NATIONAL TOXICOLOGY PROGRAM

The National Toxicology Program (NTP), established in 1978, develops and evaluates scientific information about potentially toxic and hazardous chemicals. This knowledge can be used for protecting the health of the American people and for the primary prevention of disease. By bringing together the relevant programs, staff, and resources from the U.S. Public Health Service, DHHS, the National Toxicology Program has centralized and strengthened activities relating to toxicology research, testing and test development/validation efforts, and the dissemination of toxicological information to the public and scientific communities and to the research and regulatory agencies.

The NTP is made up of four charter DHHS agencies: the National Cancer Institute (NCI), National Institutes of Health; the National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health; the National Center for Toxicological Research (NCTR), Food and Drug Administration; and the National Institute for Occupational Safety and Health (NIOSH), Centers for Disease Control. In July 1981, the Carcinogenesis Bioassay Testing Program, NCI, was transferred to the NIEHS.

NTP TECHNICAL REPORT ON THE

TOXICOLOGY AND CARCINOGENESIS STUDIES OF DIMETHYLVINYL CHLORIDE (1-CHLORO-2-METHYLPROPENE)

(CAS NO. 513-37-1)

NOTE TO THE READER

These studies are designed and conducted to characterize and evaluate the toxicologic potential, including carcinogenic activity, of selected chemicals in laboratory animals (usually two species, rats and mice). Chemicals selected for testing in the NTP Carcinogenesis Program are chosen primarily on the bases of human exposure, level of production, and chemical structure. Selection per se is not an indicator of a chemical's carcinogenic potential. Negative results, in which the test animals do not have a greater incidence of cancer than control animals, do not necessarily mean that a test chemical is not a carcinogen, inasmuch as the experiments are conducted under a limited set of conditions. Positive results demonstrate that a test chemical is carcinogenic for animals under the conditions of the test and indicate that exposure to the chemical has the potential for hazard to humans. The determination of the risk to humans from chemicals found to be carcinogenic in animals requires a wider analysis which extends beyond the purview of this study.

Five categories of interpretative conclusions were adopted for use in June 1983 in the Technical Reports series to specifically emphasize consistency and the concept of actual evidence of carcinogenicity. For each definitive study result (male rats, female rats, male mice, female mice), one of the following quintet will be selected to describe the findings. These categories refer to the strength of the experimental evidence and not to either potency or mechanism.

- Clear Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of malignant neoplasms, studies that exhibit a substantially increased incidence of benign neoplasms, or studies that exhibit an increased incidence of a combination of malignant and benign neoplasms where each increases with dose.
- Some Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of benign neoplasms, studies that exhibit marginal increases in neoplasms of several organs/tissues, or studies that exhibit a slight increase in uncommon malignant or benign neoplasms.
- Equivocal Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related marginal increase of neoplasms.
- No Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing no chemically related increases in malignant or benign neoplasms.
- Inadequate Study of Carcinogenicity demonstrates that because of major qualitative or quantitative limitations, the studies cannot be interpreted as valid for showing either the presence or absence of a carcinogenic effect.

Additionally, the following concepts (as patterned from the International Agency for Research on Cancer Monographs) have been adopted by the NTP to give further clarification of these issues:

The term *chemical carcinogenesis* generally means the induction by chemicals of neoplasms not usually observed, the earlier induction by chemicals of neoplasms that are commonly observed, or the induction by chemicals of more neoplasms than are generally found. Different mechanisms may be involved in these situations. Etymologically, the term *carcinogenesis* means induction of cancer, that is, of malignant neoplasms; however, the commonly accepted meaning is the induction of various types of neoplasms or of a combination of malignant and benign neoplasms. In the Technical Reports, the words *tumor* and *neoplasm* are used interchangeably.

This study was initiated by the National Cancer Institute's Carcinogenesis Bioassay Program, now part of the National Institute of Environmental Health Sciences, National Toxicology Program. The studies described in this Technical Report have been conducted in compliance with NTP chemical health and safety requirements and must meet or exceed all applicable Federal, state, and local health and safety regulations. Animal care and use were in accordance with the U.S. Public Health Service Policy on Humane Care and Use of Animals. All NTP toxicology and carcinogenesis studies are subjected to a data audit before being presented for peer review.

Although every effort is made to prepare the Technical Reports as accurately as possible, mistakes may occur. Readers are requested to identify any mistakes so that corrective action may be taken. Further, anyone who is aware of related ongoing or published studies not mentioned in this report is encouraged to make this information known to the NTP. Comments and questions about the National Toxicology Program Technical Reports on Toxicology and Carcinogenesis Studies should be directed to Dr. J.E. Huff, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709 (919-541-3780).

These NTP Technical Reports are available for sale from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161 (703-487-4650). Single copies of this Technical Report are available without charge (and while supplies last) from the NTP Public Information Office, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709.

ABSTRACT

Toxicology and carcinogenesis studies of dimethylvinyl chloride (96%-98% pure), a structural analog of vinyl chloride monomer, a known human carcinogen, were conducted by administering dimethylvinyl chloride in corn oil by gavage to groups of 50 male and 50 female F344/N rats and B6C3F₁ mice at doses of 0, 100, or 200 mg/kg body weight 5 days per week for 102 or 103 weeks. The selection of these doses was based on results of 13-week studies, which included depression of body weight at doses of 500 mg/kg or above in rats as well as histopathologic changes in intestinal epithelium, bone marrow, hepatocytes, and the testes at doses of 250 mg/kg and above; doses in mice were selected on the basis of histopathologic changes in lymphopoietic cells, liver, pancreatic islets, ovary, testis, and spleen, with changes being most prominent at doses of 500 mg/kg and above.

In the 2-year studies, body weights of rats and mice given 100 mg/kg were comparable to those of the vehicle controls except for the last few weeks in mice when body weights were markedly lower than those for the vehicle controls. At 200 mg/kg, the mean body weights of rats and mice were progressively decreased relative to those of vehicle controls, with the significant departure from vehicle controls occurring somewhat earlier in males than in females. Survival of vehicle control rats and mice was comparable to historical values; however, survival of dosed male and female rats was significantly lower than that of vehicle controls, with the incidence of mortality being more severe at the high dose than at the low dose. There were no survivors in the high dose group of male rats after week 85 or in the high dose group of female rats after week 97. Survival was significantly lower among dosed male and female mice compared with vehicle controls. In the absence of toxicologic findings that would explain the early deaths, it is assumed that the high incidence of tumors and chemical-related toxicity contributed to the decreased survival of dosed rats and mice.

In rats, the severity and incidence of nonneoplastic lesions were minimal; these lesions included necrosis of the duodenum and epithelial hyperplasia at the sites of tumor formation--the nasal cavity, esophagus, and forestomach. In mice, the severity of nonneoplastic lesions was also minimal; the lesions included necrosis of the liver, bone marrow granulocytic hyperplasia, and inflammation of the nasal cavity (small number, females only).

Several types of neoplastic lesions occurred with significantly increased incidences in dosed animals as shown in the following table. Among rats, these lesions included malignant epithelial tumors of the nasal cavity and squamous cell tumors of the oral cavity, esophagus, and forestomach in males and females. The increased number of fibroadenomas of the mammary gland in female rats may have been related to dimethylvinyl chloride administration. The lack of a clear dose-response relationship for certain tumors in rats is considered to be related to the increased number of early deaths observed in the high dose groups.

INCIDENCES OF NEOPLASTIC LESIONS IN RATS AND MICE IN THE TWO-YEAR GAVAGE STUDIES OF DIMETHYLVINYL CHLORIDE

(a) Mice that died before week 3 are excluded.

Among dosed mice, there were significantly increased incidences of squamous cell carcinomas of the forestomach (both sexes), squamous cell papillomas of the forestomach (males), and squamous cell carcinomas of the preputial gland (males). The increased incidence of papillary adenomas of the harderian gland and alveolar/bronchiolar adenomas or carcinomas in female mice may have been related to administration of dimethylvinyl chloride.

Limited metabolism studies of 14 C-labeled dimethylvinyl chloride were conducted in male F344/N rats and B6C3F₁ mice. Single doses of 150 mg/kg were administered to rats for 1, 2, or 4 consecutive days. About 25% of the administered doses was exhaled as carbon dioxide; this amount was independent of the number of doses administered. Another 25%-35% of the administered dose was exhaled; 96% of this was parent material. Approximately 35% and 6% were excreted in the urine and feces, respectively. The elimination half-life of radioactive label was 3-4 days for the liver and kidney, the two organs containing the greatest amounts of the administered dose. In mice, a much smaller fraction of the dose was exhaled and a larger proportion was excreted in urine compared with rats.

Dimethylvinyl chloride was not mutagenic in four strains of Salmonella typhimurium with or without metabolic activation, but it was mutagenic in the mouse lymphoma L5178Y/TK^{+/-} assay in the absence of metabolic activation. Sister-chromatid exchanges were induced in Chinese hamster ovary cells with and without metabolic activation, but there was no increase in chromosomal aberrations. When fed to Drosophila, dimethylvinyl chloride induced significant increases in the frequencies of both sex-linked recessive lethal mutations and reciprocal translocations.

Studies of the immunotoxicity of dimethylvinyl chloride were conducted in which female $B6C3F_1$ mice received 14 daily oral doses of 0, 50, 100, 200, or 400 mg dimethylvinyl chloride per kilogram body weight. Compound-related increases in susceptibility to bacterial infection and decreases in macrophage cytostasis were observed at all doses. At the highest dose, the decreased resistance to bacterial and viral challenge could be related to alterations in specific immune function. However, the increased mortality in rats and mice in the 2-year studies was not relatable to infectious processes.

An audit of the experimental data was conducted for these 2-year toxicology and carcinogenesis studies on dimethylvinyl chloride. No data discrepancies were found that influenced the final interpretations.

Under the conditions of these 2-year gavage studies, there was *clear evidence of carcinogenicity*^{*} of dimethylvinyl chloride for both sexes of F344/N rats and B6C3F₁ mice. This was based on increased incidences of neoplasms of the nasal cavity, oral cavity, esophagus, and forestomach of male and female F344/N rats. B6C3F₁ mice showed increased incidences of squamous cell neoplasms of the forestomach in males and females and squamous cell carcinomas of the preputial gland in males.

^{*}Categories of evidence of carcinogenicity are defined in the Note to the Reader on page 2. The public discussion regarding the interpretative conclusions is summarized on page 16.

CONTRIBUTORS

The NTP Technical Report on the Toxicology and Carcinogenesis Studies of Dimethylvinyl Chloride is based on the 13-week studies that began in August 1978 and ended in November 1978 and on the 2year studies that began in June 1980 (rats) or March 1981 (mice) and ended in June 1982 (rats) or March 1983 (mice) at Litton Bionetics, Inc.

PEER REVIEW PANEL

The members of the Peer Review Panel who evaluated the draft Technical Report on dimethylvinyl chloride on December 9, 1985, are listed below. Panel members serve as independent scientists, not as representatives of any institution, company, or governmental agency. In this capacity, Panel members have five major responsibilities: (a) to ascertain that all relevant literature data have been adequately cited and interpreted, (b) to determine if the design and conditions of the NTP studies were appropriate, (c) to ensure that the Technical Report presents the experimental results and conclusions fully and clearly, (d) to judge the significance of the experimental results by scientific criteria, and (e) to assess the evaluation of the evidence of carcinogenicity and other observed toxic responses.

SUMMARY OF PEER REVIEW COMMENTS ON THE TOXICOLOGY AND CARCINOGENESIS STUDIES OF DIMETHYLVINYL CHLORIDE

On December 9, 1985, the draft Technical Report on the toxicology and carcinogenesis studies of dimethylvinyl chloride received peer review by the National Toxicology Program Board of Scientific Counselors' Technical Reports Review Subcommittee and associated Panel of Experts. The review meeting was held in the Conference Center, Building 101, South Campus, National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina.

Dr. B. Schwetz, NTP Chemical Manager, introduced the toxicology and carcinogenesis studies of dimethylvinyl chloride by reviewing the experimental designs, results, and proposed conclusions (clear evidence of carcinogenicity for both sexes of rats and mice).

Dr. Crowley, a principal reviewer for the draft Technical Report, agreed with the conclusions as written. He asked for clarification or more definition of the relationship between tumors and early mortality in the dose groups vs. a relationship with compound-induced toxicity.

As a second principal reviewer, Dr. Perera agreed with the conclusions. Her principal criticisms had to do with presentation and discussion in the text of tumor incidence data displayed in the tables. She cited a number of examples and noted especially instances where there was little comment about increased tumor incidences in low dose groups. Dr. Schwetz responded that for some tumors, especially those with increases in the low dose groups, there was little or no mention in the text because of only marginally increased incidence, the lack of a high dose effect, or the primarily benign nature of the tumors. Dr. Perera noted that although harderian gland tumors were significantly increased in incidence and with a positive trend in female mice, this was considered to be an "uncertain relationship" to chemical administration. She questioned this interpretation.

As a third principal reviewer, Dr. Purchase also agreed with the conclusions. He thought there was very good evidence that early mortality was due to malignant neoplasms, noting that virtually all animals dying after about 60-70 weeks had malignant neoplasms. Dr. Schwetz replied that most of the dosed rats dying without nasal tumors died earlier than those with such tumors, citing this as an example of why the causes of death were probably a combination of cancer and dimethylvinyl chloride toxicity. Dr. Purchase said the argument that dimethylvinyl chloride acts directly on the nasal mucosa was weaker than the one suggesting that the nasal lesions were a result of systemic absorption and gave reasons in support of an indirect effect. Dr. Scala said the lack of kidney or bladder tumors in mice also spoke to the tumorigenicity occurring through systemic rather than local effects.

In other discussion, Dr. Scala commented on the introduction of information on chemical metabolism and immunotoxicology studies for the first time in the discussion without prior presentation of data in the results section.

Dr. Crowley moved that the Technical Report on dimethylvinyl chloride with the conclusions as written for rats and mice of both sexes, clear evidence of carcinogenicity, be accepted. Dr. Hooper seconded the motion, and it was approved unanimously with 11 affirmative votes.

I. INTRODUCTION

DIMETHYLVINYL CHLORIDE

CAS No. 513-37-1

(1-Chloro-2-methylpropene)

C₄H₇Cl Molecular weight 90.55

Dimethylvinyl chloride is a clear colorless liquid, which, because of its volatility and flammability at room temperature, is a significant fire hazard. It has a boiling point of 68.1° C (155° F) and a density at 20° C of 0.919 g/ml (Merck, 1976). Dimethylvinyl chloride is a byproduct in the production of 3-chloro-2-methylpropene by the chlorination of isobutene. It is not known to be produced intentionally in the United States for other than laboratory purposes. This chemical was nominated for toxicologic studies because of its reported presence in ambient air in the Baltimore area (personal communication from H. Kraybill to NCI Chemical Selection Working Group, 1976) and was selected for toxicologic characterization because of its structural similarity to the known animal and human carcinogen, vinyl chloride monomer.

No threshold limit value is identified for dimethylvinyl chloride, and no recently published toxicologic data have been found. Silverman and Abreu (1938) reported that dimethylvinyl chloride was mildly irritating to the eyes and mucous membranes of humans and mice and had anesthetic properties in mice. In "barbitalized" rabbits administered dimethylvinyl chloride by inhalation, these authors reported a moderate rise in blood pressure that rapidly returned to normal after exposure ceased. The increase in blood pressure was considered to be a reflex result of inhalation of a respiratory tract irritant.

