Vital and Health Statistics

Supplements to the Monthly Vital Statistics Report: Advance Reports, 1987

Series 24:

Compilations of Data on Natality, Mortality, Marriage, Divorce, and Induced Terminations of Pregnancy No. 4

These supplements to the Monthly Vital Statistics Report present summary tabulations from final natality, mortality, marriage, and divorce statistics for 1987. Natality and mortality data are based on information from the standard certificates filed in all States and the District of Columbia. Marriage and divorce data are based on information from the marriage- and divorce-registration areas. These reports were originally published in 1989 and 1990. More detailed tabulations are published in Vital Statistics of the United States annual volumes.

Births and birth rates

There were 3,809,394 babies born in the United States in 1987, 1 percent more than in 1986 (3,756,547) (table 1). The 1987 total is the highest reported since 1964 (4,027,490). Provisional data for 1988 indicate a 2-percent increase over the 1987number.

The birth rate for 1987 was 15.7 live births per 1,000 population, slightly

higher than the 15.6 level reported for 1986. The birth rate has ranged from 15.5 to 15.9 since 1979. Estimates for 1988 indicate a 1-percent rise over the rate for 1987.

The fertility rate, a measure that relates the number of births to women of childbearing age, rose very slightly in 1987 to 65.7 live births per 1,000 women aged 15–44 years, compared with 65.4 in 1986. Since 1983, the fertility rate has remained within a very narrow range of 65.4–66.2 (table 1 and figure 1). Provisional data for 1988 indicate a 2-percent increase in the fertility rate.

Birth rates according to age of mother rose for all age groups 15-44 years in 1987, except the rate for women 18-19 years of age. (See tables 2-4 for births and birth rates by age of mother and figure 2 for birth rates by age of mother.) There were relatively sizable increases in birth rates for young teenagers as well as for women aged 35 years and over. The birth rate for women aged 15-17 years was 31.8 births per 1,000 in 1987, 4 percent higher than in 1986 (30.6)—the largest single-year increase in this rate since 1970. Between 1970 and 1987, the birth rate for teenagers 15-17 years increased in only 5 years (1972, 1979, 1980, 1982, and 1987). Although the birth rate for young teens increased 4 percent in 1987, the rate for older

teens 18-19 years declined 1 percent, to 80.2 per 1,000. As a consequence, the overall birth rate for women aged 15-19 years rose just 1 percent in 1987, to 51.1.

Rates for women in their twenties increased just 1-2 percent, to 108.9 (ages 20-24 years) and 110.8 (ages 25-29 years), while increases for women aged 35-44 years were 7-8 percent. Because increases were very small for women in the peak ages of childbearing (20-29 years), the result was a very small increase of less than 1 percent in the general fertility rate. Since the mid 1970's, birth rates for women in their twenties have been essentially unchanged, after plummeting from 1970 to 1975 by 25 to 33 percent. Since 1980, birth rates for these women have increased in only 2 years, 1985 and 1987. Birth rates for women aged 20-29 years were 2-5 percent lower in 1987 than in 1980.

In recent years, the principal variations in childbearing have been observed among women in their thirties. The birth rate for women aged 30–34 years increased 3 percent in 1987, to 71.3 births per 1,000, and the rate for women aged 35–39 years increased by 8 percent to 26.2 (35–39 years). The increase for women 35–39 years was larger than any reported for women in this age group since 1943. It reflects the ongoing trend of women postponing

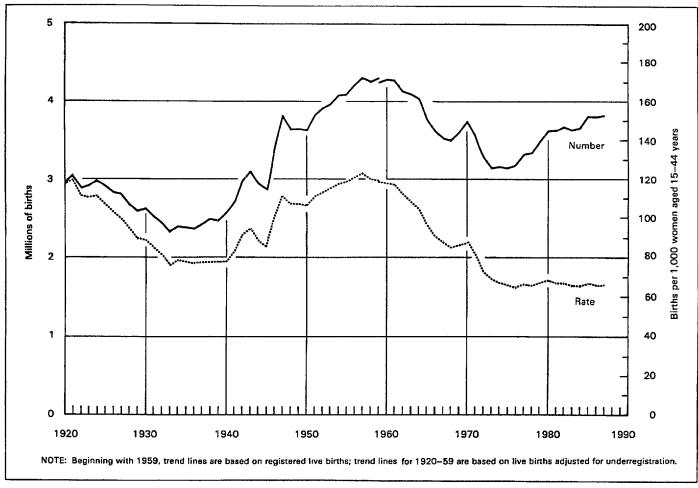

Figure 1. Live births and fertility rates: United States, 1920-87

childbearing to increasingly older ages (1). The childbearing that these women had delayed while they were in their twenties began to be made up as they reached their thirties. This pattern is clearly reflected in the increases since 1976 in birth rates for women aged 30-34 and 35-39 years; rates for these women increased by one-third or more during this period. In spite of the considerable increases in birth rates for women in their thirties over the past several years, however, the rates are substantially below those for women in their twenties; consequently, the impact on the general fertility rate has been limited. Partially as a consequence of the relative stability of teenage birth rates in contrast to the increases in rates for older women, the proportion of all births that occurred to teenagers fell to 12 percent in 1987, continuing a decline that began in 1973 when teenage mothers accounted for 20 percent of all births. Another factor associated

with the drop in the proportion of teenage mothers has been the reduction of the teenage population. Women aged 15-19 years in 1987 were born in 1968-72, years that followed the baby boom and during which the number of births declined sharply. The number of teenagers will continue to decline in the next few years as those born in the very low birth years of the mid 1970's reach the teenage years. Therefore, it is likely that the number and proportion of births to teenagers will continue to fall unless their birth rates begin to rise appreciably. For example, if the 1987 teenage birth rate of 51.1 per 1,000 is applied to the U.S. Bureau of the Census projection of the female teenage population 5 years later, in 1992 (2), approximately 420,000 babies would be born to mothers aged 15-19 years in that year, compared with the 1987 total of 462,312. To put it another way, the teenage birth rate would have to increase to about 58 per 1,000 for the number of births in 1992 to equal the 1987 level. The teen birth rate has not been as high as 58 since 1974.

Births to mothers aged 30 years and over constituted 27 percent of all births in 1987, higher than in any year since 1961 (also 27 percent). The numbers and proportions of births to mothers in their thirties and forties have increased sharply since the mid 1970's as a consequence of two factors. First, as noted above, birth rates for women in their thirties have risen by one-third or more since 1975 while at the same time rates for younger women fell or were relatively stable. Second, the number of women aged 30 years and over has increased sharply as the women born during the peak baby boom years of the late 1940's and 1950's have reached age 30. The number of women aged 30-39 years, for example, increased 54 percent from 1975 to 1987.

Birth rates for first and second order births as well as for fifth and higher

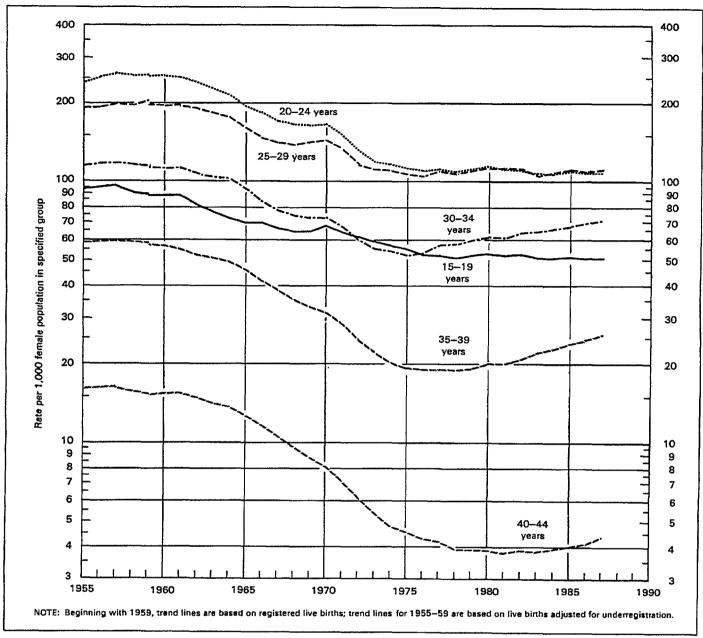

Figure 2. Birth rates by age of mother: United States, 1955-87

order births were unchanged in 1987 compared with 1986. (See table 3 for 1987 rates and table 5 for rates for 1970-87.) The rates for third and fourth order births increased by only 2 and 3 percent, respectively. This pattern marks a continuation of a trend observed since 1980 of relative stability or decline in birth rates by live-birth order. (See figure 3.)

First birth rates were unchanged for women aged 20-24 years and increased by 3-11 percent for women aged 15-17 and 25-39 years. The rate for women aged 40-44 years increased from 0.6 to 0.7 births per 1,000. The

pace of increase in these rates in 1987 was similar to that observed in 1986. Second order birth rates rose by less than 1 percent for women in their twenties and by 3 percent for women aged 30–34 years. Second order rates for women 15–17 and 35–39 years increased 9–10 percent. These increases in 1987 were considerably greater in general than in the previous year.

The changes in birth rates by livebirth order and age of mother in 1987 generally reflect a continuation of the trends observed in recent years. In most cases, first and second order birth rates for women under age 25 years were

lower in 1987 than in 1980. There was no consistent pattern in the rates for women aged 25-29 years. First, second, and third order birth rates for women aged 30-39 years were all considerably higher in 1987 than in 1980. The trend to begin childbearing at increasingly older ages has been reported on in detail elsewhere (1). Data for 1987 indicate that many of these women in their late thirties are going on to have a second or third child. During the 1970's, second order rates for women in their early thirties increased but third birth rates for these women were lower in 1980 than in 1970, and were only

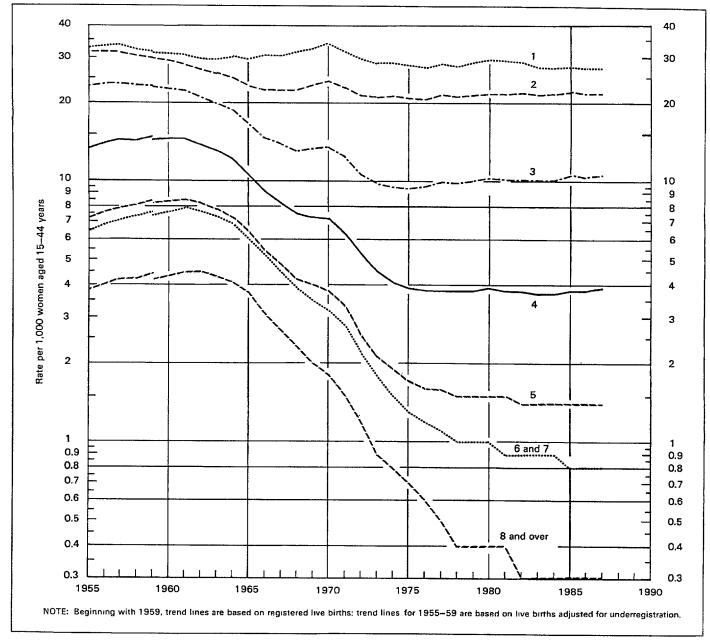

Figure 3. Birth rates by live-birth order: United States, 1955-87

slightly higher in 1987 than in 1980. Second and third birth rates for women aged 35-39 years declined or changed little during the 1970's. Since 1980, however, these rates have risen sharply, by 38-86 percent. Because of the increased birth rates and the rapid growth in the number of women aged 35-39 years, the number of second and third order births to these women was substantially higher in 1987 than in 1980 (131,546 compared with 61,246). question that will remain unanswered for now is to what extent the women who have delayed the start of their families until their early

thirties or older will ultimately have the number of children they say that they expect (3).

Although the increases in second and third birth rates among women aged 35-39 years were particularly noteworthy in 1987, the increase in their first birth rate continues to reflect rising of pattern first-time childbearing by women who had previously postponed or delayed motherhood. Large proportions of women today are reaching age 30 years still childless, 31 percent at the end of 1987 compared with 15 percent at the end of 1970. Further, there are many more women now in the age group 30-39 years than in 1970, 20,139,000 compared with 11,529,000. Consequently, the increases in first birth rates for these women are having an even greater impact on the numbers and proportions of first births they account for. In 1987, first births to women aged 30-39 years totaled 244,507, or 16 percent of all first births, compared with 54,108 in 1970, only 4 percent of first births in that year.

In spite of the recent increases in first-time childbearing by women over 30 years, the proportions of women who are still childless at relatively advanced ages have been rising, 12 percent of women 44 years of age at the end of 1987 compared with 9 percent of their counterparts at the end of 1980. Childlessness has risen in spite of surveys showing that most women intend to have children (3). Among the factors that may be involved, one is the rise in the proportion of unmarried women (including never married as well as widowed and divorced women). Between 1980 and 1987, for example, the percent unmarried among women aged 40-44 years rose from 18 to 23 percent (4.5). Because most childbearing is by married women, this trend may be increasing the likelihood that some women will remain childless. Another possible factor is an increase in the proportion of couples remaining childless because of fertility impairments. Data from the 1982 National Survey of Family Growth showed that the incidence of such impairments tends to rise sharply with advancing age (6). As women delay childbearing to increasingly older ages, it may be more difficult to treat conditions affecting their ability to conceive and bear children (7).

The racial differential in the fertility rate increased slightly in 1987, resulting from a larger increase for black compared with white women. The fertility rate for black women rose 2 percent, from 82.4 to 83.8 births per 1,000 women aged 15-44 years, compared with an increase of less than 1 percent for white women (from 61.9 to 62.0). In most cases percent changes in rates by age of mother up to age group 30-34 years between 1986 and 1987 were similar for white and black women. The major differences were a greater increase among black women in the rate for young teens 15-17 years, 4 percent compared with 3 percent, and a tendency for rates among women in their thirties to increase more for white than for black women.

The total fertility rate indicates the number of births that a group of 1,000 women would have if they experienced during their childbearing years the agespecific birth rates observed in a given calendar year. It is a hypothetical measure that shows the implications of current levels of fertility by age for completed family size. The total fertility rate is computed from age-specific

birth rates and is, therefore, age adjusted; it assumes the same number of women in each age group.

The total fertility rate in 1987 was 1.871. 2 percent above the 1986 level. 1,836, and higher than it has been since 1973 (1,879) (table 4). This increase reflects the 1-8 percent increases in birth rates for women in 5-year age groups 15-44 years. The 1987 level of 1,871 is the number of children that 1.000 women would have if they were to experience the age-specific birth rates of 1987 over their entire childbearing period. The rate of 1,871 is 11 percent below the level considered necessary for a given generation to exactly replace itself in the population over the long run (2,110). The total fertility rate has been below replacement level since 1972.

The total fertility rate for white women was 1,766.5 in 1987, 1 percent above the 1986 level (1,741.5). The rate for black women was 2,294.0, 3 percent higher than in 1986 (2,227.5). The rates for both white and black women were higher than they have been since 1973 and 1974, respectively.

Geographic division and State

Six geographic divisions consisting of States east of the Mississippi River and on the west coast of the United States reported more births in 1987 than in 1986 (table 6). Increases were less than 1 percent in the East North Central and East South Central divisions, but were 3-4 percent in the New England, Middle Atlantic, South Atlantic, and Pacific divisions. There were declines of 1-3 percent in the other three divisions. The number of births increased in 25 States and the District of Columbia and declined in 25 States.

The birth rate per 1,000 total population rose by 1-3 percent in the New England, Middle Atlantic, South Atlantic, and Pacific divisions. Declines of 1-3 percent were reported for the West North Central, West South Central, and Mountain divisions. Rates were unchanged in the East North Central and East South Central divisions. Birth rates by State rose by up to 4 percent in 19 States and the District of Columbia and were unchanged in 3 States. Rates fell in 28 States. Most declines were

3 percent or less, but in six States (North Dakota, Louisiana, Oklahoma, Wyoming, Colorado, and Utah) the declines were 4 percent or more.

Increases of up to 3 percent were measured in the fertility rate in five geographic divisions (New England, Middle Atlantic, South Atlantic, East North Central, and Pacific). The rate per 1,000 women aged 15–44 years declined by 2 percent or less in the other divisions. Fertility rates rose by up to 4 percent in 21 States and the District of Columbia. Declines were reported for 29 States. Although most declines were 3 percent or less, in five States reductions amounted to 4 percent or more.

The fertility rates by State vary widely. In 1987, rates ranged from a low of 51.1 in West Virginia to a high of 90.6 in Utah. Rates were below 60 in 10 States and exceeded 70 in 8 States.

Sex ratio

The sex ratio in 1987 was 1,050 males per 1,000 females (table 7). Since 1976, the ratio has fallen within a very narrow range of 1,050 to 1,053. The ratio for white births was 1,054, comparable to ratios of 1,053–1,058 observed since 1976. Similarly, the ratio for black births has varied little. It was 1,028 in 1987; since 1978 it has ranged from 1,027 to 1,034. Sex ratios for other specific racial groups typically show much greater year-to-year variation because they are based on relatively few births.

Month of birth

As is typical in the monthly occurrence of births, the peak months in 1987 were July, August, and September (table 8). Removal of the seasonal component from the monthly birth and fertility rates facilitates observation of the underlying trends. On the average, seasonally adjusted birth and fertility rates were higher in the first 6 months of 1987 than in the final 6 months. The highest rates were observed in June (16.1, birth rate; 67.6, fertility rate). According to provisional data for 1988. it appears that this pattern may have reversed. Seasonally adjusted rates for January-June were somewhat lower than those for July-December.

Day of week

The concentration of the occurrence of births by day of week intensified in 1987. Deliveries were increasingly reported on Tuesdays through Fridays, with correspondingly fewer on weekends, especially Sundays, and major holidays. The holiday deficits generally extend to the days immediately around the holiday.

The index of occurrence of births suggests the extent of the pattern. The index is defined as the ratio of the average number of births on a given day of the week to the average daily number of births for the year, multiplied by 100. The average daily number of births in 1987, 10,437, is equivalent to an index of 100.0 (table 9). The peak day of occurrence continues to be Tuesdays, with an index of 109.4. Relatively large numbers of births occurred Wednesdays and Fridays; the index for both days was 106.4. The fewest births occurred on Sundays with an index of 81.9, followed by Saturdays with an index of 86.3. The differential between Tuesday and Sunday births has increased sharply since 1980, from 22 percent to 34 percent.

In accounting for this pattern, most attention has centered on the growing proportion of babies delivered by cesarean section, 24.4 percent in 1987 (8). The fact that more than a third of the cesarean deliveries were repeat procedures (that is, the mother had had at least one prior cesarean delivery), and that most repeat cesareans are scheduled in advance, could explain the substantial variation in the occurrence of births by day. Physicians would be unlikely to schedule repeat cesarean deliveries or planned primary cesareans on weekends or holidays.

Place of delivery and attendant at birth

In 1987, 99.1 percent of all births occurred in hospitals, a slight increase compared with 1986 (99.0 percent) (tables 10–12). The number of babies born in nonhospital settings in 1987, 35,288, was lower than in any year since 1979. As in the past several years, black infants were more likely than white infants to have been born in hospitals in 1987, 99.4 percent compared with

99.0 percent. The vast majority of hospital deliveries are attended by physicians, 96.2 percent in 1987, but this proportion has declined since the mid 1970's as midwives have attended an increasing proportion of in-hospital deliveries (2.6 percent in 1987).

The total number of midwife-attended deliveries has risen rapidly since 1975, with annual increases in each year (except 1986) amounting to 8 percent or more. In 1987, midwives delivered a total of 113,890 babies, nearly 4 times the 1975 total of 29,413. Although total midwife deliveries have risen sharply in the past decade, most of the increase is associated with inhospital deliveries. Since the early 1980's there has been very little change in the number of out-of-hospital births attended by midwives.

