

# HIV/AIDS

SURVEILLANCE

YEAR-END EDITION

U.S. AIDS cases reported through December 1991

Issued January 1992

## Contents

Notice to readers .....	2
Figure 1. AIDS annual rates per 100,000 population .....	3
Figure 2. Adult/adolescent and pediatric AIDS cases .....	4
Figure 3. Pediatric AIDS cases .....	4
Figure 4. AIDS cases by quarter-year of report .....	5
Figure 5. AIDS cases by quarter of diagnosis, adjusted for reporting delays .....	5
Table 1. AIDS cases and annual rates per 100,000 population, by state .....	6
Table 2. AIDS cases and annual rates per 100,000 population, by metropolitan area with 500,000 or more population .....	7
Table 3. AIDS cases by age group, exposure category, and sex .....	9
Table 4. AIDS cases by age group, exposure category, and race/ethnicity .....	10
Table 5. Adult/adolescent AIDS cases by sex, exposure category, and race/ethnicity .....	11
Table 6. AIDS cases in adolescents and adults under age 25, by exposure category and year of report .....	12
Table 7. AIDS cases by age at diagnosis and exposure category .....	13
Table 8. AIDS cases by sex, age at diagnosis, and race/ethnicity .....	14
Table 9. AIDS cases and annual rates per 100,000 population, by race/ethnicity, age group, and sex .....	15
Table 10. AIDS cases by year of diagnosis and definition category .....	15
Table 11. AIDS-indicator diseases, by age group .....	16
Table 12. AIDS cases, case-fatality rates, and deaths, by half-year and age group .....	17
Table 13. AIDS deaths by race/ethnicity, age at death, and sex .....	18
Table 14. Adult/adolescent AIDS cases by single and multiple exposure categories .....	19
Figure 6. Results of investigations of AIDS cases with undetermined risk .....	20
Technical notes .....	21

Acquired immunodeficiency syndrome (AIDS) is a specific group of diseases or conditions which are indicative of severe immunosuppression related to infection with the human immunodeficiency virus (HIV).

CENTERS FOR DISEASE CONTROL

**Notice to readers:** To conserve limited resources, CDC is considering reducing the frequency of this publication to once each quarter beginning April 1992. Comments on this change may be sent to Editor, HIV/AIDS Surveillance Report, Mailstop E-48, Division of HIV/AIDS, National Centers for Infectious Diseases, Centers for Disease Control, Atlanta, GA 30333.

