NATIONAL TOXICOLOGY PROGRAM

The National Toxicology Program (NTP), established in 1978, develops and evaluates scientific information about potentially toxic and hazardous chemicals. This knowledge can be used for protecting the health of the American people and for the primary prevention of disease. By bringing together the relevant programs, staff, and resources from the U.S. Public Health Service, DHHS, the National Toxicology Program has centralized and strengthened activities relating to toxicology research, testing and test development/validation efforts, and the dissemination of toxicological information to the public and scientific communities and to the research and regulatory agencies.

The NTP is made up of four charter DHHS agencies: the National Cancer Institute (NCI), National Institutes of Health; the National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health; the National Center for Toxicological Research (NCTR), Food and Drug Administration; and the National Institute for Occupational Safety and Health (NIOSH), Centers for Disease Control. In July 1981, the Carcinogenesis Bioassay Testing Program, NCI, was transferred to the NIEHS.

NTP TECHNICAL REPORT ON THE

TOXICOLOGY AND CARCINOGENESIS STUDIES OF *n*-BUTYL CHLORIDE

NOTE TO THE READER

These studies are designed and conducted to characterize and evaluate the toxicologic potential, including carcinogenic activity, of selected chemicals in laboratory animals (usually two species, rats and mice). Chemicals selected for testing in the NTP Carcinogenesis Program are chosen primarily on the bases of human exposure, level of production, and chemical structure. Selection per se is not an indicator of a chemical's carcinogenic potential. Negative results, in which the test animals do not have a greater incidence of cancer than control animals, do not necessarily mean that a test chemical is not a carcinogen, inasmuch as the experiments are conducted under a limited set of conditions. Positive results demonstrate that a test chemical is carcinogenic for animals under the conditions of the test and indicate that exposure to the chemical has the potential for hazard to humans. The determination of the risk to humans from chemicals found to be carcinogenic in animals requires a wider analysis which extends beyond the purview of this study.

Five categories of interpretative conclusions were adopted for use in June 1983 in the Technical Reports series to specifically emphasize consistency and the concept of actual evidence of carcinogenicity. For each definitive study result (male rats, female rats, male mice, female mice), one of the following quintet will be selected to describe the findings. These categories refer to the strength of the experimental evidence and not to either potency or mechanism.

- Clear Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of malignant neoplasms, studies that exhibit a substantially increased incidence of benign neoplasms, or studies that exhibit an increased incidence of a combination of malignant and benign neoplasms where each increases with dose.
- Some Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of benign neoplasms, studies that exhibit marginal increases in neoplasms of several organs/tissues, or studies that exhibit a slight increase in uncommon malignant or benign neoplasms.
- Equivocal Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related marginal increase of neoplasms.
- No Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing no chemically related increases in malignant or benign neoplasms.
- Inadequate Study of Carcinogenicity demonstrates that because of major qualitative or quantitative limitations, the studies cannot be interpreted as valid for showing either the presence or absence of a carcinogenic effect.

Additionally, the following concepts (as patterned from the International Agency for Research on Cancer Monographs) have been adopted by the NTP to give further clarification of these issues:

The term *chemical carcinogenesis* generally means the induction by chemicals of neoplasms not usually observed, the earlier induction by chemicals of neoplasms that are commonly observed, or the induction by chemicals of more neoplasms than are generally found. Different mechanisms may be involved in these situations. Etymologically, the term *carcinogenesis* means induction of cancer, that is, of malignant neoplasms; however, the commonly accepted meaning is the induction of various types of neoplasms or of a combination of malignant and benign neoplasms. In the Technical Reports, the words *tumor* and *neoplasm* are used interchangeably.

This study was initiated by the National Cancer Institute's Carcinogenesis Bioassay Program, now part of the National Institute of Environmental Health Sciences, National Toxicology Program. The studies described in this Technical Report have been conducted in compliance with NTP chemical health and safety requirements and must meet or exceed all applicable Federal, state, and local health and safety regulations. All NTP toxicology and carcinogenesis studies are subjected to a data audit before being presented for peer review.

Although every effort is made to prepare the Technical Reports as accurately as possible, mistakes may occur. Readers are requested to identify any mistakes so that corrective action may be taken. Further, anyone who is aware of related ongoing or published studies not mentioned in this report is encouraged to make this information known to the NTP. Comments and questions about the National Toxicology Program Technical Reports on Toxicology and Carcinogenesis Studies should be directed to Dr. J.E. Huff, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709 (919-541-3780).

These NTP Technical Reports are available for sale from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161 (703-487-4650). Single copies of this Technical Report are available without charge (and while supplies last) from the NTP Public Information Office, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709.

n-Butyl Chloride

(1-Chlorobutane; Butyl Chloride; n-Propylcarbinyl Chloride)

CAS No. 109-69-3

C₄H₉Cl Molecular weight 92.57

ABSTRACT

Toxicology and carcinogenesis studies of *n*-butyl chloride (greater than 99.5% pure), a solvent as well as an alkylating agent, were conducted by exposing groups of F344/N rats and B6C3F₁ mice to *n*butyl chloride in corn oil by gavage for 14 days, 13 weeks, and 2 years. In the 14-day studies, no compound-related gross pathologic effects were observed in groups of five male or female rats or mice administered doses of up to 3,000 mg/kg body weight. However, deaths occurred in the groups administered 750, 1,500, or 3,000 mg/kg. Tremors and convulsions following gavage administration were observed.

In the 13-week studies, groups of 10 male and 10 female rats were administered up to 500 mg/kg nbutyl chloride, and similar groups of mice received up to 1,000 mg/kg. Three of 10 male rats in the 500 mg/kg dose group and one female mouse in the 120 mg/kg dose group died before the end of the studies. Mild to moderate extramedullary hematopoiesis was observed in 3/10 male rats receiving 500 mg/kg. Mean body weights of male and female rats receiving 250 or 500 mg/kg were lower than those of the vehicle controls. Convulsions were observed in male and female rats receiving 250 mg/kg or higher and in 2/10 female mice receiving 1,000 mg/kg. Based on these results, 2-year toxicology and carcinogenesis studies of n-butyl chloride were conducted by administering doses of 0, 60, or 120 mg/kg in corn oil by gavage to groups of 50 male and 50 female rats and doses of 0, 500, or 1,000 mg/kg to groups of 50 male and 50 female mice.

In the 2-year studies, survival relative to that of vehicle controls was significantly lower in high dose male rats (40/50 vs 17/50) and high dose female rats (35/50 vs 11/50) and in male mice receiving 1,000 mg/kg (33/50 vs 10/50). Due to excessive mortality in the 1,000 mg/kg female mice, the group was terminated in the 45th week and a second series of 2-year studies in mice of each sex was started at concentrations of 0 and 250 mg/kg. Male mice in the 1,000 mg/kg group had 10% lower mean body weights than the vehicle control group. No adverse effects on survival or body weights in other dosed groups of rats and mice were observed. Convulsions were observed before or after gavage administration on several occasions during the rat studies. These observations were noted primarily in the high dose groups (male: vehicle control, 1/50; low dose, 3/50; high dose, 27/50; female: vehicle control, 0/50; low dose, 7/50; high dose, 45/50). Hemorrhage of the brain and alveoli were observed primarily in high dose male and female rats dying from convulsions. Lymphoid depletion of the spleen and splenic hemosiderosis were also observed in these animals. In mice, convulsions were observed only in the first studies (in the high dose female mice that were terminated early and in 6/50 high dose male mice). Pheochromocytomas of the adrenal gland occurred at a marginally increased incidence in low dose female rats (1/50; 6/50; 1/49). Hyperplasia was observed in 3/50 vehicle controls, 7/50 low dose females, and 4/49 high dose females. The incidence of pheochromocytomas was low, not dose related, and not seen in male rats, and thus it was not considered to be compound related. Cytoplasmic vacuolization of the adrenal cortex occurred at increased incidences in male (5/50; 10/50; 20/50) but not in female rats. Nephropathy of the kidney occurred at increased incidences in female rats (13/50; 25/50; 20/50) but not in male rats. Additional nonneoplastic lesions such as congestion, inflammation, or nephrosis were not present to any degree in either vehicle control or dosed female rats.

An increased incidence of alveolar/bronchiolar adenomas or carcinomas (combined) was observed in the 500 mg/kg group of female mice (3/50 vs 9/50), but little effect was seen in the 250 mg/kg group (6/50 vs 8/50). The incidences of adenomas or carcinomas (combined) in dosed female mice were not significantly different from that in the pooled vehicle control group from the first and second studies (pooled controls, 9/100; 250 mg/kg, 8/50; 500 mg/kg, 9/50). The lack of hyperplasia in female mice and the negative trend in male mice suggest that these marginal effects were probably not related to the administration of n-butyl chloride.

An increased incidence of hepatocellular adenomas or carcinomas (combined) was observed in the 500 mg/kg group of female mice (3/50 vs 8/50) but not in the 250 mg/kg group (9/50 vs 7/50). An increased incidence of hemangiosarcomas was observed in male mice in the first study (1/50; 3/50; 4/50) but not in the second study (4/50 vs 2/50). Neither of these marginal effects was regarded as compound related.

n-Butyl chloride was not mutagenic in Salmonella typhimurium strains TA98, TA100, TA1535, or TA1537 in the presence or absence of Aroclor 1254-induced male Sprague-Dawley rat liver S9 or in the presence of male Syrian hamster liver S9. *n*-Butyl chloride was mutagenic in the mouse lymphoma L5178Y/TK^{+/-} assay in the absence of Aroclor-induced male rat liver S9 and was not tested in the presence of S9. *n*-Butyl chloride did not induce sister-chromatid exchanges or chromosomal aberrations in Chinese hamster ovary cells in the presence or absence of Aroclor-induced male rat liver S9.

An audit of the experimental data was conducted for the 2-year studies of n-butyl chloride. No data discrepancies were found that influenced the final interpretations.

Under the conditions of these 2-year gavage studies, there was no evidence of carcinogenicity* of nbutyl chloride for male and female F344/N rats at daily doses of 60 or 120 mg/kg, for male B6C3F₁ mice at doses of 250, 500, or 1,000 mg/kg, or for female B6C3F₁ mice at doses of 250 or 500 mg/kg. Chemical-induced toxicity in high dose rats (primarily females) reduced the sensitivity of the study for determining carcinogenicity.

^{*}Categories of evidence of carcinogenicity are defined in the Note to the Reader on page 2.

CONTRIBUTORS

The NTP Technical Report on the Toxicology and Carcinogenesis Studies of *n*-Butyl Chloride is based on the 13-week studies that began in March 1979 and ended in June 1979, on the 2-year studies that began in February 1980 and ended in March 1982, and on the supplemental 2-year studies in mice that began in March 1981 and ended in March 1983 at EG&G Mason Research Institute.

