# **1. Introduction**

This document provides the most currently available data on alcohol-related mortality for individual U.S. counties and is the only uniform source of county-level data on alcohol problems for the country. This is the most recent in a series of data reference manuals compiled and published by the Alcohol Epidemiologic Data System (AEDS) of the National Institute on Alcohol Abuse and Alcoholism (NIAAA) and is a major revision and update of three earlier editions showing county-level data on alcohol-related mortality (NIAAA, 1981; Colliver, 1985; Caces et al., 1991). As an update, this document includes the most recent mortality data available at the time of preparation. It is considered a major revision because it uses a definition of alcohol-related mortality based on more current scientific knowledge concerning alcohol's contribution to death than was available when earlier editions were developed.

## **1.1 Purposes and Scope**

The primary purposes of this manual are as follows: (1) to provide information that can be useful to State and local agencies in allocating resources for alcohol treatment and prevention and (2) to make county-level alcohol problem data available for national and local research efforts. The following are examples of the potential utility of the data presented here:

- Determining the prevalence of alcohol-related problems in a county or State compared to other counties or States. Such information is valuable in establishing appropriate overall program resource levels and in making differential resource allocations among catchment areas.
- Identifying patterns of abuse by examining data for several counties to determine geographical boundaries within which similar problems occur and studying demographic and ecological patterns that appear to correlate with the magnitude of alcohol problems.
- Assessing needs for alcohol programs to determine the types of programs that are most needed (e.g., programs focused on health issues for prevention of alcohol-related diseases or programs focused on situational problems, such as injuries, that are brought on by the abuse of alcohol) and identifying the geographic areas with the greatest needs (particularly unmet needs).
- Research modeling, using multivariate statistical methods that link alcohol-related mortality levels (as a problem indicator) with ecological variables, to generate hypotheses for further research or to project future alcohol program needs based on anticipated demographic changes.

The data are presented at the county level because counties are usually the smallest geographic units for which public-sector resource planning for alcohol programs is performed. A service (or catchment) area is typically one county or a combination of counties. In addition, counties are the smallest geographic units for which national data sets capture uniform information.

Counties vary considerably in population; from 1986 through 1990 the largest county was Los Angeles, California, with an average population of 8,592,335, and the smallest county was Yellowstone Park, Montana, with an average population of 54. Even with this range of population, counties are more homogeneous in the characteristics of their residents than are other geographical units for which uniform data are available.

Measures of alcohol problems resulting from abuse or dependence include:

- Health effects, such as morbidity or mortality;
- Accidents and injuries, especially from motor vehicle crashes;
- Social effects, such as family dissolution, violence, and alcohol-related crime; and
- Interference with occupational functioning, including absenteeism and diminished job performance.

For the purposes of this manual, assessment of alcohol problems is based on alcohol-related mortality. The death registration system in the United States provides one of the few national data bases that is not based on a sample; mortality data include information on every death that occurs in the country. As a result, all counties are represented equally in the available data. In addition, the assignment of cause of death is uniformly coded throughout the United States.

## **1.2 Alcohol-Related Mortality**

The research literature includes several evolving attempts to assess the overall contribution of alcohol abuse to mortality (Ravenholt, 1984; Rice et al., 1990; Parker et al., 1987; McDonnell and Maynard, 1985; and Caces et al., 1991). These estimates are based on reviews of the medical literature that attempt to assess the contribution of alcohol to various causes of death. The findings in this data reference manual are based on the newest estimates of alcohol's contribution to mortality for specific causes of death (Schultz et al., 1990); this definition is based on the most comprehensive review of findings from the medical literature currently available.

The definition of alcohol-related mortality used in this report differs from previous AEDS estimates of county-level alcohol mortality. In earlier editions of this manual (NIAAA, 1981; Colliver, 1985; Caces et al., 1991), deaths from only eight causes were counted: (1) cirrhosis of the liver, (2) alcohol dependence syndrome, (3) nondependent abuse of alcohol, (4) alcoholic psychoses, (5) alcohol poisoning, (6) motor vehicle crashes, (7) suicide, and (8) homicide. In the earliest previous edition, this reflected the current scientific knowledge. This definition of alcohol-related mortality continued to be used in later editions in order to maintain comparability of estimates for purposes of comparison over time.

