NOAA Technical Memorandum NMFS

#### Abstract

The National Marine Fisheries Service's Alaska Fisheries Science Center uses the NOAA Technical Memorandum series to issue informal scientific and technical publications when complete formal review and editorial processing are not appropriate or feasible. Documents within this series reflect sound professional work and may be referenced in the formal scientific and technical literature.

The NMFS-AFSC Technical Memorandum series of the Alaska Fisheries Science Center continues the NMFS-F/NWC series established in 1970 by the Northwest Fisheries Center. The new NMFS-NWFSC series will be used by the Northwest Fisheries Science Center.

For convenience, the 1999 and 2000 echo integration-trawl survey reports have been bound together as one document. The following individual reports, however, should be cited as follows:

Honkalehto, T., N. Williamson, and S. de Blois. 2002. Echo integrationtrawl survey results for walleye pollock (Theragra chalcogramma) on the Bering Sea shelf and slope during summer 1999. U.S. Dep. Commer., NOAA Tech. Memo. NMFS-AFSC-125, 77 p.

Honkalehto, T., W. Patton, S. de Blois, and N. Williamson. 2002. Echo integration-trawl survey results for walleye pollock (Theragra chalcogramma) on the Bering Sea shelf and slope during summer 2000. U.S. Dep. Commer., NOAA Tech. Memo. NMFS-AFSC-126, 66 p.

Reference in these documents to trade names does not imply endorsement by the National Marine Fisheries Service, NOAA.

This document is being made available in .PDF format for the convenience of users; however, the accuracy and correctness of the document can only be certified as was presented in the original hard copy format.

## PREFACE

This report contains methodology, results, and some discussion of two summer echo integration-trawl (EIT) surveys of walleye pollock (Theragra chalcogramma) on the eastern Bering Sea shelf and slope conducted in 1999 and 2000. This research was carried out by the Midwater Assessment and Conservation Engineering (MACE) Program at the Alaska Fisheries Science Center, Seattle, Washington, as part of a historical time series monitoring the midwater component of Bering Sea walleye pollock. While EIT surveys are completed in conjunction with the AFSC's Groundfish Assessment Program's annual bottom trawl surveys to separately assess the on-bottom component of Bering Sea pollock, bottom trawl results are not presented here. Although EIT survey design and timing were nearly the same between 1999 and 2000, each year's work had a slightly different scope and research team, thus the results are presented sequentially as two separate papers. To the extent possible, subheadings and sections used are the same for each year, but in some cases they differ.

# Echo Integration-trawl Survey Results for Walleye Pollock (Theragra chalcogramma) on the Bering Sea Shelf and Slope During Summer 1999

#### Abstract

Walleye pollock (Theragra chalcogramma) abundance and distribution in midwater were assessed on the eastern Bering Sea shelf and slope between 12 June and 3 August 1999, using echo integration-trawl survey (EIT) techniques aboard the NOAA ship Miller Freeman. The survey extended from Port Moller, Alaska, to the U.S./Russia Convention Line. Results showed that pollock were absent east of $162^{\circ} \mathrm{W}$ long. and were relatively abundant around the Pribilof Islands. West of the Pribilof Islands, pollock were rarely found in water shallower than the 100$m$ isobath. Highest pollock concentrations were at approximately $173^{\circ}$ and $177^{\circ} \mathrm{W}$ long. In 1999, the center of pollock distribution was south and slightly west of the center of distribution observed during previous years $(1994,1996,1997)$. Age distribution was similar east and west of the Pribilofs. The 1996 year class predominated, followed in order of decreasing importance by 1995 and 1992 in the east, and by 1997 and 1995 in the west. Age-1 pollock (1998 year class) were rarely observed. Estimated pollock abundance between 14 m from the surface and 3 m offbottom was 3.29 million metric tons $(t)$ and 9.6 million fish. East of $170^{\circ} \mathrm{W}$ long., estimated pollock abundance was 0.89 million t . West of $170^{\circ} \mathrm{W}$ long., estimated biomass was 2.41 million $t$. Nine percent ( 0.30 million $t$ ) of the total biomass was inside the Steller sea lion Conservation Area (SCA). Proportions of pollock biomass estimated east and west of $170^{\circ} \mathrm{W}$ long. and inside and outside the SCA were similar to that observed during summer EIT surveys conducted during the 1990s. Estimated pollock abundance in a small region of extended trackline in the "horseshoe area" outside of our normal survey area was 0.060 million $t$ during the first pass through the area on Leg 1 of the cruise, and 0.058 million $t$ during the second pass at the end of Leg 2. Future surveys will include trackline extensions into this area.

## INTRODUCTION

Walleye pollock (Theragra chalcogramma) is a gadid fish species that ranges from continental shelf waters of the northeastern Pacific Ocean across the entire Bering Sea, along the Kamchatka Peninsula, into the Okhotsk Sea and the Sea of Japan. It supports one of the largest single-species fisheries in the world. Eastern Bering Sea (EBS) pollock is a primary prey species for declining Steller sea lion (Eumetopias jubatus) populations (Loughlin 1998) inhabiting rookeries adjacent to historically important pollock fishing grounds. Currently, eastern Bering Sea pollock is under close scrutiny in order to quantify relationships between pollock abundance, sea lions, and ecosystem effects of pollock removal by the fishery.

Summer echo integration-trawl (EIT) surveys of Bering Sea pollock were conducted triennially between 1979 and 1994, and in 1996, 1997, and 1999. Results presented here are from the main EIT pollock survey carried out 12 June to 29 July 1999 westward from north of Port Moller, Alaska ( $160^{\circ} 20^{\prime} \mathrm{W}$ long.) to the U.S./Russia Convention Line ( $178^{\circ} 55^{\prime} \mathrm{W}$ long.), and from trackline resurveyed 1 to 3 August in the "horseshoe area"-here defined as the region west of Unimak Pass encompassing the $200-\mathrm{m}$ isobath between approximately $165^{\circ}$ to $167^{\circ} \mathrm{W}$ long., and between $55^{\circ} \mathrm{N}$ lat. and the Aleutian Island chain. The primary cruise objective was to estimate pollock abundance and distribution in the pelagic zone between 3 m off bottom and 14 $m$ from the surface throughout the eastern Bering Sea shelf. Because of the attention focused on Steller sea lions and available pollock prey in the horseshoe area and because of industry requests that we survey more of that area, we added extra transects during the main survey and later resurveyed part of the horseshoe area. The objectives of adding survey trackline were thus to assess pollock abundance in the horseshoe area outside the normal survey area, and to quantify temporal change in that area's pollock abundance during the summer.