PEER REVIEW PANEL

The members of the Peer Review Panel who evaluated the draft Technical Report on *n*-butyl chloride on August 14, 1985, are listed below. Panel members serve as independent scientists, not as representatives of any institution, company, or governmental agency. In this capacity, Panel members have five major responsibilities: (a) to ascertain that all relevant literature data have been adequately cited and interpreted, (b) to determine if the design and conditions of the NTP studies were appropriate, (c) to ensure that the Technical Report presents the experimental results and conclusions fully and clearly, (d) to judge the significance of the experimental results by scientific criteria, and (e) to assess the evaluation of the evidence of carcinogenicity and other observed toxic responses.

SUMMARY OF PEER REVIEW COMMENTS ON THE TOXICOLOGY AND CARCINOGENESIS STUDIES OF *n*-BUTYL CHLORIDE

On August 14, 1985, the draft Technical Report on the toxicology and carcinogenesis studies of *n*butyl chloride received peer review by the National Toxicology Program Board of Scientific Counselors' Technical Reports Review Subcommittee and associated Panel of Experts. The review meeting began at 9:00 a.m. in the Conference Center, Building 101, National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina.

Dr. Crowley, a principal reviewer, agreed with the conclusions for male and female rats but suggested that the findings in male and female mice indicate an inadequate study of carcinogenicity because the the first study was terminated due to toxicity after 1 year and the incidences of tumors for vehicle control groups for the two studies varied. Dr. Turnbull and Dr. Kotelchuck agreed that the mice studies were inadequate. Dr. Kotelchuck questioned the combining of the vehicle control groups. Dr. J. Huff, NIEHS, reported that in only one site were there statistically significant differences between the two vehicle control groups (liver tumors in female mice) and thus it was considered proper to combine vehicle control groups for supplemental data comparisons.

As a second principal reviewer, Dr. Kociba agreed with the conclusions. He said that the rationale for dose selection should have included some parameters other than body weights (depression) and clinical observations (convulsions). In the absence of comparative absorption and metabolism data, inhalation exposure or skin application might have been a more appropriate route than corn oil gavage. Dr. J. Roycroft, NTP, said that the overt toxicity observed in the 2-year studies was not predictable from the short-term studies in that there were only minimal effects in mean body weights and convulsive episodes only in two high dose (1,000 mg/kg) female mice.

As a third principal reviewer, Dr. Jones agreed with the conclusions.

In further discussion on the appropriateness of combining the two concurrent vehicle control groups for the studies in mice, Dr. E. McConnell, NIEHS, said that a similar combination was done for the oral asbestos studies; the current studies were conducted in the same laboratory with similar environmental factors and with genetically similar animals. Dr. Swenberg proposed adding a footnote explaining that combining vehicle control groups is done infrequently and why this was considered appropriate for n-butyl chloride. [See pages 46-48.]

Dr. Hook said that the Panel needed to decide whether the mouse studies were adequate studies before the members could rule on the conclusions as written. Dr. Swenberg moved that these be considered adequate studies for at least one dose per sex and species. Dr. Kociba seconded the motion. There were four affirmative votes (Dr. Jones, Dr. Kociba, Dr. Kotelchuck, and Dr. Swenberg), four negative votes (Dr. Crowley, Dr. Hooper, Dr. Perera, and Dr. Turnbull), and one abstention (Dr. Purchase). As Chair, Dr. Hook cast the tie-breaking vote to approve the motion.

Dr. Kociba then moved that the conclusion as written for rats and mice of both sexes be accepted, including the last sentence, "Chemical-induced toxicity in high dose rats (primarily females) reduced the sensitivity of the study for determining carcinogenicity." Dr. Turnbull seconded the motion, and the Technical Report on *n*-butyl chloride was approved by six affirmative votes (Dr. Hooper, Dr. Jones, Dr. Kociba, Dr. Kotelchuck, Dr. Perera, and Dr. Turnbull); there was one negative vote (Dr. Swenberg) with two abstentions (Dr. Crowley and Dr. Purchase).

I. INTRODUCTION

Animal Toxicity Studies Mutagenicity Carcinogenicity Human Exposure Study Rationale

n-Butyl Chloride

(1-Chlorobutane; Butyl Chloride; n-Propylcarbinyl Chloride)

CAS No. 109-69-3

C₄H₉Cl Molecular weight 92.57

n-Butyl chloride, a colorless, volatile liquid with a characteristic sweet odor, has a specific gravity of 0.878 (20° C/4° C), a boiling point of 78° C, a melting point of -123.1° C, and a vapor pressure of 80.1 mm Hg at 20° C. n-Butyl chloride is insoluble in water (0.066% at 12° C) and is miscible with alcohol and ether. It is flammable with a flash point of -7° C (closed cup). Flammable limits in air are between 1.8% and 10.1%. *n*-Butyl chloride is stable when stored in the dry state; however, it hydrolyzes in the presence of moisture, liberating hydrogen chloride. Thermal decomposition may produce phosgene. It can react vigorously with oxidizing materials (Merck, 1983; Sedivec and Flek, 1976; Oettingen, 1955; Sax, 1984).

n-Butyl chloride is used as a solvent as well as an alkylating agent in organic syntheses (e.g., in the manufacture of butyl cellulose) and in the production of tin stabilizers for vinyl chloride resins. It has also been used as an anthelmintic in veterinary medicine, primarily for removal of ascarids and hookworms in dogs (Wright and Schaffer, 1932). Although a weak central nervous system depressant, it has also been used as a veterinary anesthetic (Abreu et al., 1939).

n-Butyl chloride is prepared by heating *n*-butyl alcohol with hydrochloric acid and anhydrous zinc chloride. It is commercially available at greater than 99.5% purity. The production of *n*butyl chloride in the United States was estimated to be greater than 2,300 kilograms in 1982 (USITC, 1983). More accurate production estimates, as well as import and export figures, are not available, since only one company reports production. Information on the incidence of environmental occurrence or human exposure was not available from the literature. No occupational standard for n-butyl chloride has been established by the Occupational Safety and Health Administration.

Animal Toxicity Studies

Smyth et al. (1954) determined the oral LD_{50} value for n-butyl chloride to be 2.67 g/kg in Carworth-Wistar rats. When rats were exposed by inhalation to *n*-butyl chloride at 8,000 ppm for 4 hours, deaths in two of six animals occurred over a 14-day period. n-Butyl chloride was readily absorbed through the skin of New Zealand albino rabbits (greater than 20 ml/kg) and produced a primary skin irritation (3 in the standard Draize irritation index). In addition, eye injury to rabbits administered 0.5 ml neat nbutyl chloride was determined to be minimal (small area of corneal necrosis). The LC_{50} value for 2- to 3-month-old fish (guppies) has been determined to be 3.02 µmol/liter (Konemann, 1981).

To determine the efficacy of *n*-butyl chloride as a canine anthelmintic, Wright and Schaffer (1932) administered a single dose of *n*-butyl chloride (0.1, 0.2, 0.3, 0.5, 3.0, or 10.0 ml/kg) to dogs fasted for 12 hours. The dogs were observed daily for up to 4 days before being killed. *n*-Butyl chloride was well tolerated by all experimental animals and was effective in the removal of ascarids and hookworms. No visible reaction or

macroscopic postmortem lesions were observed. Microscopic lesions of the liver were observed in animals dosed at 0.3 ml/kg and higher and consisted of cloudy swelling and passive congestion with deposits of bilirubin. In several animals, there was a slight fatty infiltration of the liver which may have been associated with the administration of *n*-butyl chloride. Since the compound was efficacious in removing canine internal parasites and well tolerated, it was recommended for veterinary use as an anthelmintic. However, its use has been reduced in the past 10 years due to the introduction of new, more efficacious drugs.

Female Wistar rats (180-200 g) were gavaged daily with n-butyl chloride at concentrations of 0.72, 110, or 733 mg/kg in sunflower oil during the first 19 days of pregnancy and were evaluated for embryotoxic and teratogenic effects (Leonskaya, 1980). An increase in embryo mortality was seen in the 733 mg/kg dose group; no effect was seen in the lower dose groups. There was an increase in the number of fetuses with internal organ hemorrhage in the 733 mg/kg dose group. Progeny of the dosed females were observed for 30 days following birth. No compound-related effects were observed in mortality, body weight change, time of appearance of body hair, or opening of eyes. The offspring were crossbred (within dose group) and subsequently evaluated. n-Butyl chloride at a dose of 733 mg/kg substantially increased embryo mortality in the second generation. The author concluded that n-butyl chloride induced a hazardous effect on embryogenesis only in large doses that had pronounced toxic effects.

Mutagenicity

n-Butyl chloride was not mutagenic in Salmonella typhimurium when tested in a modified liquid suspension assay instead of in a plate assay (Eder et al., 1980), according to the preincubation protocol (Appendix G), or when the cells were exposed to the vapors in a sealed container (Barber et al., 1981). However, Simmon (1981) reported that when the cells were exposed to vapors in a desiccator (a protocol

similar to that of Barber et al., 1981), n-butyl chloride was mutagenic in strain TA100 of S. typhimurium in the absence of S9. The experiment was not performed in the presence of S9. n-Butyl chloride was mutagenic in the mouse lymphoma L5178Y/TK $^{+/-}$ assay in the absence of S9; it was not tested in the presence of S9 (Appendix G). n-Butyl chloride did not induce sister-chromatid exchanges or chromosomal aberrations in Chinese hamster ovary cells in the presence or absence of Aroclor 1254-induced male Sprague-Dawley rat liver S9. In summary, n-butyl chloride is mutagenic in S. typhimurium TA100 under certain conditions; it is mutagenic in mammalian cells but does not cause cytogenetic effects in mammalian cells in vitro.

Carcinogenicity

Poirier et al. (1975) evaluated pulmonary tumor response in A/Heston mice. Male and female mice were given *n*-butyl chloride (in tricaprylin) weekly by intraperitoneal injections for 24 weeks with a total dose of 1.2, 3.0, or 6.0 g/kg. No significant increase in lung tumor incidence was observed in strain A mice following the administration of *n*-butyl chloride; however, doses of 3.2 g/kg sec-butyl chloride and 1.2 g/kg tertbutyl chloride increased lung tumor incidence.

Human Exposure

Although there are no data on human exposure to *n*-butyl chloride, workers may be exposed to *n*butyl chloride during its use. *n*-Butyl chloride is a potential eye, skin, lung, and mucous membrane irritant.

Study Rationale

n-Butyl chloride was nominated by the National Cancer Institute as a model alkyl chloride following an organohalide class study. It is of particular interest because of the lack of long-term toxicity and carcinogenicity information and its potential for human exposure. Although occupational exposure occurs largely by the dermal or inhalation routes, NTP made the decision to conduct these studies by the gavage route.