Vinyl chloride monomer is a well-recognized human carcinogen and in laboratory animals is a carcinogen in multiple organs, producing a variety of tumors in all species in which it has been studied and in animals of both sexes and of different ages by different routes of administration (Maltoni et al., 1984). The potency of vinyl chloride monomer as a carcinogen and its close structural similarity to vinyl chloride monomer suggested that dimethylvinyl chloride might also be an animal carcinogen.

No information was found in the literature regarding the disposition of dimethylvinyl chloride in animals.

Dimethylvinyl chloride was not mutagenic in strains TA98, TA100, TA1535, or TA1537 of Salmonella typhimurium in the presence or absence of Aroclor 1254-induced male Sprague-Dawley rat or male Syrian hamster liver S9 when tested according to the preincubation protocol (Appendix G, Table G1). However, dimethylvinyl chloride was mutagenic in the mouse lymphoma L5178Y/TK $^{+/-}$ assay in the absence of S9 (Table G2); it was not tested in the presence of S9. The compound induced sisterchromatid exchanges in Chinese hamster ovary cells in the presence or absence of Aroclor 1254induced male Sprague-Dawley rat liver S9 (Table G3); it did not induce chromosomal aberrations in these cells (Table G4). Dimethylvinyl chloride induced a significant increase in the frequency of both sex-linked recessive lethal mutations and reciprocal translocations in the germ cells of Drosophila when fed to males at a dose of 12,750 ppm in 5% sucrose. Dimethylvinyl chloride induced greater absolute and relative increases in the frequency of reciprocal translocations than in the frequency of sex-linked recessive lethal mutations (Table G5). No information was found in the literature on the genetic toxicology of dimethylvinyl chloride.

3-Chloro-2-methylpropene recently has been reported to be a carcinogen when given by gavage to rats and mice (NTP, 1986). The lots of this

chemical which were evaluated for carcinogenicity contained as much as 5% dimethylvinyl chloride. Dose-related increases in the incidences of forestomach basal cell hyperplasia were observed in rats and mice of each sex. Forestomach squamous cell carcinomas were observed in male rats dosed with 150 mg/kg per day and in male and female mice dosed with 75 or 150 mg/kg per day. The potential role of dimethylvinyl chloride in the observed carcinogenicity in the 3-chloro-2-methylpropene studies was not established. Dimethylvinyl chloride was selected for study to characterize and evaluate its toxicologic potential, including carcinogenic activity, because of its structural similarity to the potent human and animal carcinogen, vinyl chloride monomer. Since available inhalation facilities were limited and because 3-chloro-2-methylpropene was studied by the oral route, dimethylvinyl chloride was administered orally by gavage.

II. MATERIALS AND METHODS

PROCUREMENT AND CHARACTERIZATION OF DIMETHYLVINYL CHLORIDE PREPARATION AND CHARACTERIZATION OF DOSE MIXTURES SINGLE-ADMINISTRATION STUDIES FOURTEEN-DAY STUDIES THIRTEEN-WEEK STUDIES TWO-YEAR STUDIES Study Design Source and Specifications of Animals Animal Maintenance Clinical Examinations and Pathology Statistical Methods

PROCUREMENT AND CHARACTERIZATION OF DIMETHYLVINYL CHLORIDE

Dimethylvinyl chloride (1-chloro-2-methylpropene) was obtained from the Aldrich Chemical Company in three lots (Table 1). Purity, identity, and stability analyses were conducted at Midwest Research Institute (Kansas City. Missouri) (Appendix H). All three lots were identified as dimethylvinyl chloride by spectroscopy. The infrared, ultraviolet/visible, and nuclear magnetic resonance spectra were consistent with the structure of dimethylvinyl chloride and with available literature references. The purity for all three lots ranged from 96% for lot nos. 062537 and KD090967 to 98% for lot no. 1103BH based on elemental analysis, water analysis, acid titration, and gas chromatography. No epichlorohydrin was detected in any of the lots. The identity and concentration of major impurities

observed in these lots of dimethylvinyl chloride are presented in Table 2.

The bulk chemical was stable when stored for 2 weeks at temperatures ranging from -20° to 25° C (Appendix H). Several portions of the chemical were stored at -20° C as reference samples, and the remainder was stored at room temperature. Periodic reanalysis of the study and reference samples by infrared spectroscopy and gas chromatography indicated that a decrease in the purity (approximately 1.7%) of the study material and a corresponding increase in the concentration and/or number of impurities in the reference and bulk chemical occurred in lot no. 062537 after storage for 3 years at the study laboratory. This lot was immediately replaced with lot nos. KD090967 and 1103BH.

Periodic reanalysis of these lots indicated no decomposition of dimethylvinyl chloride for the remainder of the studies (Appendix H).

TABLE 2. IDENTITY AND CONCENTRATION OF MAJOR IMPURITIES IN DIMETHYLVINYL CHLORIDE

(a) An impurity, tentatively identified as methylpropene from a comparison of its mass spectrum with a literature reference, was observed to coelute with the acetone impurity. The combined concentration of these two impurities is estimated to be 0.12%.

(b) Percent of major peak area; not quantitated against a standard.

(c) Not detected at a level $\geq 0.1\%$

(d) The concentration of chloroform could not be determined because of its low concentration and coelution with *t*-butyl chloride. When quantitated against a *t*-butyl chloride standard, the combined concentration of these two impurities was estimated to be 0.1%.

PREPARATION AND CHARACTERIZATION OF DOSE MIXTURES

Accurately measured amounts of dimethylvinyl chloride were mixed with corn oil to yield the desired concentrations (Table 3). Dose mixtures of dimethylvinyl chloride (6%, w/v) in corn oil were stable when stored at room temperature for 7 days (Appendix I). An additional stability study conducted at the study laboratory indicated that the dose formulations were stable for up to 21 days at 25° C. Dimethylvinyl chloride and corn oil mixtures were stored at 25° C for no longer than 21 days. The study laboratory experienced difficulty in preparing the dose mixtures of dimethylvinyl chloride. Periodic analysis for dimethylvinyl chloride in the corn oil vehicle was performed by the study laboratory and analytical chemistry laboratory to determine if the dose mixtures contained the correct concentrations of study material (Appendix J). Because 58/72 mixtures analyzed were within \pm 10% of the target concentration, it is estimated that the dose mixtures were prepared within specifications 81% of the time (Table 4; Appendix K, Table K1). Of the 14 dose formulations determined to be out of specification, 9 were found to be within \pm 20% of the target concentrations and the remaining 5 samples were greater than 20% above the target concentrations.

SINGLE-ADMINISTRATION STUDIES

Male and female F344/N rats and B6C3F₁ mice were obtained from Harlan Industries and observed for 2 weeks before the studies began. Groups of five male and five female unfasted rats were administered a single dose of 10, 31.6, 100, 316, 1,000, 3,160, or 10,000 mg/kg dimethylvinyl chloride in corn oil by gavage. Groups of five unfasted mice of each sex were administered 100, 316, 1,000, 3,160, or 10,000 mg/kg dimethylvinyl chloride. Groups of five mice of each sex were administered 31.6, 100, 316, 1,000, or 3,160 mg/kg; these mice were fasted 4 hours before dosing. All animals were observed 4 hours after dosing and then daily for 14 days; they were killed on day 15. A necropsy was performed on all animals that died before the end of the studies and on some animals that lived to the end of the studies. Details of animal maintenance are given in Table 5.

FOURTEEN-DAY STUDIES

Male and female F344/N rats and $B6C3F_1$ mice were obtained from Harlan Industries and held for 3 weeks (rats) or 4 weeks (mice) before the studies began. (Although water was available during the quarantine period, quarantined mice appeared to be dehydrated. They recovered

before the studies began.) Groups of five male and five female rats were administered 0, 500, 750, 1,250, 1,750, or 2,500 mg/kg dimethylvinyl chloride in corn oil by gavage for 14 consecutive days. Groups of five male and five female mice were administered 0, 250, 500, 1,000, 1,500, or 2,000 mg/kg on the same schedule.

Animals were housed five per cage and received water (acidified to pH 2.5 with hydrochloric acid) and feed ad libitum. Further details of animal maintenance are presented in Table 5. The rats and mice were observed daily and were weighed on days 1 and 15. A necropsy was performed on all animals.

THIRTEEN-WEEK STUDIES

Thirteen-week studies were conducted to evaluate the cumulative toxic effects of dimethylvinyl chloride and to determine the doses to be used in the 2-year studies.

Male and female F344/N rats and $B6C3F_1$ mice were obtained from Charles River Breeding Laboratories, observed for 14 days, and then assigned to cages according to a table of random numbers. The cages were then assigned to dosed and vehicle control groups according to a table of random numbers.

Groups of 10 rats and 10 mice of each sex were administered 0, 63, 125, 250, 500, or 750 mg/kg dimethylvinyl chloride in corn oil by gavage, 5 days per week for 13 weeks. Animals were checked twice per day; moribund animals were killed. Further experimental details are summarized in Table 5. At the end of the 13-week studies, survivors were killed. A necropsy was performed on all animals except those excessively autolyzed or cannibalized. Tissues and groups examined are listed in Table 5.

TWO-YEAR STUDIES

Study Design

Groups of 50 male and 50 female rats and groups of 50 male and 50 female mice were administered 0, 100, or 200 mg/kg dimethylvinyl chloride in corn oil by gavage, 5 days per week for 103 weeks (rats) or 102 weeks (mice).

Source and Specifications of Animals

The male and female F344/N rats and B6C3F1 (C57BL/6N, female, \times C3H/HeN MTV⁻, male) mice used in these studies were produced under strict barrier conditions at Charles River Breeding Laboratories under a contract to the Carcinogenesis Program. Breeding stock for the foundation colonies at the production facility originated at the National Institutes of Health Repository. Animals shipped for study were progeny of defined microflora-associated parents that were transferred from isolators to barriermaintained rooms. Rats were shipped to the study laboratory at 4-5 weeks of age and mice, at 5-6 weeks of age. The animals were guarantined at the study laboratory for 2.5 weeks (rats) or 2 weeks (mice). Thereafter, a complete necropsy was performed on five animals of each sex and species to assess their health status. The rats were placed on study at 7 weeks of age and the mice, at 8 weeks of age. The health of the animals was monitored during the course of the studies according to the protocols of the NTP Sentinel Animal Program (Appendix L).

A quality control skin grafting program has been in effect since early 1978 to monitor the genetic integrity of the inbred mice used to produce the hybrid $B6C3F_1$ study animal. In mid-1981, data were obtained that showed incompatibility between the NIH C3H reference colony and the C3H colony from a Program supplier. In August 1981, inbred parental lines of mice were further tested for genetic integrity via isozyme and protein electrophoresis profiles that demonstrate phenotype expressions of known genetic loci. The C57BL/6 mice were homogeneous at all loci tested. Eighty-five percent of the C3H mice monitored were variant at one to three loci, indicating some heterogeneity in the C3H line from this supplier. Nevertheless, the genome of this line is more homogeneous than that of randomly bred stocks.

Male mice from the C3H colony and female mice from the C57BL/6 colony were used as parents for the hybrid B6C3F₁ mice used in these studies. The influence of the potential genetic nonuniformity in the hybrid mice on these results is not known, but results of the studies are not affected because concurrent controls were included in each study.

Animal Maintenance

Animals were housed five per cage. Feed and water were available ad libitum. Further details of animal maintenance are given in Table 5.

Clinical Examinations and Pathology

All animals were observed twice daily, and clinical signs were recorded once per week. Body weights by cage were recorded once per week for the first 13 weeks of the studies and once per month thereafter. Mean body weights were calculated for each group. Animals found moribund and those surviving to the end of the studies were humanely killed. A necropsy was performed on all animals including those found dead, unless they were excessively autolyzed or cannibalized, missexed, or found missing. Thus, the number of animals from which particular organs or tissues were examined microscopically varies and is not necessarily equal to the number of animals that were placed on study.

During necropsy, all organs and tissues were examined for grossly visible lesions. Tissues were preserved in 10% neutral buffered formalin, embedded in paraffin, sectioned, and stained with hematoxylin and eosin. Tissues examined microscopically are listed in Table 5.

When the pathology evaluation was completed, the slides, paraffin blocks, and residual wet tissues were sent to the NTP Archives for inventory, slide/block match, and wet tissue audit. The slides, individual animal data records, and pathology tables were sent to an independent quality assessment laboratory. The individual animal records and tables were compared for accuracy, slides and tissue counts were verified, and histotechnique was evaluated. All tumor diagnoses, all target tissues, and all tissues from a randomly selected 10% of the animals were evaluated by a quality assessment pathologist. The quality assessment report and slides were submitted to the Pathology Working Group (PWG) Chairperson, who reviewed all target tissues and those about which there was a disagreement between the laboratory and quality assessment pathologists.

Representative slides selected by the Chairperson were reviewed by the PWG, which includes the laboratory pathologist, without knowledge of previously rendered diagnoses. When the consensus diagnosis of the PWG differed from that of the laboratory pathologist, the laboratory pathologist was asked to reconsider the original diagnosis. This procedure has been described, in part, by Maronpot and Boorman (1982) and Boorman et al. (1985). The final diagnoses represent a consensus of contractor pathologists and the NTP Pathology Working Group. For subsequent analysis of pathology data, the diagnosed lesions for each tissue type are combined according to the guidelines of McConnell et al. (1986).

Slides/tissues are generally not evaluated in a blind fashion (i.e., without knowledge of dose group) unless the lesions in question are subtle or unless there is an inconsistent diagnosis of lesions by the laboratory pathologist. Nonneoplastic lesions are not examined routinely by the quality assessment pathologist or PWG unless they are considered part of the toxic effect of the chemical.

Statistical Methods

Data Recording: Data on this experiment were recorded in the Carcinogenesis Bioassay Data System (Linhart et al., 1974). The data elements include descriptive information on the chemicals, animals, experimental design, survival, body weight, and individual pathologic results, as recommended by the International Union Against Cancer (Berenblum, 1969).

Survival Analyses: The probability of survival was estimated by the product-limit procedure of Kaplan and Meier (1958) and is presented in the form of graphs. Animals were censored from the survival analyses at the time they were found dead of other than natural causes or were found to be missing; animals dying from natural causes were not censored. Statistical analyses for a possible dose-related effect on survival used the method of Cox (1972) for testing two groups for equality and Tarone's (1975) life table test for a dose-related trend. When significant survival differences were detected, additional analyses utilizing these procedures were carried out to determine the week at which significant differences in the survival curves were first observed. All reported P values for the survival analysis are two-sided.

Calculation of Incidence: The incidence of neoplastic or nonneoplastic lesions is given as the ratio of the number of animals bearing such lesions at a specific anatomic site to the number of animals in which that site was examined. In most instances, the denominators include only those animals for which the site was examined histologically. However, when macroscopic examination was required to detect lesions (e.g., skin or mammary tumors) prior to histologic sampling, or when lesions could have appeared at multiple sites (e.g., lymphomas), the denominators consist of the number of animals on which a necropsy was performed.

Analysis of Tumor Incidence: Three statistical methods were used to analyze tumor incidence data. The two that adjust for intercurrent mortality employ the classical method for combining contingency tables developed by Mantel and Haenszel (1959). Tests of significance included pairwise comparisons of high dose and low dose groups with vehicle controls and tests for overall dose-response trends.

