Introduction

- Corrosion resistant material are subject to localized corrosion under atmospheric conditions
- Corrosion rate and stability are controlled by both external cathodic and internal anodic reaction rates
 - > Must match anode needs with cathode capacity
- There are many physiochemical and kinetic parameters
- Experimental work is challenging due to difficulties in measurements of interest

Stability of Localized Corrosion

Crevice with Thin Layer External Cathode

- Current demand from crevice met (or not) by current from external surface

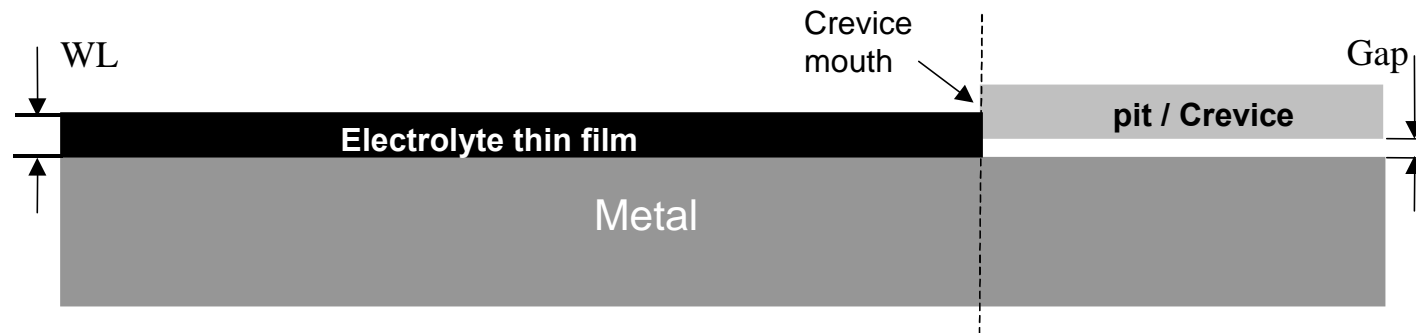

Stability Requires Cathode Current Capacity Meets Anode Current Demand

Approach

Model cathode and anode separately, link by E_{rp} of the anode at crevice mouth

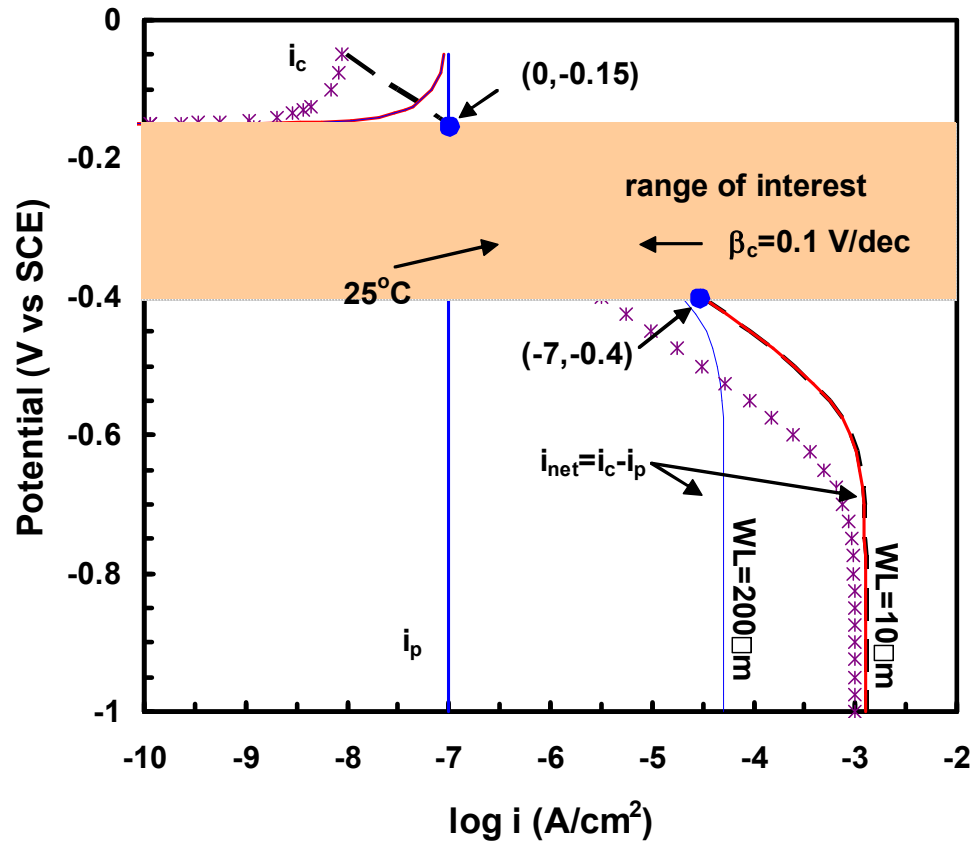

Cathode Modeling

Modeling on the External Wetted SS316L Surface (Cathode)