The definition of alcohol-related mortality introduced by Schultz et al. (1990) includes deaths from a greater number of underlying causes than were considered in earlier editions of this

manual. This definition was adopted for this manual to reflect the most current knowledge and to provide estimates that more accurately indicate the total impact of alcohol abuse on mortality. This new definition of alcohol-related mortality is described below.

Exhibit 1 following this page shows three categories of causes for deaths that are considered to be related to alcohol abuse, as reported in this manual. For each cause of death, this exhibit includes an alcohol attributable fraction (AAF)—a number representing the proportion of deaths for each cause that medical research indicates can be attributed to excessive consumption of alcohol. Also shown in this exhibit is a specification of the age of decedents whose deaths are considered to be related to alcohol. The three categories are described below:

- *Causes of death with explicit mention of alcohol.*—All causes of death (including deaths from diseases and from injuries or adverse effects) in this category mention alcohol and have an AAF of 1.0. In other words, all deaths in this category are counted as alcohol-related deaths. This is the one modification of the Schultz et al. (1990) definition. Schultz et al. (1990) did not count deaths for causes with explicit mention of alcohol among decedents below the age of 15 years. This decision overlooked a small number of alcohol poisoning deaths in young children. In this report, we counted all deaths with AAFs of 1.0 regardless of age of decedent.
- *Other alcohol-related diseases.*—Diseases in this category are counted only if the decedent is at least 35 years old. This test of age makes sense because diseases related to alcohol only manifest themselves after some lifetime history of excessive alcohol consumption.
- *Other alcohol-related injuries or adverse effects.*—There are two age tests in this category. Causes of death counted for all ages are generally those in which the decedent need not have been drinking (e.g., motor vehicle accidents or deaths from fire or flames). Other causes of death (e.g., accidental falls or suicide) are counted only for decedents at least 15 years or older.

There are some limitations in the use of mortality as an indicator of alcohol problems. Although the proportion of alcohol involvement in some causes of death may be high, the likelihood of dying from one of these causes due to abuse of alcohol is small. Because alcohol abuse does not always result in death, mortality rates do not necessarily reflect the prevalence of problem drinking. In addition, variation in reporting practices regarding cause of death—particularly deaths from socially disapproved medical conditions, such as those resulting from alcohol abuse—may introduce a bias toward underestimating the true incidence of alcohol-related mortality. Nevertheless, there is a legal requirement that each death be certified and reported to a national data system with reasonable consistency in data elements, definitions, and formats. This fact ensures a completeness and basic level of uniformity in mortality data that is not achieved in other statistical series providing county-level data relevant to alcohol problems.

The data reported in this manual are population-based mortality rates. Variability in number of deaths from a given cause may be due in large part to the population size for the area. One

