**ABSTRACT**

From July 11 to September 2, 1991, the National Oceanic and Atmospheric Administration's (NOAA) Carbon Dioxide ( $\text{CO}_2$ ) and Radiatively Important Trace Species (RITS) programs participated in an oceanographic research cruise conducted aboard the NOAA ship MALCOLM BALDRIGE. This report presents the research from that cruise that was conducted for the  $\text{CO}_2$  program, which has recently been renamed the Ocean-Atmosphere Carbon Exchange Study (OACES). During Leg 1 of this cruise, (Fortaleza, Brazil to Montevideo, Uruguay), 33 CTD hydrographic casts and 17 Go-Flo™ hydrographic (productivity) casts were conducted. Samples were also collected while underway on Leg 1, for the determination of the fugacity of  $\text{CO}_2$  ( $f\text{CO}_2$ ) of the air and surface water. Leg 2, (Montevideo, Uruguay-Fortaleza, Brazil), collected 21 days of underway  $f\text{CO}_2$  measurements, conducted five CTD hydrographic casts and nine Go-Flo™ hydrographic (productivity) casts. This report contains tables of the following data: hydrography from each CTD cast at the bottle trip depths, (including salinity, oxygen and nutrients), discrete carbon parameters, underway carbon parameter values, and data from productivity casts. Descriptions of the sampling techniques and analytical methods used in the collection and processing of these data are also presented in this report.

KEY WORDS: alkalinity,  $\text{CO}_2$ , carbon dioxide, chlorophyll, CTD, dissolved organic carbon, hydrography, nutrients, productivity, salinity, sigma-theta, South Atlantic, temperature

## **1. INTRODUCTION**

Human activity is producing gases, most notably carbon dioxide ( $\text{CO}_2$ ), and other trace gases including chlorofluorocarbons, nitrous oxide and methane, which are being released into the atmosphere and causing more of the radiation being emitted by the earth to be absorbed. This increased absorption is resulting in a net warming of the earth's atmosphere and creating a phenomenon commonly known as the "Green House Effect". Only about half of all of the anthropogenic  $\text{CO}_2$  that is released into the atmosphere each year remains there. The global ocean is thought by many to be the ultimate destination, or "sink" for the 'missing'  $\text{CO}_2$ . The understanding of the absorption and storage properties of the oceans is therefore essential to assessing the potential for climatic change due to man's effect on the radiation balance of the atmosphere.

The National Oceanic and Atmospheric Administration's (NOAA) Carbon Dioxide ( $\text{CO}_2$ ) program and Radiatively Important Trace Species (RITS) programs participated in a multifaceted oceanographic research cruise conducted aboard the NOAA ship MALCOLM BALDRIGE from July 11 to September 2, 1991. The NOAA  $\text{CO}_2$  program has been recently renamed and is now called Ocean-Atmosphere Carbon Exchange Study (OACES). The two primary objectives of the cruise were to: (1) assess the role of biomass burning emissions from surrounding continents in controlling the distribution of ozone in the tropical South Atlantic atmospheric boundary layer for the RITS program and (2) to measure and establish baseline values and determine source and sink regions of  $\text{CO}_2$  in the equatorial and the South Atlantic Ocean for OACES. This report presents only the OACES-related data from that cruise. These data include: hydrography, nutrients, discrete carbon, underway carbon parameters and productivity data from both legs of the cruise.

### **1.1. DESCRIPTION OF STUDY AREA**

This study was conducted on two consecutive research cruise legs during 1991. Leg 1 sailed from Fortaleza, Brazil on July 11, 1991, proceeded NE to approximately  $5^\circ$  N and  $25^\circ$  W and then turned south and steamed along the  $25^\circ$  W line to  $28^\circ$  S. At  $28^\circ$  S, the track line turned SW to  $32^\circ$  W and continued South to  $42^\circ$  S before turning NW and ending in Montevideo, Uruguay on August 5, 1991. Leg 2 departed Montevideo, Uruguay on August 13, 1991 and proceeded NE to a point about  $2^\circ$  S and  $4^\circ$  W before subsequently steaming NW, and then SW ending in Fortaleza, Brazil on September 2, 1991. The cruise tracks for Legs 1 and 2 are shown on Figure 1.

## **2. DATA COLLECTION AND ANALYTICAL METHODS**

Thirty-three CTD hydrographic stations on Leg 1, and five CTD hydrographic stations on Leg 2 were occupied to collect discrete water sample data. A CTD/rosette unit with a Neil Brown™ CTD instrument equipped with 24, 10-L Niskin™ bottles was utilized for these casts. Water samples were collected from the Niskin™ bottles for salinity,

c

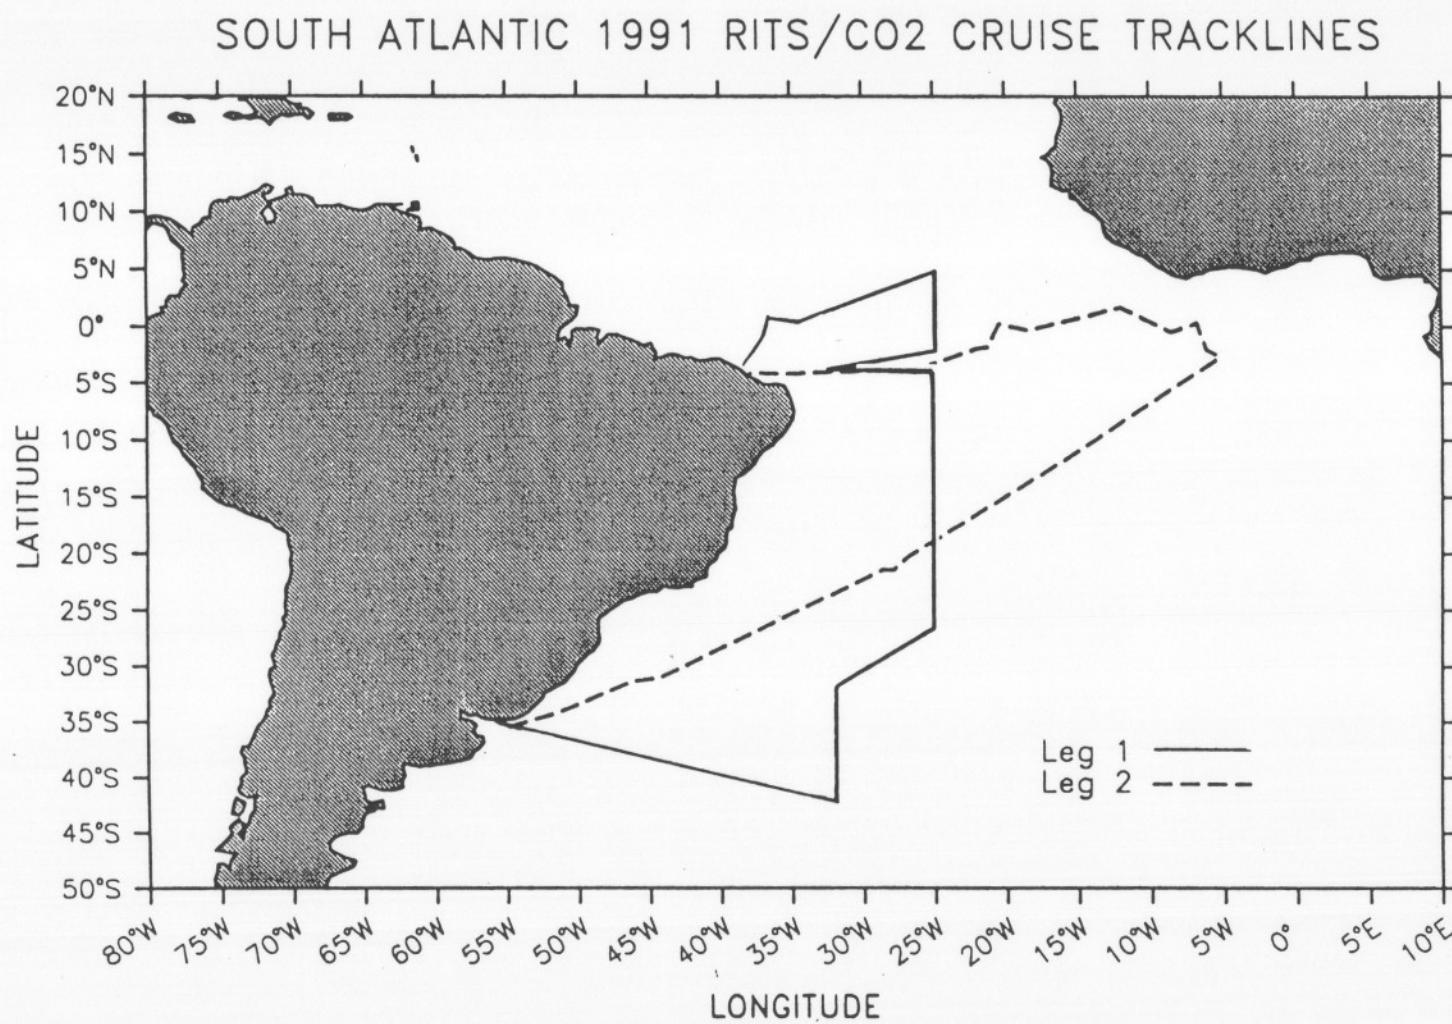

Figure 1: Study area and cruise track lines for NOAA Ship MALCOLM BALDRIGE.

oxygen and nutrient measurements as well as carbon related parameters including total dissolved inorganic CO<sub>2</sub> (TCO<sub>2</sub>), fugacity of CO<sub>2</sub> (fCO<sub>2</sub>), total alkalinity (TALK) and Dissolved Organic Carbon (DOC). Continuous underway air and seawater surface samples for fugacity of CO<sub>2</sub> (fCO<sub>2</sub>) analysis were collected during both legs of the cruise. Go-Flo™ hydrographic casts were also conducted on both legs for productivity measurements. These casts were made using 10-L Go-Flo™ bottles mounted on Kevlar™ hydrowire. Salinities and sea surface temperatures were also measured continuously during the entire cruise by a thermosalinograph. In most cases, if there was no bottle salinity value available for a given sample position, the electronically derived CTD value was used in calculations requiring a salinity measurement. More detailed information on individual data collection, or analyses procedures may be found in the respective data sections.