PROCUREMENT AND CHARACTERIZATION OF *n*-BUTYL CHLORIDE

n-Butyl chloride was obtained in one batch (lot no. 780135-3) from Publicker Industries, Inc. (Philadelphia, Pennsylvania), which was used for all the studies.

Purity and identity analyses conducted at Midwest Research Institute on lot no. 780135-3 of *n*butyl chloride showed that in addition to *n*-butyl chloride, water and 25 ppm acid components were present. The identity of the *n*-butyl chloride was confirmed by infrared, ultraviolet/ visible, and nuclear magnetic resonance spectroscopy. All spectroscopic data were consistent with the structure of *n*-butyl chloride and with literature spectra. The cumulative data from elemental analyses, gas chromatography, and free acid titration indicated the purity of the *n*butyl chloride test material to be greater than 99.5%.

n-Butyl chloride was found to be stable for 2 weeks at 60° C (Appendix H). *n*-Butyl chloride was stored at the testing laboratory in the dark at 0° C. Results of periodic analyses of the bulk test material at the testing laboratory by gas chromatography and titration for free acid indicated that *n*-butyl chloride remained stable during the course of the studies.

PREPARATION AND CHARACTERIZATION OF DOSE MIXTURES

The accurately weighed amounts of *n*-butyl chloride and corn oil were mixed to give the desired concentrations (Table 1). The analytical chemistry laboratory found dose mixtures of *n*-butyl chloride (6% in corn oil) to be stable for 7 days at room temperature (Appendix I). The testing laboratory did additional analyses during the 13-week studies which indicated that the *n*-butyl chloride dose mixtures were stable for up to 3 weeks. *n*-Butyl chloride/corn oil mixtures were stored at 0° C for no longer than 14 days.

Periodic analyses for *n*-butyl chloride in corn oil were performed by the testing and analytical chemistry laboratories to determine if the dose mixtures contained the correct concentrations of *n*-butyl chloride (Appendix J). Because 62/63 mixtures analyzed were within \pm 10% of the target concentration, it is estimated that dosing solutions were prepared within specifications 98% of the time (Table 2; Appendix K).

FOURTEEN-DAY STUDIES

Coefficient of variation (percent)

Standard deviation

Number of samples

Range (mg/ml)

Male and female F344/N rats and B6C3F1 mice were obtained from Charles River Breeding Laboratories and held for 19 days before the studies began. The rats were approximately 7 weeks old and the mice 7-9 weeks old when placed on study.

Groups of five rats and five mice of each sex were administered 0, 190, 380, 750, 1,500, or 3,000 mg/kg n-butyl chloride in corn oil by gavage for 14 consecutive days. Animals were housed five per cage. Water and feed were freely available. The rats and mice were observed twice per day; the rats were weighed daily and the mice on days 1 and 14 and at the end of the studies. A necropsy was performed on all animals; however, histologic examinations were not performed. Details of animal maintenance are presented in Table 3.

THIRTEEN-WEEK STUDIES

Thirteen-week studies were conducted to evaluate the cumulative toxic effects of repeated administration of *n*-butyl chloride and to determine the doses to be used in the 2-year studies. Four-week-old male and female F344/N rats and 5- to 6-week-old B6C3F1 mice were obtained from Charles River Breeding Laboratories, observed for 18 days (rats) or 16 days (mice), and assigned to test groups so that the average cage weights were approximately equal for all animals of the same sex and species.

Groups of 10 rats of each sex were administered

0, 30, 60, 120, 250, or 500 mg/kg n-butyl chloride in corn oil by gavage, 5 days per week for 13 weeks. Groups of 10 mice of each sex were administered 0, 60, 120, 250, 500, or 1,000 mg/kg n-butyl chloride on the same schedule. Rats and mice were housed five per cage in polycarbonate cages. Feed and water were available ad libitum.

Study Design

Groups of 50 rats of each sex were administered 0.60. or 120 mg/kg n-butyl chloride in corn oil by gavage, 5 days per week for 103 weeks. Groups of 50 mice of each sex were administered 0, 500, or 1,000 mg/kg, 5 days per week on the same schedule. All the female mice in the 1,000 mg/kg group were dead by week 52. Histologic examinations were performed on some of these animals that died early: the cause of death could not be established but was attributed to n-butyl chloride. Because of the large number of deaths in the 1,000 mg/kg mouse groups, another dose group (250 mg/kg) and matching vehicle controls were started for male and female mice approximately 13 months after initiation of the other studies.

TABLE 3. EXPERIMENTAL DESIGN AND MATERIALS AND METHODS IN THE GAVAGE STUDIESOF n-BUTYL CHLORIDE (Continued)

Source and Specifications of Animals

The male and female F344/N rats and B6C3F1 (C57BL/6N, female, \times C3H/HeN MTV⁻, male) mice used in these studies were produced under strict barrier conditions at Charles River Breeding Laboratories under a contract to the Carcinogenesis Program. Breeding stock for the foundation colonies at the production facility originated at the National Institutes of Health Repository. Animals shipped for testing were progeny of defined microflora-associated parents that were transferred from isolators to barriermaintained rooms. Rats were shipped to the testing laboratory at 4 weeks of age, mice for the first studies were shipped at 4 weeks of age, and mice for the second studies were shipped at 5 weeks of age. The animals were quarantined at the testing facility for 3 weeks. Thereafter, a complete necropsy was performed on five animals of each sex and species to assess their health status. The rodents were placed on study at 7 weeks of age (rats and mice in first studies) or at 8 weeks (mice in second studies). The health of the animals was monitored during the course of the studies according to the protocols of the NTP Sentinel Animal Program (Appendix L).

A quality control skin grafting program has been in effect since early 1978 to monitor the genetic integrity of the inbred mice used to produce the hybrid $B6C3F_1$ test animal. In mid-1981, data were obtained that showed incompatibility between the NIH C3H reference colony and the C3H colony from a Program supplier. In August 1981, inbred parental lines of mice were further tested for genetic integrity via isozyme and protein electrophoretograms that demonstrate phenotype expressions of known genetic loci.

The C57BL/6 mice were homogeneous at all loci tested. Eighty-five percent of the C3H mice monitored were variant at one to three loci, indicating some heterogeneity in the C3H line from this supplier. Nevertheless, the genome of this line is more homogeneous than that of randomly bred stocks.

Male mice from the C3H colony and female mice from the C57BL/6 colony were used as parents

for the hybrid $B6C3F_1$ mice used in these studies. The influence of the potential genetic nonuniformity in the hybrid mice on these results is not known, but results of the studies are not affected because concurrent controls were included in each study.

Animal Maintenance

Animals were housed five per cage. Feed and water were available ad libitum. Further details of animal maintenance are given in Table 3.

Clinical Examinations and Pathology

All animals were observed two times per day, and clinical signs were recorded once per week. Body weights by cage were recorded once per week for the first 12 weeks of the study and once per month thereafter. Mean body weights were calculated for each group. Moribund animals were killed, as were animals that survived to the end of the studies. A necropsy was performed on all animals, including those found dead unless they were excessively autolyzed or cannibalized. Thus, the number of animals from which particular organs or tissues were examined microscopically varies and is not necessarily equal to the number of animals that were placed on study in each group.

Examinations for grossly visible lesions were performed on major tissues or organs. Tissues were preserved in 10% neutral buffered formalin, embedded in paraffin, sectioned, and stained with hematoxylin and eosin. Tissues examined microscopically are listed in Table 3.

When the pathology examination was completed, the slides, individual animal data records, and summary tables were sent to an independent quality assurance laboratory. Individual animal records and tables were compared for accuracy, slides and tissue counts were verified, and histotechnique was evaluated. All tumor diagnoses, all target tissues, and all tissues from a randomly selected 10% of the animals were evaluated by a quality assurance pathologist. Slides of all target tissues and those about which the original and quality assurance pathologists disagreed were submitted to the

Chairperson of the Pathology Working Group (PWG) for evaluation. Representative coded slides selected by the Chairperson were reviewed by PWG pathologists, who reached a consensus and compared their findings with the original and quality assurance diagnoses. When diagnostic differences were found, the PWG sent the appropriate slides and comments to the original pathologist for review. This procedure has been described, in part, by Maronpot and Boorman (1982) and Boorman et al. (1985). The final diagnoses represent a consensus of contractor pathologists and the NTP Pathology Working Group. For subsequent evaluations, the diagnosed lesions for each tissue type are combined according to the guidelines of McConnell et al. (1986).

Nonneoplastic lesions are not examined routinely by the quality assurance pathologist or PWG. Certain nonneoplastic findings are reviewed by the quality assurance pathologist and PWG if they are considered part of the toxic response to a chemical or if they are deemed of special interest.

Statistical Methods

Data Recording: Data on this experiment were recorded in the Carcinogenesis Bioassay Data System (Linhart et al., 1974). The data elements include descriptive information on the chemicals, animals, experimental design, survival, body weight, and individual pathologic results, as recommended by the International Union Against Cancer (Berenblum, 1969).

Survival Analyses: The probability of survival was estimated by the product-limit procedure of Kaplan and Meier (1958) and is presented in the form of graphs. Animals were censored from the survival analyses at the time they were found dead of other than natural causes or were found to be missing; animals dying from natural causes were not censored. Statistical analyses for a possible dose-related effect on survival used the method of Cox (1972) for testing two groups for equality and Tarone's (1975) life table test for a dose-related trend. All reported P values for the survival analysis are two-sided. Calculation of Incidence: The incidence of neoplastic or nonneoplastic lesions is given as the ratio of the number of animals bearing such lesions at a specific anatomic site to the number of animals in which that site was examined. In most instances, the denominators include only those animals for which the site was examined histologically. However, when macroscopic examination was required to detect lesions (e.g., skin or mammary tumors) prior to histologic sampling, or when lesions could have appeared at multiple sites (e.g., lymphomas), the denominators consist of the number of animals on which a necropsy was performed.

Analysis of Tumor Incidence: Three statistical methods are used to analyze tumor incidence data. The two that adjust for intercurrent mortality employ the classical method for combining contingency tables developed by Mantel and Haenszel (1959). Tests of significance included pairwise comparisons of high dose and low dose groups with vehicle controls and tests for overall dose-response trends.

For studies in which compound administration has little effect on survival, the results of the three alternative analyses will generally be similar. When differing results are obtained by the three methods, the final interpretation of the data will depend on the extent to which the tumor under consideration is regarded as being the cause of death. All reported P values for tumor analyses are one-sided.

Life Table Analyses--The first method of analysis assumed that all tumors of a given type observed in animals dying before the end of the study were "fatal"; i.e., they either directly or indirectly caused the death of the animal. According to this approach, the proportions of tumor-bearing animals in the dosed and vehicle control groups were compared at each point in time at which an animal died with a tumor of interest. The denominators of these proportions were the total number of animals at risk in each group. These results, including the data from animals killed at the end of the study, were then combined by the Mantel-Haenszel method to obtain an overall P value. This method of

adjusting for intercurrent mortality is the life table method of Cox (1972) and of Tarone (1975). The underlying variable considered by this analysis is time to death due to tumor. If the tumor is rapidly lethal, then time to death due to tumor closely approximates time to tumor onset. In this case, the life table test also provides a comparison of the time-specific tumor incidences.