**Exhibit 1**

**Alcohol-Related Underlying Causes of Death, Alcohol-Attributable Fractions (AAFs), and Ages for Which AAFs Apply**

Underlying Cause of Death (ICD-9 code)	AAF	Age
<b>Causes of Death With Explicit Mention of Alcohol</b>		
Alcoholic psychoses (291)	1.00	$\geq 0$
Alcohol dependence syndrome (303)	1.00	$\geq 0$
Nondependent abuse of alcohol (305.0)	1.00	$\geq 0$
Alcoholic polyneuropathy (357.5)	1.00	$\geq 0$
Alcoholic cardiomyopathy (425.5)	1.00	$\geq 0$
Alcoholic gastritis (535.3)	1.00	$\geq 0$
Alcoholic fatty liver (571.0)	1.00	$\geq 0$
Acute alcoholic hepatitis (571.1)	1.00	$\geq 0$
Alcoholic cirrhosis of liver (571.2)	1.00	$\geq 0$
Alcoholic liver damage, unspecified (571.3)	1.00	$\geq 0$
Excess blood alcohol level (790.3)	1.00	$\geq 0$
Accidental poisoning by ethyl alcohol, not elsewhere specified (E860.0, E860.1)	1.00	$\geq 0$
<b>Other Alcohol-Related Diseases</b>		
Pulmonary and other respiratory tuberculosis (011-012)	0.25	$\geq 35$
Malignant neoplasm of lip, oral cavity and pharynx (140-149)	0.50*	$\geq 35$
Malignant neoplasm of esophagus (150)	0.75	$\geq 35$
Malignant neoplasm of stomach (151)	0.20	$\geq 35$
Malignant neoplasm of liver and intrahepatic bile ducts (155)	0.15	$\geq 35$
Malignant neoplasm of larynx (161)	0.50*	$\geq 35$
Diabetes mellitus (250)	0.05	$\geq 35$
Essential hypertension (401)	0.08	$\geq 35$
Cerebrovascular disease (430-438)	0.07	$\geq 35$
Pneumonia and influenza (480-487)	0.05	$\geq 35$
Diseases of esophagus, stomach and duodenum (530-537)	0.10	$\geq 35$
Cirrhosis of liver without mention of alcohol (571.5)	0.50	$\geq 35$
Biliary cirrhosis (571.6)	0.50	$\geq 35$
Acute pancreatitis (577.0)	0.42	$\geq 35$
Chronic pancreatitis (577.1)	0.60	$\geq 35$
<b>Other Alcohol-Related Injuries or Adverse Effects</b>		
Motor vehicle traffic and nontraffic accidents (E810-E825)	0.42	$> 0$
Pedal cycle and other road vehicle accidents (E826-E829)	0.20	$> 0$
Water transport accidents (E830-E838)	0.20	$> 0$
Air and space transport accidents (E840-E845)	0.16	$> 0$
Accidental falls (E880-E888)	0.35	$\geq 15$
Accidents caused by fire and flames (E890-E899)	0.45	$> 0$
Accidental drowning and submersion (E910)	0.38	$> 0$
Suicide and self-inflicted injury (E950-E959)	0.28	$\geq 15$
Homicide and injury purposely inflicted by other persons (E960-E969)	0.46	$\geq 15$
Other injuries and adverse effects:		
Excessive cold (E901)	0.25	$\geq 15$
Inhalation and ingestion of food causing obstruction of respiratory tract or suffocation (E911)		
Striking against or struck accidentally by objects or persons (E917)		
Caught accidentally in or between objects (E918)		
Accidents caused by machinery (E919)		
Accidents caused by cutting and piercing instruments or objects (E920)		
Accident caused by firearm missile (E922)		
Poisoning by solid or liquid substances, undetermined whether accidentally or purposely inflicted (E980)		

\* AAF is 0.40 for females.

Note: Table adapted from Schultz, J., Rice, D., and Parker, D. (1990).

would expect more deaths in counties with larger populations and fewer deaths in counties with smaller populations. The procedure of counting all deaths from a given cause group, dividing it by the population, and multiplying the result by a standardizing factor such as 100,000 yields an easily interpretable statistic that eliminates the “noise” created by variations in population size. This allows comparison of death rates between counties, whether large or small.

Mortality data and population estimates for the years 1986 through 1990 were aggregated and averaged to compute the rates reported in this manual. With relatively few deaths in many of the counties for the three death categories, and particularly for counties with small populations, year-to-year variations can be considerable. This can be further confounded by the sporadic occurrence of a rare event, such as dying of alcohol poisoning in a sparsely populated county. For this reason, the use of data from 1 or 2 years can present a misleading picture. In order to minimize the effects of this variation, the data included in this manual are averaged over a 5-year period.

### **1.3 Data Sources and Calculations**

Data presented in this manual include population-based mortality rates (both unadjusted and age-adjusted) at the State and county levels for all alcohol-related mortality and for the three subclassifications of alcohol deaths described above. Also shown are county-level maps that compare death rates for two categories of alcohol mortality: (1) causes of death with explicit mention of alcohol and (2) other alcohol-related injuries and adverse effects. Details of data sources and calculations are described below.

#### **1.3.1 Mortality Data**

The National Center for Health Statistics (NCHS) is the source of mortality data. In all cases, the data for a given county represent deaths of residents of that county. Persons who die from an alcohol-related disease or injury may have died in a county other than that in which they resided, but the place of death does not necessarily reflect the place in which a decedent's history of alcohol abuse occurred. For this reason, place of residence and not place of death is the most appropriate manner of locating alcohol-related mortality for the identification of geographic areas in need of mounting programs to deal with alcohol abuse. Deaths of nonresidents of the United States are excluded.

