NATIONAL TOXICOLOGY PROGRAM

The National Toxicology Program (NTP), established in 1978, develops and evaluates scientific information about potentially toxic and hazardous chemicals. This knowledge can be used for protecting the health of the American people and for the primary prevention of disease. By bringing together the relevant programs, staff, and resources from the U.S. Public Health Service, DHHS, the National Toxicology Program has centralized and strengthened activities relating to toxicology research, testing and test development/validation efforts, and the dissemination of toxicological information to the public and scientific communities and to the research and regulatory agencies.

The NTP is made up of four charter DHHS agencies: the National Cancer Institute (NCI), National Institutes of Health; the National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health; the National Center for Toxicological Research (NCTR), Food and Drug Administration; and the National Institute for Occupational Safety and Health (NIOSH), Centers for Disease Control. In July 1981, the Carcinogenesis Bioassay Testing Program, NCI, was transferred to the NIEHS.

NOTE TO THE READER

These studies are designed and conducted to characterize and evaluate the toxicologic potential, including carcinogenic activity, of selected chemicals in laboratory animals (usually two species, rats and mice). Chemicals selected for testing in the NTP Carcinogenesis Program are chosen primarily on the bases of human exposure, level of production, and chemical structure. Selection per se is not an indicator of a chemical's carcinogenic potential. Negative results, in which the test animals do not have a greater incidence of cancer than control animals, do not necessarily mean that a test chemical is not a carcinogen, inasmuch as the experiments are conducted under a limited set of conditions. Positive results demonstrate that a test chemical is carcinogenic for animals under the conditions of the test and indicate that exposure to the chemical has the potential for hazard to humans. The determination of the risk to humans from chemicals found to be carcinogenic in animals requires a wider analysis which extends beyond the purview of this study.

Five categories of interpretative conclusions were adopted in June 1983 for use in the Technical Reports series to specifically emphasize consistency and the concept of actual evidence of carcinogenicity. For each definitive study result (male rats, female rats, male mice, female mice), one of the following quintet will be selected to describe the findings. These categories refer to the strength of the experimental evidence and not to either potency or mechanism.

- Clear Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a
 chemically related increased incidence of malignant neoplasms, studies that exhibit a substantially increased incidence of benign neoplasms, or studies that exhibit an increased incidence of a
 combination of malignant and benign neoplasms where each increases with dose.
- Some Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of benign neoplasms, studies that exhibit marginal increases in neoplasms of several organs/tissues, or studies that exhibit a slight increase in uncommon malignant or benign neoplasms.
- Equivocal Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related marginal increase of neoplasms.
- No Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing no chemically related increases in malignant or benign neoplasms.
- Inadequate Study of Carcinogenicity demonstrates that because of major qualitative or quantitative limitations, the studies cannot be interpreted as valid for showing either the presence or absence of a carcinogenic effect.

Additionally, the following concepts (as patterned from the International Agency for Research on Cancer Monographs) have been adopted by the NTP to give further clarification of these issues:

The term chemical carcinogenesis generally means the induction by chemicals of neoplasms not usually observed, the earlier induction by chemicals of neoplasms that are commonly observed, or the induction by chemicals of more neoplasms than are generally found. Different mechanisms may be involved in these situations. Etymologically, the term carcinogenesis means induction of cancer, that is, of malignant neoplasms; however, the commonly accepted meaning is the induction of various types of neoplasms or of a combination of malignant and benign neoplasms. In the Technical Reports, the words tumor and neoplasm are used interchangeably.

This study was initiated by the National Cancer Institute's Carcinogenesis Bioassay Program, now part of the National Institute of Environmental Health Sciences, National Toxicology Program. The studies described in this Technical Report have been conducted in compliance with NTP chemical health and safety requirements and must meet or exceed all applicable Federal, state, and local health and safety regulations. Animal care and use were in accordance with the U.S. Public Health Service Policy on Humane Care and Use of Animals. All NTP toxicology and carcinogenesis studies are subjected to a data audit before being presented for peer review.

Although every effort is made to prepare the Technical Reports as accurately as possible, mistakes may occur. Readers are requested to identify any mistakes so that corrective action may be taken. Further, anyone who is aware of related ongoing or published studies not mentioned in this report is encouraged to make this information known to the NTP. Comments and questions about the National Toxicology Program Technical Reports on Toxicology and Carcinogenesis Studies should be directed to Dr. J.E. Huff, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709 (919-541-3780).

These NTP Technical Reports are available for sale from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161 (703-487-4650). Single copies of this Technical Report are available without charge (and while supplies last) from the NTP Public Information Office, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709.

PHENYLEPHRINE HYDROCHLORIDE

CAS No. 61-76-7

C₉H₁₃NO₂ • HCl Molecular weight 203.7

Synonyms: Benzene methanol,3-hydroxy-a-[(methylamino) methyl]hydrochloride (R)-;
(-)-meta-Hydroxy-a-[(methylamino) methyl] benzyl alcohol hydrochloride;

meta-Synephrine hydrochloride;

Neo-synephrine®

ABSTRACT

Phenylephrine hydrochloride is a sympathomimetic amine recommended for use as a nasal decongestant and as a mydriatic in ophthalmic applications. In 1977, total U.S. human exposure was estimated at 1.9×10^7 g per year. Phenylephrine hydrochloride was nominated for toxicology and carcinogenesis studies because of a lack of previous long-term studies and because two other sympathomimetic agents (soterenol hydrochloride and mesuprine hydrochloride) produced mesovarial leiomyomas in Sprague-Dawley rats.

Toxicology and carcinogenesis studies of USP-grade phenylephrine hydrochloride were conducted by administering diets containing the chemical (99% pure) to F344/N rats and B6C3F₁ mice of each sex in studies of 14 days, 12 weeks, and 2 years. In the 14-day studies, no toxic effects were seen in rats or mice fed diets containing up to 2,000 ppm phenylephrine hydrochloride. Doses were increased in the 12-week studies, and deaths of male rats and male mice were observed in groups fed diets containing 10,000 or 20,000 ppm; 1/10 male rats in the 5,000-ppm group died. Other than inflammatory eye lesions (considered secondary to the pharmacologic drying action of the chemical), no specific organ toxicity was noted. Body weights decreased as concentrations of phenylephrine hydrochloride in the diet were increased, and feed consumption was lower in dosed rats. Doses of 0, 620, and 1,250 ppm for rats and 0, 1,250, and 2,500 ppm for mice were selected for the 2-year studies because of decreased body weight gains in animals given higher doses in the 12-week studies. In the 2-year studies, the approximate amount of phenylephrine hydrochloride consumed per day was 24 mg/kg for low dose rats, 50 mg/kg for high dose rats, 133 mg/kg for low dose mice, and 270 mg/kg for high dose mice.

Body weight differences in rats appeared to be dose related, and dosed animals were 3%-15% lighter than controls. Body weights of dosed mice averaged 3%-14% lower than those of controls throughout the 2-year studies. Survival of high dose male rats was greater than that of the controls (control, 30/50; low dose, 33/50; high dose, 42/50); differences in survival were not significant for female rats (42/50; 34/50; 36/50), male mice (35/50; 38/50; 43/50), or female mice (37/50; 34/50; 34/50).

Few nonneoplastic lesions were related to phenylephrine hydrochloride dosing in rats or mice. Chronic focal inflammation of the liver was observed at increased incidences in dosed rats (male: 2/50; 13/50; 17/50; female: 17/50; 28/50; 35/50). Inflammation of the prostate was seen more frequently in dosed than in control males (10/50; 24/50; 24/50). The incidence of focal cellular change in the liver was increased slightly in high dose male mice (0/50; 2/50; 7/50).

In male rats, mononuclear cell leukemia (24/50; 9/50; 5/50) and pheochromocytomas of the adrenal gland (14/49; 11/50; 2/50) occurred with negative trends, and the incidences in the high dose group were lower than those in the controls. No increases in neoplasia were seen in dosed male or female rats or mice.

Phenylephrine hydrochloride was not mutagenic in four strains of Salmonella typhimurium (TA100, TA1535, TA1537, and TA98) with or without Aroclor 1254-induced liver S9 from male Sprague-Dawley rats or male Syrian hamsters. The results of mutagenicity studies of phenylephrine hydrochloride were equivocal in the mouse lymphoma L5178Y/TK^{+/-} assay in the absence of S9; it was not tested in the presence of S9. Phenylephrine hydrochloride induced sister-chromatid exchanges (SCEs) but not chromosomal aberrations in Chinese hamster ovary cells. The increase in SCEs was seen only in the absence of metabolic activation with S9.

An audit of the experimental data was conducted for the 2-year studies of phenylephrine hydrochloride. No data discrepancies were found that influenced the final interpretations.

Under the conditions of these 2-year studies, there was no evidence of carcinogenicity* of phenylephrine hydrochloride for male or female F344/N rats given 620 or 1,250 ppm in feed or for male or female B6C3F₁ mice given 1,250 or 2,500 ppm in feed. Survival of high dose male rats was greater than that of controls, and the incidences of mononuclear cell leukemia and pheochromocytomas were lower in dosed than in control male rats. Inflammation was observed more frequently in the liver and prostate gland of dosed male rats than in controls.

^{*}Categories of evidence of carcinogenicity are defined in the Note to the Reader on page 2. A summary of the Peer Review comments and the public discussion on this Technical Report appears on page 8.

PEER REVIEW PANEL

The members of the Peer Review Panel who evaluated the draft Technical Report on phenylephrine hydrochloride on March 26, 1986, are listed below. Panel members serve as independent scientists, not as representatives of any institution, company, or governmental agency. In this capacity, Panel members have five major responsibilities: (a) to ascertain that all relevant literature data have been adequately cited and interpreted, (b) to determine if the design and conditions of the NTP studies were appropriate, (c) to ensure that the Technical Report presents the experimental results and conclusions fully and clearly, (d) to judge the significance of the experimental results by scientific criteria, and (e) to assess the evaluation of the evidence of carcinogenicity and other observed toxic responses.

SUMMARY OF PEER REVIEW COMMENTS ON THE TOXICOLOGY AND CARCINOGENESIS STUDIES OF PHENYLEPHRINE HYDROCHLORIDE

On March 26, 1986, the draft Technical Report on the toxicology and carcinogenesis studies of phenylephrine hydrochloride received peer review by the National Toxicology Program Board of Scientific Counselors' Technical Reports Review Subcommittee and associated Panel of Experts. The review meeting was held at the National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina.

Dr. J. Bucher, NTP, introduced the studies by reviewing the experimental design, results, and proposed conclusions (no evidence of carcinogenicity for rats or mice).

Dr. Popp, a principal reviewer, agreed with the conclusions as written. He noted that the rationale for studying the chemical was as a response to a recommendation that it be included as part of a class study of benzyl alcohols with sympathomimetic activity. Certain members of this class have been associated with increased incidence of mesovarial leiomyomas. Thus, he asked why the ovary was not handled as a target organ for pathology. Dr. Bucher said that the mesovarial tumors were observed on gross examination in the other studies. A statement would be added indicating that such tumors were not seen grossly or microscopically in the current studies [see p. 43].

As a second principal reviewer, Dr. Sivak agreed with the conclusions and thought that the modest reductions in weight at the high doses in both rats and mice indicated probable attainment of appropriate maximum tolerated doses. He stated that the reduction in adrenal gland lipoid degeneration and focal hyperplasia in dosed male and female rats compared with controls should be reported, since the adrenal glands are likely target organs for the chemical.

As a third principal reviewer, Dr. Perera also agreed with the conclusions and the conduct of the studies. She suggested that some mention might be made in the abstract of the nonneoplastic effects seen in the liver and prostate gland in rats and in the liver in mice.

