Introduction

CH₄Ocean CO₂AIRS CO₂ vs
CarbonTrackerLand CO₂
RetrievalsLand CO₂ vs CT

- Interested in measuring CO₂ and CH₄ with AIRS/IASI/CrIS
- Primary interest is rates, for monitoring growth of greenhouse forcing gases
- Using simple techniques to get rates quickly. AIRS CDS is data source (mostly), so no CC'd data used.
- We use ECMWF temperature fields, and ...
- Internal diagnostics show ECMWF temperature fields (for troposphere) are good enough.
- 4-year CO₂ climatology published in JGR in Sept. 2008
- This presentation:
 - CH₄ growth rates
 - Comparison of 4-year CO₂ climatology to NOAA CarbonTracker (CT)
 - Progress in CO₂ retrievals (300-600 mbar range) over land, esp. with regard to cloud filtering

Introduction

CH₄Ocean CO₂AIRS CO₂ vs
CarbonTrackerLand CO₂
RetrievalsLand CO₂ vs CT

- ECMWF uses radiosonde measurements as the “anchoring network” of observations for the ECMWF tropospheric temperatures with no bias correction, see Auligne, T., A. McNally, and D. Dee (2007), Adaptive bias correction for satellite data in a numerical weather prediction system, *QJRMS*, 133, 631–642, doi10.1002/qj.56.
- ECWMF $T(z)$ fields are essentially optimially interpolated radiosondes, AIRS/IASI radiances are bias-adjusted to agree with radiosondes
- Bias of AIRS vs ECMWF has a standard deviation in CO₂ channels at the AIRS noise level - before and after assimilation of AIRS at ECMWF.
- 4-year CO₂ growth rates derived from AIRS biases relative to ECMWF gives 2.2 ppm/year \pm 0.2 ppm/year, compared to MLO in-situ rate of 2.05 ppm/year. This difference corresponds to 5mK/year difference in BT units.

Introduction

CH₄Ocean CO₂AIRS CO₂ vs
CarbonTrackerLand CO₂
RetrievalsLand CO₂ vs CT

- One CH₄ channel used: 1303.2 cm⁻¹
- One CO₂ line (with similar dB_T/dT to 1303.3 cm⁻¹ CH₄ line) used to correct for variability in ECMWF upper-trop temperatures).
- dB_T/dCH₄ peaks ~300 mbar

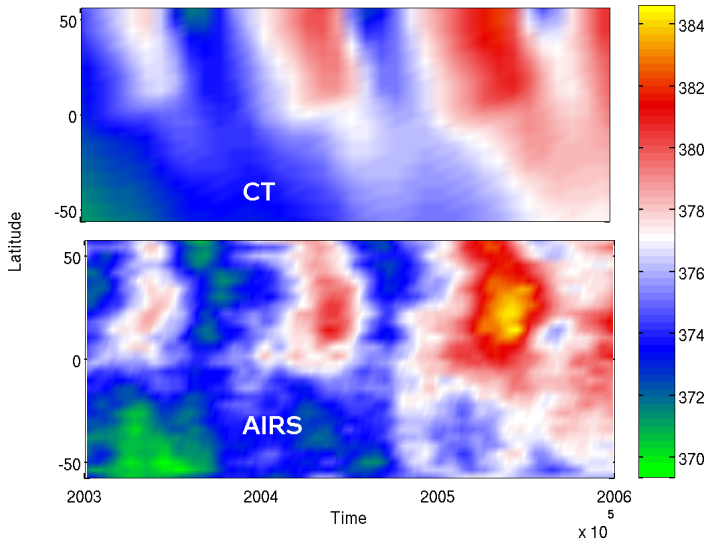

- Growth rate measured as a function of latitude
- 36 month growth rate = 0.90 ± 3.9 ppb/year
- 48 month growth rate = -1.1 ± 3.2 ppm/year
- Comparable to IPCC published rates, much lower than ~ 15 ppm/year growth rates in the 70's and 80's.

Conclusions: AIRS Ocean CO₂ vs CarbonTracker (CT)

- General agreement between AIRS and CT
- AIRS tropical CO₂ cycle more intense
- In NH, CT CO₂ general grows more quickly, AIRS and CT decrease in summer months generally similar
- In SH winter, AIRS CO₂ lower than CT, otherwise similar
- AIRS may be key instrument for improving CO₂ transport models, but more validation needed.