Incidental Tumor Analyses--The second method of analysis assumed that all tumors of a given type observed in animals that died before the end of the study were "incidental"; i.e., they were merely observed at necropsy in animals dying of an unrelated cause. According to this approach, the proportions of tumor-bearing animals in dosed and vehicle control groups were compared in each of five time intervals: weeks 0-52, weeks 53-78, weeks 79-92, week 93 to the week before the terminal-kill period, and the terminal-kill period. The denominators of these proportions were the number of animals on which a necropsy was actually performed during the time interval. The individual time interval comparisons were then combined by the previously described method to obtain a single overall result. (See Haseman, 1984, for the computational details of both methods.) A recently developed method for the analysis of incidental tumors based on logistic regression (Dinse and Lagakos, 1983) was also employed as a supplemental test in some instances. This method has the advantage of not requiring time intervals in the statistical evaluation.

Unadjusted Analyses--Primarily, survival-adjusted methods are used to evaluate tumor incidence. In addition, the results of the Fisher exact test for pairwise comparisons and the Cochran-Armitage linear trend test (Armitage, 1971; Gart et al., 1979) are given in the appendix containing the analyses of primary tumor incidence. These two tests are based on the overall proportion of tumor-bearing animals and do not adjust for survival differences.

Historical Control Data: Although the concurrent control group is always the first and most appropriate control group used for evaluation, there are certain instances in which historical control data can be helpful in the overall assessment of tumor incidence. Consequently, control tumor incidences from the NTP historical control data base (Haseman et al., 1984) are included for those tumors appearing to show compound-related effects.

FOURTEEN-DAY STUDIES

All the rats that received 1,500 or 3,000 mg/kg and 3/5 males and 1/5 females that received 750 mg/kg n-butyl chloride died before the end of the studies (Table 4). No gavage accidents were noted; therefore, all deaths were considered compound related. The final mean body weight of the male rats that received 750 mg/kg was 14% lower than that of the vehicle controls. The final mean body weight of the female rats that received 750 mg/kg was 6% lower than that of the vehicle controls. Convulsions were observed in males that received 750 mg/kg or more and in one female that received 1,500 mg/kg.

Aggressiveness and hyperactivity were observed in rats that received 750 mg/kg. A bloody discharge from the nose and mouth was observed in males that received 750 mg/kg or more and in females that received 1,500 mg/kg. At necropsy, blood was found in the cranial cavity of males that received 750 mg/kg or more and females that received 1,500 mg/kg or more. Histologic examinations were not performed. Doses selected for the 13-week studies were based on weight gain depression and clinical signs observed in the 14-day studies.

THIRTEEN-WEEK STUDIES

Six of 10 male rats that received 500 mg/kg nbutyl chloride died before the end of the studies (Table 5). Because of the increased irritability of rats at the higher doses, dosing by gavage became extremely difficult; three deaths occurred in the 500 mg/kg group because of gavage accidents. The final mean body weights of males that received 250 or 500 mg/kg were 11% or 20% lower than that of the vehicle controls. Final mean body weights of females that received 250 or 500 mg/kg were 6% or 10% lower than that of the vehicle controls. Five of 10 males and 2/10females that received 250 mg/kg and 9/10 males and 8/10 females that received 500 mg/kg had convulsions on one or more occasions. Extramedullary hematopoiesis of the spleen was observed in 3/10 males that received 500 mg/kg. The severity was mild in two rats and moderate in a third. This lesion was not observed in vehicle control animals.

Dose Selection Rationale: Because of weight

gain depression and convulsions observed at 250 mg/kg, doses selected for rats in the 2-year studies were 60 and 120 mg/kg *n*-butyl chloride administered in corn oil by gavage, 5 days per week.

TWO-YEAR STUDIES

Body Weights and Clinical Signs

The initial mean body weights of the dosed male rats were lower than that of the vehicle controls, and the mean body weights of the high dose group remained slightly lower throughout the studies (Table 6 and Figure 1). Mean body weights of dosed and vehicle control female rats were comparable throughout the studies. Many dosed rats had tremors and convulsions after being gavaged. Antibodies to Sendai virus and RC virus were detected in sentinel animals throughout the studies (Appendix L, Table L1).

Dose (mg/kg)	Survival (a)	Mean Body Weights (grams)			Final Weight Relative
		Initial (b)	Final	Change (c)	to Vehicle Controls (percent)

Survival

Estimates of the probabilities of survival for male and female rats administered *n*-butyl chloride at the doses used in these studies and for the vehicle controls are shown in the Kaplan and Meier curves in Figure 2. The survival of both the male (after week 59) and female (after week 41) high dose groups was significantly lower than that of the vehicle control groups (Table 7). Based on the survival in the 13-week studies, the high mortality in both the 60 and 120 mg/kg groups was unexpected.

Pathology and Statistical Analyses of Results

This section describes the significant or note-

worthy changes in the incidences of rats with neoplastic or nonneoplastic lesions of the adrenal gland, pancreas, urinary bladder, lung, brain, spleen, kidney, prostate, or multiple organs. Histopathologic findings on neoplasms in rats are summarized in Appendix A (Tables A1 and A2); Appendix A (Tables A3 and A4) also gives the survival and tumor status for individual male and female rats. Findings on nonneoplastic lesions are summarized in Appendix C (Tables C1 and C2). Appendix E (Tables E1 and E2) contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix E (footnotes). Historical incidences of tumors in corn oil vehicle control animals are listed in Appendix F.

TABLE 7. SURVIVAL OF RATS IN THE TWO-YEAR GAVAGE STUDIES OF n-BUTYL CHLORIDE

	Vehicle Control	60 mg/kg	120 mg/kg
MALE (a)	<u> </u>		
Animals initially in study	50	50	50
Nonaccidental deaths before termination (b)	10	18	33
Killed at termination	40	32	17
Survival P values (c)	< 0.001	0.107	< 0.001
FEMALE (a)			
Animals initially in study	50	50	50
Nonaccidental deaths before termination (b)	15	12	39
Killed at termination	34	38	11
Died during termination period	1	0	0
Survival P values (c)	< 0.001	0.561	< 0.001

(a) Terminal kill period: male--weeks 104-106; female--weeks 105-106

(b) Includes animals killed in a moribund condition

(c) The result of the life table trend test is in the vehicle control column, and the results of the life table pairwise comparisons with the vehicle controls are in the dosed columns.

FIGURE 2. KAPLAN-MEIER SURVIVAL CURVES FOR RATS ADMINISTERED n-BUTYL CHLORIDE IN CORN OIL BY GAVAGE FOR TWO YEARS

.

Adrenal Gland: Cytoplasmic vacuolization of the adrenal cortex was observed at increased incidences in dosed male rats (vehicle control, 5/50, 10%; low dose, 10/50, 20%; high dose, 20/50, 40%) but not in the dosed female rats (vehicle control, 4/50, 8%; low dose, 5/50, 10%; high dose, 3/49, 6%). The incidence of pheochromocytomas in low dose female rats was significantly greater than that in the vehicle controls (Table 8). The incidences of pheochromocytomas in dosed male rats were lower than that in the vehicle controls (vehicle control, 15/50, 30%; low dose, 11/50, 22%; high dose, 4/50, 8%). Malignant pheochromocytomas were observed in one male and one female vehicle control animal.

Pancreas: Acinar cell adenomas in male rats occurred with a significant positive trend by the life table test; the incidences in the dosed groups were not significantly greater than that in the vehicle controls (Table 9).

(a) Historical incidence at testing laboratory (mean \pm SD): 5/196 (3% \pm 1%); historical incidence in NTP studies: 47/1,086 (4% \pm 8%)
Urinary Bladder: Transitional cell papillomas were observed in one low dose male rat and in one high dose female rat.

Lung: Hemorrhage of the alveoli was observed at increased incidences in high dose male and female rats (Table 10).

Brain: Hemorrhage of the brain was observed at increased incidences in high dose male and female rats (Table 10).

Spleen: Lymphoid depletion and hemosiderosis were observed at increased incidences in high dose male and female rats (Table 10).

Kidney: Nephropathy was observed at increased incidences in dosed female rats (vehicle control, 13/50, 26%; low dose, 25/50, 50%; high dose, 20/50, 40%).

Prostate: Focal hyperplasia was observed in 5/42 (12%) low dose male rats but not in the other groups. In addition, 1/42 (2%) low dose male rats had a prostate adenoma.

Multiple Organs: Congestion of multiple organs was observed at increased incidences in high dose rats (male: vehicle control, 2/50, 4%; low dose, 6/50, 12%; high dose, 15/50, 30%; female: vehicle control, 0/50; low dose, 1/50, 2%; high dose, 28/50, 56%).

FOURTEEN-DAY STUDIES

All the mice that received 3,000 mg/kg and 3/5 males and 2/5 females that received 1,500 mg/kg died before the end of the studies (Table 11). No gavage accidents occurred; therefore, the deaths were attributed to dosing. The final mean body weight of males that received 750 mg/kg was 7% lower than that of the vehicle controls: the final mean body weight of the survivors of the 1,500 mg/kg group was greater than that of the vehicle controls. Final mean body weights of dosed and vehicle control female mice were comparable. Mice that received 1,500 or 3,000 mg/kg were hyperactive. Two of 10 males that received 3,000 mg/kg had convulsions. No compoundrelated gross pathologic effects were observed in animals that lived to the end of the studies. Histologic evaluation was not required. Doses for the 13-week studies were based on survival

and weight gain depression in the 14-day studies.

THIRTEEN-WEEK STUDIES

The incidences of deaths in the various groups are given in Table 12. A number of gavage accidents occurred during the studies (two vehicle control females, a male and female in the 60 mg/kg groups, a female in the 120 mg/kg group, and two females in the 1,000 mg/kg group) and were attributed to handling and dosing of the animals by several different technicians during the studies. The final mean body weights of dosed and vehicle control mice were comparable. Two female mice in the 1,000 mg/kg group convulsed during the course of the study. No other compound-related clinical signs were observed for male and female mice. No compound-related histopathologic effects were observed.

TABLE 12. SURVIVAL AND MEAN BODY WEIGHTS OF MICE IN THE THIRTEEN-WEEK GAVAGESTUDIES OF n-BUTYL CHLORIDE

(a) Number surviving/number in group

(b) Initial group mean body weight \pm standard error of the mean. Subsequent calculations are based on those animals surviving to the end of the study.

(c) Mean body weight change of the survivors \pm standard error of the mean. Final body weights were taken during week 12 of the study.

