NATIONAL TOXICOLOGY PROGRAM Technical Report Series No. 329

NATIONAL TOXICOLOGY PROGRAM

The National Toxicology Program (NTP), established in 1978, develops and evaluates scientific information about potentially toxic and hazardous chemicals. This knowledge can be used for protecting the health of the American people and for the primary prevention of disease. By bringing together the relevant programs, staff, and resources from the U.S. Public Health Service, DHHS, the National Toxicology Program has centralized and strengthened activities relating to toxicology research, testing and test development/validation efforts, and the dissemination of toxicological information to the public and scientific communities and to the research and regulatory agencies.

The NTP is made up of four charter DHHS agencies: the National Cancer Institute (NCI), National Institutes of Health; the National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health; the National Center for Toxicological Research (NCTR), Food and Drug Administration; and the National Institute for Occupational Safety and Health (NIOSH), Centers for Disease Control. In July 1981, the Carcinogenesis Bioassay Testing Program, NCI, was transferred to the NIEHS.

NTP TECHNICAL REPORT ON THE

TOXICOLOGY AND CARCINOGENESIS STUDIES OF 1,2-EPOXYBUTANE

(CAS NO. 106-88-7)

NOTE TO THE READER

This study was performed under the direction of the National Institute of Environmental Health Sciences as a function of the National Toxicology Program. The studies described in this Technical Report have been conducted in compliance with NTP chemical health and safety requirements and must meet or exceed all applicable Federal, state, and local health and safety regulations. Animal care and use were in accordance with the U.S. Public Health Service Policy on Humane Care and Use of Animals. All NTP toxicology and carcinogenesis studies are subjected to a data audit before being presented for public peer review.

Although every effort is made to prepare the Technical Reports as accurately as possible, mistakes may occur. Readers are requested to identify any mistakes so that corrective action may be taken. Further, anyone who is aware of related ongoing or published studies not mentioned in this report is encouraged to make this information known to the NTP. Comments and questions about the National Toxicology Program Technical Reports on Toxicology and Carcinogenesis Studies should be directed to Dr. J.E. Huff, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709 (919-541-3780).

These NTP Technical Reports are available for sale from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161 (703-487-4650). Single copies of this Technical Report are available without charge (and while supplies last) from the NTP Public Information Office, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709.

1,2-EPOXYBUTANE

CAS No. 106-88-7

C₄H₈O Molecular weight 72.1

Synonyms: 1-butene oxide; 1,2-butene oxide; butylene oxide; 1,2-butylene oxide; ethyl ethylene oxide; ethyl oxirane

ABSTRACT

1,2-Epoxybutane was selected for study because it is a short-chain epoxide that had been shown to be mutagenic and because no carcinogenicity data were available. Approximately 8 million pounds of 1,2-epoxybutane are produced annually in the United States. The chemical is used primarily as a stabilizer in chlorinated hydrocarbon solvents.

Single-Exposure, Fourteen-Day, and Thirteen-Week Studies: Single-exposure, 14-day, 13-week, and 2-year studies were conducted in F344/N rats and $B6C3F_1$ mice. The chemical was greater than 99% pure and was administered as a vapor by the inhalation route to mimic worker exposure; room air was used as the control exposure during these studies. Exposures were 6 hours per day (5 days per week), except in the single-exposure studies (4 hours). Additional studies were performed to evaluate the potential for genetic damage in bacteria and in mammalian cells. In the single-exposure studies, the chemical was administered at exposure concentrations of 400-6,550 ppm in rats and 400-2,050 ppm in mice. In the 14-day studies, rats and mice were exposed at 400-6,400 ppm, and in the 13-week studies, rats and mice were exposed at 50-800 ppm.

All rats in the single-exposure studies at 6,550 ppm died; compound-related deaths were not seen in other dosed groups. All mice at 2,050 ppm and 4/5 mice of each sex at 1,420 ppm died; compound-related mortality was not seen in other dosed groups.

In the 14-day studies, all rats at 3,200 and 6,400 ppm and 2/5 female rats at 1,600 ppm died; all mice at 1,600, 3,200, and 6,400 ppm and 1/5 male mice at 800 ppm died. Final mean body weights of surviving rats exposed at 800 or 1,600 ppm were 12%-33% lower than those of the controls; final mean body weights of surviving mice at 800 ppm were 10%-12% lower than those of the controls. Compound-related lesions included pulmonary hemorrhage and rhinitis in rats at 1,600 ppm and nephrosis in mice at 800 and 1,600 ppm.

In the 13-week studies, no compound-related mortality was observed in rats; all mice exposed at 800 ppm died. No compound-related clinical signs were seen in rats or in surviving mice. The final mean body weight of rats exposed at 800 ppm was 23% lower than that of controls for males and 16% lower for females. Final body weights of surviving mice were unaffected by exposure. Inflammation of the nasal turbinates was seen in rats at 800 ppm but not at lower exposure concentrations. Renal tubular necrosis was seen in mice at 800 ppm but not at lower concentrations. Inflammation of the nasal turbinates was observed in female mice at 100, 200, 400, and 800 ppm and in male mice at 200, 400, and 800 ppm. The highest exposure concentration selected for the 2-year studies in rats was 400 ppm because of body weight effects and nasal lesions observed at 800 ppm. The highest concentration selected for the 2-year studies in rats was 400 ppm were considered to be potentially life threatening.

3

Two-Year Studies: The 2-year toxicology and carcinogenesis studies of 1,2-epoxybutane were conducted by exposing groups of 50 animals per species and sex to the chemical by inhalation, 6 hours per day 5 days per week. Rats were exposed at concentrations of 0, 200, or 400 ppm for 103 weeks and mice at 0, 50, or 100 ppm for 102 weeks.

Body Weight and Survival in the Two-Year Studies: The survival of all groups of dosed rats was at least 50% until week 98, but final survival was reduced in the dosed groups (final survival--male: control, 30/50; low dose, 18/50; high dose, 23/50; female: 32/50; 21/50; 22/50). Mean body weights of control and exposed male rats were similar until week 86; thereafter, mean body weights of high dose male rats were 4%-8% lower than those of controls. Mean body weights of high dose female rats were 5%-10% lower than those of controls after week 22.

Survival in male mice was comparable among groups (final survival: 41/50; 45/50; 33/50). Survival in female mice was greater than 50% in all groups at week 86 and then was reduced in high dose females toward the end of the study (final survival: 29/50; 25/50; 9/50). This decreased survival was associated with suppurative inflammation of the ovary and uterus. *Klebsiella oxytoca* was isolated from these ovarian/uterine lesions. Mean body weights of high dose male mice were 10%-14% lower than those of the controls after week 69; mean body weights of low dose male mice were 4%-8% lower than those of the controls after week 86. Mean body weights of high dose female mice were 13%-23% lower than those of the controls after week 60, and mean body weights of low dose female mice were 12%-16% lower than those of the controls after week 73.

Nonneoplastic and Neoplastic Effects in the Two-Year Studies: Dosed rats had nonneoplastic lesions of the nasal cavity including inflammation, epithelial hyperplasia, squamous metaplasia, hyperostosis of the nasal turbinate bone, and atrophy of the olfactory epithelium. Seven papillary adenomas of the nasal cavity were seen in high dose male rats and two in high dose female rats. The historical incidences of nasal cavity adenomas in untreated male and untreated female F344/N rats are less than 0.1%. The incidences of alveolar/bronchiolar carcinomas (0/50; 1/50; 4/49) and adenomas or carcinomas (combined) (0/50; 2/50; 5/49) were increased in high dose male rats; no increased incidences of these tumors were observed in dosed female rats.

Dosed mice had increased incidences of nonneoplastic lesions of the nasal cavity but no significant increase in the incidence of neoplastic lesions of the nasal cavity. The nonneoplastic lesions included suppurative inflammation (empyema), epithelial hyperplasia, erosion, regeneration, and squamous metaplasia in the nasal cavity; atrophy of the olfactory sensory epithelium; hyperplasia of the nasal gland (Bowman's glands); and inflammation and hyperplasia of the nasolacrimal duct. A single squamous cell papilloma was seen in the incisive duct of one high dose male mouse.

Genetic Toxicology: 1,2-Epoxybutane was mutagenic in Salmonella typhimurium strains TA100 and TA1535 when tested with a preincubation protocol with and without rat liver S9, indicating that it is a direct-acting mutagen capable of inducing base-pair substitutions in prokaryotes; it did not cause gene reversion in strains TA1537 or TA98. 1,2-Epoxybutane induced forward mutations at the TK locus of cultured mouse L5178Y lymphoma cells with and without metabolic activation. Both chromosomal aberrations and sister chromatid exchanges were induced in cultured Chinese hamster ovary cells after exposure to 1,2-epoxybutane in the presence and absence of metabolic activation. 1,2-Epoxybutane, when fed to male Drosophila, caused significant increases in the number of sexlinked recessive lethal mutations and reciprocal translocations in the germ cells.

Data Audit: An audit of the experimental data was conducted for the 2-year studies of 1,2-epoxybutane. No data discrepancies were found that influenced the final interpretations. Conclusions: Under the conditions of these 2-year inhalation studies, there was clear evidence of carcinogenic activity* of 1,2-epoxybutane for male F344/N rats, as shown by an increased incidence of papillary adenomas of the nasal cavity, alveolar/bronchiolar carcinomas, and alveolar/bronchiolar adenomas or carcinomas (combined). There was equivocal evidence of carcinogenic activity for female F344/N rats, as shown by the presence of papillary adenomas of the nasal cavity. There was no evidence of carcinogenic activity for male or female $B6C3F_1$ mice exposed at 50 or 100 ppm. 1,2-Epoxybutane exposure was associated with adenomatous hyperplasia and inflammatory lesions of the nasal cavity in rats and inflammatory lesions of the nasal cavity in mice.

SUMMARY OF THE TWO-YEAR FEED AND GENETIC TOXICOLOGY STUDIES OF 1,2-EPOXYBUTANE

(a) With and without S9 liver enzyme fraction used for exogenous metabolic activation.

^{*}Explanation of Levels of Evidence of Carcinogenic Activity is on page 6.

A summary of the Peer Review comments and the public discussion on this Technical Report appears on pages 10-11.

EXPLANATION OF LEVELS OF EVIDENCE OF CARCINOGENIC ACTIVITY

These studies are designed and conducted to characterize and evaluate the toxicologic potential, including carcinogenic activity, of selected chemicals in laboratory animals (usually two species, rats and mice). Chemicals selected for NTP toxicology and carcinogenesis studies are chosen primarily on the bases of human exposure, level of production, and chemical structure. Selection per se is not an indicator of a chemical's carcinogenic potential.

Negative results, in which the study animals do not have a greater incidence of neoplasia than control animals, do not necessarily mean that a chemical is not a carcinogen, inasmuch as the experiments are conducted under a limited set of conditions. Positive results demonstrate that a chemical is carcinogenic for laboratory animals under the conditions of the study and indicate that exposure to the chemical has the potential for hazard to humans.

The National Toxicology Program describes the results of individual experiments on a chemical agent and notes the strength of the evidence for conclusions regarding each study. Other organizations, such as the International Agency for Research on Cancer, assign a strength of evidence for conclusions based on an examination of all available evidence including: animal studies such as those conducted by the NTP, epidemiologic studies, and estimates of exposure. Thus, the actual determination of risk to humans from chemicals found to be carcinogenic in laboratory animals requires a wider analysis that extends beyond the purview of these studies.