For studies in which compound administration has little effect on survival, the results of the three alternative analyses will generally be similar. When differing results are obtained by the three methods, the final interpretation of the data will depend on the extent to which the tumor under consideration is regarded as being the cause of death. Continuity-corrected tests are used in the analysis of tumor incidence, and reported P values are one-sided. Twenty-one mice that died before the 3rd week of the studies (two vehicle control, three low dose, and six high dose males; three low dose and seven high dose females) have been excluded from the statistical analyses of tumor incidence.

Life Table Analyses -- The first method of analysis assumed that all tumors of a given type observed in animals dying before the end of the study were "fatal"; i.e., they either directly or indirectly caused the death of the animal. According to this approach, the proportions of tumorbearing animals in the dosed and vehicle control groups were compared at each point in time at which an animal died with a tumor of interest. The denominators of these proportions were the total number of animals at risk in each group. These results, including the data from animals killed at the end of the study, were then combined by the Mantel-Haenszel method to obtain an overall P value. This method of adjusting for intercurrent mortality is the life table method of Cox (1972) and of Tarone (1975). The underlying variable considered by this analysis is time to death due to tumor. If the tumor is rapidly lethal, then time to death due to tumor closely approximates time to tumor onset. In this case, the life table test also provides a comparison of the time-specific tumor incidences.

Incidental Tumor Analyses--The second method of analysis assumed that all tumors of a given type observed in animals that died before the end of the studies were "incidental"; i.e., they were merely observed at necropsy in animals dying of an unrelated cause. According to this approach, the proportions of tumor-bearing animals in dosed and vehicle control groups were compared in each of five time intervals: weeks 0-52, weeks 53-78, weeks 79-92, week 93 to the week before the terminal-kill period, and the terminal-kill period. The denominators of these proportions were the number of animals on which a necropsy was actually performed during the time interval. The individual time interval comparisons were then combined by the previously described method to obtain a single overall result. (See Haseman, 1984, for the computational details of both methods.)

Unadjusted Analyses--Primarily, survival-adjusted methods are used to evaluate tumor incidence. In addition, the results of the Fisher exact test for pairwise comparisons and the Cochran-Armitage linear trend test (Armitage, 1971; Gart et al., 1979) are given in the appendix containing the analyses of primary tumor incidence. These two tests are based on the overall proportion of tumor-bearing animals and do not adjust for survival differences.

Historical Control Data: Although the concurrent control group is always the first and most appropriate control group used for evaluation, there are certain instances in which historical control data can be helpful in the overall assessment of tumor incidence. Consequently, control tumor incidences from the NTP historical control data base (Haseman et al., 1984) are included for those tumors appearing to show compound-related effects.

SINGLE-ADMINISTRATION STUDIES

All rats that received 10,000 mg/kg dimethylvinyl chloride and 1/5 female rats that received 3,160 mg/kg died before the end of the studies (Table 6). Compound-related clinical signs included weakness, discharge from the eyes, disorientation, staggering gait, inactivity, emaciation, hunched back, urine stains, and difficulty in breathing.

FOURTEEN-DAY STUDIES

All rats that received 1,250, 1,750, or 2,500 mg/kg dimethylvinyl chloride died before the end of the studies (Table 7). Two of the five deaths in the group of males administered 1,750 mg/kg were not compound related. The final mean body weight of males that received 750 mg/kg was 79% that of the vehicle controls, and the final mean body weight of females that received 750 mg/kg was 70% that of the vehicle controls. Compound-related signs included emaciation, urine stains, weakness, inactivity, hunched back, rough fur coat, discharge from eyes and nose, and stains around the anus.

THIRTEEN-WEEK STUDIES

Two of 10 male rats that received 750 mg/kg dimethylvinyl chloride died before the end of the study (Table 8). The deaths of two female rats were not considered to be compound related. The final mean body weights were 25% and 37% lower than that of the vehicle controls for males and 9% and 23% lower for females that received 500 or 750 mg/kg.

Compound-related clinical signs in the 500 and 750 mg/kg groups included rough hair, inactivity, and perianal wetness. Compound-related histopathologic changes were observed in the liver, intestine, bone marrow, and testis (Table 9). The necrosis in the intestine involved

mainly the crypts of either the duodenum or jejunum; the observed incidence at each location depended on the portion of the upper small intestine present on the slide. The changes were distributed focally and included minimal to mild involvement of cells at the base of the crypts. The crypts showed varying stages of degeneration with pyknosis and karyorrhexis, and the surrounding crypt cells often appeared swollen. Similar changes occurred in the colonic mucosa but at a lower incidence. Bone marrow hypoplasia was characterized by a minimal to moderate decrease in marrow cellular elements, and the erythropoietic cells appeared to be most affected. The vacuolization of hepatocytes was generally mild and had a periportal distribution.

TABLE 9. INCIDENCES OF COMPOUND-RELATED LESIONS IN RATS IN THE THIRTEEN-WEEK GAVAGE STUDIES OF DIMETHYLVINYL CHLORIDE

(a) No data available

Dose Selection Rationale: Based on histopathologic changes at doses of 250 mg/kg or more and significant effects on body weight at 500 mg/kg or more, doses selected for rats for the 2-year studies were 100 and 200 mg/kg dimethylvinyl chloride administered in corn oil by gavage, 5 days per week.

TWO-YEAR STUDIES

Body Weights and Clinical Signs

Throughout most of the study, mean body weights of dosed male rats were notably lower

than those of the vehicle controls (Table 10 and Figure 1). After week 40, the mean body weights of the high dose male rats were over 10% lower than those of the vehicle controls. Mean body weights of high dose female rats were lower than those of the vehicle controls throughout most of the study. After week 56, mean body weights of low dose female rats were greater than those of the vehicle controls. During the second year of the studies, many dosed animals, particularly in the high dose group, had crusts around the nose and mouth. Some dosed animals had swelling of the nose and, occasionally, tilted heads.

TABLE 10. MEAN BODY WEIGHTS AND SURVIVAL OF RATS IN THE TWO-YEAR GAVAGE STUDIESOF DIMETHYLVINYL CHLORIDE

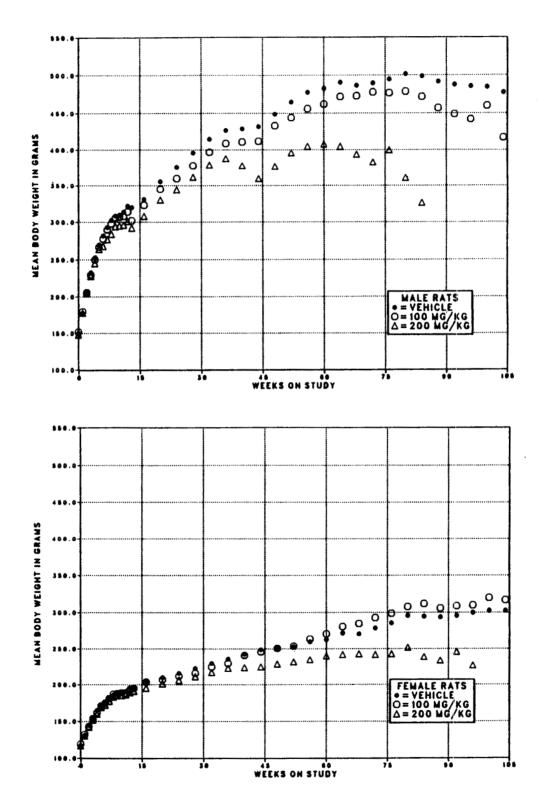

FIGURE 1. GROWTH CURVES FOR RATS ADMINISTERED DIMETHYLVINYL CHLORIDE IN CORN OIL BY GAVAGE FOR TWO YEARS

Survival

Estimates of the probabilities of survival for male and female rats administered dimethylvinyl chloride at the doses used in these studies and for vehicle controls are shown in the Kaplan and Meier curves in Figure 2. The survival of the dosed groups of males (low dose after week 88, high dose after week 55) and females (low dose after week 85, high dose after week 55) was significantly lower than that of the vehicle controls based on life table comparisons (Table 11). The survival of both the male and female high dose groups was significantly lower than that of the low dose groups (P < 0.001).

Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of rats with neoplastic or nonneoplastic lesions of the nasal cavity, brain, oral cavity, esophagus, forestomach, thyroid gland, duodenum, and mammary gland. Histopathologic findings on neoplasms in rats are summarized in Appendix A (Tables A1 and

A2); Appendix A (Tables A3 and A4) also gives the survival and tumor status for individual male and female rats. Findings on nonneoplastic lesions are summarized in Appendix C (Tables C1 and C2). Appendix E (Tables E1 and E2) contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix E (footnotes). The statistical analyses and interpretation of tumor incidence data for rats were complicated by the marked reduction in survival in dosed male and female rats when compared with that of the vehicle controls. No vehicle control animals were killed when dosed animals were dying. Consequently, the incidental tumor test has reduced sensitivity, since there is little overlapping of survival in the dosed and vehicle control groups. Hence, the incidental tumor test was not given primary emphasis, although for completeness the results of this test are given in Appendix E. Historical incidences of tumors in corn oil vehicle control animals are listed in Appendix F.

TABLE 11.	SURVIVAL	OF RATS	N THE	TWO-YEAR	GAVAGE	STUDIES OF	DIMETHYLVINYL
				CHLOR	RIDE		

	Vehicle Control	100 mg/kg	200 mg/kg
MALE (a)			
Animals initially in study	50	50	50
Nonaccidental deaths before termination (b)	12	41	48
Accidentally killed	0	0	2
Killed at termination	38	7	0
Died during termination period	0	2	0
Survival P values (c)	<0.001	<0.001	< 0.001
FEMALE (a)			
Animals initially in study	50	50	50
Nonaccidental deaths before termination (b)	6	39	50
Accidentally killed	1	0	0
Killed at termination	41	11	0
Died during termination period	2	0	0
Survival P values (c)	< 0.001	< 0.001	< 0.001

(a) Terminal-kill period: week 104

(b) Includes animals killed in a moribund condition

(c) The result of the life table trend test is in the vehicle control column, and the results of the life table pairwise comparisons with the vehicle controls are in the dosed columns.

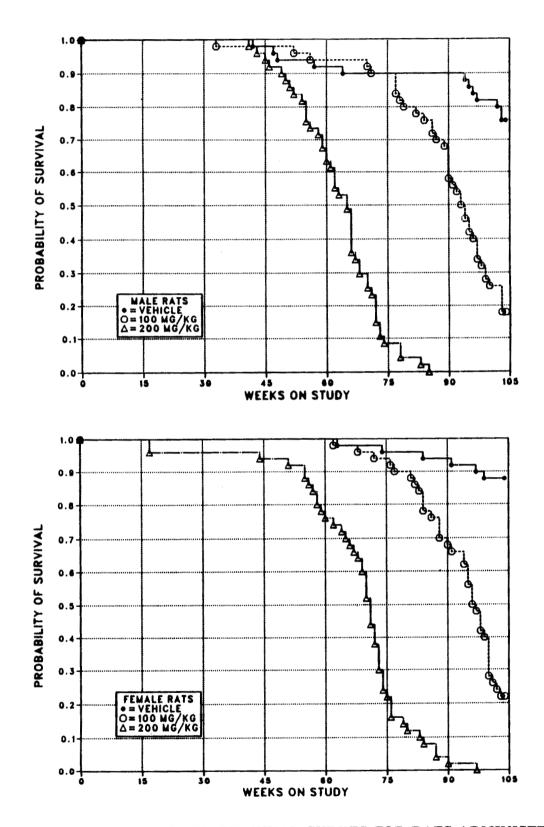

FIGURE 2. KAPLAN-MEIER SURVIVAL CURVES FOR RATS ADMINISTERED DIMETHYLVINYL CHLORIDE IN CORN OIL BY GAVAGE FOR TWO YEARS

Nasal Cavity: Epithelial hyperplasia and squamous metaplasia were seen at low incidences in dosed male and female rats, but the incidences were greater than those of the vehicle controls (Table 12).

Malignant epithelial neoplasms of the nasal cavity occurred with significantly increased incidences in dosed male and female rats; nasal cavity neoplasms were not observed in vehicle control rats (Table 13). Malignant epithelial neoplasms were combined on the premise that they all originated from the epithelial linings of the nasal cavity/adnexal structures and because of the difficulty in defining the exact epithelium of origin due to the expansile nature of the neoplasms. These tumors included carcinomas, not otherwise specified (NOS), squamous cell carcinomas, and adenocarcinomas, NOS. These neoplasms originated most often from the respiratory epithelium of the nasal septum and turbinates, epithelium of the submucosal glands, or the stratified squamous epithelium of the nasolacrimal duct. Most were poorly differentiated and contained morphologic components that included interconnecting cords of keratinized and nonkeratinized stratified squamous epithelium, cuboidal or columnar cells arranged in poorly defined tubulo-alveolar patterns, and solid clusters or sheets of pleomorphic cells. Other malignant tumors observed were two carcinosarcomas and

a rhabdomyosarcoma. The malignant neoplasms were highly aggressive and often invaded or metastasized to surrounding structures including the maxillary and cranial bones, brain, and regional lymph nodes.

Carcinomas invasive to the brain from the nasal cavity were observed in at least 52% of the high dose male rats and 50% of the high dose female rats (Table 14). According to the protocols of the studies, the nasal cavity was not one of the tissues requiring examination, and it was not saved for animals that died before week 80. The nasal cavity was recognized as an affected site after invasive carcinomas to the brain were found in some animals that died early in the studies. Several rats without diagnoses of primary carcinoma of the nasal cavity had invasive carcinomas to the brain. Of these, five male and three female rats did not have nasal sections taken. A carcinoma invasive to the brain was observed in one male and one female rat from the high dose groups, but nasal sections taken from these animals did not contain tumors. These invasive carcinomas, however, were histologically similar to those nasal carcinomas that invaded the brains of other rats in these studies and were considered to have originated in the nasal cavity. The only primary brain tumors in these studies were astrocytomas observed in 1/50 vehicle control male rat and 2/50 low dose female rats.

TABLE 13. ANALYSIS OF NASAL CAVITY TUMORS IN RATS IN THE TWO-YEAR GAVAGE STUDIES OF DIMETHYLVINYL CHLORIDE (Continued)

(a) The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix E (footnotes).

(b) The animal with the adenoma also had an adenocarcinoma.

(c) The animal with the squamous cell papilloma also had a carcinoma.

(d) No nasal cavity tumors have been observed in 350 corn oil vehicle control male rats at the study laboratory; historical incidence in NTP studies (mean): 1/1,100 (0.1%).

(e) No nasal cavity tumors have been observed in 350 corn oil vehicle control female rats at the study laboratory; historical incidence in NTP studies: 0/1,100.

TABLE 14. INCIDENCE OF RATS WITH TUMOR INVASION TO THE BRAIN FROM THE NASAL CAVITY IN THE TWO-YEAR GAVAGE STUDIES OF DIMETHYLVINYL CHLORIDE

(a) One squamous cell carcinoma has been observed in 1,037 (0.1%) male corn oil vehicle control rats in NTP studies.
 (b) No esophageal tumors have been observed in 1,036 female corn oil vehicle controls in NTP studies.

Forestomach: Epithelial hyperplasia was observed at increased incidences in dosed rats (Table 17). This lesion was considered to be preneoplastic and was characterized by a thickening of the epithelium, down-growth of basal cells, and cellular atypia consisting of a loss of cell polarity, increased basophilic staining of the cytoplasm, and pleomorphism.