Black babies were more likely than white babies to have been delivered by midwives when the birth was in a hospital, 3.1 percent compared with 2.4 percent in 1987. The reverse was true for out-of-hospital deliveries: Only 12.2 percent of black babies delivered in nonhospital settings compared with 49.6 percent of white babies were attended by midwives. Overall, midwives attended 85,199 white deliveries in 1987, more than 5 times the number in 1975 (15,158). Midwives attended 20,359 black births in 1987, compared with 12,309 in 1975.

The proportion of midwife-attended deliveries varies greatly by State. (Data are not included in this report.) In 1987, midwives attended 1 percent or fewer of all births in 19 States, but 5 percent or more in 12 States.

Age of father

The birth rate for men rose slightly in 1987 to 55.0 births per 1,000 men aged 15-54 years. Since 1983, the rate has varied little, ranging from 54.9 to 55.7. Basic data are shown in table 13, and birth rates by age of father and race of child are shown in table 14. The birth rate for white men was unchanged in 1987 at 50.9, while the rate for black men rose 2 percent to 79.5.

Birth rates rose for men in all age groups 15–19 through 45–49 years. Increases were 3 percent or less for ages under 35 and 45–49 years and 4 percent

for men aged 35–39 and 40–44 years. The rates did not change for men aged 50 years and over. The relatively greater increases in birth rates for men aged 35–39 and 40–44 years compared with rates for younger men are consistent with the trend toward delayed parenthood described in the first section of this report and in a forthcoming NCHS report (1).

Birth rates by age for white and black men followed somewhat different patterns. Changes in the rates for white men were similar to those for all races combined except for slight declines among white men aged 20–24 and 25–29 years. By contrast, rates for black men increased by as much as 4 percent for those under age 25 as well as for men aged 40–44 years, while the rate for black men aged 50–54 years declined 3 percent.

Weight at birth

The incidence of low birth weight increased to 6.9 percent in 1987 compared with 6.8 percent in 1986. This is the highest level observed since 1979 (also 6.9 percent). From 1980 to 1986 this measure had changed only twice, declining in 1984 and then increasing in 1985. Low birth weight is defined as less than 2,500 grams (5 pounds 8 ounces). The proportions of low birth weight increased for both white and black infants in 1987, so that the racial disparity continues to be substantial. The proportions increased from 5.6 to 5.7 percent for white babies and from 12.5 to 12.7 percent for black babies. (Data for 1987 are shown in table 15.)

With the exception of babies born to teenagers 17 years and under and women 35 years and over, the proportion of low birth weight infants increased for all age groups, by 1-2 percent. There were some declines for babies born to young teenagers (1-3 percent) and to mothers 40 years and over; the proportion for births to mothers 35-39 years was unchanged.

The relationship of low birth weight to age of mother remained unchanged. Infants born to women in age groups 25-34 years continue to have the lowest risk, at 6.1-6.2 percent. Babies born to teenage mothers and mothers in their forties are at greatly

elevated risk of low birth weight, with proportions ranging from 7.9 to 13.7 percent. This relationship between age of mother and low birth weight is observed for both white and black infants, but age is relatively a more critical factor for white than for black babies. That is, the range in low birth weight for white infants is 5.1 percent (mothers 25–29 years old) to 10.4 percent (mothers under 15 years) whereas among black infants the range is more limited, 12.3 percent (mothers 20–24 years) to 16.2 percent (mothers under age 15).

Between 1986 and 1987 there was no consistent pattern in the changes in low birth weight according to age of mother for each racial group. Increases for white babies amounted to 1-3 percent (ages 18-24 and 40-44 years) while declines amounted to 2 percent or less (ages 15-17), except for larger declines among babies born to teens under 15 and women aged 45-49 years. There was no change in the proportions for infants born to mothers 25-39 years. Among black infants increases ranged from 1-2 percent for babies with mothers aged 17-18 and 20-29 years, 3 percent for babies born to mothers under age 15 years, and 4 percent for babies born to mothers in their thirties. Declines of 1-4 percent were measured for births to mothers aged 15-16 years and 19 years of age. Reductions were relatively larger for births to mothers aged 40-49 years.

Several factors may be associated with the lack of improvement in low birth weight in the 1980's. One important factor is the steady increase in the proportion of preterm births during this period, from 9.4 percent in 1981 to 10.2 percent in 1987. (See the section on length of gestation later in this report.) Nearly 4 in 10 of these preterm births in 1987 weighed less than 5½ pounds.

Further examination of the data on low birth weight according to socioeconomic status as measured by the mother's educational attainment shows that the increases in levels of low birth weight babies in 1987 were generally widespread. The risk of low birth weight continues to be considerably less for babies born to better educated mothers, regardless of race. (Data are not included in this report.)

The median birth weight of babies born in 1987 was 3,370 grams (equivalent to 7 pounds 7 ounces). The median for white babies was 3,420 grams (7 pounds 9 ounces) and for black babies it was 3,180 grams (7 pounds). These medians have not changed since 1984.

The proportions of low birth weight infants are shown for each State by race of child for 1987 in table 16. Between 1986 and 1987 increases in levels of low birth weight far outnumbered declines for both white and black babies. Among white infants, the proportions rose in 25 States and the District of Columbia and declined in 16 States. There was no change in nine States. Among the 37 States and the District of Columbia in which there were at least 1,000 black births in 1987, the incidence of low birth weight rose in 24 States and the District of Columbia and declined in 11 States; the percent was unchanged in 2 States.

Multiple births

The number of babies born in multiple deliveries continued to rise in 1987, totaling 83,917, 3 percent more than in 1986 (81,299). (Data for 1987 are shown in table 17.) Multiple deliveries consist of twins, triplets, quadruplets, and higher order plural births. The vast majority of multiple births are babies born in twin deliveries, 81,778 in 1987, or 97.5 percent of the total.

The ratio of multiple births per 1,000 total births was 22.0 in 1987, 2 percent higher than the ratio for 1986 (21.6). The 1987 ratio was the highest reported in nearly 30 years. From the late 1950's to the early 1970's the ratio had decreased somewhat, from 20.6 (1958) to 18.4 (1973). Since 1973 the ratio has increased fairly steadily. The multiple birth ratio for black babies has been consistently higher than for white infants. In 1987, the ratios were 25.4, black babies and 21.6, white babies, both 2 percent higher than for 1986.

Multiple birth ratios vary in a distinctive pattern according to age of mother. The peak age of mother group for the occurrence of plural births is 35-39 years, with a ratio of 28.3 in 1987. Ratios for other age groups varied from 10.8 to 26.6. The variation by

age is observed for both white and black babies, but ratios for black plural births are higher than for white births in each age group 15–49 years.

The number of babies born in triplet and higher order deliveries increased substantially, from 1,814 in 1986 to 2,139 in 1987, an 18-percent rise. Over the past several years, triplet births have constituted a growing proportion of all multiple births, increasing from 1.9 percent in 1980 to 2.5 percent in 1987.

The increasing frequency of multiple births in recent years may be associated in part with changes in age of childbearing and the growing use of fertility drugs. As noted earlier, many more mothers are having children at relatively older ages, ages at which multiple births occur with greatest frequency. Additionally, the use of fertility drugs to enable previously childless couples to have children is associated with an increased likelihood of multiple deliveries (9).

Births to unmarried women

The incidence of childbearing by unmarried women rose considerably in 1987. Increases averaging 5-6 percent were reported for the three important measures in 1987, the third consecutive year of increases of this size. The number of babies born to unmarried women in 1987, 933,013, was 40 percent greater than the number reported in 1980 (665,747). The birth rate per 1,000 unmarried women aged 15-44 years was 36.1 in 1987, 5 percent higher than in 1986 (34.3) and 23 percent higher than the 1980 rate (29.4). During these years childbearing by married women dropped: The number of births fell 2 percent, and the birth rate declined 8 percent. Because of these divergent trends, the proportion of births that were to unmarried women rose steadily during this period, from 18.4 percent in 1980 to 24.5 percent in 1987. (See tables 18-19 for 1987 data.)

Although births and birth rates for white and black unmarried women rose in 1987, increases from 1986 levels were somewhat greater for white than for black women, repeating a pattern that has been observed for the past several years. Although birth rates and ratios of births for unmarried black

women continue to be substantially greater than for unmarried white women, the racial differential declined slightly in 1987. The number of babies born to unmarried white women increased 7 percent to 498,645, while the number of births to unmarried black women rose 5 percent, to 399,144. The birth rate for unmarried white women was 24.6 in 1987, 6 percent higher than in 1986 (23.2); the rate for unmarried black women was 84.7, 5 percent above the rate for 1986 (80.9).

Age-specific birth rates for unmarried women measure the risk that these women will bear a child in a given year. This risk continues to be greatest for women aged 18–19 and 20–24 years. The birth rates for these women in 1987 were 49.9 and 53.1, respectively, 2 and 7 percent higher than the comparable rates in 1986 (table 19). Birth rates for all other age groups increased as well in 1987, by 5–11 percent. Rates increased for white and black women in all age groups; except for women in age groups 20–29 years, the increases were greater for white than for black women.

Increases in nonmarital childbearing since 1980 have been considerably greater for white than for black women, regardless of age. Further, rates for women aged 20–39 years have risen faster than the rates for teenagers and women in their forties. Birth rates for unmarried white women in 1987 were 28–56 percent higher than comparable rates in 1980. Increases for black women ranged from 1 to 20 percent.

Between 1980 and 1987, the number of babies born to unmarried women rose 40 percent, nearly double the increase in the nonmarital birth rate (23 percent). These increases occurred while births to married women declined 2 percent and the marital fertility rate (births per 1,000 married women aged 15-44 years) declined 8 percent. The factors associated with the increase in the birth rate for unmarried women cannot be determined from birth certificate data. The 40-percent increase in the number of babies born to unmarried women has resulted not only from the increase in their birth rate but also from a considerable rise in the number of unmarried women of childbearing age. Nearly two-thirds of the women in the childbearing ages (15-44 years)

were born during the baby boom years, 1947–64. These women have been postponing marriage to a great extent; additionally, an increasing fraction of their marriages have ended in divorce. Consequently the number of unmarried women has grown 14 percent between 1980 and 1987, while the number of married women increased just 6 percent during this period.

More than two-thirds of births to unmarried mothers in 1987 were to women aged 20 years and over, up from 59 percent in 1980 and 50 percent in 1970. This shift in age distribution has resulted from the greater increase in nonmarital birth rates for women aged 20 years and over than for younger women, and from the increase in the post-teenaged proportion of the unmarried population in the childbearing ages.

The incidence of nonmarital childbearing varies widely from State to State. The number and ratio of births to unmarried women by State and race of child are shown in table 16.

Interval since last live birth

Intervals between successive births are calculated from the date of the last live birth and the date of the present birth. In 1987 as in every year since 1981, 49 States and the District of Columbia reported the date of the mother's last live birth on the birth certificate; Texas did not include this information. Intervals between births are calculated for all second and higher order births (table 20).

The proportions of births occurring within various intervals following the mother's previous live birth have been virtually unchanged over the past several years. In 1987, 13 percent of all second and higher order births followed the mother's previous birth by less than 18 months, 27 percent by less than 2 years, and 51 percent by less than 3 years.

The racial disparity in the occurrence of births at very short intervals widened slightly in 1987. Among white babies, 11 percent followed the mother's previous live birth by less than 18 months; the comparable proportion for black babies was 18 percent.

Closely spaced births are much more likely to be associated with higher levels of low birth weight and other health complications (10). For example, in 1987, 21 percent of babies born within a year and 9 percent of babies born within 18 months of the mother's previous live birth were of low birth weight compared with an average of 5 percent for babies born within 1½-5 years of the previous live birth. This pattern was observed for white and black infants, although at each interval black babies are substantially more likely than white babies to be of low birth weight. Similarly, 1-minute Apgar scores of less than 7 were reported with greater frequency for infants born after short intervals of the previous live birth. These differentials are observed even if only full-term births are considered. (See the final section of text in this report for discussion of Apgar scores.)

The heightened health risks of closely spaced births are in part associated with the greater tendency for them to occur among young mothers and black mothers, among whom the risks of low birth weight and low Apgar scores are elevated. Although teenage mothers accounted for just 7 percent of all second births in 1987, they accounted for 22 percent of all second births occurring within 11/2 years of the mother's previous live birth. Similarly black women accounted for a larger fraction of closely spaced second births (19 percent) than of all second births (15 percent).

Educational attainment of mother and father

Since 1980, 47 States and the District of Columbia have reported educational attainment of the parents on the birth certificates. Data have not been available for California, Texas, and Washington.

In 1987 as in 1986, 80 percent of mothers giving birth were high school graduates or had more advanced educations. Among fathers, in 1987 86 percent had completed high school, a slight increase compared with 1986 (85 percent). (Basic data are presented in table 21.) Because statistics on the father's educational attainment are available mainly for married couples, the proportions of fathers who are high school graduates or who have more

advanced schooling are probably overstated. Unmarried mothers tend to be much younger than married mothers; presumably this is true for fathers as well. Younger parents have had less opportunity to advance their educations.

The proportion of mothers who have completed college increased slightly from 17 to 18 percent. (See table 22 for 1987 data.) Among mothers in their late thirties and early forties, the proportions of college graduates rose to unprecedented levels, 40 percent of those aged 35–39 years and 34 percent of those aged 40 years and over. There was no change in these percents for younger mothers. The proportion of mothers with only a grade school education (8 years of school or fewer) declined slightly in 1987, to 3 percent.

Older women having their first child are particularly likely to be college graduates. (Data are not included in this report.) In 1987, 48 percent of first-time mothers aged 30–34 years and 54 percent of those aged 35–39 years had completed college. Most of these women presumably had postponed marriage and childbearing to complete their educations and become settled in their careers. This topic is discussed in more detail earlier in this report and in a forthcoming report (1).

The proportions of white and black mothers who have completed high school increased slightly in 1987, but the racial disparity remains substantial. Eighty-three percent of white mothers and 69 percent of black mothers were high school graduates. The proportion of college graduates increased only for white mothers, to 20 percent, and remained at 7 percent for black mothers.

The median years of school completed by mothers increased only for mothers aged 35 years and over, to 13.5–14.6 years. Medians for other age groups were essentially unchanged (except for a slight decline for mothers aged 30–34 years, to 14.1). This pattern was generally repeated for white mothers. Among black mothers, the median increased only for mothers aged 40 years and older (to 12.6 years).

Births to Hispanic mothers

Since 1983, 23 States and the District of Columbia have reported the Hispanic origin of the parents on the birth certificate. It is estimated that more than 90 percent of all Hispanic origin births in the United States were to residents of these States (3,11). It is believed, therefore, that the birth statistics presented here are representative of the fertility experience of the Hispanic population for the country as a whole. Previous reports have described the demographic and health characteristics of Hispanic births in the years 1978–85 (12–18).

The number of births to Hispanic mothers in the Hispanic reporting area totaled 406,153 in 1987, 4 percent more than in 1986 (389,048) and 9 percent more than in 1985. (See table 23 for 1987 data.) In 1987, 62 percent of Hispanic births were to Mexican mothers, slightly lower than in the past several years; 9 percent were to Puerto Rican women, and 12 percent were to Central and South American women. The proportion of Hispanic births to Cuban mothers declined to 2 percent.

Hispanic births as a group are very concentrated geographically, and Mexican, Puerto Rican, and Cuban births each tend to be concentrated within a few States (table 23). For example, 94 percent of Mexican births occurred to residents of Arizona, California, Illinois, and Texas. Eighty-two percent of Puerto Rican births were accounted for by three States (Illinois, New Jersey, and New York), 93 percent of Cuban births were to residents of four States (California, Florida, New Jersey, and New York), and 95 percent of Central and South American births were to mothers living in five States (California, Florida, New Jersey, New York, and Texas).

The racial distributions of Hispanic births as a group and for the specific origin groups have been very stable. Overall, 95 percent of Hispanic births in 1987 were white, 3 percent were black, and 2 percent were of other races. The racial distributions of births in specific Hispanic groups vary widely (table 24).

Birth and fertility rates for the Hispanic population have changed little in recent years. (Rates for 1987 are shown in table 25.) In 1987 as in 1986, the birth rate was 23.3 births per 1,000 population. The fertility rate in 1987

was 93.0 births per 1,000 women aged 15-44 years, 1 percent lower than in 1986 (93.9). These rates were 45-50 percent higher than rates for the non-Hispanic population (15.5 and 64.1, respectively), a relationship that has been observed for several years. (Rates for the non-Hispanic population by race cannot be computed because the necessary population data for the Hispanic reporting area are not available.) The birth and fertility rates for the Mexican population declined by 1-3 percent in 1987, to 22.5 and 94.5, respectively. Because rates for other origin groups are based on relatively small population groups, the associated sampling variability is too large for valid comparisons of annual changes. The levels of these rates, however, have been very stable in recent years.

Teenage childbearing is relatively common among Mexican and Puerto Rican women (table 26). Mothers under 20 years accounted for 17–21 percent of Mexican and Puerto Rican births compared with 9 percent of white non-Hispanic births and 23 percent of black non-Hispanic births. Births to teens are relatively uncommon among Cuban mothers (6 percent) and Central and South American mothers (8 percent).

Mexican mothers are more likely than any other specific origin group to have given birth to their fourth or higher order child (table 27). In 1987, 18 percent of Mexican births were fourth or higher order compared with 6–12 percent of births of other Hispanic origins, 8 percent of white non-Hispanic, and 14 percent of black non-Hispanic births.

Childbearing by unmarried mothers continued to increase for Hispanic and non-Hispanic women in 1987 (table 27). About a third of all Hispanic births were to unmarried women, but the proportions for individual groups varied from 16 percent for Cuban births to 53 percent for Puerto Rican births. The comparable proportions for non-Hispanic births were 14 percent, white, and 63 percent, black.

The proportions of Hispanic mothers who have completed high school increased slowly but steadily during the 1980's, but did not change between 1986 and 1987. In 1987 as in 1986,

57 percent of all Hispanic mothers were high school graduates, compared with 85 percent of white non-Hispanic mothers and 68 percent of black non-Hispanic mothers. Levels of high school completion varied considerably among the specific origin groups, from 42 percent for Mexican mothers to 81 percent for Cuban mothers.

The proportion of 1987 births to Hispanic mothers who were born in the United States was 44 percent, the same as in 1986. There were small increases in the proportions of U.S.-born mothers among Puerto Rican (to 54 percent) and Cuban women (to 15 percent), but there was a slight decline for Mexican mothers (to 43 percent).

There was a small increase in 1987 in the proportion of Hispanic mothers who began receiving prenatal care in the first trimester, to 61 percent. (See table 27 for 1987 data.) The proportions for non-Hispanic mothers were 82 percent, white, and 60 percent, black. Except for Cuban mothers, among whom 83 percent began care in the first 3 months of pregnancy, the proportions of Hispanic mothers of specific Hispanic origin groups receiving care early varied little (57–66 percent).

The incidence of mothers whose prenatal care did not begin until the third trimester or who had no care at all did not change in 1987. Thirteen percent of all Hispanic mothers had late or no care compared with 4 percent of white non-Hispanic and 12 percent of black non-Hispanic mothers. The variation among specific origin groups was considerable, from 4 percent for Cuban mothers to 17 percent for Puerto Rican mothers.