Five categories of evidence of carcinogenic activity are used in the Technical Report series to summarize the strength of the evidence observed in each experiment: two categories for positive results ("Clear Evidence" and "Some Evidence"); one category for uncertain findings ("Equivocal Evidence"); one category for no observable effects ("No Evidence"); and one category for experiments that because of major flaws cannot be evaluated ("Inadequate Study"). These categories of interpretative conclusions were first adopted in June 1983 and then revised in March 1986 for use in the Technical Reports series to incorporate more specifically the concept of actual weight of evidence of carcinogenic activity. For each separate experiment (male rats, female rats, male mice, female mice), one of the following quintet is selected to describe the findings. These categories refer to the strength of the experimental evidence and not to either potency or mechanism.

- Clear Evidence of Carcinogenic Activity is demonstrated by studies that are interpreted as showing a dose-related (i) increase of malignant neoplasms, (ii) increase of a combination of malignant and benign neoplasms, or (iii) marked increase of benign neoplasms if there is an indication from this or other studies of the ability of such tumors to progress to malignancy.
- Some Evidence of Carcinogenic Activity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of neoplasms (malignant, benign, or combined) in which the strength of the response is less than that required for clear evidence.
- Equivocal Evidence of Carcinogenic Activity is demonstrated by studies that are interpreted as showing a marginal increase of neoplasms that may be chemically related.
- No Evidence of Carcinogenic Activity is demonstrated by studies that are interpreted as showing no chemically related increases in malignant or benign neoplasms.
- Inadequate Study of Carcinogenic Activity is demonstrated by studies that because of major qualitative or quantitative limitations cannot be interpreted as valid for showing either the presence or absence of carcinogenic activity.

When a conclusion statement for a particular experiment is selected, consideration must be given to key factors that would extend the actual boundary of an individual category of evidence. This should allow for incorporation of scientific experience and current understanding of long-term carcinogenesis studies in laboratory animals, especially for those evaluations that may be on the borderline between two adjacent levels. These considerations should include:

- The adequacy of the experimental design and conduct;
- Occurrence of common versus uncommon neoplasia;
- Progression (or lack thereof) from benign to malignant neoplasia as well as from preneoplastic lesions;
- Some benign neoplasms have the capacity to regress but others (of the same morphologic type) progress. At present, it is impossible to identify the difference. Therefore, where progression is known to be a possibility, the most prudent course is to assume that benign neoplasms of those types have the potential to become malignant;
- Combining benign and malignant tumor incidences known or thought to represent stages of progression in the same organ or tissue;
- Latency in tumor induction;
- Multiplicity in site-specific neoplasia;
- Metastases;
- Supporting information from proliferative lesions (hyperplasia) in the same site of neoplasia or in other experiments (same lesion in another sex or species);
- The presence or absence of dose relationships;
- The statistical significance of the observed tumor increase;
- The concurrent control tumor incidence as well as the historical control rate and variability for a specific neoplasm;
- Survival-adjusted analyses and false positive or false negative concerns;
- Structure-activity correlations; and
- In some cases, genetic toxicology.

These considerations together with the definitions as written should be used as composite guidelines for selecting one of the five categories. Additionally, the following concepts (as patterned from the International Agency for Research on Cancer Monographs) have been adopted by the NTP to give further clarification of these issues:

The term *chemical carcinogenesis* generally means the induction by chemicals of neoplasms not usually observed, the induction by chemicals of more neoplasms than are generally found, or the earlier induction by chemicals of neoplasms that are commonly observed. Different mechanisms may be involved in these situations. Etymologically, the term *carcinogenesis* means induction of cancer, that is, of malignant neoplasms; however, the commonly accepted meaning is the induction of various types of neoplasms or of a combination of malignant and benign neoplasms. In the Technical Reports, the words *tumor* and *neoplasm* are used interchangeably.

PEER REVIEW PANEL

The members of the Peer Review Panel who evaluated the draft Technical Report on 1,2-epoxybutane on August 19, 1986, are listed below. Panel members serve as independent scientists, not as representatives of any institution, company, or governmental agency. In this capacity, Panel members have five major responsibilities: (a) to ascertain that all relevant literature data have been adequately cited and interpreted, (b) to determine if the design and conditions of the NTP studies were appropriate, (c) to ensure that the Technical Report presents the experimental results and conclusions fully and clearly, (d) to judge the significance of the experimental results by scientific criteria, and (e) to assess the evaluation of the evidence of carcinogenicity and other observed toxic responses.

SUMMARY OF PEER REVIEW COMMENTS ON THE TOXICOLOGY AND CARCINOGENESIS STUDIES OF 1,2-EPOXYBUTANE

On August 19, 1986, the draft Technical Report on the toxicology and carcinogenesis studies of 1,2epoxybutane received peer review by the National Toxicology Program Board of Scientific Counselors' Technical Reports Review Subcommittee and associated Panel of Experts. The review meeting was held at the National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina.

Dr. J. Dunnick, NTP, introduced the studies by reviewing the experimental design, results, and proposed conclusions (clear evidence of carcinogenic activity for male rats; some evidence of carcinogenic activity for female rats; no evidence of carcinogenic activity for male or female mice). Dr. Dunnick pointed out that the conclusion for female rats in the draft report, equivocal evidence of carcinogenic activity, had been changed during final staff review based on the rarity of the papillary adenomas of the nasal cavity; this change was supported by increases in the same lesions in male rats and in previous NTP studies of propylene oxide.

Dr. Popp, a principal reviewer, agreed with the conclusions for male rats and male and female mice while questioning the new conclusion for female rats. He asked whether the conclusion in male rats was based on benign or malignant lung tumors or on a combination of the two. Dr. Dunnick replied that it was based on both carcinomas and combined adenomas or carcinomas. Dr. Popp commented that there should be mention in the text of the significance of the respiratory tract viruses identified by serology. Dr. Dunnick said that there were no lesions to indicate an active infection.

As a second principal reviewer, Dr. Perera agreed with the conclusions as presented, endorsing the chemical relatedness of the papillary adenomas of the nasal cavity in high dose female rats. Since 2-year studies with 1,3-butadiene and ethylene oxide were conducted in the same animal room, she asked for inclusion of a statement that the room air was not contaminated by these chemicals. [See page 60.]

As a third principal reviewer, Dr. Sivak agreed with the conclusions for male rats and male and female mice but thought the observation of two nasal cavity adenomas in high dose female rats was not enough to justify some evidence. Dr. S. Eustis, NIEHS, elaborated on the staff decision for the stronger level. Besides the rarity of the tumors and their occurrence in male rats, the occurrence of adenomatous hyperplasia, believed by some to be preneoplastic lesions, provided additional evidence.

Further discussion focused on the strength of the evidence for male rats. Dr. Purchase contended that the zero incidence of lung tumors in controls was low contrasted with the six tumors (6/249) observed in chamber controls in previous studies at the same laboratory. Considering the difficulty of distinguishing among pulmonary hyperplasia, adenomas, and carcinomas, he believed some evidence of carcinogenic activity was more appropriate. Dr. Paul Cammer, representing the Halogenated Solvents Industry Alliance, made a brief presentation supporting a lower level of evidence. Dr. Eustis responded that the progressive nature of the pulmonary tumor process and the consistency of diagnoses introduced through the NTP pathology quality assurance process eliminated inconsistent diagnoses. Dr. J. Huff, NIEHS, added that Program pathologists have no difficulty in differentiating among hyperplasia, benign tumors, and malignant tumors. Dr. J. Haseman, NIEHS, said that the statistical significance of the increased incidence of lung neoplasms in high dose male rats (5/49) would have been similar had the comparison been based on the historical control rate at the study laboratory (6/249) rather than on the observed tumor incidence in the concurrent controls (0/50). Dr. Hooper expressed concern about the identity of the reported 1% impurity in the study chemical. Dr. Dunnick said that more recent analyses indicated a purity of 99.9% or greater.

Dr. Popp moved that the Technical Report on 1,2-epoxybutane be accepted with the conclusions as originally written, clear evidence of carcinogenic activity for male rats, equivocal evidence of carcinogenic activity for male and female mice. Dr. Sivak seconded the motion. Dr. Perera offered an amendment to the motion that the staff's modification to some evidence of carcinogenic activity for female rats be accepted. Dr. Hooper seconded the amendment, which was defeated by six votes to three (Dr. Hooper, Dr. Mirer, and Dr. Perera), with one abstention (Dr. Purchase). The original motion was then approved by seven votes to two (Dr. Hooper and Dr. Perera), with one abstention (Dr. Purchase).

CONTRIBUTORS

The NTP Technical Report on the Toxicology and Carcinogenesis Studies of 1,2-Epoxybutane is based on the 13-week studies that began in March 1981 and ended in June 1981 and on the 2-year studies that began in November 1981 and ended in November 1983 at Battelle Pacific Northwest Laboratories.

Production, Use, and Exposure Studies in Animals Teratogenicity and Reproduction Studies Metabolism Genetic Toxicology Study Rationale

1,2-EPOXYBUTANE

CAS No. 106-88-7

 C_4H_8O

Molecular weight 72.1

Synonyms: 1-butene oxide; 1,2-butene oxide; butylene oxide; 1,2-butylene oxide; ethyl ethylene oxide; ethyl oxirane

Production, Use, and Exposure

1,2-Epoxybutane is used as a stabilizer in chlorinated hydrocarbon solvents (e.g., 1,1,1-trichloroethane, trichloroethylene, and dichloromethane); more than 75% of the compound produced is used for this purpose. Other uses include production of butylene glycol, butanolamines, and surface active agents (Hine et al., 1981; Fed. Regist., 1984). 1,2-Epoxybutane is a highly flammable and reactive chemical (Table 1). In 1978, production in the United States was estimated at 8 million pounds per year. Approximately 50,000 people are exposed annually to 1,2-epoxybutane (Fed. Regist., 1984). There are no National Institute for Occupational Safety and Health (NIOSH) administrative standards or standards from the American Conference of Government Industrial Hygienists. Manufacturers have established an 8-hour timeweighted-average (TWA) limit in the workplace of 40 ppm (Fed. Regist., 1984). The U.S. Environmental Protection Agency estimates that the atmospheric half-life for the oxidation of 1.2epoxybutane is approximately 6 days;

1,2-epoxybutane could also undergo atmospheric hydrolysis.

Studies in Animals

The oral LD_{50} in male Wistar rats is 1,170 mg/kg; the dermal LD_{50} in New Zealand rabbits is 1,740 mg/kg. A 4-hour inhalation study in Wistar rats showed an LC_{100} of 8,000 ppm (6/6 dead) and a lowest lethal concentration of 4,000 ppm (1/6 dead) (Smyth et al., 1962; Weil et al., 1963). Rats, guinea pigs, and rabbits are reported to tolerate a 7-hour exposure to epoxybutane at a concentration of 400 ppm (Hine et al., 1981). Epoxybutane (10% in acetone) applied three times per week for 540 days to the clipped skin of ICR/Ha Swiss mice did not have a toxic effect (Van Duuren et al., 1967).