Secondary research objectives were to collect pollock target strength (TS) data, to test an acoustic buoy system, and to complete other scientific research projects as requested by Alaska Fisheries Science Center (AFSC) scientists and other researchers (see Appendix II). Two

Russian scientists from the Pacific Research Institute of Fisheries and Oceanography (TINRO), Vladivostok, Russia, participated in this EIT survey. Scientists from the AFSC's National Marine Mammal Laboratory monitored populations of whales and seabirds throughout the cruise (Moore et al. 2000).

## METHODS

## Itinerary (Alaska Daylight Time)

## $\underline{L e g} 1$

| 7-12 June | Embark scientists in Kodiak; acoustic system calibration in Ugak Bay, |
| :--- | :--- |
|  | Alaska. |
|  | Transit to Bering Sea. Equipment tests. |
| 12 June-3 July | Echo integration-trawl survey of the EBS shelf (transects 1 to18). |
| 4-5 July | In port Dutch Harbor, Alaska. |

## Leg 2

| 6-29 July | Acoustic system calibration in Captains Bay. Echo integration-trawl |
| :--- | :--- |
| survey of the EBS shelf (transects 19 to 29). |  |
| 1-3 August | EIT replicate survey of the horseshoe area. Acoustic system calibration in <br> Captains Bay. |

4-5 August Leg 2 end. In port Dutch Harbor.

Leg 3
6-13 August Acoustic buoy trials.
14 August End of cruise.

The survey was conducted on board the NOAA ship Miller Freeman, a 66-m stern trawler equipped for fisheries and oceanographic research. Scientific personnel are listed in Appendix I.

## Acoustic Equipment

Acoustic data were collected with a Simrad EK500 quantitative echo-sounding system (Bodholt et al. 1989; Simrad 1993a, Bodholt 1990, Bodholt and Solli 1992). Two Simrad splitbeam transducers, one operating at 38 kHz and the other at 120 kHz , were mounted on the bottom of the vessel's centerboard. With the centerboard fully extended, the transducers were 9 m below the water surface. Echo integration data sampled with a horizontal resolution of about 9 m and a vertical resolution of 0.5 to 2.0 m , and target strength data were collected simultaneously at both frequencies. Data from the $38-\mathrm{kHz}$ transducer were processed on a SUN workstation using Simrad BI500 echo integration and TS data analysis software (Foote et al. 1991, Simrad 1993b). Acoustic system settings used during the collection were based on results from calibrations (Table 1) and on experience from prior surveys. Acoustic system components, computers, and supporting electronic equipment were housed in a dedicated acoustic laboratory inside the vessel.

Digital echograms were scrutinized to apportion acoustic information into three echosign types, pollock, non-pollock fish, and an invertebrate/fish species mixture. Echograms were recorded on color printers to aid researchers in assigning echosign. SeaPlot (Advanced Marine Technology Corp., Box 1848, Seattle, WA 98111-1848) navigation and charting software was used to $\log$ position information obtained from a Geographical Positioning System (GPS). Results presented in this report were based on $38-\mathrm{kHz}$ data.

## Trawl Gear

Midwater and near-bottom echosign was sampled with an Aleutian Wing 30/26 trawl (AWT). This trawl had full-mesh wings constructed of nylon with polyethylene toward the aft section of the body and the codend (Fig. 1). The headrope and footrope each measured 81.7 m ( 268 ft ). Mesh sizes tapered from 325.1 cm ( 128 in ) in the forward section of the net to 8.9 cm ( 3.5 in ) in the codend. A $3.2-\mathrm{cm}(1.25-\mathrm{in})$ codend liner was used. The AWT was fished with $82.3 \mathrm{~m}(270 \mathrm{ft})$ of $1.9-\mathrm{cm}(0.75-\mathrm{in})$ diameter $8 \times 19$ non-rotational dandylines, and either $340.2-\mathrm{kg}$ ( $750-\mathrm{lb}$ ), $226.8-\mathrm{kg}(500-\mathrm{lb})$, or $113.4-\mathrm{kg}(250-\mathrm{lb})$ tom weights on each side.

Fish on bottom were sampled with an 83/112 bottom trawl without roller gear (hereafter referred to as "bottom trawl"; Fig. 2). Net mesh sizes ranged from 10.2 cm (4 in) forward and 8.9 cm ( 3.5 in ) in the codend to $3.2 \mathrm{~cm}(1.25 \mathrm{in})$ in the codend liner. Headrope and footrope lengths were 25.6 m and $34.1 \mathrm{~m}(83.9 \mathrm{ft}$ and 111.9 ft$)$, respectively, and the breastlines measured 3.4 m and $3.2 \mathrm{~m}(11.3 \mathrm{ft}$ and 10.5 ft$)$. The bottom trawl was fished with $54.9-\mathrm{m}(180-\mathrm{ft})$ double dandylines.