In other discussion, Dr. Scala expressed concern about the randomization of the animals, noting the variation in initial body weights among animals from various groups. Dr. J. Haseman, NIEHS, said that he had no evidence improper randomization was used and that similar variability also has occurred in other studies. Dr. Mirer said that it would be useful to have survival-adjusted tumor rates also cited in the abstract and discussion, since the life table analysis is based on the adjusted rate. Dr. Haseman agreed that this would be helpful when there were survival differences and when the tumors in question were lethal. Dr. J. Huff, NTP, stated that this would be done for all studies where appropriate and informative.

Dr. Popp moved that the Technical Report on phenylephrine hydrochloride be accepted with the conclusions as written, no evidence of carcinogenicity for rats and mice of each sex. Dr. Swenberg seconded the motion, and it was approved unanimously with 11 affirmative votes.

CONTRIBUTORS

The NTP Technical Report on the Toxicology and Carcinogenesis Studies of Phenylephrine Hydrochloride is based on the 12-week studies that began in December 1979 and ended in March 1980 and on the 2-year studies that began in September 1980 and ended in October 1982 at Physiological Research Laboratories.

(-)-meta-Hydroxy-a-[(methylamino) methyl] benzyl alcohol hydrochloride;

meta-Synephrine hydrochloride;

Neo-synephrine®

Physical Properties, Uses, Production, and Exposure

Phenylephrine hydrochloride is a sympathomimetic agent used primarily as a nasal decongestant and as a mydriatic in ophthalmic applications. It is a bitter-tasting crystalline material, soluble in water and alcohols, with a melting point of 140°-145° C (Merck, 1976). Phenylephrine hydrochloride is available under a variety of trade names as a sterile solution (10 mg/ml) for parenteral use, as an elixir (1 mg/ml), in tablets (5 mg), and as various nasal (0.125%, 0.25%, 0.5%, and 1.0%) and ophthalmic (2.5% and 10%) solutions (PDR, 1985). In 1974, production of the hydrochloride salt in the United States was estimated at 1.7×10^8 g and of the base, bitartrate salt, and tannate salt at 4.5 \times 106 g. The importation of phenylephrine hydrochloride through principal customs districts was reported to be approximately 6.6×10^6 g in 1983 (USITC, 1984), and total U.S. human exposure was estimated at 1.9×10^7 g in 1977 (SRI, 1977). No more recent figures are available.

Doses delivered during use of phenylephrine hydrochloride in nose drops or in ophthalmic solutions can vary widely, but one or two 5-mg tablets are sufficient for a decongestant effect in adult humans. The maximum recommended dose is 12 tablets in 24 hours, or 60 mg (PDR, 1985). Thus, humans could be exposed for short periods of time at approximately 1 mg/kg per day.

Pharmacologic Actions

Phenylephrine differs chemically from the endogenous compound epinephrine in that it lacks a hydroxyl group in position 4 on the benzene ring. Although not a catechol, it exhibits pharmacologic actions resembling several endogenous catecholamines (Meyer and Fraunfelder, 1980). Phenylephrine is an a-receptor agonist and through this mechanism increases systolic and diastolic blood pressure after intravenous, subcutaneous, or oral administration. A rise in blood pressure can trigger a reflex bradycardia; thus, phenylephrine hydrochloride is used to halt episodes of paroxysmal atrial tachycardia. Phenylephrine causes constriction of most vascular beds, which is the basis for its decongestant action. It reduces renal, splanchnic, cutaneous, and limb blood flow, but it increases coronary blood flow. It decreases intestinal motility (Gilman et al., 1985; Eckstein and Abboud, 1962; Aviado, 1959).

Phenylephrine activates α -receptors at low doses and has a weak action on β -receptors at higher doses (Reinhardt and Wagner, 1974; Chiba, 1977). Activation of α 1 receptors generally results in the excitatory postsynaptic effect of vasoconstriction. Activation of α 2 receptors found on presynaptic nerve terminals inhibits endogenous transmitter release. Stimulation of α 2 receptors on cholinergic nerve terminals in the gastrointestinal tract may mediate the inhibitory effects of α -agonists at this site (Gilman et al., 1985; Langer, 1977).

Absorption, Distribution, Metabolism, and Excretion

Phenylephrine hydrochloride is absorbed after oral administration (Bogner and Walsh, 1964), and the drug is rapidly absorbed following inhalation of nasal sprays or topical instillation into the eye (Ibrahim et al., 1983; Meyer and Fraunfelder, 1980). Unlike epinephrine and norepinephrine, phenylephrine does not appear to bind appreciably to albumin (Danon and Sapira, 1972), and the generally short duration of action--20 minutes following intravenous injection (Gilman et al., 1985)--suggests a rather rapid distribution, metabolism, and elimination. When male Wistar rats were given intraperitoneal injections of tritiated phenylephrine, 72% of the label was collected in the urine within 24 hours. Sixteen percent of the dose was unconjugated phenylephrine, the sulfate conjugate, or the glucuronide conjugate, and approximately 56% of the dose was found as meta-hydroxymandelic acid (6%), meta-hydroxyphenylglycol (50%), or their sulfate or glucuronide conjugates (Ibrahim et al., 1983). Phenylephrine is thought to undergo oxidative deamination by monoamine oxidase to the aldehyde. The aldehyde can be further oxidized by aldehyde oxidase to meta-hydroxymandelic acid or reduced by aldehyde dehydrogenase to meta-hydroxyphenylglycol. The general pattern of metabolism is similar in humans except that approximately 60% of an inhaled or orally ingested dose of phenylephrine appears in the urine within 24 hours as unchanged or conjugated phenylephrine, 30%-35% of the dose appears as metahydroxymandelic acid or its conjugates, and 8%-9% appears as meta-hydroxyphenylglycol or its sulfate or glucuronide conjugates (Ibrahim et al., 1983). The observation by Midgley et al. (1979) of meta-hydroxymandelic acid in the urine of untreated humans suggested that phenylephrine or meta-octopamine is an endogenous substance; it was later observed that phenylephrine occurs naturally in bovine and mouse adrenal glands (Midgley et al., 1980; Durden et al., 1980). Crowley et al. (1982) showed that both metahydroxymandelic acid and meta-hydroxyphenylglycol are normal constituents of human and rat urine.

Monoamine oxidase is a component of the outer mitochondrial membrane of a variety of cell types in many tissues (Siegel et al., 1976). It is especially prevalent in the liver and is found in presynaptic adrenergic nerve terminals (Gilman et al., 1985; Finberg and Youdim, 1983). Although this enzyme is important in the metabolic conversion of phenylephrine, the termination of pharmacologic action is due to a decrease in concentration at the receptor site. With endogenous catecholamines, the termination of pharmacologic action is due primarily to reuptake from the synaptic cleft into the presynaptic terminal rather than to enzymatic conversion to an inactive metabolite (Cooper et al., 1982). It is not clear whether phenylephrine is also taken up by the presynaptic nerve terminal (Ibrahim et al., 1983); this action is suggested because tricyclic antidepressants (drugs that inhibit this reuptake process) markedly increase the pressor effects of phenylephrine (PDR, 1985). However, other actions of these drugs may account for this observation.

Toxicity

LD₅₀ values for phenylephrine have been determined in several species by various routes of administration. In Wistar rats (sex unspecified), the LD₅₀ value by intraperitoneal injection was 17 mg/kg and by subcutaneous injection was 33 mg/kg (Warren and Werner, 1946). Using an unspecified strain and sex of rat, Stockhaus and Wick (1969) reported an oral LD₅₀ value of 350 mg/kg; values of 65 and 92 mg/kg were reported for intraperitoneal and subcutaneous injections, respectively. The LD₅₀ values in male Swiss mice were 89 mg/kg (intraperitoneal) (Sofia and Knobloch, 1974) and 22 mg/kg (subcutaneous) (Warren and Werner, 1946). New Zealand rabbits (sex unspecified) had LD₅₀ values of 0.5 mg/kg (intravenous), 7.2 mg/kg (intramuscular), and 22 mg/kg (subcutaneous) (Warren and Werner, 1946).

Phenylephrine solutions were found not to cause significant corneal edema in rabbits with an intact corneal epithelium, but ocular administration after removal or damage to the epithelium produced a cytotoxic effect to the corneal endothelium and keratocytes and significant corneal edema (Edelhauser et al., 1979). Phenylephrine has been reported to have an anesthetic effect on the cornea (Reinhardt and Wagner, 1974). No reports of dermal toxicity in animals were found, but several instances of contact dermatitis were reported in humans who used eyedrops containing phenylephrine (Barber, 1983; Camarasa, 1984). These instances followed an initial sensitizing encounter, and repeated dosing produced conjunctival injection, edema, and periorbital eczema.

Human toxicity resulting from systemic absorption of phenylephrine from ocular or nasal preparations has been reported and appears to be related to the pharmacologic action of the drug rather than to an intrinsic cytotoxicity. Side effects of ocular administration are most often associated with the use of 10% solutions and include pain, release of pigment from the iris, elevation of intraocular pressure, and headache (Meyer and Fraunfelder, 1980). The most serious reported sequelae are a marked rise in blood pressure (which has led to subarachnoid hemorrhage), ventricular arrhythmias, and cardiac infarct in susceptible patients (Fraunfelder and Scafidi, 1978). Prinzmetal's angina in one patient was also linked to the use of a 10% ocular solution (Alder et al., 1981). Most of these effects can be related to severe vasoconstriction produced by a-adrenergic stimulation. Intense vasoconstriction can lead to secondary arrhythmias (Papp and Szekeres, 1968); direct β-receptor stimulation, shown with large doses, can have positive chronotropic actions on the sinoatrial node, potentially resulting in primary arrhythmias (Chiba, 1977). Chronic hallucinosis has been related to overuse of nosedrops containing phenylephrine (Escobar and Karno, 1982).

Reproductive Toxicity

Phenylephrine given to pregnant rabbits during the last third of gestation produced fetal growth retardation and the onset of early labor (Shabanah et al., 1969). The use of medications containing phenylephrine during the first 4 months of pregnancy was associated with a greater than expected number of eye, ear, and other minor malformations in humans (Heinonen et al., 1977). Two other epidemiologic studies found no association between congenital disorders and use of phenylephrine during pregnancy (Jick et al., 1981; Colley et al., 1982). β -Sympathomimetic agents consistently caused external and cardiac malformations when administered to chick embryos, but phenylephrine did not cause similar defects (Hodach et al., 1975; Bruyere et al., 1983).

Genetic Toxicology

No studies of the genetic toxicity of phenylephrine hydrochloride were found in the literature. In NTP studies, phenylephrine hydrochloride was not mutagenic in four tester strains of Salmonella typhimurium (TA100, TA1535, TA1537, and TA98) in the presence or absence of Aroclor 1254-induced male Sprague-Dawley rat or male Syrian hamster liver S9 (Appendix E). The results of mutagenicity studies of phenylephrine hydrochloride were equivocal in the mouse lymphoma L5178Y/TK +/- assay because a positive response, noted in the first trial without metabolic activation, occurred at high doses that were toxic to the cells (relative total growth of 12.2%) and was not reproduced in the second trial. Phenylephrine hydrochloride was not tested in the presence of S9 in the mouse lymphoma assay.

Phenylephrine hydrochloride induced sister-chromatid exchanges (SCEs) but not chromosomal aberrations in Chinese hamster ovary cells. The increase in SCEs was seen only in the absence of metabolic activation with Aroclor 1254-induced male Sprague-Dawley rat liver S9. In summary, phenylephrine hydrochloride was not mutagenic in bacteria with or without metabolic activation. The evidence for mutagenicity was equivocal in mammalian cells without metabolic activation at nearly toxic doses, and phenylephrine hydrochloride induced SCEs in mammalian cells in the absence of metabolic activation.

