery Curve Name

This alpha field contains the name of the Recovery Jacket Heat curve. The curve itself is specified separately using a curve object (see **Curve:Quadratic**). The Jacket Heat Recovery Curve is a quadratic equation that determines the ratio of recovery jacket heat to fuel energy. Used to calculate the recoverable jacket heat as a function of part-load ratio.

The defining equation is:

$$\text{RecoveryJacketHeatToFuelRatio} = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Rated Power Output.

Field: Lube Heat Recovery Curve Name

This alpha field contains the name of the Recovery Lube Heat curve. The curve itself is specified separately using a curve object (see **Curve:Quadratic**). The Lube Heat Recovery Curve is a quadratic equation that determines the ratio of recovery lube heat to fuel energy. Used to calculate the recoverable lube oil heat as a function of part-load ratio. The defining equation is:

$$\text{RecoveryLubeHeatToFuelRatio} = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Rated Power Output.

Field: Total Exhaust Energy Curve Name

This alpha field contains the name of the Total Exhaust Energy curve. The curve itself is specified separately using a curve object (see **Curve:Quadratic**). The Total Exhaust Energy Curve is a quadratic equation that determines the ratio of total exhaust energy to fuel energy. Used to calculate the total exhaust heat as a function of part-load ratio. The defining equation is:

$$TotalExhaustToFuelRatio = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Rated Power Output.

Field: Exhaust Temperature Curve Name

This alpha field contains the name of the Exhaust Temperature curve. The curve itself is specified separately using a curve object (see **Curve:Quadratic**). The Exhaust Temperature Curve is a quadratic equation that determines the absolute exhaust temperature. Used to determine the exhaust gas temperature as a function of part-load ratio. The defining equation is:

$$AbsoluteExhaustTemperature = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Rated Power Output.

U-Factor Times Area (UA) Curve

The UA curve applies to the exhaust gas heat exchanger. The curve is an equation that determines the overall heat transfer coefficient for the exhaust gases with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$UAToCapacityRatio = C_1GeneratorRatedPowerOutput^{C_2}$$

The following two fields contain the coefficients for the equation.

Field: Coefficient 1 of U-Factor Times Area Curve

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

Field: Coefficient 2 of U-Factor Times Area Curve

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

Field: Maximum Exhaust Flow per Unit of Power Output

Maximum exhaust flow per unit capacity for the generator. The parameter sets an upper limit on exhaust gas flow and exhaust gas heat recovery for the generator. Units: kg/sec per kW capacity

Field: Design Minimum Exhaust Temperature

This is the design engine stack saturated steam temperature in degrees C.

Field: Fuel Higher Heating Value

This numeric field contains the higher heating value of the fuel used in kJ/kg.

Field: Design Heat Recovery Water Flow Rate

Design water volumetric flow rate through heat recovery loop in m³/sec.

Field: Heat Recovery Inlet Node Name

This alpha field contains the identifying name for the generator's heat recovery side inlet node.

Field: Heat Recovery Outlet Node Name

This alpha field contains the identifying name for the generator's heat recovery side outlet node.

Field: Fuel Type

This alpha field determines the type of fuel that the generator uses. The default is Diesel.

Field: Heat Recovery Maximum Temperature

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

The temperature is specified in degrees C.

Zone,Meter,Cogeneration:Diesel [J]
HVAC,Average,Generator Diesel Mass Flow Rate [kg/s]

```

Generator Electric Power Produced [W]**Generator Electric Energy Produced [J]**

These outputs are the electric power output from the electric generator. Energy is metered on Cogeneration:ElectricityProduced, ElectricityProduced:Plant, and ElectricityProduced:Facility.

Generator Lube Heat Recovery Rate [W]**Generator Lube Heat Recovery [J]****Generator Jacket Heat Recovery Rate [W]****Generator Jacket Heat Recovery [J]****Generator Exhaust Heat Recovery Rate [W]****Generator Exhaust Heat Recovery [J]****Generator Thermal Power Produced [W]****Generator Thermal Energy Produced [J]**

For electric generators with heat recovery these outputs are the components of recoverable energy available. For the IC engine generator, the following heat recovery components are reported: Lube (engine lubricant), Jacket (engine coolant), and Exhaust (engine exhaust). These components are totaled together for Generator Thermal Power Produced and Generator Thermal Energy Produced reports. Generator Lube Heat Recovery, Generator Jacket Heat Recovery, and Generator Exhaust Heat Recovery are metered on HeatRecovery:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

Generator Exhaust Stack Temp [C]

This is the exhaust temperature leaving the engine.

Generator Heat Recovery Inlet Temp [C]**Generator Heat Recovery Outlet Temp [C]****Generator Heat Recovery Mass Flow Rate [kg/s]**

These outputs are the heat recovery inlet and outlet temperatures and flow rate for generators with heat recovery.

Generator Fuel Consumption Rate HHV Basis [W]**Generator Fuel Consumption HHV Basis [J]**

These outputs are the generator's fuel energy and use rate. The energy content of the fuel is based on the higher heating value (HHV).

Generator Diesel Consumption Rate [W]**Generator Diesel Consumption [J]****Generator Diesel Mass Flow Rate [kg/s]**

These outputs are available if the fuel type was selected to be diesel and are the diesel fuel input to the electric generator. Consumption is metered on Cogeneration:Diesel, Diesel:Plant, and Diesel:Facility.

Generator NaturalGas Consumption Rate [W]**Generator NaturalGas Consumption [J]****Generator NaturalGas Mass Flow Rate [kg/s]**

These outputs are available if the fuel type was selected to be NaturalGas and are the natural gas fuel input to the electric generator. Consumption is metered on Cogeneration:NaturalGas, NaturalGas:Plant, and NaturalGas:Facility.

Generator PropaneGas Consumption Rate [W]**Generator PropaneGas Consumption [J]****Generator PropaneGas Mass Flow Rate [kg/s]**

These outputs are available if the fuel type was selected to be PropaneGas and are the propane fuel input to the electric generator. Consumption is metered on Cogeneration:PropaneGas, PropaneGas:Plant, and PropaneGas:Facility.

Generator Gasoline Consumption Rate [W]**Generator Gasoline Consumption [J]****Generator Gasoline Mass Flow Rate [kg/s]**

These outputs are available if the fuel type was selected to be Gasoline and are the gasoline fuel input to the electric generator. Consumption is metered on Cogeneration:Gasoline, Gasoline:Plant, and Gasoline:Facility.

Generator FuelOil#1 Consumption Rate [W]**Generator FuelOil#1 Consumption [J]****Generator FuelOil#1 Mass Flow Rate [kg/s]**

These outputs are available if the fuel type was selected to be FuelOil#1 and are the fuel oil input to the electric generator. Consumption is metered on Cogeneration:FuelOil#1, FuelOil#1:Plant, and FuelOil#1:Facility.

Generator FuelOil#2 Consumption Rate [W]**Generator FuelOil#2 Consumption [J]****Generator FuelOil#2 Mass Flow Rate [kg/s]**

These outputs are available if the fuel type was selected to be FuelOil#2 and are the fuel oil input to the electric generator. Consumption is metered on Cogeneration:FuelOil#2, FuelOil#2:Plant, and FuelOil#2:Facility.

Generator:CombustionTurbine

EnergyPlus has two different models for combustion turbine style generators. This one stems for a model that was originally in the BLAST computer program. A newer model with a different formulation is also available—see the Generator:MicroTurbine input object. The basic combustion-turbine cycle is the Brayton Cycle or open cycle, which consists of an adiabatic compression, constant pressure heating, and adiabatic expansion. The Combustion turbine model uses the electrical load and engine generator size to compute part-load ratios (PLR). Fuel energy input and recoverable lube oil heat are then computed. Finally, the recoverable exhaust heat is calculated.

Combustion turbine generators use performance parameters to compute fuel energy consumption as a function of part-load and ambient (entering) air temperature. Recoverable fuel energy equipment, recoverable lube oil heat/fuel energy input equipment performance, total exhaust heat/fuel energy input equipment, exhaust gas temperature/fuel energy input equipment performance parameters are all specified with a quadratic curve fit.

When the heat recovery curve fits = 0.0, this means that no heat recovery is done on the diesel generator exhaust gas; and no heat recovery is specified.

Field: Name

Unique name to identify this combustion turbine generator.

Field: Rated Power Output

The design nominal capacity of the combustion turbine generator in Watts [W].

Field: Electric Circuit Node Name

This Named node contains where the electric power is put in the program simulation for use by the electric equipment in the Load Center.

Field: Minimum Part Load Ratio

This field contains the minimum allowed operating fraction of full load.

Field: Maximum Part Load Ratio

This field contains the maximum allowed operating fraction of full load.

Field: Optimum Part Load Ratio

This alpha field contains the optimal operating fraction of full load. This is the part load ratio that gives the optimal production of electric power with the least amount of fuel usage.

Field: Part Load Based Fuel Input Curve Name

Needs a Curve:Quadratic object to be specified.

Fuel Input = $a + b \cdot \text{PLR} + c \cdot \text{PLR}^2$

PLR = Ratio of Generator Load to Rated Power Output. This curve is multiplied to the Temperature Based Fuel Input Curve to determine Fuel Energy In.

Field: Temperature Based Fuel Input Curve Name

Needs a Curve:Quadratic object to be specified.

Fuel Input = a + b*AT + c*AT**2 where: AT = Ambient Delta T

Field: Exhaust Flow Curve Name

The Total Exhaust Energy Curve is a quadratic equation that needs to be specified by a curve object. Used to calculate the total exhaust heat as a function of part-load ratio.

Field: Part Load Based Exhaust Temperature Curve Name

The Exhaust Temperature Curve is a quadratic equation that needs to be specified by a curve object. Used to determine the exhaust gas temperature as a function of part-load ratio.

Field: Temperature Based Exhaust Temperature Curve Name

The Exhaust Temperature Curve is a quadratic equation that needs to be specified by a curve object. Used to determine the exhaust gas temperature as a function of part-load ratio.

Field: Heat Recovery Lube Energy Curve Name

This alpha field contains the name of the Recovery Lube Heat curve. The curve itself is specified separately using a curve object (see **Curve:Quadratic**). The Recovery Lubricant Heat Curve is a quadratic equation that determines the ratio of recovery lube heat to fuel energy. Used to calculate the recoverable lube oil heat as a function of part-load ratio. The defining equation is:

$$RecoveryLubeHeatToFuelRatio = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Rated Power Output.

U-Factor Times Area (UA) Curve

The UA curve applies to the exhaust gas heat exchanger. The curve is an equation that determines the overall heat transfer coefficient for the exhaust gases with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$UAToCapacityRatio = C_1GeneratorRatedPowerOutput^{C_2}$$

The following two fields contain the coefficients for the equation.

Field: Coefficient 1 of U-Factor Times Area Curve

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

Field: Coefficient 2 of U-Factor Times Area Curve

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

Field: Maximum Exhaust Flow per Unit of Power Output

Maximum exhaust flow per unit capacity for diesel engines. The parameter sets an upper limit on exhaust gas flow and exhaust gas heat recovery for diesel engines. Units: kg/sec per kW capacity

Field: Design Minimum Exhaust Temperature

This is the design engine stack saturated steam temperature in degrees C.

Field: Design Air Inlet Temperature

Design air inlet temperature in degrees C.

Field: Fuel Higher Heating Value

This numeric field contains the higher heating value of the fuel used in kJ/kg.

Field: Design Heat Recovery Water Flow Rate

Design water volumetric flow rate through heat recovery loop in m³/sec.

Field: Heat Recovery Inlet Node Name

This alpha field contains the identifying name for the combustion turbine generator heat recovery side inlet node.

Field: Heat Recovery Outlet Node Name

This alpha field contains the identifying name for the combustion turbine generator heat recovery side outlet node.

Field: Fuel Type

This alpha field determines the type of fuel that the generator uses. The default is Natural Gas.

Field: Heat Recovery Maximum Temperature

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

The temperature is specified in degrees C.

Field: Outdoor Air Inlet Node Name

This field is optional. It is used to explicitly define an outdoor air node for the inlet for combustion air stream. Defining an outdoor air node here allows using the height-dependent model for outdoor air conditions.

Generator:CombustionTurbine Outputs

The output variables that are available for the combustion turbine generator are:

```

HVAC,Average,Generator Electric Power Produced [W]
HVAC,Sum,Generator Electric Energy Produced [J]
Zone,Meter,ElectricityProduced:Facility [J]
Zone,Meter,ElectricityProduced:Plant [J]
Zone,Meter,Cogeneration:ElectricityProduced [J]

HVAC,Average,Generator Lube Heat Recovery Rate [W]
HVAC,Sum,Generator Lube Heat Recovery [J]

HVAC,Average,Generator Exhaust Heat Recovery Rate [W]
HVAC,Sum,Generator Exhaust Heat Recovery [J]

HVAC,Average,Generator Total Heat Recovery Rate [W]
HVAC,Sum,Generator Total Heat Recovery [J]

HVAC,Average,Generator Exhaust Stack Temp [C]

HVAC,Average,Generator Heat Recovery Inlet Temp [C]
HVAC,Average,Generator Heat Recovery Outlet Temp [C]
HVAC,Average,Generator Heat Recovery Mass Flow Rate [kg/s]

HVAC,Average,Generator Gas Consumption Rate [W]
Zone,Meter,Cogeneration:Gas [J]
HVAC,Sum,Generator Gas Consumption [J]
HVAC,Average,Generator Gas Mass Flow Rate [kg/s]

```

All of these outputs, except for the Combustion use outputs, are described above under "Generator:IC Engine Outputs."

Generator Gas Consumption Rate [W]

Generator Gas Consumption [J]

Generator Gas Mass Flow Rate [kg/s]

These outputs are the natural gas fuel input to the electric generator. Consumption is metered on Cogeneration:Gas, Gas:Plant, and Gas:Facility.

Generator:MicroTurbine

MicroTurbine generators are small combustion turbines that produce electricity on a relatively small scale (e.g., 25kW to 500kW). This model uses nominal performance at reference conditions along with several modifier curves to determine electrical power output and fuel use at non-reference conditions. Standby and ancillary power can also be taken into account. Furthermore, energy recovery from exhaust air can be used to heat water. Similar to electrical power output, thermal power (heat recovery) output is calculated using nominal performance at reference conditions with modifier curves to account for variations at non-reference conditions.

The following inputs define the MicroTurbine electric generator. The ElectricLoadCenter:Generators and ElectricLoadCenter:Distribution objects are used to define the availability and control of all electric generators included in the simulation (ref. ElectricLoadCenter:Generators and ElectricLoadCenter:Distribution).

Field: Name

This alpha field specifies a unique user-defined name to identify this generator. This is a required input.

Field: Reference Electrical Power Output

This numeric field specifies the full-load electrical power output of the microturbine generator in Watts at reference conditions. The reference conditions are defined via additional input fields for this object (see below). This is a required input, and the value entered in this field must be greater than zero.

Field: Minimum Full Load Electrical Power Output

This numeric field specifies the minimum electrical power output in Watts at full-load conditions. The electrical power output of the generator is determined by multiplying the Reference Electrical Power Output by the Electrical Power Function of Temperature and Elevation modifier curve. If the result is less than the numeric value specified in this input field, then the generator's electrical power output is reset to the minimum full-load value specified in this input field. The value entered in this field must be greater than or equal to zero. If this field is left blank, the default value of 0.0 will be used.

Field: Maximum Full Load Electrical Power Output

This numeric field specifies the maximum electrical power output in Watts at full-load conditions. The electrical power output of the generator is determined by multiplying the Reference Electrical Power Output by the Electrical Power Function of Temperature and Elevation Modifier curve. If the result is greater than the numeric value specified in this input field, then the generator's electrical power output is reset to the maximum full-load value specified in this input field. The value entered in this field must be greater than zero. If this field is left blank, then the value entered for the Reference Electrical Power Output field (above) will be used as the Maximum Full Load Electrical Power Output.

Field: Reference Electrical Efficiency Using Lower Heating Value

This numeric field contains the electrical efficiency of the generator at reference conditions, based on the lower heating value of the fuel. The electrical efficiency is the electric power output divided by the fuel energy consumption rate (LHV basis). The reference conditions are defined via additional input fields for this object (see below). This is a required input, and the value entered in this field must be greater than zero and less than or equal to 1.0.

Field: Reference Combustion Air Inlet Temperature

This numeric field specifies the reference temperature for the combustion inlet air in degrees Celsius. If this field is left blank, the default value of 15°C will be used.

Field: Reference Combustion Air Inlet Humidity Ratio

This numeric field specifies the reference humidity ratio for the combustion inlet air in kg-H₂O/kg-air. The value specified for this field must be greater than zero. If this field is left blank, the default value of 0.00638 kg-H₂O/kg-air will be used.

Field: Reference Elevation

This numeric field specifies the reference elevation in meters (relative to sea level). The value specified for this field must be greater than or equal to -300.0 meters. If this field is left blank, the default value of 0.0 meters will be used.

Field: Electrical Power Function of Temperature and Elevation Curve Name

This alpha field specifies the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of electrical power output as a function of the combustion air inlet temperature and elevation. The output of this curve is multiplied by the Reference Electrical Power Output to give the full-load power output at a specific combustion air inlet temperature and elevation (i.e., at values different from the reference conditions). This curve should be normalized to have a value of 1.0 at the reference conditions, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period and for the actual elevation of the generator.

Field: Electrical Efficiency Function of Temperature Curve Name

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of electrical efficiency as a function of the combustion air inlet temperature. The output of this curve is multiplied by the Reference Electrical Efficiency Using Lower Heating Value to give the full-load electrical efficiency at specific combustion air inlet temperatures (i.e., at inlet air temperatures different from the Reference Combustion Air Inlet Temperature). This curve should be normalized to have a value of 1.0 at the Reference Combustion Air Inlet Temperature, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period.

Field: Electrical Efficiency Function of Part Load Ratio Curve Name

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of electrical efficiency as a function of the generator's part-load ratio (part-load ratio is the actual electrical power output divided by the full-load electrical power output at the current operating conditions). The output of this curve is multiplied by the Reference Electrical Efficiency Using Lower Heating Value and the output of the Electrical Efficiency Function of Temperature modifier curve to give the electrical efficiency at specific part-load and combustion air inlet (temperature) conditions. This curve should be normalized to have a value of 1.0 when the generator's part-load ratio is 1.0, and the curve should be valid for the range of part-load ratios anticipated for the simulation period.

Field: Fuel Type

This choice field specifies the type of fuel used by the generator. If the field is left blank, the fuel type will be assumed to be NaturalGas.

Field: Fuel Higher Heating Value

This numeric field specifies the higher heating value of the fuel used in kJ/kg. The value specified for this field must be greater than zero and greater than the specified Fuel Lower Heating Value. If this field is left blank, the default value of 50,000 kJ/kg will be used.

Field: Fuel Lower Heating Value

This numeric field specifies the lower heating value of the fuel used in kJ/kg. The value specified for this field must be greater than zero but less than the specified Fuel Higher Heating Value. If this field is left blank, the default value of 45,450 kJ/kg will be used.

Field: Standby Power

This numeric field specifies the standby electric power consumed by the generator in Watts. The standby power is the electrical power consumed by the generator (e.g., air fans and controls) when the generator is available to operate but the generator electrical power output is zero (power output is not being requested by the electric load center). The value specified for this field must be greater than or equal to zero. If this field is left blank, the default value of 0.0 W will be used.

Field: Ancillary Power

This numeric field specifies the ancillary electric power consumed by the generator in Watts. The ancillary power is the electrical power consumed by other associated equipment (e.g., external fuel pressurization pumps) when the generator is operating. Specify this input as 0.0 if the Reference Electrical Power Output and Reference Electrical Efficiency Using Lower Heating Value input fields and associated modifier curves reflect the "net" electrical power output from the generator (i.e., ancillary power already deducted from the generator's gross electrical power output). A value greater than zero indicates that this electrical power is consumed whenever the generator is operating and will be deducted from the generator's overall electrical power output (Generator Electric Power Produced). The value specified for

this field must be greater than or equal to zero. If this field is left blank, the default value of 0.0 W will be used.

Field: Ancillary Power Function of Fuel Input Curve Name

This alpha field specifies the name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of ancillary power as a function of the generator's input fuel mass flow rate (kg/s). The output of this curve is multiplied by the ancillary power to give the ancillary power at a specific fuel mass flow rate. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation (i.e., the ancillary power is constant whenever the generator operates).

Field: Heat Recovery Water Inlet Node Name

This alpha field specifies the identifying name for the generator's heat recovery water inlet node.

Field: Heat Recovery Water Outlet Node Name

This alpha field specifies the identifying name for the generator's heat recovery water outlet node.

Field: Reference Thermal Efficiency Using Lower Heat Value

This numeric field specifies the thermal efficiency (heat recovery to water) at reference conditions, based on the lower heating value of the fuel. The thermal efficiency is the thermal power output (to water) divided by the fuel energy consumption rate (LHV basis). The reference conditions are defined via additional input fields for this object. This value must be from 0.0 to 1.0. If this field is left blank, the default value of 0.0 will be used.

Field: Reference Inlet Water Temperature

This numeric field specifies the reference temperature for the inlet water to the heat recovery heat exchanger in degrees Celsius.

Field: Heat Recovery Water Flow Operating Mode

This field is used to choose between different modes of controlling the mass flow rate of water being heated by energy recovered from exhaust air. There are two options available for this field: "PlantControl" or "InternalControl." The "PlantControl" option indicates that the heat recovery water flow rate through the generator is determined externally (by the wider balance of plant). In this case, the generator will request the Reference Heat Recovery Water Flow Rate whenever it operates but the actual flow rate may be limited by other plant components (e.g., pump). The "InternalControl" option indicates the flow of water is controlled inside the generator based on current operating conditions. For InternalControl, the generator should (probably) include a bypass branch when connecting to the plant loop.

Field: Reference Heat Recovery Water Flow Rate

This numeric field is the reference heat recovery (volumetric) water flow rate in cubic meters per second. Entered values must be greater than zero.

Field: Heat Recovery Water Flow Rate Function of Temperature and Power Curve Name

This alpha field specifies the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of heat recovery water flow rate as a function of the inlet water temperature and net electrical power output. This field is only used if the Heat Recovery Water Flow Operating Mode is 'InternalControl'. The output of this curve is multiplied by the Reference Heat Recovery Water Flow Rate to give the water flow rate at the specific inlet water temperature and net power operating conditions. This curve should be normalized to have a value of 1.0 at the reference conditions, and the curve should be valid for the range of inlet water temperatures and net electrical power output anticipated for the

simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Field: Thermal Efficiency Function of Temperature and Elevation Curve Name

This alpha field specifies the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of thermal efficiency as a function of the combustion air inlet temperature and elevation. The output of this curve is multiplied by the Reference Thermal Efficiency Using Lower Heating Value to give the full-load thermal efficiency at a specific combustion air inlet temperature and elevation (i.e., at values different from the reference conditions). This curve should be normalized to have a value of 1.0 at the reference conditions, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period and for the actual elevation of the generator. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Field: Heat Recovery Rate Function of Part Load Ratio Curve Name

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of heat recovery to water (thermal power output) as a function of the generator's part-load ratio (part-load ratio is the actual electrical power output divided by the full-load electrical power output at the current operating conditions). The output of this curve is multiplied by the steady-state heat recovery at the current combustion inlet air temperature and elevation to give the heat recovery rate (thermal power output) at specific part-load operating conditions. This curve should be normalized to have a value of 1.0 when the generator's part-load ratio is 1.0, and the curve should be valid for the range of part-load ratios anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Field: Heat Recovery Rate Function of Inlet Water Temperature Curve Name

This alpha field specifies the name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of heat recovery to water (thermal power output) as a function of the inlet water temperature. The output of this curve is multiplied by the steady-state heat recovery at the current combustion inlet air temperature and elevation to give the heat recovery rate (thermal power output) at non-reference inlet water conditions. This curve should be normalized to have a value of 1.0 at the Reference Inlet Water Temperature, and the curve should be valid for the range of inlet water temperatures anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Field: Heat Recovery Rate Function of Water Flow Rate Curve Name

This alpha field specifies the name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of heat recovery to water (thermal power output) as a function of the heat recovery water flow rate. The output of this curve is multiplied by the steady-state heat recovery at the current combustion inlet air temperature and elevation to give the heat recovery rate (thermal power output) at non-reference heat recovery water flow rates. This curve should be normalized to have a value of 1.0 at the Reference Heat Recovery Water Flow Rate, and the curve should be valid for the range of water flow rates anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Field: Minimum Heat Recovery Water Flow Rate

This numeric field specifies the minimum (volumetric) water flow rate through the heat recovery heat exchanger in cubic meters per second. The minimum input value is 0.0, and a value of 0.0 is assumed if this field is left blank.

Field: Maximum Heat Recovery Water Flow Rate

This numeric field specifies the maximum (volumetric) water flow rate through the heat recovery heat exchanger in cubic meters per second. The minimum input value for this field is 0.0, and a value of 0.0 is assumed if this field is left blank. The maximum heat recovery water flow rate must be greater than or equal to the minimum heat recovery water flow rate.

Field: Maximum Heat Recovery Water Temperature

This field sets the maximum water temperature, in degrees Celsius, that this generator can produce via heat recovery. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the water loop approach this maximum temperature, the temperature difference between the entering water and the surfaces in generator's heat recovery heat exchanger becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The amount of heat recovered will diminish if the inlet water temperature approaches the maximum temperature, and this will show up in the reporting.

Field: Combustion Air Inlet Node Name

This alpha field specifies the name of the combustion air inlet node. If a node name is specified, this node must be an outdoor air node and must also be specified elsewhere in the input (ref: OutdoorAir:Node and OutdoorAir:NodeList). If this field is left blank, the combustion air inlet conditions are assumed to be the outdoor weather conditions used for the simulation.

Field: Combustion Air Outlet Node Name

This alpha field specifies the name of the combustion air outlet node.

Field: Reference Exhaust Air Mass Flow Rate

This numeric field is the reference exhaust air mass flow rate in kilograms per second. Entered values must be greater than zero.

Field: Exhaust Air Flow Rate Function of Temperature Curve Name

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of exhaust air flow rate as a function of the combustion air inlet temperature. The output of this curve is multiplied by the Reference Exhaust Air Mass Flow Rate to give the exhaust air mass flow rate at non-reference combustion air inlet temperatures. This curve should be normalized to have a value of 1.0 at the Reference Combustion Air Inlet Temperature, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Field: Exhaust Air Flow Rate Function of Part Load Ratio Curve Name

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of exhaust air flow rate as a function of the generator's part-load ratio (part-load ratio is the actual electrical power output divided by the full-load electrical power output at the current operating conditions). The output of this curve is multiplied by the Reference Exhaust Air Mass Flow Rate to give the exhaust air mass flow rate at specific part-load operating conditions. This curve should be normalized to have a value of 1.0 when the generator's part-load ratio is 1.0, and the curve should be valid for the range of part-load ratios anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Field: Nominal Exhaust Air Outlet Temperature

This numeric field is the exhaust air outlet temperature at nominal (reference) conditions in degrees Celsius.

Field: Exhaust Air Temperature Function of Temperature Curve Name

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of exhaust air outlet temperature as a function of the combustion air inlet temperature. The output of this curve is multiplied by the Nominal Exhaust Air Outlet Temperature to give the exhaust air temperature at non-reference combustion air inlet temperatures. This curve should be normalized to have a value of 1.0 at the Reference Combustion Air Inlet Temperature, and the curve should be valid for the range of inlet air temperatures anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Field: Exhaust Air Temperature Function of Part Load Ratio Curve Name

This alpha field specifies the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of exhaust air outlet temperature as a function of the generator's part-load ratio (part-load ratio is the actual electrical power output divided by the full-load electrical power output at the current operating conditions). The output of this curve is multiplied by the Nominal Exhaust Air Outlet Temperature to give the exhaust air temperature at specific part-load operating conditions. This curve should be normalized to have a value of 1.0 when the generator's part-load ratio is 1.0, and the curve should be valid for the range of part-load ratios anticipated for the simulation period. If this field is left blank, the model assumes that the modifier curve is 1.0 for the entire simulation.

Generator:MicroTurbine Outputs

The output variables that are available for the microturbine generator are:

```

HVAC,Average,Generator Electric Power Produced [W]
HVAC,Sum,Generator Electric Energy Produced [J]
HVAC,Average,Generator Electric Efficiency LHV Basis [-]
HVAC,Average,Generator <Fuel Type> Consumption Rate HHV Basis [W]
HVAC,Average,Generator Fuel Consumption Rate HHV Basis [W]
HVAC,Sum,Generator <Fuel Type> Consumption HHV Basis [J]
HVAC,Sum,Generator Fuel Consumption HHV Basis [J]
HVAC,Average,Generator <Fuel Type> Mass Flow Rate [kg/s]

If Standby Power input field > 0.0:
HVAC,Average,Generator Standby Electric Power [W]
HVAC,Sum,Generator Standby Electric Consumption [J]

If Ancillary Power input field > 0.0:
HVAC,Average,Generator Ancillary Electric Power [W]
HVAC,Sum,Generator Ancillary Electric Consumption [J]

If heat recovery water inlet and outlet node names are entered (and valid):
HVAC,Average,Generator Thermal Power Produced [W]
HVAC,Sum,Generator Thermal Energy Produced [J]
HVAC,Average,Generator Thermal Efficiency LHV Basis [-]
HVAC,Average,Generator Heat Recovery Inlet Temperature [C]
HVAC,Average,Generator Heat Recovery Outlet Temperature [C]
HVAC,Average,Generator Heat Recovery Water Mass Flow Rate [kg/s]

```

Generator Electric Power Produced [W]

This output variable is the average electric power produced by the generator in Watts for the timestep being reported. This is the “net” electric power produced, accounting for ancillary electric power consumed during generator operation.

Generator Electric Energy Produced [J]

This output variable is the electric energy produced by the generator in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = ElectricityProduced, End Use Key = Cogeneration, Group Key = Plant (Ref. Report Meter). This is the “net” electric energy produced, accounting for ancillary electric consumption during generator operation.

Generator Electric Efficiency LHV Basis [-]

This output variable is the average electric efficiency of the generator (lower heating value basis) for the timestep being reported. The electric efficiency is the Generator Electric Power Produced in Watts divided by the generator’s fuel energy consumption rate in Watts (lower heating value basis).

Generator <FuelType> Consumption Rate HHV Basis [W]

This output variable is the average fuel-specific energy consumption rate of the electric generator in Watts (higher heating value basis) for the timestep being reported. <FuelType> is the name of the fuel used by this electric generator. <FuelType> can be one of the following: Natural Gas (=> 'Gas') or Propane Gas (=>'Propane').

Generator Fuel Consumption Rate HHV Basis [W]

This output variable is the average fuel energy consumption rate of the electric generator in Watts (higher heating value basis) for the timestep being reported. The output variable name is non-fuel specific.

Generator <FuelType> Consumption HHV Basis [J]

This output variable is the fuel-specific energy consumption of the electric generator in Joules (higher heating value basis) for the timestep being reported. This output is also added to a report meter with Resource Type = <FuelType>, End Use Key = Cogeneration, Group Key = Plant (Ref. Report Meter). <FuelType> is the name of the fuel used by this electric generator. <FuelType> can be one of the following: Natural Gas (=> 'Gas') or Propane Gas (=>'Propane').

Generator Fuel Consumption HHV Basis [J]

This output variable is the fuel energy consumption of the electric generator in Joules (higher heating value basis) for the timestep being reported. The output variable name is non-fuel specific.

Generator <FuelType> Mass Flow Rate [kg/s]

This output variable is the average mass flow rate of fuel being consumed by the electric generator in kg/s for the timestep being reported. <FuelType> is the name of the fuel used by this electric generator. <FuelType> can be one of the following: Natural Gas (=> 'Gas') or Propane Gas (=>'Propane').

Generator Standby Electric Power [W]

This output variable is the average standby electric power consumed by the generator in Watts for the timestep being reported. Standby power is electrical power consumed by the generator (e.g., air fans and controls) when the generator is available to operate but the generator electrical power output is zero (power output is not being requested by the electric load center). This output variable is only produced when the user enters a value greater than 0.0 for the input field Standby Power.

Generator Standby Electric Consumption [J]

This output variable is the standby electric energy consumption for the generator in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cogeneration, Group Key = Plant (Ref. Report Meter). This output variable is only produced when the user enters a value greater than 0.0 for the input field Standby Power.

Generator Ancillary Electric Power [W]

This output variable is the average ancillary electric power consumed by the generator in Watts for the timestep being reported. Ancillary power is the electrical power consumed by other associated equipment (e.g., external fuel pressurization pumps) when the generator is operating. This output variable is only produced when the user enters a value greater than 0.0 for the input field Ancillary Power.

Generator Ancillary Electric Consumption [J]

This output variable is the ancillary electric energy consumption for the generator in Joules for the timestep being reported. This energy consumption is already deducted from the output

variable Generator Electric Energy Produced (“net” electric energy produced by the generator). This output variable is only produced when the user enters a value greater than 0.0 for the input field Ancillary Power.

Generator Thermal Power Produced [W]

This output variable is the average thermal power produced (i.e., exhaust energy recovery to heat water) in Watts for the timestep being reported.

Generator Thermal Energy Produced [J]

This output variable is the thermal energy produced (i.e., exhaust energy recovery to heat water) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = HeatRecovery, Group Key = Plant (Ref. Report Meter).

Generator Thermal Efficiency LHV Basis [-]

This output variable is the average thermal efficiency of the generator (lower heating value basis) for the timestep being reported. The thermal efficiency is the Generator Thermal Power Produced in Watts divided by the generator’s fuel energy consumption rate in Watts (lower heating value basis).

Generator Heat Recovery Inlet Temperature [C]

This output variable is the average heat recovery inlet water temperature in degrees Celsius for the timestep being reported.

Generator Heat Recovery Outlet Temperature [C]

This output variable is the average heat recovery outlet water temperature in degrees Celsius for the timestep being reported.

Generator Heat Recovery Water Mass Flow Rate [kg/s]

This output variable is the average heat recovery water mass flow rate in kilograms per second for the timestep being reported.

Generator:MicroCHP

This object is used to model small-scale combined heat and power (micro CHP) electric generators using the model developed by IEA/ECBCS Annex 42 – see www.cogen-sim.net. The model was developed for both internal combustion and Stirling cycle engines, but might be used for other types of residential CHP devices.

Note that unlike other component models in EnergyPlus, this model is not normalized. Therefore, performance coefficients developed for one type and capacity of CHP device cannot be used for a device with a different capacity.

This model is an empirical, curve fit model. This object describes the connections to the rest of the building model and includes a reference to another object called Generator:MicroCHP:NonNormalizedParameters that provides the operating characteristics.

```

Generator:MicroCHP,
  A1, \field Name
      \reference MicroCHPNames
  A2, \field Performance Parameters Name
      \Note Enter the name of a Generator:MicroCHP:NonNormalizedParameters object.
      \object-list MicroCHPParametersNames

      \object-list GenFuelSupNames
      \Note Enter the name of a Generator:FuelSupply object.
  A9; \field Availability Schedule Name
      \object-list ScheduleNames

```

Field: Name

This field contains a unique name for the residential CHP device.

Field: Performance Parameters Name

This field contains the name of a Generator:MicroCHP:NonNormalizedParameters object defined elsewhere in the input.

Field: Zone Name

This field contains the name of the thermal zone where the CHP device is located in the model. If the device is outdoors, or you do not want skin losses to be added to a zone, then leave this field blank.

Field: Cooling Water Inlet Node Name

This field provides the name of a node that is the inlet to the CHP device. The node should be on the plant loop that will receive the heat from the residential CHP unit. This inlet serves as the cooling water for the CHP device.

Field: Cooling Water Outlet Node Name

This field provides the name of a node that is the outlet to the CHP device. The node should be on the plant loop that will receive the heat from the residential CHP unit. This outlet serves as the exit of the cooling water leaving the CHP unit.

Field: Air Inlet Node Name

The name of an air node that supplies the CHP unit with air for use inside the generator.

Field: Air Outlet Node Name

The name of an air node that receives the exhaust from the CHP unit.

Field: Generator Fuel Supply Name

This field contains the name of a Generator:FuelSupply object defined elsewhere in the input file.

Field: Availability Schedule Name

This field contains the name of a schedule used to control whether or not the unit is available. It is "available" any time the value is greater than zero. If it is available, it may consume standby power at times when there is no request for power from the Electric Load Center. If it is not available (schedule value = 0.0) then the CHP unit is in a completely off "mode" and will not consume standby power.

An example IDF showing how this object is used is provided below:

```

Generator:MicroCHP,
  MicroCoGen1,           !- Name

Field: Name

Unique name to identify this set of parameter data.

Field: Maximum Electric Power

This is the size of the CHP unit in terms of the maximum electrical power it can produce [W]. If the electric load center requests more power than this maximum, then the unit will restrict its output to this level.

Field: Minimum Electric Power

This is the size of the CHP unit in terms of the minimum electrical power it can produce [W]. If the electric load center requests less power than this minimum, then the unit will hold its output to this level.

Field: Minimum Cooling Water Flow Rate

This is the minimum flow rate of cooling water that must be available for the unit to operate [kg/s]. If the plant loop is not providing this flow of water, the unit will shut down to protect it from overheating.

Field: Maximum Cooling Water Temperature

This is the maximum temperature of cooling water inlet or outlet that can occur without the unit shutting down to protect from overheating [°C].

Field: Electrical Efficiency Curve Name

This is the name of Curve:Triquadratic object that defines the steady-state net electrical efficiency. The electrical efficiency, η_e , is a function of the cooling water mass flow rate, \dot{m}_{cw} , the temperature of the cooling water at the inlet, T_{cw} , the steady-state net electrical power produced, $P_{net,ss}$.

$$\eta_e = f(P_{net,ss}, \dot{m}_{cw}, T_{cw})$$

The associated Curve:Triquadratic object should be defined with the independent variables $P_{net,ss}$, \dot{m}_{cw} , T_{cw} corresponding to x, y, and z, respectively.

Field: Thermal Efficiency Curve Name

This is the name of a Curve:Triquadratic object that defines the steady-state net thermal efficiency. The thermal efficiency, η_q , is a function of the cooling water mass flow rate, \dot{m}_{cw} , the temperature of the cooling water at the inlet, T_{cw} , the steady-state net electrical power produced, $P_{net,ss}$.

$$\eta_q = f(P_{net,ss}, \dot{m}_{cw}, T_{cw})$$

The associated Curve:Triquadratic object should be defined with the independent variables $P_{net,ss}$, \dot{m}_{cw} , T_{cw} corresponding to x, y, and z, respectively.

Field: Cooling Water Flow Rate Mode

This field is used to choose between different modes of controlling the mass flow rate of cooling water. There are two options available for this field: "PlantControl" or "InternalControl." The "PlantControl" option indicates that the cooling water flow rate through the CHP device is determined externally (by the wider balance of plant). The "InternalControl" option indicates the flow of cooling water is controlled inside the CHP device (e.g., like an automobile's thermostat).

For internal control, the following field is used to define a Biquadratic curve that will determine the cooling water flow rate. For internal control, the CHP device should (probably) include a bypass branch when connecting to the plant loop.

Field: Cooling Water Flow Rate Curve Name

This field contains the name of a Curve:Biquadratic object that defines the mass flow rate of cooling water, \dot{m}_{cw} . This field is only used if the prior field is set to "InternalControl." The mass flow of cooling water is a function of steady-state power, $P_{net,ss}$, and the inlet temperature of the cooling water, T_{cw} . The associated Curve:Biquadratic should be defined with the independent variables $P_{net,ss}$ and T_{cw} corresponding to x and y, respectively.

Field: Air Flow Rate Curve Name

This is the name of a Curve:Quadratic object that defines the steady state air flow into the CHP device as a function of the mass flow rate of fuel.

Field: Maximum Net Electrical Power Rate of Change

This field contains input on the limits for how fast the generator can ramp up or down in terms of the net electrical power.

Field: Maximum Fuel Flow Rate of Change

This field contains input on the limits for how fast the generator can ramp up or down in terms of the fuel flow rates.

Field: Heat Exchanger U-Factor Times Area Value

This field describes the effective UA value for the heat exchanger that transfers heat from the generator to the cooling water.

Field: Skin Loss U-Factor Times Area Value

This field describes the effective UA value for the heat transfer from the generator to the surrounding air.

Field: Skin Loss Radiative Fraction

This field describes the split between thermal radiation and thermal convection for the heat losses from the skin of the generator.

Field: Aggregated Thermal Mass of Energy Conversion Portion of Generator

This field describes the aggregated thermal mass of the energy conversion portion of the generator. This includes the engine block in an internal combustion engine.

Field: Aggregated Thermal Mass of Heat Recovery Portion of Generator

This field describes the aggregated thermal mass of the heat recovery portion of the generator. This includes the encapsulated cooling water and heat exchanger shell in immediate thermal contact.

Field: Standby Power

This field describes the power used by the CHP unit's control systems while in standby operation. Standby operation mode occurs whenever the unit is available but not being called upon to produce power. Power is entered as a positive value but indicates negative generation.

Field: Warm Up Mode

This field is used to choose between different modes of controlling the warm up characteristics. Residential CHP units such as Stirling engines have different warm up characteristics than internal combustion engines. There are two warm up modes available: "NominalEngineTemperature" or "TimeDelay." If the former mode is input in this field, then the next three fields are used to model warm up. If the later mode is input, then the fourth field below is used to model warm up.

Field: Warm Up Fuel Flow Rate Coefficient

This field describes the value for the coefficient used to determine the rate of fuel flow during warm up. The coefficient, k_f , is used in the following relation,

$$\dot{m}_{fuel, warm-up} = \dot{m}_{fuel, ss-max} + k_f \dot{m}_{fuel, ss-max} \left(\frac{T_{eng, nom} - T_{room}}{T_{eng} - T_{room}} \right)$$

Field: Nominal Engine Operating Temperature

This field describes the nominal engine temperature during normal, steady-state operation, $T_{eng, nom}$ [°C].

Field: Warm Up Power Coefficient

This field describes the value for the coefficient used to determine the rate of power production during warm up. The coefficient k_p is used in the following relation,

$$P_{net, warm-up} = P_{max} k_p \left(\frac{T_{eng} - T_{room}}{T_{eng, nom} - T_{room}} \right)$$

Field: Warm Up Fuel Flow Rate Limit Ratio

This field is used to describe a limit to the fuel flow rate during warm up. The limit is a ratio multiplied by the maximum fuel flow rate during normal operation (corresponding to the fuel flow for maximum electrical power). If the warm up operating fuel flow rate is twice the steady state fuel flow at maximum power, then a value of 2.0 would be entered in this field. This field

is only used with the nominal engine temperature warm up mode and is intended for Stirling engines.

Field: Warm Up Delay Time

This field is used to model the warm up operation when the warm up mode is “TimeDelay.” Enter the time between activation and power generation in seconds.

Field: Cool Down Power

This field describes the power used by the CHP unit’s ancillary systems while in cool down operation mode. Cool down operation mode occurs whenever the unit has recently been told to stop producing power. Power here is consumed and entered as a positive value that indicates negative generation. For example, a component such as a cooling fan might continue to run during cool down.

Field: Cool Down Delay Time

This field is used to describe the time it takes for the CHP unit to cool off and complete the cool down operation. Enter the time between deactivation and the end of a cool down period in seconds.

Field: Restart Mode

This field is used to choose between two different control situations for the cool down operation. The two options for this field are “MandatoryCoolDown” and “OptionalCoolDown.” The former is used to direct the model to complete the entire cool down period before the generator can subsequently enter warm up mode. The latter directs the model to allow immediately switching to warm up mode, if power is requested before the cool down period is completed.

An example IDF showing how this object is used is provided below:

```

Generator Time in Off Mode [s]

This report is the amount of time the generator spent in “Off” mode in seconds.

Generator Time in Standby Mode [s]

This report is the amount of time the generator spent in “Stand By” mode in seconds.

Generator Time in Warm Up Mode [s]

This report is the amount of time the generator spent in “Warm Up” mode in seconds.

Generator Time in Normal Operating Mode [s]

This report is the amount of time the generator spent in “Normal Operating” mode in seconds.

Generator Time in Cool Down Mode [s]

This report is the amount of time the generator spent in “Cool Down” mode in seconds.

Generator Electric Power Produced [W]

This report is the net electrical power produced by the generator in watts.

Generator Electric Energy Produced [J]

This report is the net electrical energy produced by the generator in joules. This report variable is also put on the meter for on-site production.

Generator Electrical Efficiency []

This is the result for electrical efficiency.

Generator Thermal Efficiency []

This is the result for thermal efficiency.

Generator Gross Heat Input Rate to Engine [W]

This is the gross rate of heat input (from fuel consumption) into the engine control volume.

Generator Steady-State Rate of Heat Generation in Engine [W]

This is an interim value in the dynamic thermal calculation that describes the steady-state heat generation in the engine.

Generator Thermal Power Produced [W]**Generator Thermal Energy Produced [J]**

These are the rate and energy of thermal heat transferred from the engine to the heat recovery fluid in the coolant control volume.

Generator Air Flow Rate [kg/s]

This is the rate of air flow thru the engine on a mass basis.

Generator Molar Fuel Flow Rate [kmol/s]

This is the rate of fuel flow thru the engine on a molar basis.

Generator Fuel Flow Rate [kg/s]

This is the rate of fuel flow thru the engine on a mass basis.

Generator Engine Temperature [C]

This is the model result for engine temperature in C. This is the lumped temperature for the engine control volume.

Generator Coolant Inlet Temperature [C]

This is the temperature of the inlet water used for heat recovery. It is determined by the balance of plant connected to the generator.

Generator Coolant Outlet Temperature [C]

This report is the model prediction for the leaving temperature of water used for heat recovery. If there is no flow this is the modeled prediction for the mass of cooling water in contact with the engine.

Generator Fuel Consumption HHV Basis [J]

This is the energy used by the cogeneration device in terms of higher heating value in joules. This is the report variable is also put on the meter for natural gas.

Generator Fuel Consumption Rate HHV Basis [W]

This is the rate of fuel energy use by the cogeneration device in terms of higher heating value in watts.

Generator Fuel Consumption LHV Basis [J]

This is the fuel energy used by the cogeneration device in terms of lower heating value in joules.

Generator Fuel Consumption Rate LHV Basis [W]

This is the rate of fuel energy use by the cogeneration device in terms of lower heating value in watts

Generator Heat Loss Rate to Zone [W]

Rate of heat gain to zone from cogeneration unit.

Generator Heat Loss Energy to Zone [J]

Heat gains to zone from cogeneration unit.

Generator Convection Heat Loss Rate to Zone [W]

Portion of rate of heat gain to zone in the form of surface convection heat transfer.

Generator Radiation Heat Loss Rate to Zone [W]

Portion of heat gains to zone in the form of surface radiation heat transfer (to other surfaces in zone).

Generator:FuelCell

This object is used to model small Fuel Cell (FC) generators. IEA/ECBCS Annex 42 – see www.cogen-sim.net, developed the FC model implemented in EnergyPlus. The model can be used for two general types of fuel cells, solid oxide fuel cells (SOFC) and proton exchange membrane fuel cells (PEMFC). Warning! This is a complicated model, intended primarily for research. Because fuel cells for cogeneration (producing both heat and electricity) are not yet a mature product for building systems, the input data for this model are extremely difficult to obtain. However, the model is designed to allow investigating the relative implications of a broad array of subsystems and interactions with the building.

There should be one Generator:FuelCell object for each individual FC generator in the model. Multiple fuel cell generators can be included in a given simulation. Because there are a large number of inputs to the FC model and numerous, somewhat separable subsystems within a fuel cell, the EnergyPlus input objects have been organized into a number of separate input objects. This object simply refers to the names of all the other input objects that provide the input details for individual subsystems within the fuel cell cogeneration device. The following figure diagrams these separate subsystems. (not shown is an optional stack cooler with separate connections to heat recovery water loop and surrounding zone air).

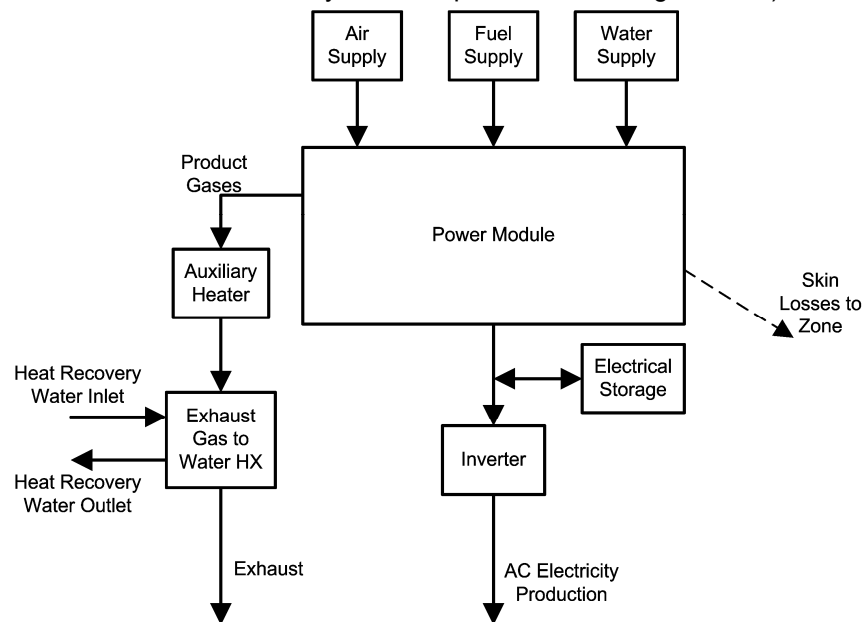

Figure 126. Fuel cell subsystems.

Note that the FC model is formulated using the Lower Heating Value (LHV) of the fuel, whereas most other parts of EnergyPlus use the Higher Heating Value (HHV). LHV has important advantages over HHV in the context of the quality of heat recovered. While model coefficients for input performance descriptions are to be based on LHV, energy consumption and tariff calculations are also reported on HHV basis when using this model.

Field: Name

This field contains a unique name for the fuel cell.

Field: Power Module Name

This field contains the name of a Generator:FuelCell:PowerModule input object.

Field: Air Supply Name

This field contains the name of a Generator:FuelCell:AirSupply input object.

Field: Fuel Supply Name

This field contains the name of a Generator:FuelSupply input object.

Field: Water Supply Name

This field contains the name of a Generator:FuelCell:WaterSupply input object.

Field: Auxiliary Heater Name

This field contains the name of a Generator:FuelCell:AuxiliaryHeater input object.

Field: Heat Exchanger Name

This field contains the name of a Generator:FuelCell:ExhaustGasToWaterHeatExchanger input object.

Field: Electrical Storage Name

This field contains the name of a Generator:FuelCell:ElectricalStorage input object.

Field: Inverter Name

This field contains the name of a Generator:FuelCell:Inverter input object.

Field: Stack Cooler Name

This field contains the name of a Generator:FuelCell:StackCooler input object. This is optional. The presence of a stack cooler distinguishes between SOFC and PEMFC with PEMFC operating at lower temperatures and requiring a separate subsystem to maintain stack temperatures.

An example input data file (IDF) entry for this object is provided below:

```

Generator Electric Power Produced [W]

This report is the net electrical power produced by the generator in watts.

Generator Electric Energy Produced [J]

This report is the net electrical energy produced by the generator in joules. This report variable is also put on the meter for on-site production.

Generator Thermal Power Produced [W]**Generator Thermal Energy Produced [J]**

These are the rate and energy of thermal heat transferred from the engine to the heat recovery fluid in the coolant control volume.

Generator Fuel Consumption HHV Basis [J]

This is the energy used by the cogeneration device in terms of higher heating value in joules. This is the report variable is also put on the meter for natural gas.

Generator Fuel Consumption Rate HHV Basis [W]

This is the rate of fuel energy use by the cogeneration device in terms of higher heating value in watts.

Generator Fuel Consumption LHV Basis [J]

This is the fuel energy used by the cogeneration device in terms of lower heating value in joules.

Generator Fuel Consumption Rate LHV Basis [W]

This is the rate of fuel energy use by the cogeneration device in terms of lower heating value in watts.

FC Heat Loss Rate to Zone [W]

This variable provides the results for the total rate of skin losses from the fuel cell to the surrounding zone.

FC Heat Loss Energy to Zone [J]

This variable provides the results for the total energy in skin losses from the fuel cell to the surrounding zone.

FC Convection Heat Loss Rate to Zone [W]

This variable provides the results for the rate of skin losses in the form of surface convection heat transfer from the fuel cell to the surrounding zone.

FC Radiation Heat Loss Rate to Zone [W]

This variable provides the results for the rate of skin losses in the form of radiation heat transfer from the fuel cell to the surrounding zone.

Using the FC model with DisplayAdvancedReportVariables (see Diagnostics object or use of operating system's environment variables) makes the following output variables available as listed in the RDD file. There are a large number of output variables that provide access to the inner workings of the model and individual subsystems that are not likely to be useful for the average user.

FC Air Temperature at Inlet [C]

This variable provides the temperature of air supplied to the FC.

FC Air Temperature Entering Power Module [C]

This variable provides the temperature of the air supplied to the power module after it has gone through the blower and received any heat recovered from other subsystems.

FC Air Flow Rate [kmol/s]

This variable provides the results for \dot{N}_{air} , the flow rate of air into the FC.

FC Air Enthalpy Entering Power Module [W]

This variable provides the results for $\sum_i \left(\dot{N}_i \cdot \left[\hat{h}_i - \Delta_f \hat{h}_i^0 \right] \right)_{air}$, which is the enthalpy flow in the air stream entering the power module relative to 25°C.

FC Air Blower Electrical Power [W]

This variable provides the results for $P_{blower-el}$, which is the electrical power used by the air supply blower.

FC Air Blower Electrical Energy [J]

This variable provides the results for the energy used by the air supply blower. It is also added to the appropriate meters.

FC Air Blower Skin Losses [W]

This variable provides the results for $q_{blower-heat-loss}$, which is the rate of energy “lost” to the surroundings.

FC Fuel Temperature at Inlet [C]

This variable provides the temperature of the fuel supplied to the FC.

FC Fuel Temperature Entering Power Module [C]

This variable provides the temperature of the fuel supplied to the power module after it has gone through the compressor.

FC Fuel Flow Rate [kmol/s]

This variable provides the results for \dot{N}_{fuel} , which is the flow rate of fuel into the FC.

FC Fuel Enthalpy Entering Power Module [W]

This variable provides the results for $\sum_i \left(\dot{N}_i \cdot \left[\hat{h}_i - \Delta_f \hat{h}_i^0 \right] \right)_{fuel}$, which is the enthalpy flow in the fuel stream entering the power module relative to 25°C.

FC Fuel Compressor Electrical Power [W]

This variable provides the results for $P_{comp-el}$, which is the electrical power used by the fuel supply compressor.

FC Fuel Compressor Electrical Energy [J]

This variable provides the results for the energy used by the fuel supply compressor. It is also added to the appropriate meters.

FC Fuel Compressor Skin Losses [W]

This variable provides the results for the rate of energy “lost” to the surroundings.

FC Reforming Water Temperature at Inlet [C]

This variable provides the temperature of the water supplied to the FC for reforming.

FC Reforming Water Temperature Entering Power Module [C]

This variable provides the temperature of the water supplied to the power module after it has gone through the pump.

FC Reforming Water Flow Rate [kmol/sec]

This variable provides the results for \dot{N}_{water} , which the flow rate of reforming water into the FC.

FC Reforming Water Pump Electrical Power [W]

This variable provides the results for $P_{pump-el}$, which is the electrical power used by the water pump.

FC Reforming Water Pump Electrical Energy [J]

This variable provides the results for energy used by the water pump. It is also added to the appropriate meters.

FC Reforming Water Enthalpy Entering Power Module [W]

This variable provides the results for $\dot{H}_{liq-water}$ which is the enthalpy flow of the water stream entering the power module relative to 25°C.