A Methot trawl (Fig. 3) and a bongo net system were used to sample age-0 gadids (these were mainly age- 0 pollock, but as Pacific cod (Gadus macrocephalus) may also have been captured, final identification to species was made in the laboratory after the cruise) and macrozooplankton. The Methot trawl had a rigid square frame with $2.27-\mathrm{m}$ ( 89.5 in ) sides forming the mouth of the net. Mesh sizes were $2 \mathrm{~mm} \times 3 \mathrm{~mm}(0.08 \mathrm{in} \times 0.12 \mathrm{in})$ in the body of the net and $1 \mathrm{~mm}(0.04 \mathrm{in})$ in the codend. To generate additional downward force, a $1.83-\mathrm{m}$ ( $6-$ ft ) dihedral depressor modified from an Isaacs-Kidd midwater trawl was suspended from the square frame. The trawl was attached to a single cable that was fed through the ship's sternmounted A-frame and deployed off the stern ramp. A calibrated General Oceanics flow meter was attached to the mouth of the Methot trawl to determine the volume of water filtered during trawling. The bongo net system consisted of a $60-\mathrm{cm}$ bongo frame with $505-\mu \mathrm{m}$ mesh nets and a 40-kg lead weight used as a depressor. It was deployed from the ship's starboard winch.

Age-0 gadids and zooplankton were also targeted with a Marinovich trawl (Fig. 4). Meshes in the Marinovich trawl measured $7.6 \mathrm{~cm}(3.0 \mathrm{in})$ forward, $3.2 \mathrm{~cm}(1.3 \mathrm{in})$ in the codend, and $0.32 \mathrm{~cm}(0.125 \mathrm{in})$ in the codend liner. Headrope and footrope lengths were each 9.1 m ( 30 $\mathrm{ft})$.

Five $-\mathrm{m}^{2}\left(53.8-\mathrm{ft}^{2}\right)$ "Fishbuster" trawl doors [1,247.4 $\left.\mathrm{kg}(2,750 \mathrm{lb})\right]$ were used with the AWT, bottom trawl, and Marinovich trawl. To prevent the trawl doors from overspreading and damaging the Marinovich trawl when it was towed, a $15.24-\mathrm{m}(50-\mathrm{ft})$ long, $2.5-\mathrm{cm}$ ( $1-\mathrm{in}$ ) diameter restrictor line was used. From each trawl door, two $16.8-\mathrm{m}(55-\mathrm{ft})$ long, $1.9-\mathrm{cm}$ ( $0.75-$ in) diameter, $8 \times 19$ wire ropes connected to a single $82.3-\mathrm{m}(270-\mathrm{ft}), 1.9-\mathrm{cm}(0.75-\mathrm{in})$ bridle. At the net end of the bridle, the restrictor was attached across to the single bridle on the other side.

Two pairs of $18.3-\mathrm{m}$ long $(60-\mathrm{ft}), 1.3-\mathrm{cm}(0.5-\mathrm{in})$ diameter $6 \times 19$ wire ropes led aft from the restrictor line to the head and foot ropes.

A WESMAR third wire or a Furuno wireless net sounder system attached to the head rope of the AWT, bottom trawl, and Marinovich trawl hauls monitored vertical net opening, headrope depth, and water temperature. A Scanmar sounder system monitored Methot trawl depths with a depth sensor attached to the top of the Methot trawl frame. Vertical net openings averaged 21.4 m for the AWT, 2.2 m for the bottom trawl, and 2.0 m for the Marinovich trawl.

Water temperature at depth and tow profiles for all trawls was obtained by attaching a small, retrievable micro-bathythermograph (MBT; Richard Brancker Research, Ltd.) to the net headrope, or, with Methot trawls, to the frame. Water temperature and salinity profile data were collected at calibration sites, at the end of transects 23 to 29 along the U.S./Russia Convention Line, and at other selected locations with a conductivity-temperature-depth (CTD; Sea-Bird Inc.) system. Sea surface temperature, salinity, barometric pressure, true wind speed, true wind direction, ship speed, pitch, roll, and main engine pitch/RPM were collected and stored on the Miller Freeman's Scientific Computing System (SCS).

## Survey Design

The main 1999 EIT survey (Fig. 5) consisted of two segments. During Leg 1, we surveyed transects 1 through 18 between 12 June and 3 July. During Leg 2, we surveyed transects 19 through 29 between 6 and 29 July. The approximately 6,100 nautical mile ( nmi ) survey trackline consisted of parallel north-south transects that began near Port Moller, Alaska, and proceeded westward to the U.S./Russia Convention Line. Southern transect endpoints were either limited by the Alaska Peninsula and the Aleutian Island chain (transects 1 to 12) or the shelf break (transects 13 to 29). Northern endpoints of transects 1 to 20 were based on historical pollock distribution and were moved northward if significant fish echosign was observed. Bottom depths at these endpoints were about 56 to 85 m . As permission to enter the Russia Exclusive Economic Zone (EEZ) was not granted, transects 21 to 29 ended at the U.S./Russia Convention Line. Bottom depths at transect endpoints along the convention line increased westward from 77 m to 252 m . Survey timing was approximately one month earlier than the
three previous summer Bering Sea surveys (1994, 1996, 1997). Transects were designed to coincide with lines of groundfish trawl stations sampled by demersal survey vessels and were spaced 20 nmi apart except in the horseshoe area where transects 9 to 12 were extended and spacing was 10 nmi . These tracklines were modified to better quantify pollock distribution in the horseshoe area both within and outside the historical survey area.

Since we were not able to survey the Cape Navarin area in the Russian EEZ, we used the time originally allocated for that to resurvey the horseshoe area (extended transects 9 to 12) at the end of Leg 2 between 1 and 3 August at 10-nmi spacing, and to deploy an acoustic buoy system (9 to 13 August, Leg 3 of the cruise) to study fish avoidance reactions to a factory trawler and to the Miller Freeman.

The EIT survey was conducted between sunrise and sunset; night operations consisted primarily of collecting pollock TS data and Methot trawl sampling for age-0 gadids and zooplankton. Daylight ranged from about 16.75 hours to 18.75 hours depending on latitude and date. Vessel speed during survey data collection averaged 12 knots.