Despite the relatively high proportion of teen mothers, low proportion of high school graduates, and high proportion of mothers who received late or no prenatal care, the levels of low birth weight among babies born to Hispanic mothers have been relatively favorable. Mexican, Cuban, and Central and South American babies particularly have low percents of low birth weight, 5.7–5.9 percent, compared with 5.6 percent of white non-Hispanic babies and 12.9 percent of black non-Hispanic babies. The incidence of low birth

weight among Puerto Rican babies was relatively high, 9.3 percent.

In contrast to the incidence of low birth weight, levels of preterm births among Hispanic babies tend to be noticeably higher than among white non-Hispanic babies. In 1987, 11 percent of Hispanic births were born prior to 37 completed weeks of gestation compared with 8 percent of white non-Hispanic and 18 percent of black non-Hispanic births (table 27). Again, there was considerable variation among the specific Hispanic groups, from 9 percent for Cuban babies to 13 percent for Puerto Rican babies.

The proportions of babies with 1-minute Apgar scores below 7 declined in 1987 for all Hispanic groups except Central and South American infants. Overall, 7.8 percent of Hispanic babies had 1-minute Apgar scores less than 7 in 1987 compared with 8.1 percent in 1986. The proportions for non-Hispanic babies were 8.2 percent, white, and 11.4 percent, black (table 27).

There was very little change in proportions of low 5-minute Apgar scores in 1987. Overall, 1.5 percent of Hispanic babies had 5-minute Apgar scores below 7 in both 1986 and 1987. The levels for non-Hispanic babies were 1.3 percent, white, and 2.9 percent, black. There were small increases in the proportions of Puerto Rican, Cuban, and Central and South American babies with low scores. The proportion for Mexican babies was unchanged.

Births of other race and national origin groups

The number of babies born of "other Asian or Pacific Islander" races increased 11 percent from 1986 to 1987, to a total of 68,532. This was the largest single-year increase in this racial category since 1982 when the number rose 19 percent. Other Asian or Pacific Islander births include those reported as Asian Indian, Cambodian, Korean, Laotian, Thai, and Vietnamese, but exclude Chinese, Japanese, Filipino, and Hawaiian births, which are tabulated separately (table 28).

The number of Hawaiian births increased 1 percent; Japanese births, 2 percent; American Indian births, 3 percent; and Filipino and Chinese

births, 5 and 6 percent, respectively. The 11-percent rise in the number of other Asian or Pacific Islander births resulted principally from increases in a few States, particularly California, Georgia, Illinois, and New York. In most of these States, the increases are accounted for primarily by foreign-born mothers. (Data by State are not shown in this report.)

Although it is not possible to compare levels of childbearing by age using birth rates for these groups, inferences can be drawn by comparing distributions of births according to age of mother. Childbearing by teenage mothers is extremely rare for Chinese and Japanese women (1 and 3 percent, respectively) and relatively uncommon for Filipino and other Asian or Pacific Islander women as well (6 percent) (table 28). By contrast, 15 percent of Hawaiian mothers and 19 percent of American Indian mothers were under 20 years of age. The comparable proportions for white and black women were 10 and 23 percent, respectively.

Conversely, mothers aged 30 years and over account for an extraordinarily large proportion of Chinese and Japanese births (55 and 53 percent, respectively) and large fractions of Filipino (44 percent) and other Asian or Pacific Islander births (38 percent) as well. In contrast, only 20 percent of American Indian and black mothers and 22 percent of Hawaiian mothers were aged 30 years and over. The proportion for white mothers was 29 percent.

In general, a relatively high proportion of teenage mothers is associated with a comparably high proportion of births of fourth or higher order and with a lower proportion of mothers who are college graduates. This is because women who begin childbearing at relatively young ages can be expected to have more children and to have less opportunity to advance their educations. For example, 7 percent or fewer of Chinese, Japanese, and Filipino births were fourth or higher order in 1987 compared with 10 percent of all births, and 36-41 percent of Chinese, Japanese, and Filipino mothers were college graduates compared with 18 percent of all mothers. (Data on these topics are not presented in this report.)

Except for American Indian and Hawaiian births, a large proportion of births of races other than white and black are to mothers born outside the United States. The proportions in 1987 were 39 percent for Japanese births, 77 percent for Filipino births, 82 percent for Chinese births, and 87 percent for other Asian or Pacific Islander births. Overall, 58 percent of births of races other than white and black were to foreign-born mothers, compared with 13 percent of all births.

The proportion of babies of low birth weight in the various racial and national origin groups changed little in 1987, except for Hawaiian and Japanese infants. (Data for 1987 are shown in table 29.) The levels ranged from 5.0 percent for Chinese births to 7.3 percent for Filipino births. The proportion increased for Japanese births from 5.6 to 6.3 percent and declined for Hawaiian births from 7.4 to 6.6 percent. Generally, the levels of low birth weight among these groups are comparable to those for white births. To some extent the low levels may be associated with the relatively small fractions of teen mothers in these groups, who are much more likely than older mothers to have low birth weight babies. (See the earlier section of this report on birth weight.)

Month of pregnancy prenatal care began

The proportion of mothers who began prenatal care in the critical first trimester of pregnancy was essentially unchanged during the 8-year period 1979–87, at 76 percent annually (except for 1984 when it was 77 percent). During the years 1969–78, the proportion of mothers beginning care early had increased from 68 to 75 percent. (See table 30 for 1987 data.)

Similarly there was no change in the proportion of mothers whose first visit for prenatal care was delayed until the third trimester or who had no care at all. During the years 1983–87, this proportion was 6 percent. From 1978 through 1982, the proportion had been 5 percent.

The racial disparity in the timely receipt of prenatal care increased slightly in 1987, because the proportion of white mothers beginning care early stayed at 79 percent while the comparable proportion of black mothers declined from 62 to 61 percent. Delayed or no prenatal care was reported for 5 percent of white mothers and 11 percent of black mothers, the same levels as in 1986.

Gains in the early receipt of prenatal care in 1987 were limited, as in 1986, to women aged 35 years and over, and amounted to 1–2 percent. Reductions were measured for mothers in age groups under 15 and 20–29 years. There was no change in the proportions for other age groups.

The proportion of mothers receiving late or no care declined only for mothers aged 35–39 and 40 years and over by 7–12 percent. Except for mothers aged 19 and 30–34 years, for whom there was no change, the proportion of women receiving late or no care increased by 2–5 percent for all other ages. This pattern of change for 1986–87 was similar to that measured for 1985–86.

A considerable proportion of teenage mothers is at high risk of receiving delayed or no prenatal care. In 1987, 13 percent of all mothers under age 20 years were in this category. More than 1 in 5 mothers under 15 years did not begin prenatal care until the third trimester or had no care at all. By single year of age, the proportions declined from 17 percent for mothers aged 15 to 11 percent for those 19 years of age.

The proportions of white and black mothers receiving care early and having delayed or no care were similar for those 16 years of age and younger. The racial differential increased thereafter with advancing age, reaching a peak at ages 25–29 years.

More than 9 in 10 mothers who have graduated from college began prenatal care in the first trimester, compared with just over half of those who are not high school graduates. (Data are not shown in this report.) This relationship between prenatal care and educational attainment has been evident for many years (19). In 1987, as in the past several years (except 1984), gains in the receipt of prenatal care were confined to the best educated women.

A review of the data on prenatal care by State (not presented in this report) shows a wide variation in the

proportions of mothers receiving delayed or no care. Among white mothers, the proportion ranged from 2 to 13 percent, with the highest levels reported in States with substantial Hispanic populations. Earlier in this report it was noted that Hispanic mothers are much more likely than non-Hispanic mothers to begin prenatal care late or to have no care at all. Among black mothers in States reporting at least 1,000 black births in 1987, the range in the proportion with delayed or no care was 6-18 percent. Between 1986 and 1987, 32 States showed increases in the proportion of white mothers receiving late or no care while 18 States and the District of Columbia reported declines. Among the 37 States and the District of Columbia reporting 1,000 or more black births, 21 States showed increases in the percent with delayed or no care while 16 States and the District of Columbia showed reductions.

Number of prenatal visits

Forty-nine States and the District of Columbia provided information in 1987 on the number of visits made by pregnant women to receive prenatal care. This reporting area, which excludes only California, has not changed since 1982. In this 5-year period, the median number of visits has increased steadily from 11.4 in 1982 to 12.0 in 1987. The median increased for white mothers during these years from 11.8 to 12.2; for black mothers it increased from 10.2 to 10.6 visits. (Basic data for 1987 are shown in table 31.)

The medians vary substantially according to the trimester in which prenatal care began. The median for mothers beginning care in the first trimester was 12.4, one-third higher than the median for mothers beginning care in the second trimester, 9.3 visits, and almost 2½ times the median for those beginning care in the third trimester, 5.1 visits.

The continued increase in prenatal visits during a period when the timing of the first visit did not change and the period of gestation did not lengthen (see next section) may be associated with changes in the distribution of mothers according to age and educational attainment. One change is the

reduction in the proportion of teenage mothers associated with the declining teenage population. At the same time there has been an increase in the proportion of births to relatively older mothers, which is associated with rising birth rates and an increasing number of women aged 30 years and over. As noted in an earlier section, teen mothers are least likely to begin prenatal care early and consequently have fewer visits, while very high proportions of older mothers begin prenatal care in the first trimester, therefore completing their pregnancies with more visits.

A second factor, related to the changing age distribution, is the increasing proportion of well-educated mothers. In 1987, 18 percent of all mothers were college graduates compared with 15 percent in 1982. Ninetytwo percent of these mothers in 1987 began prenatal care in the first trimester. Although the relative increase in college graduates has been greater for black than for white mothers, the absolute level is substantially lower for black mothers, 7 percent compared with 20 percent. Consequently, the racial disparity in receipt of prenatal care remains substantial.

Length of gestation

The proportion of babies born prior to 37 completed weeks of gestation increased to 10.2 percent in 1987, compared with 10.0 percent in 1986. This marks the fifth nearly consecutive year of increase (there was a decline between 1983 and 1984) in the proportion of preterm infants. In 1981, the proportion had been 9.4 percent. (Data for 1987 are shown in table 32.) The length of gestation is measured as the interval between the first day of the mother's last normal menstrual period and the date of birth. The interval is computed in days, which are converted to weeks.

The proportion of preterm infants increased for both white and black babies. Because the increase was greater for black than for white infants, the racial disparity increased. Among white

infants, the proportion increased from 8.4 to 8.5 percent; among black infants, it increased from 17.7 to 18.0 percent.

It was noted in the earlier section on birth weight that the length of gestation has a significant effect on the likelihood that a baby will be of low birth weight. In 1987, 38.9 percent of preterm babies weighed less than 5½ pounds, compared with 3.0 percent of term and postterm babies. Among preterm births, the racial differential in low birth weight is relatively small, but the proportions are high for both white and black infants. In 1987, 37.9 percent of white preterm babies and 42.1 percent of black preterm babies weighed less than 5½ pounds. Among term and postterm infants, however, the racial gap in low birth weight is substantial, although the absolute levels are much lower, 2.5 percent of white babies and 5.8 percent of black babies are of low birthweight. Because black babies are much more likely to be born preterm when the risk of low birth weight is elevated, the overall level of low birth weight among black infants is considerable.

The proportions of preterm births vary considerably by age of mother; the pattern is very similar to that observed for low birth weight and age of mother. (Data are not shown in this report.) One quarter of births to teenage mothers under 15 years and 15 percent of births to those 15-19 years of age were born preterm in 1987. The proportions declined to a low of 9 percent for births to mothers aged 25-29 years and then increased to 15 percent for births to mothers aged 45-49 years. This relationship between age and risk of preterm birth is observed for both white and black infants, but at each age the proportion was higher for black than for white infants.

Apgar score

The Apgar score is a summary measure used to evaluate the newborn infant's overall physical condition at birth. The score, named after the late physician Virginia Apgar, is a composite evaluation of five factors-the infant's heart rate, respiratory effort, muscle tone, irritability, and coloreach of which is assigned a value from 0 to 2. The overall score is the sum of the five values, with a score of 10 being optimum. In 1987, as in each year since 1983, the Apgar scores at 1 and 5 minutes after birth were reported by 46 States and the District of Columbia. (See tables 33 and 34 for 1987 data.)

In 1987, for the first time since 1978 when the data first became available, the proportion of high 1-minute Apgar scores (scores of 9-10) increased to 41.9 percent compared with 41.4 percent in 1986. This proportion had been declining since 1978 when it was 49.0 percent. Black babies continued to have a slightly higher proportion of high 1-minute scores than white babies, 43.1 percent compared with 41.7 percent.

There was an increase in the percent of high 5-minute Appar scores as well in 1987, continuing a trend of increase observed since 1983. The 1987 level was 88.6 percent. There were increases for white and black infants as well, to 89.1 and 86.2 percent, respectively.

The 5-minute Appar score is considered to have better long-term predictive value concerning the infant's health status and survival chances. The proportions of babies with low 5-minute scores (scores less than 7) declined in 1987 for infants born to teenage mothers and to mothers aged 35 years and over. The relationship between age of mother and low Apgar scores is similar to that for age of mother and low birth weight, and for age and preterm birth. Babies born to mothers aged 25-34 years are at lowest risk of low 5-minute Appar scores. 1.5 percent in 1987 compared with 2.2-3.5 percent for births to teens and to mothers in their forties. This relationship was observed for white and black infants, but the risk of low scores was higher for black babies at each age; the racial gap was greatest for births to mothers aged 30-34 years.

¹Includes races other than white and black.

Table 14. Birth rates by age of father and race of child: United States, 1970, 1975, and 1980-87

[Rates are live births per 1,000 men in specified group, enumerated as of April 1 for 1970 and 1980 and estimated as of July 1 for all other years. Figures for age of father not stated are distributed]

Rates computed by relating total births, regardless of age of father, to men aged 15-54 years.
Rates computed by relating births of fathers under 20 years of age to men aged 15-19 years.
Based on 100 percent of births in selected States and on a 50-percent sample of births in all other States; see Technical notes.
Based on a 50-percent sample of births.

¹Rates computed by relating total births to unmarried mothers, regardless of age of mother, to unmarried women aged 15–44 years. Rates computed by relating births to unmarried mothers aged 40 years and over to unmarried women aged 40-44 years.

NOTE: For 41 States and the District of Columbia, marital status of mother is reported on the birth certificate; for 9 States, mother's marital status is inferred; see Technical notes.

Table 19. Birth rates for unmarried women by age of mother and race of child: United States, 1970-87

Rates computed by relating total births to unmarried mothers, regardless of age of mother, to unmarried women aged 15–44 years.

Rates computed by relating births to unmarried mothers aged 40 years and over to unmarried women aged 40–44 years.

Data for States in which marital status was not reported have been inferred and included with data from the remaining States; see Technical notes.

Based on 100 percent of births in selected States and on a 50-percent sample of births in all other States; see Technical notes.

Births to unmarried women are estimated for the United States from data for registration areas in which marital status of mother was reported; see Technical notes.

Based on a 50-percent sample of births.

Table 20. Live births by interval since last live birth, live-birth order, and race of child: Total of 49 reporting States and the District of Columbia, 1987

Technical notes

Source of data

Data shown in this report for 1987 are based on 100 percent of the birth certificates in all States and the District of Columbia. The data are provided to the National Center for Health Statistics through the Vital Statistics Cooperative Program. In 1984 and earlier years, the Vital Statistics Cooperative Program included varying numbers of States. Information on sampling procedures and sampling errors for 1984 and earlier years is provided in the annual report, Vital Statistics of the United States, Volume I, Natality.

Concurrent with the 1978 revision of the U.S. Standard Certificate of Live Birth, NCHS recommended that States add items to identify the Hispanic or ethnic origin of the newborn's mother and father. In 1987, 23 States and the District of Columbia included questions on origin, selecting one of two basic formats. The first format was an open-ended item to obtain the specific origin or descent of each parent (for example, Italian, Mexican, German, Puerto Rican, English, or Cuban). The second format was directed toward the Hispanic population and asked whether the mother and father were of Spanish origin. If so, the specific origin, such as Mexican, Puerto Rican, or Cuban, was to be indicated.

Birth data by Hispanic origin are based on 100 percent of the births occurring in the 23 reporting States and the District of Columbia. The data shown in the tables are for births to all residents of the reporting area, regardless of where the births occurred. Births occurring in nonreporting States to residents of the reporting area are included in the "not stated" origin category.

Racial classification

The racial designation used in the report is that of the child, which is determined from the race of the parents as entered on the birth certificate. When the parents are of different races and one parent is white, the child is assigned to the other parent's race. When the parents are of different races and neither parent is white, the child is

assigned to the father's race with one exception: If the mother is Hawaiian or part Hawaiian, the child is considered Hawaiian. When the race of one parent is missing on the certificate, the child is assigned the race of the other parent. When race is not reported for either parent, the child is assigned the race of the child on the immediately preceding record.

Population denominators

Birth and fertility rates for 1987 shown in tables 1 and 3–5 are based on populations estimated as of July 1, 1987. The population estimates for the United States were published by the U.S. Bureau of the Census (20) and are based on the 1980 census count. The 1980 census counts by race were modified to be consistent with Office of Management and Budget categories and historical categories for birth data. The modification procedures are discussed in detail in a U.S. Bureau of the Census report (21).

Birth and fertility rates for the Hispanic population, shown in table 25, are based on estimates of the Hispanic population from the Current Population Survey conducted in March 1987. Beginning with 1986, the Current Population Survey figures include estimates of undocumented immigrants (11). The effect of this change may be to reduce the levels of the birth and fertility rates by about 1 percent.

Estimates of the Hispanic population were provided for 11 States— Arizona, California, Colorado, Florida, Illinois, Indiana, New Jersey, New Mexico, New York, Ohio, and Texas. These estimates are consistent with postcensal independent estimates of the Hispanic population for the United States by age and sex, based on 1980 census data. The population data are based on small samples and may, therefore, be subject to substantial sampling error. Information on the derivation of these estimates and the sampling error is presented in a U.S. Bureau of the Census report (11).

NOTE: A list of references follows the text.

Computation of rates

In computing birth and fertility rates for the Hispanic population, births with origin of mother not stated are included with non-Hispanic births rather than being distributed. Thus, rates for the Hispanic population are underestimates of the true rates to the extent that the births in the 11-State area with origin of mother not stated (2.9 percent) were actually to Hispanic mothers. The population with origin not stated was imputed. The effect on the rates is believed to be small.

Births by marital status of mother

Beginning with 1980 data, national estimates of births to unmarried women have been derived from two sources. For 41 States and the District of Columbia, marital status is reported directly on the birth certificate; for the remaining 9 States, which lack such an item, marital status is inferred from a comparison of the child's and parents' surnames. This procedure represents a substantial departure from the method used prior to 1980 to prepare national estimates of births to unmarried women. The previous method assumed that the incidence of births to unmarried women in States with no direct question on marital status was the same as the incidence in reporting States in the same geographic division.

The current method represents an attempt to use related information on the birth certificate to improve the quality of national data as well as to provide data for the individual nonreporting States. An evaluation of this method and its validity for California (the largest nonreporting State) has been published (22). Because of the continued substantial increases in all measures of nonmarital childbearing in 1987, an intensive evaluation of the national data was made. There has been continuing concern that the current method, incorporating data based on a comparison of surnames, might overstate the number of births to unmarried women. This is because births to women who have retained their maiden

surname as their legal surname after marriage and who are frequently older. well-educated women would be classified as births to unmarried women. The evaluation included comparisons of trends in nonmarital births in States with a marital status item on the birth certificate with trends in those States providing inferential data based on a comparison of surnames. The comparisons were made for white and black births separately by age of mother. The results were similar for both sets of States. Nonmarital births increased at virtually the same rate for white and black women and for the various ageof-mother groups.