FC Product Gas Temperature [C]

This variable provides the results for the temperature of the product gas stream leaving the fuel cell power module.

FC Product Gas Enthalpy [W]

This variable provides the results for $\sum_i \left(\dot{N}_i \cdot \left[\hat{h}_i - \Delta_f \hat{h}_i^0 \right] \right)_{FCPM-cg}$, which is the enthalpy flow in the product gas stream leaving the power module relative to 25°C.

FC Product Gas Flow Rate [kmol/s]

This variable provides the results for the flow rate of all the product gases leaving the fuel cell power module.

FC Product Gas Argon Flow Rate [kmol/s]

This variable provides the results for the flow rate of the argon gas leaving the fuel cell power module.

FC Product Gas Carbon Dioxide Flow Rate [kmol/s]

This variable provides the results for the flow rate of the carbon dioxide gas leaving the fuel cell power module.

FC Product Gas Water Vapor Flow Rate [kmol/s]

This variable provides the results for the flow rate of the water gas leaving the fuel cell power module.

FC Product Gas Nitrogen Flow Rate [kmol/s]

This variable provides the results for the flow rate of the nitrogen gas leaving the fuel cell power module.

FC Product Gas Oxygen Flow Rate [kmol/s]

This variable provides the results for the flow rate of the oxygen gas leaving the fuel cell power module.

FC Power Conditioning Losses [W]

This variable provides the results for the power losses associated with inefficiencies in the inverter.

FC DC Power Generated [W]

This variable provides the results for P_{el} , which is the net DC electrical power produced by the fuel cell power module.

FC DC Power Efficiency []

This variable provides the results for ε_{el} , which is the electrical efficiency of the fuel cell power module.

FC Electrical Storage State of Charge [J]

This variable provides the results for state of charge of the electrical storage device inside the fuel cell. Although the units are Joules, this is a state variable and is reported as an average rather than a sum.

FC DC Power Into Storage [W]

This variable provides the rate at which power was stored into the fuel cell's electrical storage subsystem.

FC DC Energy Into Storage [J]

This variable provides the energy stored into the fuel cell's electrical storage subsystem.

FC DC Power From Storage [W]

This variable provides the rate at which power was drawn from the fuel cell's electrical storage subsystem.

FC DC Energy From Storage [J]

This variable provides the energy drawn from the fuel cell's electrical storage subsystem.

FC AC Ancillaries Power [W]

This variable provides the results for $P_{el,ancillaries-AC}$, which is the rate at which ancillary devices within the power module use electricity supplied to the fuel cell by an external source.

FC AC Ancillaries Energy [J]

This variable provides the results for the energy used by AC ancillaries. It is also added to the appropriate meters.

FC Model Iterations []

This variable provides information on the numerical method used to calculate the FC model. EnergyPlus uses a sequential substitution iterative algorithm to solve the main heat balance equation for the FC model. This report variable indicates the number of iterations needed to converge.

FC Regula Falsi Iterations []

This variable provides information on the numerical method used to calculate product gas temperature as a function of the product gas's enthalpy. A Regula Falsi numerical method is used to invert the Shomate equation for enthalpy as a function of temperature. This report variable indicates the number of iterations needed for the Regula Falsi method to converge.

Generator:FuelCell:PowerModule

This object is used to describe the core power module subsystem of the FC. This includes the fuel cell stack, fuel reformer, and whatever ancillary devices are included inside. If the model has multiple FC generators that are of the exact same type, then only one of these objects is needed and all the Generator:FuelCell can reference it. The model uses a number of curves to describe operating performance. Input data for specific models of FC are not yet available but will be produced by IEA Annex 42 and should be available in the future.

Field: Name

This field contains a unique name for the fuel cell power module subsystem.

Field: Efficiency Curve Mode

This field is used to choose between different modes of inputting the electrical efficiency curve. There are two options available for this field: “Annex42” and “Normalized”. The “Annex42” option indicates that the efficiency curves are not normalized and are used for the single size and type of FC product. The “Normalized” option indicates that the efficiency curves are normalized (as is standard practice in EnergyPlus) relative to a single rating point. In the Annex42 mode, the curves directly represent efficiency as a function of fuel use, but in the Normalized mode, the curves represent an efficiency modification that is applied to the efficiency at the rating point.

Field: Efficiency Curve Name

This field contains the name of a Curve:Quadratic input object described elsewhere in the input file. The curve is a function of the net DC electric power, P_{el} (W), produced by the power module and describes either the electrical efficiency or the how the efficiency is modified depending on the mode selected in the previous field. This quadratic curve is just one part of the entire parametric relation used to describe electrical efficiency ϵ_{el} . For the Annex42 mode the full relation for efficiency is,

$$\epsilon_{el} = \left[\epsilon_0 + \epsilon_1 \cdot P_{el} + \epsilon_2 \cdot P_{el}^2 \right] \cdot \left[1 - N_{stops} \cdot D \right] \cdot \left[1 - (MAX(\int dt - t_{threshold}, 0.0)) \cdot L \right]$$

where the Curve:Quadratic input object named in this field serves to define the quadratic portion in the first set of brackets. For the Normalized mode the full relation for efficiency is,

$$\epsilon_{el} = \left[\epsilon_0 + \epsilon_1 \cdot \frac{P_{el}}{P_{nom}} + \epsilon_2 \cdot \left(\frac{P_{el}}{P_{nom}} \right)^2 \right] \cdot \epsilon_{nom} \cdot \left[1 - N_{stops} \cdot D \right] \cdot \left[1 - (MAX(\int_0 dt - t_{threshold}, 0.0)) \cdot L \right]$$

where ϵ_{nom} is the nominal electrical efficiency at the rating point P_{nom} which are described in the next two fields. The Normalized mode may be more useful for a simulation study that needs to vary the capacity of the FC.

Field: Nominal Efficiency

This field is used for the “Normalized” efficiency curve mode and provides the nominal efficiency ϵ_{nom} (dimensionless) at the rating point. This field can be left blank if using the “Annex42” mode.

Field: Nominal Electrical Power

This field is used for the “Normalized” efficiency curve mode and provides the nominal net DC electrical power produced P_{nom} (W) at the rating point. This field can be left blank if using the “Annex42” mode.

Field: Number of Stops at Start of Simulation

This field is used to describe the number of times the FC has been cycled on and off prior to the start of the simulation. FC products might degrade as a result of starting and stopping the fuel cell stack, so the model includes terms to model the degradation effects of cycling FC units on and off. This is the initial value of the N_{stops} term in the efficiency relation above.

Field: Cycling Performance Degradation Coefficient

This field is used to describe the fixed value representing the fractional performance degradation associated with each start and stop cycle. This is the value of D in the efficiency relations above. If there is no degradation from cycling, then D should be 0.0.

Field: Number of Run Hours at Beginning of Simulation

This field is used to describe the amount of time the FC has been operating prior to the start of the simulation. FC products might degrade over time so the model includes terms to model the degradation effects of FC run time. This is the initial value of the integrated run time term

$$\int_0 dt .$$

Field: Accumulated Run Time Degradation Coefficient

This field is used to describe the fixed value representing the fractional performance degradation associated with the total amount of run time. This is the value of L in the efficiency relations above. If there is no degradation from run time, the L should be 0.0.

Field: Run Time Degradation Initiation Time Threshold

This field is used to describe the time period for which there is no degradation associated with the amount of run time. This provides the ability to model a system that initially operates without degradation for some period time before it starts to degrade. This is the value of $t_{threshold}$ in the efficiency relations above.

Field: Power Up Transient Limit

This field is used to describe the maximum allowable rate at which the fuel cell can increase the level of power it produces (W/s). This is a time derivative of the net DC electrical power used to limit how fast the FC can ramp up.

Field: Power Down Transient Limit

This field is used to describe the maximum allowable rate at which the fuel cell can decrease the level of power it produces (W/s). This is a time derivative of the net DC electrical power used to limit how fast the FC can ramp down.

Field: Start Up Time

This field is used to describe the length of time (seconds) of the start up period when the FC is turned on.

Field: Start Up Fuel

This field is used to describe the amount of fuel (kmol) used during the entire start up period. The fuel is the same type as what is described in the Generator:FuelSupply object elsewhere in the input file.

Field: Start Up Electricity Consumption

This field is used to describe the amount of electricity (Joules) used by ancillary equipment during the entire start up period.

Field: Start Up Electricity Produced

This field is used to describe the amount of electricity (Joules) produced by the power module during the entire start up period.

Field: Shut Down Time

This field is used to describe the length of time (seconds) of the shut down period.

Field: Shut Down Fuel

This field is used to describe the amount of fuel (kmol) used during the entire shut down period. The fuel is the same type as what is described in the Generator:FuelSupply object elsewhere in the input file.

Field: Shut Down Electricity Consumption

This field is used to describe the amount of electricity (J) used by ancillary equipment during the entire shut down period.

Field: Ancillary Electricity Constant Term

This field is used to describe the constant term, anc_0 , in a relation that describes the AC electrical power used by ancillary equipment located inside the power module, $P_{el,ancillaries-AC}$. The model uses this relation,

$$P_{el,ancillaries-AC} = anc_0 + anc_1 \cdot \dot{N}_{fuel}$$

where \dot{N}_{fuel} is the rate of fuel use in the power module (kmol/s).

Field: Ancillary Electricity Linear Term

This field is used to describe the linear term, anc_1 , in the relation shown in the previous field.

Field: Skin Loss Calculation Mode

This field is used to select the mode for how skin losses are modeled. Skin losses are heat energy “lost” from the power module and transferred to the surrounding thermal zone named in the following field. There are three alpha options to choose from: “ConstantRate”, “UAForProcessGasTemperature”, or “QuadraticFunctionOfFuelRate.” Enter ConstantRate in this field to model skin losses using a constant rate, e.g. 100 watts. Enter UAForProcessGasTemperature to model skin losses using a “UA-Delta-T” calculation method with the temperature difference determined by the power module’s product gas temperature and the surrounding zone. Enter QuadraticFunctionOfFuelRate to model skin losses as a function of the rate of fuel use.

Field: Zone Name

This field is used to describe the thermal zone that will receive skin and other heat losses from the FC. This should be the name of a Zone input object declared elsewhere in the input file.

Field: Skin Loss Radiative Fraction

This field is used to describe the portion of skin losses that are in the form of thermal radiation. This controls the radiative/convective split for the energy transferred to the zone by the FC.

Field: Constant Skin Loss Rate

This field is used to describe the constant rate of skin losses (W). This field is used with the ConstantRate mode. It can be left blank for other skin loss modes.

Field: Skin Loss U-Factor Times Area Term

This field is used to describe the “UA” term (W/K). This field is used with the UAForProcessGasTemperature mode. It can be left blank for other skin loss modes. “UA” is the product of the overall heat transfer coefficient “U” and the area “A.”

Field: Skin Loss Quadratic Curve Name

This field is used to refer to the name of a quadratic curve object defined elsewhere in the input file. The quadratic curve should define skin heat loss rate as a function of the fuel use rate (kmol/s) so that,

$$q_{skin-loss} = s_0 + s_1 \cdot \dot{N}_{fuel} + s_2 \cdot \dot{N}_{fuel}^2$$

Field: Dilution Air Flow Rate

This field is used to describe the rate of dilution air (kmol/sec) drawn into, or through, the power module. This air stream may not be present in all FC products. It is used for limiting skin and stack heat losses and for strategies that mitigate potential safety issue were fuel gases to escape the stack.

Field: Stack Heat loss to Dilution Air

This field is used to describe the rate at which the fuel cell stack adds energy to the dilution air stream. It is entered as a constant heat rate (W).

Field: Dilution Inlet Air Node Name

This field is used to describe the air node where the dilution air is drawn from. This would typically be the name of the air node associated with the thermal zone where the FC is located.

Field: Dilution Outlet Air Node Name

This field is used to describe the air node where the dilution air is exhausted to. This could be the inlets to a heat recovery ventilator or an exhaust node.

Field: Minimum Operating Point

This field is used to describe the minimum operating point for the net DC electric power, P_{el} (W).

Field: Maximum Operating Point

This field is used to describe the maximum operating point for the net DC electric power, P_{el} (W).

An example input data file (IDF) entry for this object is provided below:

Field: Name

This field contains a unique name for the PEM fuel cell stack cooler

Field: Heat Recovery Water Inlet Node Name

This field contains the node name for the water inlet to the stack cooler.

Field: Heat Recovery Water Outlet Node Name

This field contains the node name for the water outlet from the stack cooler.

Field: Nominal Stack Temperature

This field contains the nominal stack operating temperature for the PEMFC, T_{stack}^o . This field and the next five provide values for use in the empirical equation for the rate of heat extracted from the fuel cell power module by the stack cooler using the following relation

$$q_{s-cool} = \left[r_0 + r_1 \left(T_{stack} - T_{stack}^o \right) \right] \cdot \left[1 + r_2 P_{el} + r_3 P_{el}^2 \right]$$

Field: Actual Stack Temperature]

This field contains the actual stack operating temperature for the PEMFC, T_{stack} .

Field: Coefficient r0

This field contains the coefficient r_0 in the equation above.

Field: Coefficient r1

This field contains the coefficient r_1 in the equation above.

Field: Coefficient r2

This field contains the coefficient r_2 in the equation above.

Field: Coefficient r3

This field contains the coefficient r_3 in the equation above.

Field: Stack Coolant Flow Rate

The stack cooler is assumed to have a closed water circulation loop that is used to extract heat from the stack and move it to a cogeneration heat exchanger and/or an air cooler. This field is used to enter the flow rate of coolant in this loop.

Field: Stack Cooler U-Factor Times Area Value

This is the heat transfer coefficient between the stack and the coolant.

Field: Fs-cogen Adjustment Factor

This field provides the value for an adjustment factor, $F_{s-cogen}$, used in the following relation for the cogeneration heat transfer coefficient, $(UA)_{s-cogen}$:

$$(UA)_{s-cogen} = \left[\frac{1}{(hA)_{s-cogen}} + F_{s-cogen} \right]^{-1}$$

Field: Stack Cogeneration Exchanger Area

This field provides the value for the cogeneration heat exchanger area, $A_{s-cogen}$

Field: Stack Cogeneration Exchanger Nominal Flow Rate

This field provides the value for $\dot{N}_{s-cogen}^0$ in the following relation for the cogeneration heat exchanger convection coefficient, $h_{s-cogen}$:

$$h_{s-cogen} = h_{s-cogen}^0 \cdot \left(\frac{\dot{N}_{s-cogen}}{\dot{N}_{s-cogen}^0} \right)^{n_s}$$

Field: Stack Cogeneration Exchanger Nominal Heat Transfer Coefficient

This field provides the value for $h_{s-cogen}^0$ in the relation above for the cogeneration heat exchanger convection coefficient, $h_{s-cogen}$.

Field: Stack Cogeneration Exchanger Nominal Heat Transfer Coefficient Exponent

This field provides the value for n_s is the relation above for the cogeneration heat exchanger convection coefficient, $h_{s-cogen}$.

Field: Stack Cooler Pump Power

This field is the power used by the stack cooler's circulating pump in Watts. It is a constant power draw whenever the stack cooler is active.

Field: Stack Cooler Pump Heat loss

This field is the fraction of the pump power consumption that is lost to the surround zone.

Field: Stack Air Cooler Fan Coefficient f0

This field and the next two are used to define coefficients for the following relation for the power used by the air-cooler's fan to dump excess heat into the surrounding zone:

$$P_{s-air-el} = f_0 + f_1 \cdot q_{s-air} + f_2 \cdot q_{s-air}^2$$

Field: Stack Air Cooler Fan Coefficient f1

This field provides a value for the coefficient f_1 in the relation above.

Field: Stack Air Cooler Fan Coefficient f2

This field provides a value for the coefficient f_2 in the relation above.

Generator:FuelCell:AirSupply

This object is used to define details of the air supply subsystem.

Field: Name

This field contains a unique name for the fuel cell air supply subsystem.

Field: Air Inlet Node Name

This field is used to define the air node where the inlet air stream is drawn from. If the FC uses outdoor air then the node named here should be designated an outdoor air node. If the FC draws air from its surroundings, then this would be the name of the air node associated with the thermal zone containing the FC.

Field: Blower Power Curve Name

This field contains the name of a Curve:Cubic input object described elsewhere in the input file. The curve provides the power used by the air blower (W) as a cubic function of the rate of air supply (kmol/s).

$$P_{blower-el} = b_0 + b_1 \cdot \dot{N}_{air} + b_2 \cdot \dot{N}_{air}^2 + b_3 \cdot \dot{N}_{air}^3$$

Field: Blower Heat Loss Factor

This field describes the portion of blower electrical power that is “lost” to the surroundings. The rest of the energy is added to the air stream. A heat loss factor of 1.0 indicates that all the heat is lost to the surroundings and no energy is added to the air inlet stream.

Field: Air Supply Rate Calculation Mode

This field describes how the model will calculate the air supply rate. There are three options to choose from: “AirRatiobyStoics”, “QuadraticFunctionofElectricPower”, and “QuadraticFunctionofFuelRate.” The choice will determine how the model calculates the rate of air and will depend on the formulations used to develop model input data. The choices are described in the next four fields.

Field: Stoichiometric Ratio

This field describes the excess air ratio beyond stoichiometric air supply. This field is only used if the air supply rate calculation mode is AirRatiobyStoics. The total air supply ratio will be the value entered here plus 1.0. Thus if 1.0 is entered in this field, the total air flow will be 2.0 times what is needed to exactly match stoichiometry with the fuel supply.

Field: Air Rate Function of Electric Power Curve Name

This field contains the name of a QuadraticCurve input object described elsewhere in the input file. This field is only used if the air supply rate calculation mode is QuadraticFunctionofElectricPower. The quadratic curve named here describes the first part of the relation below used to calculate the rate of inlet air, \dot{N}_{air} (kmol/s). It is a quadratic function of the net DC electrical power, P_{el} (W).

$$\dot{N}_{air} = \left[a_0 + a_1 \cdot P_{el} + a_2 \cdot P_{el}^2 \right] \cdot \left[1 + a_3 \cdot T_{air} \right]$$

Field: Air Rate Air Temperature Coefficient

This field is used to describe the air temperature coefficient, a_3 , used to adjust inlet air flow rate in the relations for inlet air rate.

Field: Air Rate Function of Fuel Rate Curve Name

This field contains the name of a Curve:Quadratic input object described elsewhere in the input file. This field is only used if the air supply rate calculation mode is QuadraticFunctionofFuelRate. The quadratic curve named here describes the first part of the relation used to calculate the rate of inlet air, \dot{N}_{air} (kmol/s). It is a quadratic function of the fuel flow rate, \dot{N}_{fuel} .

$$\dot{N}_{air} = \left[a_0 + a_1 \cdot \dot{N}_{fuel} + a_2 \cdot \dot{N}_{fuel}^2 \right] \cdot \left[1 + a_3 \cdot T_{air} \right]$$

Field: Air Intake Heat Recovery Mode

This field is used to control how heat losses from three other subsystems within the FC may or may not be recovered by the air inlet. There are six possible choices for what to use in this field: “NoRecovery” “RecoverBurnerInverterStorage” “RecoverAuxiliaryBurner” “RecoverInverterandStorage” “RecoverInverter” and “RecoverElectricalStorage”. If heat is recovered then that means that energy “losses” from those subsystems are added to the inlet air and fed back into the FC power module. The following table clarifies the meaning of the six possible choices.

Table 29. Air Intake Heat Recovery Mode Choices

Field Choice	Inverter Heat Losses Recovered?	Electrical Storage Heat Losses Recovered?	Auxiliary Heater Losses Recovered?
NoRecovery”	No	No	No
RecoverBurnerInverterStorage	Yes	Yes	Yes
RecoverAuxiliaryBurner	No	No	Yes
RecoverInverterandStorage	Yes	Yes	No
RecoverInverter	Yes	No	No
RecoverElectricalStorage	No	Yes	No

Field: Air Supply Constituent Mode

This field is used to choose between two different modes for describing the make up of the inlet air stream. There are two possible choices: "AmbientAir" or "UserDefinedConstituents." Choosing the AmbientAir mode will automatically set the composition of air to be usual at: 77.28% nitrogen, 20.73% oxygen, 1.04% water, 0.92% argon, and 0.03% carbon dioxide. Choosing UserDefinedConstituents allows the user to customize the make up the inlet air in the remaining fields.

Field: Number of UserDefined Constituents

This field is used to describe the number of constituents in the inlet air. This field is only used if the air supply constituent mode is set to UserDefinedConstituents. The maximum number is 5.

The remaining fields in this object are repeating pairs of fields with one pair for each constituent and the same number as described in the previous field. The pairs consist of the name of the constituent followed by the molar fraction of that constituent.

Field: Constituent 1-5 Name

These fields describe the air stream constituents by name. The name field for each pair must be filled with one of these choices: "CarbonDioxide", "Nitrogen," "Oxygen," "Water," or "Argon."

Field: Molar Fraction 1-5

These fields describe the molar fraction of the air stream constituents. It is very important that the sum of the molar fractions add up to 1.0.

An example input data file (IDF) entry for this object is provided below:

Field: Name

This field contains a unique name for the fuel cell water supply subsystem.

Field: Reformer Water Flow Rate Function of Fuel Rate Curve Name

This field contains the name of a Curve:Quadratic input object described elsewhere in the input file. The curve provides the rate of water flow (kmol/sec) as a function of fuel flow rate (kmol/sec).

$$\dot{N}_{liq-water} = w_0 + w_1 \cdot \dot{N}_{fuel} + w_2 \cdot \dot{N}_{fuel}^2$$

If the unit does not use water for reforming then use a “null” quadratic where all the coefficients are 0.0.

Field: Reformer Water Pump Power Function of Fuel Rate Curve Name

This field contains the name of a Curve:Cubic input object described elsewhere in the input file. The curve provides the power used by the water pump (W) as a cubic function of the rate of water supply (kmol/s).

$$P_{pump-el} = p_0 + p_1 \cdot \dot{N}_{water} + p_2 \cdot \dot{N}_{water}^2 + p_3 \cdot \dot{N}_{water}^3$$

If the unit does not use water for reforming then use a “null” cubic where all the coefficients are 0.0.

Field: Pump Heat Loss Factor

This field describes the portion of pump electrical power that is “lost” to the surroundings. The rest of the energy is added to the water stream. A heat loss factor of 1.0 indicates that all the heat is lost to the surroundings and no energy is added to the water inlet stream.

Field: Water Temperature Modeling Mode

This field describes how the model will determine the inlet temperature of the water stream. There are four options to choose from: “TemperatureFromAirNode,” “TemperatureFromWaterNode,” “TemperatureFromSchedule,” and “MainsWaterTemperature.” For the first two options, the temperature of the water inlet is determined by the temperature at the node named in the next field. For the third option, the temperature is determined by the schedule in the last field. Using the

MainsWaterTemperature option requires also defining a separate "Site:WaterMainsTemperature" input object elsewhere in the input file.

Field: Water Temperature Reference Node Name

This field is used to define the node where the temperature of the inlet water stream is obtained. This can be either an air node or a water node.

Field: Water Temperature Schedule Name

This field is used to define the name of a schedule, defined elsewhere in the input file, that will be used to determine the temperature of the water inlet stream when using the TemperatureFromSchedule mode.

An example input data file (IDF) entry for this object is provided below:

Generator:FuelCell:AuxiliaryHeater

This object is intended for modeling an auxiliary heater, however this portion of the model is not yet available in EnergyPlus. An auxiliary heater may be present in fuel cell products so that the unit can meet much higher thermal loads than would be possible using only cogeneration. This portion of the model will be added in the future once suitable cogeneration control capabilities are also available. The input fields are described for future reference but may change. The program still requires one of these objects be included even though the data are not yet used (so that internal data structures can be allocated).

```

```

Field: Name

This field contains a unique name for the fuel cell auxiliary heater subsystem.

Field: Excess Air Ratio

This field describes the excess air ratio beyond stoichiometric air supply for the heater. The total air supply ratio will be the value entered here plus 1.0. Thus if 1.0 is entered in this field, the total air flow will be 2.0 times what is needed to exactly match stoichiometry with the fuel supply.

Field: Ancillary Power Constant Term

This field describes the constant term, x_0 , used to model the auxiliary burner's ancillary devices such as fans and ignition controls. The electrical power for ancillaries is calculated using,

$$P_{el,aux-ancillaries} = x_0 + x_1 \cdot \dot{N}_{aux-fuel}$$

Field: Ancillary Power Linear Term

This field describes the linear term, x_1 , used to model the auxiliary burner's ancillary devices.

Field: Skin Loss U-Factor Times Area Value

This field describes the "UA" term (W/K) for calculating skin losses in the auxiliary burner. "UA" is the product of the overall heat transfer coefficient "U" and the area "A." The skin heat losses are calculated using,

$$q_{aux-skin-losses} = (UA)_{aux} \cdot (T_{aux-mix} - T_{room})$$

where, $T_{aux-mix}$ is temperature of product gases leaving the auxiliary burner and includes the mixing of the product gases from the fuel cell power module. Thus, the input for UA should reflect this choice of reference temperature rather than an exterior surface temperature of the auxiliary burner.

Field: Skin Loss Destination

This field describes the user's choice for what happens to the skin losses. There are two options: "SurroundingZone" and "AirInletForFuelCell". Entering SurroundingZone will direct the model to put the "lost" energy into the surrounding thermal Zone named in the next field. Entering AirInletForFuelCell will direct the model to put the "lost" energy into the air inlet stream for the fuel cell to preheat that air.

Field: Zone Name to Receive Skin Losses

This field is used to determine the zone that will receive the skin losses. Enter the name of a Zone declared elsewhere in the input file. This field is only used if the "SurroundingZone" mode is used in the previous field.

Field: Heating Capacity Units

This field describes the user's choice for how the capacity of the auxiliary heater will be defined. There are two options: "Watts" or "kmol/s." Entering Watts will direct the program to use the next two fields to determine the maximum and minimum heating capacity. Entering kmol/s will direct the program to use the last two fields to determine the maximum and minimum heating capacities.

Field: Maximum Heating Capacity in Watts

This field is used to describe the maximum heating capacity of the auxiliary burner (W).

Field: Minimum Heating Capacity in Watts

This field is used to describe the minimum heating capacity of the auxiliary burner (W).

Field: Maximum Heating Capacity in Kmol per Second

This field is used to describe the maximum fuel use rate for the auxiliary burner (kmol/s).

Field: Minimum Heating Capacity in Kmol per Second

This field is used to describe the minimum fuel use rate for the auxiliary burner (kmol/s).

An example input data file (IDF) entry for this object is provided below:

```

Field: Name

This field contains a unique name for the fuel cell power module subsystem.

Field: Heat Recovery Water Inlet Node Name

This field contains the name of the node that connects the heat exchanger's inlet to the plant loop. This water is used for heat recovery.

Field: Heat Recovery Water Outlet Node Name

This field contains the name of the node that connects the heat exchanger's outlet to the plant loop.

Field: Heat Recovery Water Maximum Flow Rate

This field describes the design maximum flow rate of the heat recovery water (m³/s). The value should match the design flow rate of the plant loop connected to the FC.

Field: Exhaust Outlet Air Node Name

This field is used to determine which node will receive the exhaust air stream leaving the FC. This node will usually be outside and not be referenced elsewhere. However, if the exhaust stream is used in a heat recovery ventilator (as described in section 11 of the Annex 42 specification) then the node would be reference in the heat recovery ventilator object.

Field: Heat Exchanger Calculation Method

This field is used to direct how EnergyPlus will calculate heat exchanger performance. The Annex 42 model provides for four different methods of modeling the heat exchanger. The choices available for this field are: "FixedEffectiveness" (method 1 in Annex 42 specification), "EmpiricalUAeff" (method 2), "FundamentalUAeff" (method 3), or "Condensing" (method 4).

The remaining fields provide input data for the different methods. The heat exchanger correlations are described below.

Field: Method 1 Heat Exchanger Effectiveness

This field describes constant heat exchanger effectiveness, ε_{HX} . This field is only used with the “FixedEffectiveness” mode, which corresponds to “method 1” in the Annex 42 specification. For this mode, the heat exchange between the exhaust gases and the heat recovery water are calculated using,

$$q_{HX} = \varepsilon_{HX} \cdot (\dot{N}\hat{c}_p)_{\min} \cdot (T_{aux-mix} - T_{water,in})$$

where, $(\dot{N}\hat{c}_p)_{\min}$ is the minimum value of $(\dot{N}\hat{c}_p)_{aux-mix}$ and $(\dot{N}\hat{c}_p)_{water}$.

Field: Method 2 Parameter hxs0

This field describes the value of $hx_{s,0}$ in the relation below for effective UA. This field is used with the “EmpiricalUAeff” mode, which corresponds to “method 2” in the Annex 42 specification and with the “Condensing” mode, which corresponds to “method 4”. This method uses the log mean temperature difference (LMTD) approach to calculate the heat exchange:

$$q_{HX} = (UA)_{eff} \cdot \frac{(T_{aux-mix} - T_{water,out}) - (T_{HX-exh} - T_{water,in})}{\ln\left(\frac{T_{aux-mix} - T_{water,out}}{T_{HX-exh} - T_{water,in}}\right)}$$

The user input in this field, and the next four fields, describe coefficients in an empirical relation for $(UA)_{eff}$:

$$(UA)_{eff} = hx_{s,0} + hx_{s,1} \cdot \dot{N}_{water} + hx_{s,2} \cdot \dot{N}_{water}^2 + hx_{s,3} \cdot \dot{N}_{aux-mix} + hx_{s,4} \cdot \dot{N}_{aux-mix}^2$$

Field: Method 2 Parameter hxs1

This field describes the value of $hx_{s,1}$ in the relation above for effective UA. This field is used with the “EmpiricalUAeff” mode, which corresponds to “method 2” in the Annex 42 specification and with the “Condensing” mode, which corresponds to “method 4”.

Field: Method 2 Parameter hxs2

This field describes the value of $hx_{s,2}$ in the relation above for effective UA. This field is used with the “EmpiricalUAeff” mode, which corresponds to “method 2” in the Annex 42 specification and with the “Condensing” mode, which corresponds to “method 4”.

Field: Method 2 Parameter hxs3

This field describes the value of $hx_{s,3}$ in the relation above for effective UA. This field is used with the “EmpiricalUAeff” mode, which corresponds to “method 2” in the Annex 42 specification and with the “Condensing” mode, which corresponds to “method 4”.

Field: Method 2 Parameter hxs4

This field describes the value of $hx_{s,4}$ in the relation above for effective UA. This field is used with the “EmpiricalUAeff” mode, which corresponds to “method 2” in the Annex 42 specification and with the “Condensing” mode, which corresponds to “method 4”.

Field: Method 3 h0Gas Coefficient

This field describes the value of h_{gas}^0 in the relation below. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification. For this mode, the heat exchange is calculated using the LMTD method, but the effective UA is determined using:

$$(UA)_{eff} = \left[\frac{1}{(hA)_{gas}} + \frac{1}{(hA)_{water}} + F_{HX} \right]^{-1}$$

where,

F_{HX} is an adjustment factor,

$$h_{gas} = h_{gas}^0 \cdot \left(\frac{\dot{N}_{gas}}{\dot{N}_{gas}^0} \right)^n,$$

$$h_{water} = h_{water}^0 \cdot \left(\frac{\dot{N}_{water}}{\dot{N}_{water}^0} \right)^m$$

Field: Method 3 NdotGasRef Coefficient

This field describes the value of \dot{N}_{gas}^0 in the relation above. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification.

Field: Method 3 n Coefficient

This field describes the value of n in the relation above. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification.

Field: Method 3 Gas Area

This field describes the value of A_{gas} in the relation above. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification.

Field: Method 3 h0 Water Coefficient

This field describes the value of h_{water}^0 in the relation above. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification.

Field: Method 3 N dot Water ref Coefficient

This field describes the value of \dot{N}_{water}^0 in the relation above. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification.

Field: Method 3 m Coefficient

This field describes the value of m in the relation above. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification.

Field: Method 3 Area Water Coefficient

This field describes the value of A_{water} in the relation above. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification.

Field: Method 3 F Adjustment Factor

This field describes the value of F_{HX} in the relation above. This field is only used with the “FundamentalUAeff” mode, which corresponds to “method 3” in the Annex 42 specification.

Field: Method 4 hxl1 Coefficient

This field describes the value of $hx_{l,1}$ in the relation below for the rate of condensation of water from the gas stream, $\dot{N}_{H_2O-cond}$. This field is only used with the “Condensing” mode, which corresponds to “method 4” in the Annex 42 specification. This method uses a modified version of the LMTD approach to calculate heat exchange:

$$q_{HX} = (UA)_{eff} \cdot \frac{(T_{aux-mix} - T_{water,out}) - (T_{HX-exh} - T_{water,in})}{\ln\left(\frac{T_{aux-mix} - T_{water,out}}{T_{HX-exh} - T_{water,in}}\right)} + \dot{N}_{H_2O-cond} \cdot \hat{h}_{fg}$$

where,

$$\dot{N}_{H_2O-cond} = (T_{cond-threshold} - T_{water,in}) \cdot \left[hx_{l,1} \cdot \left(\frac{\dot{N}_{H_2O}}{\dot{N}_{aux-mix}} \right) + hx_{l,2} \cdot \left(\frac{\dot{N}_{H_2O}}{\dot{N}_{aux-mix}} \right)^2 \right]$$

Field: Method 4 hxl2 Coefficient

This field describes the value of $hx_{l,2}$ in the relation above for the rate of condensation of water from the gas stream, $\dot{N}_{H_2O-cond}$. This field is only used with the “Condensing” mode, which corresponds to “method 4” in the Annex 42 specification.

Field: Method 4 Condensation Threshold

This field describes the value of $T_{cond-threshold}$ in the relation above for the rate of condensation of water from the gas stream, $\dot{N}_{H_2O-cond}$. This field is only used with the “Condensing” mode, which corresponds to “method 4” in the Annex 42 specification.

An example input data file (IDF) entry for this object is provided below:

      \units W
  N6; \field Initial Charge State
      \units J

```

Field: Name

This field contains a unique name for the fuel cell electrical storage subsystem.

Field: Choice of Model

This field is used to direct how EnergyPlus will model electrical storage. The only choice currently available is “SimpleEfficiencyWithConstraints,” which should be entered in this field. Future developments may expand the number of models available for electrical storage.

Field: Nominal Charging Energetic Efficiency

This field describes the value of ϵ_{charge} in the relation for the State of Charge, $Q_{battery}^{t+\Delta t}$:

$$Q_{battery}^{t+\Delta t} = Q_{battery}^t + P_{battery-charge} \cdot \epsilon_{charge} \cdot \Delta t$$

This is the energetic efficiency of charging the storage device. A value of 1.0 means that the storage device does not lose any energy when charging. Note that the model can recover the “lost” energy into the air supply intake.

Field: Nominal Discharging Energetic Efficiency

This field describes the value of $\epsilon_{discharge}$ in the relation for the State of Charge, $Q_{battery}^{t+\Delta t}$:

$$Q_{battery}^{t+\Delta t} = Q_{battery}^t + \frac{P_{battery-discharge} \cdot \Delta t}{\epsilon_{discharge}}$$

This is the energetic efficiency of discharging the storage device. A value of 1.0 means that the storage device does not lose any energy when discharging. Note that the model can recover the “lost” energy into the air supply intake.

Field: Simple Maximum Capacity

This field describes the maximum amount of electrical energy that can be stored in the device (J).

Field: Simple Maximum Power Draw

This field describes the maximum rate at which electrical power can be discharged from the storage device (W).

Field: Simple Maximum Power Store

This field describes the maximum rate at which electrical power can charge the storage device (W).

Field: Initial Charge State

This field describes the value for the initial state of charge (J). This allows the storage device to contain some amount of stored electricity at the beginning of the simulation period.

An example input data file (IDF) entry for this object is provided below:

      \object-list QuadraticCurves

```

Field: Name

This field contains a unique name for the fuel cell inverter subsystem.

Field: Inverter Efficiency Calculation Mode

This field is used to direct how EnergyPlus will calculate the inverter efficiency. There are two possible choices: “Constant” or “Quadratic”.

Field: Inverter Efficiency

This field describes the value for inverter efficiency when using the **Constant** mode.

Field: Efficiency Function of DC Power Curve Name

This field names a Curve:Quadratic object defined elsewhere in the input file. The curve determines inverter efficiency as a function of the DC power entering the inverter as follows:

$$\eta_{PCU} = u_0 + u_1 \cdot P_{PCU-in} + u_2 \cdot P_{PCU-in}^2$$

An example input data file (IDF) entry for this object is provided below:

```

Generator:FuelSupply

This object is used to define details of the fuel supply for certain generators. This object allows the user to describe a wide array of possible fuel mixtures. The program contains data and internal methods to calculate the properties of the various mixtures of gaseous fuels. The program will calculate the Lower Heating Value (LHV), Higher Heating Value (HHV), and molecular weight for the fuel mixture. The fuel properties are then use by both fuel cell and Micro CHP models. Results of the gas phase thermochemistry modeling are also reported in the EIO file.

In addition to gaseous mixtures, the Micro CHP model is able to use generic liquid fuels and this object is used to describe the properties.

Note that the fuel consumption metering is currently handled by the Natural Gas meter. So no matter what fuel mixture is defined in this object, the aggregated reports from EnergyPlus

meters for (natural) Gas will include the fuel used for the generator (with the Joule content based on HHV).

Field: Name

This field contains a unique name for the fuel cell fuel supply subsystem.

Field: Fuel Temperature Modeling Mode

This field describes how the model will determine the temperature of the fuel. There are two options for this field to choose from: "TemperatureFromAirNode" and "Scheduled." If this field contains TemperatureFromAirNode then the fuel is modeled as having the same temperature as the air node that is named in the next field. If this field contains Scheduled then the fuel is modeled as having the temperature described in a schedule defined elsewhere in the input file.

Field: Fuel Temperature Reference Node Name

This field contains the name of the air node used to obtain the inlet temperature of the fuel. This field is only used if the Fuel Temperature Modeling Mode is set to TemperatureFromAirNode.

Field: Fuel Temperature Schedule Name

This field contains the name of a temperature schedule defined elsewhere in the input file. This field is only used if the Fuel Temperature Modeling Mode is set to Scheduled. The temperature of the fuel inlet will be obtained from the schedule.

Field: Compressor Power Function of Fuel Rate Curve Name

This field contains the name of a Curve:Cubic input object described elsewhere in the input file. The curve provides the electrical power used by the fuel compressor (W) as a cubic function of the rate of fuel supply (kmol/s).

$$P_{comp-el} = c_0 + c_1 \cdot \dot{N}_{fuel} + c_2 \cdot \dot{N}_{fuel}^2 + c_3 \cdot \dot{N}_{fuel}^3$$

Field: Compressor Heat Loss Factor

This field describes the portion of the compressor electrical power that is “lost” to the surroundings. The rest of the energy is added to the fuel stream. A heat loss factor of 1.0 indicates that all the heat is lost to the surroundings and no energy is added to the fuel inlet stream.

Field: Fuel Type

Choose between “GaseousConstituents” or “LiquidGeneric”.

Field: Liquid Generic Fuel Lower Heating Value

For fuel type “LiquidGeneric,” this field is used to enter the lower heating value of the fuel in units of kJ/kg.

Field: Liquid Generic Fuel Higher Heating Value

For fuel type “LiquidGeneric,” this field is used to enter the higher heating value of the fuel in units of kJ/kg.

Field: Liquid Generic Fuel Molecular Weight

For fuel type “LiquidGeneric,” this field is used to enter the molecular weight of the fuel in units of g/mol.

Field: Liquid Generic Fuel CO2 Emission Factor

This field is not used. This part of the Annex 42 model was not implemented in EnergyPlus; see the FuelFactors object.

Field: Number of Constituents in Gaseous Constituent Fuel Supply

This field is used to describe the number of constituents in the inlet fuel supply. The maximum number of different types of constituents is currently set to 12.

The remaining fields in this object are repeating pairs of fields with one pair for each constituent and the same number as described in the previous field. The field set pairs consist of the name of the constituent followed by the molar fraction of that constituent.

Field: Constituent 1-12 Name

These fields describe the fuel stream constituents by name. The name field for each pair must be filled with one of these 14 choices: "CarbonDioxide", "Nitrogen", "Oxygen", "Water", "Argon", "Hydrogen", "Methane", "Ethane", "Propane", "Butane", "Pentane", "Hexane", "Methanol", and "Ethanol". No other fuel constituents can currently be modeled. The properties of the constituents are already contained inside the program as provided in the Annex 42 model specification.

Field: Constituent 1-12 Molar Fraction

These fields describe the molar fraction of the fuel stream constituents. It is very important that the sum of the molar fractions add up to 1.0.

Generator:FuelSupply Outputs

In addition to the following report variables, the resulting fuel heating values are also reported to the eio file.

```
HVAC,Average,FuelCell Fuel Compressor Electrical Power [W]
HVAC,Sum,FuelCell Fuel Compressor Electrical Energy [J]
HVAC,Average,FuelCell Fuel Compressor Skin Losses [W]
```

Generator Fuel Compressor Electrical Power [W]

This is the rate of energy use by the gas compressor, if any, that provides fuel at a higher pressure.

Generator Fuel Compressor Electrical Energy [J]

This is the energy used by the gas compressor, if any, that provides fuel at a higher pressure.

Generator Fuel Compressor Skin Losses [W]

Convective heat gains to zone from gas compressor, if any, that provides fuel at a higher pressure.

Photovoltaic Generators

EnergyPlus offers different options for predicting the electricity produced by solar electric photovoltaic (PV) panels. The three different options are "Simple", "Equivalent One-Diode" and "Sandia" and the choice will determine the mathematical models used to determine energy production. The first allows the user to input an arbitrary efficiency. The other two models use empirical relationships to predict PV operating performance based on many environmental variables such as cell temperature. The PV models can be used with either normal PV modules or as part of a hybrid photovoltaic/thermal (PVT) flat plat collector.

The generator is connected to an Electric Load Center. The PV models refer to surface input objects defined elsewhere in the input file. This object describes an array that is "attached" to a surface object in order to describe its orientation and to access results of the solar insolation calculations. These can be either HeatTransfer or Shading objects (see Surfaces). This will define the orientation of the solar panel for the detailed models and also the area for the simple model. The exposure of that surface to incident solar radiation is calculated using the full set of models in EnergyPlus that are used to account for solar thermal loads arising from building windows and walls. Therefore the incident solar radiation is calculated to include the effects of shading and reflections from other surfaces declared in the input file. In addition to the output variables associated with PV models, there are numerous related output variables available for the surfaces including: 'Surface Ext Sunlit Area', 'Surface Ext Sunlit Fraction', 'Surface Ext Solar Incident', 'Surface Ext Solar Beam Incident', 'Surface Ext Solar Sky Diffuse Incident', 'Surface Ext Solar Ground Diffuse Incident', 'Surface Ext Solar Beam Cosine Of Incidence Angle', 'Surface Ext Solar From Sky Diffuse Refl From Ground', 'Surface Ext Solar From Sky Diffuse Refl From Obstructions', 'Surface Ext Beam Sol From Bm-To-Bm Refl From Obstructions', 'Surface Ext Diff Sol From Bm-To-Diff

Refl From Obstructions', and 'Surface Ext Solar From Bm-To-Diff Refl From Ground.' Note that it is possible to define a PV array area that doesn't conform to the surface area (i.e. model a PV array area that is larger or smaller than what is available on the surface) so it is the users responsibility to not over-specify area when determining how many modules will fit onto a surface. However this type of input is allowed.

EnergyPlus does not include models for ancillary equipment for a PV array including charge controllers or power-point trackers. The operation of the entire electrical system that must go along with a PV array is not currently modeled in EnergyPlus and is therefore assumed to operate in ideal ways. The PV production models do not resolve voltage and current, only power (and energy). Electricity production is metered based on the output of the inverter. Output results are available before and after the inverter. One assumption is that the array is assumed to be always operating at the maximum power point. Energy production is based on the assumption that the quasi-steady power prediction is constant and continuous over the simulation timestep.

For a variety of reasons, actual installations of photovoltaics are often observed to exhibit system-level problems that significantly reduce electricity production. Therefore this modeling should be considered a method of bracketing the upper end of electricity production rather than an accurate prediction of what the panels will produce. Also note that the model predictions are closely related to the solar radiation data (typically of of TMY2 origin) in the EnergyPlus weather file, that the solar data in these is usually from a model rather than direct measurements, and that solar resources encountered by a real installation in a given year are likely to differ from the weather data file.

Generator:Photovoltaic

This object is used to describe an array of PV modules and how they are to be modeled. A series of different PV arrays can be connected to a single electric load center (and inverter) by listing them all in an ElectricLoadCenter:Generator object.

Field: Name

This field is a unique name for the PV array.

Field: Surface Name

This field is the name of a surface that defines the location and geometry of the array.

Field: Photovoltaic Performance Object Type

This field is the type of PV performance model. The choices are the class names for the three modeling options:

```
PhotovoltaicPerformance:Simple
PhotovoltaicPerformance:EquivalentOne-Diode
PhotovoltaicPerformance:Sandia.
```

Field: Module Performance Name

This is the name of the PV performance object define elsewhere (corresponding to the object type listed in the previous field)

Field: Heat Transfer Integration Mode

The PV model allows for different ways of integrating with other EnergyPlus heat transfer surfaces and models and calculating cell temperature. For Building Integrated PV (BIPV), the "Integrated" options allow for the PV modeling to be coupled to the surface heat transfer models elsewhere in EnergyPlus. The user must select one of these options for this field:

- **Decoupled.** The cell temperature of modules in the array is computed based on a energy balance relative to NOCT conditions. The input fields for Module Heat Capacity and Module Heat Loss Coefficient are ignored.

- **DecoupledUllebergDynamic** the cell temperature is calculated based on a dynamic model developed by Ulleberg¹³. The input fields for Module Heat Capacity and Module Heat Loss Coefficient are required.
- **IntegratedSurfaceOutsideFace** The cell temperature is obtained from the outside face of the Surface:Heat Transfer named in the previous field. Energy exported by the module is removed from the heat transfer surface (at the position determined by the associated Construction with Internal Source). The input fields for Module Heat Capacity and Module Heat Loss Coefficient are ignored.
- **IntegratedTranspiredCollector** The cell temperature is obtained from the collector surface temperature in the unglazed transpired collector model. Energy exported by the module is removed from the collector surface. The input fields for Module Heat Capacity and Module Heat Loss Coefficient are ignored.
- **IntegratedExteriorVentedCavity** The cell temperature is obtained from the exterior baffle temperature in the naturally ventilated exterior cavity model. Energy exported by the module is removed from the exterior baffle surface. The input fields for Module Heat Capacity and Module Heat Loss Coefficient are ignored.
- **PhotovoltaicThermalSolarCollector** The cell temperature is obtained from the photovoltaic/thermal solar collector model. If the PV layer is inside the collector, then the incident solar is modified by the photovoltaic/thermal solar collector model.

Field: Number of Modules in Parallel

This field is the number of modules wired in parallel to form the PV array.

Field: Number of Modules in Series

This field is the number of modules wired in series to form the PV array.

Generator:Photovoltaic Outputs

Using the Generator:PV:Simple object makes a number of output variables available.

PV Generator DC Power [W]

This output variable is the power of DC electricity delivered.

PV Generator DC Energy [J]

This output variable is the energy in DC electricity.

PV Array Efficiency []

This output variable is the resulting efficiency .

The two more detailed PV models also have the following output variables.

PV Cell Temperature [°C]

This output variable represents the temperature of the solar cell used in the calculation of cell performance.

PV Array Short Circuit Current [A]

This output variable represents the short circuit current of the PV array. This is provided to describe the I-V characteristics.

PV Array Open Circuit Voltage [V]

This output variable represents the open circuit voltage of the PV array. This is provided to describe the I-V characteristics.

PhotovoltaicPerformance:Simple

The PhotovoltaicPerformance:Simple object describes a simple model of photovoltaics that may be useful for early phase design analysis. In this model the user has direct access to the efficiency with which surfaces convert incident solar radiation to electricity and need not specify arrays of specific modules. The full geometric model for solar radiation is used, including shading and reflections, to determine the incident solar resource. This model is intended to be useful for design purposes to quickly get an idea of the levels for annual production and peak power. The model can also accept arbitrary conversion efficiencies and does not require actual production units be tested to obtain performance coefficients.

Field: Name

This field is the name of the PV array. The name is only used as an identifier. Multiple instances need have unique names.

Field: Fraction of Surface Area with Active Solar Cells

This field is the user defined fraction for the area of surface named in the parent PV object that will have active PV cells on it. The area actually covered with solar cells will be the net area of the surface (gross area less any subsurfaces like windows) times the fraction entered here. This fraction includes the difference between PV module area and active cells within it and any losses for how closely packed modules can be arranged on surface. The value should be between 0.0 and 1.0.

Field: Conversion Efficiency Input Mode

This field specifies how the PV array efficiency values are input. There are two choices, **Fixed** and **Scheduled**. If this field is set to 'Fixed' then the PV array always has the efficiency value specified in the next field. If this field is set to 'Scheduled' then the efficiency is determined by a user defined schedule named in the second field to follow.

Field: Value for Cell Efficiency if Fixed

This field specifies the efficiency with which solar incident energy is converted to electricity. Efficiency = (electrical power generated [W])/(power of incident solar[W]). These efficiency values are dimensionless and should be between 0.0 and 1.0.

Field: Efficiency Schedule Name

This field should be set to the name of schedule defined elsewhere in the input file. This schedule should specify dimensionless efficiency values between 0.0 and 1.0. This could be used for example to vary the efficiency to match results computed with more detailed models.

  0.12 , !- Value for cell efficiency if fixed
  ; !- Name of Schedule that Defines Efficiency
    
```

PhotovoltaicPerformance:EquivalentOne-Diode

This object describes the performance characteristics of Photovoltaic (PV) modules to be modeled using an equivalent one-diode circuit. This model is also known at the 4- or 5-parameter TRNSYS model for photovoltaics.

The following table shows several sample PV array types with their input values.

Table 30. Photovoltaics Array Types with Values

Where:

Shunt Resistance: the value of shunt resistance is finite only if the PV Module being modeled is a thin film variety. For all crystalline silicon modules the value is essentially infinite

Shunt Resistance value: 1,000,000 Ω (ohms)

Module Heat Loss Coefficient: this value is dependent more on the array configuration than on the module itself.

Module Heat Loss Coefficient value: 30 W/m²-K

Module Heat Capacity: this is a typical value for a silicon based sandwich construction framed PV panel.

Module Heat Capacity Value: 50,000 J/m²-K

Reference Temperature: 298K (25C)

Insolation at Reference Conditions: 1000 W/m²

Ambient Temperature at NOCT conditions: 293K (20C)

Insolation at NOCT Conditions: 800 W/m²

Average tau-alpha Product: .9

Semiconductor Bandgap: 1.12 eV

Field: Name

This field contains the unique name for the photovoltaic module performance data. The name is only used as an identifier.

Field: Cell Type

This field is used to describe the type of technology used in the PV module. There are two options available, **CrystallineSilicon** and **AmorphousSilicon**. The choice affects the modeling.

Field: Number of Cells in Series

This field is an integer representing the number of individual cells wired in series to make up a single module. The typical number for a 12V crystalline silicon PV module is 36.

Field: Active Area

This field is the active area of the PV module in m².

Field: Transmittance Absorptance Product

This field indicates the transmittance-absorptance product at normal incidence angles for the PV modules. If the $\tau\alpha$ product is positive, that value will be used for all angles of incidence. If the value specified is negative, then the magnitude of the given value will be used for normal incidence and the IAM modifier correlation will be used for all other angles.

Field: Semiconductor Bandgap

This field is the semiconductor bandgap for the PV material. The bandgap for silicon is 1.12 eV (electron volts).

Field: Shunt Resistance

This field is the shunt (parallel) resistance (in Ω) in the single diode electrical model of the PV. The shunt resistance is effectively infinite for crystalline silicon based PV modules and is finite for thin film and exotic metal modules.

Field: Short Circuit Current

This field is the short circuit current (in Amps) for an individual module in the PV array at reference conditions.

Field: Open Circuit Voltage

This field is the open circuit voltage (in Volts) for an individual module in the PV array at reference conditions.

Field: Reference Temperature

This field is the ambient temperature (in Kelvin) at reference conditions. The value is usually 298K

Field: Reference Insolation

This field is the radiation level (in W/m²) at reference conditions. The value is usually 1000 W/m².

Field: Module Current at Maximum Power

This field is module current (in Amps) at the maximum power point and reference conditions.

Field: Module Voltage at Maximum Power

This field is module voltage (in Volts) at the maximum power point and reference conditions.

Field: Temperature Coefficient of Short Circuit Current

This field accounts for the fact that the module short circuit current is temperature dependent. The coefficient is given in Amps/Kelvin.

Field: Temperature Coefficient of Open Circuit Voltage

This field accounts for the fact that the module open circuit voltage is temperature dependent. The coefficient is given in Volts/Kelvin.

Field: Nominal Operating Cell Temperature Test Ambient Temperature

This field is the ambient temperature (in Kelvin) from the Nominal Operating Cell Temperature (NOCT) test. The value is usually 293 K

Field: Nominal Operating Cell Temperature Test Cell Temperature

This field is the cell temperature (in Kelvin) from the Nominal Operating Cell Temperature (NOCT) test.

Field: Nominal Operating Cell Temperature Test Insolation

This field is the insolation level (in W/m^2) from the Nominal Operating Cell Temperature (NOCT) test. The value is usually $800 W/m^2$.

Field: Module Heat Loss Coefficient

This field is the heat loss coefficient (in $W/m^2.K$) for the array. The heat loss coefficient is dependent upon measures taken to actively or passively promote airflow over the array surface. The heat loss coefficient value is used only if the Integration and Cell Temperature Mode is set to "Decoupled Ulleberg Dynamic."

Field: Total Heat Capacity

This field is the heat capacity (in $J/m^2.K$) of the modules in the array. It describes the module's ability to store incident solar radiation internally. Such energy storage is manifested as a temperature increase in the modules that is considered to be undesirable. The total heat capacity value is used only if the Integration and Cell Temperature Mode is set to "Decoupled Ulleberg Dynamic."

```

PhotovoltaicPerformance:Sandia

This 'PhotovoltaicPerformance:Sandia' object describes the performance of a single type of module. The model used with this object for predicting the electricity generated by photovoltaics is referred to as the Sandia model. This model is based on work done at Sandia National Lab, Albuquerque, NM by David King -- with the help of many others.

This object describes performance input data needed for specific makes and models of production PV panels using the empirical coefficients assembled by Sandia National Laboratory. There are a large number of empirical coefficients required to use the Sandia model. These data are obtained after extensive measurements and data reduction. This testing has been performed for some types of production panels and Sandia publishes a database of module and array performance parameters on the web at www.sandia.gov/pv. The entries in the database as of January 15, 2004 were converted to idf segments and are included with the EnergyPlus release in the library file SandiaPVData.imf. There are more than hundred different module types included in the library and identified by the manufacturer's model names listed at the beginning of the file SandiaPVData.imf. This data library file is arranged for use with EpMacro but the user can also copy .idf segments directly from the macro data set.

The Sandia model itself can aggregate multiple PV modules. Therefore, an instance of a 'PhotovoltaicPerformance:Sandia' object could actually represent an array of modules as well as the more usual single module. These can be thought of as simple larger modules and used by Generator:PV:Sandia objects in the usual manner.

The many empirical coefficients for the model are listed below and are described in more detail in the EnergyPlus engineering documentation EngineeringDoc.pdf.

The field descriptions below focus on providing the parameter's variable name as identified in the Sandia database. See the the EngineeringDoc.pdf for details on how the input fields are used in the correlations. The user generally would not need to worry about the details of the fields since he/she is not likely to generate the data on their own.