Trawl hauls were made on echosign to provide information on walleye pollock and to identify associated biota. The decision to trawl in a particular area was based on absolute density of echosign, change in echosign appearance (suggesting a potential change in size or species), and/or to maintain adequate spatial coverage. Researchers processed the catches using standard catch sorting and enumeration procedures (random sampling techniques; Traynor and Nelson 1985, MACE Sampling Manual ${ }^{1}$ ). Catches less than about $1,500 \mathrm{~kg}$ were completely sorted; larger catches were usually subsampled. Total numbers and weights were determined for all species. Weights were determined to the nearest 0.1 kg for the sorted portions of the catch using an electronic, motion-compensating scale ( $60-\mathrm{kg}$ Marel M2000). Walleye pollock were subsampled to determine fork length (FL) composition by sex, as well as to collect stomachs, otoliths, maturity, and individual length-weight measurements. Individual fish weights were

[^0]determined to the nearest 2 g using a $6-\mathrm{kg}$ Marel M2000 scale, and lengths of fish greater than about 5 cm FL were determined to the nearest centimeter (e.g., a fish measuring between 49.5 cm FL and 50.5 cm FL was recorded as 50 cm FL ) using a polycorder measuring device (a combination of bar code reader and hand-held computer, Sigler 1994). Lengths of micronekton including age- 0 gadids were determined to the nearest millimeter and recorded manually. Ages were determined from fish otoliths using the break-and-burn method by scientists in the AFSC Age and Growth Lab. Sexual maturity was determined by visual inspection and was categorized as immature, developing, pre-spawning, spawning, and post-spawning. Samples of age-0 gadids for young-of-the-year walleye pollock studies were either preserved in formalin or frozen whole. Stomach samples for food habits studies were preserved in $10 \%$ formalin, and fish otoliths were preserved in 50\% ethanol.

Methot trawl hauls to sample micronekton and zooplankton were towed obliquely with one or two (targeted tow) exceptions. Catches were divided into gelatinous and non-gelatinous plankton. Jellyfish were weighed and discarded. Non-jellyfish portions were split into fish and non-fish and grouped by species or to the extent possible by visual cues. Fish lengths were measured to the nearest millimeter and individuals were frozen. Invertebrates were preserved in formalin for later identification to species.

Calibrations using standard sphere techniques were made to monitor acoustic system performance. During calibrations, the Miller Freeman was anchored at bow and stern. Two copper calibration spheres, $23 \mathrm{~mm}(120-\mathrm{kHz}$ sphere, $\mathrm{TS}=-40.3 \mathrm{~dB})$ and $60 \mathrm{~mm}(38-\mathrm{kHz}$ sphere, $\mathrm{TS}=-33.6 \mathrm{~dB}$ ) diameters, were suspended at about 25 m and 30 m , respectively, below the centerboard-mounted transducers. Weather, sea state conditions, and acoustic system settings were recorded. After each sphere was centered on the acoustic axis, split-beam target strength and echo integration data were collected to determine acoustic system gain parameters. The average of 10 on-axis target strength and 10 on-axis integration values were recorded. Transducer beam characteristics were measured using a Simrad software program (EKLOBES). Each sphere was pulled through its corresponding transducer beam, TS data were collected on a grid of angle coordinates, and beam shape was estimated (Foote et al. 1987). A CTD was deployed to measure water temperature at the transducer faces and sphere depths.

Target strength data, which are used to scale echo integration data to estimates of absolute fish abundance, were collected on fish when conditions were suitable, that is, relatively calm seas, low fish density at ranges less than 150 m from the transducer, single species, and unimodal size distribution. Low fish density usually occurred after sunset. A midwater trawl was conducted to determine whether species and size distribution were appropriate. If so, the EK500 echosounder was set to ping interval 0 to maximize the number of data points collected. The vessel was passed repeatedly over the fish at speeds of 1 to 3 kts while collecting acoustic target strength data. After data collection, another midwater trawl was made to ensure that fish size/species composition had not changed. Trace data were transferred from the SUN workstation to a laptop PC and processed with Sonardata software (Echoview). Results from analysis of these data will be reported elsewhere.

Echo integration-trawl survey methodology depends on a number of assumptions. For example, we assume that pollock do not react to vessel or trawl noise in ways that adversely affect our data collection. One objective of this cruise was to collect acoustic data from an acoustic buoy to help determine the effects of ship and trawl noise on the behavior of walleye pollock. These results will be reported elsewhere.

## Data Analysis

Estimates of pollock abundance were derived by combining echo integration and trawl data. Echo integration data from 14 m below the surface to within 0.5 m of the bottom, or in the upper $1,000 \mathrm{~m}$ of water, were examined for pollock echosign and stored in a database. Pollock echosign data were classified into two types based on appearance 1) aggregations near or on bottom which were usually fish ranging in size from juveniles to adults, and 2) discrete midwater schools in the upper water column which were usually juveniles. Pollock length data sampled from 107 hauls were aggregated into 25 analytical strata according to echosign distribution, similarity in size composition data, and geographic proximity of hauls. Average pollock backscattering strength along each 0.5 nmi of transect was multiplied by transect width to estimate area backscattering for transect segments. Area backscattering from individual segments were summed to compute total pollock area backscattering for each analytical stratum. They were then scaled using a previously derived relationship between TS and fish fork length
(FL), TS $=20$ Log FL - 66 (Traynor 1996) and the length composition data, to estimate numbers of pollock by size. A length-weight relationship observed from the trawl data was applied to estimate biomass of pollock for each 1-cm length category. Age-specific estimates of biomass and numbers were computed using two age-length keys (east and west of $170^{\circ} \mathrm{W}$ long.) constructed from the ages and lengths of pollock collected from the trawl catch. Vertical distribution of pollock biomass (weighted by total biomass) was computed for each transect using echo integration data collected between 0.5 m from the bottom and 14 m from the surface.