Computation of percents, percent distribution, and medians

Births with unknown live-birth order, attendant at birth, educational at-

tainment of mother, nativity of mother, month of pregnancy prenatal care began, number of prenatal visits, date of last live birth, birth weight, length of gestation, and 1- and 5-minute Appar scores were subtracted from the figures for total births that were used as denominators before percents, percent distributions, and medians were computed. In the case of birth intervals, the percent distributions exclude the second or later born child in a multiple delivery (interval of 0 months). Percent distributions and the median number of prenatal visits also exclude births to mothers who had no prenatal care. Computations of the median number of prenatal visits were based on tabulations of ungrouped data.

Related reports

Many of the topics discussed in this report are covered in more analytical

detail in other reports published by the National Center for Health Statistics. Topics of reports published within the past 5 years include Asian births (23), American Indian and Alaska Native births (24), teenage childbearing (25), births of Hispanic parentage (15–18), and midwife-attended births (26). Also available are methodological reports on imputing length of gestation (27) and on evaluating inferred birth statistics for unmarried women in California (22) and a report presenting birth and fertility rates by State for 1980 (28).

Technical notes	21

According to final data from the vital registration system, the number of U.S. couples that married declined in 1987 for the third consecutive year. In 1987 the number of marriages was 2,403,378, down less than 1 percent from 1986 and 3 percent from the record high of 2,477,192 in 1984 (table 1 and figure 1). The 1987 total was lower than any year since 1980. According to provisional data, marriages dropped further in 1988 and 1989.

The marriage rate in 1987 was 9.9 per 1,000 population, down to the level

it had been a decade earlier, but lower than in any year in the interim. While the marriage rate for the total population rose and fell twice during the 1970's and 1980's, the marriage rate for the most eligible group of unmarried women, 15–44 years of age, fell every year except 1972 and 1981.

Tables 1-3 are based on total counts of marriages that are obtained annually from all States and the District of Columbia. Tables 4-13 contain detailed demographic information about brides and grooms. This information is drawn from a sample of certificates of marriages performed in the marriage-registration area (MRA), which is composed of 42 States and the District of Columbia. Eighty percent of all marriages took place in the MRA in 1987. The marriage rate for the MRA was 9.2 per 1,000 population, 7 percent below the U.S. rate of 9.9. (See Technical notes.)

Marital status in the MRA was quite similar to that in the entire United States: 58 percent of the population was married, 27 percent was single, 8 percent was widowed, and 7 percent was divorced. Thus while a lower marriage rate shows that residents of States in the MRA are less

likely than residents of other States to marry, the proportions of the population that are currently single, married, divorced, and widowed are quite similar.

Seasonal and daily variation

In the United States, marriages typically follow a seasonal pattern. Most marriages occur in the summer, particularly in June, and fewest occur in January. In 1987 the marriage rate for June was 13.5 per 1,000 population, more than twice the January rate of 5.7 (table 2).

Saturday is the most preferred day of the week to marry. More than half of the marriages in the MRA in 1987 were performed on Saturdays (data not shown). In most years since 1970 the last Saturday in June has been the single day most frequently chosen for weddings in the MRA. In 1987, however, St. Valentine's Day (February 14) fell on a Saturday and 46,000 couples in the MRA got married, more than on any other day of the year. The next most popular days were Saturday, June 20 (38,000 marriages) and Saturday, June 27 (37,000 marriages). St. Valentine's Day also fell on a Saturday in

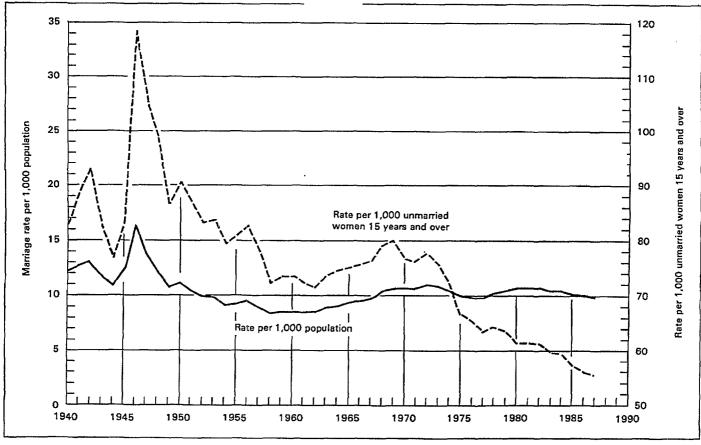

Figure 1. Marriage rates: United States, 1940-87

1976 and 1981. In those years, too, more couples married on St. Valentine's Day than on any other day of the year. The next time February 14 falls on a Saturday will be 1998. In the intervening years a Saturday in June will probably be the most popular day for American weddings.

Geographic variation

In 1987 marriage rates declined in most States, dropping as much as 5 percent in New Hampshire, Michigan, South Dakota, and Oklahoma, and 7 percent in Wyoming (table 3). Rates of marriage were unchanged in three States and increased in only nine States and the District of Columbia. In Hawaii, Kentucky, New Mexico, Oregon, and the District of Columbia, the rates increased only 1 percent while in Nevada the rate surged 9 percent.

Total marriage rate

Like the rates discussed previously, the total marriage rate is a period rate

based on marriages that occurred during 1 year. However, there is an important difference between this rate and the others. The total marriage rate is intended to show the number of marriages that a group of 1,000 men and women would have if they experienced during their entire adult lives the agespecific marriage rates observed in a given calendar year. It is a hypothetical measure that shows the implication of current levels of marriage by age for lifetime experience. The rate has been calculated separately for first marriages and for remarriages to show the implications of the current level of marriage rates on patterns of family formation in the United States.

In 1987 the total first marriage rate was 699.4 for women and 689.6 for men (table 4). This means that if current rates were to continue, 70 percent of women and 69 percent of men would marry at least once. Both rates were up slightly from 1986. While the total first marriage rates rose in 1987, the total remarriage rates declined. The total remarriage rate was 406.8 for women

and 449.0 for men. That is, for every 100 women there would be 41 remarriages, and for every 100 men there would be 45 remarriages.

Previous marital status

States in the MRA record the previous marital status of brides and grooms, making it possible to follow the trends in first marriage and remarriage separately. These are not hypothetical rates like the total marriage rates discussed above that show what would happen over a lifetime; rather, these are annual rates that show only what happened in a specific year.

In 1987 the marriage rate for divorced women (80.7 per 1,000) was 37 percent higher than the rate for single women (58.9) and almost 14 times higher than the rate for widows (5.4), see table 5. The 1987 marriage rate for divorced men (115.7 per 1,000) was 137 percent higher than the rate for single men (48.8) and more than four times the rate for widowers (26.1). Thus divorced persons are more

likely to marry than single or widowed persons, single women are more likely to marry than single men, but divorced or widowed men are much more likely to marry than divorced or widowed women.

In 1987 most rates for single, divorced, and widowed men and women continued the downward trend that predominated during the 1970's and 1980's, when the marriage rates dropped for both sexes and for all marital statuses (figure 2). The one exception in 1987 was the rate for previously divorced women that increased 2 percent, but was still below the rates for any year from 1970 through 1985. The rates for single, divorced, and widowed persons dropped by 35 to 47 percent between 1970 and 1987, but have generally maintained their levels relative to each other.

Age-specific marriage rates for women showed complex trends in which rates declined for some age groups but increased for others between 1986 and 1987. Marriage rates for single women dropped for age groups under 25 years but increased for ages 25-39 years (table 6). Before 1984 single women 20-24 years had the highest first marriage rate, but the rate dropped fairly steadily during the 1980's, and in 1984 it fell below the rate for women 25-29 years. The first marriage rate for women 30-34 years has risen consistently since 1983. These changes indicate that at least some of the young women who did not marry in the 1970's and 1980's were postponing. but not rejecting, the institution of marriage. Age-specific rates for divorced women show that marriage rates increased in 1987 for all age groups

25-49, 55-59, and 60-64 years. The marriage rate for widowed women 25-44 years of age increased, while the rate for widowed women 45-64 years of age declined.

Although the rates for single, divorced, and widowed men of all ages combined declined in 1987, the age-specific rates showed no clear trend. Some age groups were more likely and some were less likely to marry in 1987 than in 1986.

Age at marriage

In 1987 nearly 9 out of 10 brides were under 40 years of age and 9 out of 10 grooms were under 45 years of age. Of the brides embarking on a first marriage, 18 percent were teenagers, 44 percent were 20–24 years of age, 25 percent were 25–29 years, and only

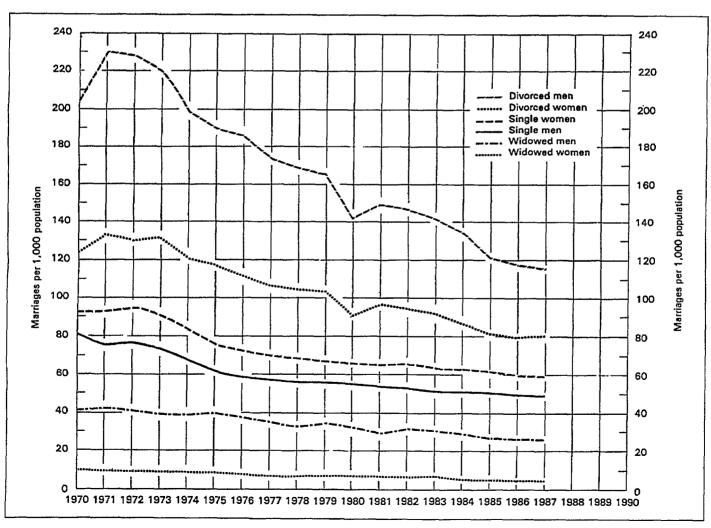

Figure 2. Marriage rates of single, divorced, and widowed men and women: Marriage-registration area; 1970-87

13 percent were 30 years of age and over (table 7 and figure 3).

Although the largest proportion of first marriages was for brides 20–24 years of age, as indicated above, the rate was highest for single women 25–29 years of age. This is because the number of single women aged 25–29 years was much smaller than the number aged 20–24 years, but a larger proportion of these women was getting married at ages 25–29 years. Of the

brides who were remarrying after a divorce, less than 1 percent were teenagers, 33 percent were in their twenties, 42 percent were in their thirties, and 24 percent were 40 years of age and over. As might be expected, the brides who were previously widowed were older. Only 22 percent were under 40 years of age, 20 percent were in their forties, 21 percent were in their fifties, and 38 percent were 60 years of age and over. The ages of grooms in each

category were less concentrated in the twenties and thirties and more of them were older.

Americans are marrying later than they used to. In 1970, 42 percent of brides and 18 percent of grooms were teenagers at first marriage. By 1987 the proportions dropped to 18 percent of brides and 7 percent of grooms. Complementary shifts were occurring at the older ages. For example, in 1970 only 12 percent of brides were over 25 years

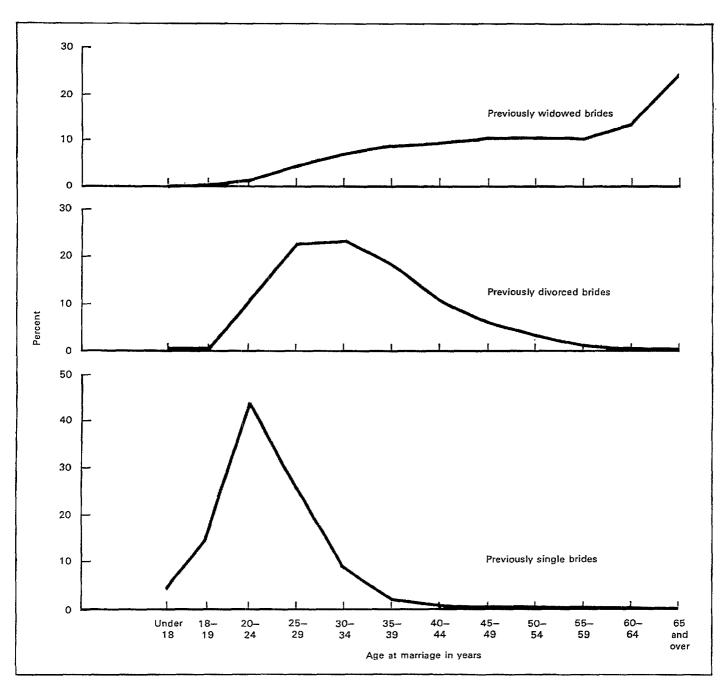

Figure 3. Percent distribution of marriages by age of bride, according to previous marital status: Marriage-registration area, 1987

of age at first marriage. By 1987 the comparable figure was 38 percent. For men the proportion of grooms who were over 25 years of age at first marriage rose from 25 percent in 1970 to 53 percent in 1987.

The shift to older ages at marriage is also shown by the median age. The median age at first marriage was 23.6 years for brides and 25.3 years for grooms, up for the 13th consecutive year (table 8). The median age for brides who had been previously divorced was 33.3 years and for grooms, 36.7 years. This represents the 11th consecutive annual increase in age for previously divorced brides and the 10th consecutive annual increase in age for previously divorced grooms. In contrast, previously widowed brides and grooms were younger in 1987 than in 1986.

Interval to remarriage

The date when a previous marriage of the bride or groom ended is reported by 27 States. From this information, interval between marriages can be calculated. In 1987 some of the people who remarried had been divorced or widowed as long as 50 years. Most, however, were remarrying just a few years after their divorce. In fact, just under one-third of the divorced men and women were remarrying within a year of the date their last marriage ended.

Half of previously divorced and widowed grooms were marrying within 2.2 years of the date their last marriage ended (table 9). The median interval to remarriage was slightly longer for previously divorced brides, 2.5 years. The interval for previously widowed brides (4.6 years in 1987) was considerably longer than the interval for divorced brides or for divorced or widowed grooms.

Race

Thirty-four States report race of bride and groom on marriage records. In these States 87 percent of brides were white, 11 percent were black, and less than 2 percent were of other races (table 10). Although the distribution by race for grooms was very similar, there were slightly more white brides than

white grooms, fewer black brides than black grooms, and more brides than grooms of other races. White brides and grooms were younger than black brides and grooms at both first marriage and remarriage (data not shown).

Educational attainment

Twenty-one States report years of school completed by bride and groom on the marriage records. The distribution of educational attainment is shown for previously single, divorced, and widowed brides and grooms in table 11 along with summary measures, the mean and median. On average, single brides have slightly more education (13.7 years) than single grooms (13.6 years), while divorced brides have less (13.1 years) than previously divorced grooms (13.4 years).

Couples

Most tables in this report show characteristics of brides and grooms separately since each has his or her own age, race, education, and previous marital history. However, the characteristics of brides and grooms can also be viewed in combination.

Previous marital status-In 1987. 54.3 percent of marriages in the MRA were primary marriages, that is, first marriages for both bride and groom (table 12). The remaining 45.7 percent of marriages were remarriages for the bride, the groom, or both. In 19.1 percent of the marriages both the bride and the groom were previously divorced; in 11.0 percent the bride was previously single and the groom was previously divorced; and in 10.7 percent the bride was previously divorced and the groom was previously single. In 4.9 percent of marriages one or both spouses had been widowed.

Age—In 1987 the ages of the bride and groom differed with different combinations of previous marital status (table 13). Couples in primary marriages were youngest: The average (mean) age of the bride was 23.9 years and of the groom, 25.8 years; the age difference was 1.9 years. For couples who were both previously divorced, the average age of the bride was 36.1 years, more than 12 years older than the

brides in primary marriages; the average age of the groom was 39.8 years. The age difference of 3.7 years between the bride and groom was almost twice that of primary marriages. For couples who were both previously widowed, the average age of the bride was 63.2 years and of the groom, 68.0 years; the age difference was 4.8 years.

For couples where one spouse was single and the other previously divorced, brides and grooms were older than in primary marriages, but not as old as couples where both spouses were divorced. Single brides who married previously divorced grooms were 27.7 years of age, almost 4 years older than brides in primary marriages. The average age of their previously divorced grooms was 34.4 years; the age difference between the bride and groom was 6.7 years.

For all except two combinations of previous marital status shown in table 13, husbands were older than their wives. However, previously divorced and widowed brides who married single men were older, on the average, than their grooms. Divorced brides marrying single grooms were 30.7 years of age, 1.3 years older than their grooms who were 29.4 years. Previously widowed brides marrying single grooms were 39.4 years of age, 2.3 years older than their grooms who were 37.1 years. These are the only combinations of previous marital status in which brides were older, on the average, than their

Type of ceremony—Although the majority of U.S. couples had religious ceremonies, the proportion was smaller when both the bride and groom were previously divorced (54.8 percent) than when they were both single (76.7). For marriages in which the previous marital status of the spouses was mixed, the proportion that had religious ceremonies was intermediate.

Race—In the States that report race on the marriage records, 86 percent of the couples were white, 11 percent were black, 1 percent were of other races, and 2 percent were interracial.

Education—Education was broadly grouped into six categories—elementary, 1-3 years of high school, high school graduate, 1-3 years of college,

college graduate, and graduate level. If both the bride and groom could be grouped into the same category, they were considered to have the same educational level. Half (50.1 percent) of the brides in primary marriages had the same education as their grooms, while a quarter had less (25.2 percent) and another quarter (24.7) had more. However, education was less equal in remarriages than in primary marriages.

When both spouses were previously divorced, fewer of the couples had the same education (42.0 percent), and a larger proportion of the previously divorced grooms (32.8 percent) had more education than their brides.

Previously divorced brides not only had less education than single brides (table 11), they also had a greater gap relative to their grooms. This difference is due both to greater rates of divorce for women with less education and to less remarriage for divorced women with more education (1).

Table 3. Marriages and marriage rates: United States, each region, division, and State, 1977, 1986, and 1987—Con.

[By place of occurrence. Data are counts of marriages performed, except as noted. Rates per 1,000 population estimated as of July 1]

		Rate				
Region, division, and State	1987	1986	1977	1987	1986	1977
Pacific:						
Washington	43,503	43,255	43,835	9.6	9.7	11.6
Oregon	22,301	22,015	20,303	8.2	8.1	8.3
California	234,035	225,018	¹ 149,416	8.5	8.3	¹ 6.7
Alaska	5,470	5,734	5,143	10.4	10.8	13.0
Hawall,	16,567	16,219	10,266	15.3	15.2	11.2

Data exclude 32,008 nonlicensed marriages registered in California; see Technical notes.

Table 4. Total marriage rate by marriage order of women and men: Marriage-registration area, 1972-87

[Based on sample data. Marriages per 1,000 women or men if age-sex specific rates for a given year were constant throughout their lives. Figures for marriage order not stated have been distributed. Beginning in 1977, figures exclude data for lowa. For a description of the marriage-registration area, see Technical notes]

	Total mar	riage rate	Total first-ma	arriage rate	Total remarriage rate		
Year	Women	Men	Women	Men	Women	Men	
1987	1,106.2	1,138.6	699.4	689.6	406.8	449,0	
1986	1,113.5	1,150.1	698.6	689.4	414.9	460.7	
1985	1,113.0	1,155.5	699,3	688.9	413.7	466.6	
1984	1.139.2	1.192.4	704.6	698.1	434.6	494.3	
1983	1,131.9	1,189,4	703.0	697.4	428.9	492.0	
1982	1,143,6	1,206,4	710.9	703.4	432.7	503.0

972	95.1	130.6	9.4	73.9 77.2	229.0	40.6	
971	93.3	132.8	9.6	75.2	230.7	40.6 42.5	
1970	93.4	123.3	10.2	80.4	200.7 204.5	42.5 40.6	

Data are incomplete.

SFigure used for New York City is the total number of valid marriage certificates provided to NCHS.