- Consider only the cathode in detail
 - > Potential hold at E_{rp} at mouth
- Calculate total net cathodic current, I_{net}
 - > Effects of WL, [Cl⁻] and Lc
 - >> Using a 3³ factorial design
 - > Effect of T
 - >> 95 vs 25°C
 - > Effect of kinetic parameters
 - >> ($i_{o,c}$, b_c , E_{rp} and i_p) (full factorial of [Cl⁻] and Lc)

Electrochemical Kinetics Used for Cathode

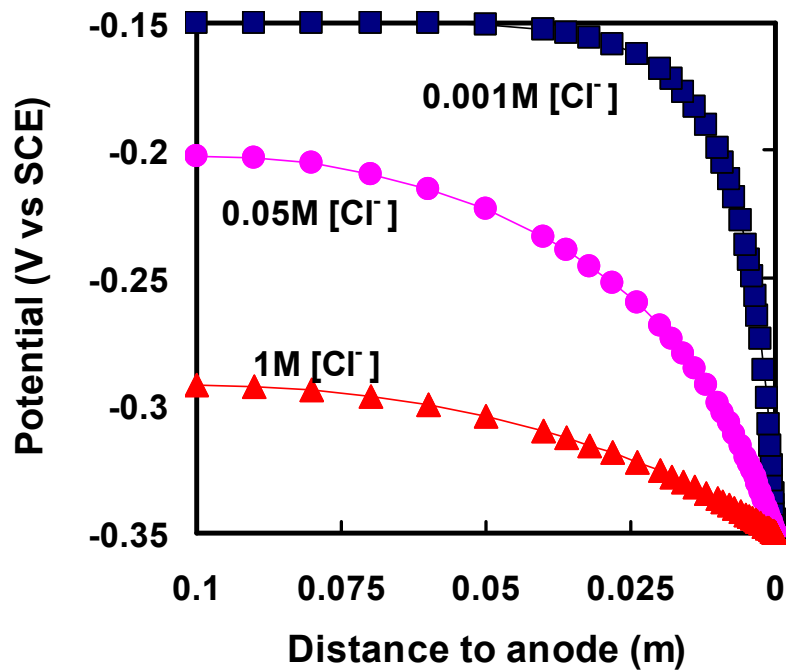

Base Case
 $E_{\text{corr}} = -0.15 \text{ V}$
 $E_{\text{o,c}} = -0.05 \text{ V}$
 $E_{\text{rp}} = -0.4 \text{ V}$
 $i_{\text{o,c}} = 10^{-8} \text{ A/cm}^2$
 $i_{\text{p}} = 10^{-7} \text{ A/cm}^2$
 $B_{\text{c}} = 100 \text{ mV/dec}$
 $i_{\text{lim}} = nFDC_{\text{o}_2}/WL$
 $T = 95^\circ\text{C}$

D.S. Dunn, G.A. Cragnolino, N. Sridhar, Corrosion 56, 1 (2000). p. 90
 N. Scridhar and G.A. Cragnolino, Corrosion 49, 11 (1993), p885