Biomass was estimated 1) for the survey area normally covered as in 1991, 1994, 1996, and 1997, excluding data from extended transects in the horseshoe area in 1999, 2) for the entire geographic area covered by the survey, and 3) for the portion of the horseshoe area not normally covered in the survey. To estimate pollock population and biomass on the Bering Sea shelf, we used midwater and bottom hauls 1 to 116 except for those that caught too few fish. We used hauls 7,10 to 12,15 , and 20 to 23 to scale horseshoe area data. Estimates were made for pollock in midwater, with midwater defined as the water column from 14 m below the surface waters to within 3 m from bottom. Pollock occurring between the bottom and 3 m off bottom were assessed by the 1999 eastern Bering Sea bottom trawl survey for groundfish and crab. Population estimates described were for the normal triennial EIT survey area without added horseshoe trackline, unless stated otherwise. Pollock abundance and distribution were compared and contrasted between known biophysical-oceanographic regions of the Bering Sea shelf (Kinder and Schumacher 1981, Coachman 1986): east and west of $170^{\circ} \mathrm{W}$ long. (Pribilof Islands), and for bottom depths less than $50 \mathrm{~m}, 50$ to $100 \mathrm{~m}, 100$ to 200 m , and greater than 200 m . Because it is not normally surveyed to the extent that it was in 1999, the horseshoe area was treated as a separate stratum. Summary tables include some data collected after the main survey during the acoustic buoy work.

Error bounds on the acoustic data were derived using a one-dimensional (1D) geostatistical approach described in Petitgas (1993), Williamson and Traynor (1996), and Rivoirard et al. (2000). We chose geostatistical methods for computation of error ( $\pm 2$ relative estimation error) because they account for the observed spatial structure and thus provide more realistic estimates of error than those derived from the random sample variance. The 1D method
required equal spacing between transects and no fewer than 10 transects (Petitgas, pers. comm.). Sampling error bounds on the acoustic data were then used to provide confidence intervals on the estimates of biomass. These error bounds quantified only acoustic data sampling variability and hence should be treated as preliminary. Other sources of error (e.g., target strength, trawl sampling, echosign identification) were not included.

## RESULTS AND DISCUSSION

## Calibration

Three acoustic system calibrations were made in conjunction with the cruise: in Ugak Bay, Alaska, prior to the start of Leg 1, and at the ends of Legs 1 and 2 in Captains Bay, Alaska (Table 1). No significant differences were observed in either the $38-\mathrm{kHz}$ or $120-\mathrm{kHz}$ systems during that time period.

## Target Strength

On ten occasions during the survey, suitable conditions were encountered and TS data were collected (Table 2). On each occasion, associated trawl hauls confirmed that 1) pollock was the dominant species in the catch and 2) pollock size composition was unimodal. For preliminary analysis of the acoustic data, a low-density section of the water column was selected and targets accepted within 3 dB of the acoustic axis were averaged to provide estimates of TS. For pollock 36 to 49 cm in length, variability about $\mathrm{TS}=20 \log \mathrm{FL}-66$, the relationship used to scale acoustic data to abundance (Fig. 6), was similar to that reported in Traynor (1996). Further analyses such as checks on the probability of multiple targets, the effect of beam pattern location, and the depth dependence of TS are required to finalize these results.

## Oceanographic Conditions

Physical oceanographic data from 173 MBT casts, 13 CTD casts, and continuous surface thermo-salinograph recordings (Tables 3-5 and Figs. 7-12) showed that summer 1999 was
extremely cold. Surface water temperatures encountered during the survey ranged from just above $0^{\circ} \mathrm{C}$ to slightly above $8^{\circ} \mathrm{C}$ (Fig. 7). Surface water temperatures observed north of the Alaska Peninsula and Unimak Island in mid-June were colder than surface temperatures observed in the northwest survey area in July which by then had begun to stratify. Relatively cool surface water surrounded the Pribilof Islands, especially near St. Paul Island. Average surface water temperature in $1999\left(6^{\circ} \mathrm{C}\right)$ was $3^{\circ}$ to $4^{\circ} \mathrm{C}$ cooler than during the $1996\left(9^{\circ} \mathrm{C}\right)$ and $1997\left(10^{\circ} \mathrm{C}\right)$ EIT surveys, respectively. Salinity of surface water ranged from about 30.2 to just over 33.2 (Fig. 8), and decreased to the north. Bottom temperatures observed during annual bottom trawl surveys were much lower in 1999 than in 1998 (Fig. 9, T. Sample, pers. commun. Alaska Fisheries Science Center, Seattle WA 98115). Midwater temperatures at 50 m depth revealed cold water features in the northwest near $60^{\circ} \mathrm{N}$ lat., $176^{\circ} \mathrm{W}$ long., and adjacent to the U.S./Russia convention line (Fig. 10). In each case, temperatures at 50 m were less than $-1^{\circ} \mathrm{C}$. Along the U.S./Russia Convention Line the depth of the mixed layer was about 20 m (Figs. 11 and 12). Near bottom, warmer, more saline water from the Aleutian Basin appeared to be mixing with colder water on the shelf.

## Biological Sampling

Between mid-June and mid-August 1999, we conducted 108 midwater trawl hauls (103 AWT, 1 bottom trawl flown in midwater, and 4 Marinovich), 14 bottom trawls, 48 Methot trawls, and 2 bongo net tows to identify echosign and collect biological data and samples (Tables 4-10, Figs. 13 and 14). During the main Bering Sea shelf EIT survey, pollock was the dominant catch species in 99 AWT and 13 bottom trawl hauls, accounting for about $96 \%$ and $79 \%$, respectively, of catch composition by weight (Tables 6 and 7). About 5\% of bottom trawl haul catch was composed of Pacific cod and about $8 \%$ of three species of sole (yellowfin (Limanda aspera), flathead (Hippoglossoides elassodon), and rock (Lepidopsetta sp.) sole). All arctic cod (Boreogadus saida) encountered during the survey were caught in haul 65, the northernmost tow which also had the coldest recorded gear temperature $\left(-1.7^{\circ} \mathrm{C}\right)$.