Two-week and 13-week inhalation studies of 1,2epoxybutane in male and female F344 rats and B6C3F₁ mice were reported by Miller et al. (1981). In the 2-week studies, rats and mice were exposed to 1,2-epoxybutane at concentrations of 0, 400, 800, or 1,600 ppm, 6 hours per

TABLE	1.	PHYSICAL	PROPERTIES	OF	1,2	2-EPOXYBUTANE (a)	
-------	----	----------	------------	----	-----	-------------------	--

Physical description	Water-white liquid
Specific gravity at 25° C	0.826
Freezing point	Below - 60° C
Boiling point (760 mm Hg)	62.0°-64.5° C
Refractive index at 25° C	1.381
Density of saturated air (air = 1)	~0.977
Vapor density (mm Hg)	176
Solubility at 25° C (g/100 g H_2O)	~8.24
Solubility in common solvents	Miscible with common aliphatic and aromatic solvents
Flash point (closed cup)	– 15° F
Flammability limits (at 25° C and 760 mm Hg)	~1 ppm (2.94 mg/m ³) to 340 ppm (1.00 g/m ³)

(a) Hine et al., 1981; NIOSH, 1982a,b

day, 5 days per week for a total of 9 exposure days. Exposure at 1,600 ppm was fatal to mice; all rats survived. Decreased body weight gain was seen at 800 and 1,600 ppm in rats and mice. In the 13-week studies, animals were exposed at 0, 75, 150, or 600 ppm, 6 hours per day, 5 days per week for 13 weeks. Histologic examination revealed compound-related lesions in the nasal mucosa (focal thickening and flattening of the respiratory epithelium and inflammatory cells in the nasal mucosa) of rats and mice exposed at 600 ppm, whereas none was found at 75 or 150 ppm. Body weight gain was lower at 600 ppm in female rats and in male and female mice; survival of dosed groups was comparable to that of controls. No data on long-term toxicity have been reported.

Teratogenicity and Reproduction Studies

Sikov et al. (1980) reported a teratogenicity study in Wistar rats and New Zealand white rabbits. Female rats were exposed by inhalation to epoxybutane 7 hours per day, 5 days per week for 3 weeks prior to mating, and from day 0 to 19 of gestation at 0, 250, or 1,000 ppm. Animals were evaluated at gestation day 21. The only maternal toxicity observed in the high dose group was a slight decrease in body weight relative to that of the controls; no teratogenic effects were seen in any exposed group. Artificially inseminated rabbits were exposed to epoxybutane at 0, 250, or 1,000 ppm 7 hours per day from gestation day 0 to 24; animals were examined at gestation day 30. Some maternal deaths occurred at both exposure concentrations, but no teratogenic effects were seen. The pregnancy rate was reduced in the high dose group.

Reproductive studies have not been reported, although Miller et al. (1981) noted no histopathologic abnormalities in the reproductive organs of male and female F344 rats or B6C3F₁ mice exposed to 1,2-epoxybutane at 600 ppm for 13 weeks.

Metabolism

The metabolism of 1,2-epoxybutane has not been studied extensively. Jones (1975) suggested that epoxides are detoxified in vivo by conjugation with glutathione. In one study in which 1,2epoxybutane was administered as a single dose to rats (1.9 mmol/kg), 11% of the original dose was excreted in the urine as 2-hydroxybutyl mercapturic acid (James et al., 1968).

Genetic Toxicology

There are extensive data in the literature on the mutagenicity of 1,2-epoxybutane. In general, the compound exhibited mutagenic activity across a wide spectrum of species ranging from bacteria to mammals. 1,2-Epoxybutane induced gene mutations in Klebsiella pneumoniae in the absence of metabolic activation (Voogd et al... 1981; Knaap et al., 1982) and exhibited strainspecific mutagenic activity that was sometimes dependent on S9 metabolic activation in tests with Escherichia coli (McMahon et al., 1979; McCarroll et al., 1981; De Flora et al., 1984). In tests with Salmonella typhimurium, 1,2-epoxybutane induced gene reversion, usually at doses above 500 µg/plate, in strains TA100, TA100-FR1, TA1535, and TA1530, all of which indicate base-pair substitutions (McCann and Ames, 1976; Rosenkranz and Speck, 1975, 1976; Chen et al., 1975; Speck and Rosenkranz, 1976; Henschler et al., 1977; Wade et al., 1978; De Flora, 1979; Weinstein et al., 1981) but not in strains TA1536, TA1537, TA1538, TA98, C3076, or D3052, which are used to detect frame-shift mutations (Rosenkranz and Poirier, 1979; Simmon, 1979a; McMahon et al., 1979; Katz et al., 1980; De Flora, 1981; De Flora et al., 1984). Similarly, the NTP found 1,2-epoxybutane at doses of 1,000 µg and above to be mutagenic in S. typhimurium strains TA100 and TA1535 with a preincubation protocol with and without S9 from the livers of Aroclor 1254-induced male Sprague Dawley rats and male Syrian hamsters; the compound did not cause gene reversion in strains TA1537 and TA98 (Canter et al., 1986; Appendix E, Table E1).

1,2-Epoxybutane produced a dose-related increase in gene mutations in *Neurospora crassa* (Kolmark and Giles, 1955) and in *Schizosaccharomyces pombe* (Migliore et al., 1982; Rossi et al., 1983), as well as an increase in the frequency of mitotic recombination in *Saccharomyces cerevisiae* (Simmon, 1979b) with and without S9. Conflicting results have been reported in the Drosophila sex-linked recessive lethal assays which are probably related to differences in dose or route of administration. McGregor (1981) reported no increase in sex-linked recessive lethal mutations following inhalation of 1,2-epoxybutane at 1,000 ppm over a period of 7 hours, whereas induction of sex-linked recessive lethal mutations was observed by Knaap et al. (1982) following an injection of 117-233 mM solutions of the chemical. NTP studies showed that 1,2epoxybutane fed for 72 hours to male Drosophila at doses of 50,000 or 60,000 ppm caused significant increases in the number of sex-linked recessive lethal mutations and reciprocal translocations in the germ cells (Yoon et al., 1985; Tables E5 and E6).

The results of assays in mouse L5178Y lymphoma cells in the absence of exogenous metabolic activation were positive for induction of gene mutations (Amacher et al., 1980; Knaap et al., 1982). The results of NTP-sponsored mouse lymphoma assays, both in the presence and absence of Aroclor 1254-induced F344 rat liver S9, confirmed the mutagenicity of 1,2-epoxybutane in these L5178Y cells (Table E2). In Chinese hamster ovary cells, 1,2-epoxybutane produced a strong, dose-related increase in the number of sister chromatid exchanges (SCEs) in the presence and absence of Aroclor 1254-induced male Sprague Dawley rat liver S9, as well as an increase in the frequency of chromosomal

aberrations (Tables E3 and E4). Because the increase in chromosomal aberrations in the absence of S9 activation, although significant, occurred at doses that were severely toxic to the cells and resulted in poor chromosomal morphology, the overall results of the assay were judged to be "weakly positive." Treatment of human fibroblast cell cultures with up to 84 µg/ml 1,2epoxybutane in the presence of S9 did not induce unscheduled DNA synthesis (UDS) (McGregor, 1981); neither was UDS induced after exposure of rat hepatocyte cultures to 1,2-epoxybutane at 10 mg/ml in the absence of S9 (Williams et al., 1982). In vivo mammalian tests for genotoxicity were also negative. No sperm abnormalities were induced in male mice after inhalation exposure at up to 1,000 ppm 1,2-epoxybutane for 7 hours per day for 5 consecutive days, and no dominant lethal mutations were observed in rats after similar exposures (McGregor, 1981).

Study Rationale

1,2-Epoxybutane was selected for toxicology and carcinogenesis studies because it was representative of the short-chain epoxides and had a relatively high volume of production and because no carcinogenicity data were available for this chemical. The inhalation route was selected to mimic the potential human exposure in the workplace.

Clinical Examinations and Pathology

Statistical Methods

PROCUREMENT AND CHARACTERIZATION OF 1,2-EPOXYBUTANE

1,2-Epoxybutane was obtained in two lots from Dow Chemical Company (Richmond, Virginia) (Table 2). Purity and identity analyses of the bulk chemical were conducted at Midwest Research Institute (MRI) (Kansas City, Missouri). (MRI reports on the analyses performed in support of the epoxybutane studies are on file at NIEHS.) Both lots of study material were a clear, colorless liquid with a boiling point of 63°C. Each lot was identified as 1,2-epoxybutane by infrared, ultraviolet/visible, and nuclear magnetic resonance spectroscopy. Infrared and nuclear magnetic resonance spectra were consistent with the structure and with literature spectra. (See Figures 1 through 4 for representative spectra.) The ultraviolet/visible spectrum was consistent with the structure of 1.2-epoxybutane; no absorbance was found in the visible region.

Purity of both lots used in the study was determined by elemental analysis, Karl Fischer water analysis, titration of the epoxide group by hydrogen iodide generated in situ from tetrabutylammonium iodide with perchloric acid, and gas chromatography. Gas chromatographic analysis was performed with flame ionization detection and either a Carbopack C/0.1% SP1000, 80/100, 1.8 m \times 4 mm ID glass column (system 1) or a Tenax-GC, 60/80, 1.8 m \times 4 mm ID glass column (system 2). Cumulative data indicated a purity of greater than 99% for both lots used in these studies. Results of elemental analysis of both lots were consistent with theoretical values. Water content by Karl Fischer titration ranged from 0.016% to 0.03%. Nonaqueous titration of the epoxide group gave a purity of 92.4% for lot no. MM10258 and 96.5% for lot no. RR810402. These titration values are considered to be inaccurate due to the inherent difficulties in this type of titration analysis. Gas chromatographic analyses of both lots by the two systems listed above detected a single homogeneous major peak and no impurities with peak areas greater than 0.1% of that of the major peak in either lot. A retrospective analysis of both lots by gas chromatography/mass spectroscopy indicated a purity of greater than 99% and only one impurity (identified as 1,2-butanediol and found to be present at less than 0.2%) in each lot.

Stability studies of the bulk chemical were run for 2 weeks at -20° to 60° C. Analysis by gas chromatography with system 1 indicated that 1,2-epoxybutane was stable as a bulk chemical when kept for 2 weeks at temperatures up to 60° C. Further confirmation of the stability of the bulk chemical (stored at room temperature) during the toxicology and carcinogenesis studies was obtained by periodic gas chromatographic analysis with a Porapak QS, 2.3 m \times 2 mm ID glass column. No degradation was seen over the course of the studies. The identity of the chemical at the study laboratory was confirmed by infrared spectroscopy.

GENERATION AND MEASUREMENT OF CHAMBER CONCENTRATIONS

Vapor Generation System

The liquid to be vaporized was contained in a 1.6-liter stainless steel reservoir housed in a vapor hood in the exposure room (Figure 5). The liquid was pumped from this reservoir to a stainless steel cylinder covered with a glass fiber wick from which the liquid was vaporized (Decker et al., 1982) (Figure 6). An 80-watt heater and a temperature-sensing element were incorporated within the cylinder. The heater maintained the vaporizer at approximately 58° C. The surface temperature of the vaporizer was slightly lower. To minimize material loss due to condensation on duct walls, each cylindrical vaporizer was positioned in the fresh air duct leading directly into the exposure chamber.