Data are premarital health examination forms issued.

⁵Data include marriage licenses issued for some counties.

Table 6. Marriage rates by age and previous marital status of women and men: Marriage-registration area, 1982-87

[Based on sample data. Figures exclude data for lowa. For a description of the marriage-registration area, see Technical notes. Marriages of persons under 15 years of age are included in the youngest age groups; rates are based on populations that exclude persons under 15 years of age. Rates for all marriages are based on the unmarried population; for first marriages, on the never-married population; and for remarriages, on the widowed and divorced populations. Rates per 1,000 population in specified age group estimated as of July 1]

Monthly Vital Statistics Report

Table 7. Marriages, 1987, and percent distribution of marriages, 1970, 1980, 1986, and 1987 by age according to previous marital status of women and men: Marriage-registration area—Con.

[Based on sample data. For sampling errors of estimates and a description of the marriage-registration area, see Technical notes]

			Women		Men					
	Number Percent			Number	Percent					
Age and previous marital status	1987	1987	1986	1980	1970	1987	1987	1986	1980	1970
Not stated if widowed or divorced	85,302					83,470				
Not stated if previously married										
Total	31,214					30,064				

¹Figures for first marriages and remarriages exclude data for lowa beginning in 1977; these data are included in "Not stated If previously married."

²Data exclude remarriages in Michigan and Ohio for all years, for South Carolina beginning in 1972, and for the District of Columbia for 1970. These data are included in "Not stated if wildowed or divorced."

Table 8. Median and mean age of bride and groom by previous marital status: Marriage-registration area, 1963-87

[Based on sample data. Figures by previous marital status exclude data for lowa beginning with 1977. Figures for previously divorced and previously widowed exclude data for Michigan and Ohlo for all years, for South Carolina beginning with 1972, and for the District of Columbia for 1970. For a description of the marriageregistration area, see Technical notes]

¹Figures include divorced or widowed not stated.

NOTE: In 1970 data on interval between marriages were reported by 18 registration States (California, Florida, Georgia, Hawali, Illinois, Kansas, Louisiana, Montana, New Hampshire, New York, North Carolina, Pennsylvania, Rhode Island, Tennessee, Utah, Vermont, Wisconsin, and Wyoming). By 1987, 9 additional States were reporting interval between marriages (Colorado, Kentucky, Maine, Minnesota, Mississippi, Missouri, Nebraska, Oregon, and Virginia).

NOTE: In 1970 previous marital status was reported by 38 States: Alabama, Alaska, California, Connecticut, Delaware, Florida, Georgia, Hawaii, Idaho, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Minnesota, Mississippi, Missouri, Montana, Nebraska, New Hampshire, New Jersey, New York, North Carolina, Oregon, Pennsylvania, Rhode Island, South Dakota, Tennessee, Utah, Vermont, Virginia, West Virginia, Wisconsin, and Wyoming. Starting in 1971, the District of Columbia also reported this item. After 1976, Iowa no longer reported it. In 1979 Colorado joined the MRA, bringing the total of reporting areas back to 38 States plus the District of Columbia for the 1979–87 period.

Technical notes

Place and time of occurrence

Marriages and marriage rates for States and other areas are by place of occurrence. Marriages are those performed during the calendar year.

Sources of data

Figures in tables 1-3 are based on totals reported by States and counties, except for New York City, where the count of marriages is the total number of valid marriage certificates provided to the National Center for Health Statistics (NCHS). Figures in tables 4-13 are based on data tabulated from Statecoded data tapes and from probability samples of records selected and coded in NCHS from copies of the records sent by States participating in the marriage-registration area (MRA). In 1987 the MRA consisted of the District of Columbia and all except eight States-Arizona, Arkansas, Nevada, New Mexico, North Dakota, Oklahoma, Texas, and Washington. Marriages performed in the MRA included 80 percent of the marriages registered in the United States in 1987 and 79 percent in 1977.

Nonlicensed (confidential) marriages for California

Section 4213 of the California Civil Code allows unmarried couples who have been living together to be married confidentially without obtaining a marriage license or health certificate. In March 1972 this section was amended to require county clerks to keep sealed records of these marriages and to report periodically the total number to the California State Department of Health Services. Since reporting began, nonlicensed marriages have increased rapidly, from 2.857 in 1973 to 90,494 in 1987. NCHS has not included the nonlicensed California marriages in totals or rates for years prior to 1978. However, beginning with final statistics for 1978, nonlicensed marriages, which totaled 37,462 in that year, are included in the national and regional totals and rates.

Marriage sample

Total counts of marriages are available from all States and are shown in tables 1–3. Data on characteristics of bride and groom shown in tables 4–12 are available only from States in the MRA and exclude nonlicensed marriages in California.

Twelve States-Florida, Illinois, Maine, Missouri, Montana, Nebraska, New Hampshire, New York (except New York City), Rhode Island, South Carolina, Vermont, and Virginia-supplied State-coded data tapes of all their marriage records through the Vital Statistics Cooperative Program, and 100 percent of these records were used by NCHS. For all other States in the MRA, records were sampled at rates designed to give a sample of at least 2,500 for each State. All records were included in the samples for Delaware, District of Columbia, Wyoming, where totals of less than 5,000 marriages had been expected, and for New York City and Wisconsin. All other States were sampled at 5, 10, 20, or 50 percent, depending on the number of marriages in the State. The total sample size, including records supplied through the Vital Statistics Cooperative Program was 783,087 marriages. Sampling errors shown in table I are for frequencies that equal a specified percent of the total MRA marriages.

Nonlicensed marriages, as previously mentioned, are included in the total count for California. However, they are not available for inclusion in the MRA marriage sample. The 5-percent sample of California marriages for 1987 was drawn only from licensed marriages. The corresponding weights for sample records were based on these totals. Because no information is available on the characteristics of persons obtaining nonlicensed marriages, no accurate estimate is available for the bias introduced in sample estimates by the omission of these marriages.

Marriage rates were lower for the MRA than for the entire United States. The crude marriage rate for the MRA

Table I. Approximate sampling errors of estimated number of marriages shown in tables 7, 10, and 11: Marriage-registration area, 1987

Percent of total MRA marriages	
in subclass	Sampling error
1 or 99	446
2 or 98	628
3 or 97	765
4 or 96	878
5 or 95	977

10 or 90	1,345
15 or 85	1,601
20 or 80	1,793
25 or 75	1,941
50	2,241

HOW TO USE THE SAMPLING ERROR TABLE: The total number of MFIA marriages in 1987 (excluding nonlicensed California marriages) was 1,839,052. For any estimate of marriages shown in tables 7, 10, and 11, determine its percent of the total MRA marriages. Then look in the table of sampling errors for the row containing the computed percent to determine the sampling error for the estimated number of marriages for the year. For example, in 1987 there were an estimated 628,606 remarriages of women, or 34.8 percent of all 1987 marriages (table 7). Because 34.8 is between 25 and 50 percent, the sampling error is between 1,941 and 2,241, or, by interpolation, 2,059 remarriages. The chances are about 68 out of 100 that the actual number of 1987 remarriages is between 625,547 and 630,665 (628,606 ± 2,059).

(9.2 per 1,000) was 7 percent below the U.S. rate (9.9) and the rate for married women 15 years of age and over (48.3 per 1,000) was 13 percent below the U.S. rate (55.7). This is because residents of the MRA constituted 86 percent of the U.S. population, while only 80 percent of U.S. marriages occurred in the MRA and 77 percent were included in the MRA sample. At least two reasons for these differences can be identified.

First, many residents of States in the MRA married in States not in the MRA and were not counted in the MRA marriage total. However, because they lived within the MRA, they were counted in the population on which the rates were based. Although the number of such marriages was not known for 1987, in 1980, when a special marriage sample was drawn from five States not in the MRA, 93,433 brides who were residents of States in the MRA married in States not in the MRA. In contrast, only 13,634 brides who lived in a State not in the MRA married within it, so there was a substantial net loss from the MRA marriage total.

Nevada accounted for a large proportion of this net loss from the MRA total. Of the 108,220 (1980) Nevada brides whose residence was reported, 83,080 (76.8 percent) lived in the MRA, but their marriages were not included in the MRA total. Only 15,580 of the Nevada brides were residents of that State. Assuming that this was also true in 1987, a substantial portion of the 474,646 marriages that took place in States not in the MRA were marriages of MRA residents.

A second reason was that the 90,494 nonlicensed California marriages were not in the MRA sample to count as marriages, but the entire population of California was in the population on which MRA rates were based. If these 90,494 marriages had been included in the MRA sample, the rate would have been 50.8 rather than 48.3 per 1,000 unmarried women 15 years of age and over.

There may also be a difference in the rate at which residents of States in the MRA marry, divorce, and remarry compared with residents of States not in the MRA.

Sampling errors

All statistics for the MRA are estimates based on the systematic sample of marriages described above; therefore, these statistics are subject to sampling errors. The sampling error is a measure of variation that occurs by chance between sample estimates and the actual quantity being estimated. Chances are about 68 out of 100 that an estimate would differ from the true value by less than the sampling error and about 95 out of 100 that the difference would be less than twice the sampling error.

Population denominators

Marriage rates for the MRA by age, sex, and previous marital status for 1982–87 are based on unpublished population estimates as of July 1, prepared by the U.S. Bureau of the Census (2). National and State rates for 1987 are based on population estimates as of July 1, published by the U.S. Bureau of the Census (3).

Computation of percent distributions, medians, and means

Figures for marriage order and previous marital status not stated were subtracted from figures for marriages used as denominators before medians were computed. Computations of median and mean age at marriage were based on tabulations of ungrouped data.

Nonreporting bias

Age was more than 99 percent complete on marriage records, but in 1987 marriage order for brides was not stated on 2 percent of the MRA records. No allocation of missing data was done before rates were calculated. The percent not stated for grooms was similar.

Divorces and divorce rates

The number of divorces in the United States fell 1 percent for the second consecutive year, from 1,178,000 in 1986 to 1,166,000 in 1987 (table 1). The 1987 total was 4 percent below the record high of 1,213,000 reached in 1981. The number of divorces fluctuated during the 1980's, but the 1987 total was lower than that for any year since 1983.

The divorce rate per 1,000 population dropped 2 percent between 1986 and 1987, from 4.9 to 4.8. This rate has not been as low since 1975. During the

1980's, the divorce rate declined 9 percent from a high of 5.3 in 1981. The divorce rate per 1,000 married women 15 years of age and over dropped 2 percent in 1987, from 21.2 per 1,000 to 20.8. This was lower than it has been since 1975.

Divorce rates dropped in two of the four geographic regions in 1987, the South and the West, to 5.4 and 5.5, respectively (table 2). Rates in these two regions were considerably higher than rates for the Northeast (3.6 per 1,000) or the Midwest (4.4), which were unchanged from 1986.

States with the highest divorce rates in 1987 were Nevada (13.8). Oklahoma (7.3), Arizona (7.0).Arkansas (6.7), Florida (6.6), Wyoming (6.5), Alaska (6.5), Indiana (6.4), Tennessee (6.2), and Alabama (6.0). These States all had rates that were at least 25 percent higher than the national rate (4.8). The lowest divorce rates in 1987 were reported for Massachusetts (2.9), Pennsylvania (3.3), North Dakota and Maryland (3.4) each), and Minnesota, Wisconsin, and New Jersey (3.5 each). The number and rate of divorce dropped sharply, 14 and 15 percent, respectively, in Massachusetts between 1986 and 1987

in the wake of 1985 legislative changes that speeded the process of divorce and thus inflated divorce totals for 1985 and early 1986. The 1987 rate of 2.9 for Massachusetts may represent a return to what will be a more typical annual level for that State. Other States that reported a more than 5-percent decline in the 1987 divorce rate were Wyoming, Alaska, Hawaii, Delaware, Mississippi, West Virginia, and Arkansas.

Data for the preceding discussion are from counts of the number of divorces that are provided annually by officials in 50 States. The count of divorces for the District of Columbia was taken from the 100-percent sample of divorce records. For the following discussions of children involved in divorce, ages at divorce and marriage, duration of marriage, and petitioner of divorce, detailed information comes from the 31 States and the District of Columbia that constitute the divorce-registration area (DRA). About 49 percent of the divorces in the United States in 1987 took place in the DRA, and 55 percent of the population aged 15 years and over live in DRA States. The divorce rate for the DRA was 4.3 per 1,000 population, 10 percent below the rate for the entire United States.

U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES Public Health Service Centers for Disease Control National Center for Health Statistics

Manning Feinleib, M.D., Dr. P.H., Director

Children involved in divorce

Divorces affect at least two people, the husband and the wife. In addition, there may be children affected by divorce. In 1979 the number of children under 18 involved in divorce reached a record high of 1,181,000; and it has fluctuated, generally downward, since then (table 3 and figure 1). In 1987 there were 1,038,000 children involved in divorce, 2 percent fewer than in 1986 and fewer than in any year since 1973. The average number of children per decree was 0.89, down 1 percent from 1986 and lower than it has been since 1954. The rate per 1,000 children under 18 years of age was 16.3, down 3 percent from 1986 and lower than it has been since 1975. Taken together, these numbers reflect both the declining number of divorces and the shrinking size of American families. In the 51.5 million married-couple families in the United States in 1987, the average

number of children was 0.88 compared with 1.30 in 1970 (1, 2).

Almost one-half (48 percent) of the couples divorcing in 1987 had no children under 18 years of age. Twenty-five percent had one child, 20 percent had two children, and only 7 percent had three children or more (table 4). These proportions have been similar in recent years, but compared with 1970, more of the couples who are currently divorcing had no children and fewer had large families of three children or more.

The proportion of divorces that involved children depended on the

duration of marriage. In general, as duration lengthened to 14 years, the proportion of couples with children increased. Twelve percent of those married less than a year had children, as did 26 percent of those married 1–2 years, 42 percent of those married 3–4 years, 60 percent of those married 5–9 years, and 75 percent of those married 10–14 years. The proportion with children decreased for couples married more than 14 years because some of their children were no longer minors.

Race and education made some difference in the proportion of divorcing couples with children. For white couples, 52 percent had one or more children; for black couples and for couples of other races, 49 and 47 percent, respectively, had children. Information on education of divorcing men and women shows that college graduates were less likely than those with less education to have minor children. These data are from the 27 States and

the District of Columbia that report race and the 21 States that report education on divorce records.

Age

Age-specific divorce rates have been calculated using data from 28 States and the District of Columbia, where age at divorce was reported with sufficient completeness to provide reliable rates (table 5). The rates are based on population estimates prepared by the U.S. Bureau of the Census and, as in the past, fewer men than women are reported as married. This causes the rate of divorce for married men to be slightly higher than the rate for married women because the base population is smaller. The 1987 divorce rate per

1,000 married men was 18.8, slightly higher than the rate of 18.6 per 1,000 women.

The age-specific divorce rate for women was highest for married teenaged women 15–19 years of age (49.5). The rate then dropped for successive 5-year age groups. For men, the highest rate was for those 20–24 years of age (52.2 per 1,000 married men). Then, as with the married women, the divorce rate dropped for each successive age group (figure 2).

Most men are married to women younger than themselves. Consequently, except for teenagers, rates for men are higher than those for women in each age group. For example, the divorce rate for married men aged 40–44 years was 21.4 per 1,000, and that for women was 18.7.

Between 1986 and 1987, the divorce rate declined for married women of all ages combined, from 18.8 to 18.6 per 1,000. When the data are broken down into 5-year age groups, however, different patterns emerge. Rates declined for married women under 35 years of age and for those aged 40-44, 50-54, and 60-64 years. In contrast, rates increased for married women aged 35-39, 45-49, and 55-59 years. The divorce rate for married men of all ages combined decreased from 19.0 in 1986 to 18.8 in 1987. Rates increased, however, for some ages: 20-24 years, 35-39 years, and the three 5-year groups from 50-64 years.

From 1970 to 1980, the divorce rate for married men or women of all ages increased 39 percent, and divorce rates rose for every age group except

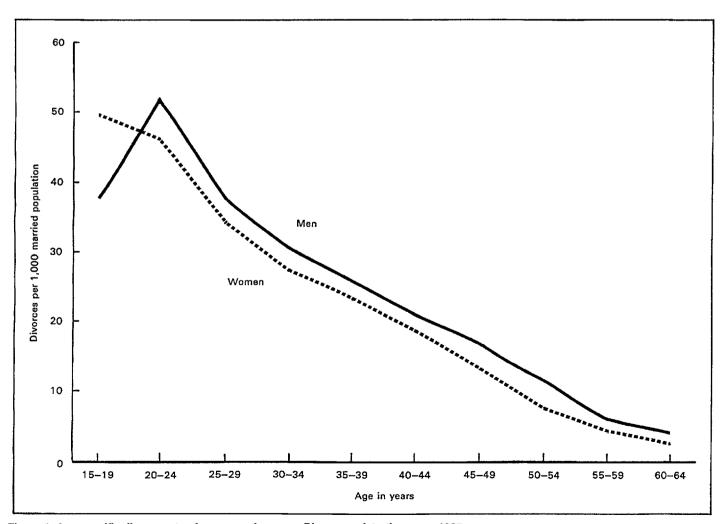

Figure 2. Age-specific divorce rates for men and women: Divorce-registration area, 1987

for men 65 years of age and over. The percent of increase was much greater for younger than for older men and women. Subsequently, from 1980 to 1987, the rates for married men and women of all ages dropped 5 percent although rates fluctuated from year to year for most age groups. For a few groups. there were rather persistent and substantial increases. The divorce rate for men 45-49 increased 19 percent between 1980 and 1986 before dropping slightly in 1987. Although the divorce rate for married men 60-64 years of age is low, it rose 16 percent, from 3.7 in 1980 to 4.3 in 1987. The divorce rate for women ages 50-54 years increased 15 percent, from 6.6 in 1980 to 7.6 in 1986, before dropping to 7.5 in 1987.

For both sexes divorce is concentrated between 20 and 45 years of age. Only 19 percent of husbands and 13 percent of wives were 45 years of age or over when they divorced in 1987, and 3 percent of husbands and 2 percent of wives were 60 years and over (table 6).

There are two summary measures of age, the median and the mean, that facilitate comparisons over time, between sexes, and among different marital histories (table 7). In 1987 the median age of men at divorce was 34.9 years, meaning that half of the divorcing men were under 35 years of age when they divorced and half were 35 or older. The mean, or average, age was 36.8 in 1987, up for the ninth consecutive year and 2.0 years older than it was in 1978 (34.8).

The age at divorce varies with the number of times divorcing men and women have been married. In 1987, 72 percent of divorcing men and women were ending first marriages, 21 percent were ending second marriages, and 7 percent were ending third or higher order marriages. The mean age of men ending first marriages was 34.6 years of age; while for men ending second and third or higher order marriages it was 41.3 and 45.5 years, respectively.

There was also an increase in the age at which divorcing men and women had been married, but the majority were still under 25 years of age at

marriage (table 8). The trends in average ages at first marriage showed that the age at which divorcing men had married was relatively stable during the 1970–80 decade and ended the decade just as it began, at 23.0 years of age. In every year after 1980, there was an increase in the age at which divorcing husbands had first married, and by 1987 the age reached 23.9 (table 9).

In part, the increase in age at divorce between 1978 and 1987 was due to increasing age at marriage for both first marriages and remarriages. For example, average age of divorcing husbands at first marriage increased a year between 1978, when it was 22.9 years, and 1987, when it was 23.9 years (table 9). Age at second marriage of men divorcing in 1987 was 34.0, 1.2 years older than in 1978. Age at third or higher order marriage of men who divorced in 1987 was 40.2, 1.2 years older than in 1978. Also contributing to the increase in age at divorce were a slightly longer duration of marriage (table 10) and an increase in the proportion of husbands and wives ending remarriages (28 percent in 1987 compared with 24 percent in 1978).