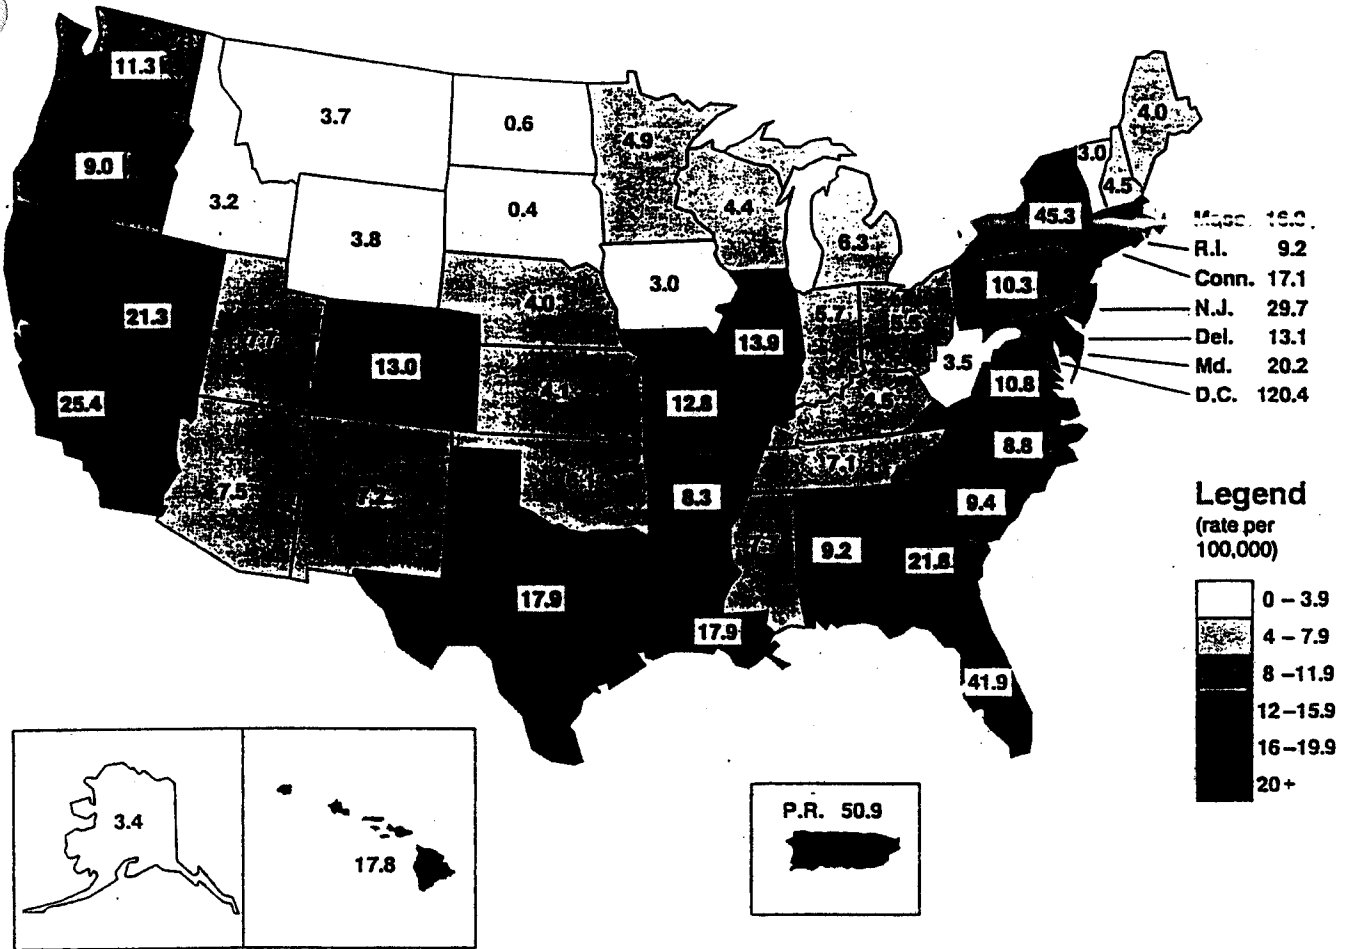

The *HIV/AIDS Surveillance Report* is published each month by the Division of HIV/AIDS, National Center for Infectious Diseases, Centers for Disease Control, Atlanta, GA 30333. An expanded, year-end edition is published each January. All data contained in the *Report* are provisional.

**Suggested Citation:** Centers for Disease Control. HIV/AIDS Surveillance Report, January 1992:1-22

<sup>1</sup>Includes 3 patients known to be infected with human immunodeficiency virus type 2 (HIV-2). See MMWR 1989;38:572-580.

<sup>2</sup>See technical notes.

<sup>3</sup>Eighteen adults/adolescents and 2 children developed AIDS after receiving blood screened negative for HIV antibody. Five additional adults developed AIDS after receiving tissue or organs from HIV-infected donors. Two of the five received organs or tissue from a donor who was negative for HIV antibody at the time of donation.

<sup>4</sup>"Other" refers to 4 persons who developed AIDS after exposure to HIV-infected blood within the health care setting, as documented by evidence of seroconversion or other laboratory studies. "Undetermined" refers to patients whose mode of exposure to HIV is unknown. This includes patients under investigation; patients who died, were lost to follow-up, or refused interview; and patients whose mode of exposure to HIV remains undetermined after investigation. See Figure 6.

Injecting drug use; hemophilia; heterosexual contact; receipt of transfusion	8	(0)
<b>Multiple modes of exposure subtotal</b>	<b>25,508</b>	<b>(13)</b>
<b>Total</b>	<b>202,921</b>	<b>(100)</b>

<sup>1</sup>Eighteen adults/adolescents and 2 children developed AIDS after receiving blood screened negative for HIV antibody. Five additional adults developed AIDS after receiving tissue or organs from HIV-infected donors. Two of the five received organs or tissue from a donor who was negative for HIV antibody at the time of donation.

<sup>2</sup>"Other" refers to 4 persons who developed AIDS after exposure to HIV-infected blood within the health care setting, as documented by evidence of seroconversion or other laboratory studies. "Undetermined" refers to patients whose mode of exposure to HIV is unknown. This includes patients under investigation; patients who died, were lost to follow-up, or refused interview; and patients whose mode of exposure to HIV remains undetermined after investigation. See Figure 6.