Vapor Concentration Monitoring

Two online methods were used during the course of the 2-year studies to monitor the

concentration of 1,2-epoxybutane in the chambers. A schematic diagram of the monitoring system is shown in Figure 7. Initially, a photoionization detector (model PI201, HNU Systems, Inc., Newton, Massachusetts) was used. On May 21, 1982, the photoionization detector was replaced by a gas chromatograph (HP-5710 or HP-5840) equipped with a flame ionization detector, a nickel column packed with 1% SP1000 on Carbopack B, and an automatic sampling valve. All exposure chambers and the room air were sampled approximately twice during each exposure hour. Starting December 22, 1981, a standard gas, 25 ppm propylene in air, was used to establish instrument performance. The calibration of the monitoring photoionization detector and gas chromatograph was confirmed and corrected as necessary by periodic assay of grab samples taken from the chambers and analyzed on a second gas chromatograph. Weekly mean exposure concentrations for the 2-year studies are presented in Figures 8 through 11. A summary of the chamber concentrations is presented in Table 3; Table 4 summarizes the distribution of the mean daily concentrations.

Vapor Concentration Uniformity in Chamber

Uniformity of vapor concentration in each exposure chamber was measured with a portable photoionization detector periodically throughout the studies. The data showed that when expressed as a percentage of the normalized average concentration of all 12 sampling positions, the standard deviation did not exceed 5% for all but two measurements. (For those two measurements, the standard deviation was within 10%.)

Degradation Study of 1,2-Epoxybutane in Chamber

Samples of the atmosphere in the 1,2-epoxybutane exposure chamber were examined for the occurrence of potential degradation products, specifically 1,2-butandiol. Through the use of a Hewlett Packard model 5840A gas chromatograph equipped with a flame ionization detector and a 6 ft \times 4 mm ID glass column packed with 10% Carbowax 20M on 80/100 Chromosorb WAW, a single homogeneous peak was observed; no evidence for any degradation was detected. It is concluded from this study that the 1,2-epoxybutane vapor generated during these studies was at least 99% pure.

SINGLE-EXPOSURE STUDIES

Male and female F344/N rats and B6C3F₁ mice were obtained from Charles River Breeding Laboratories and observed for 22-23 days before the studies began. The animals were 7-9 weeks old when placed on study. A high exposure concentration of 8,000 ppm (target concentration) was selected based on an estimate of LC_{100} of 8,000 ppm in rats (Weil et al., 1963). Mice were exposed at 4,000 ppm 1 day earlier than mice at the other exposure concentrations, and because all mice died at this concentration, mice were not included in the 8,000-ppm (target concentration) groups.

Groups of five rats and mice of each sex were exposed for 4 hours to air containing 1,2-epoxybutane concentrations of 398, 721, 1,420, 2,050, and (for rats only) 6,550 ppm. These concentrations were lower than the target concentrations of 500, 1,000, 2,000, or 4,000 ppm because of a

malfunctioning detector. Controls were not used. Animals were weighed before exposure and were observed three times per day throughout the 14-day observation period. Necropsies were not performed on the animals. Details of animal maintenance are presented in Table 5.

FOURTEEN-DAY STUDIES

Male and female F344/N rats and $B6C3F_1$ mice were obtained from Charles River Breeding Laboratories and observed for 27 days before being placed on study. The animals were 8-10 weeks old when the studies began.

Groups of five rats and mice of each sex were exposed to air containing 1,2-epoxybutane at target concentrations of 0, 400, 800, 1,600, 3,200, or 6,400 ppm for 6 hours per day, 5 days per week for 14 days (10 exposures). (Although the results of the single-exposure studies suggested the use of lower concentrations in the 14-day studies in mice, a decision was made to use the same exposure concentrations for both species, so that all animals could be accommodated in the same exposure chambers.) Rats and mice were observed three times daily and were weighed before exposure, after 1 week, and at necropsy. A necropsy was performed on all animals. Details of animal maintenance are presented in Table 5.

THIRTEEN-WEEK STUDIES

Thirteen-week studies were conducted to evaluate the cumulative toxic effects of repeated exposure to 1,2-epoxybutane and to determine the concentrations to be used in the 2-year studies.

Male and female F344/N rats and $B6C3F_1$ mice were obtained from Charles River Breeding Laboratories, observed for 20-21 days, and assigned to groups according to tables of random numbers. Feed was available ad libitum during nonexposure periods; water was available at all times.

Groups of 10 rats and 10 mice of each sex were exposed to air containing 1,2-epoxybutane at target concentrations of 0, 50, 100, 200, 400, or 800 ppm, 6 hours per day, 5 days per week for 13 weeks (65 exposures). Further experimental details are summarized in Table 5.

TABLE 5. EXPERIMENTAL DESIGN AND MATERIALS AND METHODS IN THE INHALATION STUDIESOF 1,2-EPOXYBUTANE (Continued)

Animals were checked twice per day; moribund animals were killed. Individual animal weights were recorded weekly. At the end of the 13-week studies, survivors were killed. A necropsy was performed on all animals except those excessively autolyzed or cannibalized. Tissues and groups examined are listed in Table 5.

TWO-YEAR STUDIES

Study Design

Groups of 50 rats of each sex were exposed to air containing 1,2-epoxybutane at concentrations of 0 (chamber controls), 200, or 400 ppm, 6 hours per day, 5 days per week for 103 weeks. Groups of 50 mice of each sex were exposed to 1,2-epoxybutane at concentrations of 0, 50, or 100 ppm on the same schedule for 102 weeks. Actual concentrations are summarized in Tables 3 and 4 and Figures 8 to 11.

Source and Specifications of Animals

The male and female F344/N rats and B6C3F1 (C57BL/6N, female \times C3H/HeN MTV⁻, male) mice used in these studies were produced under strict barrier conditions at Charles River Breeding Laboratories under a contract to the Carcinogenesis Program. Breeding stock for the foundation colonies at the production facility originated at the National Institutes of Health Repository. Animals shipped for study were progeny of defined microflora-associated parents that were transferred from isolators to barrier-maintained rooms. Animals were shipped to the study laboratory at 4-6 weeks of age and were quarantined for 3 weeks. Thereafter, a complete necropsy was performed on five animals of each sex and species to assess their health status. The rodents were placed on study at 7-9 weeks of age.

Animal Maintenance

All animals were housed individually in Hazleton chambers throughout the study. Feed and water were available ad libitum except during exposure periods; water was available at all times. Details of animal maintenance are given in Table 5. Serologic analyses were performed as described in Appendix F.

Clinical Examinations and Pathology

All animals were observed two times per day, and clinical signs were recorded once per month. Individual body weights were recorded once per week for the first 13 weeks of the studies and once per month thereafter. Mean body weights were calculated for each group. Animals found moribund and those surviving to the end of the studies were humanely killed. A necropsy was performed on all animals including those found dead, unless they were excessively autolyzed or cannibalized, missexed, or found missing. Thus, the number of animals from which particular organs or tissues were examined microscopically varies and is not necessarily equal to the number of animals that were placed on study.

During necropsy, all organs and tissues were examined for grossly visible lesions. Tissues were preserved in 10% neutral buffered formalin, embedded in paraffin, sectioned, and stained with hematoxylin and eosin. Tissues examined microscopically are listed in Table 5.

When the pathology evaluation was completed, the slides, paraffin blocks, and residual wet tissues were sent to the NTP Archives for inventory, slide/block match, and wet tissue audit. The slides, individual animal data records, and pathology tables were sent to an independent quality assessment laboratory. The individual animal records and tables were compared for accuracy, slides and tissue counts were verified, and histotechnique was evaluated. All tumor diagnoses, all target tissues, and all tissues from a randomly selected 10% of the animals were evaluated by a quality assessment pathologist. The quality assessment report and slides were submitted to the Pathology Working Group (PWG) Chairperson, who reviewed all target tissues and those for which there was a disagreement between the laboratory and quality assessment pathologists.

Representative slides selected by the Chairperson were reviewed by the PWG, which includes the laboratory pathologist, without knowledge of previously rendered diagnoses. When the consensus diagnosis of the PWG differed from that of the laboratory pathologist, the laboratory pathologist was asked to reconsider the original diagnosis. This procedure has been described, in
part, by Maronpot and Boorman (1982) and Boorman et al. (1985). The final diagnoses represent a consensus of contractor pathologists and the NTP Pathology Working Group. For subsequent analysis of pathology data, the diagnosed lesions for each tissue type are combined according to the guidelines of McConnell et al. (1986).

Slides/tissues are generally not evaluated in a blind fashion (i.e., without knowledge of dose group) unless lesions in question are subtle or unless there is inconsistent diagnosis of lesions by the laboratory pathologist. Nonneoplastic lesions are not examined routinely by the quality assessment pathologist or PWG unless they are considered part of the toxic effect of the chemical.

Statistical Methods

Data Recording: Data on this experiment were recorded in the Carcinogenesis Bioassay Data System (Linhart et al., 1974). The data elements include descriptive information on the chemicals, animals, experimental design, survival, body weight, and individual pathologic results, as recommended by the International Union Against Cancer (Berenblum, 1969).

Survival Analyses: The probability of survival was estimated by the product-limit procedure of Kaplan and Meier (1958) and is presented in the form of graphs. Animals were censored from the survival analyses at the time they were found to be missing or dead from other than natural causes; animals dying from natural causes were not censored. Statistical analyses for a possible dose-related effect on survival used the method of Cox (1972) for testing two groups for equality and Tarone's (1975) life table test for a doserelated trend. When significant survival differences were detected, additional analyses using these procedures were carried out to determine the time point at which significant differences in the survival curves were first detected. All reported P values for the survival analysis are two-sided.

Calculation of Incidence: The incidence of neoplastic or nonneoplastic lesions is given as the ratio of the number of animals bearing such lesions at a specific anatomic site to the number of animals in which that site was examined. In most instances, the denominators include only those animals for which the site was examined histologically. However, when macroscopic examination was required to detect lesions (e.g., skin or mammary tumors) prior to histologic sampling, or when lesions could have appeared at multiple sites (e.g., lymphomas), the denominators consist of the number of animals on which a necropsy was performed.

Analysis of Tumor Incidence: Three statistical methods are used to analyze tumor incidence data. The two that adjust for intercurrent mortality employ the classical method for combining contingency tables developed by Mantel and Haenszel (1959). Tests of significance included pairwise comparisons of high dose and low dose groups with controls and tests for overall doseresponse trends.

For studies in which compound administration has little effect on survival, the results of the three alternative analyses will generally be similar. When differing results are obtained by the three methods, the final interpretation of the data will depend on the extent to which the tumor under consideration is regarded as being the cause of death. Continuity-corrected tests were used in the analysis of tumor incidence, and reported P values are one-sided.

