Utilization of Analgesic Drugs in Office-Based Ambulatory Care: National Ambulatory Medical Care Survey, 1980–81

by Hugo Koch, Division of Health Care Statistics, and Deanne E. Knapp, Ph.D., National Center for Drugs and Biologics

Introduction

The purpose of this report is to describe the utilization canalgesic drugs in office-based ambulatory care. The report bines the 1980 and 1981 findings of the National Ambulary Medical Care Survey, an annual, sample survey of officebased physicians conducted from 1973 through 1981 by the National Center for Health Statistics. The National Ambulatory Medical Care Survey (NAMCS) is scheduled to take the field again in 1985 and every third year following.

The term *utilization* is limited to the ordering or providing of an analgesic drug by the office-based physician in the course of an office visit. It does not include drugs ordered by phone contact, nor does it attempt to measure ultimate patient compliance with the doctor's instruction.

The drugs described are those classified as *Central Nerv*ous System Drugs: Analgesics and Antipyretics, according to the American Hospital Formulary Service Classification System.¹ Description centers on drugs of this class that were named by physician respondents in 1980–81. A list of the named analgesics appears in figure 1. Along with all *new* analgesics ordered or provided, the physician also recorded *continued* analgesics if the patient was specifically instructed during the visit to continue the medication. (However, the data base does not distinguish between the new and the continued medication.) The listed agents appear as brand² or generic names, depending on the choice made by the physician in ordering the analgesic. They are divided into two subcategories:³

Opioids: Produce analgesia by their interaction with specific opioid binding sites in the central nervous system. (The terms "opioid" and "opiate" are interchangeable). Nonopioids: Do not bind to the opioid receptors. (Indeed, the exact mechanism of their analgesic action remains unknown).

By restricting its scope to an arbitrarily selected class of analgesics this study understates the overall use of pain-relieving drugs in office practice. For example, it does not account for the presence of analgesic ingredients in drugs primarily classified under other rubrics, as in the following cases:

| Drug class | Members with analgesic ingredients |
|---------------------|--|
| Psychotropic agents | |
| Antihistamines | . such as Synalgos . codeine combinations |

Because the estimates presented in this report are based on a sample of office visits and drug mentions rather than the entire universe of visits and mentions, they are subject to sampling variability. The technical notes at the end of the report provide a brief description of the sample design, an explanation of sampling errors, and guidelines for judging the precision of the estimates.

NOTES: Included in the category Opioids are all opioid-nonopioid combinations; included in the category Nonopioids are nonopioid-nonopioid combinations Drug names are listed in brand or generic form, according to actual survey responses.

Figure 1. Analgesic drugs named by physician respondents: United States, 1980-81

General findings

According to findings from the National Ambulatory Medical Care Survey for 1980 and 1981 combined, an estimated 1,160,922,000 visits were made to physicians who identified themselves as primarily engaged in office-based, patient care practice. Of this total, 717,775,000 (62 percent) were *drug visits*; that is, visits at which one or more of any type of drug was ordered or provided. The total number of drug mentions for the 2-year span amounted to an estimated 1,330,746,000 mentions.

Visits involving the utilization of an inscope analgesic numbered 106,718,000, about 9 percent of the overall number of office visits and about 15 percent of all drug visits. The total number of analgesic drug mentions was 116,641,000. Of these an estimated 31,380,000 (27 percent) were opioids. The remaining 85,261,000 (73 percent) were nonopioids.

Table 1 lists the 25 analgesic products most frequently mentioned. They accounted for virtually nine-tenths of all analgesic mentions. The generic names most frequently represented among these 25 products are shown in the following listing:

ug Enforcement Administration.

Drug dimensions

Table 2 describes some key dimensions of the analgesic drugs.

Entry status—In ordering an analgesic, physicians showed a strong tendency to favor brand name choices over their generic counterparts. About 4 of every 5 of the overall class were identified by trade name. The tendency was strongest in the opioid subclass; here, only 1 of every 10 mentions was generically identified.