Study Rationale

Phenylephrine hydrochloride and three β -agonists (ephedrine, epinephrine, and isoproterenol) were four sympathomimetic agents considered by the National Cancer Institute as part of a benzyl alcohols class study. Interest focused

on these drugs primarily because mesovarial leiomyomas had been reported in Sprague-Dawley rats given the β -agonists soterenol hydrochloride and mesuprine hydrochloride (Nelson et al., 1972; Nelson and Kelly, 1971). Since no reports on the long-term effects of phenylephrine were found in the literature and no such studies have been made available to the

Bureau of Drugs of the Food and Drug Administration (FDA), the FDA recommended that the National Cancer Institute nominate phenylephrine hydrochloride to the NTP for toxicology and carcinogenesis studies. The feed route of administration was selected to mimic the oral use of phenylephrine hydrochloride in elixir and tablet form by humans.

PROCUREMENT AND CHARACTERIZATION OF PHENYLEPHRINE HYDROCHLORIDE

USP-grade (97.5%-102.5% active ingredient by the USP standard test) phenylephrine hydrochloride was obtained in one lot from Ganes Chemical Company (New York, New York). The identity of phenylephrine hydrochloride was confirmed by infrared, ultraviolet/visible, and nuclear magnetic resonance spectroscopy (Appendix F).

The purity of phenylephrine hydrochloride was determined to be approximately 99% by elemental analysis, high-performance liquid chromatography, nonaqueous titration of the amine group, and the USP titration method that uses bromination of three aromatic ring positions. Results of the elemental analysis agreed with the theoretical values. Water content was 0.08%. Phenylephrine hydrochloride was 99.3% pure by nonaqueous titration of the amine group and was 101% pure by the USP titration method. Two impurities with a total peak area of 0.09% that of the major peak were detected by high-performance liquid chromatography; these impurities were not identified.

Phenylephrine hydrochloride was stable in storage for at least 2 weeks at 60° C (Appendix F) and was stored at the laboratory in the dark at 25° C. Periodic characterization of phenylephrine hydrochloride by infrared spectroscopy, USP titration method, or high-performance liquid chromatography detected no deterioration over the course of the studies (Appendix F).

PREPARATION AND CHARACTERIZATION OF FORMULATED DIETS

A formulated diet mixture was homogeneous to ± 1.5% (Appendix G). Phenylephrine hydrochloride at 800 ppm was stable in feed when stored for 2 weeks at temperatures of 4° C or lower. The formulated diets were prepared by adding a dry premix of feed and phenylephrine hydrochloride to the appropriate amount of feed. The mixture was blended for 15 minutes (Table 1). The feed mixtures were analyzed periodically to determine if they contained the correct concentrations of phenylephrine hydrochloride (Appendix H). All of the analyzed feed mixtures were within ± 10% of the target concentrations (Table 2; Appendix I).

FOURTEEN-DAY STUDIES

Three- to four-week-old male and female F344/N rats and 4- to 5-week-old B6C3F₁ mice were obtained from Charles River Breeding Laboratories and held for approximately 3 weeks before the studies began. Groups of five rats of each sex were fed diets containing 0, 125, 250, 500, 1,000, or 2,000 ppm phenylephrine hydrochloride for 14 consecutive days. Groups of five mice of each sex were fed diets containing 0, 63, 125, 250, 500, or 1,000 ppm.

Rats and mice were observed twice per day and were weighed once per week. Further details on animal maintenance are given in Table 3. A necropsy was performed on all animals.

TWELVE-WEEK STUDIES

Twelve-week studies were conducted to evaluate the cumulative toxic effects of repeated administration of phenylephrine hydrochloride and to determine the concentrations to be used in the 2-year studies.

Four- to five-week-old male and female F344/N rats and 4- to 6-week-old B6C3F₁ mice were obtained from Charles River Breeding Laboratories, observed for 14 days, distributed to weight classes, and then assigned to cages according to a table of random numbers. Cages were assigned to dosed and control groups according to another table of random numbers.

Groups of 10 rats and 10 mice of each sex were given diets containing 0, 1,250, 2,500, 5,000, 10,000, or 20,000 ppm phenylephrine hydrochloride for 12 weeks. Control diets consisted of

NIH 07 Rat and Mouse Ration. Formulated diets or control diets and water were available ad libitum. Further experimental details are summarized in Table 3.

Animals were observed two times per day; moribund animals were killed. Feed consumption was measured weekly by cage. Individual animal weights were recorded once per week.

At the end of the 12-week studies, survivors were killed. A necropsy was performed on all animals except those excessively autolyzed or cannibalized. Tissues and groups examined are listed in Table 3. Adrenal glands and hearts were weighed for controls and for the 20,000-ppm groups. Bilateral measurements of pupil diameter were taken for all groups.

TWO-YEAR STUDIES

Study Design

Diets containing 0, 620, or 1,250 ppm phenylephrine hydrochloride were fed to groups of 50 rats of each sex for 103 weeks. Diets containing 0, 1,250, or 2,500 ppm were fed to groups of mice of each sex for 103 weeks.

Source and Specifications of Animals

The male and female F344/N rats and B6C3F₁ (C57BL/6N, female, × C3H/HeN MTV⁻, male) mice used in these studies were produced under strict barrier conditions at Charles River Breeding Laboratories under a contract to the Carcinogenesis Program. Breeding stock for the foundation colonies at the production facility originated at the National Institutes of Health

Repository. Animals shipped for study were progeny of defined microflora-associated parents that were transferred from isolators to barrier-maintained rooms. Rats were shipped to the study laboratory at 4-5 weeks of age and mice at 5-6 weeks of age. The animals were quarantined at the study laboratory for 2 weeks. Thereafter, a complete necropsy was performed on five animals of each sex and species to assess their health status. The rats were placed on study at 6-7 weeks of age and mice at 7-8 weeks of age. The health of the animals was monitored during the course of the studies according to the protocols of the NTP Sentinel Animal Program (Appendix J).

A quality control skin grafting program has been in effect since early 1978 to monitor the genetic integrity of the inbred mice used to produce the hybrid B6C3F₁ study animal. In mid-1981, data were obtained that showed incompatibility between the NIH C3H reference colony and the C3H colony from a Program supplier. In August 1981, inbred parental lines of mice were further tested for genetic integrity via isozyme and protein electrophoresis profiles that demonstrate phenotype expressions of known genetic loci.

The C57BL/6 mice were homogeneous at all loci tested. Eighty-five percent of the C3H mice monitored were variant at one to three loci, indicating some heterogeneity in the C3H line from this supplier. Nevertheless, the genome of

this line is more homogeneous than that of randomly bred stocks.

Male mice from the C3H colony and female mice from the C57BL/6 colony were used as parents for the hybrid B6C3F₁ mice used in these studies. The influence of the potential genetic non-uniformity in the hybrid mice on these results is not known, but results of the studies are not affected because concurrent controls were included in each study.

Animal Maintenance

Animals were housed five per cage. Feed and water were available ad libitum. Further details of animal maintenance are given in Table 3.

Clinical Examinations and Pathology

All animals were observed two times per day, and clinical signs were recorded once per week. Body weights by cage were recorded once per week for the first 12 weeks of the studies and once per month thereafter. Mean body weights were calculated for each group. Animals found moribund and those surviving to the end of the studies were humanely killed. A necropsy was performed on all animals including those found dead, unless they were excessively autolyzed or cannibalized, missexed, or found missing. Thus, the number of animals from which particular organs or tissues were examined microscopically

varies and is not necessarily equal to the number of animals that were placed on study.

During necropsy, all organs and tissues were examined for grossly visible lesions. Tissues were preserved in 10% neutral buffered formalin, embedded in paraffin, sectioned, and stained with hematoxylin and eosin. Tissues examined microscopically are listed in Table 3.

When the pathology evaluation was completed. the slides, paraffin blocks, and residual wet tissues were sent to the NTP Archives for inventory, slide/block match, and wet tissue audit. The slides, individual animal data records, and pathology tables were sent to an independent quality assessment laboratory. The individual animal records and tables were compared for accuracy, slides and tissue counts were verified, and histotechnique was evaluated. All tumor diagnoses, all target tissues, and all tissues from a randomly selected 10% of the animals were evaluated by a quality assessment pathologist. The quality assessment report and slides were submitted to the Pathology Working Group (PWG) Chairperson, who reviewed all target tissues and those about which there was a disagreement between the laboratory and quality assessment pathologists.

Representative slides selected by the Chairperson were reviewed by the PWG, which includes the laboratory pathologist, without knowledge of previously rendered diagnoses. When the consensus diagnosis of the PWG differed from that of the laboratory pathologist, the laboratory pathologist was asked to reconsider the original diagnosis. This procedure has been described, in part, by Maronpot and Boorman (1982) and Boorman et al. (1985). The final diagnoses represent a consensus of contractor pathologists and the NTP Pathology Working Group. For subsequent analysis of pathology data, the diagnosed lesions for each tissue type are combined according to the guidelines of McConnell et al. (1986).

Slides/tissues are generally not evaluated in a blind fashion (i.e., without knowledge of dose group) unless the lesions in question are subtle or unless there is an inconsistent diagnosis of lesions by the laboratory pathologist. Nonneoplastic lesions are not examined routinely by the quality assessment pathologist or PWG unless they are considered part of the toxic effect of the chemical.

Statistical Methods

Data Recording: Data on this experiment were recorded in the Carcinogenesis Bioassay Data System (Linhart et al., 1974). The data elements included descriptive information on the chemicals, animals, experimental design, survival, weight, and individual pathologic results, as recommended by the International Union Against Cancer (Berenblum, 1969).

Survival Analyses: The probability of survival was estimated by the product-limit procedure of Kaplan and Meier (1958) and is presented in the form of graphs. Animals were censored from the survival analyses at the time they were found dead of other than natural causes or were found to be missing; animals dying from natural causes were not censored. Statistical analyses for a possible dose-related effect on survival used the method of Cox (1972) for testing two groups for equality and Tarone's (1975) life table test for a dose-related trend. When significant survival differences were detected, additional analyses using these procedures were carried out to determine the time point at which significant differences in the survival curves were first detected. All reported P values for the survival analysis are two-sided.

Calculation of Incidence: The incidence of neoplastic or nonneoplastic lesions is given as the ratio of the number of animals bearing such lesions at a specific anatomic site to the number of animals in which that site was examined. In most instances, the denominators include only those animals for which the site was examined histologically. However, when macroscopic examination was required to detect lesions (e.g., skin or mammary tumors) prior to histologic sampling, or when lesions could have appeared at multiple sites (e.g., lymphomas), the denominators consist of the number of animals on which a necropsy was performed.

Analysis of Tumor Incidence: Three statistical methods are used to analyze tumor incidence data. The two that adjust for intercurrent

mortality employ the classical method for combining contingency tables developed by Mantel and Haenszel (1959). Tests of significance included pairwise comparisons of high dose and low dose groups with controls and tests for overall dose-response trends.

For studies in which compound administration has little effect on survival, the results of the three alternative analyses will generally be similar. When differing results are obtained by the three methods, the final interpretation of the data will depend on the extent to which the tumor under consideration is regarded as being the cause of death. Continuity-corrected tests are utilized in the tumor analysis, and reported P values are one-sided.

Life Table Analyses--The first method of analysis assumed that all tumors of a given type observed in animals dying before the end of the studies were "fatal"; i.e., they either directly or indirectly caused the death of the animal. According to this approach, the proportions of tumor-bearing animals in the dosed and control groups were compared at each point in time at which an animal died with a tumor of interest. The denominators of these proportions were the total number of animals at risk in each group. These results, including the data from animals killed at the end of the studies, were then combined by the Mantel-Haenszel method to obtain an overall P value. This method of adjusting for intercurrent mortality is the life table method of Cox (1972) and of Tarone (1975). The underlying variable considered by this analysis is time to death due to tumor. If the tumor is rapidly lethal, then time to death due to tumor closely approximates time to tumor onset. In this case, the life table test also provides a comparison of the time-specific tumor incidences.