(d) Day of death: 12

(e) Day of death: 6, gavage accident

(f) Day of death: 1, 9, gavage accidents

(g) Day of death: 12, gavage accident

(h) Day of death: 7, 8, 12, two were gavage accidents

Dose Selection Rationale: The doses selected for mice in the 2-year studies were 500 and 1,000 mg/kg *n*-butyl chloride administered in corn oil by gavage, 5 days per week. The dose selection was based on the absence of reduction in body weight in males and females and on the absence of dose-related clinical signs in male mice and minimal clinical signs in female mice at the 1,000 mg/kg dose in the 13-week studies.

TWO-YEAR STUDIES

Body Weights and Clinical Signs

In the first study, the mean body weights of the male mice that received 1,000 mg/kg were lower than those of the vehicle controls after week 36; the mean body weights of the female mice that received 500 mg/kg were greater than those of the vehicle controls throughout most of the study (Table 13 and Figure 3). Compound-related clinical signs included convulsions, primarily in high dose male mice. Because of the large number of deaths in the 1,000 mg/kg mouse groups, another dose group (250 mg/kg) and matching vehicle controls were started for male and female mice approximately 13 months after initiation of the other studies.

Sendai virus was present in female sentinel mice in the first study but not in the second study. Mouse hepatitis virus (MHV) was detected in vehicle controls at the end of both the first and second studies.

In the second studies, the mean body weights of the 250 mg/kg groups of male and female mice were greater than those of the vehicle controls throughout most of the studies (Table 14 and Figure 4).

Survival

Estimates of the probabilities of survival for male and female mice administered *n*-butyl chloride at the doses used in these studies and for the vehicle controls are shown in the Kaplan and Meier curves in Figures 5 and 6. Because of the large number of deaths in the 1,000 mg/kg mouse groups, another dose group (250 mg/kg) and matching vehicle controls were started for male and female mice approximately 13 months after initiation of the other studies. The survival of the 1,000 mg/kg male group in the first study was significantly lower than that of the vehicle control group after week 89 (Table 15). No significant differences in survival were observed between the vehicle control and the 500 mg/kg groups in the first studies or the 250 mg/kg groups in the second studies (Tables 15 and 16).

Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of mice with neoplastic or nonneoplastic lesions of the lung. liver, circulatory system, ovary, or uterus. Histopathologic findings on neoplasms in mice are summarized in Appendix B (Tables B1-B4); Appendix B (Tables B5-B8) also gives the survival and tumor status for individual male and female mice. Findings on nonneoplastic lesions are summarized in Appendix D (Tables D1-D4). Appendix E (Tables E3-E6) contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the two or three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix E (footnotes). Historical incidences of tumors in corn oil vehicle control animals are listed in Appendix F. A comparison of the vehicle control groups used in the first and second studies suggested that certain differences in survival and/or tumor incidence may have been present between the two groups. Consequently, these vehicle control groups were not combined routinely in the statistical analyses. Nevertheless, as a supplemental analysis the groups were pooled for those specific tumors showing some suggestion of a compound-related effect relative to the concurrent vehicle control.

Lung: The incidence of alveolar/bronchiolar adenomas or carcinomas (combined) in the 500 mg/kg group in the first study of female mice was significantly greater (P=0.028) than that in the vehicle controls by the incidental tumor test (Table 17). The use of logistic regression, an alternative test procedure for incidental tumors (Chapter II), had little effect on the P value (P=0.04). However, this increased incidence was not significant relative to the pooled vehicle control group.

Liver: The incidence of hepatocellular adenomas or carcinomas (combined) in female mice that received 500 mg/kg in the first study was significantly greater (P=0.04) than that in the vehicle controls by the incidental tumor test; however, it was not significant by logistic regression analysis (P=0.08). In addition, this increased Incidence was not significant relative to the pooled vehicle control group. Moreover, the incidence of hepatocellular adenomas or carcinomas (combined) in the female vehicle controls in the second study was greater than that in the 500 mg/kg group in the first study (Table 18).

Circulatory System: The incidence of hemangiosarcomas in the male mice that received 1,000 mg/kg in the first study was significantly greater than that in the vehicle controls by life table analysis. The significance of this effect was essentially unchanged when comparison was based on the pooled vehicle control groups. The incidence of hemangiosarcomas in the vehicle controls in the second study was the same as that in the 1,000 mg/kg group in the first study (Table 19).

Ovary or Uterus: Suppurative inflammation in the first study was observed in 15/50 female vehicle control mice and 6/49 female mice in the 500 mg/kg group. Klebsiella pneumoniae was diagnosed in 4/59 uterine lavage samples taken from vehicle control and dosed mice in the first study. Suppurative inflammation in the second study was observed in 17/50 female vehicle control mice and 9/50 female mice in the 250 mg/kg group. Uterine lavage samples were not taken in the second study.

TABLE 18. ANALYSIS OF LIVER TUMORS IN FEMALE MICE IN THE TWO-YEAR GAVAGE STUDIES OF n-BUTYL CHLORIDE (a)

(a) The incidences of adenomas alone or combined with carcinomas were significantly different for the two vehicle control groups. Adenomas alone (vehicle control group first study, 1/50; vehicle control group second study, 8/50) were significantly different by the life table test (P = 0.01), incidental tumor test (P = 0.007), and the Fisher exact test (P = 0.02). However, when adenomas were combined with carcinomas, the significance was not as great for the life table test (P=0.04) and incidental tumor test (P = 0.03). The combined tumors were not significantly different by the Fisher exact test (P = 0.06). (b) Terminal kill at week 105

(c) Terminal kill at week 104

(d) Historical incidence at testing laboratory (mean \pm SD): 17/198 (9% \pm 5%); historical incidence in NTP studies: 74/1,092 $(7\% \pm 4\%)$

(e) Terminal kill regarded as being week 104 for both studies; thus, one 500 mg/kg and two vehicle control natural deaths at week 104 of the first study are considered as terminal kills in the pooled analysis.

(f) Pooled control groups are not normally used in NTP carcinogenesis studies; they are used here only as a supplemental analysis in the overall data evaluation.

IV. DISCUSSION AND CONCLUSIONS

. .

n-Butyl chloride was administered in corn oil by gavage to male and female F344/N rats and B6C3F₁ mice at the following doses: 0-3,000 mg/kg for 14 days (rats and mice), 0-500 mg/kg for 13 weeks (rats), 0-1,000 mg/kg for 13 weeks (mice), 0, 60, or 120 mg/kg for 2 years (rats), and 0, 250, 500, or 1,000 mg/kg for 2 years (mice).

Short-Term Studies

In the 14-day studies, all rats that received 1,500 or 3,000 mg/kg and 3/5 males and 1/5 females that received 750 mg/kg n-butyl chloride died before the end of the studies. Only males receiving 750 mg/kg had lower body weights than did the vehicle controls. Hyperactivity and convulsions following gavage administration and bloody discharge from the nose and mouth were observed in male rats that received 750 mg/kg or more. One female rat that received 1,500 mg/kg had convulsions. Similar effects occurred in mice, although *n*-butyl chloride appeared to be less toxic. These clinical signs are indicative of central nervous system effects, and they have been reported previously by Smyth et al. (1954). All mice that received 3,000 mg/kg and 3/5 males and 2/5 females that received 1,500 mg/kg died before the end of the studies. No deaths occurred in groups administered 750 mg/kg or less. No compound-related reductions in weight gain occurred. Mice were hyperactive when administered doses of 1,500 mg/kg or more. Furthermore, only 2/10 male mice in the 3,000 mg/kg group had convulsions. There were no compound-related pathologic effects.

In the 13-week studies, all rats survived except for six males in the 500 mg/kg dose group; three of these died as a result of gavage accidents. As in the 14-day studies, animals were hyperactive and convulsed on one or more occasions (5/10 males and 2/10 females at 250 mg/kg and 9/10 males and 8/10 females at 500 mg/kg). Convulsions were not observed in the lower dose groups. Final mean body weights of males that received 250 or 500 mg/kg were 11%-20% lower than those of the vehicle controls, whereas only females in the 500 mg/kg group had 10% lower body weights. Mild to moderate compound-related extramedullary hematopoiesis in the spleen was observed in 3/10 males receiving 500 mg/kg. Because of weight gain depression and

convulsions observed at 250 mg/kg and deaths in the male 500 mg/kg group, doses of 60 and 120 mg/kg *n*-butyl chloride were selected for male and female rats in the 2-year studies.

Gavage accidents during the mouse studies killed two vehicle control females, a male and a female in the 60 mg/kg groups, a female in the 120 mg/kg group, and two females in the 1,000 mg/kg group. Only one death, that of a female that received 1,000 mg/kg, was attributed to compound administration. Two females in this same group convulsed during the study. There were no compound-related effects on weight gain and no histopathologic effects. Based on these findings, doses of 500 and 1,000 mg/kg were selected for male and female mice in the 2-year studies. The difference in doses selected for rats and mice in the 2-year studies likely demonstrates a difference in sensitivity to, or in metabolism and disposition of, *n*-butyl chloride.

Two-Year Studies: Rats

In the 2-year studies, survival of both male rats (after week 59) and female rats (after week 41) in the high dose groups was significantly lower than that of the vehicle controls due to n-butyl chloride-related toxicity (see Figure 2). Hyperactivity, leading to tremors and convulsions, was noted in some animals before they died; this finding was consistent with the results of the 14day and 13-week studies in which higher doses were used. Neither gross observations nor histopathologic evaluations revealed toxic morphologic lesions directly attributable to administration of n-butyl chloride, but there were incidences of small, usually perivascular hemorrhages in the brain which were consistent with rats dying suddenly during convulsions. Likewise, agonal or terminal congestion, edema, and hemorrhage of the lung were common in such animals. The actual cause of death could not be determined. Similar histopathologic findings were observed in animals dying later in the study but not in those killed at the end of the studies. The excessive mortality in both high dose male and female groups suggests that toxic levels were reached. There was no compoundrelated decrease in relative weight gain in any dose group. Death was considered to be compound related and not due to errors in gavage

administration. The mortality in the high dose groups was evaluated, and the studies were continued because of good survival in the low dose groups and no apparent compound-related reductions in weight gains in any dose groups. Based on the findings in the 13-week studies, high mortality in the 120 mg/kg high dose groups was not expected and reduced the sensitivity for determining carcinogenic responses in these groups. In retrospect, it might have been desirable to have conducted additional studies at a dose lower than 60 mg/kg.