Field: Name

This field provides a unique name for the PV module. This is often the manufacturer's identifier for a particular model of a PV module.

Field: Active Area

Units m^2 , real number, area of active solar electric cell for the entire module.

Field: Number of Cells in Series

"Series_Cells" in Sandia Database.

Field: Number of Cells in Parallel

"Parallel_Cells" in Sandia Database

Field: Short-Circuit Current

"Isco" in Sandia Database. Short-circuit current is a basic parameter Typically supplied by manufacturers at Standard Report Conditions. (Amps)

Field: Open-Circuit Voltage

"Voco" in Sandia Database, Open-circuit voltage is a basic parameter typically provided by manufacturers at Standard Report Conditions. (Volts)

Field: Current at Maximum Power Point

"Impo" in Sandia Database. Current at maximum powerpoint is a basic parameter provided by manufacturers at Standard Report Conditions. (Amps)

Field: Voltage at Maximum PowerPoint

"Vmpto" in Sandia Database. Voltage at maximum powerpoint is a basic parameter typically provided by manufacturers at Standard Report Conditions. (Volts)

Field: Sandia Database Parameter alsC

When using EpMacro with an typical installation of EnergyPlus, the above entry can be included in an input file by adding the following two lines to an input macro file (*.imf).

```

##include C:\EnergyPlus\MacroDataSets\SandiaPVdata.imf
ASE-50-ATF-17_45[]

```

Group – Water Systems

This group of objects is used to describe the water systems in the building. EnergyPlus offers water modeling capabilities that include not only hot water systems but also the overall water systems including cold water uses, on-site water collection (e.g., from rain, condensate, or well), and storage. HVAC components may consume or collect a significant portion of the water making it appropriate to include water modeling in EnergyPlus.

All water systems are collected into an end use category called “Water Systems”. This category includes hot and cold water. Water consumed by an HVAC component will be assigned to the end use category for that component. End use subcategories are available to separate hot water from cold water if desired. Simple hot water systems can be configured as stand-alone or use a PlantLoop. The Water Systems can be connected to PlantLoops for modeling heated water end uses. However PlantLoops are not used to model cold water and the WaterUse:Storages portions of the water system. Cold water systems are connected together using WaterUse:Storage objects. WaterUse:Connections are used at the zone level to connect to both cold and hot water.

In addition to the input objects described in this section below, there are a variety of HVAC components that can be configured to interact with the water systems. These component input objects include optional fields that allow describing how the water systems are connected to them by providing the name of a storage tank. The following table lists EnergyPlus input objects that include provisions for connecting to the water systems but are described elsewhere in this document:

Table 31. Water Systems Objects

Input Object Name	Type of Water Interactions
Site:Precipitation	Describes rainfall for WaterUse:RainCollector
Coil:Cooling:Water	Condensate collection to WaterUse:Storage
Coil:Cooling:Water:DetailedGeometry	Condensate collection to WaterUse:Storage
Coil:Cooling:DX:SingleSpeed	Optional evaporative condenser can be supplied by WaterUse:Storage Condensate collection to WaterUse:Storage
Coil:Cooling:DX:TwoSpeed	Evaporative condenser supplied by WaterUse:Storage Condensate collection to WaterUse:Storage
Coil:Cooling:DX:TwoStageWithHumidityControlMode	Evaporative condenser supplied by WaterUse:Storage Condensate collection to WaterUse:Storage
Coil:Cooling:DX:MultiSpeed	Evaporative condenser supplied by WaterUse:Storage Condensate collection to WaterUse:Storage
Humidifier:Steam:Electric	Water supplied by WaterUse:Storage

Input Object Name	Type of Water Interactions
CoolingTower:SingleSpeed	Water supplied by WaterUse:Storage
CoolingTower:TwoSpeed	Water supplied by WaterUse:Storage
CoolingTower:VariableSpeed	Water supplied by WaterUse:Storage
ZoneCoolTower:Shower	Water supplied by WaterUse:Storage
Refrigeration:CompressorRack	Water supplied by WaterUse:Storage
Refrigeration:Condenser:EvaporativeCooled	Water supplied by WaterUse:Storage
EvaporativeCooler:Direct:CelDekPad	Evaporation water supplied by WaterUse:Storage
EvaporativeCooler:Indirect:CelDekPad	Evaporation water supplied by WaterUse:Storage
EvaporativeCooler:Indirect:WetCoil	Evaporation water supplied by WaterUse:Storage
EvaporativeCooler:Indirect:ResearchSpecial	Evaporation water supplied by WaterUse:Storage

WaterUse:Equipment

The WaterUse:Equipment object is a generalized object for simulating all water end uses. Hot and cold water uses are included, as well as controlled mixing of hot and cold water at the tap. The WaterUse:Equipment object can be used stand-alone, or coupled into a plant loop using the WaterUse:Connections object (see below). The WaterUse:Connections object allows water uses to be linked to WaterUse:Storage objects to store and draw reclaimed water. The WaterUse:Connections object can also simulate drainwater heat recovery.

The WaterUse:Equipment object serves all of the same purposes as the existing objects: Exterior:WaterEquipment, and HotWaterEquipment.

The WaterUse:Equipment object does a better job of modeling domestic hot water by allowing mixing at the tap in order to account for both hot and cold water used at sinks, showers, etc. It also improves on the stand-alone energy modeling of domestic hot water. Because all of the temperatures and flow rates can be solved, the energy usage can be accounted for as "Purchased Heating".

In either stand-alone mode or used with the WaterUse:Connections object, the WaterUse:Equipment object will attempt to meet a scheduled target temperature at the tap by mixing hot and cold water flows. If the hot water flow is not hot enough, or if the flow is limited by plant loop constraints, the result is a cooler mixed water temperature and the target temperature will not be met. In stand-alone mode the hot and cold water temperatures are specified by schedules. However, if the cold water schedule is omitted, the water temperature will be calculated by the Site:WaterMainsTemperature object. If the hot water schedule or target temperature schedule are omitted, all water is delivered as cold water. If only using cold water, the WaterUse:Equipment object is similar to the Exterior:WaterEquipment object.

The WaterUse:Equipment object improves on the internal gains object HotWaterEquipment by associating actual water usage with a sensible and latent gain to a zone. Equipment, such as showers, that generate a significant heat gain can be modeled using the Sensible Fraction Schedule and Latent Fraction Schedule fields. The schedules are used to set the fraction of the maximum possible heat gain (based on inlet water conditions and ambient zone

conditions) that should be added to the zone. The split between sensible and latent will vary depending on the type of equipment that is to be modeled. Typically, both fractions should be small numbers.

```

Field: Name

The unique object name for reference by other objects.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Laundry", "Dish Washing", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table under the "Water Systems" end-use category. If this field is omitted or blank, the water use will be assigned to the "General" end-use subcategory.

Field: Peak Flow Rate

The peak demanded hot water flow rate [m³/s]. This value is multiplied by the Flow Rate Fraction Schedule (below) to determine the actual volumetric flow rate.

Field: Flow Rate Fraction Schedule Name

Reference to the schedule object specifying the flow rate fraction relative to the Peak Flow Rate (above). If blank, the schedule defaults to 1.0 at all times.

Field: Target Temperature Schedule Name

Reference to the schedule object specifying the target water temperature [C]. Hot and cold water are mixed at the tap to attain the target temperature. If insufficient hot water is available to reach the target temperature, the result is cooler water at the tap. If blank, the target temperature defaults to the hot water supply temperature.

Field: Hot Water Supply Temperature Schedule Name

Reference to the schedule object specifying the hot water temperature [C]. The hot water temperature is used to calculate the "Purchased Heating" energy usage in stand-alone mode. If blank in stand-alone mode, the hot water supply temperature defaults to the cold water supply temperature. This field is ignored if the object is used with the WaterUse:Connections object.

Field: Cold Water Supply Temperature Schedule Name

Reference to the Schedule object specifying the cold water temperature [C] from the supply mains that provides the cold water to the tap and makes up for all water lost down the drain. If blank, water temperatures are calculated by the Site:WaterMainsTemperature object. This field is ignored if the object is used with the WaterUse:Connections object.

Field: Zone Name

Reference to the zone name where the water equipment will be considered as latent load to the zone.

Field: Sensible Fraction Schedule Name

Reference to the schedule object specifying the fraction of the maximum possible sensible heat gain (based on inlet water conditions and ambient zone conditions) that is added to the zone. If blank, the schedule defaults to 0 at all times.

Field: Latent Fraction Schedule Name

Reference to the schedule object specifying the fraction of the maximum possible latent heat gain (based on inlet water conditions and ambient zone conditions) that is added to the zone. If blank, the schedule defaults to 0 at all times.

Water Use Equipment Hot Water Mass Flow Rate [kg/s]

The mass flow rate of hot water supplied to the equipment.

Water Use Equipment Cold Water Mass Flow Rate [kg/s]

The mass flow rate of cold water supplied to the equipment.

Water Use Equipment Total Mass Flow Rate [kg/s]

The total mass flow rate of water (hot + cold) supplied to the equipment.

Water Use Equipment Hot Water Consumption Rate [m3/s]

The volumetric flow rate of hot water supplied to the equipment and consumed down the drain.

Water Use Equipment Cold Water Consumption Rate [m3/s]

The volumetric flow rate of cold water supplied to the equipment and consumed down the drain.

Water Use Equipment Total Consumption Rate [m3/s]

The total volumetric flow rate of water (hot + cold) supplied to the equipment and consumed down the drain.

Water Use Equipment Hot Water Consumption [m3]

The volume of hot water supplied to the equipment and consumed down the drain.

Water Use Equipment Cold Water Consumption [m3]

The volume of cold water supplied to the equipment and consumed down the drain.

Water Use Equipment Total Consumption [m3]

The total volume of water (hot+cold) supplied to the equipment and consumed down the drain.

Water Use Equipment Hot Water Temperature [C]

The temperature of hot water supplied to the equipment.

Water Use Equipment Cold Water Temperature [C]

The temperature of cold water supplied to the equipment.

Water Use Equipment Target Water Temperature [C]

The user-specified target temperature for the mixing of hot and cold supply flows.

Water Use Equipment Mixed Water Temperature [C]

The actual mixed water temperature possible with the available hot and cold temperatures and flow rates.

Water Use Equipment Drain Water Temperature [C]

The water temperature at the drain equal to the mixed water temperature minus any heat loss to the zone.

Water Use Equipment Heating Rate [W]

The heating rate defined by the hot water flow and the temperature difference between the hot water supply and the cold makeup return water.

Water Use Equipment Heating Energy [J]

The heating energy accumulated by the heating rate above.

Water Use Equipment Sensible Heat Rate To Zone [W]

The sensible heat rate to the zone due to the water flow being exposed to zone air.

Water Use Equipment Sensible Heat Gain To Zone [J]

The sensible heat energy accumulated by the latent heat rate above.

Water Use Equipment Latent Heat Rate To Zone [W]

The latent heat rate to the zone due to the water flow being exposed to zone air.

Water Use Equipment Latent Heat Gain To Zone [J]

The latent heat energy accumulated by the latent heat rate above.

Water Use Equipment Moisture Rate To Zone [kg/s]

The moisture rate of evaporation to the zone due to the water flow being exposed to zone air.

Water Use Equipment Moisture Gain To Zone [kg]

The moisture mass accumulated by the moisture rate above.

WaterUse:Connections

The WaterUse:Connections object can be thought of as a subsystem that groups together multiple WaterUse:Equipment components. As its name suggests, the object provides connections that are shared by these components, including:

- Inlet node and outlet node connections to a plant loop
- Connections to WaterUse:Storage objects to store and draw reclaimed water
- Internal connections to simulate drainwater heat recovery.

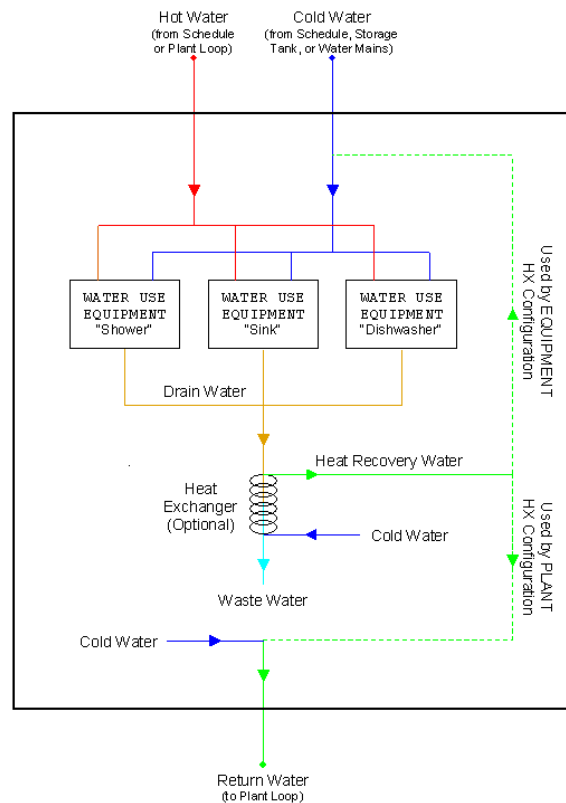

Figure 127. Diagram of internal connections for WaterUse:Connections

The WaterUse:Connections object can be used stand-alone or coupled into a plant loop. In stand-alone mode, the Hot and Cold Water Supply Temperature Schedules override the values for the listed WaterUse:Equipment objects. When coupled to the plant, the Hot Water Supply Temperature Schedule is overridden by the actual plant loop inlet water temperature. When coupled to the plant, the WaterUse:Connections object should be on a Branch object whose control type is set to “Active.”

```

Field: Name

The unique object name for reference by other objects.

Field: Inlet Node Name

The hot water inlet node when connected to a plant loop. The hot water supplies all of the WaterUse:Equipment objects that demand hot water. Insufficient supply temperature or flow results in cooler water at the tap.

Field: Outlet Node Name

The cold water outlet node, i.e. the cold water supply mains, when connected to a plant loop. The return node provides make-up water for the hot water lost down the drain.

Field: Supply Water Storage Tank Name

Reference to the WaterUse:Storage object that supplies cold water to the listed WaterUse:Equipment objects. If the field is blank, or the tank is empty, fresh water is supplied from the water mains.

Field: Reclamation Water Storage Tank Name

Reference to the WaterUse:Storage object that stores the resulting graywater from the listed WaterUse:Equipment objects. If the field is blank, the graywater is not reclaimed.

Field: Hot Water Supply Temperature Schedule Name

Reference to the schedule object specifying the hot water temperature [C]. If blank in stand-alone mode, the hot water supply temperature defaults to the cold water supply temperature. This field (even if blank) overrides the Hot Water Supply Temperature Schedule in all of the listed WaterUse:Equipment objects.

Field: Cold Water Supply Temperature Schedule Name

Reference to the schedule object specifying the cold water temperature [C] from the supply mains that provides the cold water to the tap and makes up for all water lost down the drain. If blank, water temperatures are calculated by the Site:WaterMainsTemperature object.

This field (even if blank) overrides the Cold Water Supply Temperature Schedule in all of the listed WaterUse:Equipment objects.

Field: Drain Water Heat Exchanger Type

The heat exchanger type to be used for drainwater heat recovery. None indicates no heat recovery is to be simulated. Ideal sets a heat exchanger effectiveness of 1.0. Effectiveness is calculated dynamically for CounterFlow and CrossFlow options.

One popular type of drainwater heat exchanger is the Gravity-Film Heat Exchanger (GFX). The GFX is most closely approximated with the CounterFlow option, but keep in mind that the UA varies more with flow rate for the GFX than for most traditional heat exchangers.

Field: Drain Water Heat Exchanger Destination

The heat exchanger configuration to be used for drainwater heat recovery. The configuration determines where the heat will be used after it is recovered.

Plant indicates that the all of the recovered heat will be sent to the return flow at the outlet node of the WaterUse:Connections object to preheat the make-up cold water from the water mains.

Equipment indicates that the all of the recovered heat will be used to preheat the cold water flow side of the WaterUse:Equipment objects listed *in this* WaterUse:Connections object

PlantAndEquipment indicates the recovered heat will be divided between the plant and the WaterUse:Equipment objects, as described above. This is the only option where the flow rates are equal in the drain and the heat exchanger.

Field: Drain Water Heat Exchanger U-Factor Times Area

The UA is the heat transfer coefficient [W/K] for the heat exchanger and is the product of U, the overall heat transfer coefficient, and A, the heat exchanger surface area.

Field: Water Use Equipment 1-10 Name

References to WaterUse:Equipment objects.

HVAC,Sum,Water Use Connections Plant Hot Water Consumption [J]

```

Water Use Connections Hot Water Mass Flow Rate [kg/s]

The mass flow rate of hot water supplied to all equipment.

Water Use Connections Cold Water Mass Flow Rate [kg/s]

The mass flow rate of cold water supplied to all equipment.

Water Use Connections Total Mass Flow Rate [kg/s]

The total mass flow rate of water (hot + cold) supplied to all equipment.

Water Use Connections Drain Mass Flow Rate [kg/s]

The mass flow rate of drainwater from all equipment.

Water Use Connections Heat Recovery Mass Flow Rate [kg/s]

The mass flow rate of make-up water in the heat exchanger.

Water Use Connections Hot Water Consumption Rate [m3/s]

The volumetric flow rate of hot water supplied to all equipment and consumed down the drain.

Water Use Connections Cold Water Consumption Rate [m3/s]

The volumetric flow rate of cold water supplied to all equipment and consumed down the drain.

Water Use Connections Total Consumption Rate [m3/s]

The total volumetric flow rate of water (hot + cold) supplied to all equipment and consumed down the drain.

Water Use Connections Hot Water Consumption [m3]

The volume of hot water supplied to all equipment and consumed down the drain.

Water Use Connections Cold Water Consumption [m3]

The volume of cold water supplied to all equipment and consumed down the drain.

Water Use Connections Total Consumption [m3]

The total volume of water (hot+cold) supplied to all equipment and consumed down the drain.

Water Use Connections Hot Water Temperature [C]

The temperature of hot water supplied to all equipment.

Water Use Connections Cold Water Temperature [C]

The temperature of cold water supplied to all equipment.

Water Use Connections Drain Water Temperature [C]

The water temperature at the drain equal to the mixed water temperature minus any heat losses to the zone.

Water Use Connections Return Water Temperature [C]

The temperature of make-up water returned to the plant loop.

Water Use Connections Waste Water Temperature [C]

The temperature of the water leaving the heat exchanger. If no heat exchanger, the waste water temperature equals the drain water temperature.

Water Use Connections Heat Recovery Water Temperature [C]

The temperature of the water leaving the heat exchanger. If no heat exchanger, the waste water temperature equals the drain water temperature.

Water Use Connections Heat Recovery Effectiveness []

The effectiveness value of the heat exchanger.

Water Use Connections Heat Recovery Rate [W]

The heat recovered by the heat exchanger and used to preheat the cold make-up water.

Water Use Connections Heat Recovery Energy [J]

The energy recovered by the heat exchanger and used to preheat the cold make-up water.

Water Use Connections Plant Hot Water Consumption [J]

The plant loop energy consumed by the hot water used.

WaterUse:Storage

The WaterUse:Storage object is a central component for complex water systems. This object is not needed if the only use of water is directly from the mains, or utility service water. If the building model is to include any on-site collection or wells or storing and reuse of graywater,

then a WaterUse:Storage is needed. Each WaterUse:Storage can serve as a central node and make connections to numerous sources of supply or numerous components with demand. If a maximum capacity is not specified, the tank is assumed to have unlimited capacity. This is useful for sizing.

Storage tanks may handle a lot of water but show no use. This is because water usage is metered at the component level where water is “used up.” The only water a storage tank might use up is overflow water if it is discarded.

Field: Name

The unique object name for reference by other objects.

Field: Water Quality Subcategory

Describes the quality of the water contained in the tank. Used for reporting and to check that the uses and supply match the category of water quality.

Field: Maximum Capacity

The maximum volumetric capacity [m3] of the water tank. If blank, this field defaults to unlimited capacity.

Field: Initial Volume

The volume of water in the storage tank at the beginning of each simulation environmental period [m3]. This provides a starting point for the amount of water in storage.

Field: Design In Flow Rate

The design flow rate [m3/s] of fittings that provide water into the tank from external sources. In a scenario where a heavy rain fall is being harvested, the actual reclamation rate might be limited by pipe size or filtration. If blank, this field defaults to unlimited rate.

Field: Design Out Flow Rate

The design flow rate [m3/s] of fitting that withdraw water from the tank to end uses. Heavy demand (landscaping?) might be limited by pipe size or filtration. If Blank, this field defaults to unlimited rate.

Field: Overflow Destination

Name of a second WaterUse:Storage that would receive overflow. Overflow could occur if the maximum capacity is reached or if the design in flow rate is exceeded. If left blank, then the overflow is discarded and lost from the water system.

Field: Type of Supply Controlled by Float Valve

The storage tank can include the capability of modeling a float valve that will call for water to be added to the tank. This field is used to select the type of system used to respond to fill requests made by a float valve. The available options are 'None', 'Mains', 'GroundwaterWell', or 'OtherTank.' The float valve settings are described in the next two fields.

Field: Float Valve On Capacity

The volumetric capacity [m3] of the water tank when a floating valve would turn on to allow filling the tank.

Field: Float Valve Off Capacity

The volumetric capacity [m3] of the water tank when a floating valve would turn off after having been filling the tank.

Field: Backup Mains Capacity

The volumetric capacity of the tank that indicates where a secondary float valve will maintain the volume by calling for mains water. Used if the well or other tank cannot keep up with the needs of the main float valve. If left blank or equal 0.0, then there is no mains water backup.

If specified, then mains water will be drawn once the storage tank reaches this level and then the mains water will fill all the way to capacity specified in the previous field.

Field: Other Tank Name

This field contains the name of another WaterUse:Storage defined elsewhere in the input file. This field is only used if the Type of Controlled Supply field is set to 'OtherTank' and the current tank is to be configured to be supplied by a second tank in response to a float valve.

Field: Water Thermal Mode

Controls the method of determining the temperature of the water in the storage tank. The only available option at the current time is ScheduledTemperature.

Field: Water Temperature Schedule Name

Reference to the schedule object specifying the temperature [C] of the water in the tank. This takes the place of a full thermal model of the tank.

Field: Ambient Temperature Indicator

Reserved for future use. The field can be Schedule, Zone, or Outdoors.

Field: Ambient Temperature Schedule Name

Reserved for future use. Schedule name for ambient temperature when previous field is Schedule.

Field: Zone Name

Reserved for future use. Name of zone where the tank is located.

Field: Tank Surface Area

Reserved for future zone thermal model.

Field: Tank U Value

Reserved for future zone thermal model.

Field: Tank Outside Surface Material Name

Reserved for future zone thermal model.

WaterUse:Storage Outputs

The following output variables are available for reporting for each WaterUse:Storage object.

Storage Tank Volume [m3]

This is the volume of water stored in the storage tank

Storage Tank Net Volumetric Flow Rate [m3]

This is the net rate of flows in and out of the storage tank.

Storage Tank Inlet Volumetric Flow Rate [m3/s]

This is the rate of flows into the storage tank

Storage Tank Outlet Volumetric Flow Rate [m3]

This is the rate of flows out of the storage tank

Storage Tank Mains Water [m3/s]

This is the volume of water drawn from the mains in order to fill the tank.

Storage Tank Mains Water Volumetric Rate [m3/s]

This is the rate of water draw from the mains in order to fill the tank.

Tank Water Temperature [C]

This is the temperature of the water in the tank.

Storage Tank Overflow Volumetric Flow Rate [m3/s]

This is the rate of water flows that overflow the tank either because of limits on how fast the tank can fill or because the tank is full and cannot handle the water provided.

Storage Tank Overflow Water [m3]

This is the volume of water overflowing the tank because of limits on how fast the tank can fill or because the tank is full and cannot handle the water provided.

WaterUse:RainCollector

The WaterUse:RainCollector object is used for harvesting rainwater falling on building surfaces. The rainwater is sent to a WaterUse:Storage object. In order to use this object it is necessary to also include a Site:Precipitation object to describe the rates of rainfall.

IDD specification:

```

WaterUse:RainCollector,
  \extensible:1 - repeat last field
A1 , \field Name
  \required-field
  \type alpha
A2 , \field Storage Tank Name

  \type alpha
  \type object-list
  \object-list AllShadingAndHTSurfNames

```

Field: Name

The unique object name for reference by other objects.

Field: Storage Tank Name

A reference to a WaterUse:Storage object where the rainwater will be collected and stored for later use.

Field: Loss Factor Mode

The WaterUse:RainCollector model includes a loss factor that indicates the portion of incident rain that is not successfully collected. Two modes are available: Constant and Scheduled. Enter Constant in this field for the model to use a simple fixed loss factor defined in the next field. For versatility, the loss factor can follow a schedule by entering Scheduled in this field and then the name of a schedule in the second field below.

Field: Collection Loss Factor

Constant loss factor for how much of the incident rainwater is lost and not collected. The factor should be between 0 and 1.

Field: Collection Loss Factor Schedule Name

Name of a schedule that defines a variable collection loss factor if the mode is selected as Scheduled.

Field: Maximum Collection Rate

The maximum flow rate [m³/s] for rainwater collection. In a scenario where a heavy rain fall is being harvested, the actual reclamation rate might be limited by pipe size or the filtration system.

Field: Collection Surface 1-10 Name

A reference to the name of a surface object which will collect the rain. Typically the collection surfaces would correspond to roof surfaces on the building. The effective area for rainwater collection is the horizontal component (area * cosine of the slope, etc.). More detailed modeling of rainwater collection can be added later to account for factors such as wind speed and direction, etc.

IDF examples:

  NorthRoof3 , !- Collection Surface 3 Name
  NorthRoof2 ; !- Collection Surface 4 Name
```

WaterUse:RainCollector Outputs**Rainwater Collector Volumetric Rate [m³/s]****Rainwater Collector Water [m³]**

These output variables provide the rate and volume of water collected by the WaterUse:RainCollector.

WaterUse:Well

The WaterUse:Well object is for simulating on-site water supply from a well. Well water is pumped out of the ground and into a WaterUse:Storage. The operation of the ground water well is controlled by the associated WaterUse:Storage which is assumed to be operated as a vented cistern with no pressure tank. The current implementation is very simple and only requires two numeric inputs: the rated pump flow and power. A more elaborate well model may be added and many input fields are reserved for this future expansion.

IDD specification:

```

WaterUse:Well,

Field: Name1

Unique name of this well.

Field: Storage Tank Name

A reference to a WaterUse:Storage object where the rainwater will be collected and stored for later use.

Field: Pump Depth

Reserved for future use. Effective depth of well [m]

Field: Pump Rated Flow Rate

This is the nominal pump flow rate [m3/s]. This field is required.

Field: Pump Rated Head

Reserved for future use [Pa]. Pump head at rated conditions in Pascals.

Field: Pump Rated Power Consumption

This is the pump power at the nominal pump flow rate [W]. This field is required.

Field: Pump Efficiency

Reserved for future use.

Field: Well Recovery Rate

Reserved for future use. Rate at which ground water enters well during a sustained draw, e.g., 2 hour well test [m3/s].

Field: Nominal Well Storage Volume

Reserved for future use. Capacity in well after long period of inactivity and the usual water table depth. [m3]

Field: Water Table Depth Mode

Reserved for future use. Two options available: Constant or Scheduled

Field: Water Table Depth

Reserved for future use. Depth of water table from WaterUse:Storage

Field: Water Table Depth Schedule Name

Reserved for future use.

  ,  !- Water Table Depth Mode
  ,  !- Water Table Depth
  ;  !- Water Table Depth Schedule Name
```

Group – Performance Curves

This group of objects consists of polynomial curves which are used to characterize the performance of HVAC equipment. The curves are input, stored, and evaluated entirely within the CurveManager module. The curves are usually derived from fits or regressions to data covering a limited range. Results for independent variable values outside this range are likely to be invalid, so curve input always contains a range of validity (maximum and minimum permitted values) for each independent variable and can optionally have limits on the curve output. No error or warning message is issued if an independent variable is outside the range. Instead, the curve manager uses the minimum value if an independent variable is less than the minimum, and the maximum if a variable exceeds the maximum. Similarly, no error or warning message is issued if the curve output is outside the range of the optional minimum and maximum curve output limits. Instead, the curve manager uses the minimum and maximum curve limits to cap the output of the performance curve.

Curve:Linear

Input for the linear curve consists of a curve name, the two coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the linear curve is:

$$y = C_1 + C_2 * x$$

Field: Name

A user assigned unique name for an instance of a linear curve. When a curve is used, it is referenced by this name.

Field: Coefficient1 Constant

The constant coefficient (C_1) in the equation.

Field: Coefficient2 x

The linear coefficient (C_2) in the equation.

Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Field: Minimum Curve Output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

The Input Data Dictionary is shown below:

```
Curve:Linear,
  A1 , \field Name
      \required-field
      \type alpha
      \reference LinearCurves
      \reference AllCurves
      \note curve = C1 + C2*x
  N1 , \field Coefficient1 Constant
      \required-field

      \note Specify the minimum value calculated by this curve object
  N6 ; \field Maximum Curve Output
      \type real
      \note Specify the maximum value calculated by this curve object
```

Following is an example input:

```
Curve:Linear,
  Curve-Linear, ! name
  -1,           ! Coefficient1 Constant
  2,           ! Coefficient2 x
  0.0,         ! min
  1.0;         ! max
```

Curve:Quadratic

Input for a quadratic curve consists of the curve name, the three coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the quadratic curve is:

$$y = C_1 + C_2 * x + C_3 * x^2$$

Field: Name

A user assigned unique name for an instance of a quadratic curve. When a curve is used, it is referenced by this name.

Field: Coefficient1 Constant

The constant coefficient (C_1) in the equation.

Field: Coefficient2 x

The linear coefficient (C_2) in the equation.

Field: Coefficient3 x2**

The quadratic coefficient (C_3) in the equation.

Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Field: Minimum Curve Output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

The Input Data Dictionary description is shown below.

```

Curve:Cubic

Input for a cubic curve consists of the curve name, the 4 coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the cubic curve is:

$$y = C_1 + C_2 * x + C_3 * x^2 + C_4 * x^3$$

Field: Name

A user assigned unique name for an instance of a cubic curve. When a curve is used, it is referenced by this name.

Field: Coefficient1 Constant

The constant coefficient (C_1) in the equation.

Field: Coefficient2 x

The linear coefficient (C_2) in the equation.

Field: Coefficient3 x2**

The quadratic coefficient (C_3) in the equation.

Field: Coefficient4 x3**

The cubic coefficient (C₄) in the equation.

Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Field: Minimum Curve Output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

The Input Data Dictionary description is shown below.

Curve:Exponent

Input for an exponent curve consists of the curve name, the 3 coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the exponent curve is:

$$y = C1 + C2 * x^{C3}$$

Field: Name

A user assigned unique name for an instance of an exponent curve. When a curve is used, it is referenced by this name.

Field: Coefficient1 Constant

The constant coefficient (C_1) in the equation.

Field: Coefficient2 Constant

The linear coefficient (C_2) in the equation.

Field: Coefficient3 Constant

The exponent coefficient (C_3) in the equation.

Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Field: Minimum Curve Output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

The Input Data Dictionary description is shown below.

Curve:Bicubic

This curve type is a function of two independent variables. Input consists of the curve name, the ten coefficients, and the minimum and maximum values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the bicubic curve is:

$$z = C_1 + C_2 * x + C_3 * x^2 + C_4 * y + C_5 * y^2 + C_6 * xy + C_7 * x^3 + C_8 * y^3 + C_9 * x^2 y + C_{10} * xy^2$$

Field: Name

A user assigned unique name for an instance of a bicubic curve. When a curve is used by another object, it is referenced by this name.

Field: Coefficient1 Constant

The constant coefficient (C_1) in the equation.

Field: Coefficient2 x

The coefficient C_2 in the equation.

Field: Coefficient3 x2**

The coefficient C_3 in the equation.

Field: Coefficient4 y

The coefficient C_4 in the equation.

Field: Coefficient5 y2**

The coefficient C_5 in the equation.

Field: Coefficient6 x*y

The coefficient C_6 in the equation.

Field: Coefficient7 x3**

The coefficient C_7 in the equation.

Field: Coefficient8 y3**

The coefficient C_8 in the equation.

Field: Coefficient9 x2*y**

The coefficient C_9 in the equation.

Field: Coefficient10 x*y2**

The coefficient C_{10} in the equation.

Field: Minimum Value of x

The minimum allowable value of x. Values of x less than this minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than this maximum will be replaced by the maximum.

Field: Minimum Value of y

The minimum allowable value of y. Values of y less than this minimum will be replaced by the minimum.

Field: Maximum Value of y

The maximum allowable value of y. Values of y greater than this maximum will be replaced by the maximum.

Field: Minimum Curve Output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

The Input Data Dictionary definition for this object is shown below.

Curve:Biquadratic

This curve is a function of two independent variables. Input consists of the curve name, the six coefficients, and min and max values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the bicubic curve is:

$$z = C_1 + C_2 * x + C_3 * x^2 + C_4 * y + C_5 * y^2 + C_6 * xy$$

Field: Name

A user assigned unique name for an instance of a biquadratic curve. When a curve is used, it is referenced by this name.

Field: Coefficient1 Constant

The constant coefficient (C_1) in the equation.

Field: Coefficient2 x

The coefficient C_2 in the equation.

Field: Coefficient3 x**2

The coefficient C_3 in the equation.

Field: Coefficient4 y

The coefficient C_4 in the equation.

Field: Coefficient5 y**2

The coefficient C_5 in the equation.

Field: Coefficient6 x*y

The coefficient C_6 in the equation.

Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Field: Minimum Value of y

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

Field: Maximum Value of y

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

Field: Minimum Curve Output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

The following shows the Input Data Dictionary definition of the object.

Curve:QuadraticLinear

This curve is a function of two independent variables. Input consists of the curve name, the six coefficients, and min and max values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the quadratic linear curve:

$$y = (C_1 + C_2 * x + C_3 * x^2 + C_4 * x^3) + (C_4 + C_5 * x + C_6 * x^2) * y$$

Field: Name

A user assigned unique name for an instance of a quadratic-linear curve. When a curve is used, it is referenced by this name.

Field: Coefficient1 Constant

The constant coefficient (C₁) in the equation.

Field: Coefficient2 x

The coefficient C₂ in the equation.

Field: Coefficient3 x2**

The coefficient C₃ in the equation.

Field: Coefficient4 y

The coefficient C₄ in the equation.

Field: Coefficient5 x*y

The coefficient C₅ in the equation.

Field: Coefficient6 x2*y**

The coefficient C₆ in the equation.

Field: Minimum Value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Field: Maximum Value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Field: Minimum Value of y

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

Field: Maximum Value of y

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

Field: Minimum Curve Output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Group – Fluid Properties

The Fluid Property routines in EnergyPlus have been designed for ease of use and to allow users to add refrigerant and glycol data to the input file without having to make any changes to the program code. Fluid properties are calculated by interpolating the tabulated data in the input file. The main input requirement is that in order to add a new fluid, a user must enter a full set of data. The user may determine the interval between data points according to the desired accuracy and range required. Data for a number of common fluids are available in the required format in a reference dataset so that the user may append this data to their input file. In addition, data for Water, Ethylene Glycol (in various concentrations from 0 to 90%), and Propylene Glycol (in various concentrations from 0 to 90%) are available as default values within EnergyPlus.

Each fluid is categorized as either a 'Refrigerant' or 'Glycol'. Refrigerant data is further categorized as either saturated or superheated. Saturated refrigerant data is indexed, in the input data, according to pressure and temperature i.e. the specific heat, density, enthalpy in the input data are given for a given combination of pressure and temperature. Saturated refrigerant data is indexed according to pressure and quality. In the case of saturated pressure data only a temperature index is used. Glycol data is indexed in the input data according to temperature and concentration. The input data structure for each property is essentially two-dimensional (a matrix). However, since all fluid loops are assumed to be of constant concentration, EnergyPlus internally will interpolate from input data to data for the actual concentration being used in a particular loop. This reduces internally to a one-dimensional array of data for various properties where temperature is the only variable. This saves time since it reduces all interpolations for glycols to a single dimension.

In most cases there will be combinations of index variable (e.g. some combination of pressure and temperature) at which either no data is available, or the property data is invalid/irrelevant. For example, in the superheated refrigerant data, some combinations of temperature and pressure may correspond to a state in the saturated rather than superheated region. Similarly, in the case of glycols there may be some combinations of temperature and concentration that would correspond to the frozen state. In these cases, and where data is just not available, a zero should be present in the data at these points to indicate an invalid condition. EnergyPlus uses the presence of zeros to detect invalid conditions and give warning messages.

FluidProperties:Names

The names of each fluid for which property data is given in the user input have to be specified in a FluidProperties:Names data object. If data is to be included for a given fluid, either a refrigerant or a glycol, then its name must be included in the FluidProperties:Names data.

Field: Fluid <x> Name

Each fluid name is a unique identifier that will be used in conjunction with the data statements described later in this section. The fluid name is either referred to by a component (in the case of a Refrigerant) or by another input line (in the case of a Glycol). This list is simply a list of user defined fluids present in the input data file.

Field: Fluid <x>Type

Each fluid name must be identified by type - either **Refrigerant** or **Glycol**. This designation determines what type of data EnergyPlus expects for the fluid name. If the fluid name is defined as a Refrigerant, the user must supply valid data for pressure, enthalpy, specific heat, and density in the saturated region and enthalpy and density in the superheated region. If the fluid name is defined as a Glycol, the user must supply valid data for specific heat, conductivity, viscosity, and density at various concentrations (percentage of non-water liquid) and temperatures.

```
FluidProperties:Names,
    \unique-object
    \extensible:2 repeat last two fields
    \memo list of potential fluid names/types in the input file, maximum of ten
A1, \field Fluid 1 Name
    \type alpha
A2, \field Fluid 1 Type
    \type choice
    \key Refrigerant
    \key Glycol
... same thing repeated over and over again ...
```

An example of this statement in an input data file is:

```
FluidProperties:Names,
R11, Refrigerant,
R12, Refrigerant,
R22, Refrigerant,
NH3, Refrigerant,
Steam, Refrigerant,
SaltBrine, Glycol,
NewGlycol, Glycol;
```

FluidProperties:GlycolConcentrations

This input syntax is used to specify fluids that will be used with HVAC loops such as plant and condenser loops or that could be used within particular components (if necessary). It allows the user to define a mixture of water and some other substance and the particular concentration being used. The fluid name will be referred to by the loops or components and thus used to identify which value is valid for a particular fluid at a particular temperature. A series of three inputs is required for each fluid concentration definition; this may be repeated for up to 10 fluids. Only one GlycolConcentrations input may be entered in any single EnergyPlus run.

Field: Fluid <x> Name

Each fluid name is a unique identifier that will be used to define a particular combination of water and some other substance (usually another fluid). Other input (such as loop definitions) will refer to this name, linking the other input to the proper fluid definition.

Field: Glycol <x> Name

This field refers to the substance that is being mixed with water to create the glycol. The user may either select from the two default fluids (Ethylene Glycol or Propylene Glycol) or from fluids that have been entered elsewhere in the input file. It should be noted that users must enter a complete definition of new glycols—including values for conductivity, specific heat, density, and viscosity at various concentrations and temperatures—in order for them to be used in conjunction with this statement.

Field: Glycol <x> Concentration

This field allows the user to specify the actual concentration of glycol being used for this particular fluid. A concentration of 0.0 refers to pure water. A concentration of 1.0 would denote 100% of the fluid referenced in the Glycol Name input discussed above. Users should enter this value as a decimal fraction since EnergyPlus will limit the range of valid input values to between 0.0 and 1.0.

```
FluidProperties:GlycolConcentrations,
  \unique-object
  \memo list of glycols and what concentration they are, maximum of ten

  \memo or UserDefined Fluid (must show up as a glycol in FluidProperties:Names list)
N1, \field Glycol 1 Concentration
  \type real
  \minimum 0.0
  \maximum 1.0
<repeated up to 10 fluid/glycol pairs>
```

An example of this statement in an input data file is:

```
FluidProperties:GlycolConcentrations,
EthGly25Percent, EthyleneGlycol, 0.25,
ProGly40Percent, PropyleneGlycol, 0.40,
HalfAndHalf, NewBrine, 0.5;
```

FluidProperties:Temperatures

It is assumed that all fluid properties vary with temperature. A common set of temperatures is required for each set of fluid property data. Fluid property data supplied by the user must correspondingly be given at these temperatures. Since in most cases, refrigerant data can be specified at a common set of temperatures, a single set of 'FluidPropertyTemperatures' can be referenced by a number of sets of property data. This provides a more compact input structure and avoids listing the temperatures multiple times. In the case of glycol data the same set of temperatures have to be used for each set of data at a given concentration. Units for the temperatures are degrees Celsius.

Field: Name

This field is simply an unique identifier name that is used to cross reference the list of temperatures with a specific list of fluid property data. A single temperature list can be used for more than one thermal property or fluid. For example, the same temperature list can be used for the superheated enthalpy of a refrigerant and the specific heat of a glycol if appropriate.

Field(s) 1-250: Temperature

These fields (up to 250) are the temperatures at which the data for the thermal properties are to be expected. Temperatures are assumed to be in ascending order in units of Celsius.

```

FluidProperties:Temperatures,
  \memo property values for fluid properties
  \memo list of up to 250 temperatures, note that number of property values must match the number of
properties
  \memo in other words, there must be a one-to-one correspondance between the property values in this
list and
  \memo the actual properties list in other syntax
  \memo degrees C (for all temperature inputs)
  \format FluidProperty

  165,170,175,180,185,190,198;

```

FluidProperties:Saturated

Refrigerant property data for the saturated region is entered with the following syntax. For each set of property data a unique name, the type of property, phase and the corresponding list of temperatures have to be specified along with the property values.

Field: Name

This name identifies the fluid for which data follows in the remaining syntax. This fluid name must also be given in the fluid names list (ref: FluidProperties:Names object) as a **Refrigerant**.

Field: Fluid Property Type

This field identifies the fluid property for which data is being entered with this statement. The options for the saturated region are **Enthalpy**, **Density**, **SpecificHeat**, and **Pressure**. The units for these properties are J/kg, kg/m³, J/kg-K and Pa, respectively.

Field: Fluid Phase

In the saturated region, each property has two values: one for the saturated liquid state and one for the saturated gaseous state. Accordingly, the phase for which the saturated property data applies is specified as either **Fluid** or **FluidGas**. Data for each phase are required and are interpolated according to quality. However, in the case of saturated pressure data values for only one phase are required (i.e. can be specified with phase specified as either Fluid or FluidGas, as this is irrelevant).

Field: Temperatures Values Name

This name refers to the corresponding list of temperatures (ref: FluidProperties:Temperatures object). Each temperature in the temperature list corresponds to a data item found in the remaining fields of this syntax. The first temperature in the temperature list corresponds to the first fluid property value, the second temperature in the temperature list corresponds to the second fluid property value, etc.

Field(s) 1-250: Property Value

These fields (up to 250) are the values of the thermal property specified in the fluid property type field for the phase specified in the fluid phase field. The temperature list specified in the temperature list name field links the data with the corresponding temperatures.

```

```

FluidProperties:Superheated

The format of the data for the superheated region is similar to that of the saturated region but with the addition of the pressure for which each set of property values applies. A single temperature specification is required for each set of property data at a number of pressures.

Field: Fluid Name

This name identifies the fluid for which data follows in the remaining syntax. This fluid name must show up in the fluid names list (ref: FluidProperties:Names object) as a **Refrigerant**.

Field: Fluid Property Type

This field identifies the fluid property for which data is being entered with this statement. The options for the superheated region are **Enthalpy** and **Density**. The units for these properties are J/kg and kg/m³, respectively.

Field: Temperatures Values Name

This name refers to the corresponding list of temperatures (ref: FluidProperties:Temperatures object). Each temperature in the temperature list corresponds to a given property data item at each pressure. The first temperature in the temperature list corresponds to the first fluid property value, the second temperature in the temperature list corresponds to the second fluid property value, etc.

Field: Pressure

In the superheated region, each fluid property is indexed according to temperature and pressure. Thus, a pressure must be listed for each set of property values. The units for

pressure are Pascals (Pa). Lists of properties are various pressures and temperatures form a two-dimensional table from which EnergyPlus interpolates to find the property value at a specified temperature and pressure.

Field(s) 1-250: Property Value

These fields (up to 250) are the values of the thermal property specified in the fluid property type field for the phase specified in the fluid phase field. The temperature list specified in the temperature list name field links the data with the corresponding temperatures.

```

```

Glycol Fluid Type

A full data set for a glycol fluid type in EnergyPlus includes: a temperature list and lists of values for specific heat at a given concentration. Data have to be given for at least two different concentrations. The syntax lines for the property value lists are described below.

FluidProperties:Concentration

The format of the data for the glycols is similar to that of superheated refrigerants except that data at a number of concentrations is given, rather than pressures. The concentration is listed before the rest of the data and is normalized (i.e. in the range 0.0 to 1.0, rather than a percentage). Note that glycol solutions are assumed to exist in liquid form only in EnergyPlus.

Field: Fluid Name

This name identifies the fluid for which data follows in the remaining syntax. This fluid name must show up in the fluid names list (ref: FluidProperties:Names object) as a **Glycol..** Note that users should not use Water, EthyleneGlycol, or PropyleneGlycol as names since these are default fluids.

Field: Fluid Property Type

This field identifies the fluid property for which data is being entered with this statement. The required data for glycols includes **SpecificHeat** with units of J/kg-K, **Density** with units of kg/m³, **Conductivity** with units of W/m-K, and **Viscosity** with units of N-s/m².

Field: Temperatures Values Name

This name refers to the corresponding list of temperatures (ref: FluidProperties:Temperatures object). Each temperature in the temperature list corresponds to a data item found in the remaining fields of this syntax. The first temperature in the temperature list corresponds to the first fluid property value, the second temperature in the temperature list corresponds to the second fluid property value, etc.

Field: Concentration

A concentration must be listed for the values of specific heat that follow. Lists of properties are various concentrations and temperatures form a two-dimensional table from which EnergyPlus interpolates to find the property value at a specified temperature and concentration. Concentrations are specified in a normalized form (i.e. in the range 0.0 to 1.0, rather than a percentage)

Field(s) 1-250: Property Value

These fields (up to 250) are the values of the thermal property specified in the fluid property type field for the phase specified in the fluid phase field. The temperature list specified in the temperature list name field links the data with the corresponding temperatures.

HVAC Template Objects

Group – HVAC Templates

This group of objects allows for the specification of simple zone thermostats and HVAC systems with automatically generated node names. The combinations of HVACTemplate objects are shown below.

For a simple ideal loads system to use for sizing and loads oriented simulations:

HVACTemplate:Thermostat
HVACTemplate:Zone:IdealLoadsAirSystem

For packaged terminal air conditioner (PTAC) systems with optional hot water boiler:

HVACTemplate:Thermostat
HVACTemplate:Zone:PTAC
HVACTemplate:Plant:HotWaterLoop (optional)
HVACTemplate:Plant:Boiler (optional)

For packaged terminal air-to-air heat pump (PTHP) systems:

HVACTemplate:Thermostat
HVACTemplate:Zone:PTHP

For direct-expansion cooling, packaged and split system simulations:

HVACTemplate:Thermostat
HVACTemplate:Zone:Unitary
HVACTemplate:System:Unitary

For direct-expansion heat pump systems:

HVACTemplate:Thermostat
HVACTemplate:Zone:Unitary
HVACTemplate:System:UnitaryHeatPump:AirToAir

For packaged variable air volume systems using direct-expansion cooling:

HVACTemplate:Thermostat
HVACTemplate:Zone:VAV
or HVACTemplate:Zone:VAV:FanPowered
HVACTemplate:System:PackagedVAV
HVACTemplate:Plant:HotWaterLoop
HVACTemplate:Plant:Boiler

For variable air volume systems with boilers and air-cooled chillers:

HVACTemplate:Thermostat
HVACTemplate:Zone:VAV
or HVACTemplate:Zone:VAV:FanPowered
HVACTemplate:System:VAV
HVACTemplate:Plant:ChilledWaterLoop
HVACTemplate:Plant:HotWaterLoop
HVACTemplate:Plant:Chiller
HVACTemplate:Plant:Boiler

For variable air volume systems with boilers and water-cooled chillers, an object related to towers is added:

HVACTemplate:Thermostat
HVACTemplate:Zone:VAV
HVACTemplate:System:VAV
or HVACTemplate:Zone:VAV:FanPowered
HVACTemplate:Plant:ChilledWaterLoop
HVACTemplate:Plant:HotWaterLoop
HVACTemplate:Plant:Chiller
HVACTemplate:Plant:Boiler
HVACTemplate:Plant:Tower

For fan coil systems with boilers and chillers:

HVACTemplate:Thermostat
HVACTemplate:Zone:FanCoil
HVACTemplate:Plant:ChilledWaterLoop
HVACTemplate:Plant:HotWaterLoop
HVACTemplate:Plant:Chiller
HVACTemplate:Plant:Boiler
HVACTemplate:Plant:Tower

The only other objects besides the HVACTemplate objects that need to be specified related to HVAC systems are:

- Schedule:Year or Schedule:Compact
- SizingPeriod objects (one for heating and one for cooling) Note: all SizingPeriod objects can be used but for simplicity in the following descriptions, we will only reference SizingPeriod:DesignDay
- SimulationControl
- Sizing:Parameters

This makes the input requirements much smaller but sacrifices some of the flexibility normally found in EnergyPlus.

HVACTemplate Processing

Unlike other EnergyPlus objects, the HVACTemplate objects are not handled by EnergyPlus directly. Instead, they are preprocessed by a program called ExpandObjects. If you use EP-Launch or RunEPlus.bat, this preprocessor step is performed automatically using the following sequence:

- 1)** The preprocessor program, ExpandObjects, reads your IDF file and converts all of the HVACTemplate objects into other EnergyPlus objects.
- 2)** The ExpandObjects program copies the original idf file with the HVACTemplate objects commented out (i.e., inserts a “!” in front of the object name and its input fields) plus all of the new objects created in Step 1 and writes a new file which is saved with the extension “expidf”. This “expidf” file may be used as a standard EnergyPlus IDF file if the extension is changed to idf; however, for safety’s sake, both filename and extension should be changed.
- 3)** The EnergyPlus simulation proceeds using the expidf file as the input stream.
- 4)** If there are error messages from EnergyPlus, they will refer to the contents of the expidf file. Specific objects referred to in error messages may exist in the original idf, but they may be objects created by ExpandObjects and only exist in the expidf. Remember that the expidf will be overwritten everytime the original idf is run using EP-Launch or RunEPlus.bat.

If you are trying to go beyond the capabilities of the HVACTemplate objects, one strategy you can use is to start your specification using the HVACTemplate objects, run EnergyPlus using EP-Launch and producing an expidf file, rename that file and start making modifications. This approach may help with getting all of the objects needed and the node names set consistently.

Users need to remember that no objects related to HVAC except for HVAC template objects are needed in the IDF file. The existence of other objects (unless specifically described in the following sections) may cause unexpected errors to occur. Sizing:Zone, Sizing:System, and Sizing:Plant objects will be generated by the corresponding HVACTemplate objects; the user does not need to create these elsewhere in the input file.

HVACTemplate:Thermostat

Each type of HVAC template zone object may reference one of these HVAC template thermostat objects. Multiple HVAC template zones can reference the same HVAC template thermostat object. The object allows the setpoints to be specified either as a constant for the entire simulation or as schedules. Referenced schedules must be defined elsewhere in the idf. Thermostat control type is dual setpoint with deadband. This object may be omitted and the user may define zone thermostat controls directly using standard EnergyPlus objects (ZoneControl:Thermostat and related objects).

Field: Name

A name used to reference this object. This name is referenced by HVACTemplate:Zone objects: i.e., HVACTemplate:Zone:IdealLoadsAirSystem, HVACTemplate:Zone:FanCoil, HVACTemplate:Zone:Unitary, HVACTemplate:Zone:VAV or HVACTemplate:Zone:VAV:FanPowered objects.

Field: Heating Setpoint Schedule Name

Enter the name of a heating setpoint schedule that has values that change at different times of the day or year. If a constant set point is needed simply leave this field blank and use the next field. The values in the schedule are in degrees C.

Field: Constant Heating Setpoint

Enter the heating setpoint temperature in degrees C if constant throughout the year. If the previous field is used this field should be left blank and will be ignored.

Field: Cooling Setpoint Schedule Name

Enter the name of a cooling setpoint schedule that has values that change at different times of the day or year. If a constant set point is needed simply leave this field blank and use the next field. The values in the schedule are in degrees C.

Field: Constant Cooling Setpoint

Enter the cooling setpoint temperature in degrees C if constant throughout the year. If the previous field is used this field should be left blank and will be ignored.