Incidental Tumor Analyses--The second method of analysis assumed that all tumors of a given type observed in animals that died before the end of the studies were "incidental"; i.e., they were merely observed at necropsy in animals dying of an unrelated cause. According to this approach, the proportions of tumor-bearing animals in dosed and control groups were compared in each of five time intervals: weeks 0-52, weeks 53-78, weeks 79-92, week 93 to the week before the terminal-kill period, and the terminal-kill period. The denominators of these proportions were the number of animals actually examined for tumors during the time interval. The individual time interval comparisons were then combined by the previously described method to obtain a single overall result. (See Haseman, 1984, for the computational details of both methods.)

Unadjusted Analyses--Primarily, survivaladjusted methods are used to evaluate tumor incidence. In addition, the results of the Fisher exact test for pairwise comparisons and the Cochran-Armitage linear trend test (Armitage, 1971; Gart et al., 1979) are given in the appendixes containing the analyses of primary tumor incidence. These two tests are based on the overall proportion of tumor-bearing animals and do not adjust for survival differences.

Historical Control Data: Although the concurrent control group is always the first and most appropriate control group used for evaluation, there are certain instances in which historical control data can be helpful in the overall assessment of tumor incidence. Consequently, control tumor incidences from the NTP historical control data base (Haseman et al., 1984, 1985) are included for those tumors appearing to show compound-related effects.

Survival
Pathology and Statistical Analyses of Results

FOURTEEN-DAY STUDIES

None of the rats died before the end of the studies (Table 4). No clinical signs were associated with phenylephrine hydrochloride dosing. Feed consumption and final mean body weights of dosed rats were not adversely affected by phenylephrine hydrochloride. No compound-related effects were observed at necropsy or upon microscopic examination of tissues from 10% of the study animals. Since no toxic effects were evident in the 14-day studies, doses were increased for the 12-week studies.

TWELVE-WEEK STUDIES

Four of 10 male rats that received 20,000 ppm, 2/10 males that received 10,000 ppm, and 1/10 males that received 5,000 ppm died before the end of the studies (Table 5). Final mean body weights of all groups of dosed males and all but the lowest dose group of female rats were more than 10% lower than those of the controls. The final mean body weights of rats that received 5,000, 10,000, or 20,000 ppm were 57%, 45%, or 35% that of the controls for males and 70%, 58%, or 51% that of the controls for females. Feed consumption by dosed rats was consistently lower than that by the controls and decreased as dose

was increased. Rats that received 10,000 or 20,000 ppm were hyperexcitable. Pupil size in dosed groups was generally smaller than that of the controls (Appendix L, Table L1). Absolute adrenal gland weights and heart weights of males and females that received 20,000 ppm were lower than those of the controls (Table L2).

Relative adrenal gland weights and heart weights of males and females that received 20,000 ppm were greater than those of the controls. Pupil size and adrenal gland and heart weights were consistent with the differences in body weight between the dose groups and, because of the large weight differences, were of little value in demonstrating a selective pharmacologic or toxic effect of dosing.

Chronic keratitis of the eve was observed in 4/8 males and 8/10 females at 20,000 ppm and 4/10 males and 6/10 females at 10,000 ppm. Minimal to mild testicular atrophy was observed in 4/8 males, and seminal vesicle atrophy was observed in 5/6 males that received 20,000 ppm; mild to moderate ovarian atrophy was observed in 5/10 females that received 20,000 ppm. No other observed histopathologic effects appeared compound related.

Dose Selection Rationale: Because of weight gain depression and the incidence of deaths of males, doses selected for rats for the 2-year studies were 620 and 1,250 ppm phenylephrine hydrochloride in feed.

TWO-YEAR STUDIES

Body Weights and Clinical Signs

The initial mean body weight of high dose male rats was 5% lower than that of the controls, and the mean body weights were 4%-15% lower throughout the study (Table 6 and Figure 1). The mean body weight of low dose male rats ranged from 3% to 8% lower than that of the

controls. The initial mean body weight of high dose female rats was 4% lower than that of the controls and was 4%-10% lower throughout most of the study. Body weights of low dose females were similar to those of controls. No specific clinical signs of toxicity or ophthalmologic findings noted in any group of dosed rats were attributed to phenylephrine hydrochloride dosing. The average daily feed consumption was similar for dosed and control male and female rats (Appendix K, Tables K1 and K2). The average amount of phenylephrine hydrochloride consumed per day was approximately 22 mg/kg or 47 mg/kg for low dose or high dose male rats and 26 mg/kg or 54 mg/kg for low dose or high dose female rats.

FIGURE 1. GROWTH CURVES FOR RATS FED DIETS CONTAINING PHENYLEPHRINE HYDROCHLORIDE FOR TWO YEARS

Survival

Estimates of the probabilities of survival for male and female rats fed diets containing phenylephrine hydrochloride at the concentrations used in these studies and for controls are shown in the Kaplan and Meier curves in Figure 2. The survival of the high dose group of male rats was significantly greater than that of the controls after week 98 (Table 7).

Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of rats with neoplastic or nonneoplastic lesions of the liver, lung, hematopoietic system, adrenal gland, and prostate gland.

Lesions in male rats are summarized in Appendix A. Histopathologic findings on neoplasms are summarized in Table A1. Table A2 gives the

survival and tumor status for individual male rats. Table A3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table A3 (footnotes). Historical incidences of tumors in control male rats are listed in Table A4. Findings on nonneoplastic lesions are summarized in Table A5.

Lesions in female rats are summarized in Appendix B. Histopathologic findings on neoplasms are summarized in Table B1. Table B2 gives the survival and tumor status for individual female rats. Table B3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table B3 (footnotes). Findings on nonneoplastic lesions are summarized in Table B4.

⁽c) The result of the life table trend test is in the control column, and the results of the life table pairwise comparisons with the controls are in the dosed columns.

FIGURE 2. KAPLAN-MEIER SURVIVAL CURVES FOR RATS FED DIETS CONTAINING PHENYLEPHRINE HYDROCHLORIDE FOR TWO YEARS

Liver: Chronic focal inflammation was observed at increased incidences in dosed rats (male: control, 2/50; low dose, 13/50; high dose, 17/50; female: 17/50; 28/50; 35/50). The incidence of neoplastic nodules in low dose male rats was significantly lower than that in the controls (5/50; 0/50; 2/50). The incidences of neoplastic nodules or hepatocellular carcinomas (combined) in dosed male rats were not significantly different from that in the controls. Bile duct hyperplasia was observed more frequently in controls than in dosed male rats (46/50; 16/50; 11/50) and female rats (20/50; 5/50; 2/50).

Chronic focal inflammation appeared increased in both incidence and degree in low dose and high dose rats of each sex. The lesion did not differ in character from the lesion that occurs spontaneously in the F344 rat. It was characterized by the presence of mononuclear cells scattered around bile ducts in the portal triad regions of hepatic lobules. Small granulomas were frequently adjacent to or replacing bile ducts in the portal regions. The granulomas appeared to consist entirely of macrophages.

Lung: Perivascular cuffing of the lung was observed at increased incidences in dosed male rats (control, 2/50; low dose, 12/50; high dose, 8/50). The lesion was seen in 4/50 control, 6/50 low dose, and 7/50 high dose females.

Hematopoietic System: Leukemia in male rats occurred with a negative trend, and the incidences in the dosed groups were lower than that in the controls (Table 8). Leukemia was seen in 15/50 control, 14/50 low dose, and 10/50 high dose female rats.

TABLE 8. ANALYSIS OF MONONUCLEAR CELL LEUKEMIA IN MALE RATS IN THE TWO-YEAR FEED STUDY OF PHENYLEPHRINE HYDROCHLORIDE (a,b)

| | Control | 620 ppm (c) | 1,250 ppm (c) |
|---------------------------|-------------|--------------------|---------------|
| Overall Rates | 24/50 (48%) | 9/50 (18%) | 5/50 (10%) |
| Adjusted Rates | 54.9% | 21.4% | 11.4% |
| Terminal Rates | 11/30 (37%) | 3/33 (9%) | 3/42 (7%) |
| Week of First Observation | 70 | 74 | 91 |
| Life Table Tests | P<0.001N | P = 0.003N | P<0.001N |
| Incidental Tumor Tests | P<0.001N | P = 0.002N | P = 0.003N |

⁽a) The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix A, Table A3 (footnotes).

⁽b) Historical incidence of leukemia in NTP studies (mean ± SD): 458/1,727 (27% ± 9%)

⁽c) The estimated dose in milligrams per kilograms per day is given in Chapter III (Body Weights and Clinical Signs) and in Appendix K.

Adrenal Gland: The incidence of medullary hyperplasia in dosed male rats was lower than that in the controls. Pheochromocytomas in male rats occurred with a negative trend, and the incidence in the high dose group was lower than that in the controls (Table 9). The incidences of medullary hyperplasia and of pheochromocytomas in dosed female rats were not significantly different from those in the controls (medullary hyperplasia: control, 2/50; low dose, 3/50; high dose, 1/50; pheochromocytomas or malignant pheochromocytomas: 6/50; 6/50; 2/50).

Incidences of adrenal cortical hyperplasia and lipoid degeneration in dosed male and female rats were lower than those in the controls (Tables A5 and B4).

Prostate Gland: The incidence of inflammation was increased in dosed versus control male rats (control, 10/50; low dose, 24/50; high dose, 24/50). These lesions were similar to those that spontaneously arise in the F344 rat but were subjectively judged to be more severe in dosed rats than in control rats.

TABLE 9. ANALYSIS OF ADRENAL GLAND LESIONS IN MALE RATS IN THE TWO-YEAR FEED STUDY OF PHENYLEPHRINE HYDROCHLORIDE

⁽a) Historical incidence in NTP studies (mean \pm SD): 358/1,702 (21% \pm 10%)

FOURTEEN-DAY STUDIES

None of the mice died before the end of the studies (Table 10). No clinical signs were related to phenylephrine hydrochloride dosing. Final mean body weights and feed consumption were not affected by phenylephrine hydrochloride. No compound-related gross or microscopic pathologic effects were observed. Since no toxic effects were noted in the 14-day studies, doses were increased for the 12-week studies.

TWELVE-WEEK STUDIES

Three of 10 male mice receiving 20,000 ppm and 2/10 males receiving 10,000 ppm died before the end of the study (Table 11). All female mice survived to the end of the study. The final mean body weights of males that received 10,000 or 20,000 ppm were 18% or 25% lower than that of the controls. Final mean body weights of all dosed groups of female mice were 10%-32% lower than that of the controls. Estimated feed

consumption by the 20,000-ppm groups was greater than that of the controls.

Rough hair coats and lethargy were considered to be compound-related effects. Pupil size of dosed mice was generally not significantly different from that in controls (Appendix L, Table L3). Inflammatory eye lesions (acute keratitis, panophthalmitis, or phthisis bulbi) were observed in 3/10 males and 2/10 females that received 20,000 ppm. The absolute and relative adrenal gland weights for mice that received 20,000 ppm were greater than those of the controls (Table L4). The relative heart weight for females that received 20,000 ppm was significantly greater than that of the controls. No histopathologic changes were noted in the adrenal gland or heart; no compound-related changes were found in other tissues.

Dose Selection Rationale: Because of decreased weight gain and deaths of male mice at higher doses in the 12-week studies, doses selected for mice for the 2-year studies were 1,250 and 2,500 ppm phenylephrine hydrochloride.