Life Table Analysis--The first method of analysis assumed that all tumors of a given type observed in animals dying before the end of the studies were "fatal"; i.e., they either directly or indirectly caused the death of the animal. According to this approach, the proportions of tumor-bearing animals in the dosed and control groups were compared at each point in time at which an animal died with a tumor of interest. The denominators of these proportions were the total number of animals at risk in each group. These results, including the data from animals killed at the end of the studies, were then combined by the Mantel-Haenszel method to obtain an overall P value. This method of adjusting for intercurrent mortality is the life table method of Cox (1972) and of Tarone (1975). The underlying variable considered by this analysis is time to death due to tumor. If the tumor is rapidly lethal, then time to death due to tumor closely approximates time to tumor onset. In this case,

the life table test also provides a comparison of the time-specific tumor incidences.

Incidental Tumor Analysis--The second method of analysis assumed that all tumors of a given type observed in animals that died before the end of the studies were "incidental"; i.e., they were merely observed at necropsy in animals dying of an unrelated cause. According to this approach, the proportions of tumor-bearing animals in dosed and control groups were compared in each of five time intervals: weeks 0-52, weeks 53-78, weeks 79-92, week 93 to the week before the terminal-kill period, and the terminal-kill period. The denominators of these proportions were the number of animals actually examined for tumors during the time interval. The individual time interval comparisons were then combined by the previously described method to obtain a single overall result. (See Haseman, 1984, for the computational details of both methods.)

Unadjusted Analyses--Primarily, survival-adjusted methods are used to evaluate tumor incidence. In addition, the results of the Fisher exact test for pairwise comparisons and the Cochran-Armitage linear trend test (Armitage, 1971; Gart et al., 1979) are given in the appendixes containing the analyses of primary tumor incidence. These two tests are based on the overall proportion of tumor-bearing animals and do not adjust for survival differences.

Historical Control Data: Although the concurrent control group is always the first and most appropriate control group used for evaluation, there are certain instances in which historical control data can be helpful in the overall assessment of tumor incidence. Consequently, control tumor incidences from the NTP historical control data base (Haseman et al., 1984, 1985) are included for those tumors appearing to show compound-related effects.

Body Weights and Clinical Signs Survival Pathology and Statistical Analyses of Results

SINGLE-EXPOSURE STUDIES

All rats exposed at 6,550 ppm died during the exposure period. No other deaths occurred. Final body weights were not taken, and necropsies were not performed. Clinical signs observed in males and females at 2,050 and 6,550 ppm were ocular discharge and dyspnea. Rats had signs of eye irritation during exposure at 1,400 ppm. A top exposure concentration of 6,400 ppm was selected for the 14-day studies in order to have an exposure concentration at which target organs could be identified.

FOURTEEN-DAY STUDIES

All rats exposed at 3,200 or 6,400 ppm and 2/5

female rats exposed at 1,600 ppm died before the end of the studies (Table 6). The final mean body weight of rats exposed at 800 or 1,600 ppm was 12% or 33% lower than that of the controls for males and 12% or 17% lower for females. Erratic movements and piloerection were compoundrelated effects in rats exposed at 1,600 ppm. Multifocal pulmonary hemorrhage of moderate severity was observed in 2/2 males and 1/2 females exposed at 1,600 ppm. Acute suppurative rhinitis of moderate severity was observed in 2/2males and 2/2 females exposed at 1,600 ppm. Controls were not examined microscopically. Because of body weight effects and/or mortality at 1,600 ppm and above, the highest exposure concentration selected for the 13-week studies was 800 ppm.

(h) Day of death: 2,2,2,2,3

THIRTEEN-WEEK STUDIES

No compound-related deaths occurred (Table 7). The final mean body weight of rats exposed at 800 ppm was 23% lower than that of the controls for males and 16% lower for females. No compound-related clinical signs were observed. Liver weight to body weight ratios were similar in dosed and control rats (Table 8). Inflammation of the nasal cavity was seen in all rats that received 1,2-epoxybutane at 800 ppm but not at lower concentrations. The inflammation was present primarily in the dorsal and lateral portions of the nasal cavity and affected the respiratory and olfactory epithelium. The lesion was characterized by lymphocytic and neutrophilic infiltration of the mucosa and accumulation of purulent exudate in the lumen of the nasal cavity, with focal loss of epithelial cells from the mucosa.

Dose Selection Rationale: Because of the lower body weight gain and nasal cavity inflammation at 800 ppm, 1,2-epoxybutane concentrations selected for rats for the 2-year studies were 200 and 400 ppm.

TWO-YEAR STUDIES

Body Weights and Clinical Signs

Mean body weights of exposed and control male rats were similar until week 86; thereafter, mean body weights of high dose male rats were 4%-8% lower than those of the controls (Table 9

and Figure 12). Mean body weights of high dose female rats were 5%-10% lower than those of the controls after week 22. No compound-related clinical signs were observed in either males or females.

1

FIGURE 12. GROWTH CURVES FOR RATS EXPOSED TO 1,2-EXOPYBUTANE BY INHALATION FOR TWO YEARS

Survival

Estimates of the probabilities of survival for male and female rats exposed to 1,2-epoxybutane by inhalation at the concentrations used in these studies and for controls are shown in Table 10 and in the Kaplan and Meier curves in Figure 13. The survival of the low dose groups of both male (after week 101) and female (after week 90) rats was significantly lower than that of the control groups.

Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of rats with neoplastic or nonneoplastic lesions of the nasal cavity, lung, hematopoietic system, thyroid gland, anterior pituitary gland, and preputial gland.

Lesions in male rats are summarized in Appendix A. Histopathologic findings on neoplasms are summarized in Table A1. Table A2 gives the survival and tumor status for individual male rats. Table A3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table A3 (footnotes). Historical incidences of tumors in control male rats are listed in Table A4. Findings on nonneoplastic lesions are summarized in Table A5.

Lesions in female rats are summarized in Appendix B. Histopathologic findings on neoplasms are summarized in Table B1. Table B2 gives the survival and tumor status for individual female rats. Table B3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table B3 (footnotes). Historical incidences of tumors in control female rats are listed in Table B4. Findings on nonneoplastic lesions are summarized in Table B5.

FIGURE 13. KAPLAN-MEIER SURVIVAL CURVES FOR RATS EXPOSED TO 1,2-EPOXYBUTANE BY INHALATION FOR TWO YEARS

44

Nasal Cavity: Suppurative and serous inflammation, hyperplasia of the respiratory epithelium, and squamous metaplasia were observed at increased incidences in exposed male and female rats (Table 11). Suppurative inflammation was characterized by the presence of neutrophils within the nasal cavity and mucosa; serous inflammation consisted of an eosinophilic proteinaceous material containing few inflammatory cells within the lumen of the nasal cavity. Other inflammatory lesions with lymphocyte and macrophage infiltrates were diagnosed as unspecified inflammation. Epithelial hyperplasia consisted of diffuse crowding of epithelial cells and increased thickness of the respiratory epithelium. In focal areas, nodular proliferation of respiratory epithelium formed glandlike structures that were diagnosed as adenomatous hyperplasia. Squamous metaplasia was a focal or multifocal lesion that occurred frequently within the respiratory epithelium, especially in the anterior section of the nasal cavity. Atrophy of the olfactory sensory epithelium was observed at increased incidences in exposed male and female rats. Hyperostosis of the nasal turbinate bone, consisting of a periosteal cell proliferation and new bone formation, was observed at increased frequency in high dose male rats.

The incidence of papillary adenomas in high dose male rats was significantly greater than that in the controls (Table 12). These tumors were exophytic papillary growths of a cuboidal to columnar nonciliated epithelium which were attached to the underlying mucosa by thin stalks or broad bases. There was no evidence of local invasive growth by these adenomas. Papillary adenomas were observed in two high dose female rats.

Lung: Alveolar/bronchiolar carcinomas and alveolar/bronchiolar adenomas or carcinomas (combined) in male rats occurred with significant positive trends; the incidences in the high dose group were significantly greater than those in the controls (Table 13). The incidences of adenomas or carcinomas (combined) in female rats were as follows: control, 2/50; low dose, 0/49; high dose, 1/50.

Hematopoietic System: The incidence of mononuclear cell leukemia was significantly greater by the life table test (P=0.011) in low dose (but not in high dose) male rats than that in the controls (control, 25/50; low dose, 31/50; high dose, 22/50).

TABLE 12. ANALYSIS OF NASAL CAVITY PAPILLARY ADENOMAS IN RATS IN THE TWO-YEARINHALATION STUDIES OF 1,2-EPOXYBUTANE (a)

(a) The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix A, Table A3 (footnotes).
(b) Historical incidence of nasal cavity neoplasms in chamber controls at study laboratory: 0/249; historical incidence in untreated controls in NTP studies: 2/1,977 (0.1%)

(c) No P value is reported because no tumors were observed in the 200-ppm and control groups.

(d) Historical incidence of nasal cavity neoplasms in chamber controls at study laboratory: 0/249; historical incidence in untreated controls in NTP studies: 1/2,021 (0.05%)

Adenoma or Carcinoma (b)			
Overall Rates	0/50 (0%)	2/50 (4%)	5/49 (10%)
Adjusted Rates	0.0%	8.9%	17.6%
Terminal Rates	0/30 (0%)	1/18 (6%)	3/23 (13%)
Week of First Observation		100	95
Life Table Tests	P = 0.013	P = 0.161	P = 0.022
Incidental Tumor Tests	P=0.019	P = 0.234	P = 0.036

(a) Historical incidence in chamber controls at study laboratory (mean \pm SD): 4/249 (2% \pm 2%); historical incidence in untreated controls in NTP studies: 14/1,973 (0.7% \pm 1%)

(b) Historical incidence in chamber controls at study laboratory (mean \pm SD): 6/249 (2% \pm 0.9%); historical incidence in untreated controls in NTP studies: 38/1,973 (2% \pm 2%)

Thyroid Gland: Follicular cell adenomas or carcinomas (combined) in female rats occurred with a significant positive trend by the life table test (P=0.043) but not by the incidental tumor test (the more appropriate test for analysis of these nonfatal tumors); the incidences in the dosed groups were not significantly greater than that in the controls (control, 0/45; low dose, 1/48; high dose, 3/48). Follicular cell hyperplasia was not observed in either control or high dose rats.

Anterior Pituitary Gland: Adenomas in female rats occurred with a significant positive trend, and the incidence in the high dose group was significantly greater than that in the controls (Table 14). The incidences of adenomas or carcinomas (combined) are significant by the life table test but not by the incidental tumor test (the latter test is considered more appropriate for analysis of nonfatal tumors).

Preputial Gland: The incidences of adenomas, carcinomas, or squamous cell carcinomas (combined) in male rats (control, 3/50; low dose, 3/50; high dose, 8/50) were marginally significant by the life table trend test (P=0.050) but not by the incidental tumor trend test (the more appropriate test for analysis of these nonfatal tumors). The incidence in the high dose group was not significantly greater than that in the controls.

(a) Historical incidence in chamber controls at study laboratory (mean \pm SD): 123/241 (51% \pm 7%); historical incidence in untreated controls in NTP studies: 931/1,952 (48% \pm 11%)

SINGLE-EXPOSURE STUDIES

All mice exposed at 2,050 ppm, 4/5 males and 4/5 females exposed at 1,420 ppm, and 1/5 males exposed at 398 ppm died before the end of the studies (Table 15). Final body weights were not taken, and necropsies were not performed. Dyspnea was seen in mice exposed at 2,050 ppm. During exposure, mice exposed at 1,420 ppm were restless and showed signs of eye irritation. Mice were housed in the same exposure chambers as rats.