```

HVACTemplate:Thermostat,
  \min-fields 5
  \memo Zone thermostat control. Referenced schedules must be
  \memo defined elsewhere in the idf. Thermostat control type is
  \memo dual setpoint with deadband. It is not necessary to create
  \memo a thermostat object for every zone, only for each unique
  \memo set of setpoint schedules. For example, an office building
  \memo may have two thermostat objects, one for "Office" and one
  \memo for "Storage".

```

HVACTemplate:Zone:IdealLoadsAirSystem

This object provides an ideal system to supply conditioned air to the zone that meets all the load requirements and consumes no energy. It is often used for load calculations, an evaluation where the load components of the building are all that is being investigated, or as the first step to a more realistic model of a building.

Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple HVACTemplate:Zone:IdealLoadsAirSystem objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

```

All Zones;                !- Thermostat Name

```

HVACTemplate:Zone:FanCoil

This object simulates a 4 pipe fan coil unit with hot water heating coil, chilled water cooling coil, and an outdoor air mixer. The coils are served directly by HVACTemplate:Plant:ChilledWaterLoop and HVACTemplate:Plant:HotWaterLoop objects. No HVACTemplate:System object is required. Reference ZoneHVAC:FourPipeFanCoil for more details about the fan coil model.

Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple COMPACT zone objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay and cooling SizingPeriod:DesignDay. Note that the zone must have a thermostat specified in order to autosize the flow rate. If a value is entered it is used as the maximum supply air flow rate into the zone. The units are in m³/s.

Field: Supply Air Sizing Factor

This input is a zone level sizing ratio. The zone design heating and cooling air flow rates and loads will be multiplied by the number input in this field when Zone Supply Air Max Flow Rate is autosized. If this field is left blank, the building level sizing factor from Sizing:Parameters will be used.

Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, or *Maximum*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means

that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

If the air handler serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system. The amount of outdoor air flow is specified in units of m³/s. The default 0.00944 m³/s is 20 cfm per person

Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all People statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m³/s-m²). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. Fan coil systems are modeled with continuous fan operation, so this is also the supply fan operating schedule.

Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1.

Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20°C at sea level, 101325 Pa.

Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

Field: Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Field: Cooling Coil Type

There are two coil types available:

- ChilledWater
- ChilledWaterDetailedFlatModel

Chilled Water uses the COIL:Cooling:Water object with the DetailedAnalysis option. This is the preferred coil model for most applications. *ChilledWaterDetailedFlatModel* uses the Coil:Cooling:Water:DetailedGeometry object. This option is available for special applications. The default is *ChilledWater*.

Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of one indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

Field: Cooling Coil Design Setpoint

This is the design supply air temperature in C used to size the cooling supply air flow and the cooling coil.

Field: Heating Coil Type

Only one possible value may be entered here:

- HotWater

Future versions may have additional heating coil types.

Field: Heating Coil Availability Schedule Name

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of one indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period.

Field: Heating Coil Design Setpoint

This is the design supply air temperature in C used to size the heating supply air flow and the heating coil.

HVACTemplate:Zone:PTAC

This object simulates a packaged terminal air conditioner (PTAC) with a DX cooling coil, a heating coil (electric, gas, or hot water), and an outdoor air mixer. The optional hot water heating coil is served directly by HVACTemplate:Plant:HotWaterLoop and HVACTemplate:Plant:Boiler objects. No HVACTemplate:System object is required. Reference ZoneHVAC:PackagedTerminalAirConditioner for more details about the PTAC model.

Figure 128. Schematic of a packaged terminal air conditioner with draw through fan placement

Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple COMPACT zone objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

Field: Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the DX cooling coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling SizingPeriod:DesignDay. The units are in m³/s. The default is autosize.

Field: Heating Supply Air Flow Rate

This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay. The units are in m³/s. The default is autosize.

Field: No Load Supply Air Flow Rate

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). This field specifies the supply

air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. The units are in m³/s. The default is autosize.

Field: Supply Air Sizing Factor

This input is a zone level sizing ratio. The zone design heating and cooling air flow rates and loads will be multiplied by the number input in this field when Zone Supply Air Max Flow Rate is autosized. If this field is left blank, the building level sizing factor from Sizing:Parameters will be used.

Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, or *Maximum*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

If the air handler serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system. The amount of outdoor air flow is specified in units of m³/s. The default 0.00944 m³/s is 20 cfm per person

Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all People statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m³/s-m²). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. When the fan operating mode schedule indicates continuous fan operation, the fan will operate whenever this schedule is 1.0. If the fan operating schedule indicates cycling fan operation, then fan will only cycle on as needed to meet a load.

Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. The keywords *Cycling* or *Continuous* may also be used to specify a single mode of operation for the entire simulation. The default is *Cycling*.

Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1. The default is 0.7.

Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20°C at sea level, 101325 Pa. The default is 75.

Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. The default is 0.9.

Field: Cooling Coil Type

Enter the type of cooling coil. There is currently only one choices for this field, SingleSpeedDX.

Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

Field: Cooling Coil Rated Capacity

Enter autosize to let the automatic sizing algorithm determine the cooling coil capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the "gross" capacity where the impact of supply air fan heat is NOT included. The units are in W. The default is autosize.

Field: Cooling Coil Rated Sensible Heat Ratio

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the sensible

capacity divided by total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross” capacity where the impact of supply air fan heat is NOT included. The default is autosize.

Field: Cooling Coil Rated COP

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 3.0.

Field: Heating Coil Type

Enter the type of heating coil. The choices for this field are

- Electric
- HotWater
- Gas

If HotWater is specified, then a HVACTemplate:Plant:HotWaterLoop and a HVACTemplate:Plant:Boiler must be included in the input file to serve this hot water coil. The default is Electric.

Field: Heating Coil Availability Schedule Name

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of 1.0 indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period

Field: Heating Coil Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the coil can deliver in Watts. The default is autosize.

Field: Gas Heating Coil Efficiency

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field applies only if the heating coil type is gas.

Field: Gas Heating Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas heating coil operation, such as a combustion fan. The units are in W. This field applies only if the heating coil type is gas.

HVACTemplate:Zone:PTHP

This object simulates a packaged terminal air-to-air heat pump (PTHP) with a DX cooling coil, a DX air-to-air heat pump heating coil, a supplemental heating coil (electric or gas), and an outdoor air mixer. No HVACTemplate:System object is required. Reference ZoneHVAC:PackagedTerminalHeatPump for more details about the PTHP model.

Figure 129. Schematic of a packaged terminal heat pump (draw through fan placement)

Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple COMPACT zone objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

Field: Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the DX cooling coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling SizingPeriod:DesignDay. The units are in m³/s. The default is autosize.

Field: Heating Supply Air Flow Rate

This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay. The units are in m³/s. The default is autosize.

Field: No Load Supply Air Flow Rate

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be

greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. The units are in m³/s. The default is autosize.

Field: Supply Air Sizing Factor

This input is a zone level sizing ratio. The zone design heating and cooling air flow rates and loads will be multiplied by the number input in this field when Zone Supply Air Max Flow Rate is autosized. If this field is left blank, the building level sizing factor from Sizing:Parameters will be used.

Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, or *Maximum*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

If the air handler serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system. The amount of outdoor air flow is specified in units of m³/s. The default 0.00944 m³/s is 20 cfm per person

Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all People statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m³/s-m²). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. When the fan operating mode

schedule indicates continuous fan operation, the fan will operate whenever this schedule is 1.0. If the fan operating schedule indicates cycling fan operation, then fan will only cycle on as needed to meet a load.

Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. The keywords *Cycling* or *Continuous* may also be used to specify a single mode of operation for the entire simulation. The default is *Cycling*.

Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1. The default is 0.7.

Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 75.

Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. The default is 0.9.

Field: Cooling Coil Type

Enter the type of cooling coil. There is currently only one choices for this field, SingleSpeedDX.

Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

Field: Cooling Coil Rated Capacity

Enter autosize to let the automatic sizing algorithm determine the cooling coil capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the "gross" capacity where the impact of supply air fan heat is NOT included. The units are in W. The default is autosize.

Field: Cooling Coil Rated Sensible Heat Ratio

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the sensible capacity divided by total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross” capacity where the impact of supply air fan heat is NOT included. The default is autosize.

Field: Cooling Coil Rated COP

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 3.0.

Field: Heat Pump Heating Coil Type

Enter the type of heat pump heating coil. There is currently only one choices for this field, SingleSpeedDXHeatPump.

Field: Heat Pump Heating Coil Availability Schedule Name

Usually set to blank, which allows the heat pump heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. A schedule value of 1.0 indicates that the heat pump heating coil can be on during a given time period. A value of zero denotes that the heat pump heating coil cannot be used during that time period.

Field: Heat Pump Heating Coil Rated Capacity

Enter autosize to let the automatic sizing algorithm determine the heat pump heating coil capacity based on the maximum heating loads during the heating design day. If a value is entered, it represents the full load heating capacity, in watts of the DX heat pump unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. Capacity should be the “gross” capacity where the impact of supply air fan heat is NOT included. The units are in W. The default is autosize.

Field: Heat Pump Heating Coil Rated COP

Enter the coefficient of performance defined as the gross heating coil capacity in watts divided by electrical power input in watts of the DX heating coil unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 2.75.

Field: Heat Pump Heating Minimum Outdoor Dry-Bulb Temperature

This numeric field defines the minimum outdoor dry-bulb temperature in degrees Celsius for PTHP compressor operation. The compressor will not operate (for DX heating or DX cooling) when outdoor dry-bulb temperatures fall below this value. The minimum value must be greater than or equal to -20 °C. The default value is -8°C.

Field: Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 C and less than or equal to 7.22 C. If this input field is left blank, the default value is 5 C.

Field: Heat Pump Defrost Strategy

This alpha field has two choices: *ReverseCycle* or *Resistive*. If the *ReverseCycle* strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a *Resistive* defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is *ReverseCycle*.

Field: Heat Pump Defrost Control

This alpha field has two choices: *Timed* or *OnDemand*. If *Timed* control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For *Timed* defrost control, the fractional amount of time the unit is in defrost is entered in the input field "Defrost Time Period Fraction" described below. If *OnDemand* defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field "Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature" described above. If this input field is left blank, the default defrost control is *Timed*.

Field: Heat Pump Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to "timed" defrost (see Heat Pump Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter $3.5/60 = 0.058333$. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

Field: Supplemental Heating Coil Type

Enter the type of supplemental heating coil. The choices for this field are

- Electric
- Gas

The default is Electric.

Field: Supplemental Heating Coil Availability Schedule Name

Usually set to blank, which allows the supplemental heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when supplemental heating is only available seasonally. The schedule values denote whether the supplemental heating coil can run during a given time period. A schedule value of 1.0 indicates that the supplemental heating coil can be on during a given time period. A value of zero denotes that the supplemental heating coil cannot be used during that time period

Field: Supplemental Heating Coil Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the supplemental heating coil can deliver in Watts. The default is autosize.

Field: Supplemental Heating Coil Maximum Outdoor Dry-Bulb Temperature

This numeric field defines the outdoor air dry-bulb temperature above which the supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Supplemental Gas Heating Coil Efficiency

Enter supplemental heating coil gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field applies only if the supplemental heating coil type is gas.

Field: Supplemental Gas Heating Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas supplemental heating coil operation, such as a combustion fan. The units are in W. The default is 0.0. This field applies only if the supplemental heating coil type is gas.

HVACTemplate:Zone:Unitary

This object simulates the zone portion of a constant volume direct-expansion based HVAC configuration with several different heating options. Often a single HVACTemplate:Zone:Unitary object will be used with a single HVACTemplate:System:Unitary object to simulate single zone direct-expansion based air conditioning systems. In addition, multiple HVACTemplate:Zone:Unitary objects may appear that all reference the same HVACTemplate:System:Unitary object in a multiple zone version. For a multizone system, only one zone is specified as the control zone (see HVACTemplate:System:Unitary for more information). Direct expansion includes single packaged rooftop systems commonly seen in commercial applications and split systems commonly seen in residential applications.

Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

Field: Template Unitary System Name

Enter the name of the HVACTemplate:System:Unitary object serving this zone.

Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple HVACTemplate zone objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay and cooling SizingPeriod:DesignDay. Note that the zone must have a thermostat specified in order to autosize the flow rate, even if it is not the control zone in a multiple zone unitary system. If a value is entered it is used as the maximum supply air flow rate into the zone. The HVACTemplate:System:Unitary object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it should be consistent with the sum of the zone values. The units are in m³/s.

Field: Supply Air Sizing Factor

This input is a zone level sizing ratio. The zone design heating and cooling air flow rates and loads will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the building level sizing factor from Sizing:Parameters will be used.

Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, or *Maximum*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

If the air handler serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system. The amount of outdoor air flow is specified in units of m³/s. The default 0.00944 m³/s is 20 cfm per person

Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all People statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m³/s-m²). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

Field: Supply Plenum Name

This field allows the user to specify a supply plenum which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no AirLoopHVAC:SupplyPlenum is to be modeled. If a AirLoopHVAC:SupplyPlenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

Field: Return Plenum Name

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

Field: Baseboard Heating Type

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the unitary air handling system. The baseboard heating will be set to heating priority 2, which means it will meet any remaining heating load not met by the unitary system.

HVACTemplate:Zone:VAV

This object simulates the zone portion of a variable air volume HVAC configuration with several different heating options. Multiple HVACTemplate:Zone:VAV or HVACTemplate:Zone:VAV:FanPowered objects are usually specified for each HVACTemplate:System:VAV object. Reheat is specified at the zone level. Reference SINGLE DUCT:VAV:REHEAT and SINGLE DUCT:VAV:NOREHEAT for more details about VAV terminal units.

Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

Field: Template VAV System Name

Enter the name of the HVACTemplate:System:VAV object serving this zone.

Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple COMPACT zone objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

Field: Supply Air Maximum Flow Rate

By entering Autosize, the maximum supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay and cooling SizingPeriod:DesignDay. If a value is entered it is used as the maximum supply air flow rate into the zone. The HVACTemplate:System:VAV object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it should be consistent with sum of the zone values. The units are in m3/s.

Field: Supply Air Sizing Factor

This input is a zone level sizing ratio. The zone design heating and cooling air flow rates and loads will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the building level sizing factor from Sizing:Parameters will be used.

Field: Supply Air Minimum Flow Fraction

Enter the fraction that the VAV box can reduce to based on the supply air maximum flow rate.

Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, or *Maximum*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

If the air handler serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system. The amount of outdoor air flow is specified in units of m³/s. The default 0.00944 m³/s is 20 cfm per person

Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all People statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m³/s-m²). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

Field: Reheat Coil Type

A reheat coil may be added to the VAV box with this field. The choices are:

- HotWater
- Electric
- None

The default choice is None.

Field: Reheat Coil Availability Schedule Name

Leave this field blank if you want the reheat coil to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the coil is available should be specified as 1.0. Those times that the coil is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the coil is providing heat but a schedule of when it can provide heat.

Field: Damper Heating Action

The VAV box flow rate can be controlled in one of two ways during heating operation:

- Normal
- Reverse

Under “Normal” operation, the supply air flow into the zone is the minimum air flow rate of the VAV system during heating, essentially acting like a constant volume system during heating. Under “Reverse” the air flow rate through the VAV box may increase above the minimum air flow when the heating demand cannot be satisfied unless greater air flow is provided. The default value is Normal.

Field: Supply Plenum Name

This field allows the user to specify a supply plenum which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no AirLoopHVAC:SupplyPlenum is to be modeled. If a AirLoopHVAC:SupplyPlenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

Field: Return Plenum Name

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

Field: Baseboard Heating Type

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the VAV air handling system. The baseboard heating will be set to heating priority 2, which means it will meet any remaining heating load not met by the VAV system.

HVACTemplate:Zone:VAV:FanPowered

This object simulates the zone portion of a variable air volume HVAC configuration with a series or parallel fan powered terminal unit (also know as a powered induction unit or PIU) and several different heating options. Multiple HVACTemplate:Zone:VAV or HVACTemplate:Zone:VAV:FanPowered objects are usually specified for each HVACTemplate:System:VAV object. Reheat is specified at the zone level.

The series powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a fixed flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The fan runs at a constant volume flow rate whenever the unit is on. The fan is downstream of the primary and secondary air inlets. The variable mixing is accomplished by a damper in the unit's primary air supply inlet duct. This damper can move from fully open (100% primary air. 0% secondary air) to a minimum stop that is specified in the input description. At full cooling the damper will be fully open. At minimum cooling and for heating the damper will be at the minimum stop and the secondary air flow will be at its maximum. Reference object AirTerminal:SingleDuct:SeriesPIU:Reheat for more details.

The parallel powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a variable total flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The secondary and primary air streams enter the unit in parallel. The fan sits in the secondary air stream and runs only when secondary air is needed. The primary air inlet contains a damper that can move from fully open (maximum primary air) to a minimum stop (minimum primary air). At full cooling load the primary air damper is fully open and the fan is off. The primary air flow is at maximum and there is little or no secondary air flow. As the cooling load decreases, the primary air damper gradually closes and the secondary air flow remains close to zero. At some point, usually when the primary air flow has reached the minimum, the fan switches on and secondary air is induced. The heating coil will switch on as needed to meet any heating demand. Reference object AirTerminal:SingleDuct:ParallelPIU:Reheat for more details.

Field: Zone Name

Enter the name of the zone. The name must match a building zone name used in the ZONE object.

Field: Template VAV System Name

Enter the name of the HVACTemplate:System:VAV object serving this zone.

Field: Template Thermostat Name

Enter the name of a HVACTemplate:Thermostat object. Multiple HVACTemplate zone objects can reference the same HVACTemplate:Thermostat object which makes it easier to revise the thermostat controls for portions of a building.

When this field is blank, it has a special meaning. A blank entry means that traditional thermostat objects referencing the same zone name are used instead of HVACTemplate:Thermostat.

Field: Primary Supply Air Maximum Flow Rate

In a fan powered VAV terminal unit, the primary air flow is the air supplied by the central air handler. By entering Autosize, the maximum primary supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified and cooling SizingPeriod:DesignDay. If a value is entered it is used as the maximum supply air flow rate into the zone. The HVACTemplate:System:VAV object that is referenced also allows the specification of supply air flow. If the value is specified at the system level it should be consistent with sum of the zone values. The units are in m³/s.

Field: Supply Air Sizing Factor

This input is a zone level sizing ratio. The zone design heating and cooling air flow rates and loads will be multiplied by the number input in this field when Supply Air Maximum Flow Rate is autosized. If this field is left blank, the building level sizing factor from Sizing:Parameters will be used.

Field: Primary Supply Air Minimum Flow Fraction

Enter the fraction that the VAV box can reduce to based on the primary supply air maximum flow rate. This field may be sized automatically by entering Autosize.

Field: Secondary Supply Air Minimum Flow Fraction

In a fan powered VAV terminal unit, the secondary air flow is the air taken from the zone by the terminal unit fan. By entering Autosize, the maximum secondary supply air flow rate is automatically determined for the zone based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay. The units are in m³/s.

Field: Flow Type

This field specifies the type of fan powered unit (PIU). The choices for this field are:

- *Series*
- *Parallel*

See descriptions of these configurations in the general description for this object, above.

Field: Parallel Fan On Flow Fraction

For parallel PIUs, this field specifies the fraction of the primary air flow at which fan turns on. In the parallel PIU the fan operation is intermittent. If the primary air flow is above this fraction of the maximum, the fan is off. Otherwise it is on. This field does not apply to series PIUs.

Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, or *Maximum*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Flow/Area* means the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

If the air handler serves more than one zone, the total outdoor air flow for the system is the sum of the zone outdoor air flows if the system outdoor air flow is autosized. Since the zones share a single outdoor air source, the amount of outdoor air actually delivered to the zone is based on the fraction of supply air delivered to the zone to the total supply air from the system. The amount of outdoor air flow is specified in units of m³/s. The default 0.00944 m³/s is 20 cfm per person

Field: Outdoor Air Flow Rate per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all People statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

Field: Outdoor Air Flow Rate per Zone Floor Area

The design outdoor air volumetric flow rate per square meter of floor area (units are m³/s-m²). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

Field: Outdoor Air Flow Rate per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

Field: Reheat Coil Type

A reheat coil may be added to the VAV box with this field. The choices are:

- *HotWater*
- *Electric*

The default choice is *Electric*.

Field: Reheat Coil Availability Schedule Name

Leave this field blank if you want the reheat coil to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the coil is available should be specified as 1.0. Those times that the coil is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the coil is providing heat but a schedule of when it can provide heat.

Field: Fan Total Efficiency

Enter the total efficiency of the zone induction fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1.

Field: Fan Delta Pressure

Enter the pressure rise of the zone induction fan in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa.

Field: Fan Motor Efficiency

Enter the shaft power of the zone induction fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1. Note that the zone fan motor is assumed to be 100% in the air stream.

Field: Supply Plenum Name

This field allows the user to specify a supply plenum which serves only this zone. The plenum zone is added to the supply air path after the system splitter or system-level supply plenum and before the zone terminal unit. Set to blank if no AirLoopHVAC:SupplyPlenum is to be modeled. If a AirLoopHVAC:SupplyPlenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

Field: Return Plenum Name

This field allows the user to specify a return plenum which serves only this zone. The plenum zone is added to the return air path immediately after the zone and before the system mixer or system-level return plenum. Set to blank if no zone return plenum is to be modeled. If a zone return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here.

Field: Baseboard Heating Type

This field specifies the availability of thermostatically controlled baseboard heat in this zone. The choices are:

- HotWater
- Electric
- None

The default choice is None.

Field: Baseboard Heating Availability Schedule Name

Leave this field blank if you want the baseboard heating to be available for the entire year to perform heating if called for by the thermostat. If a schedule name is specified, those times that the baseboard heating is available should be specified as 1.0. Those times that the baseboard heating is not available should have a zero value in the schedule. Please note that

this is not a schedule of when the baseboard is providing heat but a schedule of when it can provide heat.

Field: Baseboard Heating Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the baseboard heating can deliver in Watts. Note that EnergyPlus autosizing will autosize the baseboard heating to meet the full heating load of the zone, regardless of the heating capability of the VAV air handling system. The baseboard heating will be set to heating priority 2, which means it will meet any remaining heating load not met by the VAV system.

HVACTemplate:System:Unitary

This object simulates the system portion of a constant volume direct-expansion based HVAC configuration with several different heating options. Often a single HVACTemplate:Zone:Unitary object will be used with a single HVACTemplate:System:Unitary object to simulate single zone direct-expansion based air conditioning systems. In addition, multiple HVACTemplate:Zone:Unitary objects may appear that all reference the same HVACTemplate:System:Unitary object in a multiple zone version. For a multizone system, only one zone is specified as the control zone. Direct expansion includes single packaged rooftop systems commonly seen in commercial buildings and split systems commonly seen in residential buildings.

Field: Name

Enter a name for the HVACTemplate:System:Unitary object. This name is used in the HVACTemplate:Zone:Unitary object to reference this system.

Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. If the "Supply Fan Operating Mode" (see below) is set to Cycling, then this is the supply fan operating schedule. If the fan mode is Cycling this is not a schedule of when the system is providing heating, cooling or air flow but a schedule of when it can provide either heating, cooling, or air flow.

Field: Control Zone or Thermostat Location Name

Enter the name of the HVACTemplate:Zone:Unitary object that contains the thermostat. While multiple HVACTemplate:Zone:Unitary objects can be part of a HVACTemplate:System:Unitary system, only one of the zones contains a thermostat that controls heating and cooling operation. For a single zone system, this field should contain the name of that zone.

Field: Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. The units are m³/s.

Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. The keywords *Cycling* or *Continuous* may also be used to, specify a single mode of operation for the entire simulation. The default is *Cycling*.

Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1.

Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20°C at sea level, 101325 Pa.

Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

Field: Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Field: Cooling Coil Type

Enter the type of cooling coil. The choices for this field are:

- None
- SingleSpeedDX

Set this value to "SingleSpeedDX" if you want to simulate a system that provides cooling. You may set this value to "None" if no cooling is desired. The default value is SingleSpeedDX. Future versions may have additional cooling coil types.

Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

Field: Cooling Coil Capacity

Enter autosize to let the automatic sizing algorithm determine the cooling coil capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it

represents the full load cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the “gross” capacity where the impact of supply air fan heat is NOT included. The units are in W.

Field: Cooling Coil Rated Sensible Heat Ratio

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the sensible capacity divided by total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross” capacity where the impact of supply air fan heat is NOT included.

Field: Cooling Coil Rated COP

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan.

Field: Heating Coil Type

Enter the type of heating used in the unitary system. The choices for this field are

- Electric
- Gas

Field: Heating Coil Availability Schedule Name

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of 1.0 indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period

Field: Heating Coil Capacity

Enter autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the coil can deliver in Watts.

Field: Gas Heating Coil Efficiency

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

Field: Gas Heating Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas heating coil operation, such as a combustion fan. The units are in W.

Field: Maximum Outdoor Air Flow Rate

Enter autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. If a value is entered, it is used instead of the autosize value. The units are in m³/s. That is, the entered value is used to define the Maximum Outside Air Flow Rate for the Controller:OutdoorAir object that will be generated by this template.

Field: Minimum Outdoor Air Flow Rate

Enter autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m³/s. Note if heat recovery is specified (see Heat Recovery Type below), then a value must be entered in this field, because heat recovery equipment is not yet autosizable. That is, the entered value is used to define the Minimum Outside Air Flow Rate for the Controller:OutdoorAir object that will be generated by this template.

Field: Minimum Outdoor Air Schedule Name

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours.

Field: Economizer Type

The options for this field are

- 'FixedDryBulb'
- 'DifferentialDryBulb'
- 'FixedEnthalpy'
- 'DifferentialEnthalpy'
- 'ElectronicEnthalpy' (i.e., humidity ratio curve strategy)
- 'FixedDewPointAndDryBulb'
- 'DifferentialDryBulbAndEnthalpy'
- 'NoEconomizer'

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

FixedEnthalpy checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

DifferentialEnthalpy does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit

and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

Field: Economizer Lockout

Enter one of the following choices for this field:

- NoLockout
- LockoutWithHeating
- LockoutWithCompressor

The default value is **NoLockout**. The **LockoutWithHeating** means that if the packaged unit is in heating mode, the economizer is locked out – i.e., the economizer dampers are closed and there is minimum outdoor air flow. **LockoutWithCompressor** means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is on. In other words, when the DX coil is off, the economizer must meet the entire cooling load – it isn't allowed to operate in conjunction with the DX cooling coil. Similarly, when the DX coil is operating, the economizer is not allowed to operate. The **LockoutWithCompressor** option is sometimes called a “nonintegrated” economizer.

Field: Economizer Upper Temperature Limit

Enter the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature high limit control.

Field: Economizer Lower Temperature Limit

Enter the outdoor air temperature low limit (°C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

Field: Economizer Upper Enthalpy Limit

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

Field: Supply Plenum Name

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any AirLoopHVAC:SupplyPlenums have been specified, the outlet from the system supply plenum will flow through the AirLoopHVAC:SupplyPlenum to the zone terminal unit.

Field: Return Plenum Name

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling

and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *BlowThrough*.

Field: Night Cycle Control

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, or *CycleOnControlZone*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. The default is *StayOff*.

Field: Night Cycle Control Zone Name

For the Night Cycle Control option *CycleOnControlZone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

Field: Heat Recovery Type

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- *None*
- *Sensible*
- *Enthalpy*

The default is **None**. If heat recovery is specified (i.e., **Sensible** or **Enthalpy**), then a value must be entered in the Minimum Outdoor Air Flow Rate field, because heat recovery equipment is not yet autosizable. The entered Minimum Outdoor Air Flow Rate is used to define the Nominal Supply Air Flow Rate for the HeatExchanger:AirToAir:SensibleAndLatent object generated by this template.

Field: Sensible Heat Recovery Effectiveness

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

Field: Latent Heat Recovery Effectiveness

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

Field: Dehumidification Control Type

There are three dehumidification control type options available:

- *None*
- *CoolReheatHeatingCoil*
- *CoolReheatDesuperheater*

The *CoolReheatHeatingCoil* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the heating coil. In the simulation, two instances of the heating coil are modeled, one for heating, and one for reheat. The two coil objects represent the same physical coil and never operate simultaneously.

The *CoolReheatDesuperheater* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided by a desuperheater coil (see object Coil:WaterHeating:Desuperheater).

The default is *None* which meets the sensible cooling load only.

Field: Dehumidification Control Zone Name

This field specifies the zone name where the humidistat is located for controlling dehumidification.

Field: Dehumidification Setpoint

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%.

Field: Humidifier Type

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the Humidifier:Steam:Electric object. The default is *None*.

Field: Humidifier Availability Schedule Name

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period

Field: Humidifier Rated Capacity

Enter the rated moisture output rate in m3/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m3/s.

Field: Humidifier Rated Electric Power

Enter the electric power input at the rated capacity moisture output. The humidifier does not currently autosize, so the default power input is consistent with the default capacity input (2690 W per 0.000001 m3/s output) Power consumption is proportional to moisture output with no part-load penalty.

Field: Humidifier Control Zone Name

This field specifies the zone name where the humidistat is located for controlling humidification.

Field: Humidifier Setpoint

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%.

HVACTemplate:System:UnitaryHeatPump:AirToAir

This object simulates the system portion of an air to air direct-expansion unitary heat pump. Often a single HVACTemplate:Zone:Unitary object will be used with a single HVACTemplate:System:UnitaryHeatPump:AirToAir object to simulate single zone direct-expansion based heat pump systems. In addition, multiple HVACTemplate:Zone:Unitary objects may appear that all reference the same HVACTemplate:System:UnitaryHeatPump:AirToAir object in a multiple zone version. For a multizone system, only one zone is specified as the control zone. The model can simulate heat pumps seen in commercial buildings and split systems commonly seen in residential buildings.

Field: Name

Enter a name for the HVACTemplate:System:UnitaryHeatPump:AirToAir object. This name is used in the HVACTemplate:Zone:Unitary object to reference this system.

Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. During times when the system is available, the supply fan operating mode controls fan operation. (See "Supply Fan Operating Mode Schedule Name" below)

Field: Control Zone or Thermostat Location Name

Enter the name of the HVACTemplate:Zone:Unitary object that contains the thermostat. While multiple HVACTemplate:Zone:Unitary objects can be part of a HVACTemplate:System:UnitaryHeatPump:AirToAir system, only one of the zones contains a thermostat that controls heating and cooling operation. For a single zone system, this field should contain the name of that zone.

Field: Cooling Supply Air Flow Rate

This field specifies the supply air flow rate when the DX cooling coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified cooling SizingPeriod:DesignDay. The units are in m3/s. The default is Autosize.

Field: Heating Supply Air Flow Rate

This field specifies the supply air flow rate when the heating coil is operating. By entering Autosize, the supply air flow rate is automatically determined based on the loads experienced by the zone during the specified heating SizingPeriod:DesignDay. The units are in m3/s. The default is Autosize.

Field: No Load Supply Air Flow Rate

This field specifies the supply air flow rate when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation). By entering Autosize, the supply air flow rate will be sized to match the smaller of the Cooling and Heating flow rates. The units are in m³/s. The default is Autosize.

Field: Supply Fan Operating Mode Schedule Name

This field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load. The keywords Cycling or Continuous may also be used to, specify a single mode of operation for the entire simulation. The default is Cycling.

Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the dx cooling/heating coil and before the supplemental heating coil. *BlowThrough* models a system where the supply air fan is before the dx cooling/heating coil and the supplemental heating coil. The default is *BlowThrough*.

Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1. The default is 0.7.

Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20 C at sea level, 101325 Pa. The default is 600 Pa.

Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater or equal to the Supply Fan Total Efficiency and less than or equal to 1. The default is 0.9.

Field: Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

Field: Cooling Coil Type

Enter the type of cooling coil. There is currently only one choices for this field, SingleSpeedDX. Future versions may have additional cooling coil types.

Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of 1.0 indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

Field: Cooling Coil Capacity

Enter Autosize to let the automatic sizing algorithm determine the cooling coil capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the “gross” capacity where the impact of supply air fan heat is NOT included. The units are in W. The default is Autosize.

Field: Cooling Coil Rated Sensible Heat Ratio

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the sensible capacity divided by total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross” capacity where the impact of supply air fan heat is NOT included. The default is Autosize.

Field: Cooling Coil Rated COP

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 3.0.

Field: Heat Pump Heating Coil Type

Enter the type of heat pump heating coil. There is currently only one choice for this field, SingleSpeedDXHeatPump.

Field: Heat Pump Heating Coil Availability Schedule Name

Usually set to blank, which allows the heat pump heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. A schedule value of 1.0 indicates that the heat pump heating coil can be on during a given time period. A value of zero denotes that the heat pump heating coil cannot be used during that time period.

Field: Heat Pump Heating Coil Rated Capacity

Enter Autosize to let the automatic sizing algorithm determine the heat pump heating coil capacity based on the maximum heating loads during the heating design day. If a value is entered, it represents the full load heating capacity, in watts of the DX heat pump unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. Capacity should be the “gross” capacity where the impact of supply air fan heat is NOT included. The units are in W. The default is Autosize.

Field: Heat Pump Heating Coil Rated COP

Enter the coefficient of performance defined as the gross heating coil capacity in watts divided by electrical power input in watts of the DX heating coil unit at rated conditions. Rated conditions are air entering the heat pump heating coil at the heating supply air flow rate at 21.11°C drybulb/15.55°C wetbulb with air entering the outdoor coil at 8.33°C drybulb/6.11C wetbulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 2.75.

Field: Heat Pump Heating Minimum Outdoor Dry-Bulb Temperature

This numeric field defines the minimum outdoor dry-bulb temperature in degrees Celsius for compressor operation. The compressor will not operate (for DX heating or DX cooling) when outdoor dry-bulb temperatures fall below this value. The minimum value must be greater than or equal to -20 °C. The default value is -8°C.

Field: Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 C and less than or equal to 7.22 C. If this input field is left blank, the default value is 5 C.

Field: Heat Pump Defrost Strategy

This alpha field has two choices: *ReverseCycle* or *Resistive*. If the *ReverseCycle* strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a *Resistive* defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is *ReverseCycle*.

Field: Heat Pump Defrost Control

This alpha field has two choices: *Timed* or *OnDemand*. If *Timed* control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For *Timed* defrost control, the fractional amount of time the unit is in defrost is entered in the input field "Defrost Time Period Fraction" described below. If *OnDemand* defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field "Heat Pump Defrost Maximum Outdoor Dry-Bulb Temperature" described above. If this input field is left blank, the default defrost control is *Timed*.

Field: Heat Pump Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to "timed" defrost (see Heat Pump Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter $3.5/60 = 0.058333$. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

Field: Supplemental Heating Coil Type

Enter the type of supplemental heating coil. The choices for this field are

- Electric
- Gas

The default is Electric.

Field: Supplemental Heating Coil Availability Schedule Name

Usually set to blank, which allows the supplemental heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when supplemental heating is only available seasonally. The schedule

values denote whether the supplemental heating coil can run during a given time period. A schedule value of 1.0 indicates that the supplemental heating coil can be on during a given time period. A value of zero denotes that the supplemental heating coil cannot be used during that time period

Field: Supplemental Heating Coil Capacity

Enter Autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the supplemental heating coil can deliver in Watts. The default is Autosize.

Field: Supplemental Heating Coil Maximum Outdoor Dry-Bulb Temperature

This numeric field defines the outdoor air dry-bulb temperature above which the supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Supplemental Gas Heating Coil Efficiency

Enter supplemental heating coil gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default. This field applies only if the supplemental heating coil type is gas.

Field: Supplemental Gas Heating Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas supplemental heating coil operation, such as a combustion fan. The units are in W. The default is 0.0. This field applies only if the supplemental heating coil type is gas.

Field: Maximum Outdoor Air Flow Rate

Enter Autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. The units are in m3/s. That is, the entered value is used to define the Maximum Outside Air Flow Rate for the Controller:OutdoorAir object that will be generated by this template.

Field: Minimum Outdoor Air Flow Rate

Enter Autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m3/s. The default is Autosize. Note if heat recovery is specified (see Heat Recovery Type below), then a value must be entered in this field, because heat recovery equipment is not yet autosizable. That is, the entered value is used to define the Minimum Outside Air Flow Rate for the Controller:OutdoorAir object that will be generated by this template.

Field: Minimum Outdoor Air Schedule Name

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate during unoccupied or start up hours.

Field: Economizer Type

The options for this field are

- 'FixedDryBulb'
- 'DifferentialDryBulb'
- 'FixedEnthalpy'

- 'DifferentialEnthalpy'
- 'ElectronicEnthalpy' (i.e., humidity ratio curve strategy)
- 'FixedDewPointAndDryBulb'
- 'DifferentialDryBulbAndEnthalpy'
- 'NoEconomizer'

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

FixedEnthalpy checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

DifferentialEnthalpy does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**

Field: Economizer Lockout

Enter one of the following choices for this field:

- NoLockout
- LockoutWithHeating
- LockoutWithCompressor

The default value is **NoLockout**. The **LockoutWithHeating** means that if the packaged unit is in heating mode, the economizer is locked out – i.e., the economizer dampers are closed and there is minimum outdoor air flow. **LockoutWithCompressor** means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is on. In other words, when the DX coil is off, the economizer must meet the entire cooling load – it isn't allowed to operate in conjunction with the DX cooling coil. Similarly, when the DX coil is operating, the economizer is not allowed to operate. The **LockoutWithCompressor** option is sometimes called a "nonintegrated" economizer.

Field: Economizer Maximum Limit Dry-Bulb Temperature

Input for this field is the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor airflow rate will be set to the minimum.

This field is required if Economizer Control Type 'FixedDryBulb' or 'FixedDewPointAndDryBulb' has been specified. No input (blank) in this field means that there is no outdoor air temperature high limit control.

Field: Economizer Maximum Limit Enthalpy

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

Field: Economizer Maximum Limit Dewpoint Temperature

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type 'FixedDewPointAndDryBulb' has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

Field: Economizer Minimum Limit Dry-Bulb Temperature

Enter the outdoor air temperature low limit (C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

Field: Supply Plenum Name

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any zone supply plenums have been specified, the outlet from the system supply plenum will flow through the zone supply plenum to the zone terminal unit.

Field: Return Plenum Name

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

Field: Night Cycle Control

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, or *CycleOnControlZone*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. The default is *StayOff*.

Field: Night Cycle Control Zone Name

For the Night Cycle Control option *CycleOnControlZone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

Field: Heat Recovery Type

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- *None*

- *Sensible*
- *Enthalpy*

The default is **None**. If heat recovery is specified (i.e., **Sensible** or **Enthalpy**), then a value must be entered in the Minimum Outdoor Air Flow Rate field, because heat recovery equipment is not yet autosizable. The entered Minimum Outdoor Air Flow Rate is used to define the Nominal Supply Air Flow Rate for the HeatExchanger:AirToAir:SensibleAndLatent object generated by this template.

Field: Sensible Heat Recovery Effectiveness

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

Field: Latent Heat Recovery Effectiveness

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

Field: Humidifier Type

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the Humidifier:Steam:Electric object. The default is *None*.

Field: Humidifier Availability Schedule Name

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period

Field: Humidifier Rated Capacity

Enter the rated moisture output rate in m³/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m³/s.

Field: Humidifier Rated Electric Power

Enter the electric power input at the rated capacity moisture output. The humidifier does not currently autosize, so the default power input is consistent with the default capacity input (2690 W per 0.000001 m³/s output) Power consumption is proportional to moisture output with no part-load penalty.

Field: Humidifier Control Zone Name

This field specifies the zone name where the humidistat is located for controlling humidification.

Field: Humidifier Setpoint

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%.

```

HVACTemplate:System:VAV

This object simulates the system portion of a variable air volume HVAC configuration with several different heating options. Multiple HVACTemplate:Zone:VAV objects are usually specified for each HVACTemplate:System:VAV object.

Field: Name

Enter a name for the HVACTemplate:System:VAV object. This name is used in the HVACTemplate:Zone:VAV object to reference this system.

Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. Please note that for this system type, this is a schedule of when the system is providing air flow.

Field: Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. The units are m³/s.

Field: Supply Fan Minimum Flow Rate

Enter the minimum supply air volume that may be provided. This field may be set to autosize and then the supply fan minimum is determined by the zone minimum air flow requirements. The units are in m³/s.

Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor

efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1.

Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20°C at sea level, 101325 Pa.

Field: Supply Fan Motor efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater than 0 and less than or equal to 1.

Field: Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Field: Cooling Coil Type

There are two coil types available:

- ChilledWater
- ChilledWaterDetailedFlatModel

ChilledWater uses the COIL:Cooling:Water object with the DetailedAnalysis option. This is the preferred coil model for most applications. *ChilledWaterDetailedFlatModel* uses the Coil:Cooling:Water:DetailedGeometry object. This option is available for special applications. The default is *ChilledWater*.

Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of one indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

Field: Cooling Coil Setpoint Schedule Name

If a constant setpoint for the cooling coil is to be specified, leave this field blank, and the Cooling Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the cooling coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the cooling coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Cooling Coil Setpoint Reset Type is something other than None (see below).

Field: Cooling Coil Design Setpoint

Enter the cooling supply air temperature in C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8C. If no Cooling Coil Setpoint Schedule or Cooling Coil Setpoint Reset Type is specified, this value is used as a constant cooling supply air setpoint temperature.

Field: Heating Coil Type

The heating coil is located in the supply air stream, upstream of the cooling coil and after the outdoor air mixing box. If no central heating coil is used in the VAV system, then the option

“none” should be specified here. Otherwise this indicates the type of heating coil. It is unlikely that both a heating coil and a preheat coil would be used at the same time. The choices for this field are

- HotWater
- Electric
- Gas
- None

The default value is None. Note that the configuration of HVACTemplate:System:VAV assumes that there will be reheat coils or baseboard heating to provide heating control at the zone level. If a heating coil is specified, the heating and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other.

Field: Heating Coil Availability Schedule Name

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of one indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period

Field: Heating Coil Setpoint Schedule Name

If a constant setpoint for the heating coil is to be specified, leave this field blank, and the Heating Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the heating coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the heating coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Heating Coil Setpoint Reset Type is something other than None (see below).

Field: Heating Coil Design Setpoint

Enter the heating supply air temperature in C to be used for sizing the heating coil and zone supply air flow rates. If no Heating Coil Setpoint Schedule or Heating Coil Setpoint Reset Type is specified, this value is used as a constant heating supply air setpoint temperature. The default is 10.0C.

Field: Gas Heating Coil Efficiency

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

Field: Gas Heating Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas heating operation, such as a combustion fan. The units are in W.

Field: Preheat Coil Type

The preheat coil is located in the outdoor air stream, upstream of the outdoor air mixing box and tempers the outdoor air. If no preheat coil is used in the VAV system, then the option “none” should be specified here. Otherwise this indicates the type of preheat coil. It is unlikely that both a heating coil and a preheat coil would be used at the same time. The choices for this field are

- Electric
- Gas
- None

The default value is None. If a preheat coil is specified, the preheat and cooling coil setpoint controls and availability schedules must coordinate to prevent the coils from opposing each other.

Field: Preheat Coil Availability Schedule Name

Usually set to blank, which allows the preheat coil to be available anytime the system is operating. If a schedule name is specified, it defines when the preheat coil is available. This is most often used when preheat is only available seasonally. The schedule values denote whether the preheat coil can run during a given time period. A schedule value of 1.0 indicates that the preheat coil can be on during a given time period. A value of zero denotes that the preheat coil cannot be used during that time period

Field: Preheat Coil Setpoint Schedule Name

If a constant setpoint for the preheat coil is to be specified, leave this field blank, and the Preheat Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the preheat coil specify the schedule name here. The schedule should control the leaving air temperature from the preheat coil. The values in the schedule are in degrees C.

Field: Preheat Coil Design Setpoint

Enter the preheat supply air temperature in C to be used for sizing the preheat coil. If no Preheat Coil Setpoint Schedule is specified, this value is used as a constant preheat supply air setpoint temperature. The default is 7.2C.

Field: Gas Preheat Coil Efficiency

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

Field: Gas Preheat Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas heating operation, such as an combustion fan. The units are in W.

Field: Maximum Outdoor Air Flow Rate

Enter autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. If a value is entered, it is used instead of the autosize value. The units are in m³/s. That is, the entered value is used to define the Maximum Outside Air Flow Rate for the Controller:OutdoorAir object that will be generated by this template.

Field: Minimum Outdoor Air Flow Rate

Enter autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m³/s. Note if heat recovery is specified (see Heat Recovery Type below), then a value must be entered in this field, because heat recovery equipment is not yet autosizable. That is, the entered value is used to define the Minimum Outside Air Flow Rate for the Controller:OutdoorAir object that will be generated by this template.

Field: Minimum Outdoor Air Control Type

Choices for this field are **FixedMinimum** or **ProportionalMinimum**. FixedMinimum means that the minimum outdoor air flow rate is fixed no matter what the actual system flow rate is. ProportionalMinimum means the minimum outdoor air flow rate varies in proportion to the total system air flow rate. The default is ProportionalMinimum.

Field: Minimum Outdoor Air Schedule Name Name

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours.

Field: Economizer Type

The options for this field are

- 'FixedDryBulb'
- 'DifferentialDryBulb'
- 'FixedEnthalpy'
- 'DifferentialEnthalpy'
- 'ElectronicEnthalpy' (i.e., humidity ratio curve strategy)
- 'FixedDewPointAndDryBulb'
- 'DifferentialDryBulbAndEnthalpy'
- 'NoEconomizer'

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

FixedEnthalpy checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

DifferentialEnthalpy does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

Field: Economizer Lockout

The only choice for this field is

- NoLockout

The default value is NoLockout. Future versions may have additional options.

Field: Economizer Upper Temperature Limit

Enter the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature high limit control.

Field: Economizer Lower Temperature Limit

Enter the outdoor air temperature low limit (°C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

Field: Economizer Upper Enthalpy Limit

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

Field: Supply Plenum Name

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any AirLoopHVAC:SupplyPlenums have been specified, the outlet from the system supply plenum will flow through the AirLoopHVAC:SupplyPlenum to the zone terminal unit.

Field: Return Plenum Name

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *Draw Through*.

Field: Supply Fan Part-Load Power Coefficients

Select the set of generic pre-defined coefficients to use for the supply fan part-load power consumption. This alpha field has the following choices:

- *InletVaneDampers*
- *OutletDampers*
- *VariableSpeedMotor*
- *ASHRAE90.1-2004Appendix G*

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 130 below. The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table.

Figure 130. VAV Supply Fan Part-Load Power Coefficient Options

Field: Night Cycle Control

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, *CycleOnControl Zone* or *CycleOnAnyZoneFansOnly*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. *CycleOnAnyZoneFansOnly* is the same as *CycleOnAny* except that only the zone fans are cycled on and the central air handler fan is left off (applicable only if using HVACTemplate:Zone:VAV:FanPowered in one or more zones). The default is *StayOff*.

Field: Night Cycle Control Zone Name

For the Night Cycle Control option *Cycle On Control Zone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

Field: Heat Recovery Type

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- *None*
- *Sensible*
- *Enthalpy*

The default is **None**. If heat recovery is specified (i.e., **Sensible** or **Enthalpy**), then a value must be entered in the Minimum Outdoor Air Flow Rate field, because heat recovery equipment is not yet autosizable. The entered Minimum Outdoor Air Flow Rate is used to define the Nominal Supply Air Flow Rate for the HeatExchanger:AirToAir:SensibleAndLatent object generated by this template.

Field: Sensible Heat Recovery Effectiveness

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

Field: Latent Heat Recovery Effectiveness

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

Field: Cooling Coil Setpoint Reset Type

Select the type of automatic reset control for the cooling supply air temperature. The choices are:

- *None* – no reset, use the Cooling Coil Setpoint Schedule or Cooling Coil Design Setpoint.
- *Warmest* – reset the cooling supply air temperature to the highest supply air temperature that will meet the cooling requirements of all the zones. The minimum setpoint allowed is the Cooling Coil Design Setpoint. The maximum setpoint allowed is defaulted to 18C. (Reference SetpointManager:Warmest)
- *OutdoorAirTemperatureReset* – reset the cooling supply air temperature based on the following default rules. When the outdoor dry-bulb temperature (ODB) is at or below 15.6C the setpoint is 18.0C. When the ODB is at or above 26.7C the setpoint is the Cooling Coil Design Setpoint. In between, the setpoint is varied linearly. (Reference SetpointManager:OutdoorAirReset)

The default is *None*.

Field: Heating Coil Setpoint Reset Type

Select the type of automatic reset control for the central heating supply air temperature. The choices are:

- *None* – no reset, use the Heating Coil Setpoint Schedule or Heating Coil Design Setpoint.
- *OutdoorAirTemperatureReset* – reset the heating supply air temperature based on the following default rules. When the outdoor dry-bulb temperature (ODB) is at or below -6.7C the setpoint is the Heating Coil Design Setpoint. When the ODB is at or above 10.0C the setpoint is 20.0C. In between, the setpoint is varied linearly. (Reference SetpointManager:OutdoorAirReset).

The default is *None*.

Field: Dehumidification Control Type

There are two dehumidification control type options available:

- *None*
- *CoolReheat*

The *CoolReheat* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the terminal unit reheat coils if available.

The default is *None* which meets the sensible cooling setpoint only..

Field: Dehumidification Control Zone Name

This field specifies the zone name where the humidistat is located for controlling dehumidification.

Field: Dehumidification Setpoint

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%.

Field: Humidifier Type

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the Humidifier:Steam:Electric object. The default is *None*.

Field: Humidifier Availability Schedule Name

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period

Field: Humidifier Rated Capacity

Enter the rated moisture output rate in m3/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m3/s.

Field: Humidifier Rated Electric Power

Enter the electric power input at the rated capacity moisture output. The humidifier does not currently autosize, so the default power input is consistent with the default capacity input (2690 W per 0.000001 m3/s output) Power consumption is proportional to moisture output with no part-load penalty.

Field: Humidifier Control Zone Name

This field specifies the zone name where the humidistat is located for controlling humidification.

Field: Humidifier Setpoint

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%.

HVACTemplate:System:PackagedVAV

This object simulates the system portion of a packaged direct-expansion based variable air volume HVAC configuration with several different heating options. Multiple HVACTemplate:Zone:VAV objects are usually specified for each HVACTemplate:System:PackagedVAV object.

Field: Name

Enter a name for the HVACTemplate:System:PackagedVAV object. This name is used in the HVACTemplate:Zone:VAV object to reference this system.

Field: System Availability Schedule Name

Leave this field blank if you want the system to be available for the entire year to perform heating or cooling if called for by the thermostat. If a schedule name is specified, those times that the system is available should be specified as 1.0. Those times that the system is not available should have a zero value in the schedule specified. Please note that for this system type, this is a schedule of when the system is providing air flow.

Field: Supply Fan Maximum Flow Rate

Enter Autosize to set the system maximum air-flow rate to the sum of the zone air flow rates. If a value is entered here for the maximum air-flow rate, it is the upper limit on system flow, even if the zone level air flow inputs sum to a greater value. The units are m³/s. The default is Autosize.

Field: Supply Fan Minimum Flow Rate

Enter the minimum supply air volume that may be provided. This field may be set to Autosize and then the supply fan minimum is determined by the zone minimum air flow requirements. The units are in m³/s. The default is Autosize.

Field: Supply Fan Placement

Enter the supply fan placement type. This alpha field has two choices, *DrawThrough* or *BlowThrough*. *DrawThrough* models a system where the supply air fan is after the cooling and heating coils. *BlowThrough* models a system where the supply air fan is before the cooling and heating coils. The default is *DrawThrough*.

Field: Supply Fan Total Efficiency

Enter the total efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow. This is also the product of the fan motor efficiency and fan (impeller) efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is the power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 1. The default is 0.7.

Field: Supply Fan Delta Pressure

Enter the pressure rise in Pa at full flow and standard conditions. Standard conditions are considered 20° C at sea level, 101325 Pa. The default is 1000 Pa.

Field: Supply Fan Motor Efficiency

Enter the shaft power of the supply fan divided by the electrical power consumed. Must be greater or equal to the Supply Fan Total Efficiency and less than or equal to 1. The default is 0.9.

Field: Supply Fan Motor in Air Stream Fraction

Enter the fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat will go into the air stream and act to cause a temperature rise. Must be between 0 and 1. The default is 1.0.

Field: Cooling Coil Type

The coil types available:

- TwoSpeedDX
- TwoSpeedHumidControlDX

TwoSpeedDX uses the Coil:Cooling:DX:TwoSpeed object. This is the preferred coil model for most applications. The *TwoSpeedHumidControlDX* option uses the Coil:Cooling:DX:TwoStageWithHumidityControlMode object.

Field: Cooling Coil Availability Schedule Name

Usually set to blank, which allows the cooling coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when cooling is only available seasonally. A schedule value of one indicates that the cooling coil can be on during a given time period. A value of zero denotes that the cooling coil cannot be used during that time period.

Field: Cooling Coil Setpoint Schedule Name

If a constant setpoint for the cooling coil is to be specified, leave this field blank, and the Cooling Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the cooling coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the cooling coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Cooling Coil Setpoint Reset Type is something other than None (see below). The default is None.

Field: Cooling Coil Design Setpoint

Enter the cooling supply air temperature in degrees C to be used for sizing the cooling coil and zone supply air flow rates. The default is 12.8C. If no Cooling Coil Setpoint Schedule or Cooling Coil Setpoint Reset Type is specified, this value is used as a constant cooling supply air setpoint temperature.

Field: Cooling Coil Capacity

Enter Autosize to let the automatic sizing algorithm determine the cooling coil capacity based on the maximum cooling loads during the cooling design day. If a value is entered, it represents the full load cooling capacity, including both sensible and latent capacity, in watts of the DX coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Capacity should be the "gross" capacity where the impact of supply air fan heat is NOT included. The units are in W. The default is Autosize.

Field: Cooling Coil Rated Sensible Heat Ratio

Enter Autosize to allow the sizing algorithm to determine the sensible heat ratio based on the rated capacity and air flow rate. Otherwise, enter the value of the ratio of the sensible capacity divided by total cooling capacity of the DX cooling coil at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. Both the sensible and total cooling capacities used to define the Rated Sensible Heat Ratio (SHR) should be “gross” capacity where the impact of supply air fan heat is NOT included. The default is Autosize.

Field: Cooling Coil Rated COP

Enter the coefficient of performance defined as the gross cooling coil capacity in watts divided by electrical power input in watts of the DX cooling coil unit at rated conditions. Rated conditions are air entering the cooling coil at the maximum supply air flow rate at 26.7°C drybulb/19.4°C wetbulb with air entering the outdoor condenser coil at 35°C drybulb. The input power includes electric power for the compressor and condenser fan but does not include the power consumption of the supply air fan. The default is 3.0.

Field: Heating Coil Type

Enter the type of heating used in the unitary system. The choices for this field are

- Electric
- Gas
- HotWater

Field: Heating Coil Availability Schedule Name

Usually set to blank, which allows the heating coil to be available anytime the system is operating. If a schedule name is specified, it defines when the coil is available. This is most often used when heating is only available seasonally. The schedule values denote whether the heating coil can run during a given time period. A schedule value of 1.0 indicates that the heating coil can be on during a given time period. A value of zero denotes that the heating coil cannot be used during that time period

Field: Heating Coil Setpoint Schedule Name

If a constant setpoint for the heating coil is to be specified, leave this field blank, and the Heating Coil Design Setpoint value will be used at all times. If a set point schedule is to be used for the heating coil specify the schedule name here. The schedule should control the supply air temperature delivered to the zones. For Blow Through fan placement, this is the leaving air temperature from the heating coil. For Draw Through fan placement, this is the leaving air temperature after the supply fan. The values in the schedule are in degrees C. This field is ignored if the Heating Coil Setpoint Reset Type is something other than None (see below).

Field: Heating Coil Design Setpoint

Enter the heating supply air temperature in degrees C to be used for sizing the heating coil and zone supply air flow rates. If no Heating Coil Setpoint Schedule or Heating Coil Setpoint Reset Type is specified, this value is used as a constant heating supply air setpoint temperature. The default is 10.0C.

Field: Heating Coil Capacity

Enter Autosize to allow the sizing algorithm to determine the proper capacity required based on the loads experienced during the heating design day. If a value is specified, it is the maximum amount of heat that the coil can deliver in Watts.

Field: Gas Heating Coil Efficiency

Enter gas burner efficiency as a decimal, not as a percent. A burner that is 80% efficient would have an entry of 0.8 here, which is the default

Field: Gas Heating Coil Parasitic Electric Load

Enter the parasitic electric load associated with the gas heating coil operation, such as a combustion fan. The units are in W. The default is 0.0 W.

Field: Maximum Outdoor Air Flow Rate

Enter Autosize or a value for the maximum amount of outdoor air flow into the unit when the economizer is operating. Autosize means that 100% of the full supply flow may be taken from outdoor air. If a value is entered, it is used instead of the autosize value. The units are in m³/s. That is, the entered value is used to define the Maximum Outside Air Flow Rate for the Controller:OutdoorAir object that will be generated by this template. The default is Autosize.

Field: Minimum Outdoor Air Flow Rate

Enter Autosize or the value for the minimum amount of outdoor air that can enter the unit and be distributed to the zones. Usually this is set to autosize and the value is calculated by the outdoor air requirements of each zone. If a value is entered it overrides the outdoor air specification from the zone level. The units are in m³/s. The default is Autosize. Note if heat recovery is specified (see Heat Recovery Type below), then a value must be entered in this field, because heat recovery equipment is not yet autosizable. That is, the entered value is used to define the Minimum Outside Air Flow Rate for the Controller:OutdoorAir object that will be generated by this template.

Field: Minimum Outdoor Air Control Type

Choices for this field are **FixedMinimum** or **ProportionalMinimum**. FixedMinimum means that the minimum outdoor air flow rate is fixed no matter what the actual system flow rate is. ProportionalMinimum means the minimum outdoor air flow rate varies in proportion to the total system air flow rate. The default is ProportionalMinimum.

Field: Minimum Outdoor Air Schedule Name

Leave this field blank if you want the minimum outdoor air to be the same for all hours in the entire year. If a schedule name is specified, values are decimal fractions (0.0 – 1.0) that multiply the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours.

Field: Economizer Type

The options for this field are

- 'FixedDryBulb'
- 'DifferentialDryBulb'
- 'FixedEnthalpy'
- 'DifferentialEnthalpy'
- 'ElectronicEnthalpy' (i.e., humidity ratio curve strategy)
- 'FixedDewPointAndDryBulb'
- 'DifferentialDryBulbAndEnthalpy'
- 'NoEconomizer'

Choosing **NoEconomizer** means the economizer will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.

Choosing **FixedDryBulb** means the economizer will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.

Choosing **DifferentialDryBulb** will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.

FixedEnthalpy checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.

DifferentialEnthalpy does the same thing but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.

Choosing **ElectronicEnthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.