Typical Model Outputs

(Base cases, $WL=25$ mm, $L_c=10$ cm)

Potential increased and i_{net} decreased with distance to anode

Analysis of Variance

Quantified Effect of WL, L_c and [Cl⁻] from 3³ Factorial Design

Source of Variation	Ratio to WL
WL	1
L_c	1.97
Cl	4.74
$WL \times L_c$	0.60
$WL \times Cl$	0.24
$Cl \times L_c$	1.28
$WL \times L_c \times Cl$	0.36
Total	

For Cathode Area = 0.01cm²
(10cmx10μm)

$6.6 \times 10^{-10} < I_{total} < 7.2 \times 10^{-8}$ (A)

Significant interactions between $L_c \times Cl$; None of the three effects include WL

Effect of Temperature (95 vs 25° C)

$$R_T = \frac{I_{\text{net}} (T = 95^\circ \text{C})}{I_{\text{net}} (T = 25^\circ \text{C})}$$

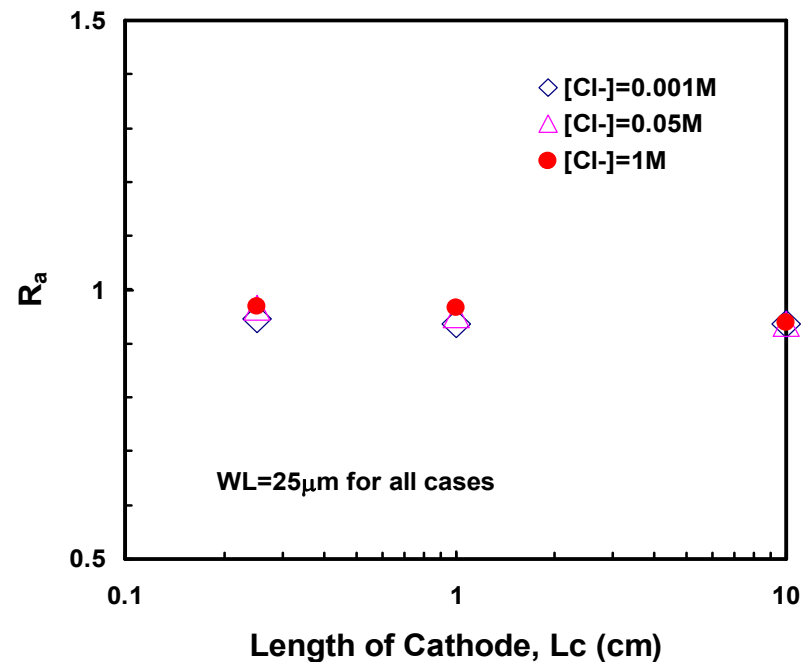

- Total net cathodic current increased at least 5.5 times
- R_T decrease with L_c

Effect of Kinetic Parameters

$$R_c = \frac{I_{\text{net}} (i_{\text{oc}} = 10^{-8})}{I_{\text{net}} (i_{\text{oc}} = 10^{-9})}$$