## 2.1 HYDROGRAPHIC METHODS

### 2.1.1 CTD and Hydrographic Operations

All CTD operations were conducted using the same Neil Brown™ Instrument Systems Mark III CTD equipped with standard temperature and conductivity sensors, a Beckman™ polarographic dissolved oxygen sensor, and an auxiliary Seabird™ temperature sensor. Laboratory calibrations were performed, before and after the cruise, and were used in conjunction with Niskin™ bottle data, to calibrate the CTD data. Pressure and temperature data listed in this report are based on the post-cruise calibration. Temperature accuracy is estimated to be ± .005°C, and pressure accuracy to be ± 5 decibars.

#### *Water sampling*

Water samples were collected in 10-L sampling bottles using a General Oceanics 24-place rosette system. Bottles were electronically fired during the upcast, with markers placed in the digital file for use in determining exact bottle trip CTD values for calibration. Once on deck, aliquots were taken for laboratory analyses. Figure 2 shows the CTD cast bottle trip locations used for hydrographic and other discrete water sample measurements collected during Leg 1 of the cruise. More detailed information about the subsampling and analysis procedures for the various water property measurements may be found below. Tables with the hydrographic data from this study may be found in Appendix B.

#### *Oxygen*

Dissolved oxygen samples were the first samples collected from 10-L Niskin™ bottles once the CTD unit was back on deck. The oxygen samples were collected, in 150-mL ground-glass stoppered sample bottles and were analyzed using the method described by Carpenter (1965), with computer-controlled colorimetric endpoint determination as described in Friederich, Sherman, and Codispoti (1984). Oxygen samples that have been collected and analyzed using the above methodology have a precision greater than one percent. Values are marked as questionable by italicizing them in the data tables for any of the following reasons: High or low photometric endpoints in the titration process due to improper light levels; possible contamination during processing (air bubbles seen in bottle, etc.); inexplicable large differences between bottle sample data values and apparently valid electronic CTD values.

SOUTH ATLANTIC 1991 RITS/CO<sub>2</sub> CRUISE  
HYDROGRAPHIC AND DISCRETE CARBON DATA SAMPLE POSITIONS

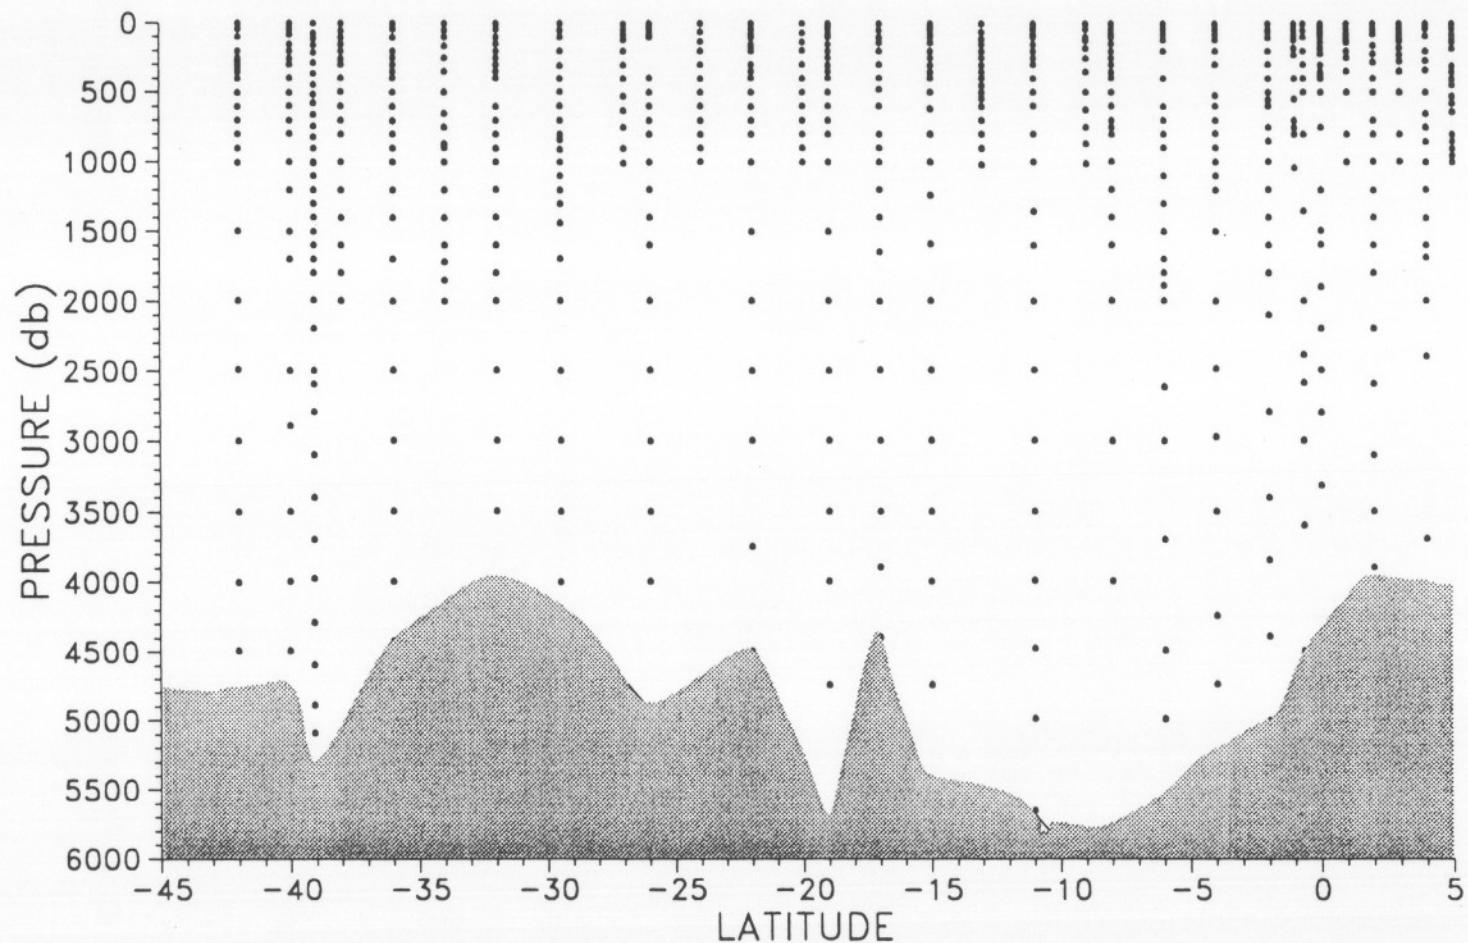

Figure 2: Sampling positions for all Niskin™ Bottle derived data. The coarse smoothing grid for bottom topography causes sharp topographic features, such as the mid Atlantic Ridge at 0° N, to be eliminated.

### *Salinity*

Salinity samples were collected in 200-mL bottles. New caps were used for each sample. Bottle salinities were measured using a Guildline™ 8400 Autosal and P114 standard seawater in a temperature controlled van. Conductivity ratios were converted to salinities conforming to the PSS78 standard. Since CTD conductivity was relatively stable (except casts 32 and 33), bottle salinities that differed substantially from CTD salinity measurements are marked as questionable in the data tables.

### *Temperature Density and Depth*

Depth, Potential Temperature and Density ( $\sigma$ -theta) values listed in the tables were calculated using standard Woods Hole Oceanographic Institute (W.H.O.I.) hydrographic subroutines. Depth is calculated from pressure using methods based on Saunders and Fofonoff (1976); density is determined by methods presented in F. Millero and A. Poisson (1981); and potential temperature referenced to zero pressure ( $\theta$ ) is calculated by integrating the adiabatic lapse rate using a fourth-order Runge-Kutta algorithm. Sigma-theta values, (ten meter averages), from the Leg 1 CTD casts are contoured and presented in Figure 3.

### 2.1.2 Nutrient Analysis Methods

Nutrient samples were collected from 10-L Niskin™ bottles in aged 60-mL linear polyethylene bottles after three complete seawater rinses and stored in the dark at 4°C until analysis was completed (within 24 hours of sample collection). Concentrations of dissolved inorganic nitrite ( $\text{NO}_2$ ), dissolved inorganic nitrate ( $\text{NO}_3$ ), and silicate ( $\text{SiO}_4$ ), reported in micromoles/liter, were determined using an AlpKem™ RFA/2 Auto-Analyzer aboard ship.

#### *Nitrates*

The automated colorimetric procedures and methodologies used in the analysis of nitrite and nitrate are essentially similar to those described by Armstrong et al. (1967), with modifications described in Atlas et al. (1971). Standardizations were performed prior to each sample run with working solutions prepared aboard ship from pre-weighed "Baker Analyzed" reagent grade standards. Nitrite ( $\text{NO}_2$ ) was determined by diazotizing with sulfanilamide and coupling with N-1 napthylethelendiamine dihydrochloride to form an azo dye. The color produced is proportional to the nitrite concentration. Samples for nitrate ( $\text{NO}_3$ ) analysis were passed through a copperized cadmium column, which reduces nitrate to nitrite and the resulting nitrite concentration was then determined as described above. The detection limits for nitrite and nitrate were 0.1  $\mu\text{moles/L}$  and 0.4  $\mu\text{moles/L}$ , respectively. The precision of duplicate standards measurements was  $\pm 0.25\%$  at 8  $\mu\text{moles/L}$  for nitrite and  $\pm 0.2\%$  at 40  $\mu\text{moles/L}$  for nitrate. The accuracy for both analytes was assumed to be  $\pm 1\%$  since no absolute standards were available. Contoured nitrate values from Leg 1 of this study are presented in Figure 4.