Despite the low survival of high dose male and female rats, the present studies are considered adequate because survival of male and female rats in the 60 mg/kg dose groups was sufficient to permit evaluation and interpretation of the data. Thirty-two of 50 male rats administered 60 mg/kg n-butyl chloride survived to the end of the study (compared with 40/50 vehicle controls), and 38/50 females administered the same dose survived to the end of the study (compared with 35/50 vehicle controls). The mean body weights of high dose males were slightly (less than 9%) lower than those of the vehicle controls throughout most of the study. Mean body weights of dosed females and low dose males and concurrent vehicle controls were comparable throughout the studies. No clinical signs other than convulsions were observed following gavage administration.

There was a marginally (P=0.04) increased incidence of pheochromocytomas of the adrenal gland in low dose female rats (vehicle control, 1/50; low dose, 6/50; high dose, 1/49). There was no supporting increase in the high dose group, and most of the tumors were observed at the end of the study. Pheochromocytomas are latedeveloping tumors, and this lesion was not observed in the 11 high dose females that survived 2 years. The incidences of hyperplasia of the adrenal medulla were not strongly supportive (vehicle control, 3/50; low dose, 7/50; high dose, 4/49). If these effects were compoundrelated, higher incidences of hyperplasia and tumors would have been expected. The historical incidence of this tumor is 6%-7%. There was no significant trend for the incidence of this tumor, pairwise statistical significance was marginal, and the incidences of hyperplasia provided limited support. In addition, a negative trend

was seen in male rats (vehicle control, 15/50; low dose, 11/50; high dose, 4/50). One vehicle control female rat had a malignant pheochromocytoma. Thus, this marginal increase in female rats is considered unlikely to be the result of *n*-butyl chloride administration.

In male rats, there was a positive trend in the incidences of cytoplasmic vacuolization in the adrenal cortex (vehicle control, 5/50; low dose, 10/50; high dose, 20/50). In female rats, the incidences were lower and not different among the groups (vehicle control, 4/50; low dose, 5/50; high dose, 3/49). Although increased cytoplasmic vacuolization indicates an increased accumulation of lipid material, the biologic significance of this compound-related effect in male rats is not clear. No other compound-related nonneoplastic lesions were seen in the adrenal cortex.

Transitional cell papillomas of the urinary bladder were observed in one low dose male rat and one high dose female rat. The overall historical incidence of this tumor is 0% in male rats and 0.3% in female rats throughout the Program, and none has been observed previously at this laboratory. The significance of this lesion is not clear and is reported here only because it is not normally observed.

Several nonneoplastic effects were observed primarily in high dose male and female rats as a probable result of chemical-related toxicity (see Table 10). Convulsions after dosing, especially in high dose animals, were common throughout the studies. Mortality was excessive in both high dose male and female groups. Toxic effects included hemorrhage in the brain and lung and lymphoid depletion and hemosiderosis of the spleen. Hemorrhage of the brain and alveoli are often observed in animals dying from convulsions. In addition, lymphoid depletion of the spleen is consistent with a stressed state of the animals. The cause of the splenic hemosiderosis is not known. Hemorrhage in the brain and lung and splenic hemosiderosis and lymphoid depletion in high dose animals were observed only in animals dying during the studies except for one high dose rat at the end of the studies that had brain hemorrhage. The other nonneoplastic lesion in rats was nephropathy, which was observed in females (vehicle control, 13/50; low dose, 25/50; high dose, 20/50). Although there

were higher incidences in the dosed animals, the significance of this lesion is not clear, especially since other nonneoplastic kidney effects such as congestion, inflammation, or nephrosis were not present to any degree in either vehicle control or dosed groups.

Two-Year Studies: Mice

Survival of female mice in the 1,000 mg/kg group was reduced to 50% by the 25th week of exposure. Ninety percent of the high dose male mice were alive at that time. No biologically significant decreases in weight gain or survival were observed in the 13-week studies at the doses selected for the 2-year studies. Hyperactivity, tremors, and convulsions were observed in female mice and were seen in the 14-day and 13-week studies. Gross observations and histopathologic evaluation of females dying early did not reveal any morphologic lesions attributable to *n*-butyl chloride; however, hemorrhage of the brain and lung, as reported for rats, was observed.

The poor survival could not be attributed to gavage accidents, disease, or deviations from the study protocol and was therefore considered compound related. Since mortality was excessive, the rest of the high dose females were killed at week 45 and additional 2-year studies with male and female mice were started at a lower dose of 250 mg/kg, with concurrent vehicle controls. At the end of the first 2-year study, a decrease in survival was dose related in male mice. Survival in the high dose male group was reduced (vehicle control, 33/50; 1,000 mg/kg, 10/50), and the mean body weight was 10% lower than that of the vehicle controls. The decline in survival occurred relatively late in the study. Although survival in the low dose male group was lower than that of the vehicle controls, 54% of the animals survived to the end. Survival in the 500 mg/kg female group (first study) and in both male and female 250 mg/kg groups of the second studies was not significantly different from that of the corresponding vehicle control groups. Mean body weights of the animals were the same as or greater than those of the vehicle controls throughout most of the first 2-year studies. Hyperactivity, often followed by tremors and convulsions, was seen primarily in the high dose animals of the first studies. There were no

compound-related clinical signs in either male or female mice during the second 2-year studies.

Proliferative lesions were observed in the lung (female), liver (female) and circulatory system (male) with a greater incidence in dosed mice than in the vehicle controls. Alveolar/bronchiolar adenomas or carcinomas (combined) occurred at increased incidences in dosed female mice in the first study but showed little difference in the second study (see Table 17). The incidences of these lesions in vehicle controls were within the range of the historical control incidence for the laboratory and for NTP studies in general. Since there were no significant differences in the incidences of adenomas, carcinomas, or adenomas or carcinomas (combined) between the two vehicle control groups, additional statistical analyses comparing dosed groups to pooled vehicle control groups were performed. The combined incidence of alveolar/bronchiolar adenomas and carcinomas in the 500 mg/kg group was significant (P=0.03) by the incidental tumor test, but the incidences of adenomas or carcinomas alone were not significant when compared with the vehicle controls.

When the incidences of alveolar/bronchiolar adenomas and carcinomas from each dose group of the two studies were compared with those in the pooled vehicle control group, the increased incidence of carcinomas alone in the high dose group was of borderline significance (P=0.05)(vehicle control. 1/100; 250 mg/kg. 3/50; 500 mg/kg, 4/50). The incidence of adenomas or carcinomas (combined) compared with that in the pooled vehicle controls was not significant (vehicle control, 9/100; 250 mg/kg, 8/50; 500 mg/kg, 9/50). There were no significant increases in the incidences of adenomas or carcinomas (combined) in dosed male mice. A negative trend was found for alveolar/bronchiolar carcinomas in dosed male groups in the first study (vehicle control, 3/50; low dose, 2/50; Hyperplasia of the high dose, 0/50). alveolar/bronchiolar region was present in only one animal of each of the vehicle control male and female groups and of the 500 mg/kg female group. The lack of hyperplasia and insignificant differences in adenomas in dosed versus vehicle control animals did not support a progression of compound-induced neoplasia. Thus, the marginal increase in lung lesions in female mice is not considered the result of *n*-butyl chloride administration.

A marginally significant (P=0.04) increased incidence of hepatocellular adenomas or carcinomas (combined) was seen in the 500 mg/kg female mouse group (vehicle control, 3/50; 500 mg/kg, 8/50) (see Table 18). This increase was not significant by logistic regression analysis (P=0.08). Neither adenomas nor carcinomas alone were significantly increased in either dosed group. Comparison of the vehicle control groups from both studies revealed a significant (P < 0.05) difference in adenomas (1/50 vs 8/50)and adenomas or carcinomas (combined) (3/50 vs 9/50). Even so, when the increased incidence of combined tumors from the dosed groups was compared with that of the pooled vehicle control groups, the incidence was no longer significant. Since the incidences of adenomas and carcinomas were highly variable between the two vehicle control groups, showed no significant effects when the two studies were combined, and showed no dose-related effects in male mice, this marginal increase in females was not considered to be compound related.

A marginal dose-related incidence of hemangiosarcomas was observed in male mice (vehicle control, 1/50; low dose, 3/50; high dose, 4/50) in the first study. The increase in the 1,000 mg/kg group was marginally significant (P=0.04) by life table analysis; one animal in the low dose group and two in the high dose group had two or more lesions. In the second study, hemangiosarcomas occurred in 4/50 vehicle controls (five tumors) and in 2/50 dosed animals (three tumors). One hemangioma was observed in the 250 mg/kg group. The second study does not support a chemical-induced incidence of hemangiosarcomas, particularly since the vehicle control incidence was equal to the incidence observed in the high dose group in the first study. When the vehicle control groups of the two studies were compared, there was no difference in the incidence of hemangiosarcomas. When the vehicle control groups were pooled and the incidence in

dosed animals compared with this pooled vehicle control group (vehicle control, 5/100; 250 mg/kg, 2/50; 500 mg/kg, 3/50; 1,000 mg/kg, 4/50), the statistical significance of the incidence in the 1,000 mg/kg group was essentially unchanged (P=0.03; by the life table test). Of interest, all hemangiosarcomas observed in both vehicle control groups and in the 250 mg/kg group were observed at the end of the study as opposed to 5/7hemangiosarcomas in the 500 and 1,000 mg/kg group being observed between weeks 91 and 104. The historical incidence of hemangiosarcomas at this laboratory (1.5%) is lower than the incidence for all NTP studies (4%). Since the incidence of these tumors was only marginally increased and the vehicle control incidence in the first study was lower than the historical incidence for the NTP studies and the incidence in the vehicle controls of the second study, the marginal increase in hemangiosarcomas was not considered to be compound related.

n-Butyl chloride was not mutagenic in Salmonella typhimurium strains TA98, TA100, TA1535, or TA1537 in either the presence or absence of Aroclor 1254-induced male Sprague-Dawley rat liver S9 or in the presence of male Syrian hamster S9. *n*-Butyl chloride was mutagenic in the mouse lymphoma L5178Y/TK^{+/-} assay in the absence of Aroclor-induced male rat liver S9 and was not tested in the presence of rat liver S9. *n*-Butyl chloride did not induce sisterchromatid exchanges or chromosomal aberrations in Chinese hamster ovary cells in the presence or absence of Aroclor-induced male Sprague-Dawley rat liver S9.

Conclusions: Under the conditions of these 2year gavage studies, there was no evidence of carcinogenicity* of n-butyl chloride for male and female F344/N rats at daily doses of 60 or 120 mg/kg, for male B6C3F₁ mice at doses of 250, 500, or 1,000 mg/kg, or for female B6C3F₁ mice at doses of 250 or 500 mg/kg. Chemical-induced toxicity in high dose rats (primarily females) reduced the sensitivity of the study for determining carcinogenicity.

^{*}Categories of evidence of carcinogenicity are defined in the Note to the Reader on page 2.