The incidences of squamous cell papillomas and squamous cell carcinomas in low dose male rats,

squamous cell carcinomas in low dose female rats, and squamous cell papillomas or carcinomas (combined) in low dose male and low dose female rats were significantly greater than those in the vehicle controls (Table 17). The squamous cell papillomas were exophytic papilliferous growths consisting of keratinized, stratified squamous epithelium overlaying thin connective tissue cords. The carcinomas consisted of cords and nests of stratified squamous epithelium which invaded adjacent tissues.

TABLE 17. ANALYSIS OF FORESTOMACH LESIONS IN RATS IN THE TWO-YEAR GAVAGE STUDIES OF DIMETHYLVINYL CHLORIDE (Continued)

(a) Historical incidence at study laboratory (mean): 0/350; historical incidence of squamous cell papillomas of the stomach in NTP studies: 4/1,091 (0.4%)

(b) No P values are reported because no tumors were observed in the 200 mg/kg and vehicle control groups.

(c) Historical incidence at study laboratory: 0/350; historical incidence of squamous cell carcinomas of the stomach in NTP studies: 0/1,091

(d) Historical incidence at study laboratory (mean): 1/349 (0.3%); historical incidence of squamous cell papillomas of the stomach in NTP studies: 4/1,096 (0.4%)

(e) Historical incidence at study laboratory: 0/349; historical incidence in NTP studies: 0/1,096

Thyroid Gland: The incidences of follicular cell hyperplasia in dosed and vehicle control rats of each sex were similar (male: vehicle control, 1/50, 2%; low dose, 1/48, 2%; high dose, 0/47; female: vehicle control, 0/49; low dose, 1/49, 2%; high dose, 1/47, 2%). The incidences of follicular cell carcinomas and follicular cell adenomas or carcinomas (combined) in low dose female rats were significantly greater than those in the vehicle controls by life table analysis but not by the Fisher exact test (Table 18). In male rats, the incidences of follicular cell adenomas were as follows: vehicle control, 1/50 (2%); low dose, 2/48 (4%); high dose, 0/47. Duodenal Mucosa: Necrosis was observed at increased incidences in dosed male and female rats (male: vehicle control, 0/45; low dose, 2/49, 4%; high dose, 6/48, 13%; female: vehicle control, 0/47; low dose, 1/50, 2%; high dose, 8/47, 17%).

Mammary Gland: The incidence of fibroadenomas in low dose female rats was significantly greater than that in the vehicle controls by the life table test but not by the Fisher exact test (Table 19). Early deaths among female rats in the high dose group may account for the lower incidence of these tumors for this group when compared with the low dose and vehicle control groups.

(a) Historical incidence of all benign mammary gland tumors at study laboratory (mean \pm SD): 86/350 (25% \pm 9%); historical incidence in NTP studies: 280/1,100 (26% \pm 8%)

(b) Historical incidence of all malignant mammary gland tumors at study laboratory (mean \pm SD): 4/350 (1% \pm 2%); historical incidence in NTP studies: 17/1,100 (2% \pm 2%)

SINGLE-ADMINISTRATION STUDIES

Unfasted: All mice that received 3,160 or 10,000 mg/kg dimethylvinyl chloride died by day 5 (Table 20). Compound-related clinical signs included weakness, staggering gait, prostration, shallow breathing, diarrhea, and distended stomach.

Fasted: All mice that received 3,160 mg/kg dimethylvinyl chloride died by day 2 (Table 20). Compound-related clinical signs included distended stomach, inactivity, prostration, and incoordination.

FOURTEEN-DAY STUDIES

All mice that received 1,500 or 2,000 mg/kg dimethylvinyl chloride and 4/5 males and 5/5 females that received 1,000 mg/kg died before the end of the studies (Table 21). Compoundrelated signs included inactivity, staggering gait, rough fur coat, labored/shallow breathing, weakness, hunched back, prostration, and opaque eyes.

THIRTEEN-WEEK STUDIES

The vehicle control male mice received 750 mg/kg dimethylvinyl chloride once during week 10; as a result, four died (Table 22). All male and 9/10 female mice that received 750 mg/kg also died before the end of the studies. Clinical signs observed in the 750 mg/kg groups included decreased activity and prostration. At week 12, mean body weights relative to those of the vehicle controls were 7% lower for male mice that received 500 mg/kg dimethylvinyl chloride and 4.5% lower for female mice that received 750 mg/kg.

Necrosis of lymphopoietic cells (leading to atrophy of lymphoid tissue) was observed in the

thymus, lymph nodes, and spleen (Table 23). Compound-related necrotic and/or degenerative changes also occurred in the pancreatic islets, liver, ovary, and testis. The severity of the lesions was greater in males than in females.

Dose Selection Rationale: Based on the pattern of histopathologic, necrotic, and degenerative changes at all doses (but most prominent at doses of 500 mg/kg and above), the doses originally selected for mice for the 2-year studies were 200 and 400 mg/kg dimethylvinyl chloride, administered in corn oil by gavage, 5 days per week. Because of the large number of deaths in the 400 mg/kg groups, the studies were restarted at doses of 100 and 200 mg/kg dimethylvinyl chloride.

TABLE 23. INCIDENCES OF LESIONS IN MICE IN THE THIRTEEN-WEEK GAVAGE STUDIES OF DIMETHYLVINYL CHLORIDE

(a) Controls from another study at the same laboratory (for comparison only)

(b) Male controls from present study (received dimethylvinyl chloride, 750 mg/kg, once during week 10)

TWO-YEAR STUDIES

Body Weights and Clinical Signs

Mean body weights of high dose male mice were 6%-24% lower than those of the vehicle controls after week 4 (Table 24 and Figure 3). The mean body weights of the low dose male mice were 2%- 8% lower than those of the vehicle controls between weeks 2 and 76 and 9%-16% lower thereafter. Mean body weights of high dose female mice were at least 5% lower than those of the vehicle controls after week 44. Mean body weights of low dose female mice were 4%-11% lower than those of the vehicle controls after week 88.

TABLE 24. MEAN BODY WEIGHTS AND SURVIVAL OF MICE IN THE TWO-YEAR GAVAGE STUDIESOF DIMETHYLVINYL CHLORIDE

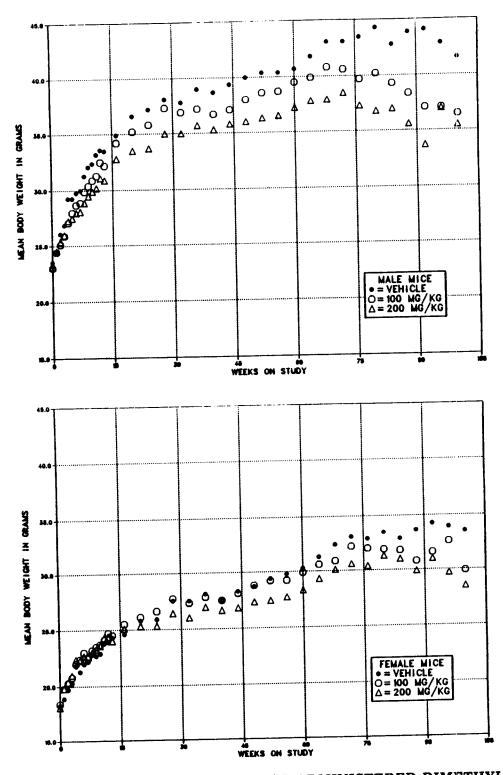

FIGURE 3. GROWTH CURVES FOR MICE ADMINISTERED DIMETHYLVINYL CHLORIDE IN CORN OIL BY GAVAGE FOR TWO YEARS

Survival

Estimates of the probabilities of survival for male and female mice administered dimethylvinyl chloride at the doses used in these studies and for vehicle controls are shown in the Kaplan and Meier curves in Figure 4. The survival of the dosed groups of both males (low dose after week 83, high dose after week 67) and females (low dose after week 58, high dose after week 54) was significantly lower than that of the vehicle control groups (Table 25).

Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of mice with neoplastic or nonneoplastic lesions of the forestomach, preputial gland, harderian gland, liver, bone marrow, spleen, thyroid gland, testis, nasal cavity, and lung. Histopathologic findings on neoplasms in mice are summarized in Appendix B (Tables B1 and B2); Appendix B (Tables B3

and B4) also gives the survival and tumor status for individual male and female mice. Findings on nonneoplastic lesions are summarized in Appendix D (Tables D1 and D2). Appendix E (Tables E3 and E4) contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix E (footnotes). The statistical analyses and interpretation of tumor incidence data for mice were complicated by the marked reduction in survival in dosed male and female mice when compared with that of the vehicle controls. No vehicle control animals were killed when dosed animals were dying. Consequently, the incidental tumor test has reduced sensitivity, since there is little overlapping of survival in dosed and vehicle control groups. Hence, the incidental tumor test was not given primary emphasis, although for completeness the results of this test are presented in Appendix E. Historical incidences of tumors in corn oil vehicle control animals are listed in Appendix F.

TABLE 25. SURVIVAL OF MICE IN THE TWO-YEAR GAVAGE STUDIES OF DIMETHYLVINYL CHLORIDE

	Vehicle Control	100 mg/kg	200 mg/kg

IV. DISCUSSION AND CONCLUSIONS

Dimethylvinyl chloride was studied for toxicity, including carcinogenicity, in male and female F344/N rats and B6C3F₁ mice by administering the chemical in corn oil by gavage at doses of 0, 63, 125, 250, 500, or 750 mg/kg body weight, 5 days per week, for 13 weeks and at doses of 0, 100, or 200 mg/kg per day, 5 days per week, for 102 or 103 weeks.

The 13-week studies accurately identified the sites that were affected in the 2-year studies, except for the nasal cavity of rats. The histopathologic examination revealed noteworthy pathologic alterations in the intestinal epithelium, hepatocytes, and bone marrow. Changes observed in the testis were probably secondary effects of toxicity. Mortality at 750 mg/kg per day was substantially greater in mice than in rats, but the effect on body weight was less in mice than in rats.

Compared with the histopathologic alterations in rats, those in mice in the 13-week studies presented a more diffuse pattern of toxicity; these alterations included necrosis of the lymphopoietic cells, liver, pancreatic islets, ovary, and spleen. The effects on the ovary in female mice were observed at all doses in the 13-week study, and the effect on the spleen was seen in female mice at doses of 125 mg/kg and above. The testis of mice, like that of rats, may have been a secondary site of toxicity.

Because most of the adverse effects in mice occurred at 500 mg/kg and above in the 13-week studies, doses for the 2-year studies in mice were initially set at 200 and 400 mg/kg per day. After 5 months, however, the studies in mice were terminated because of the large number of deaths in the 400 mg/kg group; the studies were restarted with doses of 100 and 200 mg/kg per day. Thus, the 13-week studies identified the sites that would be affected in the 2-year studies, but the high dose initially set for the 2-year studies in mice exceeded the maximum tolerated dose. In fact, dose levels of 100 and 200 mg/kg per day caused significant decreases in body weight gain and survival in rats and mice of each sex. However, clinical observations as well as the gross and microscopic pathologic examination did not clearly identify causes of early mortality. In the absence of toxicologic findings that would

explain the early mortality, it is assumed that the high incidence of tumors and other chemicalrelated toxicity contributed to the decreased survival of dosed rats and mice.

In the 2-year studies, malignant epithelial tumors of the nasal cavity and squamous cell carcinomas of the oral cavity, esophagus, and forestomach occurred at significantly dose-related increased incidences in male and female rats, and the incidence of fibroadenomas of the mammary gland was significantly increased in low dose female rats. The marginal increase in the incidence of mammary gland lesions and the lack of a high-dose effect make their relationship to dimethylvinyl chloride administration uncertain. Squamous cell carcinomas of the forestomach were observed at significantly increased incidences in dosed male and female mice, and the incidence of squamous cell carcinomas of the preputial gland was significantly increased in high dose males. Because of the nature and incidence of the tumors of the harderian gland and lung in female mice, their relationship to administration of dimethylvinyl chloride was considered uncertain.

Invasion and metastasis from primary tumor sites were observed in both rats and mice. For example, the malignant neoplasms of the nasal cavity of rats spread to surrounding structures including the maxillary and cranial bones, brain, and regional lymph nodes. In mice, tumors of the lymph nodes were found secondary to the high incidence of forestomach tumors.

Although both dimethylvinyl chloride and vinyl chloride are carcinogenic in laboratory animals, the types of tumors produced by vinyl chloride administration, particularly in rats, are more varied than those observed in the current studies of dimethylvinyl chloride. The following tumors have been related to exposure of rats to vinyl chloride at various concentrations: angiosarcomas of the liver, carcinomas of the Zymbal gland, nephroblastomas, adenocarcinomas of the mammary gland, papillomas and acanthomas of the forestomach, extrahepatic angiosarcomas, and hepatomas. These lesions have been generally found in rodents exposed by inhalation at concentrations greater than 10 ppm and by ingestion at 0.3 mg/kg for 2 years or more (Maltoni

et al., 1984). Although the spectrum of tumors observed has been broad even at low concentrations of vinyl chloride, the lesions observed in the present dimethylvinyl chloride studies are confined more to the squamous cells of tissues directly exposed. Although dimethylvinyl chloride was carcinogenic at both doses, the doses of vinyl chloride reported to be carcinogenic are considerably lower than those in the current studies. However, the available data are insufficient for comparison of relative carcinogenicity at lower dose levels.

Vinyl chloride is metabolized primarily in the liver by microsomal enzymes. Evidence suggests that the toxicity of vinyl chloride is due to its enzymatic oxidation to reactive polar metabolites. Bartsch and Montesano (1975) report two possible schemes, one involving alcohol dehydrogenase and the other mixed function oxidase. Chloroethylene oxide, which is thought to be formed by the mixed function oxidase system, may be the primary microsomal metabolite capable of alkylating cellular macromolecules (Laib and Bolt, 1977). The data of Hathaway (1977) suggest that vinyl chloride metabolites (chloroacetaldehyde, formed in either metabolic system) may interact with some purine and pyrimidine residues of DNA; this may explain the carcinogenicity of vinyl chloride. The predominant pathway for vinyl chloride metabolism probably depends on dose level (Hefner et al., 1975).

Knowledge of the metabolism of dimethylvinyl chloride is sparse compared with the considerable amount of data on the metabolism of vinyl chloride. However, some information on distribution, elimination, and metabolism has been provided by limited NTP studies in male F344/N rats and B6C3F₁ mice (Appendix N). Single doses of 150 mg/kg ¹⁴C-labeled dimethylvinyl chloride in corn oil were administered by gavage to rats for 1, 2, or 4 consecutive days. The exhalation of labeled carbon dioxide and volatiles and the distribution of radioactivity in tissues were measured at various intervals after the last dose. Animals were killed 24 hours after the last dose was administered to that group. Twenty-six percent of the total dose to rats was exhaled as carbon dioxide and 35% as volatile material (96% of which was the parent material)

(Table N1). Although mice eliminated 26% of the dose as expired carbon dioxide, only 5% was exhaled as dimethylvinyl chloride. Most of the retained radioactivity from dimethylvinyl chloride, like that from vinyl chloride (Watanabe et al., 1976a,b; Bolt et al., 1976), was found in the liver and kidney (Table N2). The profile of metabolites of dimethylvinyl chloride was independent of the number of days the chemical was administered. It is not possible with the available data to determine if vinyl chloride and dimethylvinyl chloride share common metabolic pathways; however, the data available from NTP indicate that metabolism occurs in large part at the methyl groups. It was determined from nuclear magnetic resonance and mass spectral data (Table N3) that the major urinary metabolite in both rats and mice was 2-amino-6-methyl-4-thia-5-heptene-1,7-dioic acid. This metabolite probably arises by oxidation of one of the methyl groups of dimethylvinyl chloride to a carboxylic acid followed by formal displacement of the chloride by glutathione and subsequent degradation of the glutathione moiety. Thus, the metabolism of dimethylvinyl chloride involves the formation of metabolites not available from vinyl chloride.