**Figure 6. Results of investigations of adult/adolescent AIDS cases with undetermined risk reported through December 1991<sup>1</sup>**

<sup>1</sup> Excludes 83 children under 13 years of age who have an undetermined risk: 73 children are under investigation and 10 have died, refused interview, or were lost to follow-up. An additional 123 children who were initially reported with an undetermined risk have been reclassified after investigation.

<sup>2</sup> Of the 518 persons classified as "No risk identified/other," 4 are persons who developed AIDS after exposure to HIV-infected blood within the health-care setting, as documented by evidence of seroconversion or other laboratory studies. For the remaining 514, the mode of exposure to HIV remains undetermined after investigation.

**Health-care workers.** 84 of the 514 patients who had no risk identified after follow-up are health-care workers, 75 of whom responded to a standardized questionnaire. 45 (60%) reported needlesticks and/or mucous membrane exposures to blood and other body fluids of patients. None of the source patients was known to be infected with HIV at the time of exposure and none of the health-care workers was evaluated at the time of the exposure to document seroconversion to HIV antibody. See *MMWR*, "Update: Acquired Immunodeficiency Syndrome and Human Immunodeficiency Virus Infection Among Health-Care Workers," (April 22, 1988)37:229-234,239.

**Heterosexual transmission.** 455 of the 514 patients who had no risk identified after follow-up responded to a standardized questionnaire; 145 (35%) of 418 persons responding to questions related to sexually transmitted disease gave a history of such disease and 104 (36%) of 290 interviewed men reported sexual contact with a prostitute. Some of these persons may represent unreported or unrecognized heterosexual transmission of HIV. See *MMWR*, "Update: Heterosexual Transmission of AIDS and HIV Infection - U.S.," (June 23, 1989) 38:423-424,429-434.

# Technical notes

---

## Surveillance and reporting of AIDS

All 50 states, the District of Columbia, U.S. dependencies and possessions, and independent nations in free association with the U.S.<sup>1</sup> report AIDS cases to CDC using a uniform case definition and case report form. The original definition was modified in 1985 (*MMWR* 1985;34:373-5) and again in 1987 (*MMWR* 1987;36 [suppl. no. 1S]:1S-15S). The revisions incorporated a broader range of AIDS-indicator diseases and conditions and used human immunodeficiency virus (HIV) diagnostic tests to improve the sensitivity and specificity of the definition. For persons with laboratory-confirmed HIV infection, the 1987 revision incorporated HIV encephalopathy, wasting syndrome, and other indicator diseases that are diagnosed presumptively (i.e., without confirmatory laboratory evidence of the opportunistic disease). AIDS cases that meet the criteria of both the pre-1987 and 1987 definitions are classified in the pre-1987 definition category. Compared with patients who meet the pre-1987 case definition, a higher proportion of patients who meet only the 1987 case definition were female, black, or Hispanic, or were injecting drug users (*MMWR* 1989;38:229-36).

Each issue of this report includes information received and tabulated by CDC through the last day of the previous month. Data are tabulated by date of report to CDC unless otherwise noted. Data for U.S. dependencies and possessions and for associated independent nations are included in the totals.

Age group tabulations are based on the person's age at diagnosis of AIDS: adult/adolescent cases include persons 13 years of age and older; pediatric cases include children under 13 years of age. Age group tabulations in Table 13 (only included in the year-end edition) are based on age at death.

Metropolitan areas are defined as the Metropolitan Statistical Areas (MSA) for all areas except the 6 New England states. For these states, the New England County Metropolitan Areas (NECMA) are used. Metropolitan areas are named for a central city in the MSA or NECMA, may include several cities and counties, and may cross state boundaries.

<sup>1</sup>Included among the dependencies, possessions, and independent nations are Puerto Rico, the U.S. Virgin Islands, Guam, American Samoa, the Republic of Palau, the Republic of the Marshall Islands, the Commonwealth of the Northern Mariana Islands, and the Federated States of Micronesia. The latter 5 comprise the category "Pacific Islands, U.S." listed in Table 1.

For example, AIDS cases and annual rates presented for the District of Columbia in Table 1 include only persons residing within the geographic boundaries of the District. AIDS cases and annual rates for Washington, D.C., in Table 2 include persons residing within the metropolitan area which includes counties in both Maryland and Virginia. State or metropolitan area data tabulations are based on the person's residence at diagnosis of the first AIDS-indicator disease(s). The cities and counties which comprise each metropolitan area in Table 2 are listed in the Bureau of Census publication, "State and Metropolitan Area Data Book, 1986."