#### *Silicates*

The analytical procedures and methodologies used in the analysis of silicate are essentially similar to those described by Armstrong et al. (1967), with modifications described in Atlas et al. (1971). Silicate

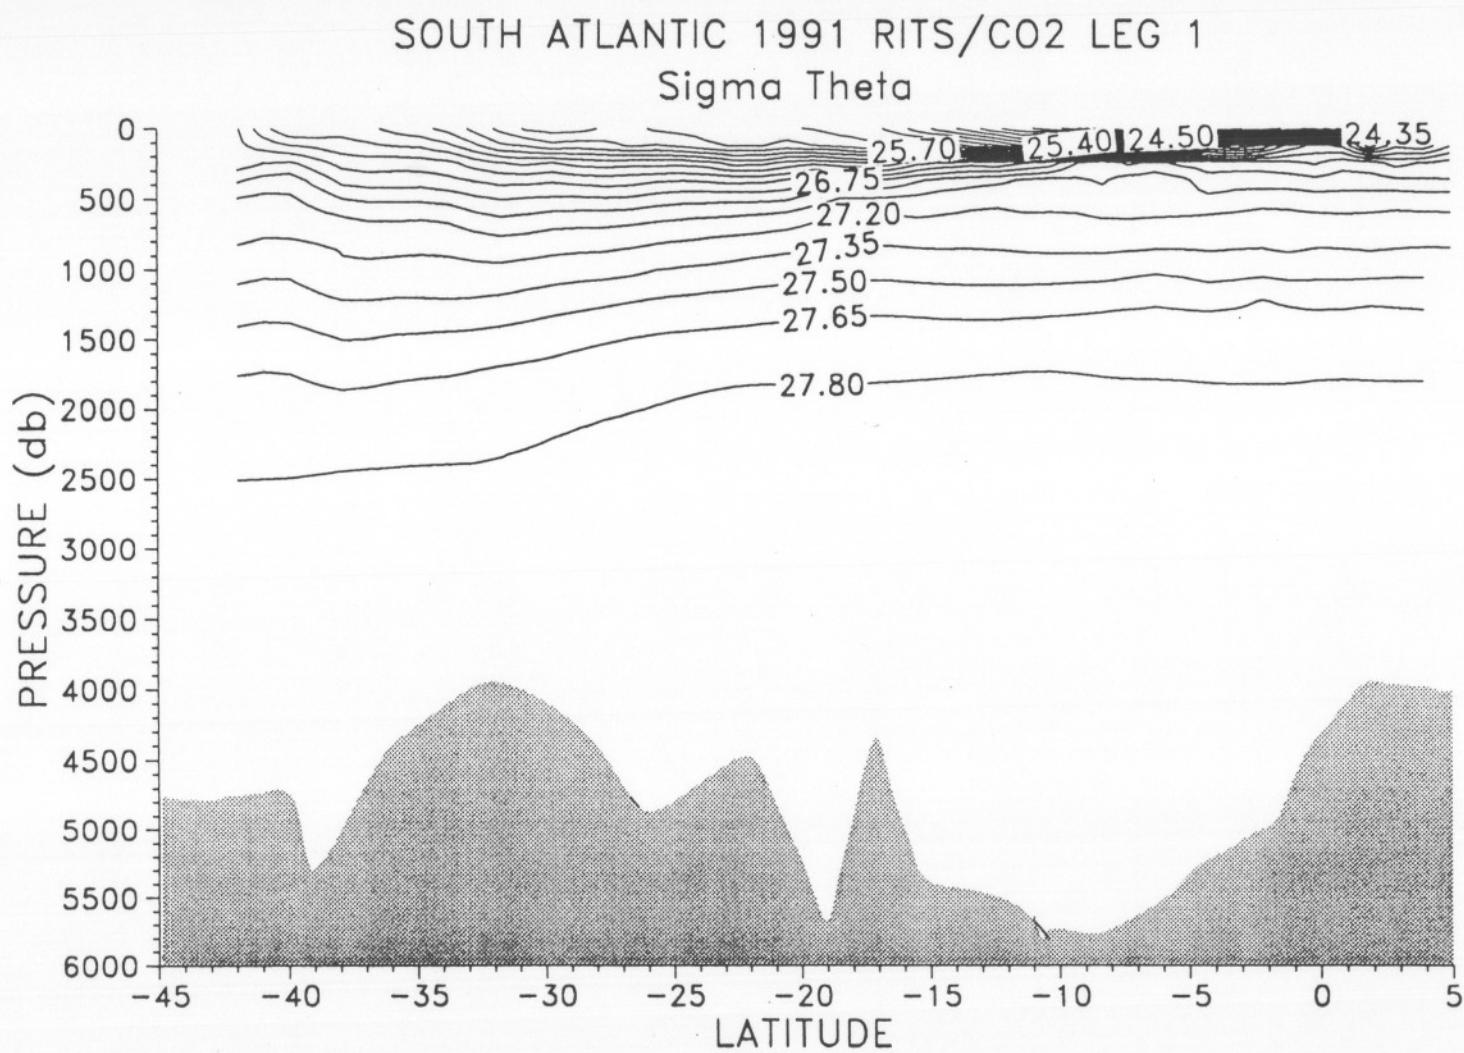

Figure 3: Potential density cross section utilizing 10 decibar averaged sigma-theta data from CTD stations on Leg 1. Contour interval = 0.15. See Figure 2 caption for comment regarding bottom topography.

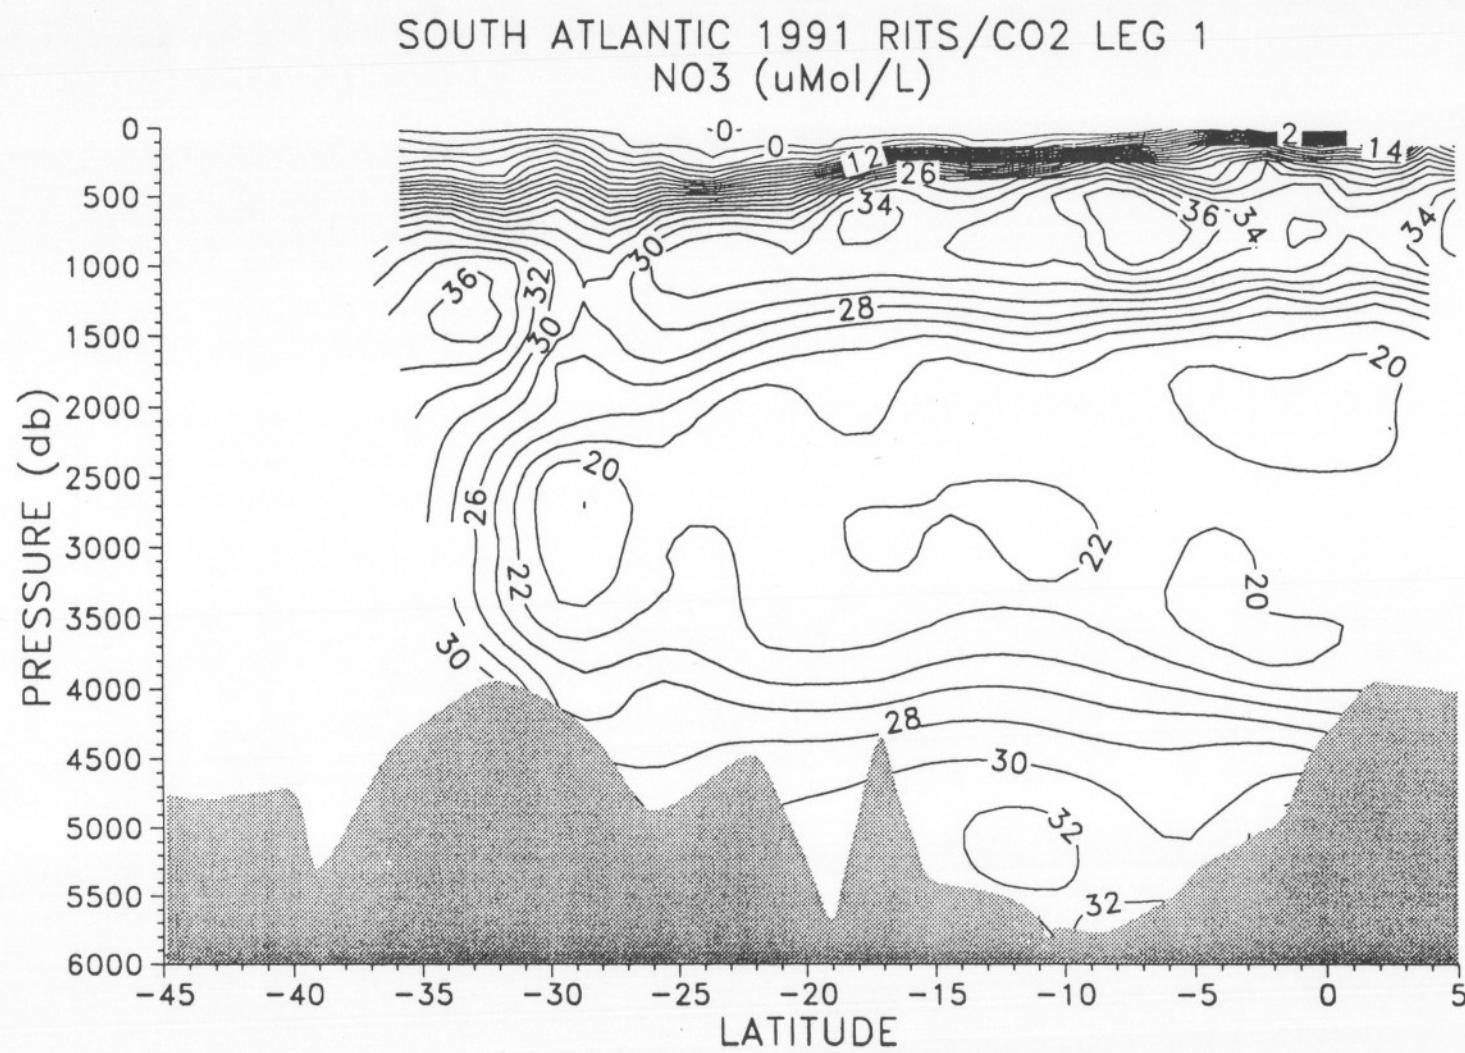

Figure 4: Nitrate data cross section for Leg 1. Contour interval = 2  $\mu\text{mol/L}$ . See Figure 2 caption for comment regarding bottom topography.