TWO-YEAR STUDIES

Body Weights and Clinical Signs

The initial mean body weight of high dose male mice was 5% lower than that of the controls, and the mean body weight was 6%-14% lower throughout the study. The mean body weight of low dose male mice was 4%-10% lower than that of the controls throughout most of the study. The mean body weights of low dose and high dose female mice were approximately 4%-7% and 4%-10% lower than that of the controls after week 25 (Table 12 and Figure 3). The average

daily feed consumption by low dose and high dose male mice was 93% and 90% that of the controls and by low dose and high dose female mice, 94% and 93% that of the controls (Appendix K, Tables K3 and K4). The average amount of phenylephrine hydrochloride consumed per day was approximately 130 mg/kg or 260 mg/kg for low dose or high dose male mice and 140 mg/kg or 280 mg/kg for low dose or high dose female mice. No specific clinical signs of toxicity or ophthalmologic findings in any group of dosed mice were attributed to phenylephrine hydrochloride.

FIGURE 3. GROWTH CURVES FOR MICE FED DIETS CONTAINING PHENYLEPHRINE HYDROCHLORIDE FOR TWO YEARS

Survival

Estimates of the probabilities of survival for male and female mice fed diets containing phenylephrine hydrochloride at the concentrations used in these studies and for controls are shown in the Kaplan and Meier curves in Figure 4. No significant differences in survival were observed between any groups of either sex (Table 13).

Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of mice with neoplastic or nonneoplastic lesions of the liver. Lesions in male mice are summarized in Appendix C. Histopathologic findings on neoplasms are summarized in Table C1. Table C2 gives the survival and tumor status for individual male mice. Table C3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table C3 (footnotes). Findings on nonneoplastic lesions are summarized in Table C4.

Lesions in female mice are summarized in Appendix D. Histopathologic findings on neoplasms are summarized in Table D1. Table D2 gives the survival and tumor status for individual female mice. Table D3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table D3 (footnotes). Findings on nonneoplastic lesions are summarized in Table D4.

Liver: Focal cellular change was observed at an increased incidence in high dose male mice (male: control, 0/50; low dose, 2/50; high dose, 7/50); this lesion was not increased in female mice (0/50; 2/50; 1/50).

FIGURE 4. KAPLAN-MEIER SURVIVAL CURVES FOR MICE FED DIETS CONTAINING PHENYLEPHRINE HYDROCHLORIDE FOR TWO YEARS

IV. DISCUSSION AND CONCLUSIONS

IV. DISCUSSION AND CONCLUSIONS

Two-year toxicology and carcinogenesis studies of phenylephrine hydrochloride were conducted on groups of 50 F344/N rats and B6C3F₁ mice of each sex. Feed containing 0, 620, or 1,250 ppm phenylephrine hydrochloride was given to rats; mice received feed containing 0, 1,250, or 2,500 ppm. The average daily doses were estimated to be 24 mg/kg for low dose rats, 50 mg/kg for high dose rats, 133 mg/kg for low dose mice, and 270 mg/kg for high dose mice. The concentrations in feed were selected after evaluation of the results of the 12-week studies in which rats and mice received feed containing up to 20,000 ppm phenylephrine hydrochloride.

In the 12-week studies, several male rats and male mice died in the groups fed diets containing 10,000 and 20,000 ppm; one male rat in the 5,000 ppm group died. No female rats or female mice died. A dose-related decrease in body weights was observed. Feed consumption by rats decreased as the concentration of phenylephrine hydrochloride increased, suggesting that formulated diet mixtures were unpalatable. However, feed consumption by mice did not appear to be dose related, and high dose mice apparently consumed more than did controls. No attempts were made to estimate spillage by the various groups. If the feed consumption data are correct, the approximate lethal daily dose was 300 mg/kg for male rats and 1,400 mg/kg for male mice. The dose for rats is similar to the single oral LD₅₀ value of 350 mg/kg reported by Stockhaus and Wick (1969).

No specific organ toxicity was seen in the 12-week studies. Mild testicular, seminal vesicle, or ovarian atrophy was observed in mice receiving doses of phenylephrine hydrochloride sufficient to kill several of the male mice, but the cause of the deaths of male rats and male mice could not be determined. Inflammatory eye lesions were observed in higher dose rats and mice. These lesions are probably a secondary effect of the pharmacologic action of phenylephrine hydrochloride, which reduces ocular secretions and thereby predisposes the cornea to irritation and inflammation.

In the 2-year studies, body weights of dosed rats and mice of each sex were slightly lower than those of controls, and this effect was dose

related. Feed consumption was not significantly different among dosed and control rats, but dosed mice consumed 6%-10% less feed than did controls. Survival of both dosed and control rats and mice was consistent with that seen in other NTP feed studies. Only 8/50 high dose male rats died before the end of the studies; four of these deaths occurred before week 45. The cause of these four early deaths is unknown, and no neoplastic lesions were found. Nonetheless, survival of high dose male rats was greater than that of the controls, perhaps because of the fewer early deaths from mononuclear cell leukemia in dosed animals (control, 13/20; low dose, 6/17; high dose, 2/8). Three high dose female mice died before week 22. Although these deaths were considered to be natural, two of the animals died on the same day and in the same cage, suggesting that death was associated with some factor other than exposure to phenylephrine hydrochloride. No tumors were observed in these two mice. The other mouse that died early had a benign ovarian teratoma.

Dosed male and female rats had greater incidences of chronic focal inflammation of the liver than did controls (male: control, 2/50; low dose, 13/50; high dose, 17/50; female: 17/50; 28/50; 35/50), and dosed male rats had increased incidences of inflammation of the prostate gland (10/50; 24/50; 24/50) and of inflammation surrounding the vascular tissue in the lung (perivascular cuffing: 2/50; 12/50; 8/50). The liver and prostate gland lesions were similar to those that arise in older, untreated rats, but they were subjectively judged to be more severe and more frequent in dosed animals. The association of perivascular cuffing with administration of phenylephrine hydrochloride was less clear.

No increases in the incidences of neoplastic lesions were found in dosed rats. In fact, significantly lower incidences of several tumors and nonneoplastic proliferative lesions were considered to be associated with phenylephrine hydrochloride dosing. In male rats, mononuclear cell leukemia occurred with a negative trend (control, 24/50; low dose, 9/50; high dose, 5/50). The incidence in high dose males was equal to the lowest incidence observed in historical controls (mean, 27%; range 10%-46%). The incidence in the current control group was greater than the

highest incidence previously seen; thus, the negative trend may be partially explained by the chance occurrence of a much greater incidence of mononuclear cell leukemia than is usually observed in untreated controls. Pheochromocytomas of the adrenal medulla also occurred with a negative trend in male rats (14/49; 11/50; 2/50). This trend appeared to result from an incidence of pheochromocytomas in high dose animals substantially lower than would be expected based on historical control data. Incidences of adrenal medullary hyperplasia were decreased in dosed male rats; decreases in the incidences of proliferative lesions of the adrenal medulla were observed less frequently in female rats. However, dosed male and female rats had slightly lower incidences of adrenal cortical focal hyperplasia than did controls. In addition, bile duct hyperplasia was observed much less frequently in dosed than in control rats (male: control, 46/50; low dose, 16/50; high dose, 11/50; female: 20/50; 5/50; 2/50). Although it is difficult to envision a single mechanism whereby the administration of phenylephrine hydrochloride could decrease the incidence of proliferative lesions in these various organs, the decrease in proliferative lesions of the adrenal gland medulla could have occurred through some type of feedback inhibition, given the similar pharmacologic actions of phenylephrine and of epinephrine, the latter being synthesized and secreted by the adrenal medulla. Differences in body weights or survival are known to influence incidences of neoplasia, but in these studies, body weights were only slightly different between the groups. Survival of high dose male rats, the group that had the fewest proliferative lesions, was greater than that of controls. Mesovarial leiomyomas, observed in rats given β-agonists, were not seen in dosed or control rats in these studies.

In mice, no neoplastic or nonneoplastic lesions

were clearly related to dosing with phenylephrine hydrochloride, although the incidence of focal cellular change in the liver was increased slightly in high dose male mice (control, 0/50; low dose, 2/50; high dose, 7/50). The doses of phenylephrine hydrochloride in these studies are considered adequate because higher doses caused marked decreases in body weight in the 12-week studies. No marked increases in the incidences of nonneoplastic lesions resulted from dosing with phenylephrine hydrochloride, and survival of dosed animals was equal to or greater than that of the controls. The doses given to rats and mice were approximately 20-250 times the maximum daily dose recommended for use by humans.

The experimental and tabulated data for the NTP Technical Report on phenylephrine hydrochloride were examined for accuracy, consistency, and compliance with Good Laboratory Practice requirements. As summarized in Appendix N, the audit revealed no major problems with the conduct of the studies or with the collection and documentation of the experimental data. No discrepancies were found that influenced the final interpretation of the results of these studies.

Conclusions: Under the conditions of these 2-year studies, there was no evidence of carcinogenicity* of phenylephrine hydrochloride for male or female F344/N rats given 620 or 1,250 ppm in feed or for male or female B6C3F₁ mice given 1,250 or 2,500 ppm in feed. Survival of high dose male rats was greater than that of controls, and the incidences of mononuclear cell leukemia and pheochromocytomas were lower in dosed than in control male rats. Inflammation was observed more frequently in the liver and prostate gland of dosed male rats than in controls.

^{*}Categories of evidence of carcinogenicity are defined in the Note to the Reader on page 2.

A summary of the Peer Review comments and the public discussion on this Technical Report appears on page 8.

⁽a) Number of tumor-bearing animals/number of animals examined at the site

⁽b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

⁽c) Observed tumor incidence at terminal kill

⁽d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. N indicates a negative trend or lower incidence in a dosed group.

- Required tissue not examined microscopically
X. Tumor incidence
N. Necropsy, no autolysis, no microscopic examination
S- Animal missexed

| FISHER EXECT 1881 (Q) | | F-0.30114 | r - 0.030 |

⁽a) Number of tumor-bearing animals/number of animals examined at the site

⁽b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

⁽c) Observed tumor incidence at terminal kill

⁽d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. N indicates a negative trend or lower incidence in a dosed group.

TABLE C3. ANALYSIS OF PRIMARY TUMORS IN MALE MICE IN THE TWO-YEAR FEED STUDY OF PHENYLEPHRINE HYDROCHLORIDE (Continued)

| | Control | 1,250 ppm | 2,500 ppm |
|---------------------------------|------------|------------|------------|
| Tarderian Gland: Adenoma | | | |
| Overall Rates (a) | 3/50 (6%) | 0/50 (0%) | 2/50 (4%) |
| Adjusted Rates (b) | 8.6% | 0.0% | 4.7% |
| Terminal Rates (c) | 3/35 (9%) | 0/38 (0%) | 2/43 (5%) |
| Week of First Observation | 104 | , | 104 |
| Life Table Tests (d) | P=0.319N | P = 0.107N | P = 0.406N |
| Incidental Tumor Tests (d) | P=0.319N | P = 0.107N | P=0.406N |
| Cochran-Armitage Trend Test (d) | P = 0.390N | | |
| Fisher Exact Test (d) | _ 3.00011 | P = 0.121N | P=0.500N |

⁽a) Number of tumor-bearing animals/number of animals examined at the site

⁽b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

⁽c) Observed tumor incidence at terminal kill
(d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. N indicates a negative trend or lower incidence in a dosed group.

| Total malignant tumors | 18 | 26 | 23 |
| Total animals with secondary tumors## | 2 | 1 | 2 |
| Total secondary tumors | $ar{f 2}$ | 2 | $ar{f 2}$ |

^{*} Number of animals receiving complete necropsy examination; all gross lesions including masses examined microscopically.