Based on the combination of all contributory causes listed on the death certificate, NCHS assigns a single underlying cause for each death. The underlying cause of death is defined as “the disease or injury which initiated the train of morbid events leading directly or indirectly to death or the circumstances of the accident or violence which produced the fatal injury” (NCHS, 1982b, p. 4). Deaths were counted as alcohol related by applying the AAF proportions shown in exhibit 1 to the causes of death and age groups also listed in the exhibit. For example, 75 percent of deaths from malignant neoplasms of the esophagus among decedents at least 35 years old were considered to be alcohol-related.

### **1.3.2 Population Data**

The population figures presented in this report and used in the calculation of mortality rates include individuals from all age groups. The average population for the years 1986 to 1990 was computed by adding the population from each year and dividing by five. The 1986 to 1989 population data are from special intercensal estimates developed by the Bureau of the Census for the National Cancer Institute. The 1990 population data come from the 1990 census.

### **1.3.3 Mortality Rates**

This manual presents two different types of mortality rates, as described below:

- *Unadjusted (or crude) rates.*—These rates are calculated by dividing the number of deaths by the size of the population in the group under study. For example, the average annual number of U.S. deaths from causes with explicit mention of alcohol over the period from 1986 through 1990 was 18,338. When this number is divided by the average U.S. population for this same period (244,511,162), the result is a rate that equals 0.000075 deaths for each person in Census Bureau estimates of the U.S. population. Numbers with so many zeros between the decimal point and the significant digits are difficult to understand. For this reason, mortality rates usually are expressed as rates per 100,000 population and calculated by multiplying the true rate by 100,000. This makes the example rate (7.5 deaths per 100,000 population) a number that is easier to comprehend and compare with other rates.

Unadjusted rates show the true mortality experience for the group under study and are appropriate for assessing the actual incidence of mortality in any population under study. For this reason, unadjusted rates are provided for use in decisions about allocation of resources to address alcohol problems. Unadjusted rates are shown in table 1 for States and table 2 for counties. The maps in this manual display unadjusted mortality rates. However, unadjusted death rates should be interpreted with caution, particularly when comparing places with varying population age distributions. For this reason, this manual also provides age-adjusted death rates.

- *Age-adjusted rates.*—In addition to variation in the size of State or county populations, there exists wide variability in age distributions within these populations. For instance, a retirement community would have a large proportion of elderly people in its population, whereas a county with a rapidly expanding economy might have a large proportion of relatively young workers and their families. In general, elderly persons are more likely to die than young persons. Therefore, one would observe a larger number of deaths occurring in places with relatively more elderly people than in places with relatively more young people, even if the two places were of similar population size. For comparing groups with differing age structures and population sizes, age-adjusted mortality rates are necessary. The observed mortality patterns within an area are standardized, using the population distribution across age groups found in a reference (standard) population. Following convention, the age distribution of the U.S. population in 1940 is used as the

standard for this manual. Thus, in comparing two counties that differ in age structure, the age-adjusted mortality rate provides a picture of what the counties' respective rates would have been had the age distributions of their populations been the same as that of the United States in 1940.

Age-adjusted rates eliminate the confounding effect of different age distributions on mortality rates. For this reason, age-adjusted rates are the preferred indicators of mortality experience for research, in which the influences of factors other than age are of interest. In general, mortality rates for an area with a population that is older than the standard population become lower with age adjustment, while the opposite is true for areas with a younger population. Because the recent U.S. population tends to be older than the 1940 U.S. population, the majority of States and counties in this manual have lower age-adjusted rates than their respective unadjusted rates. Age-adjusted rates are shown for States in table 3 and for counties in table 4.

Although the number of deaths means little without some adjustment for the size of the population under study, there may be some need for readers to be able to derive the number of deaths represented by the mortality rates presented in tables 1 and 2. This number can be approximated by dividing the rate presented in the tables by 100,000 and multiplying this result by the population for the particular group. It will be an approximation because of rounding used in the rates presented in this manual.

#### **1.3.4 Coverage of Counties**

This manual contains data for 3,114 counties. Although an attempt was made to include all counties, no sub-State mortality rates could be computed for Alaska because area definitions used by NCHS for the registration of vital events did not match the population district boundaries used by the Census Bureau. In addition, three new counties were created in the 1980's. Because the intercensal population estimates used in calculating rates were projected for the set of counties that existed at the time of the 1980 census, population estimates for these new counties were not available and, therefore, deaths for these new counties were combined with those for the older counties from which they were created for calculating rates. As a result, the following three counties are not shown separately: (1) Cibola County New Mexico (counted as part of Valencia County); (2) Kalawao County Hawaii (counted as part of Maui County); and (3) La Paz County Arizona (counted as part of Yuma County).