The apparent correspondence between tumor type and the route of elimination of dimethylvinyl chloride is noteworthy. The very high incidence of nasal cavity tumors in these gavage studies suggests that some "active" agent is exhaled. According to the metabolism data, dimethylvinyl chloride accounted for nearly all of the exhaled radioactivity; thus, dimethylvinyl chloride may be metabolized to an active toxin and remain localized in the nasal cavity. Studies in mice indicate considerably less exhalation of non-carbon-dioxide radioactivity than was observed in the rat and a corresponding increase in the amount of radioactivity excreted in the urine. This finding was consistent with the lack of nasal cavity tumors in mice versus the significantly increased incidence in rats.

The role of dimethylvinyl chloride (as a 5% contaminant) in the carcinogenicity of 3-chloro-2methylpropene (NTP, 1986) cannot be established from the present studies of dimethylvinyl chloride. As a 5% contaminant, the oral dose of dimethylvinyl chloride received by rats and mice in the studies of 3-chloro-2-methylpropene was 3-10 mg/kg per day. These doses are considerably lower than the doses used in the present studies of dimethylvinyl chloride. However, no apparent no-observed-effect level was found in the current 2-year studies of dimethylvinyl chloride, so this chemical might be carcinogenic at doses lower than those administered.

The profile of toxicity and carcinogenicity in the 3-chloro-2-methylpropene studies (NTP, 1986) is somewhat different from that in the current studies of dimethylvinyl chloride. Although stomach tumors were observed in both studies. rats and mice in the 3-chloro-2-methylpropene studies had a very high incidence of basal cell hyperplasia, a high incidence of squamous cell papillomas, and a relatively low incidence of squamous cell carcinomas. In the dimethylvinyl chloride studies, the incidences of hyperplasia or squamous cell papillomas were considerably lower compared with the greatly increased incidence of carcinomas; in rats, there were slightly more carcinomas than papillomas in the oral cavity, esophagus, and stomach. Carcinomas of the nasal cavity were not reported in the studies of 3-chloro-2-methylpropene, but there was a high incidence of these tumors in rats administered dimethylvinyl chloride. Although the kidney may have been an affected organ in the studies of 3-chloro-2-methylpropene, it was not affected in the study of dimethylvinyl chloride. Thus, the toxic effects of these two chemicals do not overlap sufficiently to allow the toxicity of 3-chloro-2-methylpropene to be attributed solely to the presence of dimethylvinyl chloride as a 5% contaminant. Any contribution of the dimethylvinyl chloride contaminant to the toxicity of 3-chloro-2-methylpropene is uncertain.

A contaminant in one of the lots of dimethylvinyl chloride used in the 2-year studies, acrylonitrile, is also a potent animal carcinogen (IARC, 1979). However, the dose of acrylonitrile given unintentionally in these studies was very low, and the profile of tumors seen in the present studies is not consistent with that for acrylonitrile. Thus, it is unlikely that acrylonitrile played a significant role in the carcinogenicity of dimethylvinyl chloride observed in these studies. The effects of dimethylvinyl chloride on the immune system have been studied (Appendix O). In a preliminary study, B6C3F1 mice demonstrated altered immune competence without evidence of gross toxicity (Litton, 1981). The altered immunologic parameters consisted of thymic atrophy, leukopenia, diminished responsiveness of splenic T-cells to mitogens, and decreased resistance to challenge with syngeneic PYB6 tumor cells. A more comprehensive study of immune function and host resistance was thus conducted with the NTP Comprehensive Screening Panel (Luster et al., 1982; Luster et al., in preparation). Female B6C3F₁ mice received daily doses of 0, 50, 100, 200, or 400 mg/kg of dimethylvinyl chloride for 14 days. The specific cell-mediated immune function and the resistance to viral and bacterial challenge were significantly reduced at the highest dose; this dose did not alter body weight but did produce hepatomegaly, splenic and thymic atrophy, and leukopenia. The immune functions suppressed by 400 mg/kg per day consisted of lymphocyte responsiveness to T-cell mitogens, lymphocyte responsiveness to allogeneic lymphocytes (mixed lymphocyte culture), and delayed hypersensitivity response. There was also a slight suppression of natural killer cell activity. Antibody responses were not consistently altered. Host resistance to A2/Taiwan influenza virus challenge, Listeria monocytogenes, and both type 1 and type 2 herpes was decreased. Resistance to B16 tumor cell challenge and Streptococcus was not affected.

The responses of mice to dimethylvinyl chloride were biphasic in that many of the parameters suppressed at the high dose were slightly enhanced at one or more of the three lower dose levels. These parameters included lymphocyte response to mitogens, delayed hypersensitivity response, several measures of macrophage activity, thymic weight, and peripheral leukocyte counts. Biphasic patterns of immunologic responses are not uncommon and probably reflect secondary effects or additional toxicologic mechanisms coming into play as the dose level of an immunotoxin is increased. In the present immunotoxicity study, for example, some effects at the high dose might be attributed to hepatotoxicity, since hepatomegaly was seen only at the higher doses. In the NTP 13-week studies in mice, liver necrosis was observed at 750 mg/kg but not at doses of 500 mg/kg or below.

Thus, dimethylvinyl chloride affected the immune system of mice administered doses that bracketed those used in the 2-year studies, including increased susceptibility to bacterial infection. At the highest dose, 400 mg/kg per day, decreased resistance to bacterial and viral challenge could be related to alterations in specific immune functions. However, early deaths in the 2-year studies were not relatable to infectious processes.

The relationship between the genetic toxicity of dimethylvinyl chloride and its carcinogenicity is unclear. Studies regarding genetic toxicity have been performed (Appendix G). In tests with four strains of Salmonella typhimurium, there was no evidence of a mutagenic effect in the presence or absence of metabolic activation. Similarly, no chromosomal aberrations were found in Chinese hamster ovary (CHO) cells in the presence or absence or metabolic activation. However, the volatility of the compound may be responsible for the negative results. Positive effects were observed in other systems: Dimethylvinyl chloride was mutagenic in the mouse lymphoma assay in the absence of S9, induced sister-chromatid exchanges in CHO cells in both the presence and absence of metabolic activation, and exhibited highly significant effects in the tests for reciprocal translocations as well as sex-linked recessive lethal mutations in Drosophila. In the tests with Drosophila, dimethylvinyl chloride was found to be toxic even when physical contact was prevented. This suggests that the vapors per se may have been responsible for some of the exposure that produced the positive responses. Bartsch and Montesano (1975) reported induction of mutations in Salmonella after gaseous exposure to vinyl chloride both in the presence and absence of metabolic activation. Gaseous

exposure to dimethylvinyl chloride might prove mutagenic to Salmonella and perhaps to CHO cells as well.

Induction of tumors in directly exposed tissues and the chemical structure of dimethylvinyl chloride are features consistent with direct mutagenic and carcinogenic activity. However, studies by Eder et al. (1980), using S9 supernatants from livers of animals induced with a variety of different agents, demonstrated that the mutagenic activity of allyl chloride in Salmonella is reduced, rather than enhanced, by metabolic activation; Neudecker et al. (1980) found that mono-methylation of an allyl chloride enhanced mutagenic activity in Salmonella in the absence of S9. These results suggest that direct mutagenic activity by these compounds is accomplished through reactions other than an enzymatic epoxidation mechanism, as has been proposed for the structural analog and potent carcinogen vinyl chloride monomer.

The experimental and tabulated data in the NTP Technical Report on dimethylvinyl chloride were examined to determine the study laboratory's compliance with Good Laboratory Practice requirements. As summarized in Appendix P, the audit revealed no major problems with the conduct of the studies or with collection and documentation of the experimental data. No discrepancies were found that influenced the final interpretation of the results of these studies.

Conclusions: Under the conditions of these 2year gavage studies, there was clear evidence of carcinogenicity* of dimethylvinyl chloride for both sexes of F344/N rats and B6C3F₁ mice. This was based on increased incidences of neoplasms of the nasal cavity, oral cavity, esophagus, and forestomach of male and female F344/N rats. B6C3F₁ mice showed increased incidences of squamous cell neoplasms of the forestomach in males and females and squamous cell carcinomas of the preputial gland in males.

^{*}Categories of evidence of carcinogenicity are defined in the Note to the Reader on page 2. The public discussion regarding the interpretative conclusions is summarized on page 16.

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

(d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

(e) No P value could be determined because all animals in the 200 mg/kg group died before the first tumor was observed in the vehicle control group.

147

(f) A squamous cell papilloma was also observed in one of these animals.

(g) An adenoma was also observed in one of these animals.

(h) No P value is reported because no tumors were observed in the 200 mg/kg and vehicle control groups.

	Vehicle Control	100 mg/kg	200 mg/kg

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

(d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

(e) No P value is reported because no tumors were observed in the 200 mg/kg and vehicle control groups.

(f) No P value could be determined because all 200 mg/kg animals died before the first tumor was observed in the vehicle control group.

(a) Number of tumor-bearing animals/number of animals examined at the site
(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality
(c) Observed tumor incidence at terminal kill

(d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

TABLE G1. MUTAGENICITY OF DIMETHYLVINYL CHLORIDE IN SALMONELLA TYPHIMURIUM

(a) The S9 fractions were prepared from the livers of Aroclor 1254-induced male Sprague-Dawley rats and male Syrian hamsters. Cells and study compound or solvent (water) were incubated for 20 minutes at 37° C in the presence of either S9 or buffer. After the addition of soft agar, the contents of each tube were poured onto minimal medium, and the plates were incubated at 37° C for 48 hours (Haworth et al., 1983). The experiment was performed twice, each in triplicate; because the results were similar, data from only one experiment are shown. (b) Revertants are presented as mean \pm standard error.

TABLE G2. MUTAGENICITY OF DIMETHYLVINYL CHLORIDE IN L5178Y/TK^{+/-} MOUSE LYMPHOMACELLS IN THE ABSENCE OF S9 (a)

(a) Experiments were performed twice, and all doses were tested in triplicate, except the solvent control (100% ethanol) which was tested in quadruplicate. Because the results were similar, data from only one experiment are shown. The protocol was basically that of Clive et al. (1979). Cells (6×10^{5} /ml) were treated for 4 hours at 37° C in medium, washed, resuspended in medium, and incubated for 48 hours at 37° C. After expression, 3×10^{6} cells were plated in medium supplemented with trifluorothymidine for selection of cells that were mutant at the thymidine kinase (TK) locus, and 600 cells were plated in nonselective medium to determine the percentage of viable cells.

		2.0	37.36	

(a) SCE = sister chromatid exchange

(b) In the absence of S9, Chinese hamster ovary cells were incubated with study compound or solvent at 37° C; 2 hours after initiation of treatment, 10 μ M BrdU was added, and incubation was continued for an additional 22-24 hours. Cells were washed, fresh medium containing BrdU (10 μ M) and colcemid (0.1 μ g/ml) was added, and incubation was continued for 2-3 hours (Galloway et al., 1985).

(c) In the presence of S9, Chinese hamster ovary cells were incubated with study compound or solvent for 2 hours at 37° C. Then cells were washed, and medium containing 10 µM BrdU was added. Cells were incubated for a further 26 hours, with colcemid (0.1 µg/ml) present for the final 2-3 hours. S9 was from the livers of Aroclor 1254-induced male Sprague Dawley rats (Galloway et al., 1985).

(d) Cells were collected by mitotic shake-off, treated for 3 minutes with potassium chloride (75 mM), washed twice with fixative, and dropped onto slides and air-dried (Galloway et al., 1985).

0.25	21 (20)	50	34 (25)		

(a) Abs = aberrations

(b) In the absence of S9, Chinese hamster ovary cells were incubated with study compound or solvent for 8-10 hours at 37° C. Cells were then washed, and fresh medium containing colcemid (0.1 µg/ml) was added. After a further 2-3 hours of incubation, cells were harvested by mitotic shake-off, fixed, and stained in 6% Giemsa (Galloway et al., 1985).

(c) In the presence of Š9, cells were incubated with study compound or solvent for 2 hours at 37° C. Cells were then washed, fresh medium was added, and incubation was continued for 8-10 hours. Colcemid (0.1 µg/ml) was added for the last 2-3 hours of incubation; then cells were harvested by mitotic shake-off, fixed, and stained in 6% Giemsa. S9 was from the livers of Aroclor 1254-induced male Sprague-Dawley rats (Galloway et al., 1985).

TABLE G5. INDUCTION OF SEX-LINKED RECESSIVE LETHAL MUTATIONS IN DROSOPHILA BY DIMETHYLVINYL CHLORIDE

Route of	Dose		No. of Lethals/No. of X Chromosomes Tested (a)				
Exposure	(ppm)	Mating 1	Mating 2	Mating 3	Total (percent)		
Feeding	0	3/2,922	6/2,916	5/2,570	14/8,408 (0.17)		
0	12.750	7/3.128	16/2.927	10/2.249	33/8,304 (0.40)		

(a) The sex-linked recessive lethal assay was performed essentially as described by Abrahamson and Lewis (1971). Exposure by feeding was done by allowing 24-hour-old Canton-S males to feed for 3 days on a solution of the study chemical dissolved in 5% sucrose. Exposed males were mated to three *Basc* females for 3 days and given fresh females at 2-day intervals to produce three broods of 3, 2, and 2 days, after which the parents were discarded. F₁ heterozygous females were crossed to their siblings and placed in individual vials. F₁ daughters from the same parental males were kept together to identify clusters. After 17 days, presumptive lethal mutations were identified as vials containing no wild-type males; these were retested. The treated group was found to be significantly different from the controls at the 1% level (Margolin et al., 1983).

TABLE G6. INDUCTION OF RECIPROCAL TRANSLOCATIONS IN DROSOPHILA BY DIMETHYLVINYL CHLORIDE (a)

Route of	Dose			S (Transloc	torages ations/T	ests)		Total No. of	Total No. of Trans-	Percent Trans-
Exposure	(ppm)	1	2	3	4	5	6	Tests	locations	locations
Feeding Historical	12,750	8/873	6/821	8/698	3/253	1/30	0/0	2,675	26	0.9720
control	0	0/6,187	0/6,085	0/6,635	1/6,381	0/4,738	0/250	30,276	1	0.0033

(a) The reciprocal translocation assay was performed essentially as described by Abrahamson and Lewis (1971). Males were fed for 3 days; then each male was mated to a harem of bw;st;p^p females for 3 days. Females were subsequently discarded, and each male was transferred to a fresh harem for 4 days. This mating regimen allowed sampling of the spermatid population, the most sensitive stage of germ cell maturation, as indicated by the sex-linked recessive lethal mutation data (Table G5). Males were then discarded. The females were transferred to fresh medium every 3-4 days to produce a total of five cultures, and then they were discarded. In this manner, successive cultures sample sperm were stored for increasing lengths of time. Individual F_1 males were backcrossed to bw;st;p^p females, and the F_2 were screened for pseudolinkage. This procedure allows the recevery of translocations involving the Y, second, or third chromosomes in any combination. Presumptive translocations were retested. The treated group was found to be significantly different from the controls at the 1% level (Kastenbaum and Bowman, 1970).