** Primary tumors: all tumors except secondary tumors

Number of animals examined microscopically at this site

Secondary tumors: metastatic tumors or tumors invasive into an adjacent organ

⁽a) Number of tumor-bearing animals/number of animals examined at the site

⁽b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality (c) Observed tumor incidence at terminal kill

⁽d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. N indicates a negative trend or lower incidence in a dosed group.

⁽a) The S9 fractions were prepared from the liver of Aroclor 1254-induced male Sprague-Dawley rats and male Syrian hamsters. Cells and study compound or solvent were incubated for 20 minutes at 37° C in the presence of either S9 or buffer. After the addition of soft agar, the contents of each tube were poured onto minimal medium, and the plates were incubated at 37° C for 48 hours (Haworth et al., 1983). The experiment was performed twice, each in triplicate; because the results were similar, data from only one experiment are shown.

⁽b) Mean ± standard error

⁽a) Experiments were performed twice, all doses were tested in duplicate or triplicate. Because the results from the two experiments were similar, data from only one experiment are shown. The protocol was basically that of Clive et al. (1979). Cells (6 \times 105/ml) were treated for 4 hours at 37° C in medium, washed, resuspended in medium, and incubated for 48 hours at 37° C. After expression, 3×10^6 cells were plated in medium supplemented with trifluorothymidine for selection of cells that were mutant at the thymidine kinase (TK) locus, and 600 cells were plated in nonselective medium to determine the percentage of viable cells.

⁽b) The mean of the results of replicate determinations is the number in parentheses.

TABLE E3. INDUCTION OF SISTER-CHROMATID EXCHANGES IN CHINESE HAMSTER OVARY CELLS BY PHENYLEPHRINE HYDROCHLORIDE (a)

| -S9 (b |) | + | S9 (c) |

⁽a) Abs = aberrations

⁽b) In the absence of S9, Chinese hamster ovary cells were incubated with study compound or solvent (medium) for 2 hours at 37°C; 2 hours after initiation of treatment, 10 µM BrdU was added, and incubation was continued for an additional 22-24 hours. (Due to chemically induced cell cycle delay, cells treated with study compound were allowed to incubate an additional 6 hours to accumulate sufficient metaphases for analysis.) Cells were washed, fresh medium containing BrdU (10 µM) and colcemid (0.1 µg/ml) was added, and incubation was continued for 2-3 hours (Galloway et al., 1985).

⁽c) In the presence of S9, cells were incubated with study compound or solvent for 2 hours at 37°C. Then cells were washed, and medium containing 10 µM BrdU was added. Cells were incubated for a further 26 hours, with colcemid (0.1 µg/ml) present for the final 2-3 hours. S9 was from the liver of Aroclor 1254-induced male Sprague-Dawley rats (Galloway et al., 1985).

⁽b) In the absence of S9, Chinese hamster ovary cells were incubated with study compound or solvent for 8-10 hours at 37° C. Cells were then washed, and fresh medium containing colcemid (0.1 µg/ml) was added. After a further 2-3 hours of incubation, cells were harvested by mitotic shake-off, fixed, and stained in 6% Giemsa (Galloway et al., 1985).

⁽c) In the presence of S9, cells were incubated with study compound or solvent for 2 hours at 37°C. Cells were then washed, fresh medium was added, and incubation was continued for 8-10 hours. Colcemid (0.1 µg/ml) was added for the last 2-3 hours of incubation; then cells were harvested and fixed as above. S9 was from the liver of Aroclor 1254-induced male Sprague-Dawley rats (Galloway et al., 1985).

APPENDIX F

CHEMICAL CHARACTERIZATION OF PHENYLEPHRINE HYDROCHLORIDE

Identity and Purity Determinations of Phenylephrine Hydrochloride Lot No. I. 160-XX-177 Performed by the Analytical Chemistry Laboratory

| A. | Physical properties | <u>Determined</u> | <u>Literature Values</u> |

Plates: Silica Gel 60 F-254

Reference standard: o-Aminophenol, 10 µg (10 µg/µl methanol)

Amount spotted: 100 and 300 µg (10 µg/µl methanol)

Visualization: Ultraviolet (254 nm) and 0.2% ninhydrin in butanol (spray)

Solvent

System 1: acetone:chloroform:ammonium hydroxide (58:40:2)

System 2: methanol:hydrochloric acid (99:1)

Results

| Spot <u>Intensity</u> | Rf | Rst |
|--------------------------|------|------|
| System 1 Major | 0.26 | 0.52 |
| System 2 Major | 0.36 | 0.54 |

2. High-performance liquid chromatography

Instrument system

Pump: Waters 6000A Programmer: Waters 660 Detector: Waters 440 Injector: Waters U6K

Column: μ Bondapak C₁₈, 300 mm \times 3.9 mm ID

Detection: Ultraviolet, 280 nm

Guard column: CO:PELL ODS, 72 mm × 2.3 mm ID

Solvent system

A: Water with 5 mM heptane sulfonic acid sodium salt and 1% (v/v) acetic acid B: Methanol with 5 mM heptane sulfonic acid sodium salt and 1% (v/v) acetic acid

System 1

Solvent program: 40% A:60% B, isocratic

Flow rate: 1 ml/min

Samples injected: Solution (20 µl) of 1.4 mg phenylephrine hydrochloride per

ml water, filtered

Results: Major peak and two impurities before the major peak. Impurities totaled 0.08% of the major peak.

| Peak No. | Retention Time (min) | Retention Time (relative to <u>major peak)</u> | Area (percent of <u>major peak)</u> |
|----------|----------------------|--|---|
| 1 | 3.0 | 0.55 | 0.01 |
| 2 | 3.5 | 0.64 | 0.07 |
| 3 | 5.5 | 1.00 | 100 |

System 2

Solvent program: 80% A:20% B, isocratic

Flow rate: 1 ml/min

Samples injected: Solution (10µl) of 3.5 mg phenylephrine hydrochloride per

ml water, filtered

Results: Major peak and two impurities before the major peak. Impurities totaled 0.9%.

| Peak No. | Retention Time (min) | Retention Time (relative to <u>major peak)</u> | Area (percent of <u>major peak)</u> |
|----------|----------------------|--|---|
| 1 | 2.5 | 0.20 | 0.01 |
| 2 | 3.5 | 0.20 | 0.08 |
| 3 | 17.4 | 1.00 | 100 |

Peak 2 in each system was difficult to quantitate accurately because it appeared very close to the solvent front. An injection of sample solution from System 1 exhibited no additional impurities up to 65 minutes when run at 100% B. Peaks no. 1 and no. 2 in System 1 correspond to peak no. 1 and no. 2 in System 2.

H. Conclusions: The results of the elemental analysis for carbon, hydrogen, nitrogen, and chlorine were in agreement with the theoretical values. Assay using the USP method (bromination of three aromatic positions on the phenol) indicated a purity of 101.04% ± 0.37(δ)%. (The USP specifications are not less than 97.5% and not more than 102.5% based on this assay.) Nonaqueous titration of the amine group with perchloric acid indicated a purity of 99.25% ± 0.39(δ)%. The sample passed the USP test for ketones (<500 ppm compared with acetone standard). Thin-layer chromatography indicated a single major spot in each of two systems. Two high-performance liquid chromatographic systems each indicated two impurities before the major peak totaling 0.08% of the major peak in one system and 0.09% in the other. The impurity peaks in one system corresponded to those in the other system. The infrared, ultraviolet/visible, and nuclear magnetic resonance spectra were consistent with the structure of phenylephrine hydrochloride.

- II. Stability Study of Phenylephrine Hydrochloride Lot No. 160-XX-077 Performed by the Analytical Chemistry Laboratory
 - A. Sample preparation and storage: Samples of phenylephrine hydrochloride were stored for 2 weeks at temperatures of -20°, 5°, 25°, or 60° C in glass tubes with Teflon[®]-lined caps.
 - B. Analytical method: Samples from each storage temperature were analyzed by highperformance liquid chromatography

Instrumental system

Pump: Waters 6000A
Programmer: Waters 660
Detector: Waters 440
Injector: Waters U6K
Detection: Ultraviolet, 280 nm

Column: μ Bondapak C₁₈, 300 mm \times 3.9 mm ID Guard column: CO:PELL ODS, 72 mm \times 2.3 mm ID

Solvent system

A: Water with 5 mM lauryl sulfate and 1% (v/v) acetic acid B: Methanol with 5 mM lauryl sulfate and 1% (v/v) acetic acid

Program: 30% A:70% B, isocratic

Flow rate: 2 ml/min

Samples injected: Solutions (25 μ l) of 0.14% phenylephrine hydrochloride, from each storage temperature, in water containing 0.1% uracil as an internal standard

Retention times

Phenylephrine hydrochloride--3.5 min Uracil (internal standard)--1.8 min

C. Results: Sample peak heights were compared with internal standard peak heights, and the recovery of phenylephrine hydrochloride from each storage temperature was compared with the recovery of the -20° C sample.

| Storage Temperature | Percent Compound (normalized to -20° C sample) |
|---------------------|--|
| – 20° C | $100.0\pm2.0(\delta)$ |
| 5° C | $101.2 \pm 2.0(\delta)$ |
| 25° C | $99.2 \pm 2.0(\delta)$ |
| 60° C | $98.9 \pm 2.0(8)$ |

D. Conclusions: Phenylephrine hydrochloride is stable as the bulk chemical, within the limits of experimental error, when stored for 2 weeks at temperatures up to 60° C.

III. Stability Study of Phenylephrine Hydrochloride Lot. No. 160-XX-177 at the Study Laboratory

A. Storage conditions

Bulk: 25°C

Reference: -20°C

B. Analytical method

1. Infrared spectroscopy

Instrument: Perkin-Elmer 283 or Beckman Acculab 8

Phase: 1% or 2% in potassium bromide pellet

2. USP titration: Approximately 0.1 g of phenylephrine hydrochloride was accurately weighed into a 250-ml iodine flask. The phenylephrine hydrochloride was dissolved in 20 ml of distilled water. Fifty milliliters of 0.100 N bromine and then 5.0 ml of concentrated hydrochloric acid was added. The mixture was allowed to stand 15 minutes. Then 10.0 ml of potassium iodide (10% w/v) was added, and that mixture was allowed to stand 5 minutes. The mixture was then titrated with 0.1 N sodium thiosulfate with 3.0 ml starch indicator solution added as the end point was approached.

3. High-performance liquid chromatography

Instrument: Varian 5060 with Vista 401

Detection: Ultraviolet at 280 nm

Column: μ Bondapak C₁₈, 300 mm \times 3.9 mm ID Guard column: CO:PELL ODS, 72 mm × 2.3 mm ID

Solvent system

A: Water with 5 mM sodium lauryl sulfate and 1% (v/v) acetic acid B: Methanol with 5 mM sodium lauryl sulfate and 1% (v/v) acetic acid

Program: 70% B Flow rate: 2.0 ml/min

Retention volume: 3.5 ml--uracil (internal standard)

7.0 ml--phenylephrine hydrochloride

C. Results

1. Infrared spectroscopy: All bulk spectra were comparable to the reference spectra and to the spectra supplied by the analytical chemistry laboratory.

2. Titration

D. Conclusion: No notable degradation occurred throughout the studies.

APPENDIX G

PREPARATION AND CHARACTERIZATION OF FORMULATED DIETS

I. Studies Conducted at the Analytical Chemistry Laboratory

A. Formulated diet homogeneity

1. Preparation and sampling procedure: A 1.2012-g weight of phenylephrine hydrochloride was transferred to a tared 250-ml beaker and thoroughly mixed by spatula with 25 g of feed. About 25 g more feed was added to the beaker, and the contents were again thoroughly mixed.

This operation was repeated with two additional 25-g batches of feed so that the final weight of the premix was 100 g.