was determined from the reduction of silicomolybdate in acidic solution to molybdenum blue by ascorbic acid. The color produced is proportional to the concentration of silicate in the sample, with a detection limit of 0.4  $\mu$ moles/L. The precision of duplicate measurements was  $\pm 0.17\%$ , at 120  $\mu$ moles/L of silicate, with an assumed accuracy of  $\pm 1\%$ , since no absolute standards were available. Figure 5 is a contour plot of the silicate values from Leg 1 of this cruise.

## 2.2 CARBON PARAMETERS

### 2.2.1 Total Dissolved Inorganic CO<sub>2</sub>

#### *Sampling*

Samples for dissolved inorganic CO<sub>2</sub> (TCO<sub>2</sub>) analysis were drawn from 10-L Niskin™ bottles into 500-mL Pyrex™ bottles using Tygon™ tubing. Bottles were rinsed once, and while being careful to not create bubbles, they were filled from the bottom until half of the bottles' volume had overflowed. The tube was pinched off and withdrawn, creating a 5-mL headspace volume. Each sample had 0.2 mL of a saturated HgCl<sub>2</sub> solution added to act as a sample preservative. The sample bottles were then sealed with glass stoppers lightly covered with Silastic™ grease. The samples were then stored in darkness at ambient (room) temperature for a maximum of two days prior to being analyzed.

#### *Analysis*

CO<sub>2</sub> analysis was performed by extracting the inorganic carbon in the sea water samples by acidification and subsequent displacement of the gaseous CO<sub>2</sub> into a coulometer cell. Two coulometers were used on the cruise. One was patterned after that of D. Chipman of Lamont-Doherty Earth Observatory (L.D.E.O.) and shall hereafter be referred to as the "Chipman" system; the other had a Single Operator Multiparameter Metabolic Analyzer (SOMMA) inlet system developed by K. Johnson of Brookhaven National Laboratories (B.N.L.) and shall be called the "Johnson" system.

The samples were introduced into the "Chipman" system by injecting a 23-mL aliquot from a 500-mL bottle with a glass syringe. A metal syringe guide/stopper assured that the injection volume was constant and reproducible. The temperature of the water remaining in the bottle was measured immediately after withdrawing the sample and was used to determine the density of the sample injected into the extraction tube. Subsequently, 1 mL of 10% phosphoric acid was injected into the extraction tube. The acid was purged with N<sub>2</sub> prior to use and stored in a bottle with CO<sub>2</sub>-free headspace. The CO<sub>2</sub> was extracted with ultra high purity N<sub>2</sub> which was run through a Malcosorb™ CO<sub>2</sub> scrubber. The evolved CO<sub>2</sub> gas went through a PTFE™ 0.2 micron filter to remove water droplets and aerosols and then titrated coulometrically using an UIC (model 5011) CO<sub>2</sub> coulometer. The gas stream was not dried prior to introduction into the cell. Sample analyses time was set to 20 minutes.

Prior to analysis on the automated "Johnson" system, each 500-mL sample bottle was inserted into a water bath at 20°C. Water from the bottle was displaced into a thermostatted pipette with a (500 ppm CO<sub>2</sub> in air) pressure gas. The water was then injected into an extraction chamber which contained 1 mL of 10% H<sub>3</sub>PO<sub>4</sub> solution which had been stripped of CO<sub>2</sub> prior to injection of the sample. The evolved gas was

10

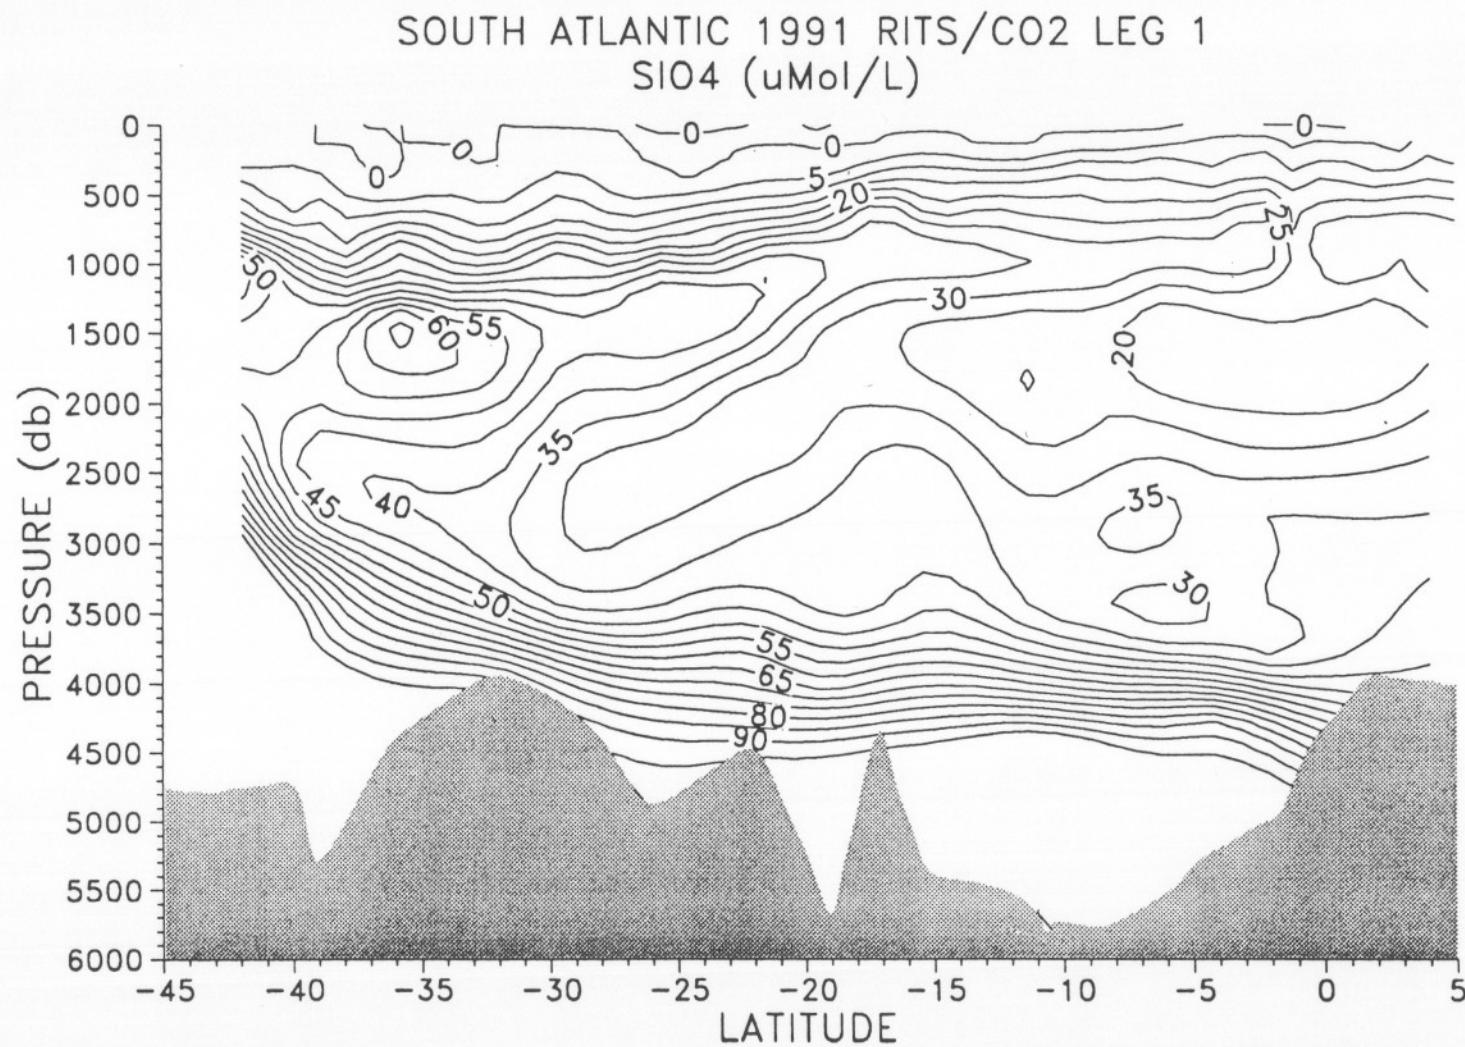

Figure 5: Silicate data cross section for Leg 1. Contour interval = 5  $\mu\text{mol/L}$ . See Figure 2 caption for comment regarding bottom topography.

run through a condenser and a MgClO<sub>4</sub> drying column to dry the gas stream, and through an ORBO-53™ tube to remove volatile acids. Additional details concerning this system and procedures are presented in Johnson (1992), and Johnson et al. (1993).