Choosing **FixedDewPointAndDryBulb** compares both the outdoor dewpoint temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.

Another option **DifferentialDryBulbAndEnthalpy** enables the control strategy to be based on both the **DifferentialDryBulb** and **DifferentialEnthalpy** economizer control strategies.

In addition to all economizer control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dewpoint limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

The default for this field is **NoEconomizer**.

Field: Economizer Lockout

Enter one of the following choices for this field:

- NoLockout
- LockoutWithHeating
- LockoutWithCompressor

The default value is **NoLockout**. The **LockoutWithHeating** means that if the packaged unit is in heating mode, the economizer is locked out – i.e., the economizer dampers are closed and there is minimum outdoor air flow. **LockoutWithCompressor** means that in addition to locking out the economizer when the unit is in heating mode the economizer is locked out when the DX unit compressor is on. In other words, when the DX coil is off, the economizer must meet the entire cooling load – it isn't allowed to operate in conjunction with the DX cooling coil. Similarly, when the DX coil is operating, the economizer is not allowed to operate. The **LockoutWithCompressor** option is sometimes called a “nonintegrated” economizer.

Field: Economizer Maximum Limit Dry-Bulb Temperature

Input for this field is the outdoor air temperature high limit (°C) for economizer operation. If the outdoor air temperature is above this limit, the outdoor airflow rate will be set to the minimum. This field is required if Economizer Control Type 'FixedDryBulb' or 'FixedDewPointAndDryBulb' has been specified. No input (blank) in this field means that there is no outdoor air temperature high limit control.

Field: Economizer Maximum Limit Enthalpy

Enter the outdoor air upper enthalpy limit (in J/kg) for economizer operation. If the outdoor air enthalpy is above this value, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air enthalpy limit control.

Field: Economizer Maximum Limit Dewpoint Temperature

Input for this field is the outdoor air dewpoint limit (°C) for economizer operation. If the outdoor air dewpoint temperature is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economizer Control Type 'FixedDewPointAndDryBulb' has been specified. No input (blank) in this field means that there is no outdoor air dewpoint limit control.

Field: Economizer Minimum Limit Dry-Bulb Temperature

Enter the outdoor air temperature low limit (C) for economizer operation. If the outdoor air temperature is below this limit, the outdoor air flow rate will be set to the minimum and heat recovery will be enabled if available. No input or zero in this field means that there is no outdoor air temperature low limit control.

Field: Supply Plenum Name

Set to blank if no supply plenum is to be modeled. If a supply plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This supply plenum serves all zones on this system. If any zone supply plenums have been specified, the outlet from the system supply plenum will flow through the zone supply plenum to the zone terminal unit.

Field: Return Plenum Name

Set to blank if no return plenum is to be modeled. If a return plenum is modeled, it must be modeled as a zone with surfaces, and the name of the plenum zone should be entered here. This return plenum serves all zones on this system. If any zone return plenums have been specified, the return air from the zone will flow through the zone return plenum and then into the system return plenum.

Field: Supply Fan Part-Load Power Coefficients

Select the set of generic pre-defined coefficients to use for the supply fan part-load power consumption. This alpha field has the following choices:

- *InletVaneDampers*
- *OutletDampers*
- *VariableSpeedMotor*
- *ASHRAE90.1-2004Appendix G*

The default is *InletVaneDampers*. The resulting power curves are shown in Figure 130 below. The ASHRAE 90.1-2004 Appendix G coefficients are from TABLE G3.1.3.15, Method 2. The other sets of coefficients are from the EnergyPlus Input Output Reference, Fan Coefficient Values table.

Figure 131. VAV Supply Fan Part-Load Power Coefficient Options

Field: Night Cycle Control

Enter the system behavior during times when the System Availability Schedule is zero (off). The possible inputs are *StayOff*, *CycleOnAny*, *CycleOnControl Zone* or *CycleOnAnyZoneFansOnly*. *StayOff* means the system will remain off, no matter how hot or cold the zones may be. *CycleOnAny* means that if any zone served by this system has an air temperature outside the cooling or heating set points the central fan will turn on even though the System Availability Schedule indicates the fan is off. *CycleOnControlZone* means the same thing except the availability manager looks at the temperature in only the zone specified in Night Cycle Control Zone Name. *CycleOnAnyZoneFansOnly* is the same as *CycleOnAny* except that only the zone fans are cycled on and the central air handler fan is left off (applicable only if using HVACTemplate:Zone:VAV:FanPowered in one or more zones). The default is *StayOff*.

Field: Night Cycle Control Zone Name

For the Night Cycle Control option *Cycle On Control Zone* enter the name of the control zone. For other Night Cycle Control options, this field is ignored.

Field: Heat Recovery Type

Enter the type of air-to-air heat recovery which is available between the relief air stream and the outdoor air inlet stream. The choices are:

- *None*
- *Sensible*
- *Enthalpy*

The default is **None**. If heat recovery is specified (i.e., **Sensible** or **Enthalpy**), then a value must be entered in the Minimum Outdoor Air Flow Rate field, because heat recovery equipment is not yet autosizable. The entered Minimum Outdoor Air Flow Rate is used to define the Nominal Supply Air Flow Rate for the HeatExchanger:AirToAir:SensibleAndLatent object generated by this template.

Field: Sensible Heat Recovery Effectiveness

Enter the sensible heat recovery effectiveness. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.70.

Field: Latent Heat Recovery Effectiveness

Enter the latent heat recovery effectiveness if Heat Recovery Type is *Enthalpy*. This is applied as a constant effectiveness at all conditions. The valid range is from 0.0 to 1.0, and the default is 0.65.

Field: Cooling Coil Setpoint Reset Type

Select the type of automatic reset control for the cooling supply air temperature. The choices are:

- *None* – no reset, use the Cooling Coil Setpoint Schedule or Cooling Coil Design Setpoint.
- *Warmest* – reset the cooling supply air temperature to the highest supply air temperature that will meet the cooling requirements of all the zones. The minimum setpoint allowed is the Cooling Coil Design Setpoint. The maximum setpoint allowed is defaulted to 18C. (Reference SetpointManager:Warmest)
- *OutdoorAirTemperatureReset* – reset the cooling supply air temperature based on the following default rules. When the outdoor dry-bulb temperature (ODB) is at or below 15.6C the setpoint is 18.0C. When the ODB is at or above 26.7C the setpoint is the Cooling Coil Design Setpoint. In between, the setpoint is varied linearly. (Reference SetpointManager:OutdoorAirReset)

The default is *None*.

Field: Heating Coil Setpoint Reset Type

Select the type of automatic reset control for the central heating supply air temperature. The choices are:

- *None* – no reset, use the Heating Coil Setpoint Schedule or Heating Coil Design Setpoint.
- *OutdoorAirTemperatureReset* – reset the heating supply air temperature based on the following default rules. When the outdoor dry-bulb temperature (ODB) is at or below -6.7C the setpoint is the Heating Coil Design Setpoint. When the ODB is at or above 10.0C the setpoint is 20.0C. In between, the setpoint is varied linearly. (Reference SetpointManager:OutdoorAirReset).

The default is *None*.

Field: Dehumidification Control Type

There are two dehumidification control type options available:

- *None*
- *CoolReheat*

The *CoolReheat* option cools beyond the dry-bulb setpoint as required to meet the humidity setpoint if the system is capable of doing so. Reheat is provided as required by the terminal unit reheat coils if available.

The default is *None* which meets the sensible cooling setpoint only.

Field: Dehumidification Control Zone Name

This field specifies the zone name where the humidistat is located for controlling dehumidification.

Field: Dehumidification Setpoint

This field specifies the zone humidistat setpoint for dehumidification in percent (0 to 100). The default is 60%.

Field: Humidifier Type

There are two humidifier type options available:

- None
- ElectricSteam

The *ElectricSteam* humidifier option uses the Humidifier:Steam:Electric object. The default is *None*.

Field: Humidifier Availability Schedule Name

If left blank, the humidifier will be available anytime the system is operating. If a schedule name is specified, it defines when the humidifier is available. The schedule values denote whether the humidifier can run during a given time period. A schedule value of 1.0 indicates that the humidifier can be on during a given time period. A value of zero denotes that the humidifier cannot be used during that time period

Field: Humidifier Rated Capacity

Enter the rated moisture output rate in m3/s. The humidifier does not currently autosize, so the default is very large to allow for adequate capacity. The default is 0.000001 m3/s.

Field: Humidifier Rated Electric Power

Enter the electric power input at the rated capacity moisture output. The humidifier does not currently autosize, so the default power input is consistent with the default capacity input (2690 W per 0.000001 m3/s output) Power consumption is proportional to moisture output with no part-load penalty.

Field: Humidifier Control Zone Name

This field specifies the zone name where the humidistat is located for controlling humidification.

Field: Humidifier Setpoint

This field specifies the zone humidistat setpoint for humidification in percent (0 to 100). The default is 30%.

HVACTemplate:Plant:ChilledWaterLoop

The piping systems that connect the chilled water coils in the HVAC template objects with the chillers and the cooling towers (if present) are described with this object. The piping systems

are called loops and this object describes the controls and pumps on the loops. Only one of these objects may be defined in an input file and all chilled water coils from HVAC template objects are served with this object.

Field: Name

The name used to designate the HVACTemplate:Plant:ChilledWaterLoop.

Field: Pump Schedule Name

Leave this field blank if the chilled water and condenser water pumps are always available. If a schedule name is specified, those times that the pumps are available should be specified as 1.0. Those times that the pumps are not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the system is providing chilled water to the coils but a schedule of when it can provide chilled water to the coils.

Field: Pump Control Type

Applies to both chilled water and condenser loop pumps. The choices for this field are:

- Intermittent
- Continuous

The default value is Intermittent.

If the pump control type is **Continuous**, the pump will run according to the Pump Schedule (see above) regardless of whether or not there is a load. If the pump control type is **Intermittent**, the pump will run if a load is sensed and will shut off if there is no load on the loop.

Field: Chiller Plant Operation Scheme Type

The choices for this field are:

- Default
- UserDefined

Default operation type makes all equipment available at all times operating in order of Priority specified in HVACTemplate:Plant:Chiller objects. If a different scheme is to be used to sequence the chillers, then this entry should be set to User Defined. If the User Defined option is chosen, then additional EnergyPlus objects must be included and completely defined in the IDF file such as shown below depending on the type of plant operation control scheme chosen:

- PlantEquipmentOperationSchemes
- PlantEquipmentOperation:CoolingLoad
- PlantEquipmentList (refer to HVACTemplate:Plant:Chiller object description for chiller key name required in this object).

The default value is Default.

Field: Chiller Plant Equipment Operation Schemes Name

This field should contain the name of a PlantEquipmentOperationSchemes object only when the previous field is set to UserDefined. It is ignored if Chiller Plant Operation Scheme Type is Default.

Field: Chilled Water Setpoint Schedule Name

Enter the name of a chilled water setpoint schedule that has values that change at different times of the year. If a constant set point is needed simply leave this field blank and the value in the next field will be used at all times. The values in the schedule are in degrees C. This field is ignored if the Chilled Water Setpoint Reset Type is something other than None.

Field: Chilled Water Design Setpoint

Enter the chilled water setpoint temperature to be used for sizing the chilled water loop and associated equipment in degrees C. If the Chilled Water Setpoint Schedule is blank and the Chilled Water Setpoint Reset Type is *None*, then this value will be used as the setpoint at all times.

Field: Chilled Water Pump Configuration

The choices for this field are

- VariablePrimaryNoSecondary – variable flow to chillers and coils
- ConstantPrimaryNoSecondary – constant flow to chillers and coils with bypass
- ConstantPrimaryVariableSecondary – constant flow to chillers with bypass, variable flow to coils
- VariablePrimaryConstantSecondary – variable flow to chillers, constant flow to coils with bypass

The default value is ConstantPrimaryNoSecondary.

The operation of a constant speed pump is fairly straightforward. If the user designates a constant speed pump that is operating continuously, the pump will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump is constant speed and operates intermittently, the pump will run at its capacity if a load is sensed and will shut off if there is no load on the loop.

A variable speed pump is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump is operating intermittently, then the pump can shutdown. For any other condition such as the loop having a load and the pump is operating intermittently or the pump is continuously operating (regardless of the loading condition), the pump will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump is running, it will try to meet the flow request made by demand side components.

Field: Primary Chilled Water Pump Rated Head

The rated head of the primary chilled water pump in Pa. The default value is 179352 Pa which is equivalent to 60 feet H₂O.

Field: Secondary Chilled Water Pump Rated Head

The rated head of the secondary chilled water pump in Pa. The default value is 179352 Pa which is equivalent to 60 feet H₂O. This field is applicable only if the “Chilled Water Pump Configuration” is *Constant Primary Variable Secondary* or *Variable Primary Constant Secondary*.

Field: Condenser Plant Operation Scheme Type

The choices for this field are:

- Default
- UserDefined

Default operation type makes all equipment available at all times operating in order of Priority specified in HVACTemplate:Plant:Tower objects. If a different scheme is to be used to sequence the towers, then this entry should be set to User Defined. May be left blank if not serving any water cooled chillers.

If User Defined option is chosen, then additional EnergyPlus objects must be included and completely defined in the IDF file such as shown below depending on the type of condenser operation control scheme chosen:

- CondenserEquipmentOperationSchemes
- PlantEquipmentOperation:CoolingLoad

- PlantEquipmentList (refer to the HVACTemplate:Plant:Tower object description for key name required for this object).

The default value is Default.

Field: Condenser Equipment Operation Schemes Name

This field should contain the name of a CondenserEquipmentOperationSchemes object only when the previous field is set to UserDefined. It is ignored if Condenser Plant Operation Scheme Type is Default. May be left blank if not serving any water cooled chillers.

Field: Condenser Water Temperature Control Type

If water cooled chillers are present the condenser water temperature control can be one of the following options:

- OutdoorWetBulbTemperature
- SpecifiedSetpoint

If a specified set point is used then the towers are operated to deliver that condenser water set point. If outdoor wet-bulb is used then the condenser water temperature decreases with decreasing outdoor wet-bulb temperature. May be left blank if not serving any water cooled chillers.

Field: Condenser Water Setpoint Schedule Name

Used when Condenser Water Temperature Control Type is set to Specified Setpoint. Ignored if Condenser Water Temperature Control Type is set to Outdoor Wet-bulb. The field may be left blank if constant setpoint temperature is used for the condenser water temperature. If may also be left blank if not serving any water cooled chillers. If specified, the schedule should contain the set point temperatures in degrees C for the condenser water loop.

Field: Condenser Water Design Setpoint

Enter the condenser water temperature to be used for sizing the condenser loop and associated equipment. If a constant setpoint control is used for the condenser water, this value will be used as the setpoint at all times. May be left blank if not serving any water cooled chillers. Used when Condenser Water Temperature Control Type is set to Specified Setpoint. Ignored if Condenser Water Temperature Control Type is set to Outdoor Wet Bulb. The units are in C.

Field: Condenser Water Pump Rated Head

The rated head of the condenser water pumps in Pa. May be left blank if not serving any water cooled chillers. The default value is 179352 Pa which is equivalent to 60 feet H₂O.

Field: Chilled Water Setpoint Reset Type

Select the type of automatic reset control for the chilled water supply temperature. The choices are:

- *None* – no reset, use the Chilled Water Setpoint Schedule or Chilled Water Design Setpoint.
- *OutdoorAirTemperatureReset* – reset the chilled water supply temperature based on the following default rules. The temperature limits and setpoints are specified using the fields below. If the default values are used, when the outdoor dry-bulb temperature (ODB) is at or below 15.6C the setpoint is 12.2C. When the ODB is at or above 26.7C the setpoint is 6.7C. In between, the setpoint is varied linearly. (Reference SetpointManager:OutdoorAirReset)

The default is *None*.

Field: Chilled Water Setpoint at Outdoor Dry-Bulb Low

The chilled water setpoint temperature in C when the outdoor dry-bulb is at or below the low limit (Chilled Water Reset Outdoor Dry Bulb Low). The default is 12.2C.

Field: Chilled Water Reset Outdoor Dry-Bulb Low

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Chilled Water Setpoint at Outdoor Dry Bulb Low. The default is 15.6C.

Field: Chilled Water Setpoint at Outdoor Dry-Bulb High

The chilled water setpoint temperature in C when the outdoor dry-bulb is at or above the high limit (Chilled Water Reset Outdoor Dry Bulb Low). The default is 6.7C.

Field: Chilled Water Reset Outdoor Dry-Bulb High

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Chilled Water Setpoint at Outdoor Dry Bulb High. The default is 26.7C.

HVACTemplate:Plant:Chiller

A chiller or purchased cooling source is described with this object. To define multiple chillers, use multiple HVACTemplate:Plant:Chiller objects. If multiple chillers are autosized, each chiller will be sized to meet the full design cooling load. Run the simulation once and locate the autosized capacity for one chiller in the eio output file. This value represents the total required chiller capacity. Copy the expidf output to a new idf file name. Edit this input file, and enter values for the capacity and flow rates of each chiller object to apportion this total capacity between the multiple chillers.

Field: Name

The name used to reference the HVACTemplate:Plant:Chiller object.

Field: Chiller Type

While EnergyPlus has a variety of chiller options, the only choices currently for this field are:

- DistrictChilledWater
- ElectricCentrifugalChiller
- ElectricReciprocatingChiller

The EnergyPlus equipment object types which are used are DistrictCooling or Chiller:Electric:EIR. These equipment type keys must be used if setting up a user-defined chiller plant operation scheme.

Field: Capacity

This field may be set to autosize, which means that the capacity is based on the peak loads during the design days. This numeric field contains the design cooling capacity of the chiller. This capacity should be at the design temperatures and water flow rates. The units are in W.

Field: Nominal COP

This numeric field contains the chiller's coefficient of performance. This value should **not** include energy use due to pumps, evap-cooled or air-cooled condenser fans, or cooling tower fans. This Nominal COP should be at the design temperatures and water flow rates. Not applicable if Chiller Type is DistrictChilledWater.

Field: Condenser Type

The choices for this field are

- AirCooled
- WaterCooled
- EvaporativelyCooled

The default value is WaterCooled. If WaterCooled, then at least one HVACTemplate:Plant:Tower object should be defined. Not applicable if Chiller Type is Purchased Chilled Water.

Field: Priority

Enter the priority number of the chiller where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Chiller Plant Operation Scheme Type is set to Default in HVACTemplate:Plant:ChilledWaterLoop. Equipment is operated in order of the priority number. This allows multiple chillers to be sequenced.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the chiller object inputs that would be altered by the sizing factor are: Reference Capacity, Reference Chilled Water Flow Rate and Reference Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

```

HVACTemplate:Plant:Tower

A cooling tower is described with this object. To define multiple cooling towers, use multiple HVACTemplate:Plant:Tower objects. If multiple towers are autosized, each tower will be sized to meet the full design heat rejection load. Run the simulation once and locate the autosized capacities for one tower in the eio output file. These values represent the total required tower capacity. Copy the expidf output to a new idf file name. Edit this input file and enter values for the capacity and flow rates of each tower object to apportion this total capacity between the multiple towers.

Field: Name

The name used to reference the HVACTemplate:Plant:Tower object.

Field: Tower Type

The choices for this field are

- SingleSpeed
- TwoSpeed

The EnergyPlus equipment object types which are used are CoolingTower:SingleSpeed or CoolingTower:TwoSpeed. These equipment type keys must be used if setting up a user-defined condenser plant operation scheme.

Field: High-Speed Nominal Capacity

Applicable for Tower Type Single Speed and Two Speed. This field may be set to autosize. If this field is set to autosize, then the Low-Speed Nominal Capacity and the Free Convection Capacity must also be autosized. The units are W. This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under high-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be 5.382E-8 m³/s per watt of high-speed nominal capacity (3 gpm/ton). 125% of this nominal tower capacity gives the actual tower heat rejection at these operating conditions

(based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator).

Field: High-Speed Fan Power

The tower fan electric consumption when at high speed. Applicable for Tower Type Single Speed and Two Speed. This field may be set to autosize. The units are W.

Field: Low-Speed Nominal Capacity

Applicable only for Tower Type Two Speed. This field may be set to autosize. If this field is set to autosize, then the High-Speed Nominal Capacity and the Free Convection Capacity must also be autosized. The units are W. This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under low-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be $5.382E-8 \text{ m}^3/\text{s}$ per watt of high-speed nominal tower capacity (input field above). 125% of this nominal tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). The value specified for this field must be greater than zero but less than the value specified for the field “Tower High-Speed Nominal Capacity”.

Field: Low-Speed Fan Power

The tower fan electric consumption when at low speed. Applicable only for Tower Type Two Speed. This field may be set to autosize. The units are W.

Field: Free Convection Capacity

Applicable for Tower Type Single Speed and Two Speed. This field may be set to autosize. If this field is set to autosize, then the High-Speed Nominal Capacity and the Low-Speed Nominal Capacity must also be autosized. The units are W. This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts when the tower is in the “free convection” regime (water flow exists but tower fan is turned off), with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be $5.382E-8 \text{ m}^3/\text{s}$ per watt of high-speed nominal tower capacity (input field above). 125% of this free convection tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). If the user does not wish to model “free convection”, then this field should be set to 0.0.

Field: Priority

Enter the priority number of the tower where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Condenser Plant Operation Scheme Type is set to Default in HVACTemplate:Plant:ChilledWaterLoop. Equipment is operated in order of the priority number. This allows multiple towers to be sequenced.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the tower object inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Air Flow Rate at High Fan Speed;
3. Fan Power at High Fan Speed;
4. U-Factor Times Area Value at High Fan Speed;

5. Air Flow Rate at Low Fan Speed (for two-speed tower);
6. Fan Power at Low Fan Speed (for two-speed tower);
7. U-Factor Times Area Value at Low Fan Speed (for two-speed tower);
8. Air Flow Rate in Free Convection Regime;
9. U-Factor Times Area Value at Free Convection Air Flow Rate.

Note that the U-Factor Times Area Value at High Fan Speed is not *multiplied* by the Sizing Factor. Instead the design tower load is multiplied by the sizing factor and the design UA then calculated as usual. The U-Factor Times Area Value at Low Fan Speed is set to 60% of the full load design UA. The U-Factor Times Area Value at Free Convection Air Flow Rate is set to 10% of the design Tower UA.

HVACTemplate:Plant:HotWaterLoop

The piping systems that connect the hot water coils in the HVAC template objects with the boilers are described with this object. The piping systems are called loops and this object describes the controls and pumps on the loops. Only one of these objects should be defined in an input file and all hot water coils from HVAC template objects are served with this object.

Field: Name

The name used to designate the HVACTemplate:Plant:HotWaterLoop.

Field: Pump Schedule Name

Leave this field blank if the hot water pump is always available. If a schedule name is specified, those times that the pump is available should be specified as 1.0. Those times that the pump is not available should have a zero value in the schedule specified. Please note that this is not a schedule of when the system is providing hot water to the coils but a schedule of when it can provide hot water to the coils.

Field: Pump Control Type

The choices for this field are

- Intermittent
- Continuous

The default value is Intermittent.

If the pump control type is **Continuous**, the pump will run according to the Pump Schedule (see above) regardless of whether or not there is a load. If the pump control type is **Intermittent**, the pump will run if a load is sensed and will shut off if there is no load on the loop.

Field: Hot Water Plant Operation Scheme Type

The choices for this field are:

- Default
- UserDefined

Default operation type makes all equipment available at all times operating in order of Priority specified in HVACTemplate:Plant:Boiler objects. If a different scheme is to be used to sequence the boilers, then this entry should be set to User Defined.

If User Defined option is chosen, then additional EnergyPlus objects must be defined in the IDF file such as shown below depending on the type of plant operation control scheme chosen:

- PlantEquipmentOperationSchemes
- PlantEquipmentOperation:HeatingLoad
- PlantEquipmentList (refer to HVACTemplate:Plant:Boiler object description for key name required in this object)

The default value is Default.

Field: Hot Water Plant Equipment Operation Schemes Name

This field should contain the name of a PlantEquipmentOperationSchemes object only when the previous field is set to User Defined. It is ignored if Hot Water Plant Operation Scheme Type is Default.

Field: Hot Water Setpoint Schedule Name

Enter the name of a hot water setpoint schedule that has values that change at different times of the year. If a constant set point is needed simply leave this field blank and the value in the next field will be used at all times. The values in the schedule are in degrees C. This field is ignored if the Hot Water Setpoint Reset Type is something other than None.

Field: Hot Water Design Setpoint

Enter the hot water setpoint temperature to be used for sizing the hot water loop and associated equipment in degrees C. If the Hot Water Setpoint Schedule is blank and the Hot Water Setpoint Reset Type is *None*, then this value will be used as the setpoint at all times.

Field: Hot Water Pump Configuration

The choices for this field are

- VariableFlow
- ConstantFlow

The default value is ConstantFlow. The variable flow option simulates a pump with variable flow to boilers and coils, excess bypassed. The constant flow option simulates constant flow to boilers and coils, excess bypassed.

The operation of a constant speed pump is fairly straightforward. If the user designates a constant speed pump that is operating continuously, the pump will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump is constant speed and operates intermittently, the pump will run at its capacity if a load is sensed and will shut off if there is no load on the loop.

A variable speed pump is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump is operating intermittently, then the pump can shutdown. For any other condition such as the loop having a load and the pump is operating intermittently or the pump is continuously operating (regardless of the loading condition), the pump will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump is running, it will try to meet the flow request made by demand side components.

Field: Hot Water Pump Rated Head

The rated head of the hot water pump in Pa. The default value is 179352 Pa which is equivalent to 60 feet H2O.

Field: Hot Water Setpoint Reset Type

Select the type of automatic reset control for the Hot Water supply temperature. The choices are:

- *None* – no reset, use the Hot Water Setpoint Schedule or Hot Water Design Setpoint.
- *OutdoorAirTemperatureReset* – reset the Hot Water supply temperature based on the following default rules. The temperature limits and setpoints are specified using the fields below. If the default values are used, when the outdoor dry-bulb temperature (ODB) is at or below –6.7C the setpoint is 82.2C. When the ODB is at or above 10.0C the setpoint is 65.6C. In between, the setpoint is varied linearly. (Reference SetpointManager:OutdoorAirReset)

The default is *None*.

Field: Hot Water Setpoint at Outdoor Dry Bulb Low

The Hot Water setpoint temperature in C when the outdoor dry-bulb is at or below the low limit (Hot Water Reset Outdoor Dry Bulb Low). The default is –6.7C.

Field: Hot Water Reset Outdoor Dry Bulb Low

The low limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or below this temperature, the setpoint is the value of Hot Water Setpoint at Outdoor Dry Bulb Low. The default is 82.2C.

Field: Hot Water Setpoint at Outdoor Dry Bulb High

The Hot Water setpoint temperature in C when the outdoor dry-bulb is at or above the high limit (Hot Water Reset Outdoor Dry Bulb Low). The default is 10.0C.

Field: Hot Water Reset Outdoor Dry Bulb High

The high limit of outdoor dry-bulb temperature in C for outdoor air reset control. When the outdoor dry-bulb is at or above this temperature, the setpoint is the value of Hot Water Setpoint at Outdoor Dry Bulb High. The default is 65.6C.

HVACTemplate:Plant:Boiler

A boiler or purchased heating source is described with this object. To define multiple boilers, use multiple HVACTemplate:Plant:Boiler objects. If multiple boilers are autosized, each boiler

will be sized to meet the full design heating load. Run the simulation once and locate the autosized capacity for one boiler in the eio output file. This value represents the total required boiler capacity. Copy the expidf output to a new idf file name. Edit this input file and enter values for the capacity and flow rates of each boiler object to apportion this total capacity between the multiple boilers.

Field: Name

The name used to reference the HVACTemplate:Plant:Boiler object.

Field: Boiler Type

While EnergyPlus has a variety of boiler options, the only choices currently for this field are:

- DistrictHotWater
- HotWaterBoiler

The EnergyPlus equipment object types which are used are DistrictHeating or Boiler:HotWater. These equipment type keys must be used if setting up a user-defined chiller plant operation scheme.

Field: Capacity

This field may be set to autosize, which means that the capacity is based on the peak loads during the design days. This numeric field contains the design heating capacity of the boiler. This capacity should be at the design water flow rates. The units are in W.

Field: Efficiency

This numeric field contains the heating efficiency (as a fraction between 0 and 1) of the boiler's burner. Not applicable if Boiler Type is DistrictHotWater.

Field: Fuel Type

The choices for this field are

- Electricity
- NaturalGas
- PropaneGas
- FuelOil#1
- FuelOil#2
- Coal
- Diesel
- Gasoline

Not applicable if Boiler Type is DistrictHotWater

Field: Priority

Enter the priority number of the boiler where 1 is the highest priority, 2 is just lower, 3 is lower than 2, etc. This is used if Boiler Plant Operation Scheme Type is set to Default in HVACTemplate:Plant:HotWaterLoop. Equipment is operated in order of the priority number. This allows multiple boilers to be sequenced.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the boiler object inputs that would be altered by the sizing factor are: Nominal Capacity and Design Water Flow Rate. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

EnergyPlus Economics

Group – Economics

EnergyPlus contains a number of objects to model construction cost and utility bill calculations.

The objects used by EnergyPlus for construction cost calculations are as follows:

ComponentCost:Adjustments

ComponentCost:Reference

ComponentCost:LineItem

The objects used by EnergyPlus for utility bill calculations are as follows:

UtilityCost:Tariff

UtilityCost:Qualify

UtilityCost:Charge:Simple

UtilityCost:Charge:Block

UtilityCost:Ratchet

UtilityCost:Variable

UtilityCost:Computation

The object used for specifying the currency symbol of the monetary unit used is:

CurrencyType

Introduction to Economics

While it is true that monthly utility bills are often directly related to monthly energy consumption and monthly peak demand, due to the elaborate regulatory environment and the changing value of the energy based on load factor, the calculations involved are often complicated. The EnergyPlus approach is to allow you to model the individual component charges that make up the utility bill and report the results on a monthly basis.

To show you how simple the specification of a rate can be here is a simple example for a flat charge of 8 cents for every kWh sold.

```
UtilityCost:Tariff,
  TariffExample1,      ! Name
  Electricity:Facility, ! Output Meter Name
  kWh,                 ! Conversion Factor Choice

UtilityCost:Charge:Simple,
  ChargeExample1,     ! Charge Variable Name
  TariffExample1,     ! Tariff Name
  totalEnergy,        ! Source Variable
  Annual,              ! Season
  EnergyCharges,      ! Category Variable Name
  0.08;                ! Cost Per Unit Value or Variable Name
```

Overall, the goals of the economics section of EnergyPlus are to make simple tariffs easy to model and complex tariffs possible to model.

The cost implications of alternative, energy-related design options may be important in determining the whether or not a particular design is viable. Although the main purpose of EnergyPlus is to determine the energy performance of a building, component cost modeling is provided to allow estimating initial construction costs associated with the building and

HVAC system being modeled. This is provided in order to ensure that cost estimates are consistent with the EnergyPlus model and it allows using results calculated during a simulation such as equipment sizes and surface areas. The cost estimating capabilities are not comprehensive and are not intended to duplicate all the types of analyses included in cost estimating software. Economics modeling is being implemented in stages. Future versions of EnergyPlus will add other investment related analyses such as life-cycle cost. The objects used by EnergyPlus for calculating first costs for construction projects are as follows:

- ComponentCost:Adjustments
- ComponentCost:Reference
- ComponentCost:LineItem

The results of the cost estimate are reported in a Construction Cost Estimate Summary table provided that the user requests the results using the object Output:Table:SummaryReports object with the Component Cost Economics Summary option selected. The style of this predefined report can be controlled using the OutputControl:Table:Style object. If the Annual Building Performance Report Summary is also requested, then cost estimate results will follow that data in the same output file.

The rest of this Economics section is organized to first present reference material on tariff calculations followed by construction cost estimating.

Conceptual Framework – Variables and Hierarchy

To understand how to use the utility bill calculation portion of EnergyPlus you first need to understand some important concepts of variables and hierarchy. A variable, for the purposes of this section, is simply a named holder of a series of numbers. In most cases, the variable will be a named holder of 12 numbers, one number for each monthly utility bill. Here is a visualization of a variable called Electric Energy Use:

Table 32. Example Electric Energy Use (for Economics Calculation)

Month	Electric Energy Use
January	12143
February	13454
March	14178
April	14876
May	15343
June	16172
July	16105
August	15762
September	14543
October	13987
November	13287
December	12403

If you have ever done any computer programming, you can think of a variable as an array. Many of the names used in the utility bill calculation portion of EnergyPlus are names of variables. In the case of the UtilityCost:Charge objects, the name of the object is also used as a name of a variable.

In many of today's utility rates, the charges for energy or demand are broken into distribution and supply charges. To allow for this, more than one charge may to be defined for a particular category. The variables assigned to the same category are added together.

The categories are combined in following hierarchy:

Figure 132. Hierarchy for Economics Charges

Any charges included in the EnergyCharges category are added together. The EnergyCharges, DemandCharges and ServiceCharges are added together to form the Basis. The Basis, Adjustments and Surcharges are added together to form the Subtotal. The Subtotal and Taxes are added together to be the Total. The total represents the total monthly charges on that tariff for the energy source used. The combining of categories together is performed automatically unless the user specifies the UtilityCost:Computation. In addition, each category, which is also a variable, may be used as a source. For example, a tax that is 5% of the subtotal would be shown as:

```

UtilityCost:Charge:Simple,
TaxOfFivePercent,      ! Charge Variable Name
TariffExample1,        ! Tariff Name
Subtotal,              ! Source Variable
Annual,                ! Season
Taxes,                 ! Category Variable Name
0.05;                  ! Cost Per Unit Value or Variable Name
  
```

As you can see, the UtilityCost:Charge:Simple and UtilityCost:Charge:Block objects do most of the “work” of computing the annual energy cost. The benefit of using this categorization is that totals of each category are shown in the output reports and it organizes the charges in the monthly calculations in a logical way that fits almost all tariffs. If no categorization is desired, theoretically, all charges could be assigned to the Total category. The categories themselves are simply variable names. Charges may also be assigned to the “NotIncluded” category if the result of the charge is used as an intermediate calculation and should not be included in the Total.

The rest of this section is divided into a reference of the objects and the fields, a set of examples, discussion of the reporting, and a description of Complex Tariff Modeling. For most tariffs, simply using a variety of UtilityCost:Charge:Simple’s and UtilityCost:Charge:Block’s will result in a good model but for some more complex tariffs, especially ones with complex block sizes, variables may be computed using a very simple programming language that may appear in the UtilityCost:Computation object. This will be described more in the Complex Tariff Modeling section.

UtilityCost:Tariff

Defines the name of the tariff, the type of tariff, and other details about the overall tariff. Each other object that is part of the tariff model references the tariff name including the

UtilityCost:Charge:Simple, UtilityCost:Charge:Block, UtilityCost:Ratchet, UtilityCost:Qualify, UtilityCost:Variable and UtilityCost:Computation objects.

Multiple UtilityCost:Tariff objects can appear in the same IDF file. It is common that electric and gas utilities have more than one rate that may be used. Only one UtilityCost:Tariff for each Report Meter and Group Name is shown in the Economics Summary Report. The one that is shown in that report is chosen by first eliminating UtilityCost:Tariff objects that are not qualified due to their UtilityCost:Qualify objects. If more than one UtilityCost:Tariff object remains, the one that has the lowest cost for a combination of Report Meter and Group Name will be selected. If the Group Name field is not used, then the lowest cost UtilityCost:Tariff is chosen for each Report Meter.

Part of the tariff description is used to transform the annual energy use of any fuel under any meter into a group of named variables containing the values for each of the periods that the bills are calculated (usually monthly). The schedules create a variable for energy use and for demand. If specified it also creates a variable for energy and a variable for demand for the “on-peak”, “off-peak”, and “shoulder” periods for use in time-of-use tariffs. It performs this allocation prior to other calculations for the tariff. The variables that are always created are:

- totalEnergy
- totalDemand

Field: Name

The name of the tariff. Tariffs are sometimes called rates. The name is used in identifying the output results and in associating all of the charges and other objects that make up a tariff.

Field: Output Meter Name

The name of any meter defined but usually set to either Electricity:Facility or Gas:Facility.

Field: Conversion Factor Choice

A choice that allows several different predefined conversion factors to be used; otherwise, user defined conversion factors are used as defined in the next two fields.

- UserDefined
- kWh
- Therm
- MMBtu
- MJ
- KBtu
- MCF
- CCF

Field: Energy Conversion Factor

Is a multiplier used to convert energy into the units specified by the utility in their tariff. If left blank, it defaults to 1 (no conversion). This field will be used only if Conversion Factor Choice is set to UserDefined. Within EnergyPlus energy always has units of J (joules). For conversion from J to kWh use the value of 0.0000002778. This is also used for all objects that reference the UtilityCost:Tariff.

Field: Demand Conversion Factor

Is a multiplier used to convert demand into the units specified by the utility in their tariff. If left blank, it defaults to 1 (no conversion). This field will be used only if Conversion Factor Choice is set to UserDefined. Within EnergyPlus demand always has units of J/s (joules/sec) which equivalent to W (watts). For conversion from W to kW use the value of 0.001. This is also used for all objects that reference the UtilityCost:Tariff.

Field: Time of Use Period Schedule Name

The name of the schedule that defines the time-of-use periods that occur each day. The period schedule is used to determine which variables are defined. The values for the different variables are:

- 1 is Peak
- 2 is Shoulder
- 3 is OffPeak
- 4 is MidPeak

The following variables are created automatically if these different periods are used in the schedule and include:

- peakEnergy
- peakDemand
- shoulderEnergy
- shoulderDemand
- offPeakEnergy
- offPeakDemand
- midPeakEnergy
- midPeakDemand

Some special variables are created that include only demand from one period that exceeds the demand from another period. For other months that do not exceed, the values are zero. These variables are seldom used but are available for the occasional rate that includes a clause looking at demands during one period that exceed another period.

- PeakExceedsOffPeak
- OffPeakExceedsPeak
- PeakExceedsMidPeak
- MidPeakExceedsPeak
- PeakExceedsShoulder
- ShoulderExceedsPeak

If no Period Schedule is specified then no peak, offPeak, midPeak or shoulder variables are defined.

Field: Season Schedule Name

The name of a schedule that defines the seasons. The seasons are

- 1 is Winter
- 2 is Spring
- 3 is Summer
- 4 is Autumn

The change in the season schedule must occur at the same time as the change in the Monthly Schedule. In other words, a season must end at the same time as a billing month. Variables are automatically created if a season schedule is used. These variables are set to 1 within the season and 0 for the months that are not in the season. The variables are:

- isWinter
- isNotWinter
- isSpring
- isNotSpring
- isSummer
- isNotSummer

- isAutumn
- isNotAutumn

Field: Month Schedule Name

The name of the schedule that defines the billing periods of the year. Normally this entry is allowed to default and a schedule will be internally used that has the breaks between billing periods occurring at the same time as the breaks between months, i.e., at midnight prior to the first day of the month. If other billing periods are used such as two month cycles or a single bill for an entire season, such as some natural gas companies do in the summer, then the month schedule may be used to redefine it. Make sure that the month schedule and season schedule are consistent, otherwise an error will be issued.

- 1 is the first month, usually January
- 2 is the second month, usually February
- 3 is the third month, usually March
- 4 is the fourth month, usually April
- 5 is the fifth month, usually May
- 6 is the sixth month, usually June
- 7 is the seventh month, usually July
- 8 is the eighth month, usually August
- 9 is the ninth month, usually September
- 10 is the tenth month, usually October
- 11 is the eleventh month, usually November
- 12 is the twelfth month, usually December

Thus, the schedule that represents this would look like the following. If no schedule is specified the following Month Schedule is used which defines the months of the year as the normal calendar months.

```
Schedule:Compact, defaultMonths, number,
Through: 1/31, For: AllDays, Until: 24:00, 1,
Through: 2/28, For: AllDays, Until: 24:00, 2,
Through: 3/31, For: AllDays, Until: 24:00, 3,
Through: 4/30, For: AllDays, Until: 24:00, 4,
Through: 5/31, For: AllDays, Until: 24:00, 5,
Through: 6/30, For: AllDays, Until: 24:00, 6,
Through: 7/31, For: AllDays, Until: 24:00, 7,
Through: 8/31, For: AllDays, Until: 24:00, 8,
Through: 9/30, For: AllDays, Until: 24:00, 9,
Through: 10/31, For: AllDays, Until: 24:00, 10,
Through: 11/30, For: AllDays, Until: 24:00, 11,
Through: 12/31, For: AllDays, Until: 24:00, 12;
```

Field: Demand Window Length

The determination of demand can vary by utility. Some utilities use the peak instantaneous demand measured but most use a fifteen minute average demand or a one hour average demand. Some gas utilities measure demand as the use during the peak day or peak week. The choices for demand window are:

- QuarterHour
- HalfHour
- FullHour
- Day
- Week

If no value is entered, QuarterHour is assumed. The choice may be overridden based on the value of Timestep so that they are consistent. If the Timestep is 6, i.e. 10 minute timesteps, then QuarterHour is not used and instead HalfHour is used instead. If Timestep is 3, i.e. 20 minute timesteps, then QuarterHour and HalfHour are not used and instead FullHour is used instead. Day and Week are primarily used by fuel utilities.

Field: Monthly Charge or Variable Name

The fixed monthly service charge that many utilities have. The entry may be numeric and gets added to the ServiceCharges variable or if a variable name is entered here, its values for each month are used.

Field: Minimum Monthly Charge or Variable Name

The minimum total charge for the tariff or if a variable name is entered here, its values for each month are used. The sum of the subtotal and taxes usually equals the total unless you have specified the minimum monthly charge. If the minimum monthly charge does not apply to the entire bill, a UtilityCost:Computation object can be specified using a Minimum function for the appropriate variables.

Field: Real Time Pricing Charge Schedule Name

Used with real time pricing rates. The name of a schedule that contains the cost of energy for that particular time period of the year. Real time rates can be modeled using a charge schedule with the actual real time prices entered in the schedule. The charges should be consistent with the conversion factor specified in the tariff.

Field: Customer Baseline Load Schedule Name

Used with real time pricing rates and often described as the CBL or customer baseline load. The name of a schedule that contains the baseline energy use for the customer. Many real time rates apply the charges as a credit or debit only to the difference between the baseline use and the actual use. The baseline use is established between the customer and the utility using a contract. If this field is used the baseline use schedule will be used for establishing the totalEnergy and totalDemand instead of the metered value and the real time rate charge is added or subtracted to the rate calculation using the real time charge schedule. If this field is not used, the real time charge schedule applies to all energy from the meter and totalEnergy and totalDemand is based on metered value as usual.

Field: Group Name

The group name of the tariff such as distribution, transmission, supplier, etc. If more than one tariff with the same group name is present and qualifies, only the lowest cost tariff is used. Usually the group name field is left blank which results in all tariffs using the same meter variable being compared and the lowest cost one being selected.

Field: Buy Or Sell

Sets whether the tariff is used for buying, selling or both to the utility. This should be allowed to default to BuyFromUtility unless a power generation system is included in the building that may generate more power than the building needs during the year. The choices are:

- BuyFromUtility – The values from the metered variable are used and are shown as being purchases from the utility.
- SellToUtility – The values from the metered variable are used for a “sell back” rate to the utility. The charges in the rate should be expressed as negative values.
- NetMetering – Negative values are used to reduce any positive values during the specific period on the tariff when negative values occur.

A warning will be issued if the selection of this field does not match the type of report meter.

UtilityCost:Qualify

Many utilities provide a large number of tariffs and separate their customers by the amount of energy use they have or by the amount of demand. The qualify object allows only certain tariffs that are modeled to be used. If the results of the simulation fall outside of the range of qualifications, that tariff is still calculated but the “Qualified” entry will say “No” and the UtilityCost:Qualify that caused its exclusion is shown. When multiple tariffs from the same utility are modeled and only one of them should be used, make sure that the qualifiers are consistent especially within the same GroupName (see UtilityCost:Tariff). Multiple UtilityCost:Qualify objects can appear for a specific rate and they can be based on any variable.

The energy used and demands for each month vary. Since it is possible that they vary across the minimum and maximum values defined by this object, a choice in how to treat the thresholds is necessary. Say that a utility has two tariffs, a small tariff that has a maximum demand requirement of 50kW and a large tariff that has a minimum demand requirement of 50kW. If the use for a building goes above the 50kW threshold during some summer months and the rest of the time is below 50kW, then how does the utility choose which rate would qualify. The utility probably has very specific requirements about which months or consecutive months can be above or below a threshold to qualify for the rate.

Field: Name

The name used for the UtilityCost:Qualify and displayed if the tariff does not qualify. It is also treated as a variable and contains:

- 1 for each month that does qualify,
- 0 for months that do not qualify, and
- -1 for months that are not part of the season selected.

Field: Tariff Name

The name of the UtilityCost:Tariff object that is associated with this UtilityCost:Qualify object.

Field: Variable Name

The name of the variable used. For energy and demand, the automatically created variables, totalEnergy and totalDemand should be used, respectively.

Field: Qualify Type

Enter either “Minimum” or “Maximum”.

Field: Threshold Value or Variable Name

The minimum or maximum value for the qualify. If the variable has values that are less than this value when the qualify type is minimum then the tariff may be disqualified. If the variable has values that are greater than this value when the qualify type is maximum then the tariff may be disqualified. For demand, it is still the minimum of the demands set each month even though the demands are, by definition, the peak value for the month. Depending on the threshold test entry (see below) this minimum applies to all months, some of the months, or just a single month.

Field: Season

If the UtilityCost:Qualify only applies to a season, enter the season name from the following list:

- Annual
- Winter
- Spring
- Summer

- Fall

If this field is left blank, it defaults to Annual.

Field: Threshold Test

Enter either “Count” or “Consecutive”. Uses the number in Number of Months in one of two different ways depending on the Threshold Test. If the Threshold Test is set to “Count” then the qualification is based on the count of the total number of months per year. If the Threshold Test is set to “Consecutive” then the qualification is based on a consecutive number of months. If left blank this field defaults to count and it should be allowed to default for most cases.

Field: Number of Months

A number from 1 to 12. If no value entered, 12 is assumed when the qualify type is minimum and 1 when the qualify type is maximum. This is the number of months that the threshold test applies to determine if the rate qualifies or not. If the season is less than 12 months (if it is not annual) then the value is automatically reduced to the number of months of the season.

UtilityCost:Charge:Simple

The UtilityCost:Charge:Simple is one of the most often used objects for tariff calculation. It is used to compute energy and demand charges that are very simple. It may also be used for taxes, surcharges and any other charges that occur on a utility bill. As many UtilityCost:Charge:Simple objects as needed may be defined for a single tariff and they will be added together.

Field: Charge Variable Name

This is the name associated with the UtilityCost:Charge:Simple object and will appear in the report. In addition, the results of the UtilityCost:Charge:Simple calculation are stored in a variable with the same name. That way, the results may be used for further calculation. Spaces are not significant in Charge Variable Names. They are removed during the utility bill calculation process.

Field: Tariff Name

The name of the tariff that this UtilityCost:Charge:Simple is associated with.

Field: Source Variable

The name of the source used by the UtilityCost:Charge:Simple. This is usually the name of the variable holding the energy or demand but may also be the name of any variable including the subtotal or basis if other charges are based on those.

Field: Season

This is the name (or number) of a season for which the UtilityCost:Charge:Simple is calculated. If this is set to Annual, the calculations are performed for the UtilityCost:Charge:Simple for the entire year (all months) otherwise it is calculated only for those months in the season defined. The season is defined by the Season Schedule in the UtilityCost:Tariff object. The choices for seasons are the following names or numbers may be used:

- Annual
- Winter
- Spring
- Summer
- Fall

Field: Category Variable Name

All charges get added somewhere in the hierarchy described in the introduction to EnergyPlus economics above. This field shows where the charge should be added. The reason to enter this field appropriately is so that the charge gets reported in a reasonable category. The charge automatically gets added to the variable that is the category. The choices for this field are limited to:

- EnergyCharges
- DemandCharges
- ServiceCharges
- Basis
- Adjustment
- Surcharge
- Subtotal
- Taxes
- Total
- NotIncluded

Field: Cost per Unit Value or Variable Name

This field contains either a single number or the name of a variable. The number is multiplied with all of the energy or demand or other source that is specified in the source field. If a variable is used, then the monthly values of the variable are multiplied against the variable specified in the source field. This field makes it easy to include a simple charge without specifying block sizes. It is added to any of the block calculations (see later fields) but is most often used by itself. If no value or variable is entered, a zero is assumed. This is a good way to include a tax or cost adjustment. For SellToUtility tariffs, the values in this field are usually expressed as negative numbers.

UtilityCost:Charge:Block

The UtilityCost:Charge:Block objects is also used extensively for tariff calculation. It is used to compute energy and demand charges that are structured in blocks of charges. It may also be used for taxes, surcharges and any other charges that occur on a utility bill but those are more commonly simple flat charges so UtilityCost:Charge:Simple is more commonly used for those functions. As many UtilityCost:Charge:Block objects as needed may be defined for a single tariff and they will be added together. Blocks are a structure used by almost all utilities for calculating energy and demand charges and they allow the utility to charge more or less per unit of energy or demand if more units are used.

Field: Charge Variable Name

This is the name associated with the UtilityCost:Charge:Block object and will appear in the report. In addition, the results of the UtilityCost:Charge:Block are stored in a variable with the same name. That way, the results may be used for further calculation.

Field: Tariff Name

The name of the tariff that this UtilityCost:Charge:Block is associated with.

Field: Source Variable

The name of the source used by the UtilityCost:Charge:Block. This is usually the name of the variable holding the energy or demand but may also be the name of any variable including the subtotal or basis if other charges are based on those.

Field: Season

This is the name (or number) of a season for which the UtilityCost:Charge:Block is calculated. If this is set to annual, the calculations are performed for the UtilityCost:Charge:Block for the entire year (all months) otherwise it is calculated only for those months in the season defined. The season is defined by the Season Schedule in the UtilityCost:Tariff object. The choices for seasons are the following names or numbers may be used:

- Annual
- Summer
- Winter
- Spring
- Fall

Field: Category Variable Name

All charges get added somewhere in the hierarchy described in the introduction to EnergyPlus economics above. This field shows where the charge should be added. The reason to enter this field appropriately is so that the charge gets reported in a reasonable category. The charge automatically gets added to the variable that is the category. The choices for this field are limited to:

- EnergyCharges
- DemandCharges
- ServiceCharges
- Basis
- Adjustment
- Surcharge
- Subtotal
- Taxes
- Total
- NotIncluded

Field: Remaining Into Variable

If the blocks do not use all of the energy or demand from the source, some energy and demand remains, then the remaining amount should be assigned to a variable. If no variable is assigned and some amount of energy or demand is not used in the block structure a warning will be issued.

Field: Block Size Multiplier Value or Variable Name

The sizes of the blocks are usually used directly but if a value or a variable is entered here, the block sizes entered in the rest of the charge are first multiplied by the entered value prior to being used. This is common for rates that are kWh/kW rates and in that case the variable that holds the monthly total electric demand would be entered. If no value is entered, a default value of one is assumed so that the block sizes remain exactly as entered. This field is unusual for the EnergyPlus syntax because it can be either a number or a name of a variable.

Field: Block Size 1 Value or Variable Name

The size of the first block of the charges is entered here. For most rates that use multiple blocks, this will be the value for the first block size. Additional block sizes are entered with every other field. A default variable named "remaining" contains a large value and this may be used when the remaining amount should be included in that block. This field and the next

field may be repeated in groups of two for as many blocks as are defined. This field is unusual for the EnergyPlus syntax because it can be either a number or a name of a variable.

Field: Block 1 Cost per Unit Value or Variable Name

The cost of the first block. This value is also repeated for every other field in the charge. As many blocks may be entered as are needed. This field and the previous field may be repeated in groups of two for as many blocks as are defined. This field is unusual for the EnergyPlus syntax because it can be either a number or a name of a variable. For SellToUtility tariffs, the values in this field are usually expressed as negative numbers.

These last two fields may be repeated fifteen times. If more blocks are defined by the utility, the computation can be continued using another UtilityCost:Charge:Block and using the variable from Remaining Into Variable as the source variable.

UtilityCost:Ratchet

The UtilityCost:Ratchet command allows the modeling of tariffs that include some type of seasonal ratcheting. Ratchets are most common when used with electric demand charges. A ratchet is when a utility requires that the demand charge for a month with a low demand may be increased to be more consistent with a month that set a higher demand charge.

While the details of the UtilityCost:Ratchet command are described further in this section, an example is probably the easiest way to learn the basic functions.

Ratchet Example: A utility has a single ratchet that says that the billing demand for each month of the year is the higher value of the actual demand or 60% of the peak summer demand

```
UtilityCost:Ratchet,
BillingDemand1,    ! Ratchet Variable Name
ExampleTariff1,   ! Tariff Name
TotalDemand,      ! Baseline Source Variable
TotalDemand,      ! Adjustment Source Variable
Summer,           ! Season From
Annual,           ! Season To
0.60,             ! Multiplier Value or Variable Name
0;                ! Offset Value or Variable Name
```

The Ratchet Variable Name (the first field) should be used wherever the ratchet should be applied and is often the source variable for UtilityCost:Charge:Simple or UtilityCost:Charge:Block.

The detailed steps taken for the ratchet are the following:

- AdjSeasonal contains either:
 - When SeasonFrom is not set to Monthly, the maximum for all months in Season From in the Adjustment Source Variable. This is a single value.
 - When SeasonFrom is set to Monthly, the monthly values of the Adjustment Source Variable.
- $AdjPeak = (AdjSeasonal + Offset) * Multiplier$
- $MaxAdjBase = \text{maximum value of either } AdjPeak \text{ or Baseline Source Variable}$
- The resulting Ratchet Variable contains:
 - For months not in SeasonTo, the values of Baseline Source Variable
 - For months in SeasonTo, the values of MaxAdjBase

If multiple ratchets occur in the same tariff, multiple UtilityCost:Ratchet commands should be “chained” together with the Baseline Source Variable subsequent ratchets referencing the Ratchet Variable Name of the previous UtilityCost:Ratchet.

Since the ratchet command can add together two variables, multiply two variables, or take the maximum value between two variables, it may be used for other difficult to model tariffs without needing to use UtilityCost:Computation. Clever use of UtilityCost:Ratchet should be well documented with comments.

Field: Ratchet Variable Name

The name of the ratchet and the name of the result of this single ratchet.

Field: Tariff Name

The name of the tariff that this UtilityCost:Ratchet is associated with.

Field: Baseline Source Variable

The name of the variable used as the baseline value. When the ratcheted value exceeds the baseline value for a month the ratcheted value is used but when the baseline value is greater then the ratcheted value the baseline value is used. Usually the electric demand charge is used. The baseline source variable can be the results of another ratchet object. This allows utility tariffs that have multiple ratchets to be modeled.

Field: Adjustment Source Variable

The variable that the ratchet is calculated from. It is often but not always the same as the baseline source variable. The ratcheting calculations using offset and multiplier are using the values from the adjustment source variable. If left blank, the adjustment source variable is the same as the baseline source variable.

Field: Season From

The name of the season that is being examined. The maximum value for all of the months in the named season is what is used with the multiplier and offset. This is most commonly Summer or Annual. When Monthly is used, the adjustment source variable is used directly for all months.

- Annual
- Winter
- Spring
- Summer
- Fall
- Monthly

Field: Season To

The name of the season when the ratchet would be calculated. This is most commonly Winter. The ratchet only is applied to the months in the named season. The resulting variable for months not in the Season To selection will contain the values as appear in the baseline source variable.

- Annual
- Winter
- Spring
- Summer
- Fall

Field: Multiplier Value or Variable Name

Often the ratchet has a clause such as “the current month demand or 90% of the summer month demand”. For this case a value of 0.9 would be entered here as the multiplier. This value may be left blank if no multiplier is needed and a value of one will be used as a default.

Field: Offset Value or Variable Name

A less common strategy is to say that the ratchet must be all demand greater than a value, in this case an offset that is added to the demand may be entered here. If entered, it is common for the offset value to be negative representing that the demand be reduced. If no value is entered it is assumed to be zero and not affect the ratchet.

UtilityCost:Variable

The UtilityCost:Variable object allows for the direct entry of monthly values into a variable.

Field: Name

The name of the variable.

Field: Tariff Name

The name of the tariff that is using the variable.

Field: January through December Values

An entry (up to 24 are available) of the monthly values of the variable. Normally 12 months are used for most utility rates and so 12 values should be entered. If any values are not entered, the value of the previous entry is used. This allows a variable that is constant for an entire year to be entered using only the first value.

UtilityCost:Computation

The UtilityCost:Computation object lists a series of computations that are used to perform the bill calculation. The object is only used for complex tariffs that cannot be modeled any other way. For 95% of the utility tariffs, using UtilityCost:Computation is unnecessary and should be avoided. If the UtilityCost:Computation object is used, it must contain references to all objects involved in the rate in the order that they should be computed.

Field: Name

The name of the UtilityCost:Computation.

Field: Tariff Name

The name of the tariff that this UtilityCost:Charge:Simple is associated with.

Field: Compute Step N

The Compute Step fields contain a simple language that describes the steps used in the computation process similar to a programming language. If no entry is made to any Compute Step fields (as usually the case) a default method of computing the rates shall be used. Compute Step is described later in this section under Complex Tariff Modeling.

Remember, this object should be omitted for almost all tariffs.

UtilityCost:Tariff Examples

One of the best ways to learn the details of EnergyPlus Economics is to see some example tariffs and how they translate into objects. To do this, several different rates of increasing complexity are shown in the following examples.

Another source of examples is the large set of tariff input objects provided with EnergyPlus in the macro data set file called "UtilityTariffObjects.imf" located in the "MacroDataSets" folder where EnergyPlus is installed. This file contains sets of objects that fully define tariffs for commercial customers from a collection of U.S. utility companies.

Example A – Flat Energy Charge

As an example of the simplest type of tariff.

Customer Charge: \$2.51 per month

Energy Charge: 5.5342 cents/kWh

This tariff would use a single UtilityCost:Charge:Simple object. The monthly charge is part of the UtilityCost:Tariff object.