Data in this report are provisional. Reporting delays (time between diagnosis and report to CDC) vary widely among exposure, geographic, racial/ethnic, and age categories and have been several years for some cases. About 55 percent of all cases are reported within 3 months of diagnosis, but about 20 percent are reported more than 1 year after diagnosis.

Completeness of reporting of diagnosed cases to state and local health departments varies by geographic region and patient population; however, mortality studies suggest that 70 to 90 percent of HIV-related deaths in men 25 to 44 years old are identified through national surveillance of AIDS (*MMWR* 1989;38:561-3). In addition, multiple routes of exposure, opportunistic diseases diagnosed after the initial case report was submitted to CDC, and vital status may not be determined or reported for all cases. Caution should be used in interpreting case-fatality rates because reporting of deaths is known to be incomplete.

## Exposure categories

For surveillance purposes, AIDS cases are counted only once in a hierarchy of exposure categories. Persons with more than one reported mode of exposure to HIV are classified in the category listed first in the hierarchy, except for men with both a history of sexual contact with other men and injecting drug use. They make up a separate category.

"Men who have sex with men" cases include men who report sexual contact with other men (i.e., homosexual contact) and men who report sexual contact with both men and women (i.e., bisexual contact).

"Heterosexual contact" cases include persons who report either specific heterosexual contact with a person with, or at increased risk for, HIV infection (e.g., an intravenous drug user), or persons presumed to have acquired HIV infection through heterosexual contact because they were born in countries with a distinctive pattern of transmission termed "Pattern II" by the World Health Organization (*MMWR* 1988;37:286-8,293-5). Pattern II transmission is observed in areas of sub-Saharan Africa and in some Caribbean countries. In these countries, most of the reported cases occur in heterosexuals and the male-to-female ratio is approximately 1:1. Injecting drug use and homosexual transmission either do not occur or occur at a low level.

"Undetermined" cases are persons with no reported history of exposure to HIV through any of the routes listed in the hierarchy of exposure categories. Undetermined cases include persons who are currently under investigation by local health department officials; persons whose exposure history is incomplete because of death, refusal to be interviewed, or loss to follow-up; and persons who were interviewed or for whom other follow-up information was available and no exposure mode was identified. Persons who have an exposure mode identified at the time of follow-up are reclassified into the appropriate exposure category.

## Rates

Rates are on an annual basis per 100,000 population. The denominators for computing rates are based on U.S. Bureau of Census data from the 1990 census and on extrapolations from the 1980 and 1990 census. Each 12-month rate is the number of cases for a 12-month period divided by the 1990 or 1991 population, multiplied by 100,000. Race-specific rates are the number of cases reported for a particular race/ethnicity during the preceding 12-month period divided by the 1991 census estimate for that race/ethnicity, multiplied by 100,000.

Case-fatality rates are on a semiannual basis by date of diagnosis. Each 6-month case-fatality rate is the number of fatal cases reported, divided by the number of total cases diagnosed in that period, multiplied by 100.

## Trends in AIDS incidence

Tabulations of AIDS cases by date of report give a general description of AIDS cases, but analyses by date of diagnosis give a more accurate description of trends. Delays in reporting, however, can have a substantial impact on tabulated numbers of cases diagnosed in recent time periods. About 55 percent of all cases are reported within 3 months of diagnosis, but about 20 percent are reported more than 1 year after diagnosis. Delays are substantially longer for pediatric cases and for transfusion-associated cases in adults.

Figure 5 (included only in the year-end edition) shows trends in AIDS incidence by quarter of diagnosis. The jagged line on the plot shows the estimated numbers of cases diagnosed, after adjusting for estimated delays in reporting. Reporting delays were estimated by a maximum likelihood statistical procedure, taking into account possible differences in reporting delays among exposure, geographic, racial/ethnic, and age categories, but assuming that reporting delays within these groups have not changed over time (J.M. Karon, O.J. Devine, and W.M. Morgan "Predicting AIDS incidence by extrapolating from recent trends." In: C. Castillo-Chavez ed. *Mathematical and Statistical Approaches AIDS Epidemiology. Lecture Notes in Biomathematics*, Vol. 83, Springer Verlag, Berlin, 1989).

The smooth curve is obtained by connecting smoothed values computed for each quarter. The smoothed value at time  $t$  is a weighted average of adjusted incidences in the interval  $t \pm 1$  year; the weights decrease for times further from  $t$ .

The smooth curve should be considered a description of the overall trend in AIDS cases but predictions of future number of cases should not be made by extrapolating the curve. This curve emphasizes that the rate of increase in incidence slowed during the middle of 1987 (see *MMWR* 1990;39:81-86).