Both the "Johnson" and "Chipman" coulometers were calibrated by injecting aliquots of pure CO<sub>2</sub> using an 8-port or 10-port valve with two sample loops of known volume. The CO<sub>2</sub> gas volumes bracketed the amount of CO<sub>2</sub> extracted from the water samples. The gas loops of the "Johnson" system were calibrated by weight with water at B.N.L. (Wilke et al., 1993). The gas loop volumes on the "Chipman" system were calibrated by alternating gas loop injections from the two gas sampling valves with the same coulometer using the "Johnson" loop volume as a reference. Liquid reference materials (RM's) consisting of bicarbonate in sodium chloride solution were supplied by A. Dickson of Scripps Institute of Oceanography (S.I.O.) and were run on each coulometer cell during the cruise. The results were close to the values determined manometrically by C. D. Keeling at S.I.O.

Av. value of RM's run on "Chipman" 2306.18 ± 1.47 n = 30

Av. value of RM's run on "Johnson" 2304.58 ± 1.50 n = 100

Manometric value [Dickson Batch #6] 2304.74 ± 0.94 n = 10

Note: All determinations, including replicates from the same bottle are pooled for the averages.

#### Calculations

The instrument was calibrated three times for each cell solution with a set of gas loop injections. Calculation of the amount of CO<sub>2</sub> injected was determined according to methods described in the Department of Energy (DOE) CO<sub>2</sub> handbook (1991). The gas loops yielded a calibration factor for the instrument defined as:

$$\text{Cal. factor} = \frac{\text{calculated moles of CO}_2 \text{ injected from gas loop}}{\text{measured moles of CO}_2 \text{ injected}}$$

The concentration of CO<sub>2</sub> ([CO<sub>2</sub>]) in the samples was determined according to:

$$[\text{CO}_2] =$$

$$\frac{\text{Cal. factor} * (\text{Counts-Blank} * \text{Run Time}) * 2.0728 * 10^{-4} \mu\text{mol/count}}{\text{pipette volume} * \text{density of sample}}$$

where Counts is equal to the instrument reading at the end of the analysis; Blank is the counts/minute determined from blank runs performed at least once for each cell solution; Run Time is the minutes the sample is run; 2.0728 \* 10<sup>-4</sup> is the conversion factor from counts to μmol. The pipette volume (or syringe volume) was determined by taking aliquots of distilled water at a known temperature from the volumes prior to, during, and after the cruise. No trend was observed in the change in volumes. Standard deviation in the series of measurements over three months was 0.03% of the total weight. The weights with the appropriate densities were used to determine the volume of the syringes

and pipette. Calculations of pipette and syringe volumes, of densities, and of final CO<sub>2</sub> concentrations were all performed according to procedures outlined in the DOE CO<sub>2</sub> handbook (1991). All total CO<sub>2</sub> values are corrected for dilution by 0.2 mL of mercuric chloride solution assuming the solution is saturated with atmospheric CO<sub>2</sub> levels and total water volume is 540 mL yielding a correction factor of 1.00037. Figure 6 shows a contour plot of the coulometer derived TCO<sub>2</sub> values from Leg 1 of this study.

### 2.2.2 Discrete fugacity of CO<sub>2</sub> (fCO<sub>2</sub>)

#### *Sampling*

Samples were drawn from 10-L Niskin™ bottles into 500-mL Pyrex™ volumetric flasks using Tygon™ tubing. Bottles were rinsed once and while taking care not to entrain air bubbles, were filled from the bottom until half the bottles' volume overflowed. Five mL of water was then withdrawn with a pipette to create a small expansion volume. A saturated HgCl<sub>2</sub> solution, (0.2 mL), was added to the samples as a preservative. The sample bottles were then sealed with a screw cap containing a polyethylene liner and stored in darkness at room temperature for a maximum of two days prior to analysis.

#### *Discrete fCO<sub>2</sub> analyzer*

The AOML discrete fCO<sub>2</sub> system is patterned after the design described in Chipman et al. (1993) and is discussed in detail in Wanninkhof and Thoning (1993). The major difference between the systems is that the AOML system uses a Licor™ (model 6262) non-dispersive infrared analyzer, while the Chipman et al. system utilizes a gas chromatograph with a flame ionization detector and a methanizer, which quantitatively converts CO<sub>2</sub> into CH<sub>4</sub> for analysis.

Samples are collected in 500-mL volumetric flasks and are brought to a temperature of 20.00 ± 0.02°C, using a pre-bath at 19–21°C and a Neslab™ (model RT-220) controlled temperature bath. A 60-mL headspace is created in the flask by replacing the water using a compressed standard gas with a CO<sub>2</sub> mixing ratio close to the fCO<sub>2</sub> of the water. The headspace is circulated in a closed loop through the infrared analyzer (IR), which measures CO<sub>2</sub> and water vapor levels in the sample cell. The headspaces of the two flasks are equilibrated simultaneously in channels A and B. While headspace from the flask in channel A goes through the IR analyzer, the headspace of the flask in channel B is recirculated in a closed loop. The sample in the A channel is equilibrated for 17 minutes while the air from the headspace of the flask flows through the IR analyzer. The sample in the B channel is circulated in a closed loop for 10 minutes and through the IR for 8 minutes. An expandable volume, consisting of a balloon, keeps the contents of the flasks at room pressure.

In order to maintain measurement accuracy and precision, a set of six gas standards is run through the system after every four to ten seawater samples. The standards have mixing ratios of 201.4, 354.1, 517.0, 804.5, 1012.2, and 1529 ppm, which bracket the fCO<sub>2</sub> at 20°C (fCO<sub>2,20</sub>) values observed in the water column of the South Atlantic.

The determination of fCO<sub>2</sub> in water from the discrete analyses involves several steps. The mixing ratio and detector response for the

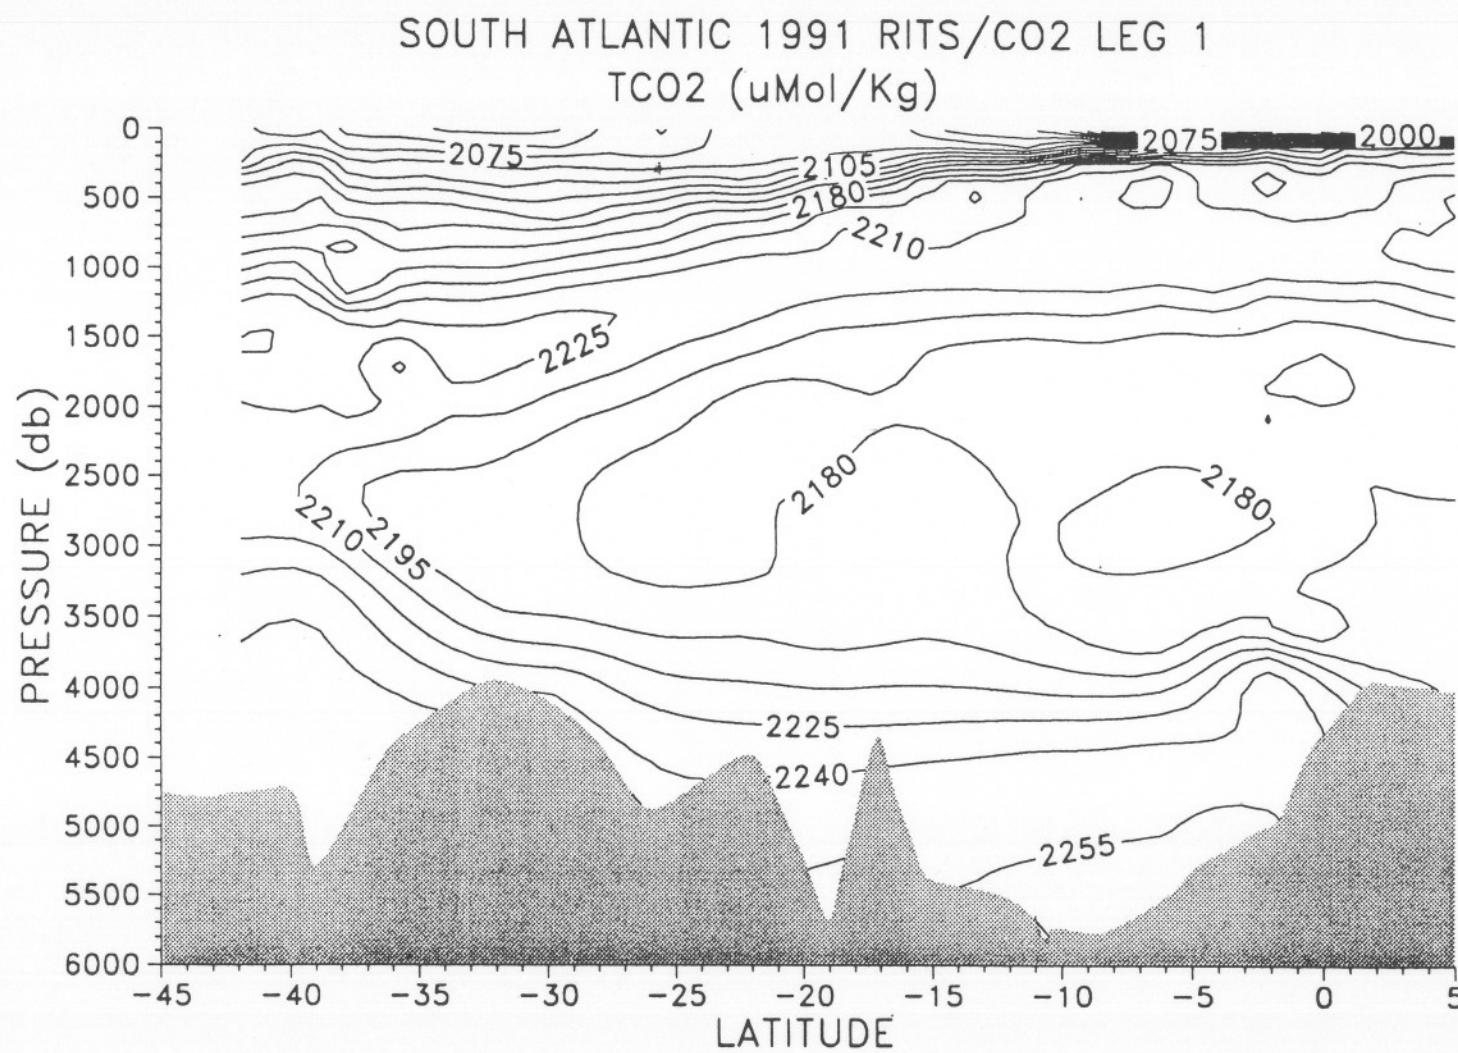

Figure 6: Dissolved inorganic carbon dioxide, TCO<sub>2</sub> (AOML value) cross section for Leg 1. Contour interval = 15  $\mu\text{mol}/\text{Kg}$ . See Figure 2 caption for comment regarding bottom topography.