FOURTEEN-DAY STUDIES

All mice exposed at concentrations of 1,600 ppm or higher and 1/5 males exposed at 800 ppm died before the end of the studies (Table 16). Clinical signs observed in mice at 800 ppm included dyspnea and listlessness on the first exposure day. The final mean body weights of mice exposed at 800 ppm were lower than the initial weights. Moderate nephrosis was observed in 2/2 males exposed at 1,600 ppm. Mild to slight nephrosis was observed in 2/2 males and 1/2 females exposed at 800 ppm. Controls were not examined microscopically. Because of mortality at 1,600 ppm and above, the highest exposure concentration selected for the 13-week studies was 800 ppm.

THIRTEEN-WEEK STUDIES

All mice exposed at 800 ppm died before the end of the studies (Table 17). Final mean body weights were not affected by exposure to 1,2epoxybutane. Mice exposed at 800 ppm were listless during and after the first day of exposure; clinical signs were not seen at lower doses. The liver weight to body weight ratio of female mice that received 400 ppm was significantly lower than that of the controls (Table 18). Renal tubular necrosis was seen in 6/10 males and 8/10 females exposed at 800 ppm but not at lower exposure concentrations. Inflammation of the nasal turbinates was observed in all mice exposed at 200 ppm or higher, in 0/10 males and 7/10 females exposed at 100 ppm, and in none of the controls. Renal and upper respiratory tract changes were considered to be compound related.

TABLE 15. SURVIVAL OF MICE IN THE SINGLE-EXPOSURE INHALATION STUDIES OF1,2-EPOXYBUTANE

Concentration (ppm)	Male (a)	Female (b)
398	(c) 4/5	5/5

TABLE 18. ABSOLUTE AND RELATIVE LIVER WEIGHTS OF MICE IN THE THIRTEEN-WEEK INHALATION STUDIES OF 1,2-EPOXYBUTANE (a)

(a) Mean ± standard deviation; P values are versus the controls by Dunnett's test (Dunnett, 1955).

(b) P<0.01

(c) P<0.05

Dose Selection Rationale: Because all mice exposed at 800 ppm died and because the respiratory tract lesions at 200 ppm and above were considered potentially life threatening, exposure concentrations selected for mice for the 2-year studies were 50 and 100 ppm 1,2-epoxybutane.

TWO-YEAR STUDIES

Body Weights and Clinical Signs

Mean body weights of high dose male mice were generally higher than those of the controls until week 47 and 10%-14% lower after week 69 (Table 19 and Figure 14). Mean body weights of low dose male mice were generally higher than those of the controls until week 69 and 4%-8% lower after week 86. Mean body weights of high dose female mice were 13%-23% lower than those of the controls after week 60. Mean body weights of low dose female mice were 12%-16% lower than those of the controls after week 73. Female mice at 100 ppm were inactive and listless during the last 2 months on study; no other doserelated clinical signs were observed in either males or females.

TABLE 19. MEAN BODY WEIGHTS AND SURVIVAL OF MICE IN THE TWO-YEAR INHALATION STUDIES OF 1,2-EPOXYBUTANE

(a) Nine survivors but only eight were weighed

FIGURE 14. GROWTH CURVES FOR MICE EXPOSED TO 1,2-EPOXYBUTANE BY INHALATION FOR TWO YEARS

Survival

Estimates of the probabilities of survival for male and female mice exposed to 1,2-epoxybutane by inhalation at the concentrations used in these studies and for controls are shown in Table 20 and in the Kaplan and Meier curves in Figure 15. The survival of the high dose female group was significantly lower than that of the controls after week 69. The survival of the high dose groups of males (P=0.002) and females (P<0.001) was significantly lower than that of the low dose groups.

Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of mice with neoplastic or nonneoplastic lesions of the respiratory epithelium of the nasal cavity, nasal gland (Bowman's glands), nasolacrimal duct, olfactory sensory epithelium, ovary, uterus, and pituitary gland. Lesions in male mice are summarized in Appendix C. Histopathologic findings on neoplasms are summarized in Table C1. Table C2 gives the survival and tumor status for individual male mice. Table C3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table C3 (footnotes). Findings on nonneoplastic lesions are summarized in Table C4.

Lesions in female mice are summarized in Appendix D. Histopathologic findings on neoplasms are summarized in Table D1. Table D2 gives the survival and tumor status for individual female mice. Table D3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table D3 (footnotes). Historical incidences of tumors in control female mice are listed in Table D4. Findings on nonneoplastic lesions are summarized in Table D5.

FIGURE 15. KAPLAN-MEIER SURVIVAL CURVES FOR MICE EXPOSED TO 1,2-EPOXYBUTANE BY INHALATION FOR TWO YEARS

Nasal Cavity, Nasal Gland, Nasolacrimal Duct, and Olfactory Sensory Epithelium: Empyema and chronic inflammation were diagnosed by the study pathologist to describe the presence of suppurative exudate in the nasal cavity and infiltration of the nasal mucosa with lymphocytes and macrophages. Erosion, respiratory epithelial regeneration and hyperplasia, and squamous metaplasia were observed at increased incidences in dosed male and dosed female mice (Table 21).

Cysts and hyperplasia of the nasal gland (Bowman's glands in the respiratory mucosa), suppurative and chronic inflammation and epithelial hyperplasia of the nasolacrimal duct, and atrophy of the olfactory sensory epithelium were also observed at increased incidences in dosed mice. A single squamous cell papilloma was seen in the incisive duct of one high dose male mouse.

Ovary or Uterus: Suppurative inflammation (primarily ovarian abscesses) of the uterus and/or ovary was present in all dosed groups (uterus: vehicle control, 6/50; low dose, 11/49; high dose, 7/48; ovary: 7/49; 20/47; 21/45). These lesions were cultured from one control, four low dose, and four high dose animals. Klebsiella oxytoca was isolated from each lesion.

Pituitary Gland: Adenomas or carcinomas (combined) in female mice occurred with a significant negative trend (P=0.018 by the incidental tumor test; control, 22/47; low dose, 12/46; high dose, 5/46).

1,2-Epoxybutane, NTP TR 329

56

IV. DISCUSSION AND CONCLUSIONS

Study Rationale Short-Term Studies Two-Year Studies in Rats Two-Year Studies in Mice Genetic Toxicology Data Audit Conclusions

Study Rationale

1,2-Epoxybutane was selected for study because it was a representative of the simple short-chain epoxides, a class of compounds that was suspected to contain carcinogens because other epoxides had been shown to be carcinogens (IARC, 1976). The chemical (greater than 99% pure) was administered as a vapor to F344/N rats and B6C3F1 mice in a series of short-term and 2-year studies by the inhalation route to mimic worker exposure. There is currently no threshold limit value for this chemical, although the manufacturer has established an 8-hour TWA of 40 ppm (Fed. Regist., 1984). The highest concentration used in the 2-year rat studies (400 ppm; 1,178 mg/m³) is 10 times this TWA, and the highest concentration used in the mouse studies (100 ppm; 294 mg/m³) is 2.5 times this TWA.

Short-Term Studies

In the single-exposure studies, compoundrelated mortality was seen at 6,550 ppm in rats and at 1,420 ppm and above in mice. In the 14day studies, compound-related mortality was seen at 3,200 ppm and above in male rats, at 1,600 ppm and above in female rats, and at 1,600 ppm and above in mice of each sex. The results of the 13-week studies were similar to those published previously by Miller et al. (1981), who reported that exposure of F344 rats and $B6C3F_1$ mice to 1,2-epoxybutane at concentrations of 0, 75, 150, or 600 ppm resulted in no compoundrelated deaths. In the NTP 13-week studies, no deaths were seen in rats at concentrations up to 800 ppm or in mice up to 400 ppm, whereas all mice at 800 ppm died. In the Miller et al. study, compound-related nasal cavity lesions were seen in rats and mice at 600 ppm but not at 75 or 150 ppm. In the NTP studies, nasal cavity lesions were seen in rats at 800 ppm but not at lower concentrations, and nasal cavity lesions were seen in mice at 200, 400, and 800 ppm. In the NTP studies, renal necrosis was observed in mice at 800 ppm, a dose that was lethal.

Results of the 13-week studies were used to select exposure concentrations for the 2-year studies. The highest concentration selected for the 2-year rat studies was 400 ppm because at 800 ppm body weight was markedly lower than that of the controls and nasal lesions were observed. The highest concentration selected for the 2-year studies in mice was 100 ppm because the nasal lesions seen at 200 ppm and above were considered to be potentially life threatening.

Two-Year Studies in Rats

Survival of rats was at least 50% in all groups until week 98, but survival was reduced after this time in exposed groups (final survival-male: control, 30/50; low dose, 18/50; high dose, 23/50; female: 32/50; 21/50; 22/50). Mean body weights of high dose male rats were 5%-8% lower than those of controls after week 86, and mean body weights of high dose female rats were 5%-10% lower after week 22.

The respiratory system of rats was adversely affected after exposure to 1,2-epoxybutane for 2 years. Nonneoplastic lesions of the nasal cavity (including inflammation, epithelial and adenomatous hyperplasia, and squamous metaplasia of the respiratory epithelium), atrophy of the olfactory epithelium, and hyperostosis were observed in exposed animals. Seven papillary adenomas of the nasal cavity were seen in high dose male rats and two in high dose female rats. The incidence of alveolar/bronchiolar adenomas or carcinomas (combined) was increased in high dose male rats (control, 0/50; low dose, 2/50; high dose, 5/49) but not in high dose female rats. Although more than 60% of the animals tested had positive serologic titers for RCV/SDA virus at 17 and 24 months, there were no lesions in the salivary gland or lung to indicate active infection.

The finding of benign neoplasms of the nasal cavity (nasal cavity neoplasms have not been seen in any of the 249 chamber control male rats at this laboratory and in only 0.1% [2/1,977] of untreated control male rats in all NTP studies) and of benign and malignant neoplasms of the lung in male rats is clear evidence that this chemical is a carcinogen. The presence in female rats of two tumors in the nasal cavity, a site for tumors in male rats, is considered equivocal evidence of carcinogenicity. The incidence of mononuclear cell leukemia was increased in low dose male rats, but because leukemia was not also increased in high dose animals, the effect is not considered to be compound related. The incidences of several nonfatal tumors, including thyroid gland follicular cell adenomas or carcinomas (combined) in female rats, adenomas or carcinomas (combined) of the pituitary gland in female rats, and preputial gland tumors in male rats, were marginally increased by the life table trend test but not by the incidental tumor trend test (the more appropriate test for analysis of nonfatal tumors), and these effects are not considered to be compound related.

Propylene oxide, a related epoxide, also was studied at the same laboratory in F344/N rats at the same inhalation exposure concentrations (0, 200, and 400 ppm) (NTP, 1985; Table 22). Inflammation, hyperplasia, and metaplasia of the nasal cavity respiratory epithelium were seen in dosed animals. Propylene oxide caused an increased incidence of papillary adenomas of the nasal cavity in male and female rats.

(d) NTP 1987--rats not studied.

(e) NTP 1984--study terminated early; rats not studied.