Undosed rodent feed (700 g) was layered in the bottom of a Patterson-Kelly® blender; the 100-g premix was added in roughly equal amounts to both sides of the blender. The fine residue adhering to the beaker was taken up by 100 g of feed stirred in the beaker for a few seconds and added to the blender. After an additional 600 g of feed was layered over the premix, the blender ports were sealed. The target concentration of phenylephrine hydrochloride in the finished blend was 800.8 ppm.

Mixing was conducted for 15 minutes with the intensifier bar for the first 5 minutes. At the end of the 15-minute mixing period, about 50 g of blended feed was sampled from the upper left- and right-hand ports and from the bottom discharge port.

Duplicate weighings (20 \pm 0.01 g) of each sample were transferred to individual 200-ml centrifuge bottles.

2. Analysis: Samples were extracted with 100 ml of a methanol:acetic acid (99:1) mixture by sonication for 30 seconds and shaken for 15 minutes on a New Brunswick® gyrotory shaker set at 300 rpm. After the extract was clarified by centrifugation at 2,000 rpm for 5 minutes, a few milliliters of solution was filtered through a 0.5-μ Millipore syringe filter. The phenylephrine hydrochloride content of the filtrate was determined with the high-performance liquid chromatographic system described below:

Instrument: Waters Associates ALC202 Liquid Chromatograph

Attenuation: 0.05 AU full scale

Column: μ Bondapak C₁₈; 300 mm \times 4 mm ID stainless steel

Mobile phase

Pump A: 5 mM sodium lauryl sulfate in methanol:acetic acid (99:1) Pump B: 5 mM sodium lauryl sulfate in water:acetic acid (99:1)

Mobile phase ratio: 40% A:60% B

Detector: Waters Model 440, 280 nm filter

Volume injected: 16 µl Flow rate: 1 ml/min Retention time: 10.3 min

3. Quality control: Duplicate injections of duplicate extracts were analyzed. Recovery of chemical was determined in triplicate, with freshly spiked feed at the same level as the samples and assayed with the samples. Linearity of detector response was evaluated with standard solutions prepared in blank feed extract.

APPENDIX G. PREPARATION AND CHARACTERIZATION

4. Results

| Sampling Location | Concentration of Phenylephrine Hydrochloride (ppm)(a,b) | Percent Recovery |
|----------------------|---|-----------------------------|
| Right | 800 | |
| | 803 | (c) $100.0 \pm 0.2(\delta)$ |
| Left | 827 | |
| | 797 | $101.2\pm1.9(\delta)$ |
| Bottom | 777 | |
| | 802 | $98.5 \pm 1.5(\delta)$ |
| | | |

⁽a) Results corrected for zero-time recovery yield of 98.2% \pm 3.2(8)% (n = 6)

5. Conclusions: The results of analysis of phenylephrine hydrochloride blended with rodent feed at a concentration of 800 ppm showed a variation in actual concentration of \pm 1.5% of target concentration between three sampling points after being mixed by the technique described.

B. Formulated diet stability

- 1. Sample preparation and storage: From the phenylephrine hydrochloride feed blend described in Sections I.A.2. and I.A.3. of this appendix, eight samples (20 g \pm 0.01 g) were transferred to individual 200-ml centrifuge bottles and sealed with screw caps. Duplicate bottles were stored at -20° , 5° , 25° , or 45° C for 2 weeks.
- 2. Extraction and analysis: The analysis procedure was the same as in Section I.A.2. of this appendix except the extracting solvent was methanol:acetic acid (95:5), and a Burrell Wrist-Action® shaker was used instead of the gyrotory shaker.
- 3. Quality control: Duplicate weighed samples were analyzed. Recovery of phenylephrine hydrochloride was determined in triplicate with freshly spiked feed at the same concentration as samples and assayed with the samples. Linearity of the detector response was evaluated with standard solutions prepared in blank feed extract.

⁽b) Target concentration of chemical in feed, 800.8 ppm

⁽c) Error values are deviations from the mean.

APPENDIX G. PREPARATION AND CHARACTERIZATION

4. Results: Two-week stability in feed

| Storage <u>Temperature</u> | Concentration of Phenylephrine Hydrochloride (ppm) (a,b) | Percent Recovery |
|-------------------------------|--|---------------------|
| -20°C | 808 | |
| | 813 | (c) 101.2 ± 0.3 |
| 5° C | 810 | |
| | 803 | 100.8 ± 0.5 |
| 25° C | 775 | |
| | 775 | 96.8 ± 0 |
| 45° C | 784 | |
| | 780 | 97.7 ± 0.3 |
| | | |

⁽a) No recovery correction was applied to the analysis values, since the spiked recovery yield of 101.1% \pm 0.5% was within the analytical error of the test.

⁽b) Target concentration of chemical in feed was 800.8 ppm.

⁽c) Error values are deviations from the mean.

^{5.} Conclusions: Phenylephrine hydrochloride at 800 ppm in feed exhibited no measurable loss in stability after 2 weeks at temperatures up to 5° C. Although there was a slight downward trend (3%) in stability under 25° C and 45° C storage, the decrease was not considered significant because of the analytical error (± 2%).

APPENDIX G. PREPARATION AND CHARACTERIZATION

II. Analysis of Formulated Diets for Mixing Homogeneity at the Study Laboratory

A. Preparation and sampling: For each dietary concentration, the premix was prepared by weighing a quantity of the bulk chemical (a 1-week supply of formulated diet) and transferring the weighed chemical to a mortar containing 25-50 g feed. The compound and feed were thoroughly mixed and then transferred to a tared beaker containing approximately 100 g of feed. An additional portion of feed was added to adjust the premix weight to 300 g. The premix was mixed thoroughly with a spatula.

Bulk mixing was performed in a Patterson-Kelly® twin-shell stainless steel blender fitted with an intensifier bar. The 2,500-ppm and 1,250-ppm formulated diets were blended in an 8-qt and a 1-ft³ blender, respectively. For each formulation, the appropriate weight of undosed feed (4,000 g and 16,200 g for the 2,500-ppm and 1,250-ppm formulations, respectively) was accurately weighed and transferred in four portions to both sides of the blender. The premix was added in roughly equal amounts to both sides of the blender. For the 2,500-ppm formulation, the fine residue adhering to the beaker was taken up by using the premix beaker to transfer equal amounts of the remaining feed to both sides of the blender. The blender ports were sealed, and mixing was conducted for 15 minutes with the intensifier bar for the first 5 minutes.

Three samples were taken from each of the 1,250-ppm and 2,500-ppm diets. About 50 g of subsurface mixture was taken from the upper left- and right-hand ports and from the discharge port of the twin-shell blender. Duplicate 10-g samples were analyzed.

B. Analysis: Samples were extracted with 100.0 ml of methanol:acetic acid (99:1) by being shaken for 20 minutes on a Kraft shaker and centrifuged for 10 minutes in a Beckman Centrifuge at 2,000 rpm. The extract was filtered and loaded into sampling vials and analyzed by high-performance liquid chromatography.

Instrument: Varian 5000 HPLC with 8000 auto sampler UV 500 variable wavelength detector and Varian recorder

Detector: 276 nm

Solvent system: 5 mM sodium dodecyl sulfate in a mixture of 1% acetic acid, 39.5% meth-

anol, and 59.5% water
Flow rate: 1.6 ml/min
Retention time: 28 min

C. Quality control measures: Duplicate injections of duplicate extracts were analyzed. Recovery was determined in duplicate, with freshly spiked NIH 07 Rat and Mouse Ration at the same concentration as the samples and assayed with the samples. Linearity of detector response was evaluated with standard solutions prepared in blank feed extract.

APPENDIX G. PREPARATION AND CHARACTERIZATION

D. Results

| Sample <u>Location</u> | Target Concentration (ppm) | Determined Concentration (ppm) (a) | Percent of Target |
|---------------------------|----------------------------|---------------------------------------|----------------------|
| Bottom | 2,500 | 2,310 | 92.4 |
| Upper right | 2,500 | 2,380 | 95.2 |
| Upper left | 2,500 | 2,570 | 102.8 |
| Batch | 2,500 | 2,510 | 100.4 |
| Bottom | 1,250 | 1,200 | 96.0 |
| Upper right | 1,250 | 1,200 | 96.0 |
| Upper left | 1,250 | 1,190 | 94.8 |
| Batch | 1,250 | 1,210 | 96.8 |

⁽a) Results of duplicate analysis

E. Conclusions: All dietary concentrations were within \pm 10% of the target value.

APPENDIX H

METHODS OF ANALYSIS OF FORMULATED DIETS

APPENDIX H. METHODS OF ANALYSIS

I. Study Laboratory

Procedure: Approximately 10 g of accurately weighed feed was placed in a 256-ml centrifuge bottle and extracted with 100 ml of methanol:acetic acid (95:5) by being shaken for 15 minutes on a Kraft shaker. The extracts were clarified by centrifugation for 10 minutes at 2,000 rpm on a Beckman TJ-6 centrifuge. The extracts were then filtered through 0.45-µ swinny-type filters directly into 2.0-ml auto sampling vials and injected in triplicate on a high-performance liquid chromatograph under the following conditions:

Instrument: Varian 5030 or Varian 5060 with Vista 401

Column: Waters μ Bondapak C₁₈ 300 mm imes 4 mm with a Whatman CO:PELL C₁₈ guard column or ALTEX Ultrasphere ODS 5 μ 150 mm imes 4.6 mm with a Whatman CO:PELL 70 mm imes

4.9 mm guard column

Detector: 250 or 280 nm

Mobile phase: Water with 1% acetic acid:methanol with 1% acetic acid, (90:10, 80:20, or 60:40)

or methanol:water (50:50) with 1% acetic acid and 5 mM sodium lauryl sulfate added

II. Analytical Chemistry Laboratory

A. Preparation of spiked feed standards: An extractant solution was prepared by diluting 50 ml of reagent-grade glacial acetic acid to 1,000 ml of methanol in a volumetric flask.

Two standard solutions of phenylephrine hydrochloride were prepared independently in extractant solution. These solutions were diluted with extractant solution to make four additional standards. Aliquots (10 or 20 ml) of the six standard solutions were pipetted into individual 200-ml centrifuge bottles containing 10 g of undosed feed to make spiked feed standards bracketing the specified concentration range of the referee sample. One 200-ml centrifuge bottle containing 10 g of undosed feed was treated with 10 or 20 ml of extractant solution for use as a blank. The spiked feed standards and the feed blank were sealed and allowed to stand overnight at room temperature before analysis.

- B. Preparation of formulated diet sample: Triplicate weights of the referee feed sample (approximately 10 g weighed to the nearest 0.001 g) were transferred to individual 200-ml centrifuge bottles. Extractant solution (10 or 20 ml) was pipetted into each sample; the bottles were sealed and allowed to stand overnight at room temperature before analysis.
- C. Analysis: Extractant solution was pipetted into each blank, standard, and referee sample bottle; the bottles were shaken at maximum stroke for 30 minutes on a wrist-action shaker. After centrifugation for 10 minutes, an aliquot of each extract was filtered through a 0.5-µ Millipore filter. The concentration of phenylephrine hydrochloride in the filtered solutions was determined by the high-performance liquid chromatographic system described below.

APPENDIX H. METHODS OF ANALYSIS

System: Waters Model 6000A Pump or Varian Model 5020 Solvent Delivery System

WISP Model 710 or Rheodyne Model 7125 Injector Waters Model 440 Detector at 280 nm, 0.1 AUFS

Column: Waters µBondapak C₁₈, 300 mm × 3.9 mm ID, with a Whatman CO:PELL ODS

guard column, $72 \text{ mm} \times 2.3 \text{ mm ID}$ Mobile phase: A:B, 20:80 or 60:40

A: 5 mM sodium lauryl sulfate in methanol:acetic acid (99:1)
B: 5 mM sodium lauryl sulfate in water:acetic acid (99:1)

Flow rate: 1.0 ml/min Volume injected: 20 or 25 µl

D. Quality assurance measures: The referee feed sample was analyzed in triplicate, and the undosed feed sample was analyzed once. Individually spiked portions of the diet (six levels bracketing the specified concentration range of the referee sample) were prepared from two independently weighed standards and were used to obtain standard data. Duplicate injections of each standard and sample were made into the chromatograph in a random order.