standards are normalized for temperature and pressure. The IR voltage output for samples are normalized with regard to pressure and are corrected for the presence of water vapor and converted to a mixing ratio. The mixing ratio in the headspace is converted to fugacity and corrected to fugacity of CO<sub>2</sub> in the water sample prior to equilibration by accounting for change in total CO<sub>2</sub> in water during the equilibration process (for details see, Wanninkhof and Thoning, 1993). The change in the fCO<sub>2</sub> of water, (fCO<sub>2</sub>w), caused by the change in TCO<sub>2</sub> is calculated using the constraint that total alkalinity (TALK), remains constant during exchange of CO<sub>2</sub> gas between the headspace and the water. The calculation is outlined in the appendix of Peng et al. (1987).

### 2.2.3 Methods for Potentiometric Total Alkalinity, TCO<sub>2</sub> and pH Measurements

The total alkalinity and inorganic carbon (Dickson, 1981) in the water samples was determined during the cruise by making potentiometric titrations. The two systems used consisted of a Metrohm™ 615 titrator and Metrohm™ 605 pH meter that are operated by an Apple™ computer (Thurmond and Millero, 1982). The titration is done by adding HCl to the seawater past the carbonic acid end point. Seawater samples were contained in a water jacketed cell controlled to a constant temperature of 25°C with a Forma™ water bath. Due to the large number of samples to be measured, the titrations were not made over the entire pH range. This allowed a complete titration to be made in about 10 minutes. Unfortunately during the cruise the disk reader of the Apple™ computers failed and the titrations had to be run by hand.

The titrant solution was prepared from standard HCl and reagent grade NaCl. The 0.25 M HCl contained 0.45 M NaCl to yield an ionic strength equivalent to the seawater (0.7 M). The acid was standardized with weighed amounts of Na<sub>2</sub>CO<sub>3</sub> dissolved in 0.7 M NaCl solution in the laboratory. A blank titration was made to evaluate the residual alkalinity (14 µM) due to impurities in the NaCl. The normality of the acid was found to be 0.2514 ± 0.0001 M). Measurements made in the laboratory after the cruise yielded the same concentration of the HCl.

The electrode system used to measure the emf of the sample during a titration consisted of a ROSS™ glass pH electrode and an Orion™ double junction reference electrode. The response of the electrodes were determined by HCl titration in 0.7 M NaCl solution. Electrodes with non-Nernstian behavior were discarded (slope larger than ± 0.5 mV of the theoretical slope). Three cells were used during the cruise (Cell 1, 2 and 3). They had volumes (V) and standard emf's, (E\*), in seawater of V = 231.10 ± 0.02 cm<sup>3</sup>, 238.99 ± 0.02 cm<sup>3</sup>, 239.64 ± 0.02 cm<sup>3</sup>; E\* = 592, 585, 580 mV (± 1 mV), respectively.

The total alkalinity and total CO<sub>2</sub> were calculated from the volumes of acid added and the measured emf's using a least-squares Gran technique. A chemical model (Dickson, 1981) was used to determine the equivalence points on the titration curve.

The initial emf reading of the seawater solution before the titration began was used to determine the pH. The pH at 25°C was determined using the E\* calculated for each titration. The concentrations of H<sup>+</sup> are in mol/kg and are on the seawater scale ([H<sup>+</sup>]<sub>T</sub>

$= [H^+]_F + [HSO_4^-] + [HF]$ ). The electrodes were calibrated before going to sea by making titrations of 0.7 M NaCl with 0.25 M HCl (with 0.45 M NaCl) and TRIS buffer. The TRIS buffer was made up in the laboratory and calibrated with hydrogen electrode system before the cruise (Millero, 1986). The total seawater pH scale (Dickson, 1984) was used for all the measurements.

#### 2.2.4 Dissolved Organic Carbon Methods

A Shimadzu™ DOC-5000 Total Organic Carbon Analyzer with the ASI-5000™ Automated Sample Injector was purchased for use on this cruise. This is an automated DOC instrument utilizing high temperature catalytic combustion (680°C) and non-dispersive infrared detection. It was installed on the ship and operated in NPOC mode (Non-purgable organic carbon) which means the "DOC" reported does not include volatile species. The only modification to the standard operating procedures for this commercial instrument was that "zero" (high-purity) oxygen was used instead of compressed air for the carrier stream.

The water column was sampled using Niskin™ water sampling bottles mounted on the 24 bottle rosette/CTD package that was described in the Hydrographic Methods section of this report. Samples for the DOC analysis were collected on deck in the 40-mL glass vials which fit the autosampler carousel. The samples were free-flowed from the Niskin™ bottle into the vial. Care was taken so that the inner surfaces of the vial and the water stream from the valve did not come into contact with any other surfaces. Each vial was filled and rinsed with sample three times, before being filled for analysis. The sample was immediately acidified to pH of 2 by addition of vacuum-distilled HCl, and sealed with Parafilm™ and a plastic snap ring. Sample levels were kept far enough below the top of the vial to insure that the water did not come into contact with the Parafilm™ during subsequent handling.

The samples were moved to the autosampler for immediate processing, or were stored at 4°C if a delay was necessary. The autosampler was set to purge each sample of inorganic carbon species by bubbling high purity oxygen through the sample for five minutes immediately before the analysis. The gas stream continued to be introduced during the analytical process, except when the water was being transferred to the instrument by the sipper. Samples and standards were run in replicate, (usually six per determination). Peak area for each replicate was recorded for later statistical handling.

Data calibrations on this cruise were produced by the standard addition method; three levels of known concentrations of KHP (Potassium Hydrogen Phthalate) were added to aliquots of a sample and the series run as if they were discrete samples. This procedure insures that matrix effects and artifacts due to handling of the samples are reflected in the calibrations. The single largest problem in calibrating the DOC instrument is evaluating the "instrument blank", the part of the reported signal which is NOT due to organic carbon. Low organic carbon water produced by redistillation of research grade distilled water over potassium permanganate, and batch UV-irradiated Gulf Stream seawater were run daily as samples to monitor this apparent blank (which was usually <4 µmol/L). Data tables with the discrete carbon-related data from this study are in Appendix B.

## 2.3 PRODUCTIVITY

### 2.3.1 Methods for Chlorophyll Measurements

Chlorophyll *a* concentrations were determined from duplicate 250-mL and 300-mL aliquots taken from a flow-through system and Go-Flo™ hydrographic casts respectively. The samples were filtered through Whatman GF/F filters which were then placed in 5 mL of a 40/60 (vol.:vol.) mixture of dimethyl sulfoxide (DMSO):90% Acetone solution and placed in the dark for one hour. This is a modification of the Shoaf and Liim, (1976) and Burnison, (1980) procedure. The fluorescence of the DMSO/Acetone extracts were measured at sea with a Turner Designs™ fluorometer model 111. The fluorometer was calibrated at sea with Sigma™ chlorophyll *a*, following the method of Parsons et al., (1984).

Water was collected hourly from the seawater flow-through system for chlorophyll *a* analysis. The intake valve is located in the bow of the ship at about 3 m below the surface. The Go-Flo™ hydrographic casts for both chlorophyll *a* and production rate measurements were made using 10-L Go-Flo™ bottles mounted on Kevlar hydrowire. Six sampling depths were selected according to light levels. Seawater samples were collected at 100, 50, 30, 15, 6, and 1 % of the incident surface irradiance ( $I_0$ ). Diffuse vertical attenuation coefficients (K), in reciprocal meters, were estimated at all stations using a Secchi disk and the relation  $K = 1.4/\text{Secchi depth}$ . Photosynthetically available radiation (PAR) was also measured with depth using a Lambda Instruments™ LI-190S  $4\pi$  spherical collector. Calculations for this measurement were done after each cast. All Go-Flo™ hydrocasts were performed within a three hour time window (between 7-10 am local), to help ensure uniform sampling conditions throughout the cruise. Contour plots of chlorophyll *a* values from Leg 1 of this cruise are found in Figure 7.