```
UtilityCost:Tariff,
ExampleA,                ! Name
Electricity:Facility,    ! Output Meter Name
kWh,                    ! Conversion Factor Choice
,                        ! Energy Conversion Factor
,                        ! Demand Conversion Factor
,                        ! Time of Use Period Schedule Name
,                        ! Season Schedule Name
,                        ! Month Schedule Name
,                        ! Demand Window Length
2.51;                   ! Monthly Charge or Variable Name

UtilityCost:Charge:Simple,
FlatEnergyCharge,       ! Charge Variable Name
ExampleA,               ! Tariff Name
totalEnergy,           ! Source Variable
Annual,                ! Season
EnergyCharges,         ! Category Variable Name
0.055342;              ! Cost Per Unit Value or Variable Name
```

Example B – Block Energy Charge

Another simple type of tariff is one where the energy charges vary by the amount of energy consumed each month.

Customer Charge: \$5.75 per month

Energy Charge: 7.231 cents/kWh for first 200 kWh

6.656 cents/kWh for next 1000 kWh

5.876 cents/kWh for over 1200 kWh

This tariff would use a single UtilityCost:Charge:Block object. The monthly charge is part of the UtilityCost:Tariff object. Note that the block sizes are every other field at the bottom of the object and the that final block size references a built in variable called “remaining” that contains a very large number.

```

UtilityCost:Tariff,
  ExampleB,                ! Name
  Electricity:Facility,    ! Output Meter Name
  kWh,                    ! Conversion Factor Choice
  ,                       ! Energy Conversion Factor
  ,                       ! Demand Conversion Factor
  ,                       ! Time of Use Period Schedule Name
  ,                       ! Season Schedule Name
  ,                       ! Month Schedule Name
  ,                       ! Demand Window Length
  5.75;                   ! Monthly Charge or Variable Name

UtilityCost:Charge:Block,
  BlockEnergyCharge,      ! Charge Variable Name
  ExampleB,              ! Tariff Name
  totalEnergy,           ! Source Variable
  Annual,                ! Season
  EnergyCharges,        ! Category Variable Name
  ,                      ! Remaining Into Variable

  0.05876;               ! Block 3 Cost per Unit Value or Variable Name

```

Example C – Block Energy and Demand Charges

This example contains both a block for energy and a block for demand and is very similar to the previous example except it now includes demand charges as well. The energy and demand charges vary by the amount of energy and demand consumed each month.

Energy Charge:	4.74 cents/kWh for first 20,000 kWh
	4.24 cents/kWh for next 180,000 kWh
	3.83 cents/kWh for additional kWh
Demand Charge:	5.38 dollars per kW for first 20 kW
	4.23 dollars per kW for next 80 kW
	3.60 dollars per kW for additional kW

This tariff would use two UtilityCost:Charge:Block objects. No monthly charge is shown so the UtilityCost:Tariff object can include just the first four fields. Note that the block sizes are every other field at the bottom of the object and the that final block size references a built in variable called “remaining” that contains a very large number.

```

UtilityCost:Tariff,
  ExampleC,                ! Name
  Electricity:Facility,    ! Output Meter Name
  KWh;                     ! Conversion Factor Choice

UtilityCost:Charge:Block,
  BlockEnergyCharge,      ! Charge Variable Name
  ExampleC,               ! Tariff Name
  totalEnergy,            ! Source Variable
  Annual,                 ! Season
  EnergyCharges,         ! Category Variable Name
  ,                       ! Remaining Into Variable

  20000,                  ! Block Size 1 Value or Variable Name
  0.0474,                 ! Block 1 Cost per Unit Value or Variable Name
  180000,                 ! Block Size 2 Value or Variable Name
  0.0424,                 ! Block 2 Cost per Unit Value or Variable Name
  remaining,              ! Block Size 3 Value or Variable Name
  0.0383;                 ! Block 3 Cost per Unit Value or Variable Name

UtilityCost:Charge:Block,
  BlockDemandCharge,     ! Charge Variable Name
  ExampleC,               ! Tariff Name
  totalDemand,           ! Source Variable
  Annual,                 ! Season
  DemandCharges,        ! Category Variable Name
  ,                       ! Remaining Into Variable
  ,                       ! Block Size Multiplier Value or Variable Name
  20,                    ! Block Size 1 Value or Variable Name
  5.38,                  ! Block 1 Cost per Unit Value or Variable Name
  80,                    ! Block Size 2 Value or Variable Name
  4.23,                  ! Block 2 Cost per Unit Value or Variable Name
  remaining,              ! Block Size 3 Value or Variable Name
  3.60;                  ! Block 3 Cost per Unit Value or Variable Name

```

Example D - Seasonal Energy Charges with Minimum Charge

Another type of tariff is one where the energy charges vary by the amount of energy consumed each month and are different for the summer and winter. In addition, this example demonstrates the minimum charge field.

Minimum Charge: \$7.00 per month

Winter – October through May

Energy Charge: 4.385 cents/kWh for first 650 kWh
 3.763 cents/kWh for next 350 kWh
 3.704 cents/kWh for over 1000 kWh

Summer – June through September

Energy Charge: 8.385 cents/kWh for first 650 kWh
 7.588 cents/kWh for next 350 kWh
 7.103 cents/kWh for over 1000 kWh

This tariff would use two UtilityCost:Charge:Block objects. The monthly charge is part of the UtilityCost:Tariff object. Note that the block sizes are every other field at the bottom of the

object and the that final block size references a built in variable called "remaining" that contains a very large number.

```

UtilityCost:Tariff,
  ExampleD,                ! Name
  Electricity:Facility,    ! Output Meter Name
  KWh,                    ! Conversion Factor Choice
  ,                       ! Energy Conversion Factor
  ,                       ! Demand Conversion Factor
  ,                       ! Time of Use Period Schedule Name
  TwoSeasonSchedule,     ! Season Schedule Name
  ,                       ! Month Schedule Name
  ,                       ! Demand Window Length
  ,                       ! Monthly Charge or Variable Name
  7.00;                  ! Minimum Monthly Charge or Variable Name

UtilityCost:Charge:Block,
  WinterEnergyCost,      ! Charge Variable Name
  ExampleD,              ! Tariff Name
  totalEnergy,          ! Source Variable
  Winter,                ! Season
  EnergyCharges,        ! Category Variable Name
  ,                     ! Remaining Into Variable
  ,                     ! Block Size Multiplier Value or Variable Name
  650,                  ! Block Size 1 Value or Variable Name
  0.04385,              ! Block 1 Cost per Unit Value or Variable Name
  350,                  ! Block Size 2 Value or Variable Name
  0.03763,              ! Block 2 Cost per Unit Value or Variable Name
  remaining,            ! Block Size 3 Value or Variable Name
  0.03704;              ! Block 3 Cost per Unit Value or Variable Name

UtilityCost:Charge:Block,
  SummerEnergyCost,     ! Charge Variable Name
  ExampleD,              ! Tariff Name
  totalEnergy,          ! Source Variable
  Summer,               ! Season
  EnergyCharges,        ! Category Variable Name
  ,                     ! Remaining Into Variable
  ,                     ! Block Size Multiplier Value or Variable Name
  650,                  ! Block Size 1 Value or Variable Name
  0.08385,              ! Block 1 Cost per Unit Value or Variable Name
  350,                  ! Block Size 2 Value or Variable Name
  0.07588,              ! Block 2 Cost per Unit Value or Variable Name
  remaining,            ! Block Size 3 Value or Variable Name
  0.07103;              ! Block 3 Cost per Unit Value or Variable Name

Schedule:Compact, TwoSeasonSchedule, number,
Through: 5/31, For: AllDays, Until: 24:00, 1,
Through: 9/30, For: AllDays, Until: 24:00, 3,
Through: 12/31, For: AllDays, Until: 24:00, 1;

```

Example E – kWh/kW Energy Charges

A more advanced rate varies the size of the blocks based on amount of demand for the month. This creates an effective demand charge if the blocks have declining values.

Customer Charge: \$14.00 per month

Energy Charge: 8.756 cents/kWh for all consumption not greater than 200 hours times the demand

6.812 cents/kWh for all consumption in excess of 200 hours and not greater than 400 hours times the demand

5.029 cents/kWh for all consumption in excess of 400 hours times the demand.

This tariff would use a single `UtilityCost:Charge:Block` object. The monthly charge is part of the `UtilityCost:Tariff` object. In this case the `Block Size Multiplier Value` (or `Variable`) is set to the `totalDemand` variable.

```
UtilityCost:Tariff,
  ExampleE,           ! Name
  Electricity:Facility, ! Output Meter Name
  KWh,               ! Conversion Factor Choice
  ,                 ! Energy Conversion Factor
  ,                 ! Demand Conversion Factor
  ,                 ! Time of Use Period Schedule Name
  ,                 ! Season Schedule Name
  ,                 ! Month Schedule Name
  ,                 ! Demand Window Length
  14;                ! Monthly Charge or Variable Name

UtilityCost:Charge:Block,
  BlockEnergyCharge, ! Charge Variable Name
  ExampleE,          ! Tariff Name
  totalEnergy,       ! Source Variable
  Annual,            ! Season
  EnergyCharges,     ! Category Variable Name
  ,                 ! Remaining Into Variable
  totalDemand,       ! Block Size Multiplier Value or Variable Name
  200,               ! Block Size 1 Value or Variable Name
  0.08756,           ! Block 1 Cost per Unit Value or Variable Name
  200,               ! Block Size 2 Value or Variable Name
  0.06812,           ! Block 2 Cost per Unit Value or Variable Name
  remaining,         ! Block Size 3 Value or Variable Name
  0.05029;           ! Block 3 Cost per Unit Value or Variable Name
```

Example F – Seasonal Time of Use Energy

Tariffs sometimes have higher costs for energy consumed during the daytime than at night. This example includes energy charges that vary by the time of day and by the season.

Monthly Charge: \$37.75 per month

Winter – October through May

On Peak: 8.315 cents/kWh

Off-Peak: 2.420 cents/kWh

Summer – June through September

On Peak: 14.009 cents/kWh

Off-Peak: 6.312 cents/kWh

The on-peak period is defined as the hours starting at 10am and ending at 7pm, Monday through Friday for June through September and 3pm to 10pm Monday through Friday for October through May. All other hours are considered off-peak.

The tariff is only applicable for customers that use 50KW for at least one month of the year.

This tariff uses four different `UtilityCost:Charge:Simple` objects to capture the variation with time of the energy cost. The monthly charge is part of the `UtilityCost:Tariff` object.

```

UtilityCost:Tariff,
  ExampleF,           ! Name
  Electricity:Facility, ! Output Meter Name
  kWh,               ! Conversion Factor Choice

                          Until: 24:00, 3;

```

Example G – Blocks within Blocks

Utilities have come up with many different ways to encourage certain load factors and discourage other load factors. One method that has been used is blocks defined within other blocks. In the following example standard kWh blocks exist within the energy allocated for the first of several kWh/kW blocks.

Monthly Charge: \$35 per month

Energy Charge: For all consumption not greater than 200 hours times the demand use

10.32 cents/kWh for the first 1000 kWh

7.43 cents/kWh for the next 4000 kWh

6.23 cents/kWh for the next 5000 kWh

4.27 cents/kWh for the remaining kWh less than 200 hours times the demand

6.82 cents/kWh for all consumption in excess of 200 hours and not greater than 400 hours times the demand

5.03 cents/kWh for all consumption in excess of 400 hours times the demand.

To set up this “block within a block” a UtilityCost:Charge:Block is first used to separate out the first 200 kWh/kW. The “EnergyFirst200kWhPerkW” charge performs this. It uses demand to multiply the first block size by 200 and the “cost” for the block is simply 1 since it passes through the energy to the variable “EnergyFirst200kWhPerkW”. The remaining energy goes into the “restOfEnergy” variable as specified as the “Remaining Into Variable” field. After this is evaluated we have two new variables that hold energy. Each of these variables are then separately used in UtilityCost:Charge:Block objects to evaluate the different parts of the example tariff. By using the “Remaining Into Variable” along with the concept of variables, many very complex tariffs may be modeled.

```

  0.0503;                !- Block 2 Cost Per Unit Value or Variable Name

```

Example H – Real Time Pricing

Some utilities have tariffs that can have different prices every hour of the year called Real Time Pricing tariffs. Often the utility will inform the customer of the prices for each hour of the day just one day in advance. To model this type of utility rate a normal schedule is used that contains the prices on an hourly basis. The “Charge Schedule” field is where the Schedule object containing the prices is referenced. In addition, the “Baseline Use Schedule” field is used to set the schedule for the customer baseline load. Not all utilities use a customer baseline load so the field can be left blank if none is needed. The Period, Season and Month Schedules are not needed for these tariffs unless UtilityCost:Charge’s are used. The Schedule:File object can be especially useful to input a complex schedule that changes throughout the year.

Example H, shown below, is an example of how to use the UtilityCost:Tariff object with a schedule to calculate a utility tariff using real time prices. The example real time pricing schedule results in the same energy cost as Example F – Seasonal Time of Use Energy. This is only an example and usually for real time pricing the schedule values would vary throughout the year.

```

```

Example I – Selling and Net-Metering

When the building contains a generator, photovoltaics, or other sources of electrical power, there is an opportunity for the building generator to produce more power than the building uses. The excess power can either be sold to the utility or offset the energy purchased.

When the excess power is sold, two utility rates need to be defined. The first can be defined just as in any of the previous examples. Since the “Buy or Sell” field of the UtilityCost:Tariff object defaults to “buyFromUtility” it does not even need to be specified. The meter specified in the “Report Meter” is usually set to “ElectricityPurchased:Facility.”

The second tariff needs to be defined with the “Buy or Sell” field set to “sellToUtility.” The “Report Meter” is usually set to “ElectricitySurplusSold:Facility.” It is important to set the

appropriate meters that correspond with the “Buy or Sell” field. The example below shows an tariff that sells the excess electricity back to utility. The UtilityCost:Charge:Simple object contains a “Cost Per Value” with a negative number. A negative number is critical if a credit for selling this electricity is expected.

```
! EXAMPLE I - Selling

UtilityCost:Charge:Simple,
  GeneratedElectricSold,  !- Charge Variable Name
  ExampleI-Sell,         !- Tariff Name
  totalEnergy,          !- Source Variable
  Annual,               !- Season
  EnergyCharges,        !- Category Variable Name
  -0.02;                !- Cost Per Unit Value (or Variable)

UtilityCost:Tariff,
  ExampleI-Sell,        !- Name
  ElectricitySurplusSold:Facility, !- Output Meter Name
  kWh,                 !- Conversion Factor Choice
  ,                    !- Energy Conversion Factor
  ,                    !- Demand Conversion Factor
  ,                    !- Time of Use Period Schedule Name
  ,                    !- Season Schedule Name
  ,                    !- Month Schedule Name
  ,                    !- Demand Window Length
  ,                    !- Monthly Charge or Variable Name
  ,                    !- Minimum Monthly Charge or Variable Name
  ,                    !- Real Time Pricing Charge Schedule Name
  ,                    !- Customer Baseline Load Schedule Name
  ,                    !- Group Name
  sellToUtility;       !- Buy Or Sell

UtilityCost:Charge:Simple,
  GeneratedElectricSold,  !- Charge Variable Name
  ExampleI-Sell,         !- Tariff Name
  totalEnergy,          !- Source Variable
  Annual,               !- Season
  EnergyCharges,        !- Category Variable Name
  -0.02;                !- Cost Per Unit Value or Variable Name
```

The next part of this example is a rate that uses net-metering. With net metering the meter conceptually turns backwards when the energy is being sold to the utility directly reducing the energy consumption being charged. Effectively, the rate charge for purchased electricity is the same as the rate credited for electricity sold to the utility. In this the “Buy or Sell” field should be set to “netMetering.” It is also important the “Report Meter” is set to a meter that represents net metering such as “ElectricityNet:Facility.” The following example shows a simple example tariff using net metering with a single UtilityCost:Charge:Simple:

```

! EXAMPLE I - Net Metering

UtilityCost:Tariff,
  ExampleI-NetMeter,      !- Name
  ElectricityNet:Facility, !- Output Meter Name
  kWh,                   !- Conversion Factor Choice
  ,                      !- Energy Conversion Factor
  ,                      !- Demand Conversion Factor
  ,                      !- Time of Use Period Schedule Name
  ,                      !- Season Schedule Name
  ,                      !- Month Schedule Name
  ,                      !- Demand Window Length
  30.00,                 !- Monthly Charge or Variable Name
  ,                      !- Minimum Monthly Charge or Variable Name
  ,                      !- Real Time Pricing Charge Schedule Name
  ,                      !- Customer Baseline Load Schedule Name
  ,                      !- Group Name
  netMetering;          !- Buy Or Sell

UtilityCost:Charge:Simple,
  NetMeteredCharge,      !- Charge Variable Name
  ExampleI-NetMeter,      !- Tariff Name
  totalEnergy,           !- Source Variable
  Annual,                !- Season
  EnergyCharges,         !- Category Variable Name
  0.065;                 !- Cost Per Unit Value or Variable Name

```

UtilityCost:Tariff Reporting

A standardized tabular output report is created which shows all components of all categories in the calculation sequence on a variable basis (usually 12 numbers, one for each month). The economics report is automatically created if any UtilityCost:Tariff objects are present. The values reported are in the units specified in the UtilityCost:Tariff object. The report includes:

Economic Results Summary Report

- Annual Cost – Shows the annual cost for qualified and selected electric and gas tariffs and the total cost
- Tariff Summary – For each tariff included shows if that tariff was selected, if it was qualified, what meter it was connected to, what group it was part of, and the annual cost. The qualified tariff with the lowest annual cost for each of the meters is indicated as “selected” and shown in the Annual Cost section of the report. If multiple groups are defined, a tariff is selected from each group.

Tariff Summary

- Summary table – Shows the if that tariff was selected, if it was qualified, which qualifier disqualified the tariff, what meter it was connected to, what group it was part of, if the computation was based on a user defined computation or was automatic.
- Categories – Shows the monthly results of all the category variables.
- Charges – Shows the monthly results for all of the simple and block charges.
- Ratchets – Shows the monthly results for all ratchets.
- Qualifies – Shows the monthly results for all qualifies.
- Native Variables – Shows the monthly values for the native variables such as TotalEnergy and TotalDemand.
- Other Variables – Shows the monthly values for any other variables not appearing in the other tables.
- Computation – Shows the computational steps used including those generated automatically.

The report is part of the tabular report and is created using the same style as specified for the tabular reports.

Complex Tariff Modeling

Much can be accomplished with the `UtilityCost:Charge:Simple` and `UtilityCost:Charge:Block` objects. In almost all cases, these structures are flexible enough to model the tariff. At times the built in approach is not sufficient to model a particular rate. In those cases, the rate may be modeled by using the `UtilityCost:Computation` object. For most rates this object can be omitted but for difficult to model rates, they may be used to modify the normal way the rate computation is performed.

Each `ComputeStep` is performed in order and can be either a variable followed by an expression or simply a variable.

- `demandMod SUM demand1 demand2`
- `chargeSummer1`

The normal calculations associated with the `UtilityCost:Qualify`, `UtilityCost:Charge:Simple`, `UtilityCost:Charge:Block`, or `UtilityCost:Ratchet` are performed the first time that object is called. Subsequent times are not recomputed but use the value stored in the appropriate variable. The result of the computation for those objects is available in the expression for further computation. The expressions allow the manipulation of variables directly using simple mathematical functions. Only variable names may be entered along with operators. Numbers may not be entered and should be entered with `UtilityCost:Variable`. Multiple operators are allowed per step. Variables names do not include spaces. If spaces are found in a variable name then an error is shown. Unused variables are flagged with a warning. All expressions are in the form:

- `assignedToVariable OPERATOR variable1 variable2`

Each step is performed for each of the months before the next step is taken. The same operation is performed for each step as specified.

The actual evaluation of the expression is performed from the end of the line to the beginning using stack based operations. Some operators pull all values from the stack (`SUM`, `MAXIMUM`, `MINIMUM`) while most use just one or two values from the stack. All operations return a single value to the stack. This stack based approach to expressions is sometimes called Polish Notation. While multiple operators are allowed per line, it reduces confusion if each line has only a single operator.

When the `UtilityCost:Computation` object is used, it must contain references to all objects involved in the rate in the order that they should be computed. No checking is performed for objects that should or should not be included; instead, the computational process is driven completely by the input of this object.

A typical rate will have a simple series of steps. For example F the following steps would be created automatically by the software:

```
UtilityCost:Computation,
SpecialStepsForF,          !- Name
ExampleF,                  !- Tariff Name
EnergyCharges SUM SummerOnPeak SummerOffPeak WinterOnPeak WinterOffPeak, Compute Step 1
Basis SUM EnergyCharges DemandCharges ServiceCharges, Compute Step 2
SubTotal SUM Basis Adjustments Surcharges, Compute Step 3
Total SUM SubTotal Taxes, Compute Step 4
MinDemand; Compute Step 5
```

This example does not have any dependency of different charges that are summed on the same line but if it did the charges could appear by themselves on lines and this would indicate the order that they should be computed. Here is the same example again showing that form.

```

UtilityCost:Computation,
SpecialStepsForF,          !- Name
ExampleF,                  !- Tariff Name
SummerOnPeak,              !- Compute Step 1
SummerOffPeak,             !- Compute Step 2
WinterOnPeak,              !- Compute Step 3
WinterOffPeak,            !- Compute Step 4
EnergyCharges SUM SummerOnPeak SummerOffPeak WinterOnPeak WinterOffPeak, !- Compute Step 5
Basis SUM EnergyCharges DemandCharges ServiceCharges, !- Compute Step 6
SubTotal SUM Basis Adjustments Surcharges, !- Compute Step 7
Total SUM SubTotal Taxes, !- Compute Step 8
MinDemand;                 !- Compute Step 9

```

This second expanded format is generated automatically when no UtilityCost:Computation object is provided.

The functions built in are (number of arguments in parentheses):

Operator: SUM (unlimited)

Adds together all of the variable values for each month for as many variables that are used.

Operator: ADD (2)

Adds together the first variable value with the second variable value.

Operator: MULTIPLY (2)

Multiplies the first variable value with the second variable value. MULT may also be used.

Operator: SUBTRACT (2)

Subtracts the second variable value from the first variable value. SUBT may also be used.

Operator: DIVIDE (2)

Divides the first variable value by the second variable value. DIV may also be used.

Operator: ABSOLUTE (1)

Takes the absolute value of the variable value. This turns negative values into positive ones. ABS may also be used.

Operator: INTEGER (1)

Removes non-integer portions of the variable values. INT may also be used.

Operator: SIGN (1)

Returns a 1 for positive values, -1 for negative values and 0 for zero values.

Operator: MAXIMUM (unlimited)

Selects the maximum value across variables for each of the months. Two or more variables may be used. MAX may also be used.

Operator: MINIMUM (unlimited)

Selects the minimum value across variables for each of the months. Two or more variables may be used. MIN may also be used.

Operator: EXCEEDS (2)

Returns the difference between the first and second variable if the first variable is greater than the second. If the second variable is greater or equal to the first variable returns a zero.

Operator: ANNUALMINIMUM (1)

Returns the minimum value of the twelve months in the variable. Zero values are ignored (see also ANNUALMINZERO). If all values are zero then zero is returned. ANMIN may also be used.

Operator: ANNUALMAXIMUM (1)

Returns the maximum value of the twelve months in the variable. Zero values are ignored (see also ANNUALMAXZERO). If all values are zero then zero is returned. ANMAX may also be used.

Operator: ANNUALSUM (1)

Returns the sum of the twelve months in the variable. ANSUM may also be used.

Operator: ANNUALAVERAGE (1)

Returns the sum of the twelve monthly values divided by the number of non-zero monthly values. If all values are zero then zero is returned. If an average is desired that includes zero valued elements the SUM() function should be used divided by 12. ANAVG may also be used.

Operator: ANNUALOR (1)

Returns 1 for all monthly values if any of the monthly values are non-zero. ANOR may also be used.

Operator: ANNUALAND (1)

Returns 1 for all monthly values if all of the monthly values are non-zero. ANAND may also be used.

Operator: ANNUALMAXIMUMZERO (1)

Returns the maximum value of the twelve monthly values in x. Zeros are counted so if a zero is the largest value (the rest would be negative) a zero may be returned. ANMAXZ may also be used.

Operator: ANNUALMINIMUMZERO (1)

Returns the minimum value of the twelve monthly values in x. Zeros are counted. ANMINZ may also be used.

Operator: IF (3)

Returns the value of the second variable if the first variable is non-zero otherwise returns the value of the third variable. Usually used with GT, GE, LT, LE, EQ, NE operators.

Operator: GREATERTHAN (2)

1 if the first variable value is greater than the second variable value otherwise 0. GT may also be used.

Operator: GREATEREQUAL (2)

1 if the first variable value is greater than or equal to the second variable value otherwise 0. GE may also be used.

Operator: LESSTHAN (2)

1 if the first variable value is less than the second variable value otherwise 0. LT may also be used.

Operator: LESSEQUAL (2)

1 if the first variable value is less than or equal to the second variable value otherwise 0. LE may also be used.

Operator: EQUAL (2)

1 if the first variable value is equal to the second variable value otherwise 0. EQ may also be used.

Operator: NOTEQUAL (2)

1 if the first variable value is not equal to the second variable value otherwise 0. NE may also be used.

Operator: AND (2)

1 if the first variable value and second variable values are both not zero otherwise 0.

Operator: OR (2)

1 if the first variable value and second variable values are either not zero, otherwise 0 if both the first and second variable value are both zero.

Operator: NOT (2)

1 if the first variable value and only variable value is zero otherwise 0 if the first variable value is not zero.

Operator: FROM (Unlimited)

Indicates what variables a variable is dependant on (or derived from). No computation is performed. The algorithm that creates the automatic sequence of equations uses these to indicate when variables are dependant on other variables so that they can be sorted into the correct order.

Cost Estimating

In order to understand how to include cost estimates, it may be helpful to first define some terminology and provide an overview of the process used in EnergyPlus. There are three broad steps involved. The first involves determining *construction* costs by summing individual "line items." The second involves determining *project* costs by adjusting construction costs to account for things like profit and design fees. The third involves comparing the current simulation to a reference case so that marginal increases can be calculated. Each of these steps involves using one of the three 'ComponentCost' objects described below.

ComponentCost:LineItem

Each instance of this object creates a cost line item and will contribute to the total for a cost estimate. Each line item is reported in table form in the tabular report file. The user must request that this report be generated by including a Output:Table:SummaryReports object with the Component Cost Economics Summary option selected. The style of a tabular report can be controlled using the OutputControl:Table:Style object.

Cost estimates are not currently general in that they cannot be performed for every type of component that could be included in an EnergyPlus model. Although a "General" option is available where all information needed for the cost line item is input by the user, the usefulness of cost modeling within EnergyPlus is expected to be enhanced when quantities are obtained from elsewhere in the input file or computed during a simulation. The cost computations are programmed in selected ways for selected objects. The objects available and the type of cost modeling that may be performed are discussed in detail in the discussion of Reference Object Type field. A particular instance of this object will always have many blank fields. Entering values in too many fields may cause an error because the program may determine how a particular cost is to be calculated based on the presence of non-zero values in particular fields. The input object includes fields that are reserved for future use in expanded cost estimate and investment analyses planned for future versions of EnergyPlus. If you would like to request additional objects or different methods of modeling component costs, feel free to describe your needs and submit a request via email to energyplus-support@gard.com.

Field: Name

This field is a user-selected name that will appear in the line item description of the cost report. It is not used in the calculation but allows identifying a line item in the subsequent report.

Field: Type

This field is not yet used and may be left blank.

Field: Line Item Type

The cost estimate line item calculation will be controlled by the name entered in this field. The requirements for the remaining input, and the cost calculations performed, will vary depending on the object referenced here. Only selected objects can be entered here. The objects available for cost estimating are listed in the following table showing the active fields and options available for each.

Object Types available (choice keys)	Cost per each	Cost per m ²	Cost per kW	Cost per kW *CO P	Cost per m ³	Cost per m ³ /s	Cost per W/K	Qty	Wildcar d for Name
General	X							X	
Construction		X							
Coil:DX Coil:Cooling:DX:SingleSpe ed	X		X	X					X
Chiller:Electric	X		X	X					
Coil:Heating:Gas	X		X	X					X
Daylighting:Controls	X								X
Shading:Zone:Detailed		X							
Lights	X		X						
Generator:Photovoltaic			X						

General

This choice of object is used to calculate costs in a general way. No quantities from internal calculations are used. All information needed for the cost line item is input by the user. The Cost per Each and the Quantity fields that follow need to have values.

Construction

This choice of object type is used to calculate the costs associated with surfaces based on the type of Construction used for the surface. Costs are entered on a per-square-meter basis. The program finds all the surfaces that have the type of Construction named in the Reference

Object Name field that follows and determines the total area. If the model includes duplicate surfaces, as for interior partitions or floors, these will be detected and not double-counted. The cost per area should include all the material layers defined in the Construction.

Coil:DX or Coil:Cooling:DX:SingleSpeed

This choice of object type is used to calculate the cost of direct expansion cooling equipment. Cost can be entered in three different ways, (1) per each, (2) per kW total cooling capacity, or (3) per kW total cooling capacity per COP (coefficient of performance). The program will determine which method to use by examining which input fields have non-zero values. It is an error to specify costs in more than one way. The per-each approach is most useful for discrete packages. The per-kW approach is useful for autosizing DX coils with the same COP. The per-kW-per-COP approach is convenient for modeling autosized DX coils with differing COPs as long as a linear relationship is sufficient.

The wildcard character "*" may be used in the object name field that follows to allow a single line item to include all of the DX coils in the model.

Chiller:Electric

This choice of object type is used to calculate the cost of a central chiller. The object name entered in following field must correspond to a Chiller:Electric object name defined elsewhere in the input file. Cost can be entered in three different ways, (1) per each, (2) per kW total cooling capacity or (3) per kW total cooling capacity per COP (coefficient of performance). The program will determine which method to use by examining which input fields have non-zero values. It is an error to specify costs in more than one way. The per-each approach is most useful for discrete chillers. The per-kW approach is useful for autosizing chillers with the same COP. The per-kW-per-COP approach is convenient for modeling autosized chillers with differing COPs as long as a linear relationship is sufficient.

Coil:Heating:Gas

This choice of object type is used to calculate the cost of gas-fired heating equipment. Cost can be entered in three different ways, (1) per each, (2) per kW of heating capacity, or (3) per kW total cooling capacity per nominal efficiency (actually uses the per kW per COP field). The program will determine which method to use by examining which input fields have non-zero values. It is an error to specify costs in more than one way. The per-each approach is most useful for discrete packages. The per-kW approach is useful for autosizing heating coils with the same efficiency. The per-kW-per-Eff approach is convenient for modeling autosized heating coils with differing efficiencies as long as a linear relationship is sufficient.

The wildcard character "*" may be used in the object name field that follows to allow a single line item to include all of the gas heating coils in the model.

Daylighting:Controls

These choices of object type are used to include the cost of controllers needed to control electric lighting in response to daylight. The only option for entering costs is "per each". The wildcard character "*" may be used in the following object name field to allow a single line item to include all of the simple and detailed daylighting controls in the cost model.

Shading:Zone:Detailed

This choice of object type is used to calculate the costs associated with attached shading surfaces. Costs are entered on a per-square-meter basis. The cost calculations are similar to those for heat transfer surfaces but are handled separately because "Construction" is not defined for a shading surface. The object name entered in the following field must correspond to a Shading:Zone:Detailed object name defined elsewhere in the input file.

Lights

This choice of object is used to calculate the costs associated with electric lighting. Costs are entered on either a cost-per-each basis or as a cost-per-kilowatt-of-design-level. (This design level is an input in the Lights object.). The object name entered into the following field must match the name of a Zone object defined elsewhere in the input file.

Generator:Photovoltaic

This choice of object is used to calculate the costs associated with a photovoltaic system. Costs are entered on a cost-per-kilowatt-of-rated-capacity. The rated capacity of a photovoltaic generator is calculated for cost modeling by exposing the surface to a 1000 W/m² incident radiation using the area fraction and nominal fixed efficiency input by the user (from the Generator:Photovoltaic object). The object name entered into the following field must match the name of a Generator:Photovoltaic object defined elsewhere in the input file.

Field: Item Name

This field is used to refer to a specific instance of an object. The wildcard character "*" is acceptable for some objects as described above for the previous field.

Field: Object End Use Key

This field is not yet used and may be left blank.

Field: Cost per Each

This field is used to enter cost information on a per-each basis. The units are dollars (\$).

Field: Cost per Area

This field is used to enter cost information on a per-area basis. The units are dollars per square meter (\$/m²).

Field: Cost per Unit of Output Capacity

This field is used to enter cost information on a per-kilowatt basis. The units are dollars per kilowatt (\$/kW).

Field: Cost per Unit of Output Capacity per COP

This field is used to enter cost information on a per-kilowatt-per-COP basis. The units are dollars per kilowatt per non-dimensional COP (\$/kW-COP). Note that this field can be used for Coil:Heating:Gas cost modeling in which case the better terminology would be per-kilowatt-per-non-dimensional-efficiency.

Field: Cost per Volume

This field is not yet used but will be used to enter cost information on a per-cubic-meter basis. The units are dollars per cubic meter (\$/m³).

Field: Cost per Volume Rate

This field is not yet used but will be used to enter cost information on a per-cubic-meter-per-second basis. The units are dollars per cubic meter (\$/(m³/s)).

Field: Cost per Energy per Temperature Difference

This field is not yet used but will be used to enter cost information on a per-watt-per-Kelvin basis. These units will be used to represent a UA description of coils and the like. The units are dollars per watt per delta K (\$/(W/K)).

Field: Quantity

This field is used to directly enter the line item quantity. The units should correspond to what is used in the Per Each field.

Field: Annual Operation, Maintenance and Repair Cost

This field is not yet used but will be used to enter annually recurring costs as fraction of the line item cost. This field is defined for future use with life-cycle cost analysis.

Field: Recurring Minor Maintenance or Repair Cost

This field is not yet used but will be used to enter recurring minor maintenance and repair costs as fraction of the line item cost. This field is defined for future use with life-cycle cost analysis.

Field: Recurring Minor Maintenance or Repair Time Interval

This field is not yet used but will be used to enter an interval for recurring minor maintenance and repair costs in years. This field is defined for future use with life-cycle cost analysis.

Field: Recurring Major Maintenance or Repair Cost

This field is not yet used but will be used to enter recurring major maintenance and repair costs as fraction of the line item cost. This field is defined for future use with life-cycle cost analysis.

Field: Recurring Major Maintenance or Repair Time Interval

This field is not yet used but will be used to enter an interval for recurring major maintenance and repair costs in years. This field is defined for future use with life-cycle cost analysis.

Field: Expected Life

This field is not yet used but will be used to enter the expected life of the line item component in years. This field is defined for future use with life-cycle cost analysis.

Field: Residual Value at Replacement

This field is not yet used but will be used to enter the remaining value of the item at the end of its expected life. This field is defined for future use with life-cycle cost analysis.

ComponentCost:Adjustments

This object can be used to perform various modifications to the construction costs to arrive at an estimate for total project costs. This object allows extending the line item model so that the overall costs of the project will reflect various profit and fees. Only one object of this type can be included in the input file. The results are included in the Construction Cost Estimate Summary table by request using the Output:Table:SummaryReports object with the Component Cost Economics Summary option selected.

Field: Miscellaneous Cost per Conditioned Area

This optional field can be used to enter a cost model for miscellaneous project costs that are not included in the line item modeling. Miscellaneous costs are entered in dollars per square meter of conditioned floor area. This field allows including the costs of project elements that go beyond what can be modeled using “ComponentCost:LineItem” input objects including such things as structural components, site preparation, finishes, etc. The value input in this field will be multiplied by the conditioned floor area and listed in the Construction Cost Estimate Summary table. The miscellaneous project costs are added to the line item model total to determine the “modeled and miscellaneous Construction costs” that will be multiplied by the fractions in the following five fields.

Field: Design and Engineering Fees

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for design and engineering fees. Note that is not the same as a fraction of the total cost estimate.

Field: Contractor Fee

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for Contractor fees. Note that is not the same as a fraction of the total cost estimate.

Field: Contingency

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added for contingency. Note that is not the same as a fraction of the total cost estimate.

Field: Permits, Bonding and Insurance

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for permitting, bonding, and insurance costs to the project. Note that is not the same as a fraction of the total cost estimate.

Field: Commissioning Fee

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for commissioning services. Note that is not the same as a fraction of the total cost estimate.

Field: Regional Adjustment Factor

This optional field can be used to enter an adjustment factor to account for regional differences in construction costs. The factor will be applied to the modeled and miscellaneous construction costs to determine an amount that should be added, or subtracted, to account for local variations in construction costs. The default factor is 1.0. The additive adjustment is calculated by subtracting 1.0 from the value entered in this field. This field is useful for using national average data in the line item and miscellaneous construction cost models and then altering the results based on regional differences.

The IDD specification:

```

ComponentCost:Adjustments,
  N1 ,\field Miscellaneous Cost per Conditioned Area

  0.015, !- Commissioning Fee
  1.136; !- Regional Adjustment Factor

```

ComponentCost:Reference

This object can be used to allow comparing the current cost estimate to the results of a previous estimate for a reference building. This object parallels the ComponentCost:Reference object but adds a field for entering the cost line item model result for the reference building. All the various adjustments to the project cost estimate are available here to allow using factors that differ between the current and the reference building models. The factors entered in the field associated with this object are applied to the reference building while the factors listed in the ComponentCost:Reference object are applied to the current building model cost estimate. Only one object of this type can be included in the input file. The results are included in the Construction Cost Estimate Summary table by request using the Output:Table:SummaryReports object with the Component Cost Economics Summary option selected.

Field: Reference Building Line Item Costs

This field is used to enter a dollar amount representing the total for the reference building that the user would like to compare to the line item cost model for the current building model. A typical source of data for this would be the "Line Item Subtotal" from a previous EnergyPlus simulation.

Field: Reference Building Miscellaneous Cost per Conditioned Area

This optional field can be used to enter a cost model for miscellaneous project costs that are not included in the line item modeling. Miscellaneous costs are entered in dollars per square meter of conditioned floor area. This field allows including the costs of project elements that

go beyond what can be modeled using “ComponentCost:LineItem” input objects including such things as structural components, site preparation, finishes, etc. The value input in this field will be multiplied by the conditioned floor area and listed in the Construction Cost Estimate Summary table. The miscellaneous project costs are added to the reference building line item subtotal to determine the “modeled and miscellaneous construction costs” that will be multiplied by the fractions in the following five fields.

Field: Reference Building Design and Engineering Fees

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for design and engineering fees. Note that is not the same as a fraction of the total cost estimate.

Field: Reference Building Contractor Fee

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for Contractor fees. Note that is not the same as a fraction of the total cost estimate.

Field: Reference Building Contingency

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added for contingency. Note that is not the same as a fraction of the total cost estimate.

Field: Reference Building Permits, Bonding and Insurance

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for permitting, bonding, and insurance costs to the project. Note that is not the same as a fraction of the total cost estimate.

Field: Reference Building Commissioning Fee

This optional field can be used to enter a fraction of modeled and miscellaneous construction costs that should be added to account for commissioning services. Note that is not the same as a fraction of the total cost estimate.

Field: Reference Building Regional Adjustment Factor

This optional field can be used to enter an adjustment factor to account for regional differences in construction costs. The factor will be applied to the modeled and miscellaneous construction costs to determine an amount that should be added, or subtracted, to account for local variations in construction costs. The default factor is 1.0. The additive adjustment is calculated by subtracting 1.0 from the value entered in this field. This field is useful for using national average data in the line item and miscellaneous construction cost models and then altering the results based on regional differences.

The IDD specification:

```

Economics Cost Estimate Reporting

Cost estimate results are only output to tabular reports; they are not available in the standard output file (.eso). The results are included in the Construction Cost Estimate Summary table by request using the object Output:Table:SummaryReports object with the Component Cost Economics Summary option selected. The figure below shows an example of summary output using html style for tabular reporting. A second table is produced that provides the line item details with one line for every line item object. Per-area cost modeling and cost normalization are based on total conditioned floor area which is also provided in the tabular report.

Construction Cost Estimate Summary

	Reference Bldg.	Current Bldg. Model	Difference
Line Item SubTotal (\$)	665082.04	718282.97	53200.93
Misc. Costs (\$)	928979.09	928979.09	0.00
Regional Adjustment (\$)	216792.31	224027.64	7235.33
Design Fee (\$)	95643.67	131780.97	36137.30
Contractor Fee (\$)	111584.28	115308.34	3724.07
Contingency (\$)	159406.11	164726.21	5320.09
Permits, Bonds, Insurance (\$)	0.00	0.00	0.00
Commissioning (\$)	7970.31	16472.62	8502.31
Cost Estimate Total (\$)	2185457.81	2299577.84	114120.03
Cost Per Conditioned Building Area (\$/m ²)	1176.27	1237.69	61.42

Difference = Current value - Reference Value

Reference Case information input by user (typ. from previous model)

Current information calculated for model

Sub total of line items

Construction Cost = sum of three terms

Adjustment fractions applied to Construction Cost

Project Cost = sum of eight terms

Normalized Project Cost = Project Cost divided by conditioned floor area

Figure 133. Economics Cost Modeling

“Line Item Subtotal” is the sum of items explicitly modeled in the cost estimate. For the reference building, this value is input by the user. For the current building, this value is the sum of line items which are detailed in Cost Line Item Details table that follows.

“Misc. Cost” is the product of the user-defined Miscellaneous Cost Model (per Square Meter) and the conditioned floor area.

“Regional Adjustment” is the produce of the user-defined Regional Adjustment Factor and the conditioned floor area.

“Design Fee” is the product of the user-defined Design and Engineering Fee Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Contractor Fee” is the product of the user-defined Contractor Fee Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Contingency” is the product of the user-defined Contingency Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Permits, Bonds, and Insurance” is the product of the Permits, Bonding, Insurance Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Commissioning” is the product of the user-defined Commissioning Fee Fraction and the subtotal for construction costs (which includes the Line Item Subtotal, Misc. Cost, and Regional Adjustment).

“Cost Estimate Total” is the sum of eight items above and represents the total project cost estimate.

“Cost per Conditioned Building Area” is the Cost Estimate Total divided by the total conditioned floor area. This represents a normalized cost intensity.

CurrencyType

By default, the predefined reports related to economics use the \$ symbol. If a different symbol should be shown in the predefined reports to represent the local currency this object can be used. If the object is not used, the \$ sign is used in the reports. Only one CurrencyType object is allowed in the input file.

Field: Monetary Unit

The commonly used three letter currency code for the units of money for the country or region. Based on ISO 4217 currency codes. Common currency codes are USD for the U.S. Dollar represented with ‘\$’ and EUR for Euros represented with ‘€’. The three letter currency codes can be seen at the following web sites (as of 2008):

http://www.iso.org/iso/support/faqs/faqs_widely_used_standards/widely_used_standards_other/currency_codes/currency_codes_list-1.htm

<http://www.xe.com/symbols.php>

When a three letter currency code is specified, the HTML file will use either an ASCII character if available or one or more UNICODE characters. Since not all browsers and all fonts used by browsers completely support UNICODE, not all currency symbols may be rendered correctly. If a box or a box with four small letters appears, this indicates that the browser and its fonts do not support a specific UNICODE character.

For text reports, an ASCII representation of the currency code will be used. Since ASCII is much more limited than UNICODE, many times the three letter currency code will be shown in the reports.

Since forms of currency change, please contact EnergyPlus support if a new currency code and symbol are needed.

Input for Output

Several items are used to specify what will appear in the output file(s). The output is described in the next section of this document.

Group – Reports

Variable Dictionary Reports

One of the most important outputs for EnergyPlus is the Variable Dictionary reports – these contain the key variable names for each simulation. This single input object is used to produce two important reports that are used to identify the specific report variables and meters available for a specific EnergyPlus model. Two output files are produced (**eplusout.rdd** & **eplusout.mdd**) that list the names of the report variables and meters for that simulation. You may need to run your simulation once and produce these files before you ask for specific output variables (**rdd**) or meters (**mdd**) (see Output:Variable and Output:Meter). Variables available, to some extent, depend on the simulation input. Variables are “set up” during the initial “get input” processing done within the modules. Therefore, an item that is specific to a certain type of coil would not be available if that coil were not used during the simulation. This command will produce a list of variables available for reporting.

In addition to the variable names, the reports provide information on the frequency and nature of the variables. “**Zone**” variables are calculated and can be reported after each Zone/Heat Balance timestep (ref: Timesteps input object). “**HVAC**” variables are calculated and can be reported with each variable HVAC timestep. “Average” variables will be averaged over the time interval being reported whereas “Sum” variables are summed over that time interval. The units of the variable are given in “[].”

In addition, the reports can be produced as IDF excerpts and also sorted by name.

An example input object for this report follows.

```
Output:VariableDictionary, regular;
```

An example of the results:

```

Program Version,EnergyPlus <version number>, <date of run>,IDD_Version <IDD Version>

HVAC,Sum,Zone Mechanical Ventilation Total Mass of Outside Air [kg]
HVAC,Average,Zone Mechanical Ventilation Air Change Rate [ach]

```

The eplusout.mdd file has a similar format for meters:

```
Program Version,EnergyPlus <version>, <date time of run>,IDD_Version <IDD Version>
Var Type (reported timestep),Var Report Type,Variable Name [Units]
Zone,Meter,Electricity:Facility [J]
Zone,Meter,Electricity:Building [J]
Zone,Meter,Electricity:Zone:SOUTHZONE_1STFLOOR [J]
Zone,Meter,InteriorLights:Electricity [J]
Zone,Meter,InteriorLights:Electricity:Zone:SOUTHZONE_1STFLOOR [J]
Zone,Meter,GeneralLights:InteriorLights:Electricity [J]
<reduced>
```

Variable Dictionary Report in IDF Format

The common workflow process of examining Variable Dictionary Reports and then adding reporting requests to an IDF file can be facilitated by using the following alternate form (Report Name = IDF) of the input object that requests the reports.

```
Output:VariableDictionary, IDF;
```

This report produces the variable names in a form that are ready to be merged into an input file. By design, hourly reporting is selected – replace this with your desired frequency. An example of the results, first the eplusout.rdd:

```
! Program Version,EnergyPlus <version>, <date time of run>,IDD_Version <IDD Version>
! Report Variable Objects (applicable to this run)
Report Variable,*,Outdoor Dry Bulb,hourly; !- Zone Average [C]
Report Variable,*,Outdoor Dew Point,hourly; !- Zone Average [C]
Report Variable,*,Outdoor Wet Bulb,hourly; !- Zone Average [C]
Report Variable,*,Outdoor Humidity Ratio,hourly; !- Zone Average [kgWater/kgAir]
Report Variable,*,Outdoor Relative Humidity,hourly; !- Zone Average [%]
Report Variable,*,Outdoor Barometric Pressure,hourly; !- Zone Average [Pa]
Report Variable,*,Wind Speed,hourly; !- Zone Average [m/s]
<reduced>
```

Then, eplusout.mdd (includes reporting for cumulative meters as well as normal reporting):

```
! Program Version,EnergyPlus <version>, <date time of run>,IDD_Version <IDD Version>
! Report Meter Objects (applicable to this run)
Report Meter,Electricity:Facility,hourly; !- [J]
Report Cumulative Meter,Electricity:Facility,hourly; !- [J]
Report Meter,Electricity:Building,hourly; !- [J]
Report Cumulative Meter,Electricity:Building,hourly; !- [J]
Report Meter,Electricity:Zone:SOUTHZONE_1STFLOOR,hourly; !- [J]
Report Cumulative Meter,Electricity:Zone:SOUTHZONE_1STFLOOR,hourly; !- [J]
Report Meter,InteriorLights:Electricity,hourly; !- [J]
Report Cumulative Meter,InteriorLights:Electricity,hourly; !- [J]
<reduced>
```

A sorted list would appear similarly:

```
Program Version,EnergyPlus <version number>, <date of run>,IDD_Version <IDD Version>
Var Type (reported timestep),Var Report Type,Variable Name [Units]
Zone,Average,Deep Ground Temperature [C]
Zone,Average,Diffuse Solar [W/m2]
Zone,Average,Direct Solar [W/m2]
Zone,Average,Exterior Beam Normal Illuminance [lux]
Zone,Average,Exterior Horizontal Beam Illuminance [lux]
Zone,Average,Exterior Horizontal Illuminance From Sky [lux]
Zone,Average,Fraction of Time Raining[]
Zone,Average,Fraction of Time Snow On Ground[]
Zone,Average,Ground Reflected Solar [W/m2]
Zone,Average,Ground Temperature [C]
```

```

Zone,Average,Outdoor Air Density [kg/m3]
Zone,Average,Outdoor Barometric Pressure [Pa]
Zone,Average,Outdoor Dew Point [C]
Zone,Average,Outdoor Dry Bulb [C]
Zone,Average,Outdoor Enthalpy [J/kg]
Zone,Average,Outdoor Humidity Ratio [kgWater/kgAir]
Zone,Average,Outdoor Relative Humidity [%]
Zone,Average,Outdoor Wet Bulb [C]
Zone,Average,Skylight Temperature [C]
Zone,Average,Solar Altitude Angle [deg]
Zone,Average,Solar Azimuth Angle [deg]
Zone,Average,Solar Hour Angle [deg]
Zone,Average,Surface Ground Temperature [C]
Zone,Average,Wind Direction [deg]
Zone,Average,Wind Speed [m/s]

```

The IDD for the object:

```

Output:VariableDictionary,
  A1, \field Key Field
  \required-field
  \type choice
  \key IDF
  \key regular
  A2; \field Sort Option
  \type choice
  \key Name
  \key Unsorted

```

Surface Reports

There are two specific objects for surfaces: Output:Surfaces:List and Output:Surfaces:Drawing – as the names imply, the list reports are simple text reports that are contained in one of the output files whereas the drawing reports will create files that are used in other graphic tools.

Information on surfaces in the EnergyPlus model can be reported in several ways:

Output:Surfaces:List

Lines Data Report

An example input object for this report follows.

```
Output:Surfaces:List, Lines;
```

The above IDF line will produce a simple file of line segments that constitute the surfaces in the IDF file. More specifics on this report can be found in the Output Details and Examples document.

The following shows an excerpt of “lines” report (**eplusout.sln**) for a single surface. It gives the coordinates in the “standard” EnergyPlus fashion (that is, UpperLeftCorner first and proceeding around, in this case, the four vertices in the surface).

```

0.00, 0.00, 4.57, 0.00, 0.00, 0.00
0.00, 0.00, 0.00, 15.24, 0.00, 0.00
15.24, 0.00, 0.00, 15.24, 0.00, 4.57
15.24, 0.00, 4.57, 0.00, 0.00, 4.57

```

Field: Report Specifications

An extra option of entering “IDF” in this field directs the Lines report to produce coordinates transformed into Surface Geometry (Lower Left Corner, CounterClockwise, WorldCoordinates). An example of this follows.

```
Output:Surfaces:List, Lines, IDF;
```

The result is put on the **eplusout.sln** file and is nearly ready for putting into a IDF:

```

Building North Axis = 0
GlobalGeometryRules,UpperLeftCorner,CounterClockwise,WorldCoordinates;
Surface=SHADING, Name=ROOMSOUTH SURF6-VFIN1-6
  4, !- Number of (X,Y,Z) groups in this surface

```

Detailed Surface Data Report

An example input object for this report follows.

```
Output:Surfaces:List, Details;
```

This report (in **eplusout.eio**) contains details about each surface – including surface name, associated zone, area, approximate height and width, tilt, outward facing angle. Specific details on this report can be found in the Output Details and Examples document.

Vertices Data Report

An example input object for this report follows.

```
Output:Surfaces:List, Vertices;
```

This report (in **eplusout.eio**) contains the vertices of each surface along with surface name and other information. Specific details on this report can be found in the Output Details and Examples document.

Detailed Surface Data With Vertices Report

An example input object for this report follows.

```
Output:Surfaces:List, DetailsWithVertices;
```

This report (in **eplusout.eio**) is the combination of the two preceding reports (Details and Vertices). Specific details on this report can be found in the Output Details and Examples document.

View Factor Information Report

An example input object for this report follows.

```
Output:Surfaces:List, ViewFactorInfo;
```

This report (in **eplusout.eio**) provides details about the thermal radiation exchange view factors and interchange factors. Specific details on this report can be found in the Output Details and Examples document.

These data reports are illustrated by the following IDD reference:

```

Output:Surfaces:List,
  A1, \field Report Type
  \required-field
  \type choice
  \key Details
  \key Vertices
  \key DetailsWithVertices
  \key ViewFactorInfo
  \key Lines
A2; Report Specifications
  \note (IDF, only for Surfaces, Lines report -- will print transformed coordinates in IDF style)
  \type choice
  \key IDF

```

Output:Surfaces:Drawing

DXF Surface Report

Examples input objects follow.

```

Output:Surfaces:Drawing, DXF;
Output:Surfaces:Drawing, DXF, RegularPolyline;
Output:Surfaces:Drawing, DXF, Triangulate3DFace, mycolorscheme;

```

The above IDF specification will produce a DXF file (**eplusout.dxf**) of the surfaces in the IDF file. Only one DXF report can be produced. More specifics on this report can be found in the Output Details and Examples document.