## 2. Area Maps

This section of the data reference manual shows area maps drawn at the county level for all counties in the coterminous United States. These area maps use different shades of gray to indicate the level of mortality for each area (i.e., county) in the map. Such maps provide an easily and quickly understood visual display showing where the highest levels of alcohol mortality occur. These maps are for clusters of States, because a single map of the entire country would result in a picture with indistinguishable shades in counties with small land areas.

The maps are based on unadjusted mortality rates. The unadjusted rates reflect the actual mortality experience in each county, and these maps highlight counties in which deaths are occurring. This information is most useful for allocating resources for treatment and prevention.

There are 20 maps—2 sets for each of 10 clusters of States. One set shows mortality rates for causes of death with explicit mention of alcohol, and the second set shows mortality rates for other alcohol-related injuries and adverse effects. The counties with the greatest rates for each of these two cause-of-death categories differ considerably. In the following pages, the maps for each cause-of-death category for a particular cluster of States are displayed on facing pages for easy comparison.

Each map displaying a particular category of cause of death uses the same scheme for coding level of mortality in order to facilitate comparison between clusters of States. Categories of mortality rate level are based on the distribution of mortality rates for the entire country. Each map shows the top, middle, and bottom thirds of counties, based on their standing in the overall national distribution of mortality rates. For causes of death with explicit mention of alcohol, counties in the lowest third of the distribution had rates less than 3.9 deaths per 100,000 population and counties in the middle third of the distribution had rates greater than 3.8 but less than 7.1 deaths per 100,000 population. For deaths from other alcohol-related injuries or adverse effects, counties in the lowest third of the distribution had rates less than 19.2 deaths per 100,000 population and counties in the middle third of the distribution had rates greater than 19.1 but less than 25.6 deaths per 100,000 population.

Pages 10 through 29 are omitted from this PDF document because of their file size. Figures on these pages are U.S. county-level maps. These maps are contained in 2 separate files, each containing 10 maps and each about 3 times as large as the remainder of the data reference manual. Users who want these map files can find them on NIAAA's web site. The maps in these files are paginated so that they can be inserted into a hard copy of the data reference manual if users choose to print this document.

### **3. Data Tables**

In this section, tables show detailed mortality rates for each State and county. Tables 1 and 2 show unadjusted mortality rates and tables 3 and 4 show age-adjusted rates. Tables 1 and 3 summarize the data at the State level while tables 2 and 4 provide data for each county.

Each table shows similar information. The first column gives an identification of the geographic area. The second column shows the average population for this place from 1986 through 1990. Columns 3, 5, 7, and 9 show mortality rates for the following alcohol-related cause-of-death categories (defined in exhibit 1): (1) all alcohol-related causes of death; (2) causes of death with explicit mention of alcohol; (3) other alcohol-related diseases; and (4) other alcohol-related injuries or adverse effects.

In columns 4, 6, 8, and 10, these tables also show ranks based on the rates to the immediate left. The ranks order the States (tables 1 and 3) or counties within States (tables 2 and 4). In the rank columns, the areas with the highest rates have the lowest ranks. In other words, a rank of 1 means that the associated rate is the highest in the country or State. In some instances, there may be ties in the value of the mortality rate, and, in these cases, there will be duplicate values for the rank. For example, if 3 counties have rates equal to 3.4 deaths per 100,000 population and this rate ranks third, then these counties will each be assigned a rank of 3 and there will be no counties assigned ranks of 4 or 5. This also means that the highest rank in a county-level table may not reflect the total number of counties in the State. This is because some small counties have no deaths in a particular cause-of-death category even though rates in this manual are based on an examination of 5 years. Rates of zero also are treated as ties in constructing the ranks presented in these tables; the associated rank for each county having no alcohol-related deaths will be equal to that for all other counties with no alcohol-related deaths reported for the particular category.

Table 1

**Unadjusted Death Rates per 100,000 Population and Associated Ranks for Different Categories of Alcohol-Related Mortality By State: United States, 1986–1990**