$$R_a = \frac{I_{\text{net}} (i_p = 10^{-6})}{I_{\text{net}} (i_p = 10^{-7})}$$

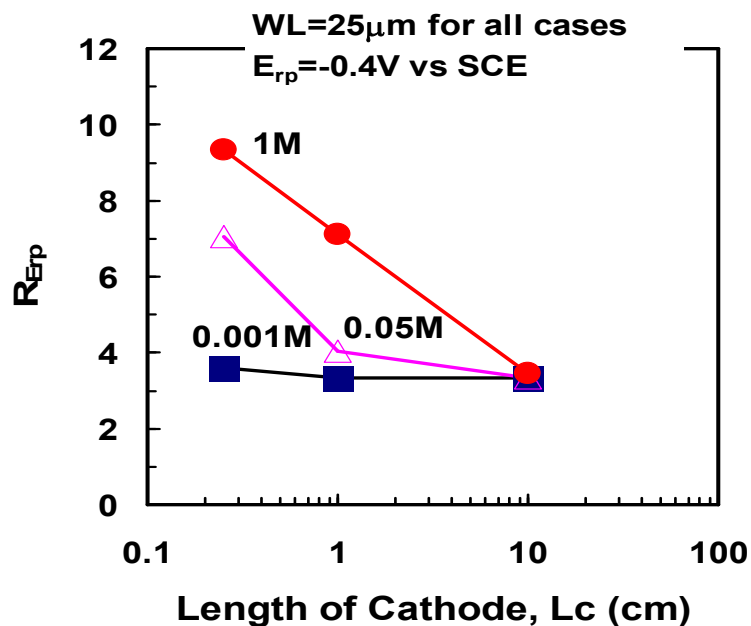

- i_{oc} has significant effect while i_p has very small effect;
- R_c approach a constant at large L_c

Effect of Kinetic Parameters (continued)

$$R_{E_{rp}} = \frac{I_{net}(E_{rp} = -0.4V)}{I_{net}(E_{rp} = -0.3V)}$$

$$R_{\beta_c} = \frac{I_{net}(\beta_c = 0.1V/dec)}{I_{net}(\beta_c = 0.06V/dec)}$$

- E_{rp} and β_c both have significant effects on I_{net}
- R values approach to a constant value at large L_c

Total Current from Cathode Saturates

(WL=25mm)

For anode= 1 x 10 μm

[Cl⁻] increases I_{net} less than linearly

WL increases I_{net} more significantly at larger cathodes

Model Projections for Cathode Size at Saturation

WL μm	10	10	10	25	25	25	200	200	200
[Cl ⁻] M	0.001	0.05	1	0.001	0.05	1	0.001	0.05	1
L _c (cm) needed for 98% I _{max}	0.25	1	4	0.25	4	10	1	10	15
98% I _{max} (A)	6.6·10 ⁻¹⁰	4.6·10 ⁻⁹	1.9·10 ⁻⁸	1.0·10 ⁻⁹	7.3·10 ⁻⁹	3.0·10 ⁻⁸	2.6·10 ⁻⁹	1.9·10 ⁻⁸	7.5·10 ⁻⁸

Base Case

$$E_{\text{corr}} = -0.15 \text{ V}, E_{\text{o,c}} = -0.05 \text{ V}, E_{\text{rp}} = -0.4 \text{ V}, i_{\text{o,c}} = 10^{-8} \text{ A/cm}^2, i_{\text{p}} = 10^{-7} \text{ A/cm}^2$$

$$B_{\text{c}} = 100 \text{ mV/dec}, i_{\text{lim}} = nFDC_{\text{o}_2}/WL, T = 95^\circ\text{C}$$