Two-Year Studies in Mice

Final survival of dosed male mice was comparable to that of controls. Survival of dosed female mice was greater than 50% at week 86 but was reduced in the high dose group toward the end of the study (final survival: control, 29/50; low dose, 25/50; high dose, 9/50). Suppurative inflammation of the ovary and uterus was seen in some female mice dying before the end of the study, and the incidences of these lesions were greater in dosed animals. Klebsiella was cultured from some of these lesions. Klebsiella infections were seen in other NTP studies conducted during this time period, and similar uterine/ovarian lesions were seen in female mice in those studies (Rao et al., 1987). Mean body weights of dosed mice were reduced during the second year of the studies.

The nasal cavity was the site primarily affected in mice. As was seen in rats, 1,2-epoxybutane caused nonneoplastic lesions of the nasal cavity in dosed mice, including suppurative (empyema) and chronic inflammation; epithelial hyperplasia, erosion, and regeneration; squamous metaplasia; atrophy of the sensory epithelium; hyperplasia of the nasal gland (Bowman's glands); and inflammation and hyperplasia of the nasolacrimal duct. The single squamous cell papilloma was seen in the incisive duct of a high dose male mouse but was not considered to be compound related. 1,2-Epoxybutane at exposure concentrations that caused nonneoplastic lesions of the nasal cavity in both rats and mice was carcinogenic in the nasal cavity of rats only. The reasons for this species difference need further investigation.

Inhalation exposure of B6C3F₁ mice to propylene oxide at concentrations of 200 and 400 ppm caused inflammation and hemangiomas or hemangiosarcomas (combined) of the nasal cavity (NTP, 1985; Table 22). 1,2-Epoxybutane at 50 or 100 ppm was not carcinogenic for mice, even though nonneoplastic inflammatory and hyperplastic lesions occurred. Two other related chemicals were studied in mice in the same room at this laboratory: 1,3-butadiene and ethylene oxide (NTP, 1984, 1987; Table 22). These chemicals given by the inhalation route were not carcinogenic in the nasal cavity but did cause increased incidences of neoplasms at other sites. Ethylene oxide caused increased incidences of lung and harderian gland tumors in male and female mice exposed at 50 or 100 ppm (NTP, 1987). 1,3-Butadiene, which is metabolized in vitro first to 1,2-epoxy-3-butene and then to diepoxybutane and 3,4-epoxy-1,2-butanediol (Malvoisin and Roberfroid, 1982), caused increased incidences of neoplasms of the lung, stomach, and heart and lymphomas in male mice and of neoplasms of the lung, stomach, mammary gland, ovary, and liver and lymphomas in female mice at concentrations of 625 or 1,250 ppm (NTP, 1984). Other epoxides have been shown to be carcinogenic in rodents after oral administration and inhalation exposure (IARC, 1985). In the 1,2-epoxybutane studies reported here, there was no cross-contamination in the exposure chamber with the other chemicals (1,3-butadiene or ethylene oxide) on study in the same room.

Adenomas or carcinomas (combined) of the pituitary gland occurred with a significant negative trend in female mice. This may be related in part to the increased mortality in exposed female mice.

Genetic Toxicology

1,2-Epoxybutane is clearly mutagenic. It induces gene mutations in a variety of bacterial species (Dunkel, 1979; McMahon et al., 1979; Voogd et al., 1981; De Flora et al., 1984), as well as in fungi (Kolmark and Giles, 1955; Migliore et al., 1982; Rossi et al., 1983), Drosophila (Knaap et al., 1982; Yoon et al., 1985), and mammalian cells in culture (Amacher et al., 1980; Knaap et al., 1982). It also induces sister chromatid exchanges (Table E3) but not unscheduled DNA synthesis in cultured mammalian cells (McGregor, 1981; Williams et al., 1982). Although 1,2-epoxybutane can be clastogenic, as demonstrated by the induction of chromosomal aberrations in cultured Chinese hamster ovary cells treated in the absence of metabolic activation (Table E4) and of translocations in Drosophila after feeding to adult males, it did not induce dominant lethal mutations in the germ cells of male rats exposed by inhalation (McGregor, 1981). The negative dominant lethal result and the absence of sperm-head

abnormalities in germ cells of male mice that were exposed to 1,2-epoxybutane by inhalation may indicate that the chemical did not reach the testis in amounts sufficient to produce an observable effect.

The mutagenicity of ethylene oxide (NTP, 1987; Embree and Hine, 1975; Pfeiffer and Dunkleberg, 1980) and propylene oxide (NTP, 1985; Canter et al., 1986), structural analogs of 1,2epoxybutane, appears to be similar to that of 1,2epoxybutane in that mutations are induced in the base-pair substitution strains TA100 and TA1535 of S. typhimurium in both the absence and presence of metabolic activation (Bootman et al., 1979; McMahon et al., 1979; De Flora, 1981). 1,3-Butadiene induces mutations in strains TA100 and TA1535 but only in the presence of metabolic activation (Wade et al., 1978).

Data Audit

The experimental and tabulated data for the NTP Technical Report on 1,2-epoxybutane were

examined for accuracy, consistency, completeness, and compliance with Good Laboratory Practice regulations. As summarized in Appendix H, the audit revealed no discrepancies that influenced the final interpretation of the results of these studies.

Conclusions: Under the conditions of these 2-year inhalation studies, there was clear evidence of carcinogenic activity* of 1,2-epoxybutane for male F344/N rats, as shown by an increased incidence of papillary adenomas of the nasal cavity, alveolar/bronchiolar carcinomas and alveolar/bronchiolar adenomas or carcinomas (combined). There was equivocal evidence of carcinogenic activity for female F344/N rats, as shown by the presence of papillary adenomas of the nasal cavity. There was no evidence of carcinogenic activity for male or female B6C3F1 mice exposed at 50 or 100 ppm. 1,2-Epoxybutane exposure was associated with adenomatous hyperplasia and inflammatory lesions of the nasal cavity in rats and inflammatory lesions of the nasal cavity in mice.

^{*}Explanation of Levels of Evidence of Carcinogenic Activity is on page 7.

A summary of the Peer Review comments and the public discussion on this Technical Report appears on pages 10-11.

TABLE A3. ANALYSIS OF PRIMARY TUMORS IN MALE RATS IN THE TWO-YEAR INHALATIONSTUDY OF 1,2-EPOXYBUTANE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

(e) No P value is reported because no tumors were observed in the dosed and control groups.

⁽d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

TABLE A4a. HISTORICAL INCIDENCE OF NASAL CAVITY TUMORS IN MALE F344/N RATS RECEIVING NO TREATMENT (a)

No nasal cavity tumors have been observed in 249 chamber control male rats at Battelle Pacific Northwest Laboratories.

Overall Historical Incidence in Untreated Controls

No. Examined	No. of Tumors	Diagnosis
1,977	1 1	Squamous cell papilloma Squamous cell carcinoma
TOTAL	2 (0.1%)	

(a) Data as of August 30, 1985, for studies of at least 104 weeks. No more than one tumor was observed in any untreated control group

TABLE B3. ANALYSIS OF PRIMARY TUMORS IN FEMALE RATS IN THE TWO-YEAR INHALATION STUDY OF 1,2-EPOXYBUTANE (Continued)
TABLE B3. ANALYSIS OF PRIMARY TUMORS IN FEMALE RATS IN THE TWO-YEAR INHALATION STUDY OF 1,2-EPOXYBUTANE (Continued)

(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

⁽a) Number of tumor-bearing animals/number of animals examined at the site

⁽c) Observed tumor incidence at terminal kill

⁽d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

TABLE B4a. HISTORICAL INCIDENCE OF NASAL CAVITY TUMORS IN FEMALE F344/N RATSRECEIVING NO TREATMENT (a)

Overall Historical Incidence in Untreated Controls							
No. Examined	No. of Tumors	Diagnosis					
2,021	1	Papilloma, NOS					
TOTAL	1 (0.05%)						

(a) Data as of August 30, 1985, for studies of at least 104 weeks. No more than one tumor was observed in any untreated control group.

TABLE C3. ANALYSIS OF PRIMARY TUMORS IN MALE MICE IN THE TWO-YEAR INHALATIONSTUDY OF 1,2-EPOXYBUTANE (Continued)

TABLE C3. ANALYSIS OF PRIMARY TUMORS IN MALE MICE IN THE TWO-YEAR INHALATION STUDY OF 1,2-EPOXYBUTANE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

(d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

TABLE D3. ANALYSIS OF PRIMARY TUMORS IN FEMALE MICE IN THE TWO-YEAR INHALATION STUDY OF 1,2-EPOXYBUTANE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site

(e) A papillary carcinoma was also observed in this animal.

⁽b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

⁽c) Observed tumor incidence at terminal kill

⁽d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

TABLE D4. HISTORICAL INCIDENCE OF PITUITARY GLAND TUMORS IN FEMALE $\rm B6C3F_1$ MICE RECEIVING NO TREATMENT (a)

(a) Data as of August 30, 1985, for studies of at least 104 weeks
(b) Includes adenoma, NOS, and chromophobe adenoma
(c) Includes carcinoma, NOS, adenocarcinoma, and chromophobe carcinoma
(d) Standard deviation
(e) Range and SD are presented for groups of 35 or more animals.

TABLE E1. MUTAGENICITY OF 1,2-EPOXYBUTANE IN SALMONELLA TYPHIMURIUM (a)

(a) Study performed at SRI International. The detailed protocol is presented in Haworth et al. (1983). Cells and study compound or solvent (dimethyl sulfoxide) were incubated in the absence of exogenous metabolic activation (-S9) or with Aroclor 1254-induced S9 from male Syrian hamster liver or male Sprague Dawley rat liver. High dose was limited by toxicity or solubility but did not exceed 10 mg/plate; 0 µg/plate dose is the solvent control.
(b) Revertants are presented as mean ± standard error from three plates.

(c) Positive control; 2-aminoanthracene was used on all strains in the presence of S9. In the absence of metabolic activation, 4-nitro-o-phenylenediamine was used with TA98, sodium azide was used with TA100 and TA1535, and 9-aminoacridine was used with TA1537.

TABLE E2. MUTAGENICITY OF 1,2-EPOXYBUTANE IN MOUSE L5178Y LYMPHOMA CELLS (Continued)

TABLE E2. MUTAGENICITY OF 1,2-EPOXYBUTANE IN MOUSE L5178Y LYMPHOMA CELLS (Continued)

(a) The experimental protocol is presented in detail by Myhr et al. (1985) and follows the basic format of Clive et al. (1979). The highest dose of study compound is determined by solubility or toxicity and may not exceed 5 mg/ml. Cells (6×10^{5} /ml) were treated for 4 hours at 37° C in medium, washed, resuspended in medium, and incubated for 48 hours at 37° C. After expression, 3×10^{6} cells were plated in medium and soft agar supplemented with trifluorothymidine for selection of cells that were mutant at the thymidine kinase (TK) locus, and 600 cells were plated in nonselective medium and soft agar to determine the cloning efficiency.

(b) Mean \pm standard error of replicate trials for approximately 3×10^6 cells each. All data are evaluated statistically for both trend and peak response. Both responses must be significantly (P<0.05) positive for a chemical to be considered mutagenic. If only one of these responses is significant, the call is "questionable"; the absence of both trend and peak response results in a "negative" call.