TABLE E1. ANALYSIS OF PRIMARY TUMORS IN MALE RATS IN THE TWO-YEAR GAVAGE STUDY OF n-BUTYL CHLORIDE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

⁽d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

TABLE E3. ANALYSIS OF PRIMARY TUMORS IN MALE MICE IN THE FIRST TWO-YEAR GAVAGE STUDY OF n-BUTYL CHLORIDE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

(d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

(e) No P value is reported because no tumors were observed in the 1,000 mg/kg and vehicle control groups.

	Vehicle Control	250 mg/kg

TABLE E4. ANALYSIS OF PRIMARY TUMORS IN MALE MICE IN THE SECOND TWO-YEAR GAVAGESTUDY OF n-BUTYL CHLORIDE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality (c) Observed tumor incidence at terminal kill

(d) Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between the dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Fisher exact test compares directly the overall incidence rates. A lower incidence in the dosed group is indicated by (N).

 (c) Observed tumor incidence at terminal kill
 (d) Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between the dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Fisher exact test compares directly the overall incidence rates. A lower incidence in the dosed group is indicated by (N).

TABLE G1. MUTAGENICITY OF n-BUTYL CHLORIDE IN SALMONELLA TYPHIMURIUM

(a) The S9 fractions were prepared from the livers of Aroclor 1254-induced male Sprague-Dawley rats and male Syrian hamsters. Cells and test compound or solvent (dimethyl sulfoxide) were incubated for 20 minutes at 37° C in the presence of either S9 or buffer. After the addition of soft agar, the contents of each tube was poured onto minimal medium, and the plates were incubated at 37° C for 48 hours (Haworth et al., 1983). The experiment was performed twice, each in triplicate; because the results were similar, data from only one experiment are shown.

TABLE G2. MUTAGENICITY OF n-BUTYL CHLORIDE IN L5178Y/TK+/- MOUSE LYMPHOMA CELLSIN THE ABSENCE OF S9 (a)

(a) Experiments were performed twice, all doses were tested in duplicate, except the solvent control dimethyl sulfoxide (DMSO), which was tested in quadruplicate. Because the results were similar, data from only one experiment are shown. The protocol was basically that of Clive et al. (1979). Cells (6×10^{5} /ml) were treated for 4 hours at 37° C in medium, washed, resuspended in medium, and incubated for 48 hours at 37° C. After expression, 3×10^{6} cells were plated in medium supplemented with trifluorothymidine for selection of cells that were mutant at the thymidine kinase (TK) locus, and 600 cells were plated in nonselective medium to determine the percentage of viable cells.

TABLE G3. INDUCTION OF SISTER-CHROMATID EXCHANGES IN CHINESE HAMSTER OVARY CELLS BY n-BUTYL CHLORIDE (a)

- S9 (b)		+ S9 (c)
Dose (µg/ml)	SCE/Cell	Dose (µg/ml)	SCE/Cell
DMSO		DMSO

0.001	26.06	0.3	10.54
0.010	51.00	2.0	25.60

(a) SCE = sister-chromatid exchange; CHO = Chinese hamster ovary

(b) In the absence of S9, CHO cells were incubated with test compound or solvent for 2 hours at 37° C. Then BrdU was added, and incubation continued for 24 hours. Cells were washed, fresh medium containing BrdU (10 μ M) and colcemid (0.1 μ g/ml) was added, and incubation was continued for 2-3 hours. Cells were then collected by mitotic shake-off, treated for 3 minutes with KCl (75 mM), washed twice with fixative, and dropped onto slides and air-dried. Staining was by a modified technique (after Perry and Wolff, 1974; Goto et al., 1978).

(c) In the presence of S9, cells were incubated with test compound or solvent for 2 hours at 37° C. Then cells were washed, and medium containing 10 μ M BrdU was added. Cells were incubated for a further 26 hours, with colcemid (0.1 μ g/ml) present for the final 2-3 hours. S9 was from the livers of Aroclor 1254-induced male Sprague-Dawley rats.

TABLE G4. INDUCTION OF CHROMOSOMAL ABERRATIONS IN CHINESE HAMSTER OVARY CELLS BY n-BUTYL CHLORIDE (a)

-S9(b)		+ \$	39 (c)
Dose (µg/ml)	Abs/100 Cells (percent cells w/abs)	Dose (µg/ml)	Abs/100 Cells (percent cells w/abs)

FIGURE 8. NUCLEAR MAGNETIC RESONANCE SPECTRUM OF n-BUTYL CHLORIDE (LOT NO. 780135-3)

- E. Free acid titration: $25 \pm 4(\delta)$ ppm (as hydrochloric acid)
- F. Chromatographic analyses: Gas chromatography

System 1

Instrument: Varian 3700 Detector: Flame ionization Column: Carbopack C/0.1% SP1000, 1.8 m × 4 mm ID, glass Inlet temperature: 250° C Detector temperature: 330° C Carrier gas: Nitrogen, 70 ml/min Sample injected: 5.6 µl of the neat compound, and 1% (v/v) and 0.5% (v/v) to quantitate the impurity and check the linearity of detector response

Results: A major peak preceded by one impurity

<u>Peak No.</u>	Retention <u>Time (min)</u>	Retention Time Relative to <u>Major Peak</u>	Area (percent of <u>major peak)</u>
1	9.2	0.81	0.27
2	11.4	1.00	100

System 2

Instrument: Perkin-Elmer 3920 Detector: Flame ionization Column: 20% SP2100/0.1% Carbowax 1500 on 100/120 Supelcoport; 1.8 m × 4 mm ID, glass Inlet temperature: 200° C Detector temperature: 260° C Carrier gas: Nitrogen, 45 ml/min Sample injected: 3.0 µl of the neat compound, and 1.0% (v/v) and 0.5% (v/v) to quantitate the impurity and check the linearity of detector response

Results: A major peak preceded by one impurity

<u>Peak No.</u>	Retention <u>Time (min)</u>	Retention Time Relative to <u>Major Peak</u>	Area (percent of <u>major peak)</u>
1	1.8	0.69	0.40
2	2.6	1.00	100

1,

- G. Conclusions: The results of the elemental analysis for carbon, hydrogen, and chlorine were in agreement with theoretical values. The water content by Karl Fischer analysis was $0.46\% \pm 0.14(\delta)\%$. Free acid titration indicated a concentration of 25 ± 4 ppm (as hydrochloric acid). Gas chromatography, with a Carbopack C/0.1% SP1000 column, detected a major peak preceded by one impurity with a relative area of 0.27%. A second gas chromatographic system, with a 20% SP2100/0.1% Carbowax 1500 column, detected a major peak preceded by one impurity with a relative area of 0.40%. The infrared and nuclear magnetic resonance spectra were identical to literature spectra. The ultraviolet and visible spectra were consistent with the structure.
- II. Test Chemical Stability Study of *n*-Butyl Chloride Lot No. 780135-3 Performed by the Analytical Chemistry Laboratory
 - A. Sample storage: Samples of *n*-butyl chloride were stored in glass vessels with Teflon[®]-lined lids for 2 weeks at temperatures of -20° , 5° , 25° , and 60° C.
 - **B.** Analytical method: Samples were analyzed by gas chromatography with the following system:

Instrument: Varian 3700 (autosampler) Detector: Flame ionization Column: Carbopack C/0.1% SP1000, 1.8 m × 4 mm ID, glass Inlet temperature: 250° C Detector temperature: 330° C Carrier gas: Nitrogen, 60 ml/min Oven temperature: 110° C Retention times: *n*-butyl chloride--3.4 min; internal standard--7.8 min Sample injected: Samples (1 ml) from each storage temperature were dissolved in methylene chloride (100 ml) containing 0.7% pentane internal standard.

C. Results: The results were compared with the values obtained for the -20° C sample.

Storage Temperature	Percent Recovery
– 20° C	100.0
5° C	$100.0 \pm 0.4(\delta)$
25° C	$99.3 \pm 0.3(\delta)$
60° C	$98.8 \pm 1.4(\delta)$

D. Conclusion: *n*-Butyl chloride is stable as the bulk chemical for 2 weeks at temperatures up to 60° C.

III. Test Chemical Stability Study of *n*-Butyl Chloride Lot No. 780135-3 Performed by the Testing Laboratory

A. Storage conditions

Bulk: 4° C until 2/1/80, then 0° C Reference: -18° C until 12/2/81, then -20° C or lower

B. Analytical methods

1. Gas chromatography

Instrument: Varian 1400 Detection: Flame ionization Column: 0.1% SP1000 on Carbopack C, 6 ft × 2 mm ID, glass Oven temperature program: 50°-170° C (or 190° C) at 6° C/minute Inlet temperature: 170°-230° C Detector temperature: 205°-240° C

2. Infrared spectroscopy

Instrument: Perkin-Elmer Infracord #137 **Cell:** Liquid film between silver chloride plates

C. Results

1. Gas chromatography

	Percent Purity	
Date	Bulk	Reference
02/27/79	99.74	99.68

12/13/82	99.73	99.73
04/29/83	99.73	99.73

2. Infrared spectroscopy: All bulk spectra were consistent with those of the reference sample.

*

D. Conclusion: No notable degradation was observed during the studies.

APPENDIX I

PREPARATION AND CHARACTERIZATION

OF DOSE MIXTURES

I. Room Temperature Stability Study of *n*-Butyl Chloride (Lot No. 780135-3) in Corn Oil Performed by the Analytical Chemistry Laboratory

A. Sample preparation and storage: *n*-Butyl chloride $(3.0137 \pm 0.0001 \text{ g})$ was placed in a 50-ml volumetric flask and diluted to the mark with corn oil. The chemical dissolved readily after manual shaking. The solution concentration was 6.02% w/v.

As soon as the solution had been prepared, 10 accurately weighed 1.59 g aliquots (the total solution weighed 45.804 \pm 0.001 g; therefore, each aliquot contained 104.6 mg of *n*-butyl chloride) were removed and sealed in separate 60-ml septum vials. Duplicate aliquots were used as initial, or zero-time, samples and for storage for 1, 2, 5, or 7 days.

B. Sample extraction and analysis: A solution containing an internal reference standard was prepared by weighing 1.6092 ± 0.0001 g of *n*-amyl alcohol, transferring it to a 25-ml volumetric flask, and diluting to the mark with absolute methanol. This solution was further diluted 10/100 with absolute methanol. The concentration of reference standard was 6.437 ± 0.008 mg/ml.