APPENDIX J

SENTINEL ANIMAL PROGRAM

| | | PAGE |
|----------|---|------|
| TABLE J1 | MURINE VIRUS ANTIBODY DETERMINATIONS FOR RATS AND MICE IN THE | |
| | TWO-YEAR FEED STUDIES OF PHENYLEPHRINE HYDROCHLORIDE | 153 |

I. Methods

Rodents used in the Carcinogenesis Program of the National Toxicology Program are produced in optimally clean facilities to eliminate potential pathogens that may affect study results. The Sentinel Animal Program is part of the periodic monitoring of animal health that occurs during the toxicologic evaluation of chemical compounds. Under this program, the disease state of the rodents is monitored via viral serology on sera from extra (sentinel) animals in the study rooms. These animals are untreated, and these animals and the study animals are both subject to identical environmental conditions. The sentinel animals come from the same production source and weanling groups as the animals used for the studies of chemical compounds.

Fifteen B6C3F₁ mice and 15 F344/N rats of each sex are selected at the time of randomization and allocation of the animals to the various study groups. Five animals of each designated sentinel group are killed at 6, 12, and 18 months on study. Data from animals surviving 24 months are collected from 5/50 randomly selected control animals of each sex and species. The blood from each animal is collected and clotted, and the serum is separated. The serum is cooled on ice and shipped to Microbiological Associates' Comprehensive Animal Diagnostic Service for determination of the viral antibody titers. The following tests are performed:

| | Hemagglutination <u>Inhibition</u> | Complement <u>Fixation</u> | <u>ELISA</u> |
|------|--|---|---|
| Mice | PVM (pneumonia virus of mice) Reo 3 (reovirus type 3) GDVII (Theiler's encephalomyelitis virus) Poly (polyoma virus) MVM (minute virus of mice) Ectro (infectious ectromelia) Sendai (6,12, 18 mo) | M.Ad. (mouse adenovirus) LCM (lymphocytic choriomeningitis virus) MHV (mouse hepatitis virus) (6, 12 mo) Sendai (24 mo) | MHV (mouse hepatitis virus) (18, 24 mo) |
| Rats | PVM KRV (Kilham rat virus) H-1 (Toolan's H-1 virus) Sendai (6, 12, 18 mo) | RCV (rat coronavirus) Sendai (24 mo) | |

II. Results

Results are presented in Table J1.

TABLE J1. MURINE VIRUS ANTIBODY DETERMINATIONS FOR RATS AND MICE IN THE TWO-YEAR FEED STUDIES OF PHENYLEPHRINE HYDROCHLORIDE (a)

| | Interval (months) | No. of Animals | Positive Serologic Reaction for |
|-----|-------------------|-------------------|------------------------------------|
| ATS | <u> </u> | | |
| | 6 | | None positive |
| | 12 | | None positive |
| | 18 | 7/9 | Sendai |
| | 24 | 8/10 | Sendai |
| CE | | | |
| | 6 | | None positive |
| | 12 | •• | None positive |
| | 18 | 5/10 | Sendai |
| | | 2/10 | MHV |
| | 24 | 6/8 | Sendai |

⁽a) Blood samples were taken from sentinel animals at 6, 12, and 18 months after the start of dosing and from the control animals just before they were killed; samples were sent to Microbiological Associates, Inc. (Bethesda, MD) for the Animal Disease Screening Program.

| TABLE M4 | CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION | 168 |

TABLE M1. INGREDIENTS OF NIH 07 RAT AND MOUSE RATION (a)

| Ingredients (b) | Percent by Weight | |
|--|-------------------|--|
| Ground #2 yellow shelled corn | 24.50 | |
| Ground hard winter wheat | 23.00 | |
| Soybean meal (49% protein) | 12.00 | |
| Fish meal (60% protein) | 10.00 | |
| Wheat middlings | 10.00 | |
| Dried skim milk | 5.00 | |
| Alfalfa meal (dehydrated, 17% protein) | 4.00 | |
| Corn gluten meal (60% protein) | 3.00 | |
| Soy oil | 2.50 | |
| Brewer's dried yeast | 2.00 | |
| Dry molasses | 1.50 | |
| Dicalcium phosphate | 1.25 | |
| Ground limestone | 0.50 | |
| Salt | 0.50 | |
| Premixes (vitamin and mineral) | 0.25 | |

⁽a) NIH, 1978; NCI, 1976

TABLE M2. VITAMINS AND MINERALS IN NIH 07 RAT AND MOUSE RATION (a)

| | Amount | Source |
|-----------------------|-----------------|---|
| /itamins | | |
| A | 5,500,000 IU | Stabilized vitamin A palmitate or acetate |
| D_3 | 4,600,000 IU | D-activated animal sterol |
| d-a-Tocopheryl acetat | e 20,000 IU | |
| Riboflavin | 3.4 g | |
| Thiamine | 10.0 g | Thiamine mononitrate |
| Niacin | 30.0 g | |
| d-Pantothenic acid | 18.0 g | d-Calcium pantothenate |
| Folic acid | 2.2 g | • |
| Pyridoxine | 1.7 g | Pyridoxine hydrochloride |
| B ₁₂ | 4,000 µg | · |
| Biotin | 140.0 mg | d-Biotin |
| K ₃ | 2.8 g | Menadione activity |
| Choline | 560.0 g | Choline chloride |
| f inerals | | |
| Iron | 120.0 g | Iron sulfate |
| Manganese | 60.0 g | Manganous oxide |
| Zinc | 16.0 g | Zinc oxide |
| Copper | 4.0 g | Copper sulfate |
| Iodine | 1.4 g | Calcium iodate |
| Cobalt | $0.4\mathrm{g}$ | Cobalt carbonate |

⁽a) Per ton (2,000 lb) of finished product

⁽b) Ingredients ground to pass through a U.S. Standard Screen No. 16 before being mixed

TABLE M3. NUTRIENT COMPOSITION OF NIH 07 RAT AND MOUSE RATION (a)

| | Mean ± Standard | | |
|-----------------------------------|-----------------|--------------|-------------------|
| Nutrient | Deviation | Range | Number of Samples |
| Crude protein (percent by weight) | 24.22 ± 1.07 | 22.6-26.3 | 24 |
| Crude fat (percent by weight) | 5.09 ± 0.46 | 4.2-6.0 | 24 |
| Crude fiber (percent by weight) | 3.42 ± 0.39 | 2.4-4.2 | 24 |
| Ash (percent by weight) | 6.63 ± 0.38 | 5.97-7.42 | 24 |
| Essential Amino Acids (percent o | f total diet) | | |
| Arginine | 1.260 | 1.21-1.31 | 2 |
| Cystine | 0.395 | 0.39-0.40 | 2 |

TABLE M4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION (Continued)

- (a) All values were less than the detection limit, given in the table as the mean.
- (b) Detection limit was reduced from 10 ppb to 5 ppb after 7/81.
- (c) Source of contamination: Alfalfa, grains, and fish meal
- (d) Source of contamination: Soy oil and fish meal
- (e) One batch contained less than 0.5 ppm. The value was <0.04 and it was produced on 4/27/81.
- (f) MPN = most probable number
- (g) Mean, standard deviation, and range exclude one value of 150 produced on 8/26/82.
- (h) Mean, standard deviation, and range include the high value given in footnote g.
 (i) All values were corrected for percent recovery.
- (j) Mean, standard deviation, and range exclude two very high values of 101.6 and 100.3 ppb for batches produced on 1/26/81 and 4/27/81.
- (k) Mean, standard deviation, and range include the very high values given in footnote j.
 (l) Mean, standard deviation, and range exclude two very high values of 97.9 and 99 produced on 1/26/81 and 4/27/81.
- (m) Mean, standard deviation, and range include the very high values given in footnote l.
- (n) BHC = hexachlorocyclohexane or benzene hexachloride
- (o) There was one observation above the detection limit. The value and the date it was obtained are given under the range.
- (p) There were two observations above the detection limit. The values and the dates they were obtained are given under the range.
- (q) Ten batches contained more than 0.05 ppm.

APPENDIX N

DATA AUDIT SUMMARY

APPENDIX N. DATA AUDIT SUMMARY

The experimental data, pathology materials, and tables for the NTP Technical Report on the toxicology and carcinogenesis studies of phenylephrine hydrochloride were examined for completeness, consistency, and accuracy and for procedures consistent with Good Laboratory Practice requirements. The audit was conducted during May and June of 1985 at the NTP Archives, Research Triangle Park, North Carolina, and at Dynamac Corporation, Rockville, Maryland, by the following Argus Research Laboratories, Inc., personnel: Jane E. Goeke, Ph.D.; Elizabeth L. Feussner, V.M.D., D.A.B.T.; Alan M. Hoberman, Ph.D.; Vanette M. Everline, B.S.; David M. Willet, B.S.; and Carol L. Veigle, HTL. Diana S. Copeland, D.V.M., D.A.C.V.P., Pathology Associates, Inc., also participated. The 2-year studies in F344/N rats and B6C3F₁ mice were conducted from September 1980 to October 1982 at Physiological Research Laboratories, under a subcontract with Tracor Jitco, Inc., for the National Toxicology Program. The full audit report has been reviewed by the NTP and is on file at the NTP Archives, Research Triangle Park, North Carolina.

The audit involved a review of all prestudy data (i.e., receipt, quarantine, randomization, animal identification) and a complete review of inlife data (body weights, clinical observations, dosing) for a random 10% of the animals in each group. In addition, all records of study animal deaths, moribund or terminal kills, tumors, lesions, and masses were verified. All available chemistry data were audited, and 10% of the dose calculations were verified. For the pathology portion of the audit, a slide/block match was conducted for all high dose and control animals; wet tissue examination and animal identification were performed on a random 10% sample of rats and mice, and gross observations and microscopic diagnoses were compared on Individual Animal Data Records of all rats and mice.

The inlife data for the 2-year studies of phenylephrine hydrochloride were found to be in generally good order. Minor discrepancies were noted concerning start and stop dates for dosing, calculations of body weights and feed consumption, and recording of the size and presence of masses in clinical observation and gross necropsy records. Essentially all chemistry data were present and verified.

In the audit of pathology data, untrimmed lesions were found in the wet tissues of 14/54 rats and 14/51 mice. Few of these were considered probable neoplasia, but this finding prompted a review for untrimmed lesions of the lung and liver from all groups of male and female mice. The results of this review have been incorporated into the pathology tables shown in this Technical Report. Lesions undiagnosed on slides were found in 11/67 rats and 13/47 mice. Each case consisted of more than 40 tissues on 10-13 slides, and most missed lesions were restricted to 1 tissue on 1 slide of each animal. Three of the undiagnosed rat lesions and two of the undiagnosed mouse lesions involved neoplasms in nontarget organs. Missed lesions were distributed between tissues and dose groups such that resolution would have no impact on the results of the studies; therefore, no further action was taken.

In summary, the audit of the data for the 2-year feed studies of phenylephrine hydrochloride revealed numerous minor discrepancies in records from the inlife portion of the studies and several untrimmed or undiagnosed lesions in the pathology materials. Those problems considered minor were not necessarily pursued to final conclusion but are listed in the full audit report. In conclusion, the data presented in the Technical Report are considered adequate to meet the objectives of these studies.