Prescription status—The utilization of nonprescription drugs, apparent in 27 percent of analgesic mentions, was more than double their proportionate use in overall, office-based drug therapy (12 percent).

Control status—Because of its opioid component, the analgesic family has a substantial proportion of controlled agents among its members. Controlled agents accounted for 26 percent of analgesic mentions, the majority of their number classified in Schedules III and IV. Thus the prescribing physician, faced with the need to moderate pain, also needs to weigh the desired therapeutic effect against the potential hazards of dependence or habituation.

Composition status

The proportionate use of combination products among analgesics (apparent in about 26 percent of mentions) conforms closely to the proportionate use of combinations throughout office-based drug therapy. By far the most common analgesic mixtures involved the combination of an opioid with a nonopioid, with codeine or propoxyphene appearing as the most common opioid ingredient. Ample support for the use of this type of analgesic combination is provided by the AMA Drug Evaluations, Fifth Edition:

The combination of an opiate or opioid with a nonopiate (analgesic-antipyretic) appears to be rational because the mechanism of action of each drug differs and the results of controlled studies have shown that the analgesic effects of the individual drugs are additive. Since the nonopiates have a ceiling analgesic effect and the dosage of opiates should be limited to prevent adverse effects, a combination of this type may provide greater pain relief with a minimum of adverse effects in a convenient form for the patient.⁴

Apparent in only 6 percent of analgesic mentions, the combination of a nonopioid with another nonopioid is manifestly uncommon in the office-based utilization of analgesics, possibly because of the reason stated in AMA Drug Evaluations, Fifth Edition: "...it can be concluded that mixtures of analgesic-antipyretic drugs with or without caffeine have not been proved to be superior to optimal doses of their individual components."⁴

Diagnosis

By far the most intensive use of analgesic therapy occurs within two diagnostic groups: "Injuries" and "Diseases of the Musculoskeletal System" (table 3).⁵ This is demonstrated more clearly in the following listing of the specific conditions most frequently associated with analgesic utilization:

| Rank | Opioid therapy Diagnosis and ICD -9- CM Code ⁵ |
|-------------|---|
| 2 3 4 | Back sprains and strains |
| | Nonopioid therapy |
| Rank | Diagnosis and ICD–9–CM Code ⁵ |
| 2 3 4 | Osteoarthrosis |

In contrast to other drug classes, the rate of analgesic utilization in the category "Symptoms and ill-defined conditions" is relatively higher, documenting the physician's tendency to respond to symptomatic pain in advance of a clearly established diagnosis. However, it would be a mistake to assume that an analgesic is automatically ordered whenever pain appears as a symptom. Indeed, according to another NAMCS study (in preparation), about 70 percent of nearly 70 million newly encountered problems where pain was the chief presenting symptom did not involve the use of an inscope analgesic.

⁴AMA Drug Evaluations, op cit, p 101.

⁵Based on International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM).

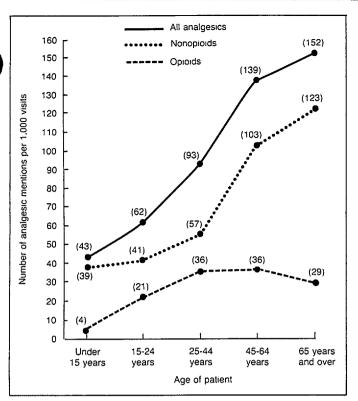

Figure 2. Analgesic utilization rates by category of analgesic and age of patient: United States, 1980–81

Patient characteristics

From its lowest rate, for patients under 15 years of age, the overall utilization of analgesics generally increased in each successive age group throughout the age spectrum, the sharpest acceleration occurring in the age interval from the 25th through the 64th year (table 4 and figure 2). It is the utilization rates for the nonopioids that chiefly determine the shape of the overall curve; these rates, in their turn, largely reflected the strong preference for the nonopioids in the treatment of the musculoskeletal diseases. Opioid utilization, probably due chiefly to the above-average preference for opioids in the treatment of injuries, rises steadily up to the 45th year (the injury-prone period), levels off in the 45-to-64 age group, and probably declines slightly in the later years of life.