To extract each sample aliquot, the septum vial was opened, 25 ml of methanol was added by volumetric pipette, and the vial was resealed immediately. The corn oil/methanol mixture was manually shaken for 30 seconds and sonicated for 30 seconds; then 10 ml of the resulting suspension was decanted into a 12-ml centrifuge tube and centrifuged for 5 minutes. A portion of the clear, methanolic supernatant solution (3 ml) was transferred to an 8.5-ml septum vial, and 3 ml of the internal standard solution was added for subsequent analysis by the gas chromatographic system outlined below:

Instrument: Varian 3700 with CDS 111 microprocessor Column: 20% SP2100/10.1% Carbowax 1500 on 100/120 mesh Supelcoport; 1.8 m × 2 mm ID, glass, silanized Detection: Flame ionization Temperatures: Inlet, 150° C Oven, 50° C, isothermal Detector, 250° C Carrier gas: Nitrogen, 30 ml/min Volume of solution injected: 4 µl Retention times: Test chemical, 2.5 minutes Reference standard, 7.2 minutes

C. Quality control protocol: Analyses were performed in duplicate with *n*-amyl alcohol as an internal reference standard. Zero-time recovery studies were performed in duplicate at the same concentration level as the test samples. Gas chromatographic linearity was determined with standard solutions in methanol for the *n*-butyl chloride and the internal reference.

D. Results

<u>Storage Time (days)</u>	Average Percent Chemical Found in <u>Chemical/Vehicle Mixture (a, b)</u>	
0	(c) 6.6 ± 0.2	
1	6.5 ± 0.2	
2	6.6 ± 0.2	
5	6.6 ± 0.2	
7	6.4 ± 0.2	

(a) Zero-time recovery yield, $87\% \pm 2\%$.

(b) Target concentration of chemical in corn oil, 6.580% ± 0.001% (w/w) or 6.02% (w/v)
(c) The error values in this table are average deviations obtained in the analytic measurements of the test solutions.

E. Conclusion: n-Butyl chloride is stable when dissolved in corn oil at a concentration of 6% and stored at room temperature for 7 days.

L

n-Butyl Chloride, NTP TR 312
APPENDIX J

METHODS OF ANALYSIS OF DOSE MIXTURES

I. Testing Laboratory

Procedure: Dose mixtures were stored at 4° C during the 13-week studies and at 0° C during the 2-year studies.

Duplicate 1-ml samples were extracted with methanol containing 2 mg/ml of *n*-amyl alcohol as an internal standard.

Instrument: Varian 1400 Column: 20% SP2100/0.1% Carbowax 1500 on 100/200 mesh Supelcoport (100/120 Supelcoport before 6/25/80), 6 ft \times 2 mm ID, glass Detector temperature: 70°C (50°C before 6/25/80)

II. Analytical Chemistry Laboratory

- A. Preparation of standard spiked corn oil: Two standard solutions of *n*-butyl chloride were prepared independently in methanol. The solutions were diluted with methanol to make three or four additional standards. Aliquots (10 or 20 ml) of the five or six standard solutions were pipetted into individual septum vials (30 or 35 ml) containing 2 g of undosed corn oil to make spiked corn oil standards bracketing the specified concentration range of the referee sample. Undosed corn oil (2 g) in a septum vial (30 or 35 ml) was treated with methanol (10 or 20 ml) for use as a blank. After the vials were sealed with Teflon[®]-lined septa, the spiked corn oil standards and the corn oil blank were analyzed.
- **B.** Preparation of referee sample: Three portions (approximately 2 g each) of the referee corn oil sample were transferred to individually tared septum vials (30 or 35 ml) and weighed to the nearest 0.001 g. Methanol (10 or 20 ml) was pipetted into each vial, the vials were sealed, and the samples were analyzed.
- C. Analysis: Vials containing the samples, standards, and the blank were agitated for 10 seconds on a vortex mixer and shaken for 15 minutes at maximum stroke on a wrist-action shaker. After being centrifuged for 3 minutes, an aliquot of the methanol layer from each vial was combined with an aliquot of internal standard solution (*n*-amyl alcohol in methanol) and diluted with methanol. The solutions were mixed, and the *n*-butyl chloride content was determined by the gas chromatography system described below.

The samples were determined from the linear regression equation computed from the standard data. To obtain the regression equation, peak areas from each injection of the spiked corn oil standards were divided by the corresponding internal standard peak areas and related to the milligrams of chemical in the respective spiked corn oil standard.

Instrument: Varian 3700 Gas Chromatograph with Autosampler and Varian CDS 111-C integrator Column: 20% SP2100/0.1% Carbowax 1500 on 100/120 mesh Supelcoport, 1.8 m × 2 mm ID, glass, silanized Detection: Flame ionization Inlet temperature: 100°C or 150°C Oven temperature: 50°C or 60°C, isothermal Detector temperature: 200°C or 250°C Carrier gas: Nitrogen, 30 ml/min Volume of solution injected: 2 or 3 µl

D. Quality assurance measures: The referee corn oil sample was analyzed in triplicate, and the undosed corn oil sample was analyzed once., Individually spiked portions of undosed corn oil (five or six concentrations bracketing the specified concentration range of the referee sample), prepared from two independently weighed standards, were used to obtain standard data. Triplicate injections of each standard and sample were made into the gas chromatograph in a randomized order. All determinations were related to an internal standard incorporated into the sample solutions.

APPENDIX L

SENTINEL ANIMAL PROGRAM

I. Methods

Rodents used in the Carcinogenesis Program of the National Toxicology Program are produced in optimally clean facilities to eliminate potential pathogens that may affect test results. The Sentinel Animal Program is part of the periodic monitoring of animal health that occurs during the toxicologic evaluation of chemical compounds. Under this program, the disease state of the rodents is monitored via viral serology on sera from extra (sentinel) animals in the test rooms. These animals are untreated, and these animals and the test animals are both subject to identical environmental conditions. The sentinel animals come from the same production source and weanling groups as the animals used for the studies of chemical compounds.

Fifteen $B6C3F_1$ mice and 15 F344/N rats of each sex are selected at the time of randomization and allocation of the animals to the various study groups. Five animals of each designated sentinel group are killed at 6, 12, and 18 months on study. Data from animals surviving 24 months are collected from 5/50 randomly selected control animals of each sex and species. The blood from each animal is collected and clotted, and the serum is separated. The serum is cooled on ice and shipped to Microbiological Associates' Comprehensive Animal Diagnostic Service for determination of the viral antibody titers. The following tests are performed:

	Hemagglutination <u>Inhibition</u>	Complement <u>Fization</u>	ELISA
Mice	(First Study) PVM (pneumonia virus of mice) Reo 3 (reovirus type 3) GDVII (Theiler's encephalomyelitis virus) Poly (polyoma virus) MVM (minute virus of mice) Ectro (infectious ectromelia) Sendai (12, 18, 24 mo)	M.Ad. (mouse adenovirus) LCM (lymphocytic choriomeningitis virus) Sendai (6 mo) MHV (6, 12, 18 mo)	MHV (mouse hepatitis virus) (24 mo)
Rats	PVM KRV (Kilham rat virus) H-1 (Toolan's H-1 virus) Sendai (12, 18, 24 mo)	RCV (rat coronavirus) Sendai (6 mo)

TABLE M4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION (Continued)

- (h) Includes the high values listed in footnote (g).
- (i) All values were corrected for percent recovery.
- (j) Mean, standard deviation, and range exclude two very high values in the range of 95.6 and 118.4 ppb obtained in batches produced on 1/26/81 and 4/27/81.
- (k) Mean, standard deviation, and range include the high values listed in footnote (j).
- (1) Not detectable on 6/24/82
- (m) BHC = hexachlorocyclohexane or benzene hexachloride
- (n) One observation was above the detection limit. The value and the date it was obtained are listed under the range.
- (o) Two observations were above the detection limit. The values and the dates are listed under the range.
- (p) Fourteen batches contained more than 0.05 ppm.

⁽a) Three batches contained more than 0.1 ppm.

⁽b) All values were less than the detection limit, which is given in the table as the mean.

⁽c) Detection limit was reduced from 10 ppb to 5 ppb after 7/81.

⁽d) Source of contamination: Alfalfa, grains, and fish meal

⁽e) Source of contamination: Soy oil and fish meal

⁽f) Six batches contained less than 0.5 ppm.

⁽g) Excludes one very high value of 150 obtained in the batch produced on 8/26/82.

APPENDIX N

DATA AUDIT SUMMARY

.

The experimental data and pathology materials for the toxicology and carcinogenesis studies of nbutyl chloride in F344/N rats and B6C3F₁ mice were audited for completeness, consistency, and accuracy and for procedures consistent with Good Laboratory Practice requirements. The experimental data audit was conducted by Argus Research Laboratories, Inc., in November 1984 and April 1985. Audit team members were Dr. J. Goeke, Dr. A. Haberman, Ms. C. Veigle, Dr. D. Copeland, Mr. M. Pielmeier, and Ms. R. Joftes. The first and second studies on n-butyl chloride were initiated at EG&G Mason Research Institute as follows: rats, started in March 1980 and completed in March 1982; first mouse study, started in February 1980 and completed in February 1982; second mouse study, started in March 1981 and completed in March 1983. The studies were started before the October 1981 NTP requirements for full compliance with Good Laboratory Practices regulations.

The full report of the audit of these studies is on file at the NIEHS, Research Triangle Park, North Carolina. The audit consisted of a review of the records for the in-life portion of the studies, including clinical observations and body weight data for 10% of the animals, and all of the environmental and mortality records; a review of all chemistry data, including chemical characterization, bulk chemical analysis, and characterization of dose mixtures; and a review of pathology data. All Individual Animal Pathology Data Records for rats and mice were reviewed for correlation of gross lesions and microscopic diagnoses. Ten percent of wet tissues were reviewed for animal identification and untrimmed lesions, and a complete slide/block match for both sexes of rats and mice was performed on the high dose and vehicle control groups.

The review of the toxicology data found minor discrepancies in the documentation of clinical observations. Several temperature and humidity readings outside the accepted range occurred during the studies. A review of the available chemistry data found no discrepancies. A review of the pathology data found no substantial problems or discrepancies. Animal identification was good; however, because of mutilated or missing ears, the following mice could not be identified: three high dose males, one vehicle control female in each study, and one dosed female in each study. The tissue bag for high dose male rat no. 39 was missing. Four blocks were missing for rats (one vehicle control female and three high dose females) and five for mice (one vehicle control female in each study, one dosed female in the second study, and a vehicle control male and a dosed male in the second study). One slide from each of two rats (vehicle control male, high dose female) and four mice (vehicle control male and female and two high dose males) were missing. Seven slide/block matches were uncertain (three vehicle control male rats, two vehicle control male mice, and two dosed male mice in the second study). A few untrimmed lesions were found in wet tissues of rats and mice. The untrimmed lesions were not in target organs. The slides were read, and the diagnoses of three neoplasms in mice were included in the final tables of this report.

A few discrepancies between gross and microscopic diagnoses of lesions were noted; these were distributed among dose groups and tissues and were determined to have no impact on the final interpretation of the studies and therefore were not pursued.

In summary, a few discrepancies were found during the audit; some that were considered not to affect the interpretation of the studies were not necessarily pursued to final conclusion but are listed in the final audit report. The data presented in this Technical Report are considered adequate to support the conclusions of the studies.