34	15.7	6.5	< 0.01
35	16.2	6.7	< 0.01
36	16.3	6.8	0.05
37	16.8	7.0	< 0.01

System 2

Column: 10% Carbowax 20M-TPA on 80/100 Chromosorb W(AW), 1.8 m \times 4 mm, ID

Oven temperature program: 50° C for 5 min, then 50° to 200° C at 10° C/min

Results: A major peak and 34 impurities were observed. The areas of six of these impurities are 0.8%, 0.6%, 0.5%, 0.2%, 0.1%, and 0.1% that of the major peak. The areas of the other 28 impurities total less than 0.3% of the major peak area.

Under these conditions 3-chloro-2-methylpropene had a retention time of 1.6 minutes. It is possible that peak no. 4 is 3-chloro-2-methylpropene, but this was not confirmed.

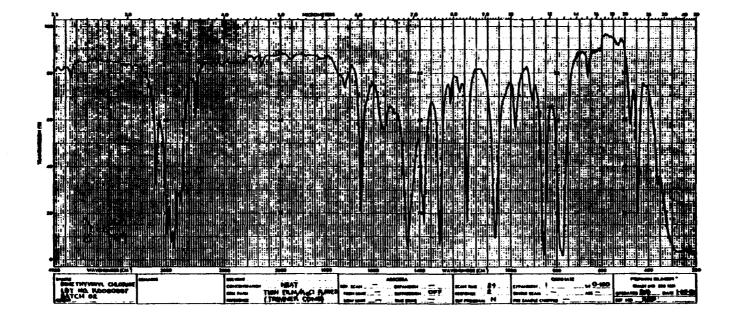

<u>Peak No.</u>	Retention <u>Time (min)</u>	Retention Time Relative to <u>Major Peak</u>	Area (percent of <u>major peak)</u>

34	15.7	14.1	< 0.01
35	16.1	14.5	< 0.01

7. Conclusions: The results of the elemental analysis agreed with the theoretical values. Gas chromatography with one system indicated 36 impurities. The six largest impurities had areas 1%, 0.9%, 0.9%, 0.3%, 0.1%, and 0.1% of the area of the major peak. The areas of the other 30 impurities totaled less than 0.5% of the major peak. A second system indicated 34 impurities. The six largest impurities had areas 0.8%, 0.6%, 0.5%, 0.2%, 0.1%, and 0.1% of the area of the major peak. The areas of the other 28 impurities totaled less than 0.3% of the major peak. The areas of the other 28 impurities totaled less than 0.3% of the major peak. Titration for acidic components indicated 210 \pm 10 ppm acidity (assumed to be hydrochloric acid). The infrared and nuclear magnetic resonance spectra were consistent with the structure, but six impurity peaks were observed in the nuclear magnetic resonance spectrum.

System 3

Column: 80/100 Carbopack C/0.1% SP1000, 1.8 m × 4 mm ID, glass Inlet temperature: 180° C

Detector temperature: 250° C

Oven temperature program: 50° C for 5 min, then 50° C to 250° C at 10° C/min **Sample injected:** Neat liquid (3 µl) and 1% and 0.5% solutions in methylene chloride to quantitate impurities and check detector linearity

Results: A major peak and 11 impurities, 5 eluting before and 6 eluting after the major peak were observed. The largest impurity (identified as 3-chloro-2methylpropene) was 2.3% of the major peak area. The cumulative area of the remaining nine impurities was 0.60% of the major peak area. Three additional impurities were observed, one before and two after the major peak, with individual areas less than 0.01% of the major peak area.

Analysis of lot no. 062537 by the system described above indicated a markedly different chromatographic profile than that reported for lot no. KD090967. A major peak and 14 impurities were observed, 7 eluting before and 7 eluting after the major peak. Three of the largest impurities had areas 0.87%, 0.78%, and 0.89% of the major peak area. The peak with a retention time corresponding to 3-chloro-2-methylpropene, observed in lot no. KD090967, had an area 0.50% relative to the major peak area in lot no. 062537. The cumulative area of the impurities in lot no. 062537 was 4.13% as compared with 2.9% observed for lot no. KD090967.

c. Quantitation by gas chromatography: 3-chloro-2-methylpropene in lot no. KD090967 was quantitated against standards of dimethylvinyl chloride

Instrument: Varian 3700 Detector: Flame ionization Carrier gas: Nitrogen, 70 ml/min Column: 80/100 Carbopack C/0.1% SP1000, 1.8 m × 4 mm ID, glass Inlet temperature: 180° C Detector temperature: 250° C Oven temperature program: 50° C for 5 min, then 50° C to 250° C at 10° C/min Sample injected: Neat liquid (3 µl) and 1% and 0.5% solutions in methylene chloride to quantitate impurities and check detector linearity

Results: 2.48% \pm 0.08 (δ)% (v/v) 3-chloro-2-methylpropene

The peak identified as acetone in the mass spectrometry section was not quantitated. The relative area of this impurity was 0.20% of the major peak area as obtained with the same gas chromatographic system.

7. Conclusions: The results of the elemental analysis for carbon, hydrogen, and chlorine agreed with theoretical values. Water content by Karl Fischer titration was 0.005% \pm $0.002(\delta)$ %. Neutralization of acidic components (assumed to be hydrochloric acid) indicated 419 \pm 18(δ) ppm. One gas chromatographic system (20% SP2100/0.1% Carbowax 1500) resolved a major peak and 14 impurities, the largest impurity having an area of 0.16% of the major peak area. The remaining 13 impurities totaled 0.40% relative to the major peak. A second gas chromatographic system (10% Carbowax 20M-TPA) resolved a major peak and nine impurities, all eluting after the major peak. The largest impurity (2.88%) was identified as 3-chloro-2-methylpropene with standards and spiking solutions. The combined area of the remaining eight impurities was 0.54% of the major peak area. A third gas chromatographic system (80/100 Carbopack C/0.1% SP1000) resolved a major peak and 11 impurities, the largest of which had an area of 2.30% of the major peak area. The remaining 10 impurities had a combined area of 0.60% of the major peak area. When lot no. 062537 was analyzed on this system, a major peak and 14 impurities were observed. Three of the larger impurities had areas of 0.87%, 0.78%, and 0.89% of the major peak.

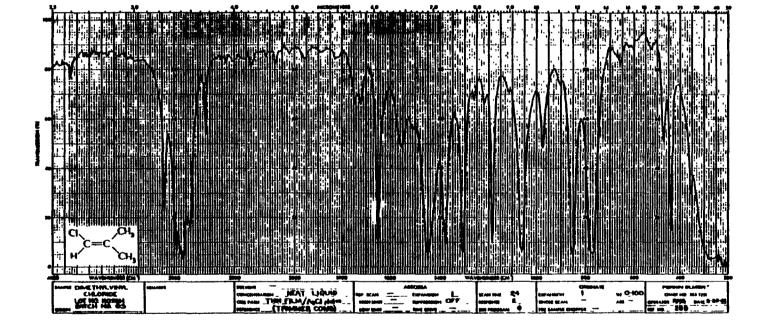

The impurity with a retention time corresponding to the 2.30% impurity in lot no. KD090967 was at a concentration of 0.5% in lot no. 062537. The cumulative area of all impurities in lot no. 062537 was 4.13%, as compared with 2.9% in lot no. KD090967. Two impurities and the major component were identified by gas chromatography (80/100 Carbopack C/0.1% SP1000)/mass spectrometry. The first impurity, acetone, was not quantitated against standards, as its relative area was only 0.20% of the major peak area, was quantitated against standards and found to be present in the sample at a concentration of 2.48% \pm 0.08% (v/v). The infrared, ultraviolet/visible, nuclear magnetic resonance, and mass spectral data were consistent with the structure of dimethylvinyl chloride.

System 2

Column: 10% Carbowax 20M-TPA on 80/100 Chromosorb W(AW), 1.8 m \times 4 mm ID, glass

Inlet temperature: 200° C

Detector temperature: 270° C

Oven temperature program: 50° C for 5 min, then 50° C to 200° C at 10° C/min **Sample injected:** Neat liquid (4 µl) and 1% and 0.5% solutions of dimethylvinyl chloride in *o*-dichlorobenzene to quantitate impurities and check detector linearity

Results: A major peak and eight impurities were observed, one before and seven after the major peak. The relative areas of the two larger impurities were 0.72% and 0.32%. The impurity with a retention time of 1.81 minutes (peak no. 3) was identified as 3-chloro-2-methylpropene (Section I.B.6.b.) The remaining six impurities had a combined area of 0.40% of the major peak. One impurity with a relative area less than 0.01% was observed eluting before the major peak.

<u>Peak No.</u>	Retention <u>Time (min)</u>	Retention Time Relative to <u>Major Peak</u>	Area (percent of <u>major peak)</u>
1	0.63	0.53	0.10

9	15.20	12.87	0.02

b. Quantitation of 3-chloro-2-methylpropene: 3-Chloro-2-methylpropene (retention time 8.8 minutes) was identified by retention time and quantitated against standards with the system described in Section I.C.6.a.

The concentration of this impurity was determined to be $0.75\% \pm 0.02(\delta)\%$.

7. Conclusions: Cumulative data indicated a purity of approximately 98%. The results of the elemental analysis for carbon, hydrogen, and chlorine agreed with the theoretical values. Water content by Karl Fischer titration was equal to or less than 0.01%. Titration indicated 844 \pm 16(8) ppm acidic components, calculated as hydrochloric acid. One gas chromatographic system resolved a major peak and nine impurity peaks. The two largest peaks had areas of 0.30% and 0.76% relative to that of the major peak. The combined relative area for the remaining impurities was 0.65%. A second gas chromatographic system resolved a major peak and eight impurity peaks. The two largest peaks had relative areas of 0.72% and 0.32%; the combined relative area of the other peaks was 0.40%. The concentration of 3-chloro-2-methylpropene was found to be 0.75% \pm 0.02(8)% quantitated by gas chromatography.

D. Identification and quantitation of impurities in dimethylvinyl chloride

The purpose of this work was to identify and quantitate impurities, including epichlorohydrin, in two samples of dimethylvinyl chloride (lot nos. 062537 and 1103BH).

The two samples of dimethylvinyl chloride were analyzed by gas chromatography/mass spectrometry. The impurities were quantitated by gas chromatography with flame ionization detection. The identity and concentration of impurities with concentrations greater than or equal to 0.1% (w/w) are reported.

1. Analytical methods

a. Identification by gas chromatography/mass spectrometry

Gas chromatography

Instrument: Varian 3700 Column: 1% SP1000 on 60/80 Carbopack B, 2.4 m \times 2 mm ID, glass Injector temperature: 200° C Carrier Gas: Helium, 30 ml/min Oven temperature program: 40° C for 4 min, then 220° C at 10° C/min Volume Injected: 1 µl Samples injected: dimethylvinyl chloride (lot nos. 062537 and 1103BH) neat liquid and 10% (v/v) solutions in methanol; available impurity standards (0.4% v/v) in methanol

Mass spectrometry

Instrument: Finnigan MAT CH4-B (interfaced to the gas chromatograph with a single-stage glass jet separator) Temperatures: Transfer line: 250° C Helium separator: 250° C Ion source: 220° C Electron energy: 70 eV Trap current: 40µA Accelerating voltage: 3,000 V Resolution: 400 Scan range: 10 to 300 amu Scan rate: 3 sec/scan Scan times (sec): Up - 1.75, Top - 0.05, Down - 0.70, Bottom - 0.50 Data system: Incos 2400

b. Quantitation by gas chromatography/flame ionization detection

The gas chromatographic system described in Section I.D.1.a was used for impurity quantitation with the following changes:

Detector: Flame ionization Detector temperature: 250° C Carrier gas: Nitrogen, 30 ml/min Volume injected: ~ $1.5 \,\mu$ l Solutions injected: 5% (v/v) solutions of dimethylvinyl chloride (lot nos. 062537 and 1103BH) in methanol, standards, in methanol, at concentrations bracketing those observed for impurities and containing *n*-butanol internal standard

c. Epichlorohydrin analysis by gas chromatography/flame ionization detection

The following gas chromatography/flame ionization detection system was developed to confirm the results of gas chromatographic/mass spectrometric analysis of epichlorohydrin.

The gas chromatographic system described above (Section I.D.2) was used with the following changes.

Column: 20% SP2401/0.1% Carbowax 1500 on 100/120 Supelcoport, 1.8 m × 4 mm ID, glass Column temperature program: 40° C, isothermal

Carrier gas: Nitrogen, 70 ml/min

Volume injected: ~2.5 µl

Solutions injected: 10% (v/v) solutions of dimethylvinyl chloride (lot nos. 062537 and 1103BH) in methanol; 0.005% (v/v) solutions of epichlorohydrin in methanol

2. Results

a. Dimethylvinyl chloride: lot no. 062537

The reconstructed ion current (RIC) and gas chromatograms obtained for this lot indicated that the sample contained numerous (≥ 19) impurities (Figure 11). The six impurity peaks estimated to be present at concentrations greater than or equal to 0.1% (w/w) were identified.

The identification and quantitation of these six impurity peaks, as well as analyses for epichlorohydrin, are discussed below.

Impurity peak no. 1

Peak no. 1 in the RIC was composed of two coeluting impurities: acetone and methylpropene. The identity of acetone was confirmed by comparison of mass spectral and retention time data with an authentic standard and a reference spectrum (EPA/NIH, 1978). The coeluting impurity, methylpropene, was tentatively identified by comparing its mass spectrum to a literature reference (EPA/NIH, 1978).

When quantitated against an acetone standard, the combined concentration of these two impurities was estimated at $0.12\% \pm 0.01(s)\%$ (w/w).

Impurity peak no. 2: t-butanol (2-methyl-2-propanol)

Impurity peak no. 2 was identified as t-butanol on the basis of mass spectral and retention time coincidence to an authentic standard and a literature reference (EPA/NIH, 1978). When quantitated against a t-butanol standard, this impurity was determined to be present at a concentration of $0.16\% \pm 0.01(s)\%$ (w/w).

Impurity peak no. 3: t-butyl chloride (2-chloro-2-methylpropane)

Impurity peak no. 3 was identified as t-butyl chloride (2-chloro-2-methylpropane). The identity of this impurity was confirmed by comparison of the mass spectral and retention time coincidence with an authentic standard and a reference spectrum (EPA/NIH, 1978). When quantitated against a t-butyl chloride standard, this impurity was determined to be present at a concentration of 0.91 \pm 0.02(s)% (w/w).

An impurity, tentatively identified as chloroform from a comparison of its mass spectrum and a reference spectrum (EPA/NIH, 1978), was observed to coelute with the *t*-butyl chloride impurity. This impurity was estimated to be present at a concentration of less than 0.1% (w/w), on the basis of gas chromatographic/mass spectrometric data.