Although the average overall rates of analgesic utilization were the same for both male and female patients (table 4), there were marked differences between the sexes in the age intervals at which the analgesic therapy was most intensely applied (table 5 and figure 3). The male rate, substantially higher in the age interval 15-44 years, results chiefly from the fact that the proportion of visits for injuries in this age group was almost twice as great among male patients as among females. The female rate, higher among patients age 45 years and over, largely reflects a growing proneness toward musculoskeletal disease that is proportionately greater among older females than among their male counterparts.

Table 5. Number of office visits, number of analgesic mentions, and number of mentions per 1,000 visits, by selected patient characteristics; and percent distribution by opioid and nonopioid mentions, according to selected patient characteristics: United States, 1980–81

| Not Hispanic | 1,107,585 | 110,497 | 100 | 27.0 | 73.0 | | | | |

¹Excludes about 12,786,000 visits by patients of races other than white or black.

<u>6</u> advancedata

The significantly higher rate among black office patients (table 5) is chiefly related to the finding that black patients suffered proportionately more than white patients from the four conditions that command the highest rates of analgesic use: musculoskeletal diseases, injuries, circulatory diseases, and symptoms and ill-defined conditions.

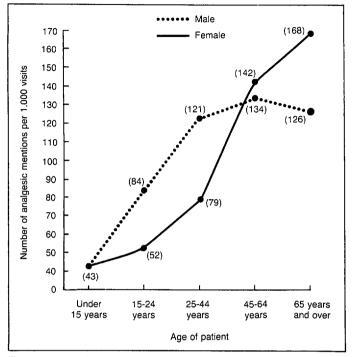

Figure 3. Analgesic utilization rates by sex and age of patient: United States, 1980–81

Physician characteristics

Of the most-visited, office-based specialities, five exceeded the average rate of analgesic utilization (table 6). Ranked by magnitude of rate, these specialties were:

| Rank | Specialty |
|------|-----------------------------|
| | Orthopedic surgery |
| 2 | Internal medicine |
| 3 | Neurology |
| 4 | General and family practice |
| 5 | Cardiovascular disease |

Shifting attention from rate of analgesic utilization to sheer volume of use, it is worthy of note, however, that two primary-care providers, the internist and the general or family practitioner, accounted for fully two-thirds of all analgesic mentions and nearly the same proportion (62 percent) of opioid mentions.

Other visit characteristics

The most conservative utilization of analgesics occurred with new patients (table 7), a pattern common throughout all office-based drug therapy. The most intensive use occurred when a new problem was presented by a patient with whom the doctor already had a clinical relationship. Thus, given what may be the same problem, the physician's decision whether or not to use an analgesic is obviously influenced by familiarity with the patient's history, including possible drug reactions.

The findings in table 8 document the associations of analgesic therapy with the forms of nondrug treatment that most frequently accompanied it. Perhaps most arresting is

| Table 6. Number of office visits, number of analgesic mentions, and number of mentions per 1,000 visits, b | by selected physician characteristics; and |

Table 7. Number of office visits, number of analgesic mentions, and number of mentions per 1,000 visits, by selected visit characteristics; and percent distribution by opioid and nonopioid mentions, according to selected visit characteristics: United States, 1980-81

| | Number of visits in thousands | Analgesic mentions | | | |
|-----------------------------------|---|---------------------------------------|-----------------------------|--|--|
| | | All analgesics | | Opioids | Nonopioids |
| Selected visit characteristic | | Number in thousands | Rate per 1,000 visits | Percent of all analgesic mentions | Percent of all analgesic mentions |
| All visits | 1,160,922 | 116,641 | 100 | 26.9 | 73.1 |
| Referral status | | | | | |
| Referred by another physician | 51,392 | 4,513 | 88 | 28.9 | 71.1 |
| Not referred by another physician | 1,109,530 | 112,128 | 101 | 26.8 | 73.2 |
| Patient visit status | | | | | |
| New patient | 166,675 994,247 258,778 735,469 | 15,346 101,294 31,793 69,501 | 92 102 123 94 | 31.0 26.3 26.4 26.2 | 69.0 73.7 73.6 73.8 |
| Problem status | | | | | |
| New problem | 425,453 735,469 | 47,140 69,501 | 111 94 | 27.9 26.2 | 72.1 73.8 |