Anode Modeling

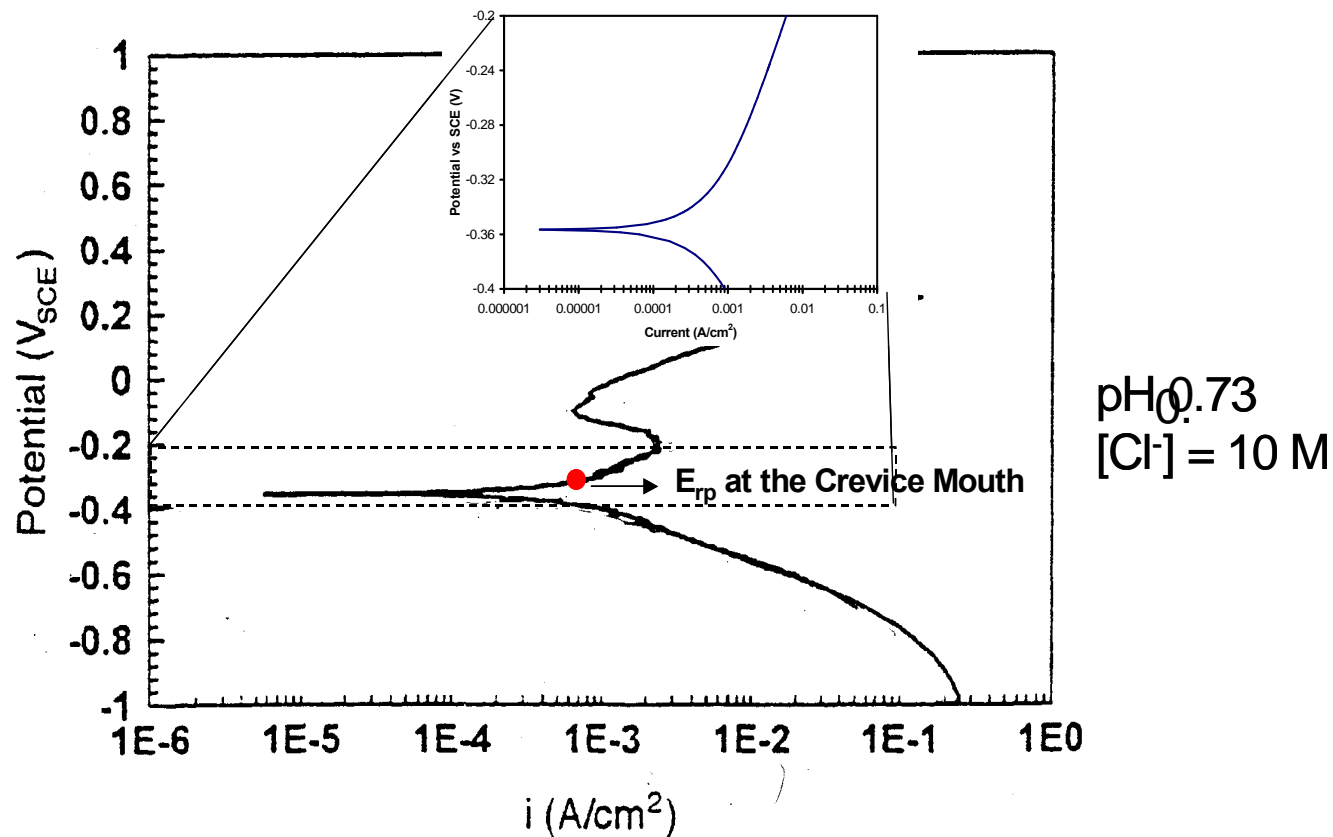

Modeling on the SS316L Crevice (anode)

- Assume constant crevice chemistry, E_{rp} at mouth
- Calculate potential and current distribution
 - > Variables: Gap, L (Crevice Depth)
 - > Constants: Anodic kinetics (E_{rp} , E-Log i) from literature
 - > Room T