Jellyfish were consistently caught by all gear types (Tables 6-8). Chrysaora sp. jellyfish were second to pollock in abundance by weight in AWT hauls. Jellyfish catch per unit effort (CPUE) in midwater trawls was highest on the outer shelf (100-200 m) near the $100-\mathrm{m}$ isobath in
the horseshoe area, near Pribilof Canyon southeast of St. George Island, and near Zhemchug Canyon south of St. Matthew Island (Fig. 15). Jellyfish comprised $93 \%$ of the catch from Methot tows (Table 8) and $96 \%$ of the catch from Marinovich tows by weight.

Almost 42,000 pollock fork lengths were recorded, and just under 5,000 otoliths were collected during the survey (Table 9). On average, 350 pollock lengths were measured and 41 pollock otoliths were collected from each haul. Over 1,500 pollock stomachs were collected (Table 10) from selected AWT and bottom trawl hauls for food habits analyses. Age-1 pollock from 8 hauls were collected for several special study requests (see Appendix II).

Age-0 gadid density was highest near $55^{\circ} \mathrm{N}$ lat., $167^{\circ} \mathrm{W}$ long., and south of St. Matthew. Island at $59^{\circ} \mathrm{N}$ lat. (Fig. 16). Although Methot trawl hauls caught more jellyfish and euphausiid zooplankton by weight, several hundred age-0 gadids were caught. A few age-0 gadids were also retained in 2 AWT hauls. Most of the age- 0 gadids caught were small relative to lengths of age- 0 gadids we have typically caught during past summer Bering Sea shelf surveys, possibly due to earlier timing of the survey in 1999 than in past survey years. Bongo tows, made primarily in conjunction with North Pacific right whale (Eubalaena glacialis) sightings, caught jellyfish, age0 gadids, other juvenile fishes, and a mixed species assemblage of zooplankton.

Pollock captured in midwater and bottom trawls ranged from 9 to 79 cm in length. Adult pollock ( $\geq 30 \mathrm{~cm}$ FL) were captured in most trawl hauls. Most smaller fish ( $<30 \mathrm{~cm}$ FL) were encountered on transects 5 and 6, north of the Pribilof Islands, and south of St. Matthew Island along a northwest-southeast band between transect 21 and transect 29 near Pervenets Canyon (Fig. 17). Pollock smaller than 20 cm FL (age-1 pollock) were only occasionally captured. Length to weight regression curves fit using Microsoft Excel Solver for length and weight data from pollock caught in midwater and bottom trawl hauls were similar between males and females (Fig. 18), leading to the use of a single, sexes combined, length-weight regression relationship for subsequent population analysis. Trawl haul sex ratios averaged $52 \%$ male over the entire survey, ranging from a minimum of $25 \%$ to a maximum of $76 \%$. Male catch compositions were higher in trawls made east of the Pribilof Islands (Fig. 19). A decline in the male sex ratio with increasing trawl gear depths (Fig. 20) and bottom depths was observed. Most pollock observed
were in developing or post-spawning maturity stages (Fig. 21). When combined, these two stages accounted for $78 \%$ and $79 \%$ of males and females, respectively. Very few pre-spawning or spawning pollock were observed.

Mean fork length at age for pollock (sexes combined), as determined from trawl catch data where otoliths were collected, ranged from about 12 cm FL at age 1 to about 59 or 60 cm FL by age 11 (Fig. 22). The oldest pollock aged was 18 . For all ages, mean length at age appeared to be larger east of $170^{\circ} \mathrm{W}$ long. than west of $170^{\circ} \mathrm{W}$ long., with the exception of age 1 , where too few were observed in the east to make a comparison. For this reason, we used two separate age-length keys when computing abundance at age estimates.

## Pollock Distribution and Abundance

## Bering Sea shelf

Pollock (from 14 m below the surface to 3 m off bottom) were absent or at very low densities in the eastern portion of the survey area. No pollock were observed on transects 1 to 3 . Pollock were first observed on transect 4 and they increased in density at $165^{\circ} \mathrm{W}$ long., northwest of Unimak Island. Abundance of pollock was lower between $166^{\circ}$ and $167^{\circ} \mathrm{W}$ long. and then increased again. Thereafter, pollock were present on each transect from about $168^{\circ} \mathrm{W}$ long. westward to the U.S./Russia Convention Line (Fig. 23). West of the Pribilof Islands, pollock were rarely found where bottom depths were shallower than 100 m . The highest pollock concentrations occurred on the outer shelf (between the 100 and 200 m isobaths) at approximately $173^{\circ} \mathrm{W}$ long. (transect 21) and $177^{\circ} \mathrm{W}$ long. (transect 27) east of Zhemchug and Pervenets Canyons, respectively, and on transect 28 near the $200-\mathrm{m}$ shelf break. In several of these areas dense pollock aggregations occupied most of the water column (Fig. 24).

Other echosign observed, categorized using trawl catch information and experience from prior surveys, were attributed to non-pollock fish and an undifferentiated mixture of jellyfish, macrozooplankton, age-0 gadids, and individual fishes. The latter was classified as an invertebrate-fish species mixture. Distribution of this invertebrate-fish species mixture was different than that for echosign attributed to age 1 and older pollock (Fig. 25). This species mixture was mainly observed in the middle shelf region (where bottom depths were shallower
than 100 m ), and was most concentrated northwest of the Pribilof Islands and south of St. Matthew Island. Since this mixture of backscatter cannot be easily scaled to biomass, its magnitude in any given location is not well known, and its representation here is not comparable to that for pollock biomass which has been properly scaled.

Vertical distribution of biomass (weighted by total biomass) for each transect (Fig. 26), averaged about $80 \%$ off bottom ( 3 m off to 14 m from the surface) and $20 \%$ near bottom ( 0.5 m to 3 m off bottom). Biomass was lower and fish were found closer to bottom on eastern transects. Western transects had higher biomass and had more of it distributed above 3 m off bottom.

When the 1999 area surveyed was matched to the areas surveyed in 1994, 1996, and 1997, estimated pollock biomass was 3.29 million metric tons ( $t$ ) and estimated numbers were 9.6 billion. The $95 \%$ confidence interval around the estimated biomass was 2.93-3.64 million t .