### 2.3.2 Methods for Productivity Measurements

Productivity measurements were made using the  $^{14}\text{C}$ arbon method, as originally described by Steemann-Nielsen (1952), with modifications by Fitzwater et al. (1982) to minimize trace metal contamination. All materials were acid-cleaned in dilute (0.1 N) HCl, then rinsed with Milli-Q™ water. Incubation bottles were rinsed with the seawater sample prior to being filled. Samples were collected from the Go-Flo bottles in darkened 2-L acid-cleaned polycarbonate bottles. Approximately 250 mL of sample was transferred to each of three (two light, one dark) acid cleaned polycarbonate bottles and inoculated with 5  $\mu\text{Ci}$  of  $\text{NaH}^{14}\text{CO}_3$  with acid cleaned Eppendorf™ pipettes. The Amersham-Serle™ isotope ( $^{14}\text{C}$ -bicarbonate) was prepared in a carrier solution of 0.3 g/L Baker Instra Analyzed™  $\text{NaHCO}_3$ . The three incubation bottles were then placed into small Plexiglas™ tubes that were wrapped with blue film, (#TS-51-xsr from Madico Inc.). The number of wraps were calibrated to simulate the 100, 50, 30, 15, 6, and 1 % of the incident surface  $I_0$ , corresponding to optical depths listed in Appendix C of 0, -0.69, -1.20, -1.90, -2.81, and -4.60. The samples were incubated on deck for 24 hours in clear Plexiglas™ cylinders filled with circulating surface seawater. The samples were then taken to the lab where they were filtered, in

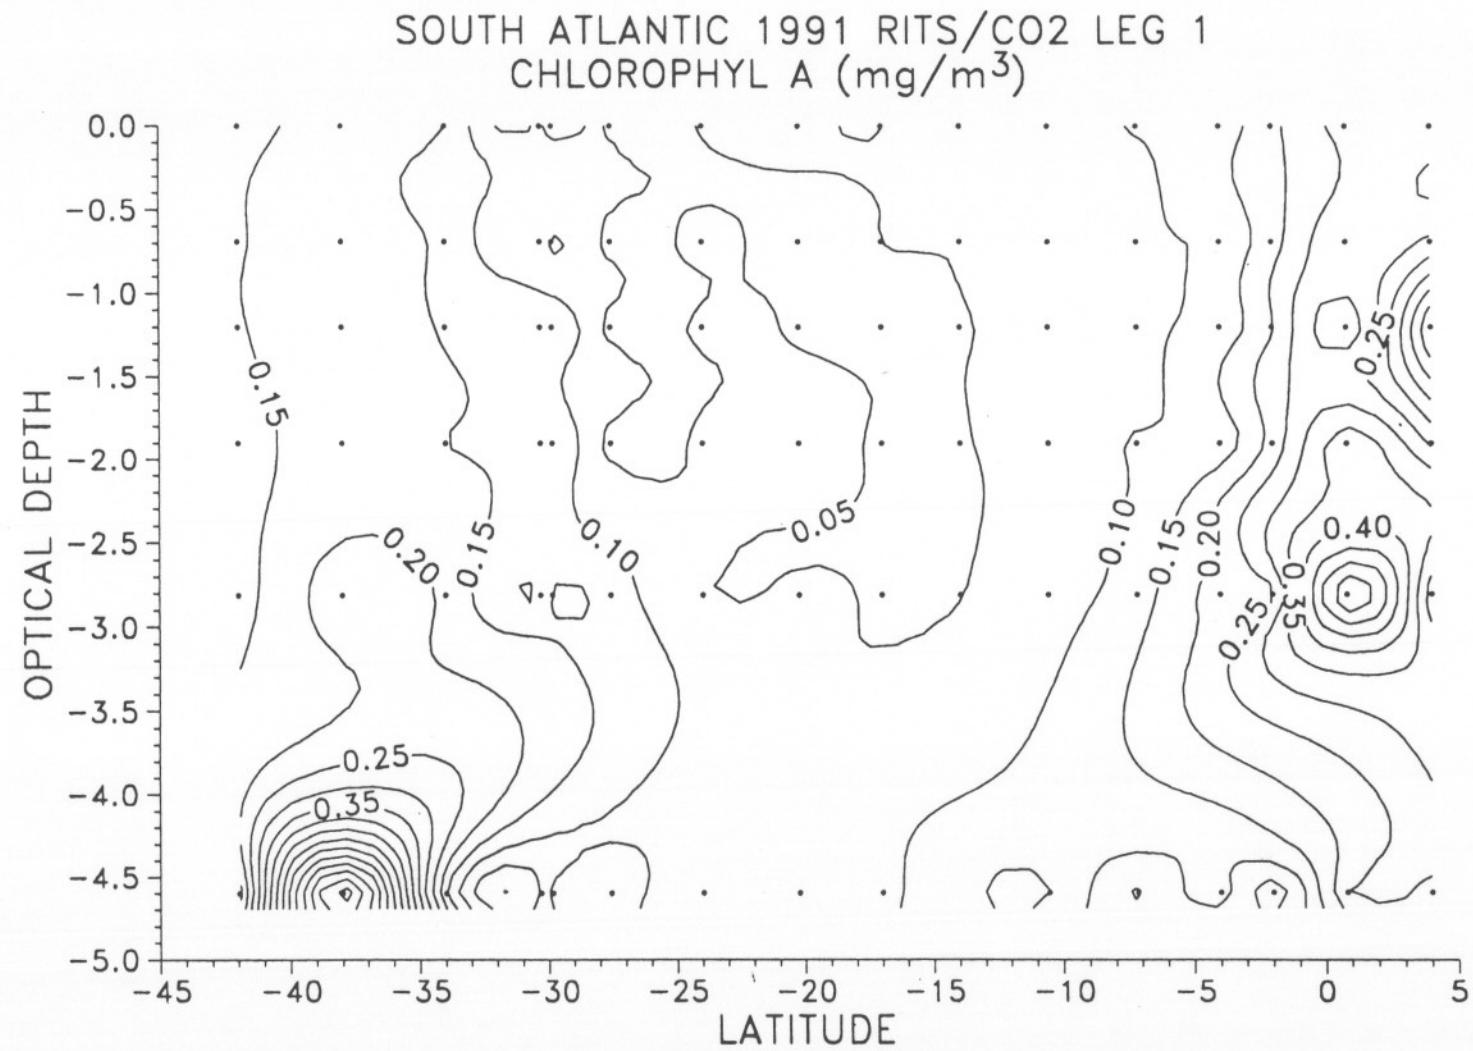

Figure 7: Chlorophyll a cross section from Leg 1. Dots represent sample locations. Contour interval = 0.05 mg/m<sup>3</sup>.

darkness, through Whatman GF/F filters, and rinsed with filtered seawater without being exposed to air.

Filtrations were performed under a pressure differential of <50 mm Hg to minimize cell breakage (Goldman and Dennett, 1985). The filters were transferred to Nalgene™ scintillation bags, and acidified with 0.5N HCl. After one hour, a 3-mL aliquot of Universol™ (ICN radiochemicals) scintillation cocktail was added to each bag as described in Hitchcock (1986).

Isotope activity of the samples was measured aboard ship with a Tracor model 300 scintillation counter. Production rate ( $\text{mg C/m}^3/\text{h}^1$ ) was calculated from the mean value of the two light bottles minus the dark bottle activity. A contour plot of productivity measurements from Leg 1 of this cruise is presented in Figure 8. Productivity data tables from this study are in Appendix C.

#### **2.4 UNDERWAY MEASUREMENT METHODS**

##### *Sampling*

During Legs 1 and 2 of the S. ATL-91 cruise, underway measurements of fugacity of  $\text{CO}_2$  in surface seawater, ( $f\text{CO}_2\text{w}$ ), and air, ( $f\text{CO}_2\text{a}$ ) were performed with an automated system. The seawater intake was located in the ship's bow bubble, approximately 3 m below the water line. A thermosalinograph, which records temperature and salinity was placed in a shunt off the main seawater intake line, in the bow bubble as well. Since there was evidence of seawater being heated prior to its reaching the thermosalinograph, water temperature was acquired from a hull mounted probe used for acoustic Doppler current profile data reduction. On Leg 2, discrete samples were taken from the underway system at six-hour intervals and analyzed for  $\text{TCO}_2$ ,  $f\text{CO}_2$ , and major nutrients in addition to the continuous  $f\text{CO}_2$  measurements. Cruise tracks from Legs 1 and 2, with the range of  $f\text{CO}_2\text{w}$ - $f\text{CO}_2\text{a}$  values represented by stick diagrams, are presented in Figures 9 and 10. The underway carbon data is presented in tables in Appendix D.

##### **2.4.1 Underway $f\text{CO}_2$ Measurements**

The shipboard automated underway  $f\text{CO}_2$  system runs on an hourly cycle during which three gas standards, a headspace sample from the equilibrator, and an ambient air sample are analyzed. The equilibrator, which was designed by R. Weiss of S.I.O., is made from a large (58 cm H x 23 cm ID) Plexiglas™ chamber. The equilibrator has a shower head in the top through which surface seawater is forced at a rate of 20-30 L/min. The water spray through the 16-L head space and the turbulence created by the jets impinging on the surface of 8-L of water, cause the gases in water and headspace to equilibrate. A drain 20 cm from the bottom of the equilibrator discharges excess water from the system over the side of the ship. Air in the equilibrator head space is circulated with an Aircadet™ pump (model 7530-40) at 6 L/min in a closed loop through a mass flow meter (MFM) and back pressure regulator. During 23 minutes of each hour, 75 mL/min is teed off upstream of the back pressure regulator through a mass flow controller (MFC) and into the 12-mL sample cell of a Licor™ (model 6251) non-dispersive infrared analyzer. The air removed from the equilibrator through the IR analyzer is replaced with ambient air through an intake/vent line that runs to the outside of the ship. The