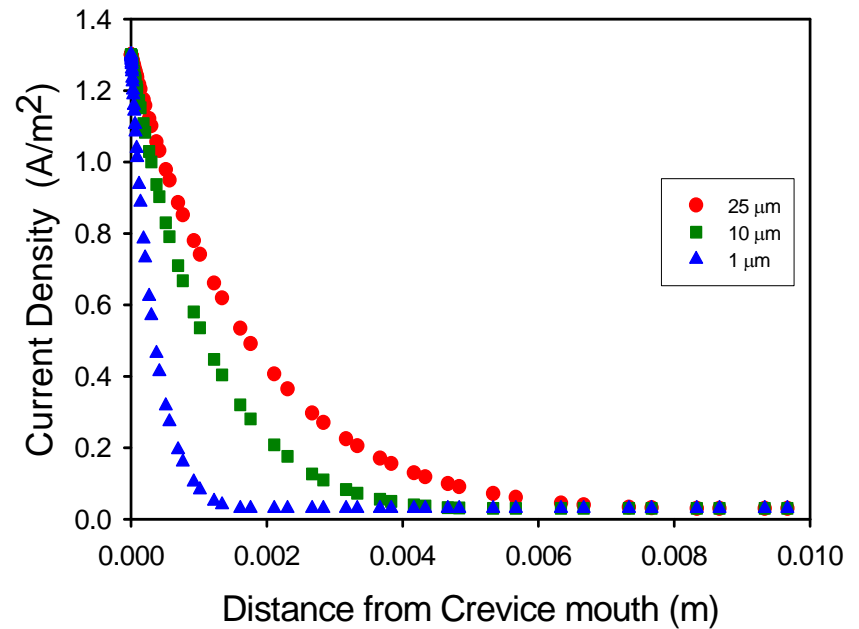

Electrochemical Kinetics

- Extracted from literature from measurements in Critical Crevice Solution

Kelly, Corrosion 51,11,p832

Typical Model Outputs

Potential and i decreased with depth into crevice

Crevice Current Demand $\sim g^{1/2}$

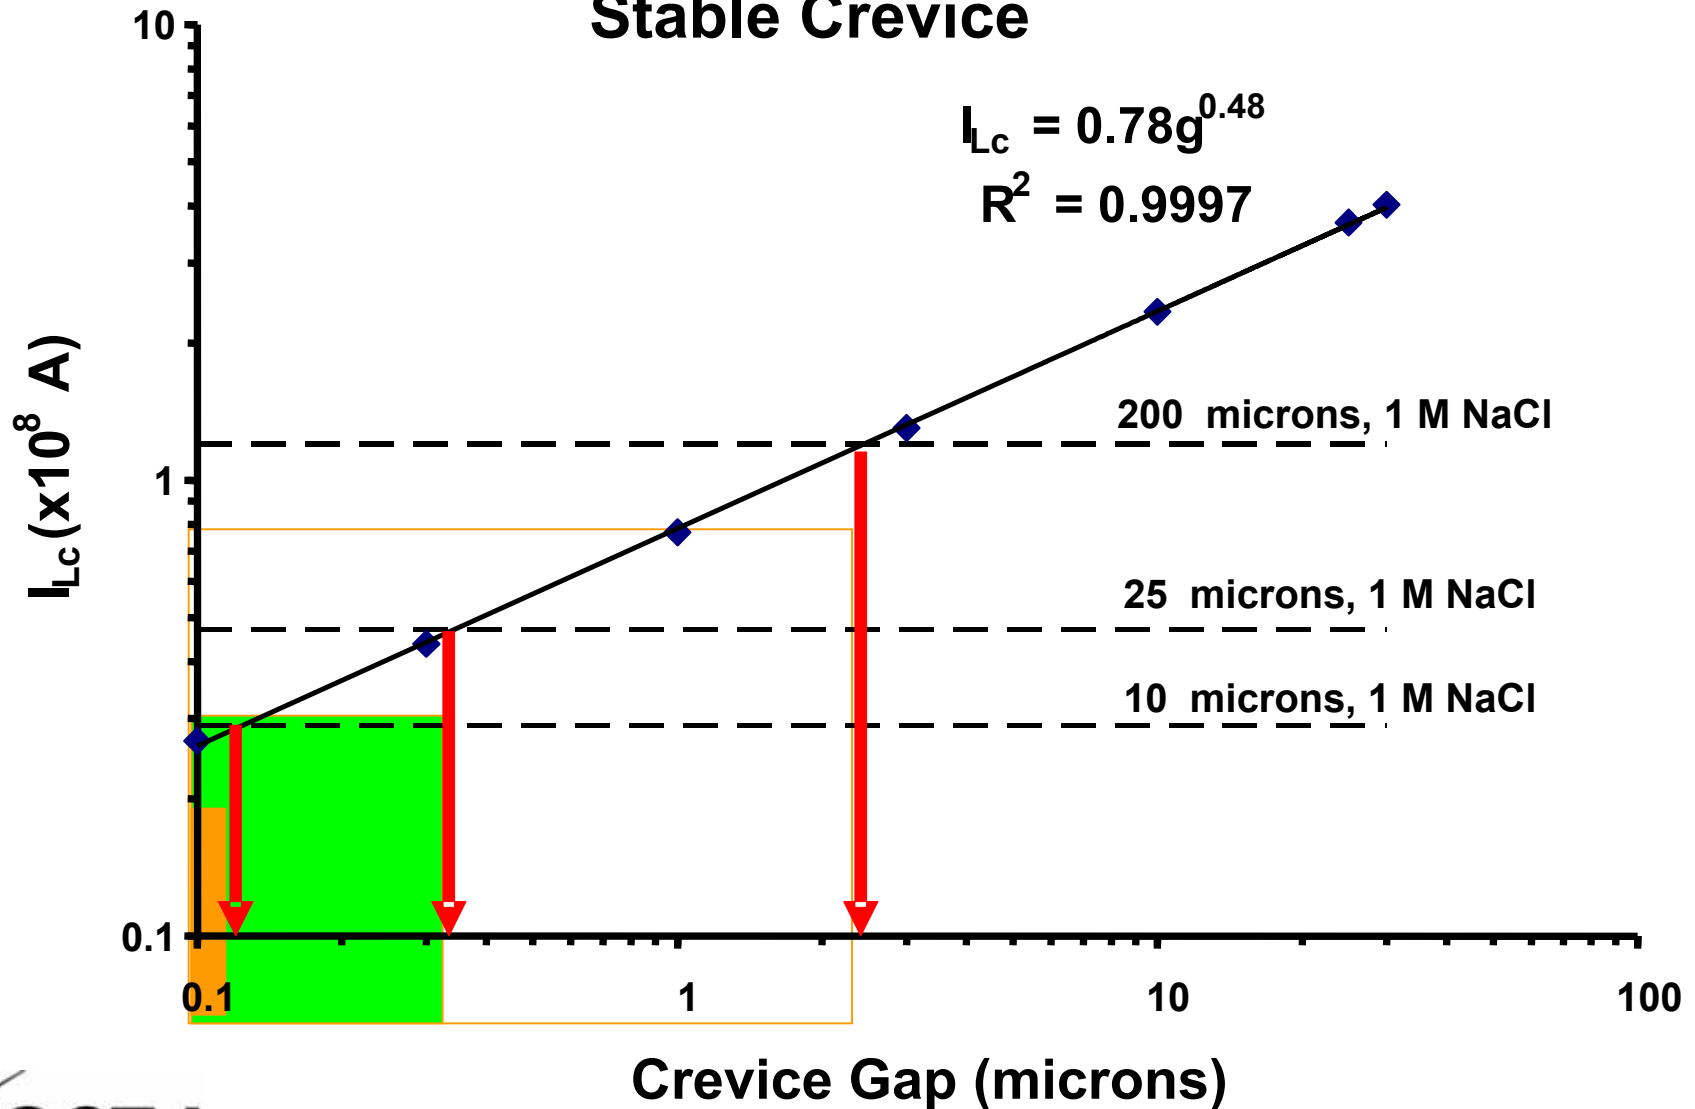

Only gaps smaller than arrows can stabilize

Recall that the I_{net} Saturates at High L_c

When Anode Demand = Cathode Capacity

Stable Crevice

Analytic Expression for Total Current from Wetted Surface

- Consider a surface with a thin electrolyte layer
- Fixed potential at one end (E_{rp}), other end has a zero flux
- Current sinks/sources along the length
- Assume:

$$I_{\text{net}} = i_{\text{eq}} \cdot L_{\text{eq}} \cdot W \quad \text{with} \quad i_{\text{eq}} = \frac{\int_{E_L}^{E_{rp}} (i_c - i_p) \cdot dE}{E_L - E_{rp}} = \frac{\int_{E_L}^{E_{rp}} (i_c - i_p) \cdot dE}{\Delta E}$$

Considering Secondary Current Distribution

- Total Resistance of Electrolyte can be shown to be:

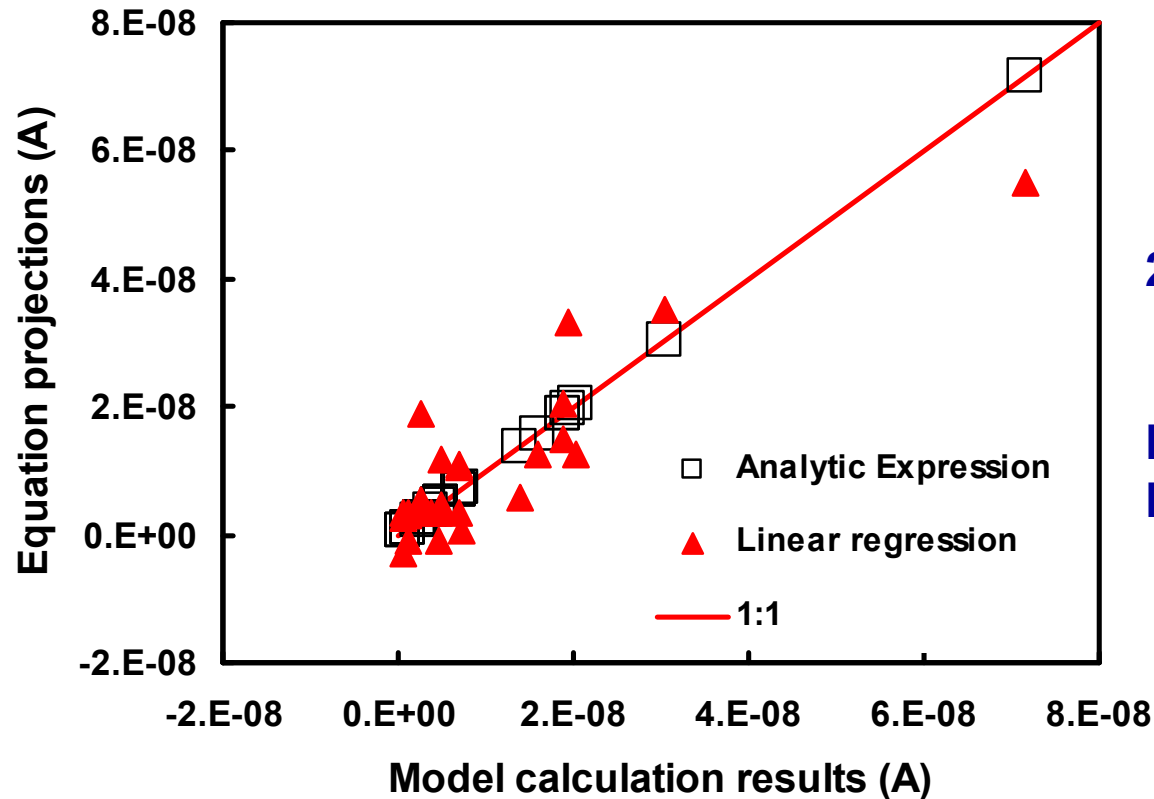

$$R = \frac{L_{eq}}{2 \cdot \sigma \cdot WL \cdot W}$$

- Ohmic Potential Drop:

$$\Delta E = E_L - E_{rp} = I_{net} \cdot R = \frac{I_{net} \cdot L_{eq}}{2 \cdot \sigma \cdot WL \cdot W}$$

$$I_{net} = W \cdot \sqrt{2 \cdot \sigma \cdot WL \cdot \int_{E_L}^{E_{rp}} (i_c - i_p) \cdot dE}$$

Analytic Expression vs. Linear Regression

26 cases varying:
 $L_c, i_{oc}, T, \beta, \sigma, WL$

R^2 (Analytic) = 1.0

R^2 (Linear Regression) = 0.8

**Expression reproduces observed effects of
physiochemical and kinetic parameters**

Conclusions

- **Computationally separating the anode and cathode of wetted SS316L allowed effects of parameters on crevice corrosion stability by comparing I_{net} and I_{Lc}**
 - **Used to determine critical gap needed for stable crevice**
- **Cathode:**
 - **All physicochemical and kinetic parameters studied except i_p were found to have significant effect on I_{net} .**
 - **The I_{net} was found to reach I_{max} as L_c increased**
- **Anode:**
 - **Total current demand increased with $g^{1/2}$**
- **Analytic expression developed for total current from restricted geometry**