Proportions of pollock biomass estimated east and west of $170^{\circ} \mathrm{W}$ long. and inside and outside the SCA were similar in summer 1999 to that observed during previous summer EIT surveys conducted in the 1990s. About $9 \%$ of the estimated biomass ( 0.30 million t) was located in the SCA, $18 \%$ ( 0.58 million t) was east of $170^{\circ} \mathrm{W}$ long. but outside the SCA, and $73 \%(2.41$ million t ) was west of $170^{\circ} \mathrm{W}$ long. (Table 11). East of the Pribilof Islands (east of $170^{\circ} \mathrm{W}$ long.), modal lengths were 36,46 , and 25 cm (Fig. 27). Inside the SCA , the $25-\mathrm{cm}$ length mode (age-2 pollock - see Fig. 22) was absent and a greater proportion of fish larger than about 50 cm was present in contrast to outside the SCA (Fig. 28). West of the Pribilof Islands, modal lengths were smaller - 30, 22, and 45 cm . Estimated pollock abundance between 14 m from the surface and 3 m off-bottom for the total survey area, including extended transects in the horseshoe area, was 3.35 million t and 9.7 billion fish.

Pollock abundance and length composition were compared and contrasted by region, bottom depth, and longitude (Fig. 29). East of $170^{\circ} \mathrm{W}$ long. on the middle shelf (between the 50 and 100 m isobaths) pollock with modal lengths at 45 cm and 37 cm (and to a lesser extent 25 cm ) predominated and abundance was about 981 million fish at 0.47 million t . About the
same number of pollock ( 957 million) were observed east of $170^{\circ} \mathrm{W}$ long. on the outer shelf (between the 100 and 200 m isobaths), but most were about $36-\mathrm{cm}$ fork length, and biomass was lower $(0.390$ million t$)$. East of $170^{\circ} \mathrm{W}$ long. in water deeper than 200 m (excluding the horseshoe area), far fewer pollock were observed ( 23 million, 0.013 million t ). West of $170^{\circ} \mathrm{W}$ long. on the middle shelf, we estimated that there were about 694 million fish ( 0.320 million t ) with a peak at the $45-\mathrm{cm}$ length mode and additional modes at 22 to 23 cm (age 2) and $13-\mathrm{cm}$ (age 1) pollock. The vast majority of pollock inhabited waters west of $170^{\circ} \mathrm{W}$ long. on the outer shelf (about 7 billion fish, 2.08 million $t$ ), comprising $30,22,38$, and 45 cm modal fork lengths, in order of decreasing importance. We also observed a few 13-cm (age-1) fish. In offshore waters deeper than 200 m and west of $170^{\circ} \mathrm{W}$ long., very few pollock were encountered ( 12 million fish, less than 0.01 million $t$ ).

In 1999, estimated pollock abundance at length (Table 12) indicated lower numbers of 12 to 18 cm fish and higher numbers of 28 to 33 cm fish in contrast to numbers from 1994, 1996, and 1997 EIT survey estimates. Estimated abundance at age (Table 13) revealed that in 1999, the 28 to 33 cm length mode was age- 3 pollock from the 1996 year class. In 1999, age-3 pollock were followed, in order of decreasing importance, by the age 4 (1995), age 2 (1997), and age 7 (1992) year classes, and age distribution was similar east and west of the Pribilof Islands (Fig. 30).

## Horseshoe area transects

The Bering Sea region to the west of Unimak Pass surrounding the $200-\mathrm{m}$ isobath is referred to by fishermen and scientists as the "horseshoe area". Previous summer EBS shelf EIT surveys have covered only part of this area. In 1999, in response to concerns that this area may hold significant quantities of pollock and should be surveyed, we added and extended transects in this region. After an initial pass through the area during Leg 1 in mid-June as part of our larger survey effort, we returned to the area at the end of Leg 2 between 1 and 3 August to look for changes in distribution and abundance. During both passes (Fig. 31), large aggregations of pollock were observed between Unimak Pass and $166^{\circ} \mathrm{W}$ long. West of $166^{\circ} \mathrm{W}$ long., very little pollock echosign was encountered, and then only at the shelf break next to the Aleutian Islands. However, during pass 1 (Fig. 31a), most pollock were concentrated on the slope between Akun
and Akutan Islands. In August, during the second pass through the area (Fig. 31b), pollock were more dispersed to the north and west of Akutan Island. Pollock in the horseshoe area were much larger than those observed elsewhere on the EBS shelf (Fig. 29) - averaging about $55-\mathrm{cm} \mathrm{FL}$. Estimated abundance in the area was about the same for both passes; 0.060 million $t$ during pass 1 and 0.058 million $t$ during pass 2 . Future surveys will include trackline extensions into this area.

## ACKNOWLEDGEMENTS

Lowell Fritz and Bill Karp provided helpful comments on earlier versions of this manuscript. Scientists in the MACE Program and officers and crew of the NOAA ship Miller Freeman provided essential support towards the completion of this work.

Table 12. Estimated length composition (numbers, and biomass in metric tons) of pollock between 14 m below the surface and 3 m off bottom from Bering Sea shelf echo integration-trawl surveys, 1994-1999. No surveys were made in 1995 or 1998; 1999 estimates exclude fish from additional sampling in the "horseshoe area" between Unimak and $167^{\circ} \mathrm{W}$ long.

## 83/112 EASTERN

Figure 2.--Diagram of the 83/112 eastern bottom trawl used during the 1999 summer echo integration-trawl survey of the Bering Sea shelf and slope.

Figure 3. Diagram of the Methot trawl used during the summer 1999 echo integration-trawl survey of the Bering Sea shelf and slope.

## MARINOVICH MIDWATER TRAWL-2

(Four Identical Panels)

Figure 4. Diagram of the Marinovich trawl used during the summer 1999 echo integration-trawl survey of the Bering Sea shelf and slope.