the broad extent to which drug therapy was the exclusive form of treatment employed. At about one-half of the visits that involved the use of an analgesic-alone or accompanied by agents of other drug classes-there was no concurrent use of any form of nondrug therapy.

Table 8. Number and percent distribution of analgesic visits, by nonmedication therapy: United States, 1980-81

| | Analgesic visits ² | |
|--|-------------------------------|-------------------------|
| Nonmedication therapy ¹ | Number in thousands | Percent distribution |
| Total visits | 106,718 | 100.0 |
| None | 52,070 | 48.8 |
| Medical counseling | 31,454 | 29.5 |
| Physiotherapy | 14,891 | 14.0 |
| Office surgery | 4,178 | 3.9 |
| Psychotherapy or therapeutic listening | 3,557 | 3.3 |
| Other | 12,436 | 11.7 |

¹Because it was possible to use more than one form of nonmedication therapy at a given visit, estimates will exceed the totals at the top of the columns. ²An analgesic visit is an office visit at which one or more analgesic agents was utilized.

Co-occurrence

Utilized at 62 percent of all office visits, drug therapy (of all types) is by far the most frequent form of treatment provided in office practice. Further, when they do use a drug, physicians tend to use more than one. The overall average is about two drugs per drug visit, but larger multiples are not uncommon, especially when the patient suffers from more than one disorder. With co-occurrence the rule rather than the exception, it is instructive to explore the patterns of concomitant utilization of drugs that occurred in the office visits at which an analgesic agent was ordered or provided.

At the 106.7 million visits at which an analgesic agent was utilized, its use (expressed as a percent of these visits) co-occurred most frequently with the use of one or more members of the following ten therapeutic families:

| Co-occurring therapeutic family ⁶ | Percent of co-occurrence |
|--|-----------------------------|
| Antibiotics | 12.2 |
| Diuretics | |
| Antianxiety agents, sedatives, hypnotics | |
| Cardiac drugs | |
| Adrenals | 6.6 |
| Antihypertensives | |
| Gastrointestinal drugs | 5.3 |
| Skeletal muscle relaxants | 3.9 |
| Antidepressives and antipsychotics | |
| Expectorants and cough preparations | 3.0 |
| | |

Technical notes

Source of data and sample design

The estimates presented in this report are based on the findings of the National Ambulatory Medical Care Survey (NAMCS), a sample survey of office-based care conducted annually from 1973 through 1981 by the National Center for Health Statistics. The target universe of NAMCS is composed of office visits made by ambulatory patients to non-Federal and noninstitutional physicians who are principally engaged in office-based, patient-care practice. Visits to physicians practicing in Alaska and Hawaii are excluded from the range of NAMCS, as are visits to anesthesiologists, pathologists, and radiologists.

NAMCS uses a multistage probability sample design that involves a step sampling of primary sampling units (PSU's), physicians' practices within PSU's, and patient visits within physicians' practices. The physician sample (5,805 physicians for 1980 and 1981) was selected from master files maintained by the American Medical Association and the American Osteopathic Association. Those members of the sample who proved to be inscope and eligible participated at a rate of 77.3 percent. Responding physicians completed visit records for a systematic random sample of office visits made during a randomly assigned weekly reporting period. Telephone contacts were excluded. During 1980 and 1981 responding physicians completed 89,447 visit records on which they recorded 97,796 drug mentions. Characteristics of the physician's practice, such as primary specialty and type of practice, were obtained during an induction interview. The National Opinion Research Center, under contract to the National Center for Health Statistics, was responsible for the field operations of the survey.