Field: Report Specifications 1

As indicated in the example and in the IDD excerpt, you can select among three different ways that surfaces with more than four sides will appear in the DXF file. These are:

- ThickPolyline – surface with >4 sides will be represented as a “thick” line in the appropriate surface color. It will look like a hole in the drawing with a thicker edge.
- RegularPolyline – surface with >4 sides will be represented as a regular line in the appropriate surface color. It will look like a hole in the drawing.
- Triangulate3DFace– surface with >4 sides will be “triangulated” internally within EnergyPlus. This is only for drawing purposes and does not affect the calculations in any way. In a line version of the DXF, it will appear that the surface is split into triangles. In a solid view, the surface will appear similar to surfaces with <=4 sides. The triangulation algorithm is not perfect and warnings do result when the software cannot triangulate the surface.

Field: Report Specifications 2

This field can be used to control the color scheme in the DXF file by entering the name of an OutputControl:SurfaceColorScheme object. Using OutputControl:SurfaceColorScheme, you can define color schemes for surface representation. This feature will let you align the colors with the software of your choice (colors don’t seem to be standard across DXF viewers).

Several software programs can render this file into something viewable. For example:

Figure 134. Example building from DXF report.

DXF Wire Frame Report

An example input object for this report follows.

```
Output:Surfaces:Drawing, DXF:WireFrame;
```

The above IDF specification will produce a DXF (Drawing Exchange Format) file (**eplusout.dxf**) of the surfaces in the IDF file using the DXF “Lines” command – producing only a wire frame capable file. More specifics on this report can be found in the Output Details and Examples document. Only one DXF report can be produced.

VRML Report

Examples input objects for this report follow.

```
Output:Surfaces:Drawing, VRML;
Output:Surfaces:Drawing, VRML, Triangulate3DFace;
```

The above IDF specification produces a VRML (Virtual Reality Modeling Language) file (**eplusout.wrl**) of the surfaces in the IDF file. Only one VRML report can be produced. VRML files can be viewed in many web browsers after adding a “plug-in” and there are some stand-alone viewers as well. More specifics on this report can be found in the Output Details and Examples document.

Field: Report Specifications 1

As indicated in the example and in the IDD excerpt, you can select several figure types (for >4 sided surfaces) in the DXF report. These are:

- ThickPolyline – surface with >4 sides will be represented as a “thick” line in the appropriate surface color. It will look like a hole in the drawing with a thicker edge.
- RegularPolyline – surface with >4 sides will be represented as a regular line in the appropriate surface color. It will look like a hole in the drawing.
- Triangulate3DFace – surface with >4 sides will be “triangulated” internally within EnergyPlus. This is only for drawing purposes and does not affect the calculations in any way. In a line version of the VRML, it will appear that the surface is split into triangles. In a solid view, the surface will appear similar to surfaces with <=4 sides. The triangulation algorithm is not perfect and warnings do result when the software cannot triangulate the surface.

Field: Report Specifications 2

Color schemes are not applicable for VRML reports.

The drawing reports are illustrated by the following IDD reference:

```

Output:Surfaces:Drawing,
  A1, \field Report Type
  \required-field
  \type choice
  \key DXF
  \key DXF:WireFrame
  \key VRML
  A2, \field Report Specifications 1

  \key RegularPolyline
  \key Lines
  \key Polylines
  A3 ; \field Report Specifications 2
      \note Use ColorScheme Name for DXF reports
      \object-list ColorSchemes

```

Output:Schedules

This is a condensed reporting that illustrates the full range of schedule values – in the style of input: DaySchedule, WeekSchedule, and Annual Schedule.

Field: Key Field

This field should contain the word **Hourly** or **TimeStep** to obtain the respective reports.

```

Output:Schedules, Hourly; ! values on hourly increments (day schedule resolution)
Output:Schedules, TimeStep; ! will give them at the timestep of the simulation

```

This report is placed on the eplusout.eio file. Details of this reporting are shown in the Output Details and Examples document. Schedule values over time can also be obtained in the EnergyPlus Standard Output (in eplusout.eso) using Output:Variable objects.

The IDD for the object is:

```

Output:Schedules,
  A1; \field Key Field
  \required-field
  \type choice
  \key Hourly
  \key Timestep

```

Output:Constructions

Constructions Report

This report content is added to the “eplusout.eio” file. It shows the calculated results related to conduction transfer functions for each construction. It also includes similar details about the windows. Specific details on this report can be found in the Output Details and Examples document. The following input object is used to obtain the Construction report.

```

Output:Constructions,Construction;

```

Field: Details Type 1, Details Type 2

Either field can contain the word “**Constructions**” to get the constructions report.

Or either field can contain the word “**Materials**” to obtain the Materials report.

Materials Report

This report content is added to the “eplusout.eio” file. It provides a summary of the thermal properties and thickness of the construction and window materials in the model. Specific details on this report can be found in the Output Details and Examples document. The following input object is used to obtain the Materials report.

```

Output:Reports,Materials;

```

The IDD for the object:

```

Output:Constructions,
  A1, \field Details Type 1
      \type choice
      \key Constructions
      \key Materials
  A2; \field Details Type 2
      \type choice
      \key Constructions
      \key Materials

```

OutputControl:SurfaceColorScheme

This object provides control over the colors that appear in the DXF report, by surface. In addition, the Datasets folder contains example objects, including the “original” color scheme (prior to the 2.1 release).

```

OutputControl:SurfaceColorScheme,
  \memo This object is used to set colors for reporting on various building elements particularly for the
  \memo DXF reports. We know the user can enter 0 to 255 and the color map is available in DXF output
  \memo as well as Google Sketchup. Therefore, we are limiting the colors in that range. You can
  \memo extend by editing the IDD but you do so on your own. Colors not changed in any scheme will
  \memo remain as the default scheme uses.
  A1, \field Name
      \required-field
      \note choose a name or use one of the DataSets
      \reference ColorSchemes
  A2, \field Drawing Element 1 Type
      \type choice
      \key Text
      \key Walls
      \key Windows
      \key GlassDoors
      \key Doors
      \key Roofs
      \key Floors
      \key DetachedBuildingShades
      \key DetachedFixedShades
      \key AttachedBuildingShades
      \key Photovoltaics
      \key TubularDaylightDomes
      \key TubularDaylightDiffusers
      \key DaylightReferencePoint1
      \key DaylightReferencePoint2
  N1, \field Color for Drawing Element 1
      \note use color number for output assignment (e.g. DXF)
      \type integer
      \minimum 0
      \maximum 255

  N15; \field Color for Drawing Element 15
      \note use color number for output assignment (e.g. DXF)
      \type integer
      \minimum 0
      \maximum 255

```

Field: Name

This assigns a unique name to this colorscheme data set. This name is used in the DXF output objects.

Field Set: Drawing Element Type and Color

This set of fields can range from none (accepting the default colors) up to 15 sets with individual types of building elements assigned a color number. (drawing element types not assigned a color number will use the default color numbers)

Field: Drawing Element <#> Type

This field uses a choice of the drawing types (Text, Walls, Windows, GlassDoors, Doors, Roofs, Floors, DetachedBuildingShades, DetachedFixedShades, AttachedBuildingShades, Photovoltaics, TubularDaylightDomes, TubularDaylightDiffusers, DaylightReferencePoint1, DaylightReferencePoint2) for the color number assignment in the following field.

Field: Color for Drawing Element <#>

This is a color “number” from 0 to 255. DXF display software is not standardized – you may need to play around with these numbers if you don’t like the supplied default color scheme.

Output:Variable

This input object is used request results reporting. As shown above in the Variable Dictionary Report section, there are many different output variables available for reporting results from EnergyPlus. The Output:Variable object is primarily used for reporting time series data at various frequencys.

```
Output:Variable,
  \memo each Report Variable command picks variables to be put onto the standard output file (.eso)
  \memo some variables may not be reported for every simulation
  \format singleLine
A1 , \field Key Value
  \default *
  \note use '*' (without quotes) to apply this variable to all keys
A2 , \field Variable Name
  \required-field
  \type object-list
  \object-list autoRDDvariable
A3 , \field Reporting Frequency
  \type choice
  \key Detailed
  \note Detailed lists every instance (i.e. HVAC variable timesteps)
  \key Timestep
  \note Timestep refers to the zone Timestep/Timestep in hour value
  \note RunPeriod, Environment, and Annual are the same
  \key Hourly
  \key Daily
  \key Monthly
  \key RunPeriod
  \key Environment
  \key Annual
  \note RunPeriod, Environment, and Annual are synonymous
A4 ; \field Schedule Name
  \type object-list
  \object-list ScheduleNames
```

Each Output:Variable object causes a specific number assignment for outputs. For example, you could request separate reporting for the outside temperature:

```
Output:Variable,*,outdoor dry bulb,timestep;
Output:Variable,*,outdoor dry bulb,hourly;
Output:Variable,*,outdoor dry bulb,monthly;
```

And the following would appear in the standard output file:

```
6,2,Environment,Outdoor Dry Bulb [C] !TimeStep
7,2,Environment,Outdoor Dry Bulb [C] !Hourly
8,2,Environment,Outdoor Dry Bulb [C] !Monthly [Value,Min,Day,Hour,Minute,Max,Day,Hour,Minute]
```

Item # 6 will be listed following the TimeStep timestamp for each timestep. Item #7 will be listed following an hourly timestamp. And item #8 will be listed following a monthly timestamp and has additional fields (because it is an “average” variable) that show the minimum and maximum values with identifying times for those minimum and maximum. An excerpt will illustrate:

```
2, 1, 7,21, 0, 1, 0.00,15.00,Monday - timestep timestamp
6,17.08889
```

```

48,21.39851
49,0.0000000E+00
53,0.0000000E+00
60,21.87214
    2, 1, 7,21, 0, 1, 0.00,60.00,Monday - hourly timestamp
7,16.75555
    4, 1, 7 - monthly timestamp
8,22.77037,15.00000,21, 4,60,32.77778,21,14,60

```

To interpret, the first value (#6) is 17.09 C, #7 is 16.76 C (average for the hour), and #8 is 22.77 C, the average for the month with the low (minimum) of 15 C occurring on 7/21 4:60 (or 5:00) and the high (maximum) occurring on 7/21 14:60 (or 15:00).

Field: Key Value

This alpha field can be used to make a specific reference for reporting. In addition to the generic variable names listed in the Variable Dictionary Report for the input file, variables will also have a key designator (such as Zone name or Surface name). You can reference the standard output file (**eplusout.eso**) to see just how these look.

```

41,2,ZN001:WALL004,Surface Inside Temperature[C]
42,2,ZN001:WALL004,Surface Outside Temperature[C]
43,2,ZN001:WALL004,Surface Int Convection Coeff[W/m2-K]
44,2,ZN001:WALL004,Surface Ext Convection Coeff[W/m2-K]
46,2,ZONE ONE,Mean Radiant Temperature[C]
47,2,ZONE ONE,Zone-Total Latent Gain[J]
51,2,ZONE ONE,Zone-Total Electric Consumption[J]
58,2,ZONE ONE,Zone/Sys Air Temp[C]

```

For example, in the previous block, the key for the surface variables is **ZN001:WALL004** whereas the key for the zone variables is **ZONE ONE** (note that the space is required and significant for this key).

You can have all keys listed in the standard output file by putting a “*” in this field or you can have specific items listed by putting in a key value.

Field: Variable Name

This alpha field is the variable name (you don’t have to put on the units) that is shown in the Variable Dictionary Report file (eplusout.rdd).

Field: Reporting Frequency

This field specifies how often the variable will be listed in the output file. “**Detailed**” will list the value each calculation step (i.e. Zone or HVAC). “**Timestep**” will be the same as “Detailed” for Zone valued variables and will be aggregated to the Zone timestep (i.e. Timestep in Hour value) for HVAC variables. “**Hourly**” will aggregate the value to the hour. “**Daily**” will aggregate to the day (i.e. one value per day). “**Monthly**” will aggregate to the month (i.e. one value per month). “**RunPeriod**” will aggregate to the runperiod specified (each Design Day is a runperiod as is each runperiod object).

Field: Schedule Name

The final field is a schedule name. This can be used to limit the number of lines that appear in your output file. For example, a schedule such as “ON PEAK” or “OFF PEAK” could provide a slice of values. Or, a seasonal schedule could be devised. The report variable will be active during any hour in which the schedule value is >0. For daily, monthly, and environment reporting frequencies, the aggregate value will be only for active schedule hours. Summed variables will report the sum for the active hours only. Averaged variables will report the average during the active hours only. If Schedule_Name is omitted, the report variable will be active for all hours.

Other IDF examples:

```
Output:Variable, * , Mean Air Temperature, hourly;
Output:Variable, * , Mean Radiant Temperature, timestep;
Output:Variable, * , Zone/Sys Sensible Heating Energy, hourly;
Output:Variable, * , Zone/Sys Sensible Cooling Energy, hourly;
Output:Variable, * , Zone/Sys Air Temp, hourly;
```

Output:Meter and Output:Meter:MeterFileOnly

Appropriate variables are grouped onto “meters” for reporting purposes. (The meters available are listed in the eplusout.mdd file, see Variable Dictionary Report section.) If the “Output:Meter” input object is used, these results written out to both the **eplusout.eso** and **eplusout.mtr** files. This allows easy graphing and comparison with “normal” values (such as Zone Temperature or Outdoor Temperature). If the “Output:Meter:MeterFileOnly” input object is used, then the values results written out to only the **eplusout.mtr** file. The **eplusout.mtr** file has the same structure as the **eplusout.eso** file. A companion file, the **eplusout.mtd** file, contains a detailed list and explanation of all meters for a given run and the component values that are accumulated on each meter.

Field: Name

Meter names applicable for the simulation are shown on the Variable Dictionary Report contained in the eplusout.mdd file described above. A snippet from that file will illustrate:

```
Zone,Meter,Electricity:Facility [J]
Zone,Meter,Electricity:Building [J]
Zone,Meter,Electricity:Zone:RESISTIVE ZONE [J]
Zone,Meter,Electricity:Zone:EAST ZONE [J]
Zone,Meter,Electricity:Zone:NORTH ZONE [J]
Zone,Meter,InteriorLights:Electricity [J]
Zone,Meter,InteriorLights:Electricity:Zone:RESISTIVE ZONE [J]
Zone,Meter,InteriorLights:Electricity:Zone:EAST ZONE [J]
Zone,Meter,InteriorLights:Electricity:Zone:NORTH ZONE [J]
```

Meter names are of three forms:

<ResourceType>:<name>

Or

<EndUseType>:<ResourceType>:<name>

Or

<EndUseSubcategory>:<EndUseType>:<ResourceType>:<name>.

The user requests reporting by either specifying the full name above (without Units) or a “wildcard” representation of that name (to obtain all meters of a type). For example, entering “Electricity:*” for the meter name will report on all the Electricity: meters (Electricity:Facility, Electricity:Building, Electricity:Zone:Resistive Zone, Electricity:Zone:East Zone, Electricity:North Zone in the example above). Both the resource types and end-use types are set within the program by the developers. End-use subcategories are user-defined and are an input field for certain objects. Current resource types are shown in the table below:

Table 33. Table of Metered Resource Types

Utility/Fuel Types
Electricity
Gas
Gasoline
Diesel
Coal
FuelOil#1
FuelOil#2
Propane
Water

Steam
DistrictCooling
DistrictHeating

Other Resource Types
EnergyTransfer

The end use types are shown in the following table (note that certain end use types apply only to the EnergyTransfer resource):

Table 34. End Use Category Types

Utility/Fuel End Use Types
InteriorLights
ExteriorLights
InteriorEquipment
ExteriorEquipment
Fans
Pumps
Heating
Cooling
HeatRejection
Humidifier
HeatRecovery
DHW
Cogeneration
Refrigeration
Miscellaneous

Additional End Use Types Only Used for EnergyTransfer
HeatingCoils
CoolingCoils
Chillers
Boilers
Baseboard
HeatRecoveryForCooling
HeatRecoveryForHeating

Specific meter types are then used for grouping the fuel type meters:

Table 35. Overall Meter Types

Meters
Facility
Building
Zone
System
Plant

Facility meters contain all the energy of a fuel type. Building meters contain the sum of each zone's energy. System meters contain the energy from the system components. Plant meters contain the energy from the plant equipments.

Thus, the following relationships should be observed:

$$Facility = \sum (Building + System + Plant + Exterior)$$

$$Building = \sum_1^{NumberOfZones} Zone$$

Further descriptions of Metering is contained in the "Getting Started" document.

Field: Reporting Frequency

Similar to the report variables, meters can be reported at different frequencies. Their resolution is the Zone Timestep interval (Number of Timesteps input). For this frequency, the elemental value of the meter will be reported. For more inclusive frequencies, the summed value along with the maximum and minimum values for the time interval will be reported.

The IDD definition for the Output:Meter object follows.

```
Output:Meter,
  \memo Meters requested here show up on eplusout.eso and eplusout.mtr
  \format singleLine
A1 , \field Name
  \required-field
  \type object-list
  \object-list autoRDDmeter
  \note Form is EnergyUseType:..., e.g. Electricity:* for all Electricity meters
  \note or EndUse:..., e.g. GeneralLights:* for all General Lights
  \note Report Meter puts results on both the eplusout.mtr and eplusout.eso files
A2 ; \field Reporting Frequency
  \type choice
  \key Timestep
  \note Timestep refers to the zone Timestep/Timestep in hour value
  \note RunPeriod, Environment, and Annual are the same
  \key Hourly
  \key Daily
  \key Monthly
  \key RunPeriod
  \key Environment
  \key Annual
  \note RunPeriod, Environment, and Annual are synonymous
```

Examples of specifying the object in the IDF follow.

```
Output:Meter,Electricity:*,RunPeriod;
Output:Meter,ExteriorEquipment*,RunPeriod;
```

The IDD definition for the Output:Meter:MeterFileOnly object follows.

```
Output:Meter:MeterFileOnly,
  \memo same reporting as Report Meter -- goes to eplusout.mtr only
  \format singleLine
A1, \field Name
  \required-field
  \type object-list
  \object-list autoRDDmeter
  \note Form is EnergyUseType:..., e.g. Electricity:* for all Electricity meters
  \note or EndUse:..., e.g. GeneralLights:* for all General Lights
  \note Report MeterFileOnly puts results on the eplusout.mtr file only
A2 ; \field Reporting Frequency
  \type choice
  \key Timestep
  \note Timestep refers to the zone Timestep/Timestep in hour value
  \note RunPeriod, Environment, and Annual are the same
  \key Hourly
  \key Daily
  \key Monthly
  \key RunPeriod
  \key Environment
  \key Annual
  \note RunPeriod, Environment, and Annual are synonymous
```

Meter Details File (eplusout.mtd)

The meter details file consists of two parts:

- For report variables that are on meters, it shows all the meters that the report variable is on. In the following example, “Meters for “ <report variable #>, <report variable name> is shown and then the meters that accumulate the value of that variable as a “meter”.

```
Meters for 1240,SPACE1-1:Lights-Electric Consumption[J]
OnMeter=Electricity:Facility [J]
OnMeter=Electricity:Building [J]
OnMeter=Electricity:Zone:SPACE1-1 [J]
OnMeter=InteriorLights:Electricity [J]
OnMeter=InteriorLights:Electricity:Zone:SPACE1-1 [J]
```

```
Meters for 1460,SPACE1-1:Zone/Sys Sensible Heating Energy[J]
OnMeter=EnergyTransfer:Facility [J]
OnMeter=EnergyTransfer:Building [J]
OnMeter=EnergyTransfer:Zone:SPACE1-1 [J]
OnMeter=Heating:EnergyTransfer [J]
```

```
Meters for 1557,SPACE1-1 ZONE COIL:Total Water Heating Coil Energy[J]
OnMeter=EnergyTransfer:Facility [J]
OnMeter=EnergyTransfer:HVAC [J]
OnMeter=HeatingCoils:EnergyTransfer [J]
```

- For each meter, the report variables that make up that meter are shown. In the following example, “For Meter=” <name of meter>, “contents are:” and then each variable that occurs on that “meter” are shown.

```
For Meter=Electricity:Facility [J], contents are:
SPACE1-1 LIGHTS:Lights Electric Consumption

Outdoor Air Ventilation Report Variables

This section provides more detailed information on the reporting available for outdoor air ventilation. Sixteen cooling and heating load variables and eight energy summary variables are available that report the impact of system outdoor air on zone loads, system demand and total energy use. The representative air system shown in the diagram below shows outdoor air (OA), return air (RA), supply air (SA) and mixed air (MA).

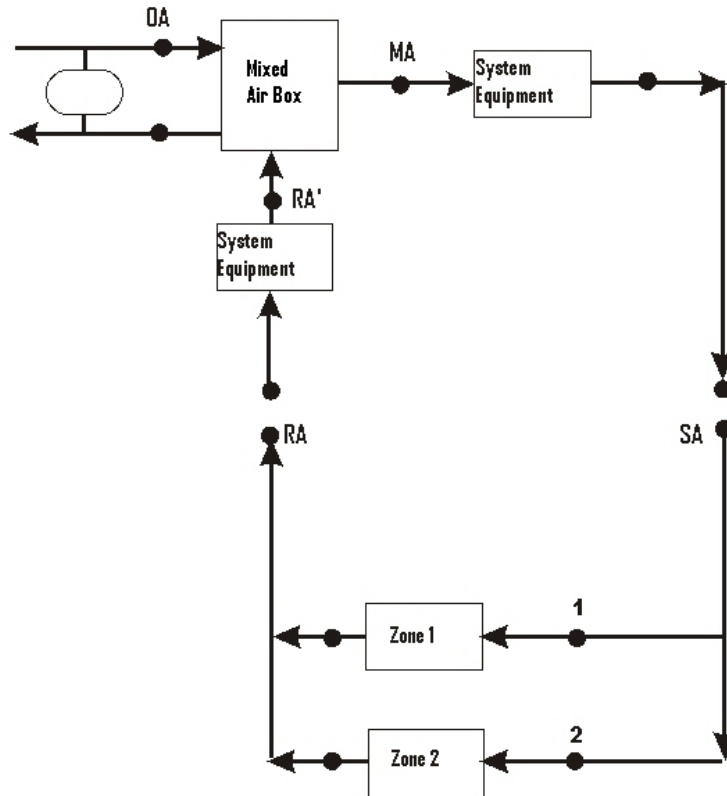

Figure 135. Example System for Ventilation Loads Report

The overall effect of outdoor air on the system shown above can be summarized by considering the mixing box. In this system, part or all of the return air is replaced by outdoor air. The presence of any heat recovery will already be taken into account and thus will automatically be accounted for by using the outdoor air inlet conditions to the mixing box (point OA in the diagram) rather than actual outdoor air conditions. Thus, the overall energy impact of outdoor air (ventilation) on a particular system can be evaluated by multiplying the outdoor air mass flow rate by the enthalpy difference between the outdoor air entering the mixing box (OA) and the return air entering the mixing box (RA') as shown in the following equation.

$$\dot{q}_{OA} = \dot{m}_{OA} (h_{OA} - h_{RA'}) = \dot{m}_{sys} (h_{MA} - h_{RA'})$$

Ventilation Flow Report Variables

The fresh air flow into each zones are reported using the ventilation flow report variables. The total outdoor air flow in a primary air system is divided to each zone based on the fraction of flow each zone is supplied. There are six variables which deals with the mechanical ventilation flow reporting. Those six variables are:

Zone Mechanical Ventilation Mass Flow Rate [kg/s]

Reports the average outdoor air mass flow rate to any zone over the reporting interval.

Zone Mechanical Ventilation Volume Flow Rate [m3/s]

Reports the average outdoor air volume flow rate to any zone over the reporting interval.

Zone Mechanical Ventilation Total Mass of Outside Air [kg]

Reports the total outdoor air mass that has been supplied to any zone over the reporting interval.

Zone Mechanical Ventilation Total Volume of Outside Air [m3]

Reports the total outdoor air volume that has been supplied to any zone over the reporting interval.

Zone Mechanical Ventilation Air Change Rate [ach]

Reports the air changes per hour in the zone due to the outside fresh air supplied by mechanical ventilation system.

The example syntax below shows the basic ventilation flow variables reported on an hourly basis.

```

Ventilation Load Reports

The impact of system outdoor air on a particular zone may be calculated by summing the mass flow weighted \dot{q}_{OA} over the supply air paths (both cooling and heating) serving the zone as follows:

$$\dot{q}_{OA,Zone1} = \sum_{n=1}^{AirPathNum} \dot{q}_{OA} \frac{\dot{m}_n}{\dot{m}_{sys}}$$

Four report variables each for cooling and heating report the impact of the ventilation air on the zone load in the absence of ventilation air system interactions. The ventilation load report variables are:

Zone Mechanical Ventilation Cooling Load Increase: OverHeating[J]**Zone Mechanical Ventilation Heating Load Increase: OverHeating[J]**

The cooling/heating load that would occur once ventilation air met the zone cooling/heating load and continued to overcool/overheat the zone. No system effects are accounted for.

Zone Mechanical Ventilation Cooling Load Decrease[J]**Zone Mechanical Ventilation Heating Load Decrease[J]**

The decrease in zone cooling/heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

Zone Mechanical Ventilation No Load Heat Removal[J]**Zone Mechanical Ventilation No Load Heat Addition[J]**

The addition or removal of heat to a zone with no load. The heat addition or removal is due to mechanical ventilation while the zone thermostat is in the deadband.

To summarize:

Cooling:**1. Zone Mechanical Ventilation No Load Heat Removal [J]**

Cooling that would be provided directly to zone by ventilation air. Ventilation occurred with no zone load.

2. Zone Mechanical Ventilation Cooling Load Increase [J]

The increase in zone cooling load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

3. Zone Mech Ventilation Cooling Load Increase: OverHeating [J]

The cooling load that would occur once ventilation air met the zone heating load and continued to overheat the zone. No system effects are accounted for.

4. Zone Mechanical Ventilation Cooling Load Decrease [J]

The decrease in zone cooling load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

Heating:**1. Zone Mechanical Ventilation No Load Heat Addition [J]**

Heating that would be provided directly to zone by ventilation air. Ventilation occurred with no zone load.

2. Zone Mechanical Ventilation Heating Load Increase [J]

The increase in zone heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

3. Zone Mech Ventilation Heating Load Increase: OverCooling[J]

The heating load that would occur once ventilation air met the zone cooling load and continued to overcool the zone. No system effects are accounted for.

4. Zone Mechanical Ventilation Heating Load Decrease [J]

The decrease in zone heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

The report variables are calculated by comparing the zone ventilation load with the zone cooling or heating load. 'Ventilation cooling' decreases the zone cooling load until the cooling load has been eliminated. The remaining 'ventilation cooling' is reported as 'overcooling'. 'Overheating' is calculated in the same manner. The actual system operation, which determines whether or not an 'overcooling' or 'overheating' load actually results in increased energy consumption, is not considered in the calculation of these report variables.

The ventilation zone load report variables are shown in Table 36. The variables report the maximum potential “cost” or “benefit” of ventilation air introduced directly into the zone.

Table 36. Ventilation Load Report Variables

	No Zone Load	Zone Cooling Load	Zone Heating Load
Ventilation Cooling	Zone Mechanical Ventilation No Load Heat Removal	Zone Mechanical Ventilation Cooling Load Decrease	Zone Mechanical Ventilation Heating Load Increase
		Zone Mech Ventilation Heating Load Increase: OverCooling	
Ventilation Heating	Zone Mechanical Ventilation No Load Heat Addition	Zone Mechanical Ventilation Cooling Load Increase	Zone Mechanical Ventilation Heating Load Decrease
			Zone Mech Ventilation Cooling Load Increase: OverHeating

The example syntax below shows the basic ventilation load variables reported on a monthly basis.

```

Output:Variable,
*,                               !- Key Value
Zone Mechanical Ventilation No Load Heat Removal, !- Variable Name
monthly;                          !- Reporting Frequency

monthly;                          !- Reporting Frequency

Output:Variable,
*,                               !- Key Value
Zone Mechanical Ventilation Heating Load Increase, !- Variable Name
monthly;                          !- Reporting Frequency

```

Reporting on a timestep or monthly level would produce a detailed report with variables intermingled with the other report variables that might be requested in the input file.

Another method will more easily encapsulate the report:

```

OutputControl:Table:Style,
HTML;                               !- ColumnSeparator

Output:Table:Monthly,
Ventilation Loads,             !- Name
,                                   !- DigitsAfterDecimal
Zone Mechanical Ventilation No Load Heat Removal,      SumOrAverage,
Zone Mech Ventilation Cooling Load Increase: OverHeating, SumOrAverage,
Zone Mechanical Ventilation Cooling Load Decrease,      SumOrAverage,
Zone Mechanical Ventilation Cooling Load Increase,      SumOrAverage,
Zone Mechanical Ventilation No Load Heat Addition,      SumOrAverage,
Zone Mech Ventilation Heating Load Increase: OverCooling, SumOrAverage,
Zone Mechanical Ventilation Heating Load Decrease,      SumOrAverage,
Zone Mechanical Ventilation Heating Load Increase,      SumOrAverage,

```

This combination will report the ventilation loads on a monthly basis in a HTML style report that can be easily read in a web browser. Review the Output:Table:Monthly object for other methods of display or further options on this report item.

Systems Level Reporting

Most report variables are a single entity reporting. Meters are a combination of like variables – specifically for Energy Consumption. This section introduces a slightly different concept – where report variables described herein are a combination of several similar items –

specifically targeted at HVAC/System level reporting. This reporting is coupled with an Air Loop (ref: AirLoopHVAC)

All items shown in this section are typical “report variables” and can be reported with the Output:Variable object.

Or, as is shown by example here, perhaps a more readable form is to generate them in Tabular Form with the “Report Table Monthly” object.

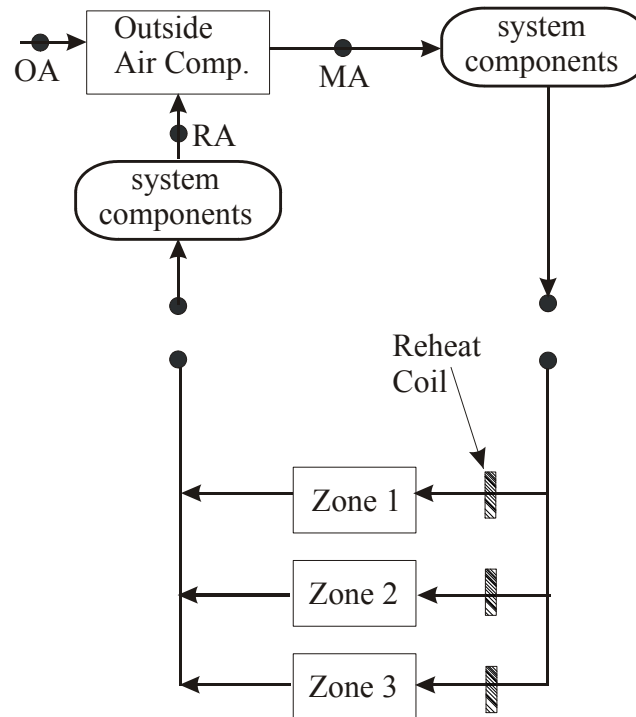

Figure 136. View of System Level Reporting

System Loads Outputs

In this category, the total system load is reported. Two aspects are reported here: Heating and Cooling. The following two variables report the heat energy that system components (including packaged equipment, fans, main coils, reheat coils, humidifiers, desiccant dehumidifiers, evaporative coolers and heat exchangers) add or remove from the air loop. Each variable within these grouping will

Air Loop Total Heating Energy

Heat Addition to the Air Loop (Sum of all components) in Joules

Air Loop Total Cooling Energy

Heat Removal from the Air Loop (Sum of all components) in Joules

In 'Output:Table:Monthly' format shown below.

```
OutputControl:Table:Style ,
  HTML;                               !- ColumnSeparator

Output:Table:Monthly,
  System Loads,                    !- Name
  ,                                     !- DigitsAfterDecimal
```

Air Loop Total Heating Energy,	SumOrAverage,
Air Loop Total Cooling Energy,	SumOrAverage;

System Energy Use Outputs

System Energy Use consists of six output variables that report the total energy (in Joules) and water consumption (in m3) for all system components and including packaged equipment, fans, main coils, reheat coils, humidifiers, desiccant dehumidifiers, and evaporative coolers. The output variables shown below show hot and cold water, steam, electric and gas energy. Hot and cold water energy includes all 'district cooling' and 'district heating' energy.

Air Loop Hot Water Consumption

Hot Water Consumption for the system (Joules).

Air Loop Steam Consumption

Steam Consumption for the system (Joules).

Air Loop Chilled Water Consumption

Chilled Water Consumption for the system (Joules).

Air Loop Electric Consumption

Electric Consumption for the system (Joules).

Air Loop Gas Consumption

Gas (Natural Gas and Propane) Consumption for the system (Joules).

Air Loop Water Consumption

Water Consumption for the system (humidifiers and evaporative coolers) (m3).

The Standard reports file includes these variables reporting in the Tabular report form as "Air Loop System Energy and Water Use".

```

OutputControl:Table:Style,
    HTML;                               !- ColumnSeparator

Output:Table:Monthly,
    Air Loop System Energy and Water Use,      !- Name
    ,                                           !- DigitsAfterDecimal
    Air Loop Hot Water Consumption ,          SumOrAverage,
    Air Loop Steam Consumption ,             SumOrAverage,
    Air Loop Chilled Water Consumption,      SumOrAverage,
    Air Loop Electric Consumption,          SumOrAverage,
    Air Loop Gas Consumption,              SumOrAverage,
    Air Loop Water Consumption,            SumOrAverage;

```

System Component Loads Outputs

Reporting System Component Loads shows the energy transferred to or extracted from the air loop by system component type. Fans, Cooling Coils, Heating Coils, Heat exchangers, humidifiers, evaporative coolers, and desiccant dehumidifiers show heat transfer rates in Joules. The components may be located in outdoor air systems bundled with packaged equipment or specified as stand-alone components. The reporting accounts for both main branch and reheat coils.

The Standard reports file includes these variables reporting in the Tabular report form as "Air Loop System Component Loads".

```

OutputControl:Table:Style,
    HTML;                               !- ColumnSeparator

Output:Table:Monthly,
    Air Loop System Component Loads,      !- Name
    ,                                       !- DigitsAfterDecimal
    Air Loop Fan Heating Energy,      SumOrAverage,
    Air Loop Total Cooling Coil Energy, SumOrAverage,
    Air Loop Total Heating Coil Energy, SumOrAverage,
    Air Loop Total Heat Exchanger Heating Energy, SumOrAverage,
    Air Loop Total Heat Exchanger Cooling Energy, SumOrAverage,
    Air Loop Total Humidifier Heating Energy, SumOrAverage,
    Air Loop Total Evap Cooler Cooling Energy, SumOrAverage,
    Air Loop Total Desiccant Dehumidifier Cooling Energy, SumOrAverage;

```

Air Loop Fan Heating Energy

Energy consumption for Fans (Joules)

Air Loop Total Cooling Coil Energy

Energy consumption for Cooling Coils (Joules)

Air Loop Total Heating Coil Energy

Energy consumption for Heating Coil(s) (Joules)

Air Loop Total Heat Exchanger Heating Energy

Heating energy consumption for heat exchangers (Joules)

Air Loop Total Heat Exchanger Cooling Energy

Heating energy consumption for heat exchangers (Joules)

Air Loop Total Humidifier Heating Energy

Heating energy consumption for humidifiers (Joules)

Air Loop Total Evap Cooler Cooling Energy

Energy consumption for evaporative coolers (Joules)

Air Loop Total Desiccant Dehumidifier Cooling Energy

Energy consumption for desiccant dehumidifiers (Joules)

System Component Energy Use Outputs

Reporting System Component Energy Use consists of eleven output variables that report the total energy consumption (in Joules) of system components by energy type and coil type. Electric energy consumption is reported for fans, heating and cooling coils in packaged (DX) systems, electric resistance heating coils, humidifiers, evaporative coolers and desiccant dehumidifiers.

Air Loop Fan Electric Consumption

Electric consumption for fans. (Joules)

Air Loop Heating Coil Hot Water Consumption

Consumption for heating coil hot water (both purchased and plant supplied) (Joules)

Air Loop Cooling Coil Chilled Water Consumption

Consumption for cooling coil chilled water (both purchased and plant supplied) (Joules)

Air Loop DX Heating Coil Electric Consumption

Compressor plus condenser fan electricity use. (Joules)

Air Loop DX Cooling Coil Electric Consumption

Compressor plus condenser fan electricity use. (Joules)

Air Loop Heating Coil Electric Consumption

Electricity consumption for the heating coil. (Joules)

Air Loop Heating Coil Gas Consumption

Gas (Propane and Natural Gas) consumption for the heating coil. (Joules)

Air Loop Heating Coil Steam Consumption

Steam consumption for the heating coil (steam coils). (Joules)

Air Loop Humidifier Electric Consumption

Electricity consumption for the humidifiers. (Joules)

Air Loop Evap Cooler Electric Consumption

Electricity consumption for the evaporative coolers. (Joules)

Air Loop Desiccant Dehumidifier Electric Consumption

Electricity consumption for the desiccant dehumidifiers. (Joules)

The Standard reports file includes these variables reporting in the Tabular report form as “Air Loop System Component Energy Use”.

```

OutputControl:Table:Style,
    HTML;                                !- ColumnSeparator

Output:Table:Monthly,

    Air Loop Evap Cooler Electric Consumption, SumOrAverage,
    Air Loop Desiccant Dehumidifier Electric Consumption, SumOrAverage;

```

Output:EnvironmentalImpactFactors

The Output:EnvironmentalImpactFactors object triggers the necessary Facility meters to be reported and the Pollutants resulting from these on and off-site energy consumptions. These values are put into the eplusout.mtr file. Facility meters contain all the energy of a fuel type. Thus, the following relationships should be observed:

$$Facility = \sum (Building + System + Plant + Exterior)$$

Information regarding how the coefficients are derived and applied can be found in the Engineering Document.

To turn on the reporting and the calculations for the environmental factors the user enters 3 objects:

Output:EnvironmentalImpactFactors: (with associated reporting frequency, more than one frequency can be requested)

EnvironmentalImpactFactors: (contains additional information necessary for the calculations not included in the Fuel Factors)

FuelFactors: (required for every fuel that is simulated and converted in this simulation input file)

Users will enter environmental impact factors for each Fuel Type or FuelFactor. This is the same for each Fuel Type: Natural Gas, Residual Oil, Distillate Oil, Coal, Off-Site Electricity, Gasoline, and Propane. For District Heating, District Cooling, and Steam there are additional fields in the EnvironmentalImpactFactors object that help in the conversion of their energy to Natural Gas and Electricity.

The energy is obtained internally from the following facility meters:

Electricity:Facility	Diesel:Facility
DistrictCooling:Facility	DistrictHeating:Facility
Gas:Facility	GASOLINE:Facility
COAL:Facility	FuelOil#1:Facility
FuelOil#2:Facility	Propane:Facility
ElectricityProduced:Facility	Steam:Facility

For the pollutant calculation only the total off-site or purchased electric energy is calculated using Electricity Factors. Off-Site Electricity = Electricity:Facility - ElectricityProduced:Facility, pollutants for the fuel type used by the on-site generator will be calculated, for example Diesel, in these cases.

Field: Reporting Frequency

Similar to the report variables and meters the environmental impact calculations can be reported at different frequencies. Their resolution is the Zone Timestep interval (Number of Timesteps input). For this frequency, the elemental value of the Environmental Impact Factors Calculation will be reported. For more inclusive frequencies, the summed value along with the maximum and minimum values for the time interval will be reported.

The IDD definition for the Report Environmental Impact Factors object is:

```
Output:EnvironmentalImpactFactors,
  \memo This is used to Automatically report the facility meters and turn on the Environmental Impact
Report calculations
  \memo for all of the Environmental Factors.
A1 ; \field Reporting Frequency
  \type choice
  \key Timestep
  \key Hourly
  \key Daily
  \key Monthly
  \key RunPeriod
```

An example of specifying in the IDF:

```
Output:EnvironmentalImpactFactors,
  Monthly; !- Reporting_Frequency
```

EnvironmentalImpactFactors

The EnvironmentalImpactFactors object contains additional information that is not individually specified in the FuelFactors object and is the second object needed to complete the calculation. Source to Site conversion factors for District Heating, District Cooling and Steam are entered in this object.

Field: District Heating Efficiency

The District Heating Efficiency value is used to convert the district (purchased) heating energy to Natural Gas for the environmental impact calculation. The efficiency is a number between 0 and 1 and divided into the district heating energy and the default is 0.3.

Field: District Cooling COP

The District Cooling COP value is used to convert the district (purchased) cooling energy to electricity for the environmental impact calculation. The Coefficient of Performance (COP) is a number greater than 0 and divided into the purchased cooling energy with a default of 3.0.

Field: Steam Conversion Efficiency

The Steam Conversion Efficiency is used to convert the Steam usage to Natural Gas for the environmental impact calculation. The efficiency is a number between 0 and 1 and divided into the purchased heating energy and the default is 0.25.

Field: Total Carbon Equivalent Emission Factor From NO_x

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. NO_x (nitrogen oxides) can be produced by all Fuel Types and has a default of carbon equivalent emission factor of 80.7272 kg C/kg NO_z.

Field: Total Carbon Equivalent Emission Factor From CH₄

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. CH₄ (methane) can be produced by all Fuel Types and has a default carbon equivalent emission factor of 6.2727 kg C/kg CH₄.

Field: Total Carbon Equivalent Emission Factor From CO₂

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. CO₂ (carbon dioxide) can be produced by all Fuel Types and has a default carbon equivalent emission factor of 0.2727 kg C/kg CO₂.

The IDD definition for the Environmental Impact Factors object is:

```

EnvironmentalImpactFactors,
  \memo Used to help convert district and ideal energy use to a fuel type and provide total carbon
equivalent with coefficients
  N1, \field District Heating Efficiency
      \note District heating efficiency used when converted to natural gas
      \minimum> 0.0
      \maximum 1.0
      \default 0.3
  N2, \field District Cooling COP
      \note District cooling COP used when converted to electricity
      \minimum> 0.0
      \default 3.0
  N3, \field Steam Conversion Efficiency
      \note Steam conversion efficiency used to convert steam usage to natural gas
      \minimum> 0.0
      \maximum 1.0
      \default 0.25
  N4, \field Total Carbon Equivalent Emission Factor From NOx
      \units kg/kg
  N5, \field Total Carbon Equivalent Emission Factor From CH4
      \units kg/kg
  N6, \field Total Carbon Equivalent Emission Factor From CO2
      \units kg/kg

```

An example of specifying in the IDF:

```

EnvironmentalImpactFactors,
  0.3,      !- District Heating Efficiency
  3.0,      !- District Cooling COP
  0.25,     !- Steam Conversion Efficiency
  80.7272,  !- Total Carbon Equivalent Emission Factor From NOx
  6.2727,   !- Total Carbon Equivalent Emission Factor From CH4
  0.2727;   !- Total Carbon Equivalent Emission Factor From CO2

```

FuelFactors

Field: Existing Fuel Resource Name

This is the name of the Fuel that is being described with this object. Source to Site conversion factors for each tool are entered with these objects. Allowable Fuel Types are: Electricity, Natural Gas, FuelOil#1, FuelOil#2, Coal, Gasoline, Propane, Diesel.

Field: Units of Measure

Units in mass with kg or by volume in m3.

Field: Energy per Unit Factor

The higher heating value of the fuel type.

Field: Source Energy Factor

Multiplied by the fuel consumption to compute the source energy contribution for the fuel. If a schedule is also specified in the next field, the value specified here, the schedule value, and the fuel consumption are multiplied together for each timestep to determine the source energy contribution for the fuel. If the multipliers in the schedule specified in the next field fully represent the source energy conversion factor, the value in this field should be set to one. If the TDV files (described in next field) are used the value should be 0.293 for electricity and 0.01 for natural gas to account for the units used in the files. Units of J/J.

Field: Source Energy Schedule Name

This field contains the name of a schedule containing values that are multiplied by the fuel consumption to determine the source energy. The values in the schedule are multiplied by the Source Energy Factor field and by the fuel consumption to determine the source energy

consumption for the fuel. If the multipliers in the schedule fully represent the source energy conversion factor, the value in the previous field, Source Energy Factor should be set to one.

The use of this field is required for evaluations using source energy factors that change throughout the year such as Time Dependent Valuation (TDV), the method used to show compliance with to California's Title 24 under the ACM (Alternative Compliance Method). Data files containing TDV factors are in the DataSets\TDV\ directory. An example file for use with TDV file is in the ExampleFiles directory and is named 5zoneTDV.IDF. When using these TDV files with EnergyPlus it is important that a consistent weather file be used. It is also important that the day of the week for January 1 is set to Tuesday since all the TDV and related weather files use 1991 as the year of reference. Also note that the values in the TDV datasets files are in non SI units of measure. The source energy factor field should contain the value of 0.293 for electricity and 0.01 for natural gas to account for the non-standard units used in the files. To learn more about TDV see:

<http://www.energy.ca.gov/title24/2005standards/archive/rulemaking/documents/tdv/index.html>

<http://www.h-m-g.com/TDV/index.htm>

WARNING

THE TDV CALCULATIONS SHOULD ONLY BE PERFORMED ON SIMULATIONS THAT USE THE CALIFORNIA THERMAL ZONE (CTZ REV2) WEATHER FILES. One must match the correct TDV file to its corresponding CTZ weather file. There are 16 TDV files, one for each of the 16 CTZ weather files. The Time Dependent Valuation of TDV files provides a relative cost estimate of the various fuel sources and their relative costs by time of day, month of year and outside temperature. Outside temperature is important as demand for electricity and thus cost of electricity is influenced by temperature. These TDV files are applicable only to the hourly weather data contained in the California Thermal Zone (CTZ rev2) weather files as the time dependent cost information is partially derived from the timing of temperatures in the weather file. Thus using the TDV files with other weather data would provide meaningless results.

Field: CO2 Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of carbon dioxide (CO₂) released into the atmosphere. The units are grams per MegaJoule. Carbon dioxide gas is naturally produced by animals during respiration and through decay of biomass, and used by plants during photosynthesis. Although it only constitutes 0.04 percent of the atmosphere, it is one of the most important greenhouse gases. The combustion of fossil fuels is increasing carbon dioxide concentrations in the atmosphere, which is believed to be contributing to global warming.

Field: CO2 Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: CO Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of carbon monoxide (CO) released into the atmosphere. The units are grams per MegaJoule. Carbon monoxide is a colorless, odorless and poisonous gas produced by incomplete fossil fuel combustion. Carbon monoxide combines with the haemoglobin of human beings, reducing its oxygen carrying capacity, with effects harmful to human beings.

Field: CO Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: CH4 Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of methane (CH₄) released into the atmosphere. The units are grams per MegaJoule. Methane is a colorless, nonpoisonous, flammable gas created by anaerobic decomposition of organic compounds

and is one of the more potent greenhouse gases. A major component of natural gas used in the home.

Field: CH4 Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: NOx Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of nitrogen oxides (NO_x) released into the atmosphere. The units are grams per MegaJoule. Nitrogen oxides refers to nitric oxide gas (NO) and nitrogen dioxide gas (NO₂) and many other gaseous oxides containing nitrogen. The main source of these gases in urban areas are motor vehicle exhaust and indoor gas stoves and kerosene heaters. The brown haze sometimes seen over cities is mainly nitrogen oxides. These gases are also partly responsible for the generation of ozone, which is produced when nitrogen oxides react with other chemicals in the presence of sunlight. Exposure to high levels of nitrogen dioxide can interfere with the ability of blood to carry oxygen, leading to dizziness and shortness of breath. Prolonged exposure can lead to respiratory failure.

Field: NOx Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: N2O Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of nitrous oxide (N₂O) released into the atmosphere. The units are grams per MegaJoule. Relatively inert oxide of nitrogen produced as a result of microbial action in the soil, use of fertilizers containing nitrogen, burning of timber and coal, chemical industry, and so forth. This nitrogen compound may contribute to greenhouse and ozone-depleting effects.

Field: N2O Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: SO2 Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of sulfur dioxide (SO₂) released into the atmosphere. The units are in grams per MegaJoule. Sulfur dioxide gas is formed when fuel containing sulfur, such as coal and oil, is burned, and when gasoline is extracted from oil, or metals are extracted from ore. Sulfur dioxide reacts with other chemicals in the air to form tiny sulfate particles, associated with increased respiratory symptoms and disease, difficulty in breathing, and premature death. Sulfur dioxide and nitrogen oxides react with other substances in the air to form acids, which fall to earth as rain, fog, snow, or dry particles. Acid rain damages forests and crops, changes the makeup of soil, and makes lakes and streams acidic and unsuitable for fish. Sulfur dioxide accelerates the decay of building materials and paints.

Field: SO2 Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: PM Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of particulate matter (PM) released into the atmosphere. The units are grams per MegaJoule. PM is the sum of all particular matter emitted, including PM10 and PM2.5. Particulate matter, or PM, are particles found in the air, including dust, dirt, soot, smoke, and liquid droplets, which can be suspended in the air for long periods of time. Some particles are large or dark enough to be seen as soot or smoke. Others are so small that individually they can only be detected with an electron microscope. Breathing particulate matter is linked to significant respiratory health problems.

Field: PM Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: PM10 Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of particulate matter 10 (PM₁₀) released into the atmosphere. The units are grams per MegaJoule. PM₁₀, includes particles with an aerodynamic diameter of less than 10 microns. These smaller particles are most likely responsible for the adverse health effects on humans because particles so small can reach the thoracic or lower regions of the respiratory tract.

Field: PM10 Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: PM2.5 Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of particulate matter 2.5 (PM_{2.5}) released into the atmosphere. The units are grams per MegaJoule. EPA's national air quality standards for fine particles, also known as "PM_{2.5} standards," are levels allowed in the outdoor air for particulate matter 2.5 microns in diameter or smaller. EPA issued the PM_{2.5} standards in 1997 to protect human health and the environment. Studies have linked increased exposure to PM_{2.5} to increases in premature death as well as a range of serious respiratory and cardiovascular effects.

Field: PM2.5 Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: NH3 Emission Factor

The Environmental impact coefficient for the Fuel for calculating the mass of ammonia (NH₃) released into the atmosphere. The units are grams per MegaJoule. Ammonia reacts with nitrogen and sulfur compounds in the atmosphere, mainly nitric and sulfuric acids, to form particulate matter.

Field: NH3 Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: NMVOC Emission Factor

The Environmental impact coefficient for the Fuel for calculating the mass of non-methane volatile organic compounds (NMVOC) released into the atmosphere. The units are grams per MegaJoule. Non-methane volatile organic compounds (NMVOC), which include propane, butane, and ethane, are emitted primarily from transportation, industrial processes, and non-industrial consumption of organic solvents. Volatile organic compounds react with nitrogen oxides in the atmosphere to form ozone.

Field: NMVOC Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: Hg Emission Factor

The Environmental impact coefficient for the Fuel for calculating the mass of mercury (Hg) released into the atmosphere. The units are grams per MegaJoule. This heavy metal can accumulate in the environment and is highly toxic if breathed or swallowed. In the U.S., primary sources of mercury air emissions are coal-fired power plants.

Field: Hg Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: Pb Emission Factor

The Environmental impact coefficient for the Fuel for calculating the mass of lead (Pb) released into the atmosphere. The units are grams per MegaJoule. A heavy metal that is hazardous to health if breathed or swallowed. Its use in gasoline, paints, and plumbing compounds has been sharply restricted or eliminated by federal laws and regulations.

Field: Pb Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: Waster Emission Factor

The environmental impact coefficient for the Fuel for calculating the volume of water (H₂O) consumed or evaporated in the generation of electricity. The units are liters per MegaJoule or a volume measurement. This is the water consumed in the production of the energy, ie. electricity off-site evaporated in cooling towers or scrubbers, or in the production or processing of the fuel itself, i.e., refinery for gasoline or diesel.

Field: Water Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: Nuclear High Level Emission Factor

The environmental impact coefficient for the Fuel for calculating the mass of high-level nuclear waste, removed as spent nuclear fuel from a nuclear reactor once it no longer is efficient at powering the reactor.. The units are grams per MegaJoule. Once a year, approximately one-third of nuclear fuel is replaced with new fuel. This used fuel is called spent nuclear fuel and is highly radioactive; containing plutonium and other radionuclides. Although there is little information on quantities of high-level nuclear waste, a few utilities are beginning to publish this information.

Field: Nuclear High Level Emission Factor Schedule Name

This schedule field is not currently implemented.

Field: Nuclear Low Level Emission factor

The environmental impact coefficient for the Fuel for calculating the volume of low-level nuclear waste, removed from a nuclear reactor after radiation contamination. The units are cubic meters per MegaJoule or a volume measurement. Low-level waste can come from nuclear reactors or other users of radioactive material, like hospitals or research institutes. Low-level waste is less hazardous than high-level waste.

Field: Nuclear Low Level Emission Factor Schedule Name

This schedule field is not currently implemented.

The IDD definition for the FuelFactors object is:

```

FuelFactors,
  A1,  \field Existing Fuel Resource Name

1114,1,Water:Facility [L] !Monthly [Value,Min,Day,Hour,Minute,Max,Day,Hour,Minute]
1125,1,Nuclear High:Facility [kg] !Monthly [Value,Min,Day,Hour,Minute,Max,Day,Hour,Minute]
1136,1,Nuclear Low:Facility [m3] !Monthly [Value,Min,Day,Hour,Minute,Max,Day,Hour,Minute]
1339,1,Carbon Equivalent:Facility [kg] !Monthly [Value,Min,Day,Hour,Minute,Max,Day,Hour,Minute]

```

What shows up in the output are the Energy Meters that were utilized in this particular input file, the pollutants, and the Total Carbon Equivalent. They show up in the meter output file and can be processed with a post processing program such as ReadVarsEso.exe to create a *.csv file or it is done automatically with EP Launch or the batch file.

Output:SQLite

Output from EnergyPlus can be written to SQLite files for manipulation outside some of the standard (such as spreadsheet) tools.

Currently, there are limited capabilities for specifying SQLite generation. The description for SQLite outputs is described in the Output Details document.

The IDD entry for this object follows.

```

Output:SQLite,
  \unique-object
A1 ; \field Option
  \type choice
  \key Simple
  \default Simple

```

And one includes it in the IDF using the following.

```
Output:SQLite, Simple;
```

Output

EnergyPlus produces several output files as shown in the section on “Running EnergyPlus”. This section will discuss the data contained in the “standard” output files (**eplusout.eso**, **eplusout.mtr**). They, too, have data dictionaries but unlike the input files, the output data dictionary is contained within the output file. Thus, the basic structure of the standard output file is:

```
Data Dictionary Information
End of Data Dictionary
Data
...
Data
End of Data
```

As with the IDF structure, there are rules associated with the interpretation of the standard output data dictionary. These rules are summarized as follows:

- The first item on each line is an integer which represents the “report code”. This “report code” will be listed in the data section where it will also be the first item on each line, identifying the data. Only 2 lines in the output file will not have an integer as the first item (“End of Data Dictionary” and “End of Data” lines).
- The second item on each line is also an integer. This integer corresponds to the number of items left on the dictionary line. Each string consists of a variable name and units in square brackets. Square brackets are required for all strings. If there are no units associated with a particular variable, then there are no characters between the brackets.

Six standard items appear at the start of every EnergyPlus Standard Output File Data Dictionary:

```
Program Version,EnergyPlus <version number indicated>
 1,5,Environment Title[],Latitude[degrees],Longitude[degrees],Time Zone[],Elevation[m]
 2,6,Day of Simulation[],Month[],Day of Month[],DST Indicator[1=yes 0=no],Hour[],StartMinute[],EndMinute[],DayType
 3,3,Cumulative Day of Simulation[],Month[],Day of Month[],DST Indicator[1=yes 0=no],DayType ! When Daily Report
Variables Requested
 4,2,Cumulative Days of Simulation[],Month[] ! When Monthly Report Variables Requested
 5,1,Cumulative Days of Simulation[] ! When Run Period Report Variables Requested
```

Item 0 is the program version statement.

Item 1 is produced at the beginning of each new “environment” (design day, run period).