Figure 5. Transect lines from the summer 1999 pollock echo integration-trawl survey, with CTD cast locations. Underlined numbers indicate transect sequence. "B" indicates a CTD done in conjunction with a Bongo net tow. CTD 501 was in Ugak Bay, Kodiak Island, Alaska, and 502 was southeast of Kodiak Island.

Figure 6. Preliminary results of in situ target strength measurements of pollock collected during the summer
1999 echo integration-trawl survey of the eastern Bering Sea shelf and slope. For reference, TS=20 Log L-66 curve (solid line) is plotted along with TS $=20 \mathrm{Log}$ L-65 and TS $=20 \mathrm{Log}$ L-67 curves (dashed lines).

Figure 7. Transect lines with surface temperature contours (in degrees C) during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf. Underlined numbers indicate transect sequence.

Figure 8. Transect lines with surface salinity contours (in ppt) during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf. Underlined numbers indicate transect sequence.

Figure 9. Near bottom water temperatures $\left({ }^{\circ} \mathrm{C}\right.$ ) observed during the summer 1999 (top) and summer 1998 (bottom) eastern Bering Sea crab and groundfish surveys. (T. Sample, pers. commun. Alaska Fisheries Science Center, Seattle, WA 98115).

Figure 10. Transect lines with temperature contours at $50-\mathrm{m}$ water depth (degrees C ) during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf. Underlined numbers indicate transect sequence, and diamonds indicate locations of vertical temperature profiles.

Figure 11. Water column temperature profile (degrees C) along the U.S./Russia Convention Line during the summer 1999 echo integrationtrawl survey of the eastern Bering Sea shelf. Vertical lines represent CTD casts taken at northern extents of transects whose sequence is indicated by underlined numbers.

Figure 12. Water column salinity profile (ppt) along the U.S./Russia Convention Line during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf. Vertical lines represent CTD casts taken at northern extents of transects whose sequence is indicated by underlined numbers.

Figure 13. Transect lines with midwater and bottom ("b") trawl haul locations during the summer 1999 pollock echo integration-trawl survey of the eastern Bering Sea shelf and slope. A "t" indicates a target strength tow. Underlined numbers indicate transect sequence.

Figure 14. Transect lines with haul locations for the Marinovich (" m ") and Methot trawl (201-248) and bongo net (301-302) during the summer 1999 pollock echo integration-trawl survey of the eastern Bering Sea shelf and slope. Underlined numbers indicate transect sequence.

Figure 15. Jellyfish CPUE in midwater hauls during the summer 1999 echo integration-trawl survey of pollock on the eastern Bering Sea shelf.

Figure 17. Transect lines with trawl haul average lengths (single value) for unimodal size compositions or length modes (e.g., 14/22/45) for multimodal size compositions during Legs 1 and 2 of the summer 1999 pollock echo integration-trawl survey of the eastern Bering Sea shelf and slope. Haul locations where fewer than 50 pollock were caught were excluded. Underlined numbers indicate transect sequence.

Figure 18. Length weight regressions with observed values and best-fit curve for male, female, and all pollock during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf.

Figure 19. Transect lines and percent male pollock in the catch at trawl haul locations during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf. Haul locations where fewer than 50 pollock were caught were excluded. Transect numbers are underlined, and the Steller sea lion Conservation Area (SCA) is outlined.

Figure 20. Trawl haul male pollock catch percentage as a function of gear depth during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf. Hauls catching fewer than 50 pollock were excluded.

Figure 21. Maturity stages of pollock observed during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf.

Figure 22. Mean lengths at age of walleye pollock collected during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf. Numbers indicate sample sizes.

Figure 24. Pollock echosign observed along transect 27 east of Pervenets Canyon from the 1999 summer echo
integration-trawl survey of the Bering Sea shelf and slope. Echosign density increases with increasing darkness of grayscale (at right). Total trackline distance shown is 10 nautical miles.
(1) SSBuItg 69

Figure 27. Estimated length composition of walleye pollock (millions of fish) east and west of
$170^{\circ} \mathrm{W}$ long. between 14 m from the surface and 3 m off bottom from the summer 1999 echo integration-trawl survey of the Bering Sea shelf.

Figure 30. Proportional population-at-age estimate obtained during the summer 1999 echo
integration-trawl survey of the eastern Bering Sea shelf.

Figure 31. Pollock acoustic backscatter along extended tracklines surveyed in mid-June (a), and along tracklines re-surveyed 1-3 August (b) in the "horseshoe area" during the summer 1999 echo integration-trawl survey of the eastern Bering Sea shelf.

## Appendix I

## Scientific personnel

The principal investigator was Neal Williamson (206) 526-6417, AFSC, Seattle, WA.

Leg 1 (7 June- 3 July)

| Name | Sex/ | Position | Organization |
| :--- | :--- | :--- | :--- |
|  | Nationality |  |  |

## Appendix II <br> Other Research Projects-List of Contacts

## Leg 1

1. Juvenile pollock for seabird diet study (Daniel D. Roby, U. of Alaska, 541-737-1955)

## Legs 2 and 3

1. Pollock fin clips for genetics study on adult pollock (Mike Canino, UW/AFSC, 206-526-2097)

## Legs 1, 2, and 3

1. Pollock stomach collections (Pat Livingston, AFSC, 206-526-4242)
2. Cold pool study on age-1 pollock (Tina Wyllie-Echieverria, Brigham Young University, 801-356-3118)
3. Observer Program fish ID training: Pacific cod, Atka mackerel, small rockfish, and sablefish collection (Sheryl Corey, AFSC, 206-526-4227)
4. Jellyfish predation study: jellyfish stomach sample/length composition collection (Ric Brodeur, AFSC, 541-867-0336)
5. Salmon catch composition data and collection of juvenile chum salmon for otoliths (Ed Farley, AFSC Auke Bay Laboratory, 907-789-6085).

## RECENT TECHNICAL MEMORANDUMS

Copies of this and other NOAA Technical Memorandums are available from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22167 (web site: www.ntis.gov). Paper and microfiche copies vary in price.