The trends in age of divorcing women at marriage and divorce were similar to those of men from 1970 through 1987; for first marriages, however, women were younger than men by more than 2 years; and for second marriages, women were younger than men by more than 3 years.

Duration of marriage

The percent distribution of 1987 divorces according to the length of time that couples had been married shows that the greatest numbers of marital dissolutions occur early in marriage and that, after the second year, there are fewer dissolutions at each subsequent duration (figure 3). In 1987 the median duration was 7.0 years and the mean, or average, duration was 9.6 years. However, average duration to decree varied according to the number of times the spouses had been married (table 10). The mean duration was 10.8 years for first divorces of husbands and wives, 7.4 years for husbands and 7.3 years for wives dissolving second marriages, and 5.4 years for husbands and 5.0 years for wives ending third or

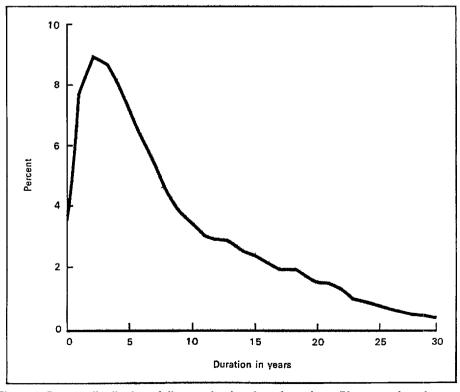

Figure 3. Percent distribution of divorces by duration of marriage: Divorce-registration area, 1987

higher order marriages. Thus, men and women ending third marriages had been married only half as long as those ending first marriages.

Taken together, data from tables 7, 9, and 10 show that husbands and wives who divorced in 1987 were older at divorce, both because they were older at marriage and because they remained married for longer durations, and that this was true for first marriages as well as for remarriages.

One of the most striking characteristics of these data is the consistency of the statistical measures from year to year. The levels of the measures are remarkably stable and, when there is a change, it is gradual. For example, despite the fact that divorce laws changed radically early in the 1970's-moving toward consistency among States, nofault legislation, and shorter waiting periods—the average duration of dissolving first marriages during the 18-year period from 1970 to 1987 varied only from 10.0 years to 10.8 years. This consistency from year to year in duration to divorce suggests that there is some underlying time-dependent process in marital stability.

In addition to the underlying process of marriage dissolution and the differences between first and remarriages, there are legislative differences that allow residents in some States to divorce much more quickly than those in other States once they have decided to divorce. In Maryland and Virginia, for example, only 0.4 percent of couples had been married less than a year when their divorce decree was granted, while in Alabama the comparable figure was 8.4 percent (table 11). Other factors that account for some of the variation among States are variations in average age at marriage, ethnic and religious differences in divorce rates, and the proportion of couples that are in remarriages. The mean duration ranged from 7.4 in Alaska to 11.4 in Maryland and Pennsylvania.

Petitioner

Wives are twice as likely as husbands to be the spouse who petitions for the divorce (table 12). In 1987 wives petitioned 60.7 percent of all divorces, husbands petitioned 32.7 percent, and both petitioned 6.5 percent. When children were present, the disparity between the sexes was even greater, with 65.1 percent of all divorces petitioned by wives. When children were not present, the proportion of divorces initiated by wives dropped to 56.2 percent and the proportion petitioned jointly increased to 7.0 percent. The proportion of jointly petitioned divorces more than doubled since 1975, when it was 2.8 percent of decrees, to 6.5 percent in 1987.

There were small racial differences in petitioner. White wives were more

likely than black wives and wives of other races to be the petitioners. In 1987, 64 percent of white wives, 60 percent of black wives, and 56 percent of wives of other races initiated the divorces.

The number of times a husband or wife had been married had almost no effect on which spouse initiated divorce proceedings. In general, there were also only very small differences by age for husbands and for wives. However, for men around retirement age, 60-64 years, the proportion of husband petitioners increased. For men in all age groups under 60 years, the proportion of husband petitioners was between 32 and 36 percent. Among husbands 60-64 years of age the proportion increased to more than 40 percent, and this was true for dissolutions of both first marriages and remarriages.

Race

In the 27 States and the District of Columbia that report race on divorce records, 85 percent of the divorcing husbands and wives were both white, 11 percent were both black, 1 percent were both of other races, and 2 percent were interracial couples (table 13). The racial composition of divorcing couples is very similar to that of couples married in recent years.

 $^{^{\}rm 1}$ This State reports number of children affected by decree.

Table 5. Divorces and annulments by age of men and women at time of decree, 1987, and rates by age of men and women at time of decree, 1970, 1980, and 1982–87: Divorce-registration area

[Based on sample data. Prior to calculation of rates, figures for age not stated were distributed. Rates exclude data for Michigan, Ohio, and South Dakota. Rates per 1,000 married population in specified group enumerated as of April 1 for census years and estimated as of July 1 for all other years]

Technical notes

Definitions

Divorces include absolute divorces, annulments, and dissolutions of marriage. Data are tabulated by State where the decree was granted, not by State of residence. Date of divorce is defined as the date the decree was granted.

Sources of data

Nationwide counts

Data in tables 1 and 2 come from the number of divorce decrees reported annually by States and counties, except for the District of Columbia, where the count of divorces was taken from the 100-percent sample of divorce records. When divorces are not reported for counties, the following criteria are applied for the data shown in table 2:

- 1. The State totals are published as reported even when there are nonreporting counties.
- If the population of nonreporting areas in the latest available census is less than 1 percent of the State population, the State total does not have a footnote to indicate that the data are incomplete.
- 3. If the population of nonreporting areas is 1.0-9.9 percent of the State population, data for the State and division have the footnote "Data are incomplete." Rates are computed and no estimates are made for the missing data.
- 4. If the population of nonreporting areas is 10 percent or more of the State population, the State and division totals have the footnote "Data are incomplete," and the divorce rate is not computed. Estimates are made for inclusion in the totals for the region and for the United States, and rates are computed. Figures for the region and United States have the footnote "Figures include estimates."

Sample data

Information about the characteristics of divorcing couples is available only from States that participate in the divorce-registration area (DRA). Data in tables 3–13 come from a probability sample of divorce records from the States participating in the DRA. The DRA has expanded from 28 States in 1970 to 31 States and the District of Columbia in 1987. About 49 percent of the divorces in the United States in 1987 took place in the DRA.

Divorce sample

The probability sample of divorce records for 1987 was selected by using five different sampling rates. For the District of Columbia and for each State

in the DRA, either 5, 10, 20, 50, or 100 percent of the divorce records were included. Sampling rates were selected so that the expected sample would contain at least 2,500 records for each State. This criterion required 100 percent sampling for Alaska, Delaware, the District of Columbia, Hawaii, Montana, New Hampshire, South Dakota, and Wyoming. One hundred percent of the divorce records also were included for eight additional States-Illinois, Missouri, Nebraska, New York, Rhode Island, South Vermont, and Virginia. These eight States supplied State-coded data tapes of 100 percent of their divorce records through the Vital Statistics Cooperative Program.

The table on this page shows sampling errors for estimates that

Sampling error of estimated percent: Divorce-registration area, 1977, 1986, and 1987, and each registration State, 1987

[Figures for Alaska, Delaware, District of Columbia, Hawaii, Illinois, Missouri, Montana, Nebraska, New Hampshire, New York, Rhode Island, South Carolina, South Dakota, Vermont, Virginia, and Wyoming have no sampling errors in 1986 or 1987 because all records were tabulated]

constitute 1, 10, 25, 50, 75, 90, and 99 percent of the annual divorce totals. These sampling errors are shown for the DRA for 1977, 1986, and 1987 and for the District of Columbia and each DRA State for 1987.

Estimates of children involved in divorce

To make the national estimates of children involved in divorce, shown in table 3, it was assumed that the average number of children per decree for the United States was the same as the average in the DRA. This average was multiplied by the national divorce total to estimate the national number of children involved in divorce. For 1950–59, the average number of children per decree was calculated using data from all reporting States; for 1960, from a

nationwide sample; for 1961-69, from 16 States; and, thereafter, from all DRA States.

Computation of rates, percent distributions, medians, and means

Divorce rates for 1987 are based on populations estimated as of July 1, 1987 (3,4). Percent distributions, means, and medians exclude cases for which the pertinent information (number of children, duration of marriage, or age) is not stated. Mean and median age at marriage and at decree, and mean and median duration of marriage were computed using ungrouped data.

The mean and the median are both measures of central tendency. The mean is computed by summing the values of the item under consideration and dividing this sum by the number of observations included. The median is the middle value of a set of observations that have been arranged in order of magnitude. There are an equal number of observations above and below the median.

This report represents summary tabulations from the final divorce statistics for 1987. More detailed tabulations for 1987 will be published in *Vital Statistics of the United States, Volume III—Marriage and Divorce*. Prior to the publication of that volume, the National Center for Health Statistics will respond to requests for unpublished data whenever possible.

Highlights

In 1987, 2,123,323 deaths were registered in the United States, 17,962 more than in 1986 and the largest annual final number ever recorded. Contributing to the increased number of deaths were population growth and the "aging" of the U.S. population, that is, the increasing proportion of older persons. The death rate for 1987 was 872.4 deaths per 100,000 population, about the same as the rate of 873.2 in 1986. Provisional data for 1988 indicate the death rate (883.0) to be up from 1987.

The age-adjusted death rate, which eliminates the effects of the aging of the population, was 535.5 per 100,000

population, lower than the rate of 541.7 in 1986. The age-adjusted rate decreased for the white population but remained essentially unchanged for the black population between 1986 and 1987. The rates decreased for white males and white females, although more for males; rates for black males and black females were essentially the same for the 2 years. For males and females of most age groups, death rates declined between 1986 and 1987. Exceptions were for males aged 35–44 years and females aged 25–34 years for whom rates increased.

In 1987 life expectancy at birth reached a record high of 75.0 years, slightly higher than in 1986. For the white population, it also attained a record; but for the black population, it remained at the 1986 level of 69.4 years, after declining during 1984-86. Although the difference in life expectancy for males and females has narrowed since the late 1970's, women are still expected to outlive men by an average of 6.9 years. Between the white and black populations, the difference in life expectancy generally has been narrowing: however, the difference has increased since 1984, from 5.6 to 6.2 vears in 1987.

As in previous years, almost three out of four deaths in the United States were caused by the first four leading

causes of death-Diseases of heart; Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues (cancer); Cerebrovascular diseases (stroke); and Accidents and adverse effects. The age-adjusted death rates for the six leading causes of death declined between 1986 and 1987. The age-adjusted death rate for cancer declined slightly between 1986 and 1987 for the second consecutive year; this is in contrast to the historic upward trend for this, the second leading cause of death in the United States. The ageadjusted death rate for Motor vehicle accidents—a component of Accidents and adverse effects-increased slightly between 1986 and 1987 for the second consecutive year. Mortality from Homicide and legal intervention, the 12th leading cause, decreased more than for any of the other leading causes of death between 1986 and 1987, by 4 percent; this contrasts with the general increase in mortality from this cause since 1980. Human immunodeficiency virus (HIV) infection was the 15th leading cause of death in 1987. This was the first year that deaths from HIV infection were included as a rankable cause of death. The age-adjusted death rate for drugrelated causes remained essentially unchanged between 1986 and 1987.

Males experienced higher mortality than females for each of the 15 leading causes of death. The greatest sex differential was for HIV infection, where the age-adjusted rate for males was 9.1 times that for females. The smallest sex differential was for Diabetes mellitus, with a male-to-female ratio of 1.1.

The black population had higher rates than the white population for most of the leading causes of death. The largest race differential continued to be for Homicide and legal intervention, for which the age-adjusted rate for the black population was 6.0 times that of the white population. The two leading causes that had lower rates for the black population were Chronic obstructive pulmonary diseases and allied conditions and Suicide. In 1987 for the Hispanic population, the two leading causes of death were Diseases of heart and Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues, the same as for the non-Hispanic white population in the 18-State Hispanic reporting area. (See Technical notes.)

The infant mortality rate (10.1 infant deaths per 1,000 live births) was at a record low in 1987. The rate declined for the white population, but the change between 1986 and 1987 for the black population was not statistically significant. For both the white and black populations, the downward trend in infant mortality has slowed in recent years. Neonatal mortality rates showed a statistically significant decline between 1986 and 1987 for the white population, while remaining at the same level for the black population; there were no statistically significant changes in postneonatal mortality rates for either major race group between 1986 and 1987. The difference between the infant mortality rate for the Hispanic population in 1987 (7.9) and that for the non-Hispanic white population (8.4) in the 18-State reporting area was statistically significant.

Deaths and death rates

Death rates shown in this report are based on population estimates prepared by the U.S. Bureau of the Census. Because the population bases used for 1984, 1985, 1986, and 1987 incorporate new estimates of net migration and net undocumented immigration, death rates for these years are not strictly comparable with those for previous years. Although trends in death rates for the total population are not substantially affected, caution should be used in comparing differences in death rates for the period 1984–87 with those of previous years for certain age-race-sex subgroups. For further discussion, see the Technical notes.

In 1987 a total of 2,123,323 deaths occurred in the United States, 17,962 more than in 1986 and the largest final number ever recorded. Contributing to the increased number of deaths were the continued increase in the size of the population as well as the increasing proportion of older persons. In contrast to the two previous years, 1987 was not characterized by a major influenza outbreak, which is often associated with elevated mortality (1). The death rate for 1987, 872.4 per 100,000 population, was essentially the same as the rate for 1986 (873.2). The provisional death rate for 1988 (883.0) was up from 1987.

The age-adjusted death rate of 535.5 deaths per 100,000 population in 1987 was a record low, about 1 percent below the rate for 1986 (541.7) (figure 1). Age-adjusted death rates show what the level of mortality would be if there were no changes in the age composition of the population from year to year. Thus, they are better indicators than unadjusted death rates for showing changes in the risk of death over a period of time when the age distribution of the population is changing. They are also better indicators of

risk when comparisons of mortality are being made for sex or race subgroups of the population that have different age compositions.

Death rates by age, sex, and race—For both sexes combined, death rates declined for most age groups between 1986 and 1987 (table A). They declined for each age group except 25–34 and 35–44 years, which had increases of 1 percent each. The largest decline (3 percent) occurred for the age group 15–24 years.

For males the increase in death rates between 1986 and 1987 for ages 35-44 years (1 percent) continued the increase begun between 1983 and 1984. a reversal of the downward trend for this age group since the late 1960's (figure 2 and table A). For males aged 25-34 years death rates remained essentially unchanged between 1986 and 1987, compared with large increases in previous years. For males aged under 1 and 45-54 and 65-74 years, declines in death rates continued. For females, all age groups, except 25-34 years, experienced declines in death rates. The 3percent increase for females aged 25-34 years continued the trend started in 1985. The largest decline for females was for ages 5-14 years (4.5 percent).

Age-adjusted death rates for white males and white females declined between 1986 and 1987—by 2 percent for white males, and by 1 percent for white females. In contrast, for black males and black females the age-adjusted death rate remained about the same between the two years. In 1987 the age-adjusted death rate for males of all

¹Death rates under 1 year (based on population estimates) differ from infant mortality rates (based on live births); see table E for 1987 infant mortality rates, and Technical notes for further discussion of the difference.

races was 1.7 times that for females, similar to the ratio in 1986. This ratio between male and female age-adjusted death rates was the same for the white and black populations. As in the past 4 years, the age-adjusted death rate for the black population in 1987 was 1.5 times that for the white population.

Expectation of life at birth and at specified ages

In 1987 the average expectation of life at birth reached a record high of 75.0 years (figure 3). This continued the general upward trend in life expectancy in the United States.

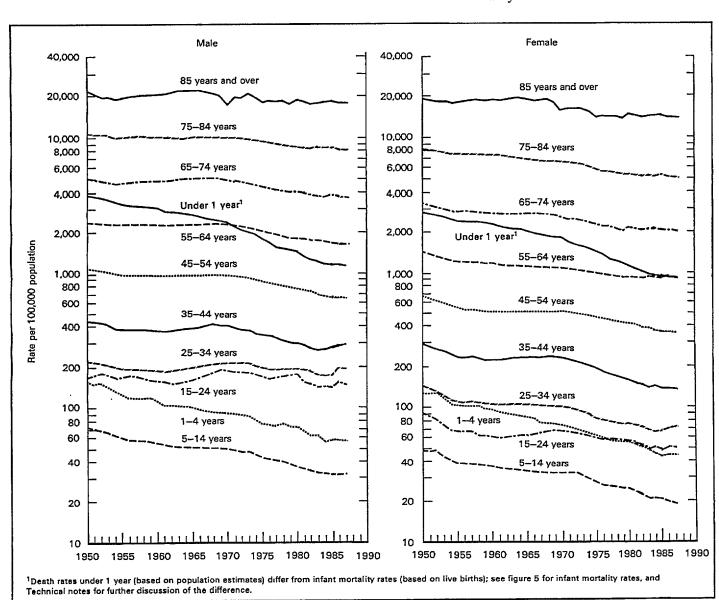

Figure 2. Death rates by age and sex: United States, 1950-87

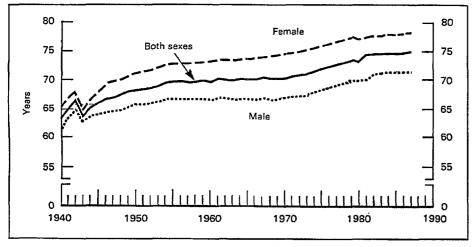

Figure 3. Life expectancy by sex: United States, 1940-87

The expectation of life at birth for 1987 represents the average number of years that a group of infants would live if they were to experience throughout life the age-specific death rates prevailing in 1987. In 1987 life expectancy for females was 78.4 compared with 71.5 years for males; both figures represent increases over 1986. The difference in life expectancy between the sexes, which had been widening from 1900 to 1972, has narrowed since 1979. The difference was 6.9 years in 1987 compared with 7.0 years in 1986, 7.4 years in 1980 and 1981, 7.7 and 7.8 years throughout the period 1972-79, 6.5 years in 1960, and 2.0 years in 1900.

Between 1986 and 1987 the white population experienced an increase in life expectancy, to a record high of 75.6 years, while the black population experienced no increase, with life expectancy remaining at 69.4 years. This stops the 2-year decline in black life expectancy that occurred from 1984 to 1986. While the difference in life expectancy between the white and black populations narrowed from 7.6 years in 1970 to 5.6 years in 1983 and 1984, it has increased since then, to 6.0 years in 1986 and 6.2 years in 1987.

Among the four race-sex groups, white females continued to have the highest life expectancy at birth (78.9 years), followed by black females (73.6 years), white males (72.2 years), and black males (65.2). The largest gain in life expectancy between 1970 and 1987 was for black females (5.3 years),

followed by black males (5.2 years), white males (4.2 years), and white females (3.3 years).

The 1987 life table may be used to compare life expectancies at any age from birth onward. For example, a person who has reached age 65 years may look forward to living to an older age, on the average, than one who has reached 50 years. On the basis of mortality experienced in 1987, a person aged 50 years could expect to live an average of 28.6 more years for a total of 78.6 years, and a person aged 65 years could expect to live an average of 16.9 more years for a total of 81.9 years.

Cause of death

Deaths assigned to the 15 leading causes accounted for 87 percent of the total number of deaths in 1987 (table B). (For ranking procedures, see Technical notes.) The ranking of the leading causes of death for 1987 remained unchanged for the first 14 causes of death based on data for 1986. The 15th leading cause of death in 1986, Congenital anomalies, was replaced by Human immunodeficiency virus infection (HIV infection), which, for the first time, was a rankable cause of death (see Technical notes and the section below on HIV infection).