Item 2 is produced prior to any variable reported at the timestep or hourly intervals. Hourly intervals will be shown with a start minute of 0.0 and an end minute of 60.0. Timestep intervals will show the appropriate start and end minutes.

Item 3 is produced prior to any variable reported at the daily interval.

Item 4 is produced prior to any variable reported at the monthly interval.

Item 5 is produced prior to any variable reported at the end of the “environment”.

Following these five standard lines will be the variables requested for reporting from the input file (ref. Report Variable). For example:

```
6,2,Environment,Outdoor Dry Bulb [C] !Hourly
21,2,ZONE ONE,Mean Air Temperature[C] !Hourly
22,2,ZONE ONE,Zone-Total Latent Gain[J] !Hourly
26,2,ZONE ONE,Zone-Total Electric Consumption[J] !Hourly
```

This example illustrates the non-consecutive nature of the “report codes”. Internally, EnergyPlus counts each variable that *could* be reported. This is the assigned “report code”. However, the user may not request each possible variable for reporting. Note that, currently, the requested reporting frequency is shown as a comment (!) line in the standard output file.

The data is produced when the actual simulation is performed (after the warmup days). Data output is simpler in format than the data dictionary lines. From the dictionary above:

```

1,DENVER COLORADO WINTER, 39.75,-104.87, -7.00,1610.26
2, 1, 1,21, 0, 1, 0.00,60.00,Monday
6,-17.22222
21,-17.22219
22,0.0000000E+00
26,0.0000000E+00
2, 1, 1,21, 0, 2, 0.00,60.00,Monday
6,-17.22222
21,-17.22219
22,0.0000000E+00
26,0.0000000E+00
2, 1, 1,21, 0, 3, 0.00,60.00,Monday
6,-17.22222
21,-17.22219
22,0.0000000E+00
26,0.0000000E+00
...
```

This output file can be easily turned into a form that is read into commonly used spreadsheet programs where it can be further analyzed, graphed, etc.

Figure 137. Example Chart from Standard Output File

Using "ReadVarsESO" (Creating Charts, etc. from Output Files)

The ReadVarsESO program is distributed with EnergyPlus as a simple approach to converting the standard output files (**eplusout.eso**, **eplusout.mtr**) into files that can be put directly into a spreadsheet program and then used to create graphs or do other statistical operations. ReadVarsESO can read the complex output files and sort the data into time-based form, it is a very quick application but does not have a lot of features. Note that all the **Output:Meter** objects are included on the **eplusout.eso** file as well as the **eplusout.mtr** file. You can choose the **Output:Meter:MeterFileOnly** object if you do not want a particular meter to show up on the **eplusout.eso** file. If you wish to see only the metered outputs, the **eplusout.mtr** file will typically be a lot smaller than the **eplusout.eso** file.

The ReadVarsESO program has a very simple set of inputs. By default, you will get all the variables listed in the Output:Variable (**eplusout.eso**) or Output:Meter (**eplusout.mtr**) objects into the appropriate output files. The outputs from ReadVarsESO are limited to 255 variables (Microsoft Excel™ limit). You can tailor how many variables to list by specifying variables for the ReadVarsESO runs.

You can override the 255 variable limit by specifying an argument on the command line (**EP-Launch** has a special option for this). You use "unlimited" or "nolimit" on the command line to get as many variables into your output file as desired. Again, this will be limited either by the number of variables in the **eplusout.eso** or **eplusout.mtr** files or the contents of the "rvi" file. If you want to use this option, you must include two arguments to the command line of the ReadVars program – 1) the "rvi" file and 2) the "unlimited" argument.

Table 37. ReadVarsESO Command Line Options

Option	Description
<filename>	To use any of these options, you must include a file name ("rvi" file) as the first argument.
Unlimited (or Nolimit)	Variables of any number will be produced on the output file.
Timestep	Only variables with reported frequency "timestep" (or detailed) will be produced on the output file.
Hourly	Only variables with reported frequency "hourly" will be produced on the output file.
Daily	Only variables with reported frequency "daily" will be produced on the output file.
Monthly	Only variables with reported frequency "monthly" will be produced on the output file.
Annual (or RunPeriod)	Only variables with reported frequency "runperiod" will be produced on the output file.

In addition, another argument can be used so that the output file is only one time frequency. (By default, all variables – hourly, monthly, annual, etc. are mixed together in the output file). By using "Timestep" as an argument, you would get only the TimeStep reported variables. Using "Monthly", only the monthly variables. This is not automated in either **EP-Launch** or the **RunEPlus** batch file but can easily be accomplished.

The program is run automatically from the **EP-Launch** program or the **RunEPlus** batch file (both these methods for executing EnergyPlus are described in the GettingStarted document). These programs use <filename>.rvi for input to the ReadVarsESO program executed first after the EnergyPlus execution and <filename>.mvi for the second execution. Ostensibly, the .rvi file would apply to the eplusout.eso file and the .mvi would apply to the eplusout.mtr file, BUT the contents of the files actually specify the "input" reporting file and the "output" reorganized file. Typical contents of an .rvi file are:

Table 38. "RVI" file contents

.rvi line description	Actual .rvi File Contents
Input File	eplusout.eso
Output File	eplusout.csv
Variable Name	Outdoor Dry Bulb
Variable Name	Zone/Sys Air Temp
Variable Name	Zone Air Humidity Ratio
Variable Name	Zone/Sys Sensible Cooling Rate

Variable Name	Zone/Sys Sensible Heating Rate
Variable Name	Zone-Total Latent Gain
Specific Variable Name	COOLING COIL AIR OUTLET NODE, System Node Temp
Specific Variable Name	AIR LOOP OUTLET NODE, System Node Temp
Specific Variable Name	AIR LOOP OUTLET NODE, System Node Humidity Ratio
Specific Variable Name	Mixed Air Node, System Node MassFlowRate
Specific Variable Name	Outdoor air Inlet Node, System Node MassFlowRate
Variable Name	Humidifier Water Consumption Rate
Variable Name	Humidifier Electric Power
Variable Name	Zone Air Relative Humidity
Variable Name	Zone/Sys Moisture Load Rate Predicted
Termination Line (optional)	0

Note that the first two lines of the file are "input file" (where to read the report variable values from) and "output file" (where to put the reorganized data). If you have only those two lines in an "rvi" file, the program will use all the available variables on indicated input file to produce the output.

ReadVarsESO takes the input stream but recognizes the date/time information and appropriately places the required data onto the "output file". Following these lines are a list of variables to be culled from the "input file" and placed onto the output file. "Variable Name" will take all variables matching that description whereas "Specific Variable Name" will only match the full description of the variable. So, in the above example, "Zone/Sys Air Temp" will report air temperatures for all the zones (but available at the HVAC timestep if you choose the "detailed" reporting frequency in your input file) but "AIR LOOP OUTLET NODE" and "COOLING COIL AIR OUTLET NODE" will be the only values reported for the "System Node Temp" variable (the node temperature is available for all nodes used in the simulation). The termination line (0) is included to terminate the input to the ReadVarsESO program and begin the scanning.

The output from ReadVarsESO is in the form commonly called "comma de-limited" or "comma separated variable". This format can be read easily in spreadsheet programs, such as Excel™.

Note as described in the "Input for Output" above, only variables as listed on the **eplusout.rdd** file are available for reporting. If you request others, they will become "Warning" messages in the **eplusout.err** file.

```
** Warning ** The following Report Variables were requested but not generated
**   ~~~   ** because IDF did not contain these elements or misspelled variable name -- check .rdd file
***** Key=*, VarName=SYSTEM SENSIBLE COOLING RATE
```

The above message was generated from an IDF that requested reporting of the "SYSTEM SENSIBLE COOLING RATE" but that variable was not available from the components in the execution.

Table 39. Example ReadVarsESO command lines and results

Command Line	Description/Result
ReadVarsESO	Take eplusout.eso and produce an eplusout.csv file with all variables (up to 255) on it

ReadVarsESO my.rvi	Use the contents of "my.rvi" to produce the appropriate output file (limited to 255 variables)
ReadVarsESO my.rvi unlimited	Use the contents of "my.rvi" to produce the appropriate output file (no longer limited to 255 variables)
ReadVarsESO my.rvi Monthly	Use the contents of "my.rvi" to produce the appropriate output file and only produce those variables reported for "monthly" frequency (up to 255 variables)
ReadVarsESO my.rvi Daily unlimited	Use the contents of "my.rvi" to produce the appropriate output file and only produce those variables reported for "daily" frequency (no longer limited to 255 variables)

Standard Output Reports

The following objects allow standard reports to be defined and utilized in EnergyPlus:

- Output:Table:TimeBins
- Output:Table:Monthly
- Output:Table:SummaryReports
- OutputControl:Table:Style

No Output:Meter or Output:Variable objects need to be specified to use the standard reports. A good set of example reports are available in the StandardReports.idf file in the DataSets directory of EnergyPlus.

Output:Table:TimeBins

The Output:Table:TimeBins report shows the amount of time in hours that occurs in different bins for the single specific variable or meter specified. Two different types of binning occur: by month and by hour of the day.

The IntervalStart, IntervalSize and IntervalCount determine the size of the bins for many of the types of reports that can be generated. The IntervalStart value is the lowest value of the first bin. The first bin is for all values greater or equal to IntervalStart and less than IntervalStart+IntervalSize. This gets repeated IntervalCount times. A bin for below the first interval and above the last interval is automatically created. Each table also has totals for the column and the rows. The report produced by Report:Table:TimeBins also indicates the total time simulated (for an annual simulation this would be 8760 hours).

NOTE: For summed variables, such as meters, the values are divided by the length of the timestep in seconds before binning. For example, the bins for a variable in Joules are reported in Joules per second (Watts). The interval values must then be entered accordingly.

Field: Key Value

The Key Value field indicates which instance of a variable is reported. An asterisk indicates that a table would be produced for every key.

Field: Variable Name

The variable name to be reported. Reference the eplusout.rdd file for names that are specific to your simulation input file. You do not need to include the units [] field in your names here.

Field: Interval Start

The lower value of the first bin. The first bin is for all values greater or equal to the IntervalStart and less than IntervalStart + IntervalSize. See note above regarding summed variables.

Field: Interval Size

The amount by which each bin range is to increase, i.e. the difference between the upper and lower limits of each bin. See note above regarding summed variables.

Field: Interval Count

The number of bins desired.

Field: Schedule Name

Optional schedule name. If left blank, binning is performed for all hours simulated. If a schedule is specified, binning is performed for non-zero hours in the schedule.

The IDD entry for this object follows.

```

Output:Table:TimeBins,
  \min-fields 5

Electricity:HVAC, ! Variable Name
4000000, ! Interval Start
500000, ! Interval Size
20; ! Interval Count

```

Output:Table:Monthly

The Output:Table:Monthly object provides a generic method of setting up tables of monthly results. These tables are good for creating reports that broadly summarize the building performance. At the bottom of the tables, three rows are added for the sum or average depending on the type of variable, the maximum and the minimum of each column. The report produced has multiple columns that are each defined using a repeated group of fields. The fields for the variable name and the aggregation type can be repeated for any number of columns. A single Output:Table:Monthly object often produces multiple tables in the output. A table is produced for every “key” for a particular output variable. A single table of results shows values only for a specific “key”. The exception to this are environment variables, such as outdoor air temperature, that are included in each table, no matter what the key.

Field: Name

The Name field allows the user to give the output table a label that is shown in the output file.

Field: Digits After Decimal

The Digits After Decimal field is a numeric value that indicates how many digits after the decimal point should be shown on the table of values.

Field Set: Variable or Meter and Aggregation Type

The VariableOrMeterName field and the AggregationType field may be repeated for each column desired in the monthly report. These two fields define each column of the report. The IDD object has been set up to allow up to 25 columns. This object is extensible, so the number of columns may be increased by editing the IDD file and adding the desired number of fields at the end of the object.

Field: Variable or Meter <#> Name

The remainder of this input object consists of pairs of fields that can be repeated. Variable Or Meter Name fields contain the name of a variable (see Output:Variable and eplusout.rdd), meter (see Output:Meter and eplusout.mdd), or schedule. This value is shown on a monthly basis using the aggregation method specified. If the selected name is used for both a variable or a meter and a schedule name, the variable or meter will be used.

Field: Aggregation Type for Variable or Meter <#>

The aggregation type determines how the variable is aggregated in the table. The choices for aggregation type are described below:

Simple Aggregation Types

SumOrAverage – For “sum” type variables adds up the values for each timestep and reports the sum of the value monthly. For “average” type variables, the value shown will be the average for the month. SumOrAverage is probably the most common choice for aggregation type.

Maximum – Reports the maximum value and the time that the maximum value occurred. When the maximum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the maximum for a variable in Joules is reported in Watts.

Minimum – Reports the minimum value and the time that the minimum value occurred. When the minimum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the minimum for a variable in Joules is reported in Watts.

HoursNonZero – The HoursNonZero option adds up the elapsed time during the month that this variable is non-zero and would be appropriate to determine the number of hour that a fan operates.

HoursZero – The HoursZero option adds up the elapsed time during the month that this variable has a zero value and would be appropriate to determine the number of hour that a fan does not operate.

HoursPositive – The HoursPositive option adds up the elapsed time during the month that this variable has a positive value. Hours with a zero value are not included.

HoursNonPositive – The HoursNonPositive option adds up the elapsed time during the month that this variable has non-positive value. Hours with a negative value and hours with a zero value are all included.

HoursNegative – The HoursNegative option adds up the elapsed time during the month that this variable has a negative value. Hours with a zero value are not included.

HoursNonNegative – The HoursNonNegative option adds up the elapsed time during the month that this variable has non-negative value. Hours with a positive value and hours with a zero value are all included.

Advanced Aggregation Types

The advanced aggregation types are described below. These aggregation types rely on doing an operation on the current variable but only during the time or times defined by a previously defined field. The ValueWhenMaxOrMin displays the value of one variable at the same time as the maximum or minimum is set on a previous field that is defined as either a maximum or minimum. The “Hours—“ aggregation types display then number of hours that a variable meets a condition. The “—DuringHoursShown” aggregation types perform those aggregations but instead of for all the hours in the month, only for the hours that the previous “Hours—“ entry applies. Multiple “—DuringHoursShown” after an “Hours—“ will all be based on that single “Hours—“ entry, in fact the “—DuringHoursShown” is based on the next column to the left that contains an “Hours—“ entry even if other types of aggregations are used in intermediate columns. Order of the variables in the report is important when using the advanced aggregation types since they often depend on a previous entry.

ValueWhenMaximumOrMinimum – The ValueWhenMaximumOrMinimum option looks at the previous variable in the report that sets a maximum or minimum and displays the value of the current variable at that same timestep. Order of the variables in the report is important when using ValueWhenMaxMin. This can be used, for example, when an outdoor temperature should be reported for the time of the maximum cooling load.

SumOrAverageDuringHoursShown – Provides the sum or average of the named variable when during the hours that the previous variable displayed with any of the aggregation types starting with “Hours”. For “sum” type variables adds up the values for each timestep and reports the sum of the value monthly during the hours reported on the previous variable. For “average” type variables, the value shown will be the average for the month during the hours reported on the previous variable. Order of the variables in the report is important when using this aggregation type.

MaximumDuringHoursShown – Reports the maximum value and the time that the maximum value occurred but only during the hours reported with the previous “hours-“ aggregation type. When the maximum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the maximum for a variable in Joules is reported in Watts. Order of the variables in the report is important when using this aggregation type.

MinimumDuringHoursShown - Reports the minimum value and the time that the minimum value occurred but only during the hours reported with the previous “hours-“ aggregation type. When the minimum option is used with a summed variable the value is divided by the length of the timestep in seconds. For example, the minimum for a variable in Joules is reported in Watts. Order of the variables in the report is important when using this aggregation type.

The IDD entry for this object follows.

```

Output:Table:Monthly,
  \extensible:2
  A1, \field Name
    \required-field
    \type alpha
    \reference StandardReportNames
  N1, \field Digits After Decimal
    \type integer
    \default 2
    \minimum 0
    \maximum 10
! The next two fields are repeated for each column
  A2, \field Variable or Meter 1 Name
    \type object-list
    \object-list autoRDDvariableMeter
    \note The name of a report variable or a meter that is available in the RDD file.
  A3, \field Aggregation Type for Variable or Meter 1
    \type choice
    \key SumOrAverage
    \key Maximum
    \key Minimum
    \key ValueWhenMaximumOrMinimum
    \key HoursNonZero
    \key HoursZero
    \key HoursPositive
    \key HoursNonPositive
    \key HoursNegative
    \key HoursNonNegative
    \key SumOrAverageDuringHoursShown
    \key MaximumDuringHoursShown
    \key MinimumDuringHoursShown
    \note The method of aggregation for the selected variable or meter.
    \note SumOrAverage adds up the values for every timestep in the month if the variable is a sum
variable. If the
    \note variable is an average variable it reports the average value. This is probably the most
common
    \note Aggregation Type option to choose.
    \note Maximum and Minimum find the maximum and minimum value for the month and report it along with
the
    \note time that it first occurred. When Maximum or Minimum are selected a column is
automatically shown
    \note in the output report for the time that it occurred. When Maximum or Minimum are used with
an average
    \note variable the value is divided by the length of the timestep.
    \note ValueWhenMaxMin looks at the previous variable in the report that sets a maximum or minimum
and
    \note displays the value of the current variable at that same timestep. Order of the variables
in the
    \note report is important when using ValueWhenMaxMin. This can be used when an outdoor
temperature
    \note should be reported for the time of the maximum cooling load.
    \note HoursNonZero adds up the elapsed time during the month that this variable is non-zero and
would
    \note be appropriate to determine the number of hour that a fan operates.
    \note HoursZero - The HoursZero option adds up the elapsed time during the month that this variable
has a zero
    \note value and would be appropriate to determine the number of hour that a fan does not operate.
    \note HoursPositive - The HoursPositive option adds up the elapsed time during the month that this
variable
    \note has a positive value. Hours with a zero value are not included.
    \note HoursNonPositive - The HoursNonPositive option adds up the elapsed time during the month
that this
    \note variable has non-positive value. Hours with a negative value and hours with a zero value
are all included.
    \note HoursNegative - The HoursNegative option adds up the elapsed time during the month that this
variable
    \note has a negative value. Hours with a zero value are not included.
    \note HoursNonNegative - The HoursNonNegative option adds up the elapsed time during the month
that this
    \note variable has non-negative value. Hours with a positive value and hours with a zero value
are all included.

```

```

    \note SumOrAverageDuringHoursShown - Provides the sum or average of the named variable when during
the hours
    \note that the previous variable displayed with any of the Aggregation Types starting with
"Hours". For "sum"
    \note type variables adds up the values for each timestep and reports the sum of the value
monthly during the
    \note hours reported on the previous variable. For "average" type variables, the value shown
will be the
    \note average for the month during the hours reported on the previous variable. Order of the
variables in the
    \note report is important when using this Aggregation Type.
    \note MaximumDuringHoursShown - Reports the maximum value and the time that the maximum value
occurred but only
    \note during the hours reported with the previous "hours-" Aggregation Type. When the Maximum
option is used
    \note with an average variable the value is divided by the length of the timestep. Order of the
variables in
    \note the report is important when using this Aggregation Type.
    \note MinimumDuringHoursShown - Reports the minimum value and the time that the minimum value
occurred but only
    \note during the hours reported with the previous "hours-" Aggregation Type. When the Minimum
option is used
    \note with an average variable the value is divided by the length of the timestep. Order of the
variables in
    \note the report is important when using this Aggregation Type.

Output:Table:SummaryReports

The Output:Table:SummaryReports object controls which predefined tabular reports are produced. The easiest option is to specify "AllSummary" which will produce all of the summary reports described in this section. In addition, "AllMonthly" will produce all of the monthly reports described. If all predefined reports are needed. "AllSummaryAndMonthly" shows all of the summary and monthly predefined reports.

Field: Report <#> Name

All of the fields in the Output:Table:SummaryReports are the same. A long list of predefined summary reports is available by entering one of the available key choices described below. Each one indicates the name of the predefined reports that should be output. The input AllSummary will cause all the reports described below to be created. The Report <#> Name field can be repeated.

Predefined Annual Summary Reports

Annual Building Utility Performance Summary (or ABUPS)

The AnnualBuildingUtilityPerformanceSummary key produces a report that is an overall summary of the utility consumption of the building. It contains a number of subtables that are each described below.

- Site and Source Energy – Indicates the total site and source energy use. For electricity the net electricity from the utility is used for the electric contribution. The site to source conversion factors are based on those entered by the user. These are entered in the EnvironmentalImpactFactors object and FuelFactors objects.

- **Building Area** – Shows the total floorspace of the building and the conditioned floorspace.
- **End Uses** – This shows the total use of electricity, natural gas, other fuels, purchased cooling, purchased heating and water for each major end-use category. The end-use categories are Heating, Cooling, Interior Lighting, Exterior Lighting, Interior Equipment, Exterior Equipment, Fans, Pumps, Heat Rejection, Humidification, Heat Recovery, Hot Water, Refrigeration, and Generators. Not all fuels have corresponding end uses. The values in this sub-table are from report meters. The source of the resource does not affect this table – the amount of electricity used for lights does not change if the electricity is from the utility or from an on-site generator. The Other Fuel column includes fuel oil#1, fuel oil#2, gasoline, coal, propane and diesel. The district heating column also includes steam.
- **End Uses By Subcategory** – Shows a breakdown of the major end uses by user-defined category. If an end-use subcategory was not input for an object, it is automatically added to the General subcategory for that major end-use category.
- **Utility Use Per Floor Area** – These two sub-tables show the results from the end-uses table divided by the total floor area defined for the building and for the total conditioned floor area. Only three categories for end-uses are used for these sub-tables, lighting, HVAC and other. HVAC includes fans, pumps, heating, cooling, heat rejection, humidification, and domestic hot water heating. The Other Fuel column includes fuel oil#1, fuel oil#2, gasoline, coal, propane and diesel. The district heating column also includes steam.
- **Electric Loads Satisfied** – Shows the different methods that electric loads are satisfied in the building. The values shown for on site power generation are: Fuel-Fired Power Generation, High Temperature Geothermal, Photovoltaic Power, and Wind Power. The flows to and from the electric utility are shown next and finally the total electricity used at the site is compared to the total generated on site plus the net amount from the electric utility. The percentages shown are based on the total electricity used by the end-uses. Note that High Temperature Geothermal and Wind Power are not yet implemented in EnergyPlus.
- **On-Site Thermal Sources** – Shows the on-site thermal sources of energy such as Water-Side Heat Recovery, Air to Air Heat Recovery for Cooling, Air to Air Heat Recovery for Heating, High-Temperature Geothermal, Solar Water Thermal, Solar Air Thermal. Note that High-Temperature Geothermal Solar Water Thermal, and Solar Air Thermal are not yet implemented in EnergyPlus.
- **Water Loads Summary** – Shows the different methods the water loads were satisfied. This table shows all zeros because water use is not yet implemented in EnergyPlus.

Input Verification and Results Summary (or IVRS)

The InputVerificationandResultsSummary key produces a report with several tables including:

- **General** which includes general information like the Program Version and Build, Weather, Latitude, Longitude, Elevation, Time Zone, North Axis Angle, and Hours Simulated.
- **Window-Wall Ratio** table for envelope which includes the wall area, the window area and the ratio of the two. These are computed for all walls and for walls that are oriented generally north, south, east and west. All walls are categorized into one of these four cardinal directions. This is computed for walls that have a tilt of 60 degrees or more.
- **Skylight-Roof Ratio** table for envelope which includes the roof area and the skylight area and the ratio of the two. This includes all surfaces with a tilt of less than 60 degrees.

- Zone Summary includes internal load summary for each zone including area, if conditioned, volume, multipliers, gross wall area, window area, design lighting, design people, design plug and process.

Climate Summary

The ClimaticDataSummary key produces a report that includes some of the details on each of the design days including: maximum dry-bulb, daily temperature range, humidity value, humidity type, wind speed, and wind direction.

Envelope Summary

The EnvelopeSummary key produces a report that includes the following tables:

- Opaque which includes all opaque surfaces and includes the name of the construction, reflectance, U-Factor, gross area, azimuth, tilt, cardinal direction.
- Fenestration which includes all non-opaque surfaces and includes the name of the construction, area, U-Factor, SHGC – the sensible heat gain coefficient based on summer conditions, presence of an overhang, projection factor, overhang multiplier, adjusted SHGC, the name of the parent surface. Not all of these fields are currently functional.

Surface Shadowing Summary

The SurfaceShadowingSummary key produces a report that includes two tables. Note that surfaces starting with "Mir-" are automatically generated by EnergyPlus and are the mirror images of user entered surfaces.

- Surfaces (Walls, Roofs, etc) that may be Shadowed by Other Surfaces and includes the name of the surface and a list of surfaces that may possibly cast shadows on that named surface. The list of possible shadow casters does not necessarily mean that they do cast shadows during the simulation, only that their relative position makes it possible that shadows from a surface in the list may fall on the named surface.
- Subsurfaces (Windows and Doors) that may be Shadowed by Surfaces, includes the name of the subsurface such as a window or a door and a corresponding list of surfaces that may be casting shadows on the windows and doors.

Shading Summary

The ShadingSummary key produces a report that includes the following tables:

- Sunlit Fraction which shows a list of windows and the fraction of the window that is sunlit for nine specific times of the year. The nine specific times include 9am, noon and 3pm on March 21, June 21, and December 21. These nine times were chosen to represent the range of sun angles. The simulation must include those times for the value to be included in the report.
- Window control includes the names of all windows that have a window shading control (see WindowProperty:ShadingControl) and includes the name of the control, the type of shading, the shaded construction, the kind of control, and if glare control is used.

Lighting Summary

The LightingSummary key produces a report that includes the following tables:

- Interior Lighting which includes the name of the lights object, the zone that it is used in, the lighting power density, zone area, total power, end use subcategory, schedule name, average hours per week, return air fraction, and whether the zone is conditioned.
- Daylighting which includes the names of the daylighting objects, the zone they are used in, the type of daylighting being used, the control type, the fraction of the

lighting controlled, the total power of the lighting installed in the zone and the lighting power that is controlled by the daylighting object.

- Exterior Lighting which includes the name of the ExteriorLights object, the total watts described by the object, if the ExteriorLights uses an astronomical clock or just a schedule, the name of the schedule used, and the average hours per week for the named schedule for the year. The effect of the astronomical clock does not get included in the averaged hours per week shown.

Equipment Summary

The EquipmentSummary key produces a report that includes some details on the major HVAC equipment present. The report has four parts.

- Central Plant includes details on chillers, boilers, and cooling towers including the capacity and efficiency.
- DX Coils includes the capacity and efficiency for each DX coil.
- Fan includes the type of fan, the total efficiency, delta pressure, max flow rate, motor heat in air fraction, and end use.
- Service Water Heating includes the type of water heater, the storage volume, input, thermal efficiency, recovery efficiency, and energy factor.

HVAC Sizing Summary

The HVAC SizingSummary key produces a report that includes the following tables:

- Zone Cooling which includes the following columns for each zone: the design load, the calculated design air flow, the user specified design air flow, the name of the design day, the time of the peak load during the design day, the temperature at the time of the peak load during the design day, and the humidity ratio at the time of the peak load during the design day.
- Zone Heating which includes the following columns for each zone: the design load, the calculated design air flow, the user specified design air flow, the name of the design day, the time of the peak load during the design day, the temperature at the time of the peak load during the design day, and the humidity ratio at the time of the peak load during the design day.
- System Design Air Flow Rates which includes the following columns for each air loop: the calculated cooling air flow rate, the user specified air flow rate for cooling, the calculated heating air flow rate, the user specified air flow rate for heating.

Component Sizing Summary

The ComponentSizingSummary key produces a report that includes different tables depending on the kinds of HVAC components that exist in the input file. A table is shown for each type of HVAC component that is sized. The table lists the objects of that type of component that appear in the input file and one or more parameters related to that component. For example, the AirTerminal:SingleDuct:VAV:Reheat component creates a table showing the maximum air flow rate from the sizing calculations and the maximum reheat water flow rate. Another example is the Fan:VariableVolume object which shows a table with both the maximum and minimum flow rates for each fan based on the results from the sizing calculations.

Outdoor Air Summary

The OutdoorAirSummary key produces a report that includes the following tables:

- Average Outside Air During Occupied Hours table shows for each zone the average and nominal number of occupants, the zone volume, the average air change rate based on mechanical ventilation, infiltration and simple ventilation during occupied hours.

- Minimum Outside Air During Occupied Hours table shows for each zone the average and nominal number of occupants, the zone volume, the minimum air change rate based on mechanical ventilation, infiltration and simple ventilation during occupied hours.

System Summary

The SystemSummary key produces a report that includes the following tables:

- Economizer which includes the following columns for each Controller:OutdoorAir object: the high limit shutoff control, the minimum outdoor air flow, the maximum outdoor air flow, if the return air temperature has a control limit, if the return air has an enthalpy limit, the outdoor air temperature limit, and the outdoor air enthalpy limit.
- Demand Controlled Ventilation table is for each Controller:MechanicalVentilation object and shows the name, the nominal outdoor air per person and the nominal outdoor air per zone area.
- Time Not Comfortable Based on Simple ASHRAE 55-2004 table shows how many hours that the space is not comfortable for each zone under the criteria of assuming winter clothes, summer clothes or both summer and winter clothes. See the People object for more information about this thermal comfort calculation.
- Time Setpoint is Not Met table shows how many hours the space is more than 0.2C from the setpoint during heating and during cooling. The last two columns indicate those hours that the setpoint is not met while the space is occupied.

Predefined Monthly Summary Reports

The predefined monthly report options are shown below. The key name of the predefined monthly report is all that is needed to have that report appear in the tabular output file. After each report name below are the report variables and aggregation types used. These cannot be modified when using the predefined reports but if changes are desired, a Output:Table:Monthly can be used instead. The StandardReports.idf file in the DataSets directory includes a Output:Table:Monthly that exactly corresponds to the predefined monthly reports shown below. They can be copied into an IDF file and extended if additional variables are desired. A listing of each available key for predefined monthly summary reports follows with a description of the variables included.

ZoneCoolingSummaryMonthly

- Zone/Sys Sensible Cooling Energy (SumOrAverage)
- Zone/Sys Sensible Cooling Rate (Maximum)
- Outdoor Dry Bulb (ValueWhenMaxMin)
- Outdoor Wet Bulb (ValueWhenMaxMin)
- Zone Total Internal Latent Gain (SumOrAverage)
- Zone Total Internal Latent Gain (Maximum)
- Outdoor Dry Bulb (ValueWhenMaxMin)
- Outdoor Wet Bulb (ValueWhenMaxMin)

ZoneHeatingSummaryMonthly

- Zone/Sys Sensible Heating Energy (SumOrAverage)
- Zone/Sys Sensible Heating Rate (Maximum)

Sample IDF Input – Report:Table:Predefined

```

Output:Table:SummaryReports,
    All Summary; !- Report 1 Name

```

OutputControl:Table:Style

The OutputControl:Table:Style object controls how all standardized reports are produced.

Field: Column Separator

You have seven different options:

- Comma
- Tab
- Fixed
- HTML
- CommaAndHTML
- TabAndHTML
- All

The Comma style produces a text file (eplustbl.csv) with the values of the table separated by commas. This is a good format for importing the results into a spreadsheet. If you do open the file with a spreadsheet, make sure you close the file prior to rerunning EnergyPlus otherwise the file will not be updated.

The Tab style produces a text file (eplustbl.tab) with the values separated by tabs. It is also a good format for using with a spreadsheet program but has the advantage of being more readable in a text editor.

The Fixed style produces a text file (eplustbl.txt) with the values at specific columns. It is the easiest to view using a text editor.

The HTML style produces a file (eplustbl.htm) that can be opened with an internet browser program. The values are shown in a tabular format that is easy to view. One advantage of the HTML style is that the results can be viewed in an internet browser program and EnergyPlus can be rerun and the “refresh” button pressed in the internet browser program to see the new results. . When the HTML style is specified, a Table of Contents for the file is generated and placed near the top of the file after the ABUPS report. The Table of Contents includes the names of each report and links for each table in the file.

The last three options combine the previous styles and allow multiple reports with different styles to be produced during a single simulation.

Field: Unit Conversion

This field is optional and if not specified defaults to no unit conversions. Four different input options are available:

- None – no conversions performed
- JtoKWH – Joules converted into kWh (1 / 3,600,000)
- JtoMJ – Joules converted into Megajoules (1 / 1,000,000)
- JtoGJ – Joules converted into Gigajoules (1 / 1,000,000,000)
- InchPound – convert all annual, monthly, economics and timebins tabular values to common Inch-Pound equivalent

The current options are limited to just how the energy is being reported. The default is to report energy in the form of Joules but since the magnitude of those numbers for many buildings is very large, these other conversion factors are available.

The JtoKWH, JtoMJ and JtoGJ unit conversion input option applies only to the Output:Table:Monthly reports and partially to the ABUPS report. For ABUPS, the JtoKWH option changes the report but the JtoMJ and JtoGJ options do not change the report since they it is already in MJ/m² and GJ.. The InchPound unit conversion input option applies to all annual, monthly, timebins and economic reports that appear in the tabular output file. In addition, this option does not effect the standard eplusout.eso file. The eplusout.eso file may be converted by using the ConvertESOMTR utility.

The IDD entry for this object follows.

```
OutputControl:Table:Style,
  \memo default style for the OutputControl:Table:Style is comma -- this works well for
  \memo importing into spreadsheet programs such as Excel(tm) but not so well for word
  \memo processing programs -- there tab may be a better choice.  fixed puts spaces between
  \memo the "columns".  HTML produces tables in HTML.
  \unique-object

Weather Data

The description of the weather data format (a simple text-based format) is well described in the Auxiliary Programs document and won't be repeated here. Descriptions here will be pertinent to running the EnergyPlus program but you may wish to peruse the other descriptions as the statistics reports from the weather files may be useful during design and simulation.

Missing Weather File Data

The weather description of data contains "missing" descriptors, a new concept not introduced previously in our IDD conventions. In this case, it will be processed as though those values are "missing" in the weather conversions and/or EnergyPlus weather processing. This may not always be desirable though EnergyPlus will fill in "missing" value with something "appropriate". Eventually, these missing values will be available through the IDD and users will be able to supply their own values or EnergyPlus will calculate those values (such as radiation and illuminance) that are not a simple value replacement. Until then, the following are used:

Table 40. Missing weather replacement values

Data item	Supplied Value	Units
Dry-bulb Temperature	6	C
Dewpoint Temperature	3	C
Relative Humidity	50	%
Atmospheric Pressure	Standard** Barometric Pressure (altitude based)	Pa
Wind Speed	2.5	m/s
Wind Direction	180	Deg
Total Sky Cover	5	(tenths)
Opaque Sky Cover	5	(tenths)
Visibility	777.7	Km
Ceiling Height	77777	m
Precipitable Water	0	Mm
Aerosol Optical Depth	0	Broadband turbidity
Snow Depth	0	Cm
Days Since Last Snow	88	Days
Radiation Values (Direct/Diffuse)	0.0	Wh/m2
Illuminance Values	0.0	lux (or CD/m2)

**Standard Barometric pressure based on location elevation is taken from ASHRAE 2001 Handbook of Fundamentals, Page 6.1 & 2.

Weather Data Hourly Interpolation

Much of the existing weather data is produced in hourly format (refer to the discussion of data formats and weather conversion processing in the Auxiliary Programs Document). In order to match the hourly data in a continuous manner for EnergyPlus (where the timesteps might be less than hourly), simple interpolation between “last hour’s” values and “this hour’s” values is performed; we will refer to this as “Last Hour Interpolation”.

Note that in versions prior to V1.0.3, the interpolation was done between “this hour” and “next hour”. If required, we will refer to this as “Next Hour Interpolation”.

Remember that hour 1 for EnergyPlus is the time interval 00:00:01AM to 1:00:00AM. Hour 2 is 1:00:01AM to 2:00:00AM (hh:mm:ss). With the interpolation scheme (Last Hour Interpolation) and reporting weather data values at timestep resolution, the “hour” values reported should match with the hourly weather data values. (Note that reporting “hourly” resolution will not do this unless your “Number of Timesteps per Hour” is 1).

Note that this interpolation applies to outdoor data only – schedule values are not interpolated in this manner.

The weighting scheme / interpolation is simply:

$$Value_{TimeStep} = LastHourValue \cdot Weight_{LastHour} + ThisHourValue \cdot Weight_{ThisHour}$$

where

$$Weight_{ThisHour} = \frac{CurrentTimeStep}{Number\ of\ TimeSteps\ in\ Hour}$$

$$Weight_{LastHour} = 1.0 - Weight_{ThisHour}$$

To explain further, the weighting for four (4) timesteps in hour is:

Table 41. Illustration of Data Interpolation for 15 minute timesteps

TimeStep	Time (mm:ss)	Weight _{LastHour}	Weight _{ThisHour}
1	00:01 to 15:00	.75	.25
2	15:01 to 30:00	.5	.5
3	30:01 to 45:00	.25	.75
4	45:01 to 60:00	0	1.0

And similarly for six (6) timesteps in hour:

Table 42. Illustration of Data Interpolation for 10 minute timesteps

TimeStep	Time (mm:ss)	Weight _{LastHour}	Weight _{ThisHour}
1	00:01 to 10:00	0.8333333333333333	0.1666666666666667

2	10:01 to 20:00	0.6666666666666667	0.3333333333333333
3	20:01 to 30:00	.5	.5
4	30:01 to 40:00	0.3333333333333333	0.6666666666666667
5	40:01 to 50:00	0.1666666666666667	0.8333333333333333
6	50:01 to 60:00	0	1.0

This interpolation gives a smooth, continuous look to the outdoor data. For day boundaries (i.e. from hour 24 to hour 1), the values from the previous day's last hour (23:00:01 to 24:00:00). For the a design day, this is the values for hour 24. For the first day of a weather simulation, it is likewise values for hour 24 of that day. For subsequent weather days, it will be the last hour of the previous day.

Weather File Data Reporting (errors) during Simulation

Missing data on the weather file used will be summarized on the **eplusout.err** file. In EnergyPlus, "missing data" is shown only for fields that EnergyPlus will use. For the "WeatherCodes", an invalid field count (where the number of items in the field does not = 9) will be shown. The number of items count refers to the number of records on the weather file that are in error or missing – for an hourly weather file, this is the number of hours. Likewise out of range values (see specific fields in the previous definition) will be counted for each occurrence and summarized. Note that the out of range values will not be changed by EnergyPlus and could affect your simulation results.

For example:

```

** Warning ** Missing Data Found on Weather Data File
***** Missing Atmospheric Pressure, Number of items= 48
***** Missing Dry Bulb Temperatures, Number of items= 4
** Warning ** Out of Range Data Found on Weather Data File
***** Out of Range Dry Bulb Temperature [>-70,<70], Number of items= 1

```

Running EnergyPlus

EnergyPlus is written in language conforming to Fortran Standard 90/95/F2003. It runs as a 32 bit console (non-Windows) application on Intel compatible computers (Windows NT, Windows 95/98). Linux and Macintosh version are also available. Details on running EnergyPlus are available in a separate document (Running EnergyPlus in Getting Started). The following files are needed to run EnergyPlus:

```
EnergyPlus.exe (the executable file)
Energy+.ini (described below)
Energy+.idd (the input data dictionary file)
In.idf (the input file)
In.epw - optional (weather data file)
```

The input data dictionary and input data file have been discussed in the previous sections of this document.

For weather simulations, EnergyPlus accepts EnergyPlus weather files. The actual file name is **in.epw**.

The usual release for Windows platform also includes bindings that require these files.

```
DElight2.dll
```

Energy+.ini

The Energy+.ini file is read by the EnergyPlus.exe program and is *very important* to the simulation run. In specific, this file contains a pointer to where the Energy+.idd file will be found. More description of the Energy+.ini contents is contained in the Auxiliary Programs document.

For the advanced user, there is also the "EPMacro" program, described in the Auxiliary programs document. You run it as a separate program before EnergyPlus (the batch file included in the install and shown in the GettingStarted document contains the commands). It is automatically run if you use the EP-Launch program.

EnergyPlus may create several output files. Whether some files are produced depends on the actual simulation (for example, the .rdd file is only produced when you request a Variable Dictionary using the Output:Report object). Similarly, the .dxf file is only produced when a DXF surface report is requested. Common output files are shown in the following table. A complete, up to date list is shown in the "Output Details and Examples Document".

Table 43. EnergyPlus Output Files

FileName	Description
Eplusout.audit	Echo of input
Eplusout.err	Error file
Eplusout.eso	Standard Output File (contains results from both Report Variable and Report Meter objects).
Eplusout.eio	One time output file
Eplusout.rdd	Report Variable Data Dictionary
Eplusout.dxf	DXF (from Output:Report,Surfaces,DXF;)
Eplusout.mtr	Similar to .eso but only has Meter outputs.

Eplusout.mtd	Meter details report – what variables are on what meters and vice versa.
Eplusout.end	A one line summary of success or failure (useful for Interface programs)
Eplusout.dbg	From Debug Output object – may be useful to support to help track down problems
Eplusout.<ext>	Not directly from EnergyPlus – produced by utility programs that read the .eso file and produce output files for spreadsheet programs
Eplusout.sln	Similar to DXF output but less “formatted”. Results of Report Surface, Lines object.
Epluszsz.<ext>	Results from the Zone Sizing object with extension noted by the Sizing Style object. This file is “spreadsheet” ready.
Eplusssz.<ext>	Results from the System Sizing object with extension noted by the Sizing Style object. This file is “spreadsheet” ready.
Eplusout.bnd	This file contains details about the nodes and branches. Useful in determining if all your nodes are connected correctly.
Eplustbl.<ext>	Results from various “Report Table” and a few other reporting commands. The extension is from the “style” command and this file is “spreadsheet” ready.

Errors

The **eplusout.err** file may contain three levels of errors (Information, Warning, Severe, Fatal) as well as the possibility of just message lines, see Table 44. EnergyPlus Errors and Required Actions. These errors may be duplicated in other files (such as the standard output file). These errors are described more completely in the Output Details and Examples document. An example .err file from the 1ZoneUncontrolled example input file:

```

Program Version,EnergyPlus 3.0.0.025, 11/4/2008 5:03 PM,IDD_Version 3.0.0.025
** Warning ** GetPollutionFactorInput: Requested reporting for Carbon Equivalent Pollution, but
insufficient information is entered.
**   ~~~   ** Both "FuelFactors" and "EnvironmentalImpactFactors" must be entered or the displayed
carbon pollution will all be zero.
*****
***** Testing Individual Branch Integrity
***** All Branches passed integrity testing
***** Testing Individual Supply Air Path Integrity
***** All Supply Air Paths passed integrity testing
***** Testing Individual Return Air Path Integrity
***** All Return Air Paths passed integrity testing
***** No node connection errors were found.
***** EnergyPlus Completed Successfully-- 1 Warning; 0 Severe Errors; Elapsed Time=00hr 00min
6.34sec

```

Table 44. EnergyPlus Errors and Required Actions

Error Level	Action
Information, shown as *****	Informative, usually a follow-on to one of the others. No action required.
** ~~~ **	This is a continuation of a previous message. String all the words/sentences together to form the complete message.
Warning	Take note. Fix as applicable.
Severe	Should Fix
Fatal	Program will abort, Must Fix

EnergyPlus produces several messages as it is executing, as a guide to its progress. These message illustrate the sequence of execution as well as provides checkpoints should the simulation fail.

For example, the run of the 1ZoneUncontrolled example input file produces the log:

```

Running d:\eppgm\intcheck\energyplus.exe
Running d:\eppgm\intcheck\energyplus.exe
Input File : d:\devtests\inputfiles\checkin\1ZoneUncontrolled.idf
Output Files: d:\devtests\inputfiles\outputs\
Weather File: USA_CO_Denver-Stapleton_TMY.epw

Speed of Execution

Extensive timing studies and fine-tuning of EnergyPlus are NOT complete. Remember that hourly simulations can not be directly compared to EnergyPlus with it's less than hourly timesteps.

Appendix A. Units and Abbreviations

Standard EnergyPlus Conditions

Standard Temperature and Pressure

Several objects specify inputs at “standard temperature and pressure”. Standard Temperature is dry air at 20° C drybulb. The program uses local barometric pressure to account for altitude using the equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$Stdpressure = 101325 \cdot (1.0 - Z \cdot 2.25577^{-5})^{5.2559}$$

where

StdPressure = pressure {Pa}

Z = altitude/elevation {m}

Standard EnergyPlus Units

EnergyPlus expects information in a single unit system (SI). This requires interface developers to convert user inputs from those preferred by architects and engineers into the standard metric units of EnergyPlus. EnergyPlus will not perform any units conversions and will not have any unit conversion routines.

ASCII with no spaces is used for abbreviations. Note that exponents appear without any indication of exponentiation: i.e., kg/m3 not kg/m^3 or kg/m**3. Also note the use of dashes. We have W/m2-K not W/m2*K or W/(m2*K).

At the end we note the “problem” variables – the inputs that have non-standard units. Inputs using these units will have to be changed and the code checked to see how the quantities are used internally.

Table 45. Standard EnergyPlus Units

Quantity	unit	abbreviation
angular degrees	degree	deg
Length	meter	m
Area	square meter	m2
Volume	cubic meter	m3
Time	seconds	s
Frequency	Hertz	Hz
Temperature	Celsius	C
absolute temperature	Kelvin	K
temperature difference	Kelvin	deltaC
speed	meters per second	m/s
energy (or work)	Joules	J
power	Watts	W
mass	kilograms	kg
force	Newton	N

Quantity	unit	abbreviation
mass flow	kilograms per second	kg/s
volume flow	cubic meters per second	m ³ /s
pressure	Pascals	Pa
pressure difference	Pascals	Pa
specific enthalpy	Joules per kilogram	J/kg
density	kilograms per cubic meter	kg/m ³
heat flux	watts per square meter	W/m ²
specific heat	-----	J/kg-K
conductivity	-----	W/m-K
diffusivity	-----	m ² /s
heat transfer coefficient	-----	W/m ² -K
R-value	-----	m ² -K/W
heating or cooling capacity	Watts	W
electric potential	volts	V
electric current	Amperes	A
illuminance	lux	lx
luminous flux	lumen	lm
luminous intensity	candelas	cd
luminance	candelas per square meter	cd/m ²
vapor diffusivity	meters squared per second	m ² /s
viscosity	-----	kg/m-s
dynamic Viscosity	-----	N-s/m ²
thermal gradient coeff for moisture capacity	-----	kg/kg-K
isothermal moisture capacity	-----	m ³ /kg

Appendix B. Version 3.0 Renamed Objects

In EnergyPlus V3.0 release, the objects, fields and key word values were scrutinized and subjected to a stricter naming convention. No spaces are allowed in objects or key words. Fields, on the other hand, are encouraged to have spaces and read more like full phrases. This section will be removed following the April 2009 (V3.1) release. The following table lists “old” and “new” object types.

Old Object Type	New V3.0 Object Type

Appendix C. Notices and Acknowledgments

Copyright Notice

Copyright © 1996-2009 The Board of Trustees of the University of Illinois and The Regents of the University of California through Ernest Orlando Lawrence Berkeley National Laboratory. All rights reserved.

Portions of the EnergyPlus™ software package have been developed and copyrighted by other individuals, companies and institutions. These portions have been incorporated into the EnergyPlus software package under license.

In addition to the primary authorship of the LBNL Simulation Research Group (<http://simulationresearch.lbl.gov/>) and the UIUC Building Systems Laboratory, the following have contributed to EnergyPlus Version 1 (includes all minor revisions):

Portions of the EnergyPlus weather processor were developed by US Department of Energy, Office of Building Technologies, www.energyplus.gov

Portions of the input processing, output processing, weather processor, BLAST Translator were developed by US Army Corps of Engineers, Construction Engineering Research Laboratories, 2902 Newmark Drive, Champaign IL 61821. www.cecer.army.mil

Portions of this software package were developed for Ernest Orlando Lawrence Berkeley National Laboratory by Linda Lawrie of DHL Consulting.

Portions of this software package were developed for Ernest Orlando Lawrence Berkeley National Laboratory by C.O. Pedersen Associates.

Portions of the EnergyPlus utility software (EP-Launch, IDFEditor, DOE2Translator, HVAC-Diagram, ExpandObjects, CSVProc, System Templates, and convertESOMTR) were developed by GARD Analytics, Inc. 1028 Busse Highway, Park Ridge, Illinois 60068-1802, USA (847) 698-5690, www.gard.com. GARD Analytics performed independent verification and validation testing of the software after developing the testing strategy and plan. GARD Analytics was also responsible for gas absorption chiller, desiccant dehumidifier, ice storage (simple), table reports and economics.

Portions of flow resolver, chiller models (absorption, electric, const cop, engine-driven, gas-turbine), generator models (diesel electric, gas turbine), furnace models, heat recovery loop, plant loop, plant condenser loop, air-change dependent inside film coefficients were

developed by Oklahoma State University, 110 Engineering North, Stillwater, OK 74078.

Portions of EnergyPlus related to the models for EMPD moisture calculations, DX coils, furnace/unitary systems, air-to-air heat pumps, changeover-bypass VAV systems, packaged terminal heat pumps, cooling towers, AirflowNetwork, refrigerated cases, reformulated and electric EIR chillers, desuperheater air and water heating coils, heat pump water heaters, desiccant and generic air-to-air heat exchangers, window screens, and thermal comfort controls were developed by University of Central Florida, Florida Solar Energy Center (FSEC), 1679 Clearlake Road, Cocoa, FL 32922, www.fsec.ucf.edu/.

Portions of the refrigeration model were developed by Oak Ridge National Laboratory, Bethel Valley Road, Oak Ridge, Tennessee 37831.

Portions of EnergyPlus were developed by the National Renewable Energy Laboratory (NREL), 1617 Cole Blvd, Golden, CO 80401.

EnergyPlus v1.0.1, v1.0.2, v1.0.3, v1.1, v1.1.1 (Wintel platform) includes a link to TRNSYS (The Transient Energy System Simulation Tool) for photovoltaic calculations developed by Thermal Energy System Specialists, 2916 Marketplace Drive, Suite 104, Madison, WI 53719; Tel: (608) 274-2577. EnergyPlus v1.2 and later includes Photovoltaic calculations implemented in EnergyPlus by Thermal Energy System Specialists. This model was originally developed by Oystein Ulleberg, Institute for Energy Technology, Norway -- based on the Duffie and Beckman equivalent one-diode model.

Portions of this software package that convert certain stand-alone heat transfer models for slab-on-grade and basement foundations were developed by William Bahnfleth, Cynthia Cogil, and Edward Clements, Department of Architectural Engineering, Pennsylvania State University, 224 Engineering Unit A, University Park, Pennsylvania 16802-1416, (814) 863-2076.

The concept and initial implementation for the EnergyPlus COM/DLL version (Wintel platform) was made possible through cooperation with DesignBuilder Software, Ltd, Andy Tindale – an EnergyPlus collaborative developer.

The thickness, conductivity, density and specific heat values of the material layers for the constructions in the Composite Wall Construction reference data set have been taken from the ASHRAE report “Modeling Two- and Three-Dimensional Heat Transfer through Composite Wall and Roof Assemblies in Hourly Energy Simulation Programs (1145-TRP),” by Enermodal Engineering Limited, Oak Ridge National Laboratory, and the Polish Academy of Sciences, January 2001.

EnergyPlus v1.2 and later versions contains DELight2, a simulation engine for daylighting and electric lighting system analysis developed at Ernest Orlando Lawrence Berkeley National Laboratory.

Portions of the EnergyPlus AirflowNetwork model were written by George Walton of the National Institute for Standards and Technology (NIST), 100 Bureau Drive, Gaithersburg, MD 20899. The EnergyPlus AirflowNetwork model also includes portions of an early version of COMIS (Conjunction Of Multizone Infiltration Specialists) developed by a multinational, multi-institutional effort under the auspices of the International Energy Agency's Buildings and Community Systems Agreement working group focusing on multizone air flow modeling (Annex 23) and now administered by the Swiss Federal Laboratories for Materials Testing and Research (EMPA), Division 175, Überlandstrasse 129, CH-8600 Dübendorf, Switzerland.

The EnergyPlus v1.2 model for displacement ventilation and cross-ventilation was developed by Guilherme Carrilho da Graça (Department of Mechanical and Aerospace Engineering, University of California, San Diego and NaturalWorks) and Paul Linden (Department of Mechanical and Aerospace Engineering, University of California, San Diego).

The EnergyPlus models for UFAD served zones were developed by Anna Liu and Paul Linden at the Department of Mechanical and Aerospace Engineering, University of California, San Diego.

ASHRAE research project 1254-RP supported the development of the following features first added in EnergyPlus v1.2.2: DXSystem:AirLoop enhancements (valid as OA system equipment, new humidity control options); New set point managers: SET POINT MANAGER:SINGLE ZONE HEATING, SET POINT MANAGER:SINGLE ZONE COOLING, and SET POINT MANAGER:OUTSIDE AIR PRETREAT; New 2-stage DX coil with enhanced dehumidification option (COIL:DX:MultiMode:CoolingEmpirical); Additional DESICCANT DEHUMIDIFIER:SOLID setpoint control option; American Society of Heating Refrigerating and Air-Conditioning Engineers, Inc., 1791 Tullie Circle, N.E., Atlanta, GA 30329. www.ashrae.org/. Work performed by GARD Analytics, Inc., 1028 Busse Highway, Park Ridge, Illinois 60068-1802, USA. www.gard.com/, November 2004.

EnergyPlus v1.2.2 and later versions contains links to SPARK, a simulation engine for detailed system modeling developed at Ernest Orlando Lawrence Berkeley National Laboratory in conjunction with Ayres Sowell Associates, Inc.

The Ecoroof (Green Roof) model, first introduced in EnergyPlus v2.0, was developed at Portland State University, by David Sailor and his students. It is based on the FASST vegetation models developed by Frankenstein and Koenig for the US Army Corps of Engineers.

The HAMT (Heat And Moisture Transfer) model, first introduced in EnergyPlus v3.0.0 was developed by Phillip Biddulph, Complex Built Environment Systems, The Bartlett School of Graduate Studies, University College London, Gower Street, London WC1E 6BT, United Kingdom. <http://www.cbes.ucl.ac.uk/>.

The SQLite output module, first introduced in EnergyPlus v3.0.0, was developed by Gregory B. Stark, P.E., Building Synergies, LLC, 1860 Washington Street, Suite 208, Denver, Colorado 80203, United States. <http://www.buildingsynergies.com/>

Refrigeration compressor performance data and refrigeration practices were provided by CDH Energy, Cazenovia, NY 12035.

NOTICE: The U.S. Government is granted for itself and others acting on its behalf a paid-up, nonexclusive, irrevocable, worldwide license in this data to reproduce, prepare derivative works, and perform publicly and display publicly. Beginning five (5) years after permission to assert copyright is granted, subject to two possible five year renewals, the U.S. Government is granted for itself and others acting on its behalf a paid-up, non-exclusive, irrevocable worldwide license in this data to reproduce, prepare derivative works, distribute copies to the public, perform publicly and display publicly, and to permit others to do so.

TRADEMARKS: EnergyPlus is a trademark of the US Department of Energy.

Other Acknowledgments

This work was supported by the Assistant Secretary for Energy Efficiency and Renewable Energy, Office of Building Technologies of the US Department of Energy.

Additional support was provided by the Gas Technology Institute and the California Energy Commission.

The ice thermal storage module development was supported by the U.S. Department of Energy Office of Electricity Delivery and Energy Reliability.

The HAMT (Heat And Moisture Transfer) model was supported by the Engineering and Physical Sciences Research Council (EPSRC), the UK government agency for funding research and training in engineering and the physical sciences.

The SQLite output module was funded by Building Synergies, LLC and was made possible by inclusion of software code from the SQLite project (<http://www.sqlite.org/>).