(c) Mutant fraction (frequency) is a ratio of the mutant count to the cloning efficiency, divided by 3 (to arrive at MF per 1×10^6 cells treated); MF = mutant fraction.

(d) Significant positive response; occurs when the relative mutant fraction (average MF of treated culture/average MF of solvent control) is greater than or equal to 1.6.

(e) Tests conducted with metabolic activation were performed as described in (a) except that S9, prepared from the liver of Aroclor 1254-induced F344 rats, was added at the same time as the study chemical and/or solvent.

TABLE E3. INDUCTION OF SISTER CHROMATID EXCHANGES IN CHINESE HAMSTER OVARY CELLSBY 1,2-EPOXYBUTANE (a)

TABLE E3. INDUCTION OF SISTER CHROMATID EXCHANGES IN CHINESE HAMSTER OVARY CELLS BY 1,2-EPOXYBUTANE (Continued)

(a) Study performed at Environmental Health Research and Testing Laboratory. SCE = sister chromatid exchange; BrdU = bromodeoxyuridine; a detailed description of the SCE protocol is presented by Galloway et al. (1985). Briefly, Chinese hamster ovary cells were incubated with study compound or solvent (dimethyl sulfoxide) as described in (c) or (d) below and cultured for sufficient time to reach second metaphase division. Cells were then collected by mitotic shake-off, fixed, air-dried, and stained. (b) SCEs/cell of culture exposed to study chemical relative to those of culture exposed to solvent

(c) In the absence of S9, Chinese hamster ovary cells were incubated with study compound or solvent for 2 hours at 37° C. Then BrdU was added, and incubation was continued for 24 hours. Cells were washed, fresh medium containing BrdU and colcemid was added, and incubation was continued for 2-3 hours. Cells were then collected by mitotic shake-off, fixed, dropped onto slides, air-dried, and stained (Galloway et al., 1985).

(d) In the presence of S9, cells were incubated with study compound or solvent for 2 hours at 37° C. Then cells were washed, and medium containing BrdU was added. Cells were incubated for a further 26 hours, with colcemid present for the final 2-3 hours. S9 was from the liver of Aroclor 1254-induced male Sprague Dawley rats.

TABLE E4. INDUCTION OF CHROMOSOMAL ABERRATIONS IN CHINESE HAMSTER OVARY CELLSBY 1,2-EPOXYBUTANE (a)

TABLE E4. INDUCTION OF CHROMOSOMAL ABERRATIONS IN CHINESE HAMSTER OVARY CELLS BY 1,2-EPOXYBUTANE (Continued)

(a) Study performed at Environmental Health Research and Testing Laboratory. A detailed presentation of the technique for detecting chromosomal aberrations is found in Galloway et al. (1985). Briefly, Chinese hamster ovary cells were incubated with study compound or solvent as indicated in (b) or (c). Cells were arrested in first metaphase by addition of colcemid and harvested by mitotic shake-off, fixed, and stained in 6% Giemsa.

(b) In the absence of S9, cells were incubated with study compound or solvent for 8-10 hours at 37° C. Cells were then washed and fresh medium containing colcemid was added for an additional 2-3 hours followed by harvest.

(c) In the presence of S9, cells were incubated with study compound or solvent for 2 hours at 37° C. Cells were then washed, medium was added, and incubation was continued for 8-10 hours. Colcemid was added for the last 2-3 hours of incubation prior to harvest. S9 was from the liver of Aroclor 1254-induced male Sprague Dawley rats.

Route of		Incidence of	Incidence of	No. of Lethals/	<u>d</u> Overall

TABLE E5. INDUCTION OF SEX-LINKED RECESSIVE LETHAL MUTATIONS IN DROSOPHILA BY1,2-EPOXYBUTANE (a,b)

(a) Study performed at University of Wisconsin, Madison

(b) A detailed protocol of the sex-linked recessive lethal assay is presented in Zimmering et al. (1985). Exposure by feeding was done by allowing 24-hour-old Canton-S males to feed for 3 days on a solution of the study chemical dissolved in 5% sucrose. Exposed males were mated to three Basc females for 3 days and given fresh females at 2-day intervals to produce three broods of 3, 2, and 2 days; sample sperm from successive matings were treated as spermatozoa (mating 1), spermatids (mating 2), and spermatocytes (mating 3). F_1 heterozygous females were crossed to their siblings and placed in individual vials. F_1 daughters from the same parental male were kept together to identify clusters; none was found. After 17 days, presumptive lethal mutations were identified as vials containing no wild-type males; these were retested. Results were significant at the 5% level (Margolin et al., 1983).

TABLE E6.	INDUCTION	OF RECIPROCAL	TRANSLOCATIONS I	N DROSOPHILA BY
		1,	2-EPOXYBUTANE (a,b)

Route of	Dose (ppm)	Transfers (translocations/total F ₁ tested)						Total No. of	Total No. of Trans-	Total Trans- locations
Exposure		1	2	3	4	5	6	Tests	locations	(percent)
Feeding	50,000 60,000	0/1,681 0/430	0/1,532 0/418	0/1,433 1/426	0/1,298 0/319	1/374 0/202	0/116 0/148	6,434 1,943	1 1	0.01 0.05
Historical control	0							104,844	2	0.0019

(a) Study performed at University of Wisconsin, Madison

(b) A detailed protocol of the reciprocal translocation assay is presented in Zimmering et al. (1985). Exposed males were mated to three bw; e females for 3 days and discarded. The females were transferred to fresh medium every 3-4 days to produce a total of six cultures, and then they were discarded. In this manner, successive cultures sample sperm that were stored for increasing lengths of time. Individual F_1 males were backcrossed to bw; e females, and the F_2 were screened for pseudolinkage. This procedure allows the recovery of translocations involving the Y, second, or third chromosomes in any combination. Presumptive translocations were retested. Results were significant at the 5% level (Kastenbaum and Bowman, 1970).

APPENDIX F

RESULTS OF SEROLOGIC ANALYSIS

PAGE

TABLE F1MURINE ANTIBODY DETERMINATIONS FOR RATS AND MICE IN THE TWO-YEARINHALATION STUDIES OF 1,2-EPOXYBUTANE

168

I. Methods

Rodents used in the Carcinogenesis Program of the National Toxicology Program are produced in optimally clean facilities to eliminate potential pathogens that may affect study results.

A few F344/N rats from each exposure group were bled from the tail during months 2 and 17. Blood was taken from 10 B6C3F₁ mice killed in a moribund state between months 20 and 22. Data from animals surviving 24 months were collected from 5/50 randomly selected control animals of each sex and species. The blood from each animal was collected and clotted, and the serum separated. The serum was cooled on ice and shipped to Microbiological Associates' Comprehensive Animal Diagnostic Service for determination of the antibody titers. The following tests were performed:

	Hemagglutination <u>Inhibition</u>	Complement <u>Fixation</u>	<u>ELISA</u>
Mice	PVM (pneumonia virus of mice) Reo 3 (reovirus type 3) GDVII (Theiler's encephalomyelitis virus) Poly (polyoma virus) MVM (minute virus of mice) Ectro (infectious ectromelia) Sendai	M. Ad. (mouse adenovirus) LCM (lymphocytic choriomeningitis virus)	MHV (mouse hepatitis virus) M. pul. (Mycoplasma pulmonis) (24 mo)
Rats	PVM KRV (Kilham rat virus) H-1 (Toolan's H-1 virus) Sendai	RCV (rat coronavirus) (2,17 mo) SDAV (Sialodacryoadenitis virus)	RCV (24 mo)

TABLE G4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION (a)

TABLE G4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION (Continued)

- (a) All values were less than the detection limit. The detection limit is given as the mean.
- (b) Sources of contamination: alfalfa, grains, and fish meal (c) Sources of contamination: soy oil and fish meal
- (d) CFU = colony forming unit
- (e) MPN = most probable number; mean, standard deviation, and range exclude one very high value of 460 MPN/g obtained for the batch produced on 9/23/82.
- (f) Mean, standard deviation, and range include the high value given in footnote d.
- (g) All values were less than 3 MPN/g. (h) All values were corrected for percent recovery.
- (i) BHC = hexachlorocyclohexane or benzene hexachloride
- (j) There was one observation above the detection limit. The value and the date it was obtained are given under the range.
- (k) Twelve batches contained more than 0.05 ppm.
- (1) Four batches (10/26/81-11/25/81) were not analyzed for endosulfan I, endosulfan II, or endosulfan sulfate.

173

1,2-Epoxybutane, NTP TR 329

.

APPENDIX H

DATA AUDIT SUMMARY

The experimental data, documents, pathology materials, and draft NTP Technical Report for the 2year toxicology and carcinogenesis studies of 1,2-epoxybutane in rats and mice were audited for accuracy, consistency, completeness, and compliance with Good Laboratory Practice regulations (implemented by the NTP beginning October 1, 1981). The studies were conducted for the NTP by Battelle Pacific Northwest Laboratories, Richland, Washington, under a subcontract with Tracor Jitco, Inc., until 1982 and then under contract with NIEHS. Animal exposures to 1,2-epoxybutane began in November 1981 and ended in November 1983. The retrospective audit was conducted at the NTP Archives in April and May 1986 by the following personnel from Argus Research Laboratories: Paul A. Wennerberg, D.V.M., M.S. (Principal Investigator); Lynn E. Blalok, M.S.; Betty L. Brandau, Ph.D.; and Sharon H. Srebro, B.S; and the following personnel from Pathology Associates, Inc.: Kathleen M. Walsh, D.V.M., Diplomate A.C.V.P.; Stephanie M. Taulbee; and Trella S. Cooper, B.A.

The audit report is on file at the NIEHS, Research Triangle Park, North Carolina. The audit included a review of the following material:

- (1) All records concerning animal receipt, quarantine, randomization, and disposition before start of studies.
- (2) Chemistry data for a random 10% of the exposure days and all other chemistry records.
- (3) Body weights and clinical observation data from a random 10% sample of the study animals.
- (4) All inlife records concerning environmental conditions, palpable masses, mortality, and animal identification.
- (5) All postmortem records for individual animals concerning identification, disposition codes, and condition codes and correlation between gross observations and microscopic diagnoses.
- (6) Wet tissues from a random 10% of the study animals to verify animal identification and to examine for untrimmed potential lesions.
- (7) Slides and blocks of tissues from all control and high dose animals to examine for proper match and inventory.
- (8) Tabulated pathology diagnoses for a random 10% of study animals to verify computer data entry.

The audit showed that the data in the Technical Report (including inlife observations, chemistry, and pathology data) correspond to the data at the NTP Archives. Clinical observations were not always consistent from month to month. Some animals were able to escape from their individual cages within the exposure chamber (a total of 41 instances during the 2 years); the animals were returned to the appropriate cage unit according to standard operating procedures. Missing ear tags were replaced according to standard operating procedures, and animal identification in the wet tissue bags agreed with the assigned study-specific number and animal number. A few untrimmed potential lesions were found in the wet tissues (predominantly in the stomach and spleen), but none was found in the target organs associated with carcinogenic effect (i.e., nose or lungs of rats). Additional diagnoses were not performed, since they would not have altered the interpretations of the study.

The NIEHS/NTP concludes that the data at the NTP Archives support the results presented in this Technical Report.