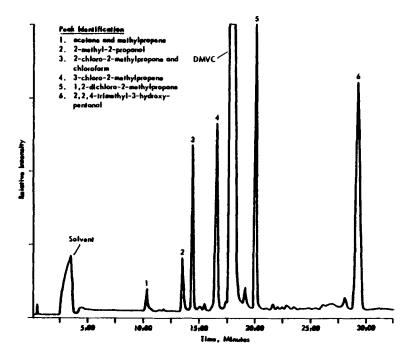

FIGURE 11. RECONSTRUCTED ION CURRENT CHROMATOGRAM OF DIMETHYLVINYL CHLORIDE (LOT NO. 062537)

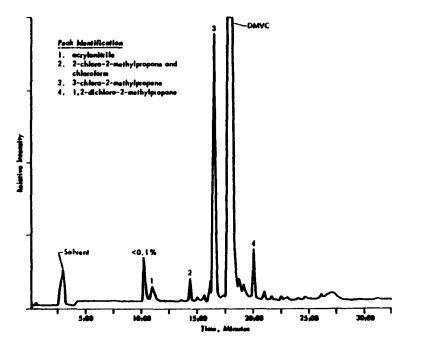

FIGURE 12. RECONSTRUCTED ION CURRENT CHROMATOGRAM OF DIMETHYLVINYL CHLORIDE (LOT NO. 1103BH)

203

Impurity peak no. 4: 3-chloro-2-methylpropene

Impurity peak no. 4 was identified as 3-chloro-2-methylpropene. The identity of this impurity was confirmed by comparison of the mass spectral and retention time data with that of a concurrently analyzed standard and a reference spectrum (EPA/NIH, 1978). Quantitation of this impurity against a 3-chloro-2-methylpropene standard indicated that 3-chloro-2-methylpropene was present in the sample at a concentration of $0.68\% \pm 0.01(s)\%$ (w/w).

Impurity peak no. 5: 1,2-dichloro-2-methylpropane

The retention time as mass spectrum of impurity no. 5 was consistent with that observed for a concurrently analyzed 1,2-dichloro-2-methylpropane standard. The reference spectrum (EPA/NIH, 1978) did not match either the impurity spectrum or a spectrum of the standard. However, infrared and nuclear magnetic resonance spectra for the standard were consistent with the structure of 1,2-dichloro-2-methylpropane and agreed with literature spectra (Sadtler Standard Spectra) for this compound.

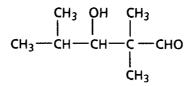

Diagnostic ions in the spectrum of the impurity and standard were as follows:

	Intensity (percent of base peak)		
<u>m/z</u>	Impurity	Standard	
126 (M ⁺)	(not obs	erved)	
111 (M ⁺ -CH ₃)	2.4	2.3	
91 (M ⁺ -Cl)	8.8	8.5	
79	31.3	30.3	
77 (M ⁺ -CH ₂ Cl)	100	100	
55	17.2	18.6	
49	5.0	5.2	
41	25.4	27.3	
39	12.6	13.7	

On the basis of quantitation against a 1,2-dichloro-2-methylpropane standard, this impurity was determined to be present at a concentration of $1.04\% \pm 0.08(s)\%$ (w/w). The presence of this impurity in the sample can be rationalized as arising from the addition of hydrochloric acid (present as a precursor during synthesis or as a trace impurity) to the double bond of dimethylvinyl chloride.

Impurity peak no. 6: 2,2,4-trimethyl-3-hydroxypentanal

The mass spectrum of impurity no. 6 was consistent with 2,2,4-trimethyl-3-hydroxypentanal, an aldol condensation product of isobutyraldehyde. The presence of this impurity can be rationalized from the probable synthetic route for dimethylvinyl chloride (Merck, 1983) (e.g., reaction of isobutyraldehyde with hydrochloric acid).

2,2,4-TRIMETHYL-3-HYDROXYPENTANAL

No standard was found for comparative analysis. No literature reference spectrum was found.

Diagnostic ions in the spectrum for this impurity were as follows:

<u>m/z</u>	Intensity (percent of base peak)
144 (M) ⁺	(not observed)
143 (M-H) ⁺	1.5
129 (M-CH ₃) ⁺	1.0
$111 (M-CH_3-H_2O)^+$	0.5
$101 (M-C_3H_7)^+$	100
$86 (M-C_3H_7-CH_3)^+$	4.8
$73(C_4H_9O)^+$	60.5
$71 (C_4 H_7 O)^+$	12.8
$56 (M-C_4H_9O-CH_2O)^+$	49.6
$55 (M-C_4H_9O-H_2O)^+$	74.9

This impurity was quantitated at $0.92\% \pm 0.03(s)\%$ (w/w) against a 3-chloro-2-methylpropene standard by gas chromatography/flame ionization detection.

Epichlorohydrin determination

Epichlorohydrin was not observed in the gas chromatographic/mass spectrometry analysis of lot no. 062537. Due to the presence of numerous impurities, the detection limit for the chromatographic/mass spectrometric analysis was 0.05% (w/w). When the dimethylvinyl chloride was analyzed by gas chromatography/flame ionization detection by the instrument parameters described in Section II.D.3., the detection limit for epichlorohydrin in dimethylvinyl chloride, lot no. 062537 was 0.03% (w/w).

Based on these results, lot no. 062537 does not contain epichlorohydrin at a concentration of greater than or equal to 0.03% (w/w).

b. Dimethylvinyl chloride: lot no. 1103BH

The reconstructed ion current (Figure 12) and gas chromatograms obtained from analysis of this lot indicated that the sample contained numerous (≥ 12) impurities. Four of these impurity peaks were determined to be present at concentrations greater than or equal to 0.1% (w/w). The identification and quantitation of these four impurity peaks, as well as analysis for epichlorohydrin, are discussed below.

Impurity peak no. 1: acrylonitrile

The retention time and mass spectrum of peak no. 1 were consistent with those of a concurrently analyzed acrylonitrile standard. The mass spectra of the impurity and the standard agreed with a reference spectrum (EPA/NIH, 1978). This impurity was quantitated at $0.14\% \pm 0.01(s)\%$ (w/w) against an acrylonitrile standard.

Impurity peak no. 2: t-butyl chloride (2-chloro-2-methylpropane)

The retention time and mass spectrum of peak no. 2 were consistent with those of a concurrently analyzed t-butyl chloride standard and with a reference spectrum (EPA/NIH, 1978). A coeluting impurity, tentatively identified as chloroform, was also observed. Chloroform was also tentatively detected in lot no. 062537. The cumulative concentration of the t-butyl chloride and chloroform impurities was quantitated at $0.10\% \pm 0.00(s)\%$ (w/w) against a t-butyl chloride standard.

Impurity peak no. 3: 3-chloro-2-methylpropene

The retention time and mass spectrum of peak no. 3 were consistent with those observed for a concurrently analyzed 3-chloro-2-methylpropene standard. The mass spectra of the impurity and the standard were consistent with a reference spectrum (EPA/NIH, 1978) for 3-chloro-2-methylpropene. Quantitation of this impurity versus a 3-chloro-2-methylpropene standard indicated it was present in the sample at a concentration of $1.18\% \pm 0.02(s)\%$ (w/w).

Impurity peak no. 4: 1,2-dichloro-2-methylpropane

The retention time and mass spectrum of peak no. 4 were consistent with those observed for a concurrently analyzed 1,2-dichloro-2-methylpropane standard. As discussed above for lot no. 062537, the EPA/NIH literature spectrum did not match that of the impurity or the spectrum of the standard. The fragmentation observed for this impurity agreed with that observed for the 1,2-dichloro-2-methylpropane standard and the impurity observed in lot no. 062537. This impurity was quantitated at $0.10\% \pm 0.01(s)\%$ (w/w) versus a 1,2-dichloro-2-methylpropane standard.

Epichlorohydrin determination

No evidence for the presence of epichlorohydrin was observed in this sample of dimethylvinyl chloride. Due to the presence of numerous impurities, the detection limit for epichlorohydrin was 0.02% (w/w) by gas chromatography/mass spectrometry. Similar analyses could not be performed with gas chromatography/flame ionization detection (Section II.D.3) because of the presence of impurities coeluting with epichlorohydrin.

Based on these results, lot no. 1103BH did not contain epichlorohydrin at levels greater than or equal to 0.02% (w/w).

3. Summary of results

Analysis of lot no. 062537 indicated six impurity peaks with concentrations greater than 0.1% of the total weight. These six peaks represent eight compounds. Five of these impurities were identified by comparison of the retention times and mass spectra with authentic standards. These impurities were acetone, t-butanol, t-butyl chloride, 3-chloro-2-methylpropene, and 1,2-dichloro-2-methylpropane. Tentative identification of three additional impurities was based on mass spectral interpretation and consideration of the route of synthesis. These impurities were chloroform, methylpropene, and 2,2,4-trimethyl-3-hydroxypentanal, an aldol condensation product of isobutyraldehyde.

Analysis of lot no. 1103BH indicated four impurity peaks with concentrations greater than 0.1% of the total weight. These four peaks represent five compounds. Four of these impurities were identified by comparison of the retention times and mass spectra with authentic standards. These impurities were acrylonitrile, *t*-butyl chloride, 3-chloro-2-methylpropene, and 1,2-dichloro-2-methylpropane. The fifth impurity, tentatively identified as chloroform, coeluted with *t*-butyl chloride.

The results of the identification and quantitation of impurities in these lots of dimethylvinyl chloride are presented in Table H1.

Epichlorohydrin was not detected in either lot of dimethylvinyl chloride. The estimated detection limits for epichlorohydrin were: 0.03%, w/w (gas chromatography/flame ionization detection) in lot no. 062537; and 0.02%, w/w (gas chromatography/mass spectrometry) in lot no. 1103BH.

Peak No.	Impurity	Concentration (percent, w/w)
t no. 062537 (b)		· · · · · · · · · · · · · · · · · · ·
1	Acetone Methylpropene	(c) 0.12 ± 0.01 (s

II. Stability of Dimethylvinyl Chloride Lot No. 062537 Performed by the Analytical Chemistry Laboratory

- A. Sample storage: Samples were stored for 2 weeks at -20° , 5°, 25°, or 60° C.
- B. Analytical method: Gas chromatography

Instrument: Bendix 2500 Detector: Flame ionization Column: 20% SP2100/0.1% Carbowax 1500 on 100/120 mesh Supelcoport, 4 mm × 1.8 m, glass Inlet temperature: 100° C Detector temperature: 28.5° C Oven temperature: 30° C, isothermal Carrier gas: Nitrogen, 40 ml/min Retention time of major component: 2.4 min

C. Results: Six impurities were detected and quantified at the detection level used for this study. The areas of the impurity peaks were identical within the error of the analysis in the -20° , 5°, and 25° C samples. The results for the 60° C samples indicated lower areas for impurities with retention times from 0.34 to 1.37 minutes as compared with the major peak and larger areas for those impurities with retention times greater than three times the major peak. This difference in the 60° C samples was probably due to the volatility of these components (boiling point of the major component, 62° C).

Storage Temperature	Area of the Major Peak <u>Relative to the – 20° C Sample</u>
– 20° C	100% ± 4%
5° C	$100\% \pm 4\%$
25° C	100% ± 4%
60° C	99% ± 4%

D. Conclusion: Dimethylvinyl chloride is stable as the bulk chemical when stored for 2 weeks at temperatures up to 25° C. At 60° C, the major component and some impurities are probably volatilized from the container.

III. Stability Study of Dimethylvinyl Chloride at the Study Laboratory

A. Storage conditions: Bulk, 4°C Reference, -20°C or less

B. Analytical methods

1. Gas chromatography

Instrument: Hewlett Packard 5880 or 5840 with 7672A liquid sampler Detector: Flame ionization Inlet temperature: 200°-270° C Detector temperature: 200°-270° C Carrier gas: Nitrogen, 20 or 40 ml/min Column: 20% SP2100/0.1% Carbowax 1500 on 100/120 mesh Supelcoport, 1.8 m × 2 mm ID, silanized glass Oven temperature: 50° C for 5 min; 50°-200° C at 10° C/min; 200° C for 0, 5, or 10 min Sample injection: 1 or 3 µl neat liquid; 1.0% and 0.5% dimethylvinyl chloride in *o*dichlorobenzene to quantitate the major peak and to check for column and/or detector overloading

2. Infrared spectroscopy

Instrument: Perkin Elmer Model 398, 457, or 283B Cell: Neat liquid between potassium bromide or sodium chloride plates

1. Gas chromatography

(a) Column used: 10% Carbowax 20M-TPA Supelcoport W(AW), 1.8 m \times 2 mm ID, glass

(b) Values for 1% solution alone reported due to overloading of analytical column during analysis of neat material

2. Infrared spectroscopy: All bulk spectra were comparable to the reference spectra and with the spectra supplied by the analytical chemistry laboratory.

APPENDIX I

PREPARATION AND CHARACTERIZATION

OF DOSE MIXTURES

211

I. Room Temperature Stability Study Conducted at the Analytical Chemistry Laboratory (Lot no. 062537)

- A. Sample preparation and storage: Two milliliters of corn oil was transferred into an 8.5-ml septum vial, which was then sealed and weighed. Approximately 120 mg of dimethylvinyl chloride was then injected with a microliter syringe, and the vial was reweighed. The sample was agitated on a vortex mixer for 30 seconds and then stored at room temperature in the dark for the appropriate period of time. Solutions (6.0% w/v) of dimethylvinyl chloride in corn oil were prepared in duplicate for storage at 0, 5, 6, and 7 days.
- **B.** Sample extraction and analysis: At the end of each storage period, the appropriate samples were extracted with 2 ml of absolute methanol that was injected into the vials with a 2-ml syringe. The two-phase mixtures were thoroughly agitated on a vortex mixer for 1 minute and placed in an ultrasonic vibratory bath for 1 minute. Aliquots for analysis were removed directly from the upper (methanol) layer of each sample by microliter syringe and analyzed by the gas chromatographic system described below.

Instrument: Bendix 2500 Column: 20% SP2100/0.1% Carbowax 1500 on 100/120 mesh Supelcoport, 4 m × 1.8 mm, glass Detection: Flame ionization Inlet temperature: 100° C Oven temperature: 30° C, isothermal Detector temperature: 28.5° C Carrier gas: Nitrogen, 40 ml/min Retention time: 2.4 min

C. Results

<u>Storage Time (days)</u>	Average Percent Chemical Found in <u>Chemical/Vehicle Mixture (a, b)</u>			
0	6.0 ± 0.5			
5	4.8 ± 0.4			
6	5.5 ± 0.4			
7	5.4 ± 0.4			

(a) Corrected for a spiked recovery of $83.0\% \pm 9.0\%$.

(b) Target concentration of chemical in corn oil, $6.04\% \pm 0.04\%$.

D. Conclusion: Dimethylvinyl chloride mixed with corn oil at the 6.0% concentration is stable, within the error limits of this study, when stored in the dark at room temperature (25° C) for 7 days.

II. Stability Study of Dimethylvinyl Chloride in Corn Oil Conducted by the Study Laboratory

- A. Methods: Solutions of dimethylvinyl chloride in corn oil were prepared at concentrations of 20 mg/ml and 40 mg/ml and stored at 25° C. Samples were analyzed 5, 20, and 44 days after preparation. The analytical procedure was the same as that described in Appendix J, Section I.
- **B.** Results

Storage Time (days)	Target	Actual	Percent of	
	Concentration	Concentration	Target	
	(mg/ml)	(a)	Concentration	
5	20	20.4	102.0	
20	20	23.8	119.0	
44	20	18.5	92.5	
5	40	40.6	101.5	
20	40	44.5	111.3	
44	40	40.0	100.0	

(a) Results of duplicate analysis

C. Conclusion: Solutions of dimethylvinyl chloride in corn oil at concentrations of 20 and 40 mg/ml were stable after 44 days' storage at 25° C.