Trends in mortality based on ageadjusted death rates are shown in figure 4 and table C for 14 of the 15 leading causes. Because deaths from Certain conditions originating in the perinatal period occur mainly among infants under 1 year, age-adjusted rates for this cause are not discussed.

For 11 of the leading causes of death the age-adjusted death rates decreased between 1986 and 1987 (table C). These causes were Diseases of heart; Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues; Cerebrovascular diseases; Accidents and adverse effects; Chronic obstructive pulmonary diseases and allied conditions; Pneumonia

Table B. Death rates and percent of total deaths for the 15 leading causes of death: United States, 1987

[Rates per 100,000 population]

Rank ¹	Cause of death (Ninth Revision International Classification of Diseases, 1975)	Rate	Percent of total deaths

and influenza; Suicide; Chronic liver disease and cirrhosis; Atherosclerosis; Nephritis, nephrotic syndrome, and nephrosis; and Homicide and legal intervention. The largest declines were for Homicide and legal intervention (4 percent) and for Diseases of heart and Pneumonia and influenza (3 percent each). The declines for Diseases of heart, Cerebrovascular diseases, and Atherosclerosis are consistent with the generally downward trends observed since 1950. Chronic liver disease and cirrhosis has exhibited a downward trend since 1979. For the second consecutive year the age-adjusted death rate for Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues declined slightly. This is in contrast to the generally increasing trend for this cause observed since 1950. This decrease in the age-adjusted rate reflects declines in death rates for this cause for most age groups under 65 years.

Increases in the age-adjusted death rates between 1986 and 1987 occurred for only two of the leading causes of death—Diabetes mellitus and Septicemia. The largest increase, 5 percent, was for Septicemia, continuing the rapid rise observed for the past three decades (figure 4). The age-adjusted

death rate for Diabetes mellitus increased by 2 percent between 1986 and 1987, reaching the level of 1979. Trends for HIV infection mortality are not available because mortality data from this cause were available for the first time in 1987 (see Technical notes).

Mortality levels for each of the 15 leading causes of death were higher for males than for females (table D). The

largest differentials were for HIV infection, and violent and accidental causes of death. Specifically the age-adjusted death rate for HIV infection was 9.1 times as high for males as for females. Suicide and Homicide and legal intervention were 3.9 and 3.2 times, respectively, as high for males as for females, and the rate for Accidents and adverse effects was 2.7 times as high for males

Table D. Ratio of age-adjusted death rates for the 15 leading causes of death by sex and race: United States, 1987

¹ Rank based on number of deaths; see Technical notes.

²Inasmuch as deaths from this cause occur mainly among infants, percent changes are based on infant mortality rates instead of age-adjusted rates.

²Inasmuch as deaths from this cause occur mainly among infants, ratios are based on infant mortality rates instead of age-adjusted death rates.

as for females. The smallest sex difference was for Diabetes mellitus, with a male-to-female ratio of 1.1.

For females the age-adjusted death rate for all causes combined declined slightly between 1986 and 1987. Decreases in rates occurred for the first three leading causes of death-Diseases of heart: Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues; and Cerebrovascular diseases-and for Pneumonia and influenza; Atherosclerosis; and Nephritis, nephrotic syndrome, and nephrosis. The decreases were offset, in part, by increases in rates for other leading causes, among which were Chronic obstructive pulmonary diseases and allied conditions, Accidents and adverse effects, and Septicemia. Of the leading causes of death, Septicemia had the largest increase in mortality between 1986 and 1987 for women; the age-adjusted death rate from this cause increased 8 percent. Age-adjusted rates for Diabetes mellitus were the same in 1986 and 1987. Increases in mortality for females aged 25-34 years between 1986 and 1987 described earlier were due to increases for the categories All other infectious and parasitic diseases (largely HIV infection); Motor vehicle accidents; and Symptoms, signs, and ill-defined conditions.

For males the age-adjusted death rate for all causes combined also declined between 1986 and 1987. Decreases occurred in the rates for 10 of the leading causes of death—Diseases of heart; Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues; Accidents and adverse Cerebrovascular diseases: effects: Chronic obstructive pulmonary diseases and allied conditions; Pneumonia and influenza; Suicide; Atherosclerosis; Nephritis, nephrotic syndrome, and nephrosis; and Homicide and legal intervention. Increases in the ageadjusted death rate occurred for Diabetes mellitus and Septicemia. For men, the largest increase was for Diabetes mellitus (4 percent). In contrast to 1986, when the age-adjusted death rate for Motor vehicle accidents increased from the previous year for both sexes, between 1986 and 1987 the rate decreased for males and increased for females. For males, the age-adjusted rate for Chronic liver disease and cirrhosis was unchanged between 1986 and 1987. Increases in mortality for males aged 35–44 years between 1986 and 1987 were due to increases for the categories All other infectious and parasitic diseases (largely HIV infection); Motor vehicle accidents; Chronic liver disease and cirrhosis; and Symptoms, signs, and ill-defined conditions.

Mortality was higher for the black population than for the white population for most of the leading causes (table D). The largest differential was for Homicide and legal intervention, for which the age-adjusted death rate for the black population was six times that of the white population. Other causes for which the differential was large include HIV infection (3.2); Nephritis, nephrotic syndrome, and nephrosis (2.8); Septicemia (2.7); and Diabetes mellitus (2.3). Age-adjusted rates for the black population were lower than those for the white population for two leading causes of death-Chronic obstructive pulmonary diseases and allied conditions and Suicide.

For the white population decreases in age-adjusted rates occurred in 11 leading causes of death. The largest decreases were for Homicide and legal intervention (5 percent); Diseases of heart, Pneumonia and influenza, and Atherosclerosis, (3 percent each); and Cerebrovascular diseases and Chronic liver disease and cirrhosis (2 percent each). Only Septicemia (3 percent) and Diabetes mellitus (2 percent) increased for the white population. For the black population rates were lower in 1987 than in 1986 for a number of the leading causes—Diseases of heart; Cerebrovascular diseases; Homicide and legal intervention; Pneumonia and influenza; and Nephritis, nephrotic syndrome, and nephrosis. Of the leading causes that increased for the black population, the largest increase was for Septicemia (6 percent). Other increases were for Chronic liver disease and cirrhosis, Suicide, Diabetes mellitus, and Chronic obstructive pulmonary diseases and allied conditions. Between 1986 and 1987 the age-adjusted death rate for Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues, decreased slightly for the black population (less than 1 percent); for the white population the rate for this cause also declined slightly between 1986 and 1987.

HIV infection

Beginning with mortality data for 1987, a new classification was introduced for HIV infection (see Technical notes). There were 13,468 deaths due to HIV infection in 1987. Of these deaths, 65 percent were for white males, 25 percent for black males, and 5 percent each for white and black females (see table 25). The largest numbers for both males and females were for age groups 25-34 and 35-44 years. Although the numbers of deaths were highest for white males, the ageadjusted death rates and almost all agespecific death rates were highest for black males, followed by white males, black females, and white females.

Overall, HIV infection was ranked as the 15th leading cause of death in 1987. It was the 10th leading cause for the black population and did not rank among the 15 leading causes of death for the white population. It was the 11th leading cause for males and did not rank among the 15 leading causes for females. By age, HIV infection ranked among the 15 leading causes for two age groups: It was the seventh leading cause of death for ages 15–24 years, and the sixth leading cause for ages 25–44 years.

Hispanic deaths

Leading causes of death for all age groups combined for the Hispanic population in an 18-State reporting area (see Technical notes) differ from those of the non-Hispanic white population. The two leading causes of death for both groups are Diseases of heart and Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues. For the non-Hispanic white population these two causes accounted for over three-fifths of all deaths in 1987, but only two-fifths of the deaths for the Hispanic population. Major differences in leading causes of death between the two groups are as follows: 3 of the 10 leading causes of death for the Hispanic population are not among the 10 leading causes for the non-Hispanic white population; they are Homicide and legal intervention (5th leading cause), HIV infection (9th), and Certain conditions originating in the perinatal period (10th). Conversely, 3 leading causes for the non-Hispanic white population not among the 10 leading causes for the Hispanic population were Chronic obstructive pulmonary diseases and allied conditions (4th), Suicide (8th), and Atherosclerosis (9th). Differences in ranking the leading causes of death between the two population groups largely reflect differences in age composition between the two groups; that is, within broad age groups leading causes are similar. However, even within age categories some differences exist. HIV infection and Homicide and legal intervention consistently ranked higher for Hispanic than non-Hispanic population for age groups under 65 years. Chronic liver disease and cirrhosis also consistantly ranked higher for Hispanic populations aged 25 years and over.

Drug-related deaths

In 1987 a total of 9,796 persons died of drug-related causes in the United States. The category drug-related causes includes not only deaths from dependent and non-dependent use of drugs, but also poisoning from medically prescribed and other drugs; it excludes homicide and other causes indirectly related to drug use. (For drug-related causes see Technical notes.) The age-adjusted death rate for drug-related causes in

1987 was 3.8 deaths per 100,000 population, about the same as the rate for the previous year. The rate increased by 23 percent from 1983–87. Mortality from drug-related causes was higher for males than for females; the ageadjusted death rate in 1987 for males was 1.8 times that for females. Mortality for drug-related causes for the black population was higher than that of the white population, with a mortality-race ratio of 2.2.

Infant mortality

In 1987 there were 38,408 deaths of infants under 1 year of age (table E). The infant mortality rate of 10.1 infant deaths per 1,000 live births was the lowest final rate ever recorded for the United States, and it compares with a rate for the previous year of 10.4. Among white infants, the rate was 8.6, a decline of 3 percent from 1986 (8.9); the rate for black infants was 17.9 in 1987 compared with 18.0 in 1986. For all infants and for white infants considered separately, the change in infant mortality rates between 1986 and 1987 was statistically significant. (For discussion of random variation and statistical significance, see Technical notes.)

Until recently, the absolute difference in infant mortality rates between black and white infants was narrowing; in 1960 the difference in rates was 21.4 infants per 1,000 live births compared with 9.1 in 1986 and 9.3 in 1987 (figure 5). However, because the infant mortality rates for the white and black populations have been decreasing by about the same average annual percent between 1960 and 1987, the black in-

fant mortality rate in 1987 continued to be about twice the white rate. The downward trend in infant mortality has slowed for the white and the black populations—since the late 1970's, for white infants; and since 1981, for black infants.

Between 1986 and 1987 the neonatal mortality rate declined from 6.7 to 6.5 deaths for infants under 28 days per 1,000 live births. By race, the rate in 1987 for the white population was 5.5 per 1,000 live births compared with 5.8 in 1986; and for the black population, 11.7, the same as in 1986. The difference in the neonatal mortality rate between 1986 and 1987 for the white population was statistically significant. Neonatal mortality rates have declined since 1960 for both races, but the rate for the white population has declined faster than that for the black population—an average annual decrease of 4 percent per year for white infants compared with 3 percent for black infants.

The postneonatal mortality rate deaths to infants 28 days-11 months per 1,000 live births—for 1987 was 3.6, the same as in 1986. For the white population, the postneonatal mortality rate in 1987 remained the same as in 1986, 3.1; and for black infants, the rate in 1987 was 6.1 compared with a rate of 6.3 in 1986. For the black population, the change between the two years was not statistically significant. In contrast to the trend for neonatal mortality, between 1960 and 1987 the postneonatal rate decreased relatively faster for the black population than for the white population—an average annual decline of 4 percent for black infants compared

Table E. Infant, neonatal, and postneonatal deaths and mortality rates by race and sex: United States, 1987 [Rates are infant (under 1 year), neonatal (under 28 days), and postneonatal (28 days–11 months) deaths per 100,000 live births in specified group]

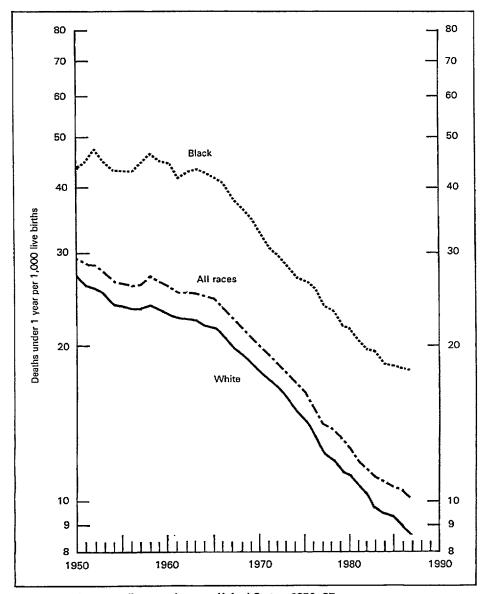

Figure 5. Infant mortality rates by race: United States, 1950-87

with an average decline of 2 percent for white infants.

As was seen in the overall infant mortality rates, the downward trends in neonatal and postneonatal mortality rates have slowed recently for the black and white populations.

The ranking of the leading causes of infant mortality for 1987 changed from 1986. Because of an increase in the number of deaths assigned to Accidents and adverse effects, the rank of this cause changed from the eighth leading cause in 1986 to the sixth in 1987. The rank for Newborn affected by complications of placenta, cord, and membranes changed from ninth in 1986 to eighth in 1987. Because of a decrease in the number of deaths assigned

to Intrauterine hypoxia and birth asphyxia, the rank of this cause changed from sixth in 1986 to ninth in 1987. Additionally, Disorders relating to short gestation and unspecified low birthweight increased from the fourth leading cause to the third leading cause. Among the 10 leading causes of infant death, the first 4-Congenital anomalies, Sudden infant death syndrome, Disorders relating to short gestation and unspecified low birthweight, and Respiratory distress syndrome—accounted for just over half of all deaths of infants under 1 year of age in 1987; and the next 6 causes accounted for only 14 percent of all infant deaths.

The difference between infant mortality rates for white and black infants varied by cause, although the risk was higher for black infants than for white infants for all the leading causes. For Congenital anomalies, the leading cause of infant death, the difference between the rate for black infants (226.5 per 100,000 live births) and for white infants (206.2) was statistically significant. Expressed as the ratio of the infant mortality rate for black infants to that for white infants, the other leading causes may be ranked, beginning with the highest ratio, as follows: Disorders relating to short gestation and unspecified low birthweight (3.9); Pneumonia and influenza (2.6); Intrauterine hypoxia and birth asphyxia (2.5); Infections specific to the perinatal period (2.2); Newborn affected by maternal complications of pregnancy (2.2); Accidents and adverse effects (2.0); Sudden infant death syndrome and Respiratory distress syndrome (1.9); and Newborn affected by complications of placenta, cord, and membranes (1.8).

Hispanic deaths—The infant mortality rate for the Hispanic population in a reporting area consisting of 18 States (see Technical notes) and the District of Columbia was 7.9 deaths of infants under 1 year of age per 1,000 live births. This rate was lower than the rate for the non-Hispanic white population (8.4). Among specified subgroups of the Hispanic population, the rates for Mexican and Puerto Rican infants were lower than the rate for non-Hispanic white infants. The difference between the rates for Cubans and the non-Hispanic white population was not statistically significant. Infant mortality rates by Hispanic origin and race for the 18-State area may be somewhat understated (see Technical notes).

Maternal mortality

In 1987, 251 women were reported to have died of maternal causes (table F). As in previous years, the number does not include all deaths occurring to pregnant women, but only those deaths assigned to Complications of pregnancy, childbirth, and the puerperium (ICD-9 Nos. 630-676). The maternal mortality rate for 1987 was 6.6 deaths per 100,000 live births. The changes in the maternal mortality rate between 1986 and 1987 were statisti-

Table F. Maternal deaths and maternal mortality rates by race: United States, 1987

[Maternal deaths are those assigned to Complications of pregnancy, childbirth, and the puerperium, category numbers 630–676 of the *Ninth Revision International Classification of Diseases*, 1975. Rates per 100,000 live births in specified group]

Race	Number	Rate	
All races	251	6.6	
White	153 98 91	5.1 12.0 14.2	

cally significant for black women, but not for white women. In 1987 black women were 2.8 times as likely as white women to die of causes associated with pregnancy, childbirth, and the puerperium.

Report of autopsy

For 1987 all States requested information on the death certificate as to whether autopsies were performed. They were reported as performed for 253,023 deaths, or 11.9 percent of the deaths that occurred in 1987, a reduction from the 12.2 percent reported for the previous year. This continues the downward trend in the percent of deaths autopsied. The percent autopsied for all causes of death combined is heavily influenced by the low rates for the three leading causes of death: Diseases of heart (8.1 percent); Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues (4.5 percent); and Cerebrovascular diseases (4.0 percent). Among the 15 leading causes of death, the highest percents reported were for traumatic causes, that is, Homicide and legal intervention (96.0 percent), Suicide (53.0 percent), and Accidents and adverse effects (48.7 percent). For nontraumatic causes, the highest percents were for Certain conditions originating in the perinatal period (26.2), Chronic liver disease and cirrhosis (20.4), and HIV infection (15.9).

Marital status

Almost 90 percent (89.7) of the persons who died in 1987 had been married. The percent was larger for females (91.7) than for males (87.8) and for the white population (90.6) than for the black population (83.2). The proportion who were widowed at the time of death was considerably greater for women (57.6 percent) than for men (17.9 percent) but about the same for both major race groups: 37.5 percent of the white population and 34.3 percent of the black population.

List of detailed tables

- 1. Deaths, death rates, and age-adjusted death rates, by race and sex: United States, 1940, 1950, 1960, 1970, and 1975–87
- 2. Deaths and death rates by age, race, and sex: United States, 1987
- 3. Abridged life table for the total population: United States, 1987
- 4. Life expectancy at birth by race and sex: United States, 1940, 1950, 1960, and 1970-87
- 5. Age-specific and age-adjusted death rates for the 15 leading causes in 1987 and selected components: United States, 1979, 1986, and 1987
- 6. Deaths and death rates for the 10 leading causes of death in specified race-sex groups: United States, 1987
- 7. Deaths and death rates for the 10 leading causes of death in specified age groups: United States, 1987
- 8. Deaths from 72 selected causes by age: United States, 1987
- 9. Death rates for 72 selected causes by age: United States, 1987
- 10. Deaths from 72 selected causes by race and sex: United States, 1987
- 11. Death rates for 72 selected causes by race and sex: United States, 1987

- 12. Age-adjusted death rates for 72 selected causes by race and sex: United States, 1987
- 13. Infant, neonatal, and postneonatal mortality rates, by race
 13 and sex: United States, 1940, 1950, 1960, 1970, and 1975-87
- 14 14. Deaths under 1 year and infant mortality rates for the 10 leading causes of infant death: United
 14 States, 1987
- 15. Deaths under 1 year and infant mortality rates for 61 selected causes by race: United States, 1987
- 15 16. Maternal deaths and maternal mortality rates for selected causes by race: United States, 1987
- 17. Total deaths and death rates, and infant and neonatal deaths and mortality rates for the United States, each division, and State; and by race and sex for the United States, 1987
- 19 18. Deaths and death rates for major causes of death for the United
- States, each division, and State; and by race and sex for the United States, 1987
- 19. Deaths by age according to specified Hispanic origin, race for non-Hispanic origin, and sex: Total of 18 reporting States and the District of Columbia, 1987

- 20. Deaths for the 10 leading causes of death for Hispanic and
 28 white non-Hispanic origin, for specified age groups: Total of 18 reporting States and the District of Columbia, 1987
- 30 21. Infant, neonatal, and postneonatal deaths and mortality rates, by specified Hispanic origin and race for non-Hispanic origin:
- Total of 18 reporting States and the District of Columbia, 1987
- 32 Number of autopsies and percent of deaths for which autopsies were reported for 15 leading causes of death: United States, 1987
- 23. Deaths and percent distribution of deaths, by marital status according to race and sex: United States, 1987
- 24. Deaths and death rates from 16 selected subcategories of Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues, by race and sex: United States, 1987
- 25. Deaths and death rates by 10-year age groups and age-adjusted death rates for Human immunodeficiency virus infection, by race and sex: United States, 1987
- 37 26. Deaths and age-adjusted death rates for drug-related causes, by race and sex: United States, 1979–87

Symbols

- --- Data not available
- . . . Category not applicable
- Quantity zero

26

- 0.0 Quantity more than zero but less than 0.05
- Z Quantity more than zero but less than 500 where numbers are rounded to thousands
- * Figure does not meet standard of reliability or precision

Table 1. Deaths, death rates, and age-adjusted death rates, by race and sex: United States, 1940, 1950, 1960, 1970, and 1975-87

[Rates per 100,000 population in specified group. Rates are based on populations enumerated as of April 1 for census years and estimated as of July 1 for all other years. Beginning 1970 excludes deaths of nonresidents of the United States]

¹Figures for age not stated included in Ali ages but not distributed among age groups.