Introduction

CH₄

Ocean CO₂

AIRS CO₂ vs
CarbonTracker

Land CO₂
Retrievals

Land CO₂ vs CT

- Input is clear FOVS in AIRS CDS
- SW and LW approach, Used LW for ocean, but SW appears better over land
 - Use channels sensitive to mid tropospheric CO₂
 - Narrow “Q branch” ν_2 transition at 791.75cm^{-1} (LW)
 - Broad “R branch” ν_3 transition around $2387 - 2390\text{cm}^{-1}$ (SW).
- Peak at 450mbar (Mid-Troposphere) $\approx 6.7\text{Km}$. Can be much lower over land in tropics.

- Assume ECMWF has good temperature profile (*unbiased*).
- Correct for surface temperature and overall water content.
- In each band, solve for CO₂ and T_s .
- For example LW:
 - 790 cm^{-1} (no sensitivity to CO₂)
 - 791 cm^{-1} (right on a CO₂ line).

$$B_{obs}^{790} - B_{calc}^{790} = J_{T_s}^{790} \delta T_s$$

$$B_{obs}^{791} - B_{calc}^{791} = J_{T_s}^{791} \delta T_s + J_{CO_2}^{791} \delta CO_2$$

- Emissivity errors (and others) go into the “effective” T_s . Corrections are applied on sensitive channels
- Also accounts for very low clouds (below the sensitivity of the weighting function).

New Steps to Approach ppm Level CO₂ Retrievals over Land

Introduction

CH₄

Ocean CO₂

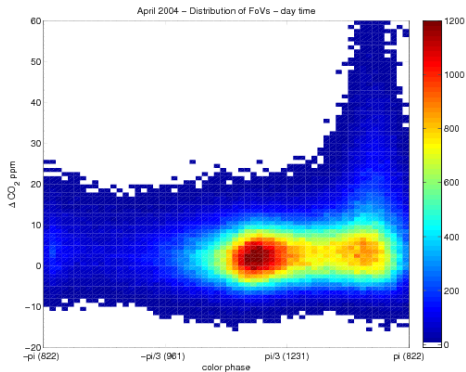

AIRS CO₂ vs
CarbonTracker

Land CO₂
Retrievals

Land CO₂ vs CT

- Cloud contamination is key issue, especially cirrus
- Detection of clouds more difficult over land
- Will present new cloud flag concept
- Retrieved CO₂ depends on secant angle due to RTA errors (up to 6 ppm max)
- Methodology to correct RTA errors (calibration) does not require external calibration data
- Will show comparisons to CarbonTracker for three months

- Empirically based cloud flag being tested. Uses ECMWF *atmospheric fields* to determine best cloud flag.
- Compute three **biases** across thermal window: 822 cm⁻¹ (cirrus), 961 cm⁻¹ (2616 cm⁻¹), 1231 cm⁻¹. Combine as RGB.
- $\tan(h) = \frac{\sqrt{3}}{2} \frac{G-B}{R-G-B}$ is X-axis, Y-axis is CO₂, color is FOV count

- RTA spectroscopy errors will accumulate according to the *secant of satellite zenith angle*.
- CO_2 versus $\sec \theta_{SZ}$ fit to a quadratic function:

$$\text{CO}_2 = A \sec^2 \theta_{SZ} + B \sec \theta_{SZ} + C.$$
- Will adjust CO_2 ppm according to:

$$\text{CO}_2^{new} = \text{CO}_2 - A(\sec^2 \theta_{SZ} - 1) - B(\sec \theta_{SZ} - 1).$$
- Note: nadir needs ~ 8 ppm spectroscopy correction (alpha)

8 ppm correction same as correction derived from zenith angle bias!

Land CO₂ vs CT

- 5 deg box around the island - Fit for the 2004 annual mean.

Comparison of Land CO₂ to CT for Several Months

- Results clearly show seasonal patterns.
- Over Ocean - reasonably confident, validated.
- Over Land - retrievals are ~ 2-6 ppm higher than CT
- See more CO₂ structure over land than CT.
- Cloud filtering algorithms significantly improved.

RetrievalsLand CO₂ vs CT

- Land CO₂ retrievals in the 400-550 mbar region are very sensitive to cloud contamination, cloud flag is improving
- May test algorithm on CC'd data.
- May have calibration correction that doesn't require external data for absolute accuracy (secant angle correction).
- Comparisons to CT are encouraging, but biased high.
- Need to process large amount of data in order to maximize number of coincidences with validation data.