APPENDIX J

METHODS OF ANALYSIS OF DOSE MIXTURES

I. Study Laboratory

A. Procedure:

- 1. **Preparation of standard solutions:** An internal standard solution (ISTD) of 1% (v/v) *t*-butanol in methanol was prepared. A stock dimethylvinyl chloride standard solution was prepared by weighing approximately 2.50 g (1.25 g after 3/81) of dimethylvinyl chloride into a 25-ml volumetric flask, brought to final volume with undosed corn oil.
- 2. Preparation of calibration standards: A set of six calibration standards was prepared by adding 100, 200, 400, 600, 800, and 1,000 µl of the stock dimethylvinyl chloride standard solution to six 50-ml capacity centrifuge tubes. The volume of corn oil in each tube was brought to final volume of 1.00 ml with undosed corn oil.
- **3.** Preparation of gavage samples: After they were thoroughly shaken, 1.00-ml (SMI pipettor) aliquots of each gavage sample were added to centrifuge tubes in duplicate.
- 4. Extraction of samples: Added to each centrifuge tube was 5.00 ml of ISTD solution. The tubes were then sealed and shaken in a shaker box for 10 minutes at 1,500 rpm. An aliquot of each methanol extract was placed in crimp cap sampler vials for gas chromatographic analysis.

B. Gas chromatographic analysis

Instrument: HP-5880A with 7672 ALS Column: 100/120 mesh Chromosorb 102 on a 1.8 m × 2mm ID, silanized glass Detection: Flame ionization Detector temperature: 275°C Injector temperature: 225°C Column Temperature: 150°C, isothermal Carrier gas: Nitrogen, 40 ml/min

II. Analytical Chemistry Laboratory

- A. Preparation of spiked corn oil standards: Two standard solutions of dimethylvinyl chloride in methanol were prepared independently. The solutions were diluted with methanol to make four additional standards. Aliquots (20 ml) of the six standard solutions were pipetted into individual 35-ml septum vials containing 2 g of undosed corn oil to make spiked corn oil standards bracketing the specified concentration range of the referee sample. One 35-ml septum vial containing 2 g of undosed corn oil was treated with 20 ml of methanol for use as a blank. After the vials were sealed with Teflon®-lined septa, the spiked corn oil and the corn oil blank were used in the analysis procedure described below.
- **B.** Preparation of referee sample: Three portions (~ 2 g each) of the referee corn oil sample were transferred to individually tared 35-ml septum vials and weighed to the nearest 0.001 g. Methanol (20 ml) was pipetted into each vial; then the vials were sealed and analyzed immediately by the procedure described below.

C. Analysis procedure: Vials containing the samples, standards, and the blank were agitated for 10 seconds on a vortex mixer and then shaken at maximum stroke for 15 minutes on a Burrell Model 75 Wrist-Action[®] shaker. After the extraction mixtures were centrifuged for 3 minutes, a 5-ml aliquot of the methanol layer from each vial was combined with 5 ml of internal standard solution (heptane in methanol, 1.5 mg/ml). The solutions were thoroughly mixed; then the dimethylvinyl chloride content was determined by the gas chromatographic system described below.

Instrument: Varian 3700 gas chromatograph with autosampler and Varian CDS 111-C integrator Column: 20% SP-2100/0.1% Carbowax 1500 on 100/120 mesh Supelcoport, 1.8 m × 4 mm ID, glass, silanized Detection: Flame ionization Detector temperature: 150° or 200°C Inlet temperature: 100° or 150°C Oven temperature: 50°C isothermal Carrier gas: Nitrogen, 30 ml/min Volume of solution injected: 3 µl

The total amount of dimethylvinyl chloride in the referee corn oil samples was computed from the linear regression equations obtained from the standard data.

D. Quality assurance measures: The referee corn oil sample was analyzed in triplicate, and the undosed corn oil sample was analyzed once. Individually spiked portions of undosed corn oil (six concentrations bracketing the specified concentration range of the referee sample) were prepared from two independently weighed standards and were used for obtaining standard data. Triplicate injections of each standard and sample were made into the gas chromatograph in a randomized order. All determinations were related to an internal standard incorporated into the sample solutions.

APPENDIX L

SENTINEL ANIMAL PROGRAM

223

I. Methods

Rodents used in the Carcinogenesis Program of the National Toxicology Program are produced in optimally clean facilities to eliminate potential pathogens that may affect study results. The Sentinel Animal Program is part of the periodic monitoring of animal health that occurs during the toxicologic evaluation of chemical compounds. Under this program, the disease state of the rodents is monitored via viral serology on sera from extra (sentinel) animals in the study rooms. These animals are untreated, and these animals and the study animals are both subject to identical environmental conditions. The sentinel animals come from the same production source and weanling groups as the animals used for the studies of chemical compounds.

Fifteen $B6C3F_1$ mice and 15 F344/N rats of each sex are selected at the time of randomization and allocation of the animals to the various study groups. Five animals of each designated sentinel group are killed at 6, 12, and 18 months on study. Data from animals surviving 24 months are collected from 5/50 randomly selected vehicle control animals of each sex and species. The blood from each animal is collected and clotted, and the serum is separated. The serum is cooled on ice and shipped to Microbiological Associates' Comprehensive Animal Diagnostic Service for determination of the viral antibody titers. The following tests are performed:

	Hemagglutination <u>Inhibition</u>	Complement <u>Fixation</u>	<u>ELISA</u>
Mice	PVM (pneumonia virus of mice) Reo 3 (reovirus type 3) GDVII (Theiler's encephalomyelitis virus) Poly (polyoma virus) MVM (minute virus of mice) Ectro (infectious ectromelia) Sendai	M.Ad. (mouse adenovirus) LCM (lymphocytic choriomeningitis virus) Sendai MHV (mouse hepatitis virus)	MHV (mouse hepatitis virus) (12 mo restart)
Rats	PVM KRV (Kilham rat virus) H-1 (Toolan's H-1 virus)	RCV (rat coronavirus) Sendai	
II. Re	sults		

No positive serologic reactions were seen in rats or mice at any of the intervals tested.

APPENDIX M

INGREDIENTS, NUTRIENT COMPOSITION, AND CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION

Pelleted Diet: April 1980 to January 1983

(Manufactured by Zeigler Bros., Inc., Gardners, PA)

225

Ingredients (b)	Percent by Weight
Ground #2 yellow shelled corn	24.50
Ground hard winter wheat	23.00
Soybean meal (49% protein)	12.00
Fish meal (60% protein)	10.00
Wheat middlings	10.00
Dried skim milk	5.00
Alfalfa meal (dehydrated, 17% protein)	4.00
Corn gluten meal (60% protein)	3.00
Soy oil	2.50
Brewer's dried yeast	2.00
Dry molasses	1.50
Dicalcium phosphate	1.25
Ground limestone	0.50
Salt	0.50
Premixes (vitamin and mineral)	0.25

TABLE M1. INGREDIENTS OF NIH 07 RAT AND MOUSE RATION (a)

(a) NIH, 1978; NCI, 1976

(b) Ingredients should be ground to pass through a U.S. Standard Screen No. 16 before being mixed.

	Amount	Source
Vitamins		
Α	5,500,000 IU	Stabilized vitamin A palmitate or acetate
D ₃	4,600,000 IU	D-activated animal sterol
K ₃	2.8 g	Menadione activity
d-a-Tocopheryl aceta	te 20,000 IU	·
Choline	560.0 g	Choline chloride
Folic acid	2.2 g	
Niacin	30.0 g	
d-Pantothenic acid	18.0 g	d-Calcium pantothenate
Riboflavin	3.4 g	•
Thiamine	10.0 g	Thiamine mononitrate
B ₁₂	4.000 µg	
Pyridoxine	1.7 g	Pyridoxine hydrochloride
Biotin	140.0 mg	d-Biotin
Ainerals		
Iron	120.0 g	Iron sulfate
Manganese	60.0 g	Manganous oxide
Zinc	16.0 g	Zincoxide
Copper	4.0 g	Copper sulfate
Iodine	1.4 g	Calcium iodate
Cobalt	0.4 g	Cobalt carbonate

TABLE M2. VITAMINS AND MINERALS IN NIH 07 RAT AND MOUSE RATION (a)

(a) Per ton (2,000 lb) of finished product

Nutrient	Mean	Range	No. of Samples
Crude protein (percent by weight)	23.95 ± 0.83	22.7-26.1

TABLE M4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION (Continued)

- (a) All values were less than the detection limit, given in the table as the mean.
- (b) The detection limit was reduced from 10 ppb to 5 ppb after 7/81.
- (c) Source of contamination: Alfalfa, grains, and fish meal
- (d) Source of contamination: Soy oil and fish meal
- (e) Three batches contained more than 0.5 ppm.

(f) Mean, standard deviation, and range exclude two very high values of 1,100 obtained for batches produced on 5/29/80 and 12/16/80.

(g) Includes the high values listed in footnote (f) (h) All values were less than 3 MPN/g (MPN = most probable number).

(i) Mean, standard deviation, and range exclude three very high values in the range of 117.6-279.5 ppb obtained for the batches produced on 1/26/81, 2/23/81, and on 4/27/81.

(j) All values were corrected for percent recovery.

(k) Mean, standard deviation, and range include the very high values given in footnote (i).

(1) Mean, standard deviation, and range exclude three very high values in the range of 115.0-278.0 ppb for batches produced on 1/26/81, 2/23/81, and 4/27/81.

(m) Mean, standard deviation, and range include the very high values given in footnote (l).

(n) The values were not detectable in batches produced on 3/24/82 and 6/24/82.

- (o) BHC = hexachlorocyclohexane or benzene hexachloride.
- (p) There was one observation above the detection limit; the value and date it was obtained are given under the range.
- (q) Ten batches (4/1/80-12/16/80) were not analyzed for chlordane.
- (r) Sixteen batches contained more than 0.05 ppm.

(s) Nineteen batches (4/1/80-11/25/81) were not analyzed for endosulfan I, endosulfan II, or endosulfan sulfate.

APPENDIX N

RESULTS OF NTP STUDIES OF THE METABOLISM AND ELIMINATION OF DIMETHYLVINYL CHLORIDE IN RATS AND MICE

TABLE N1. ELIMINATION OF ¹⁴C-DIMETHYLVINYL CHLORIDE-DERIVED RADIOACTIVITY BY VARIOUS ROUTES (a)

Route	Rats	Mice
Urine	(b) 35 ± 5	49 ± 9
Feces	4.2 ± 2.3	8.7 ± 3.7
Expired carbon dioxide	26 ± 1	26 ± 1
Expired dimethylvinyl chloride	35 ± 5	5.0 ± 0.7

(a) Male F344 rats (200-250 g) were given 150 mg/kg of ¹⁴C-dimethylvinyl chloride (51 μ Ci/kg) by gavage in corn oil (5 ml) and placed in glass metabolism cages that allow separate collection of urine, feces, and expired air. Expired air was passed first through an ethanol-filled trap or an activated carbon trap to retain expired organic compounds and then through two consecutive ethanolamine traps to retain expired carbon dioxide. Elution of the activated carbon traps followed by high-pressure liquid chromatography of the eluate allowed verification that the expired ¹⁴C-labeled organic compound was dimethylvinyl chloride. An aliquot of urine was counted without further processing; feces were oxidized in a tissue oxidizer and counted. Male B6C3F₁ mice (25-30 g) were given 150 mg/kg of ¹⁴C-dimethylvinyl chloride (150 μ Ci/kg) by gavage in corn oil (10 ml) and placed in similar glass metabolism cages as described above. Urine, feces, expired carbon dioxide, and expired dimethylvinyl chloride were assayed as described above.

(b) Values given are percentages of the administered dose eliminated by a given route in the 24 hours after administration of the compound. Values are the mean for three animals \pm SD.

TABLE N2. TISSUE DISTRIBUTION OF ¹⁴C-DIMETHYLVINYL CHLORIDE-DERIVED RADIOACTIVITY (a)

		Rats	tion of Radioactivi		<u>Mice</u> 1D
	1D (b)	2D	4D	4D-4R	1D

Thymus	0.39 ± 0.06	0.82 ± 0.03	0.98 ± 0.09	0.30 ± 0.06	0.35 ± 0.09

(a) Male F344 rats (200-250g) were given 150 mg/kg of ¹⁴C-dimethylvinyl chloride (51 μ Ci/kg) by gavage in corn oil (5 ml) and placed in glass metabolism cages that allow separate collection of urine, feces, and expired air. Male B6C3F₁ mice (25-30 g) were given 150 mg/kg of ¹⁴C-dimethylvinyl chloride (150 μ Ci/kg) by gavage in corn oil (10 ml) and placed in glass metabolism cages as described above. The animals were killed 24 hours after the last dose and tissues collected. Samples of tissue were oxidized in a tissue oxidizer to determine radioactivity present.

(b) D = one daily administration of 150 mg/kg; R = 1 day of recovery, e.g., 4D-4R = four successive daily doses of 150 mg/kg followed by 4 days' recovery.

(c) Values given are the mean for three animals \pm SD.

APPENDIX P

DATA AUDIT SUMMARY

The experimental data and tables of the NTP Technical Report on the toxicology and carcinogenesis studies of dimethylvinyl chloride in F344/N rats and B6C3F₁ mice were examined for completeness, consistency, and accuracy and for procedures consistent with Good Laboratory Practice requirements. The audit was conducted October 1-5, 1984, by Argus Research Laboratories, Inc., under contract to the NTP. The following personnel were involved in the audit: J. Goeke, Ph.D.; J. Hills, B.A.; A. Hoberman, Ph.D.; E. Feussner, V.D.M.; P. Ference, B.S.; D. Willett, B.S.; D. Copeland, D.V.M.; G. Knutsen, D.V.M., M.S.; C. Veigle, H.T. The 2-year studies in rats and mice were conducted between June 1980 and March 1983 at Litton Bionetics, Inc., Kensington, Maryland.

The full report of the audit is on file at NIEHS, Research Triangle Park, North Carolina. The audit included, but was not limited to, a review of the records of the inlife portion of the studies for 10% of the animals; 100% of the clinical observation records for animals observed to have masses during the last 6 months of the studies; 100% of the records for study material administration; 10% of the dose calculations; 100% of all other chemistry data. All Individual Animal Data Records were examined for correspondence between necropsy observations and histologic findings. An audit of randomly selected (10%) wet tissue bags was conducted to verify animal identification and to examine residual tissues for untrimmed lesions. A complete slide/block match for both sexes of both species in the vehicle control and high dose groups was performed.

Examples of the most substantive discrepancies observed during the audit are as follows. Persistent clinical signs such as "ruptured eyeball" and "loss of tail-distal" were sometimes reported intermittently after the initial observation. Some masses that were adequately described at one observation time were not subsequently noted, and there was no notation that the mass was no longer identifiable or observed. The chemical dispensing log was incomplete regarding the source of dimethylvinyl chloride used to prepare dosing solutions between 12/16/80 and 12/24/80. Inconsistencies in gross/microscopic pathology comparisons were observed, and untrimmed lesions were found in stored wet tissues. For example, a papilloma of the forestomach in 1 rat and untrimmed lesions in 7/45 mice were observed--three fibrotic or atrophied seminal vesicles, one mesenteric nodule, one small liver focus, one forestomach area of papillomas (which was partially sampled), and one granulomatous penis. These lesions were found either through lack of correlation between a gross necropsy observation and a histopathologic description or during examination of wet tissue bags.

These discrepancies were either resolved or were not considered to influence the final interpretation of these studies. Thus, the data examined during this audit are considered adequate to support the conclusions presented in this Technical Report.