²Death rates under 1 year (based on population estimates) differ from infant mortality rates (based on live births); see tables E, 13, 14, 15, 17, and 21 for infant mortality rates, and Technical notes for further discussion of the difference.

Table 3. Abridged life table for the total population, 1987

[For explanation of the columns of the life table, see section 6 of Vital Statistics of the United States, 1986, Volume II]

Age interval	Proportion dying	Of 100,000	born alive	Stationa	ary population	Average remaining lifetime
Period of life between 2 exact ages stated in years (1) x to x+n	Proportion of persons alive at beginning of age interval dying during interval (2)	Number living at beginning of age interval (3) I _X	Number dying during age interval (4) ndx	In the age interval (5) nL-x	In this and all subsequent age intervals (6) T _x	Average number of years of life remaining at beginning of age interval

Figures for age not stated are included in "All ages" but not distributed among age groups.

2 Death rates under 1 year (based on population estimates) differ from infant mortality rates (based on live births); see tables E, 13, 14, 15, 17, and 21 for infant mortality rates, and Technical notes for discussion of the difference.

3 For method of computation, see Technical notes.

4 Because deaths from this cause occur primarily among infants, age-adjusted rates are not shown.

¹Figures for age not stated included in All ages but not distributed among age groups.

²Death rates under 1 year (based on population estimates) differ from infant mortality rates (based on live births); see tables E, 13, 14, 15, 17, and 21 for infant mortality rates, and Technical notes for further discussion of the difference.

Table 10. Deaths from 72 selected causes by race and sex: United States, 1987

[For explanation of asterisk preceding cause-of-death codes, see Technical notes]

Table 12. Age-adjusted death rates for 72 selected causes by race and sex: United States, 1987

[Rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940. For explanation of asterisk preceding cause-of-death codes, see Technical notes]

Technical notes

Nature and sources of data

Data shown in this report are based on information from all death certificates filed in the 50 States and the District of Columbia.

Mortality statistics are based on information coded by the National Center for Health Statistics (NCHS) from copies of the original certificates received from the State registration offices, and on State-coded data provided to NCHS through the Vital Statistics Cooperative Program (VSCP). In 1987 all the States and the District of Columbia participated in this program and submitted part or all of the mortality data for 1987 on computer tape to NCHS. The following 22 States in the VSCP submitted precoded medical data for all deaths on computer tapes: California, Colorado, Florida, Iowa, Kansas, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Nebraska, New Hampshire, New York State (excluding New York City), North Carolina, Pennsylvania, South Carolina, Texas, Vermont, Virginia, and Wisconsin. The remaining 28 VSCP States, New York City, and the District of Columbia submitted copies of the original certificates from which NCHS coded the medical data. For 1987 all States submitted precoded demographic data for all deaths.

Data for the United States as a whole refer to events occurring within the United States. Data shown for geographic areas are by place of residence. Beginning with 1970, mortality statistics exclude deaths of nonresidents of the United States. All data exclude fetal deaths.

Cause-of-death classification

The mortality statistics presented here were compiled in accordance with the World Health Organization regulations, which specify that member nations classify causes of death by the current Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death.

Causes of death for 1979-87 were classified according to the Ninth Revision International Classification of

Diseases (2). For earlier years causes of death were classified according to the revisions then in use, as follows: 1968-78, Eighth Revision; 1958-67, Seventh Revision; and 1949-57, Sixth Revision. Changes in classification of causes of death due to these revisions may result in discontinuities in causeof-death trends. Consequently, causeof-death comparisons between revisions require consideration of comparability ratios and, where available, estimates of their standard errors. Comparability ratios between the Eighth and Ninth Revisions, between the Seventh and Eighth Revisions, and between the Sixth and Seventh Revisions may be found in other NCHS reports (3-5).

Besides specifying the classification, the World Health Organization (WHO) regulations outline the form of medical certification and the procedures to be used in coding cause of death. Cause-of-death data presented in this publication were coded by procedures outlined in annual issues of Part 2a of the NCHS instruction manual (6).

In this report, tabulations of causeof-death statistics are based solely on the underlying cause of death. The underlying cause is defined by WHO as the disease or injury that initiated the train of events leading directly to death or as the circumstances of the accident or violence that produced the fatal injury. It is selected from the conditions entered by the physician in the causeof-death section of the death certificate. When more than one cause or condition is entered by the physician, the underlying cause is determined by the sequence of conditions on the certificate, provisions of the International Classification of Diseases (ICD), and associated selection rules. In general, more medical information is reported on death certificates than is directly reflected in the underlying cause of death.

New codes for HIV infection

Beginning with data for 1987, NCHS introduced new category numbers *042-*044 for classifying and coding human immunodeficiency virus (HIV) infection, formerly referred to as human T-cell lymphotropic virus-III/ lymphadenopathy-associated (HTLV-III/LAV) infection. The asterisk before the category numbers indicates that these codes are not part of the Ninth Revision of the International Classification of Diseases (ICD-9). Deaths classified to Human immunodeficiency virus infection *042-*044) for 1987 are shown in table 25. They are included, but not shown separately, in the category All other infectious and parasitic diseases in the List of 72 selected causes of death shown in tables 8-12. Prior to 1987. deaths involving HIV infection were classified to Deficiency of cell-mediated immunity (ICD 279.1), contained in the category All other diseases; to Pneumocystosis (ICD-9 No. 136.3), contained in the category All other infectious and parasitic diseases; to Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues; and to a number of other causes. As a consequence, cause-of-death data for 1987 are not strictly comparable with data for previous years.

For data years 1983-86, acquired immunodeficiency syndrome and HIV infection, when reported on the death certificate, were assigned to the category Deficiency of cell-mediated immunity (ICD-9 No. 279.1). Because the selection rules for underlying cause of death were developed prior to the identification of acquired immunodeficiency syndrome, other conditions mentioned on the death certificate and not category No. 279.1 were often selected as the underlying cause of death during this period. Also, the category ICD-9 No. 279.1 was not uniquely specific for HIV conditions. As mentioned in more detail in the Advance Reports for 1984, 1985, and 1986, death certificates that had mention of conditions coded to ICD-9 No. 279.1 for these years numbered 2,943, 6,040, and 10,900, respectively (7-9). It is believed that HIV infection was involved in most of these deaths.

Drug-related deaths

Causes of death attributable to drug-related mortality include ICD-9 Nos. 292, Drug psychoses; 304, Drug dependence; 305.2-305.9, Nondependent use of drugs, not including alcohol and tobacco; E850-E858, Accidental poisoning by drugs, medicaments, and biologicals; E950.0-E950.5, Suicide by drugs, medicaments, and biologicals; E962.0, Assault from poisoning by and medicaments; drugs E980.0-E980.5, Poisoning by drugs, medicaments, and biologicals, undetermined whether accidentally or purposely inflicted.

Quality of reporting of cause-of-death

One index of the quality of reporting causes of death is the proportion of death certificates coded to the Ninth Revision Chapter XVI Symptoms, and ill-defined conditions signs, (ICD-9 Nos. 780-799). Although there are deaths for which it is not possible to determine the underlying cause, this proportion indicates the care and consideration given to the certification by the medical certifier. It may also be used as a rough measure of the specificity of the medical diagnoses made by the certifier in various areas. In 1987, 1.47 percent of all reported deaths in the United States were assigned to illdefined or unknown causes compared with 1.49 percent for 1986. However, trends in the percent of deaths assigned to this category vary by age. While the percent for all ages combined generally has remained stable since 1979, declines have occurred for persons in age groups 55-64 and 65-74 years since 1983, and increases have occurred for age groups under 55 years since 1984. For persons aged 75-84 and 85 years and over, there has been no clear pattern of change in the percent of deaths assigned to Symptoms, signs, and illdefined conditions.

Population bases for computing rates

The population used for computing rates shown in this report (furnished by the U.S. Bureau of the Census) represents the population residing in the specified area. Death rates for 1987 are based on population estimates as of July 1, 1987 (10,11). The estimates are based on the 1980 census counts. The 1980 census counts by race were modified to be consistent with U.S. Office of Management and Budget categories and historical categories for death data. The modification procedures are discussed in detail in a report of the U.S. Bureau of the Census (12).

Population estimates used to compute death rates for 1984-87 incorporate new estimation procedures for net migration and net undocumented immigration. Death rates for 1987 are comparable with those for 1984, 1985, and 1986 but are not strictly comparable with those of previous years. For additional detail, see Advance Report of Final Mortality Statistics, 1984 (7), and a report of the U.S. Bureau of the Census (13).

Infant mortality rates shown in figure 5 and tables E, 13, 14, 15, 17, and 21 are the most commonly used index for measuring the risk of dying during the first year of life; they are calculated by dividing the number of infant deaths in a calendar year by the number of live births registered for the same period and are presented as rates per 1,000 or per 100,000 live births. Infant mortality rates use the number of live births in the denominator to approximate the population at risk of dying before the first birthday.

In contrast to infant mortality rates based on live births, infant death rates shown in figure 2 and tables A, 2, 5, 9, and 25 are based on the estimated population under 1 year of age. Infant death rates that appear in tabulations of age-specific death rates are calculated by dividing the number of infant deaths in a calendar year by the midyear population of persons under 1 year of age (estimated from births occurring in the 12-month period ending with June) and are presented as rates per 100,000 population in this age group. Due to differences in the denominators, infant death rates may differ from infant mortality rates.

Cause-of-death rankings

The cause-of-death rankings shown in figure 4 and tables B-D, 5-7, 20, and 22 are based on the List of 72 selected causes of death and the category Human immunodeficiency virus infection (HIV infection) (*042-*044); the cause-of-death ranking for infants in table 14 is based on the List of 61 Selected Causes of Infant Death and HIV infection. HIV infection was added to the list of rankable causes effective with data year 1987.

The group titles Major cardiovascular diseases and Symptoms, signs, and ill-defined conditions are not ranked from the List of 72 Selected Causes; Certain conditions originating in the perinatal period and Symptoms, signs, and ill-defined conditions are not ranked from the List of 61 Selected Causes of Infant Death. In addition, category titles that begin with the words "Other" and "All other" are not ranked to determine the leading causes of death. When one of the titles that represents a subtotal is ranked (for example, Tuberculosis), its component parts are not ranked (in this case, Tuberculosis of respiratory system and Other tuberculosis).

Age-adjusted rates

The age-adjusted rates presented in this report were computed by the direct method, that is, by applying the age-specific death rates for a given cause of death to the standard population distributed by age. The total population as enumerated in 1940 was selected as the standard. The rates for the total population and for each racesex group were adjusted separately, by using the same standard population. The age-adjusted rates were based on 10-year age groups. It is important not to compare age-adjusted death rates with crude rates.

Random variation

Although the mortality data in this report (except data for 1972) are not subject to sampling error, they may be affected by random variation in the number of deaths involved. When the number of events is small (perhaps less than 100) and the probability of such an event is small, considerable caution must be observed in interpreting the data. Such infrequent events may be assumed to follow a Poisson probability distribution. For this distribution, a simple approximation may be used to estimate the confidence interval, as follows:

If N is the number of registered deaths in the population and R is the corresponding rate, the chances are 19 in 20 (approximate 95-percent confidence interval) that

1.
$$N=2\sqrt{N}$$
 and $N+2\sqrt{N}$

cover the "true" number of events.

2.
$$R-2\frac{R}{\sqrt{N}}$$
 and $R+2\frac{R}{\sqrt{N}}$

cover the "true" rate.

If the rate R_1 corresponding to N_1 events is compared with the rate R_2 corresponding to N_2 events, the difference between the two rates may be regarded as statistically significant at the 0.05 level if it exceeds

$$2\sqrt{\frac{R_1^2}{N_1} + \frac{R_2^2}{N_2}}$$

Additional information on random variation may be found in the Technical appendix of *Vital Statistics of the United States*, Volume II, Mortality, Part A, 1986.

Infant and maternal mortality rates—Comparisons made in the text between infant, neonatal, postneonatal, and maternal mortality rates, unless otherwise specified, were statistically significant at the 0.05 level of significance, as described above. Lack of comment in the text about any two rates does not mean that the difference was tested and found not to be significant at this level.

Life tables

U.S. abridged life tables are constructed by reference to a standard life table (14).

Hispanic origin

For 1987 mortality data for the Hispanic-origin population are based on deaths to residents of 18 reporting States and the District of Columbia whose data were at least 90 percent complete on a place-of-occurrence basis and considered to be sufficiently comparable to be used for analysis. The 18 reporting States are as follows: Arizona, Arkansas, California, Colorado, Georgia, Hawaii, Illinois, Indiana, Kansas, Mississippi, Nebraska, New Jersey, New York (including New York City), North Dakota, Ohio, Texas, Utah, and Wyoming.

Infant mortality rates for Hispanicorigin population are based on numbers of resident infant deaths reported to be of Hispanic origin and numbers of resident live births by Hispanic origin of mother for the 18 reporting States and the District of Columbia. In computing infant mortality rates, deaths and live births of unknown origin are not distributed among the specified Hispanic and non-Hispanic groups. Because for 1987 the percent of infant deaths of unknown origin was 8.0 percent and the percent of live births of unknown origin was 2.9 percent, infant mortality rates by specified Hispanic origin and race for non-Hispanic origin may be somewhat underestimated.

Small numbers of infant deaths for specific Hispanic-origin groups can result in infant mortality rates subject to relatively large random variation (see section "Random variation").

In 1980, the 18 reporting States and the District of Columbia accounted for about 80 percent of the Hispanic population in the United States, including about 89 percent of the Mexican population, 78 percent of the Puerto Rican population, 34 percent of the Cuban population, and 68 percent of the "Other Hispanic" population (15). Accordingly, caution should be exercised in generalizing mortality patterns from the reporting area to the Hispanic-origin population (especially Cubans) of the entire United States.

Computation of percent distributions

Deaths of persons of unknown marital status were subtracted from figures for total deaths used as denominators before percent distributions were computed. This report represents summary tabulations from the final mortality statistics for 1987. More detailed tabulations for 1987 will be published in *Vital Statistics of the United States, Volume II—Mortality*. Prior to the publication of that volume, the National Center for Health Statistics will respond to requests for unpublished data whenever possible.

Vital and Health Statistics series descriptions

- SERIES 1. Programs and Collection Procedures—Reports describing the general programs of the National Center for Health Statistics and its offices and divisions and the data collection methods used. They also include definitions and other material necessary for understanding the data.
- SERIES 2. Data Evaluation and Methods Research—Studies of new statistical methodology including experimental tests of new survey methods, studies of vital statistics collection methods, new analytical techniques, objective evaluations of reliability of collected data, and contributions to statistical theory. Studies also include comparison of U.S. methodology with those of other countries.
- SERIES 3. Analytical and Epidemiological Studies—Reports presenting analytical or interpretive studies based on vital and health statistics, carrying the analysis further than the expository types of reports in the other series
- SERIES 4. Documents and Committee Reports—Final reports of major committees concerned with vital and health statistics and documents such as recommended model vital registration laws and revised birth and death certificates.
- SERIES 5. Comparative International Vital and Health Statistics
 Reports—Analytical and descriptive reports comparing
 U.S. vital and health statistics with those of other countries
- SERIES 6. Cognition and Survey Measurement—Reports from the National Laboratory for Collaborative Research in Cognition and Survey Measurement using methods of cognitive science to design, evaluate, and test survey instruments.
- SERIES 10. Data From the National Health Interview Survey—Statistics on illness, accidental injuries, disability, use of hospital, medical, dental, and other services, and other health-related topics, all based on data collected in the continuing national household interview survey.
- SERIES 11. Data From the National Health Examination Survey and the National Health and Nutrition Examination Survey—
 Data from direct examination, testing, and measurement of national samples of the civilian noninstitutionalized population provide the basis for (1) estimates of the medically defined prevalence of specific diseases in the United States and the distributions of the population with respect to physical, physiological, and psychological characteristics and (2) analysis of relationships among the various measurements without reference to an explicit finite universe of persons.
- SERIES 12. Data From the Institutionalized Population Surveys—Discontinued in 1975. Reports from these surveys are included in Series 13.
- SERIES 13. Data on Health Resources Utilization—Statistics on the utilization of health manpower and facilities providing long-term care, ambulatory care, hospital care, and family planning services.
- SERIES 14. Data on Health Resources: Manpower and Facilities—
 Statistics on the numbers, geographic distribution, and characteristics of health resources including physicians, dentists, nurses, other health occupations, hospitals, nursing homes, and outpatient facilities.

- SERIES 15. Data From Special Surveys—Statistics on health and health-related topics collected in special surveys that are not a part of the continuing data systems of the National Center for Health Statistics.
- SERIES 16. Compilations of Advance Data From Vital and Health
 Statistics—These reports provide early release of data
 from the National Center for Health Statistics' health and
 demographic surveys. Many of these releases are followed
 by detailed reports in the Vital and Health Statistics
 Series.
- SERIES 20. Data on Mortality—Various statistics on mortality other than as included in regular annual or monthly reports. Special analyses by cause of death, age, and other demographic variables; geographic and time series analyses; and statistics on characteristics of deaths not available from the vital records based on sample surveys of those records.
- SERIES 21. Data on Natality, Marriage, and Divorce—Various statistics on natality, marriage, and divorce other than as included in regular annual or monthly reports. Special analyses by demographic variables; geographic and time series analyses; studies of fertility; and statistics on characteristics of births not available from the vital records based on sample surveys of those records.
- SERIES 22. Data From the National Mortality and Natality Surveys—
 Discontinued in 1975. Reports from these sample surveys based on vital records are included in Series 20 and 21, respectively.
- SERIES 23. Data From the National Survey of Family Growth—
 Statistics on fertility, family formation and dissolution, family planning, and related maternal and infant health topics derived from a periodic survey of a nationwide probability sample of women 15–44 years of age.
- SERIES 24. Compilations of Data on Natality, Mortality, Marriage, Divorce, and Induced Terminations of Pregnancy—Advance reports of births, deaths, marriages, and divorces are based on final data from the National Vital Statistics System and are published annually as supplements to the Monthly Vital Statistics Report (MVSR). These reports are followed by the publication of detailed data in Vital Statistics of the United States annual volumes. Other reports including induced terminations of pregnancy issued periodically as supplements to the MVSR provide selected findings based on data from the National Vital Statistics System and may be followed by detailed reports in Vital and Health Statistics Series.