Table I. Approximate relative standard errors of estimated numbers of office visits and of drug mentions when drug is listed by product name (for example, Darvon), based on all physician specialties: National Ambulatory Medical Care Survey, 1980–81

| Estimated number of office visits or specific drug mentions | Relative standard error |
|--|-------------------------------|
| Number in thousands | Percent |
| *200 | *44.8 |
| *400 | *31.7 |
| *450 | *30.0 |
| 600 | 26.0 |
| 800 | 22.6 |
| 1.000 | 20.2 |
| 2.000 | 14.5 |
| 5,000 | 9.5 |
| 10.000 | 7.1 |
| 20,000 | 5.6 |
| 50,000 | 4.4 |
| 100.000 | 3.9 |
| 200.000 | 3.6 |
| 500,000 | 3.5 |
| 1,000,000 | 3.4 |

Example of use of table: An aggregate estimate of 35,000,000 office visits has a relative standard error of 5.0 percent or a standard error of 1,750,000 visits (5.0 percent of 35,000,000 visits).

Sampling errors and rounding

The standard error is a measure of the sampling variability that occurs by chance because only a sample, rather the the entire universe, is surveyed. The relative standard error of an estimate is obtained by dividing the standard error by the estimate itself and is expressed as a percent of the estimate. In this report, any estimate that exceeds a relative standard error of 30 percent is marked with an asterisk. Table I should be used to obtain the relative standard error for aggregates of office visits or for mentions of drugs by specific name (for example, Darvon). Table II should be used to obtain the relative standard error for drug mentions expressed as drug groups (for example, the analgesic drug family).

In the tables of this report estimates have been rounded to the nearest thousand. For this reasons, detailed estimates do not always add to totals.

Table II. Approximate relative standard errors of estimated numbers of drug mentions when drugs appear in groups (for example, the analgesic drug family), based on all physician specialties: National Ambulatory Medical Care Survey, 1980–81

| Estimated number of grouped drug mentions | Relative standard error |
|---|-------------------------------|
| Number in thousands | Percent |
| *200 | *54.2 |
| *400 | *38.5 |
| '600 | *31.5 |
| 650 | *30.0 |
| 300 | 27.3 |
| 1,000 | 24.5 |
| 2,000 | 17.6 |
| 5,000 | 11.6 |
| 10,000 | 8.7 |
| 20,000 | 6.8 |
| 50,000 | 5.3 |
| 100,000 | 4.7 |
| 200,000 | 4.4 |
| 500,000 | 4.2 |
| 1,000,000 | 4.1 |

Example of use of table: An aggregate estimate of 30,000,000 drug mentions has a relative standard error of 7.0 percent or a standard error of 2,100,000 mentions (7.0 percent of 30,000,000 mentions).

Definitions

An *office* is a place that physicians identify as a location for their ambulatory practice. Responsibility for patient care and professional services rendered in an office resides with the individual physician rather than an institution.

A visit is a direct personal exchange between an ambulatory patient seeking health care and a physician, or staff member working under the physician's supervision, who provides the health services.

A *drug mention* is the physician's entry on the visit record of a pharmaceutical agent ordered or provided any route of administration for prevention, diagnosis, or treatment. Generic as well as brand-name drugs are included,

advancedata

9

as are nonprescription as well as prescription drugs. The physician records all new drugs and also records all continued medications if the patient is specifically instructed during the visit to continue the medication.

An *acute problem* is a morbid condition with a relatively sudden or recent onset (within 3 months of the visit).

A chronic problem is a morbid condition that existed for 3 months or longer before the visit. The care indicated is of a regular, maintenance nature. A *chronic problem flare up* is a sudden exacerbation of a preexisting chronic condition.

Nonillness care denotes health examinations and care provided for presumably healthy persons. Examples of nonillness care include prenatal and postnatal care, annual physicals, well-child examinations, and insurance examinations.