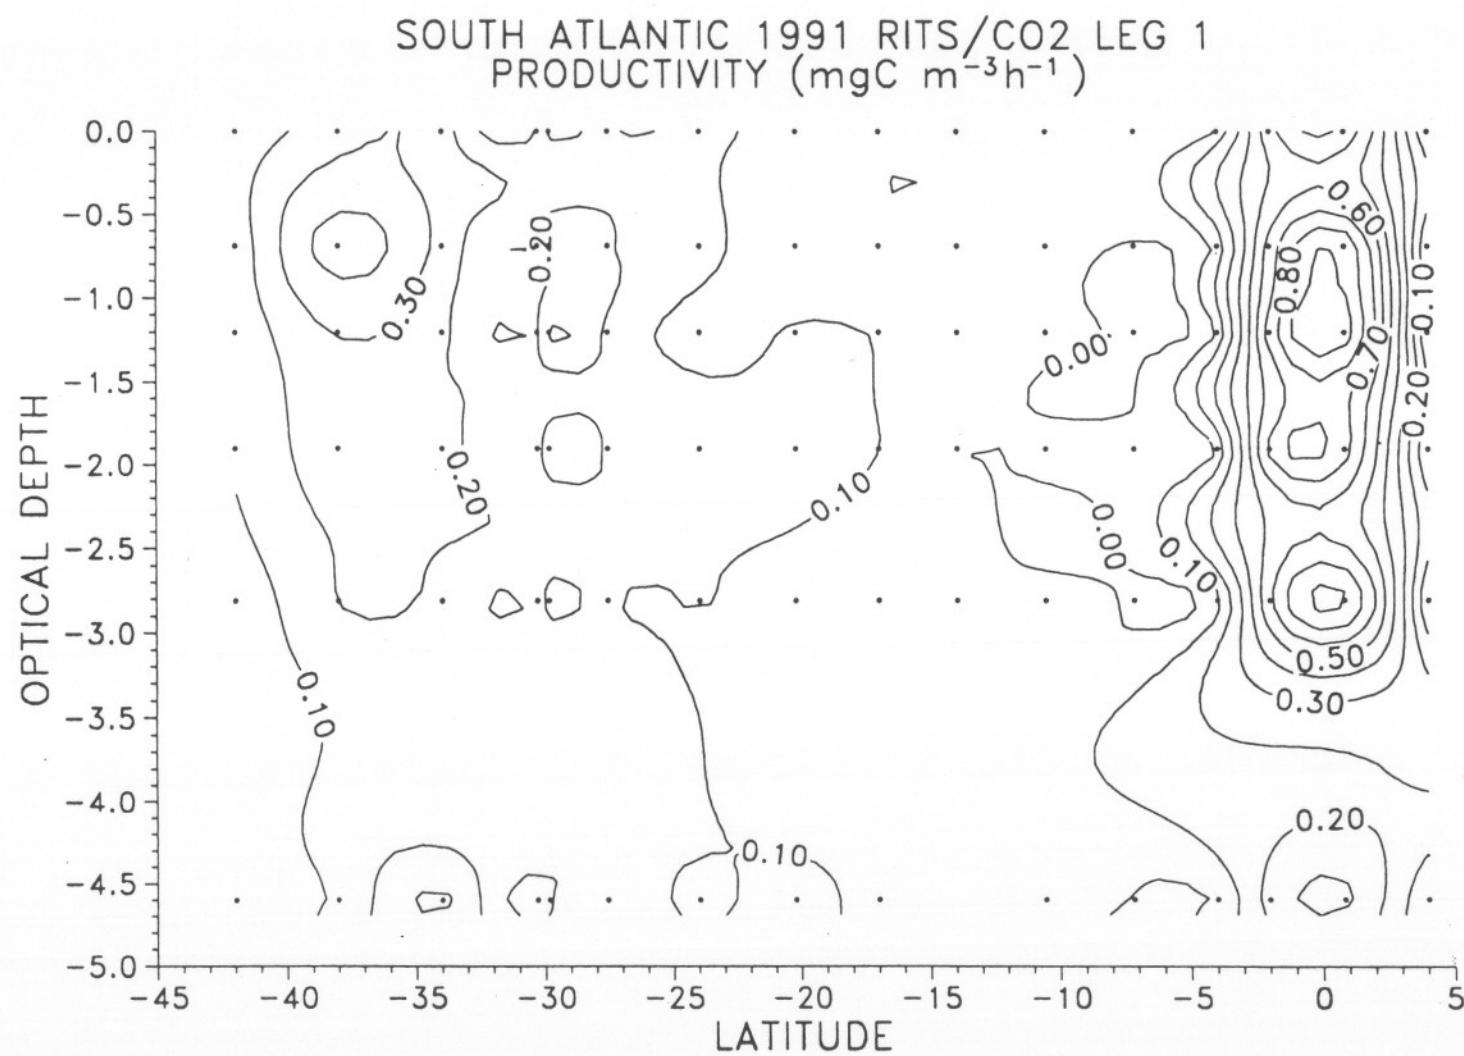

Figure 8: Productivity cross section from Leg 1. Dots represent sample locations. Contour interval = 0.1 mg C m<sup>-3</sup> h<sup>-1</sup>

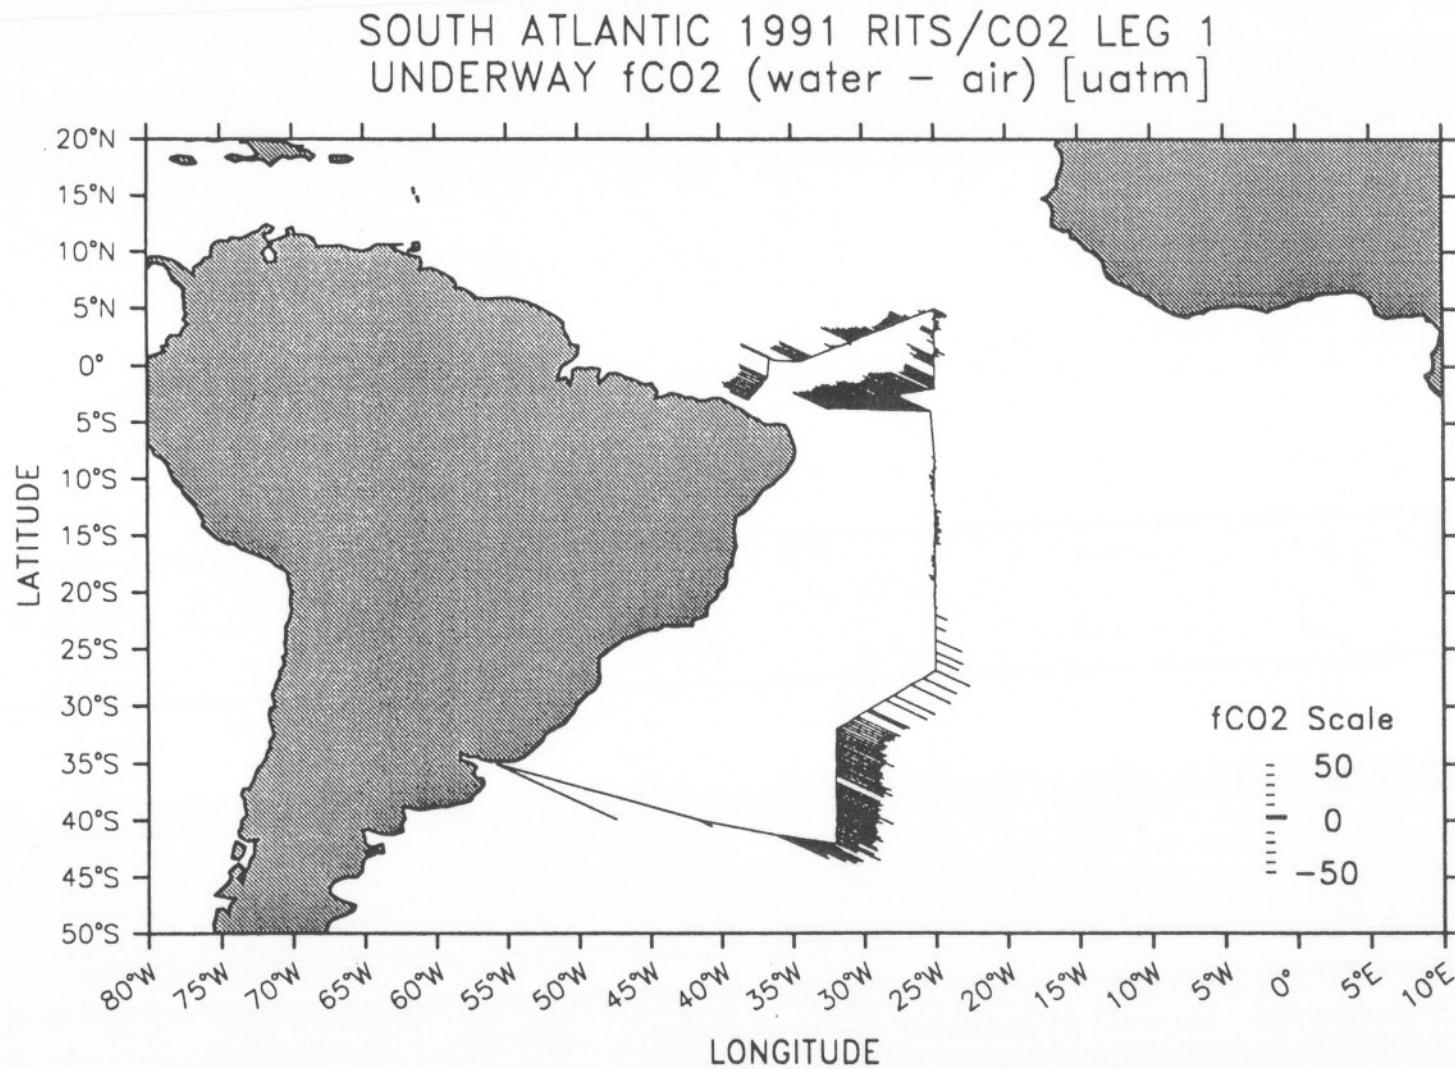

Figure 9: Underway fCO<sub>2</sub>(w-a) measurements from Leg 1. Stick height, above, or to the left of track line equals fCO<sub>2</sub>(w-a). Negative fCO<sub>2</sub>(w-a) values depict sinks and appear below, or to the right of the track line.

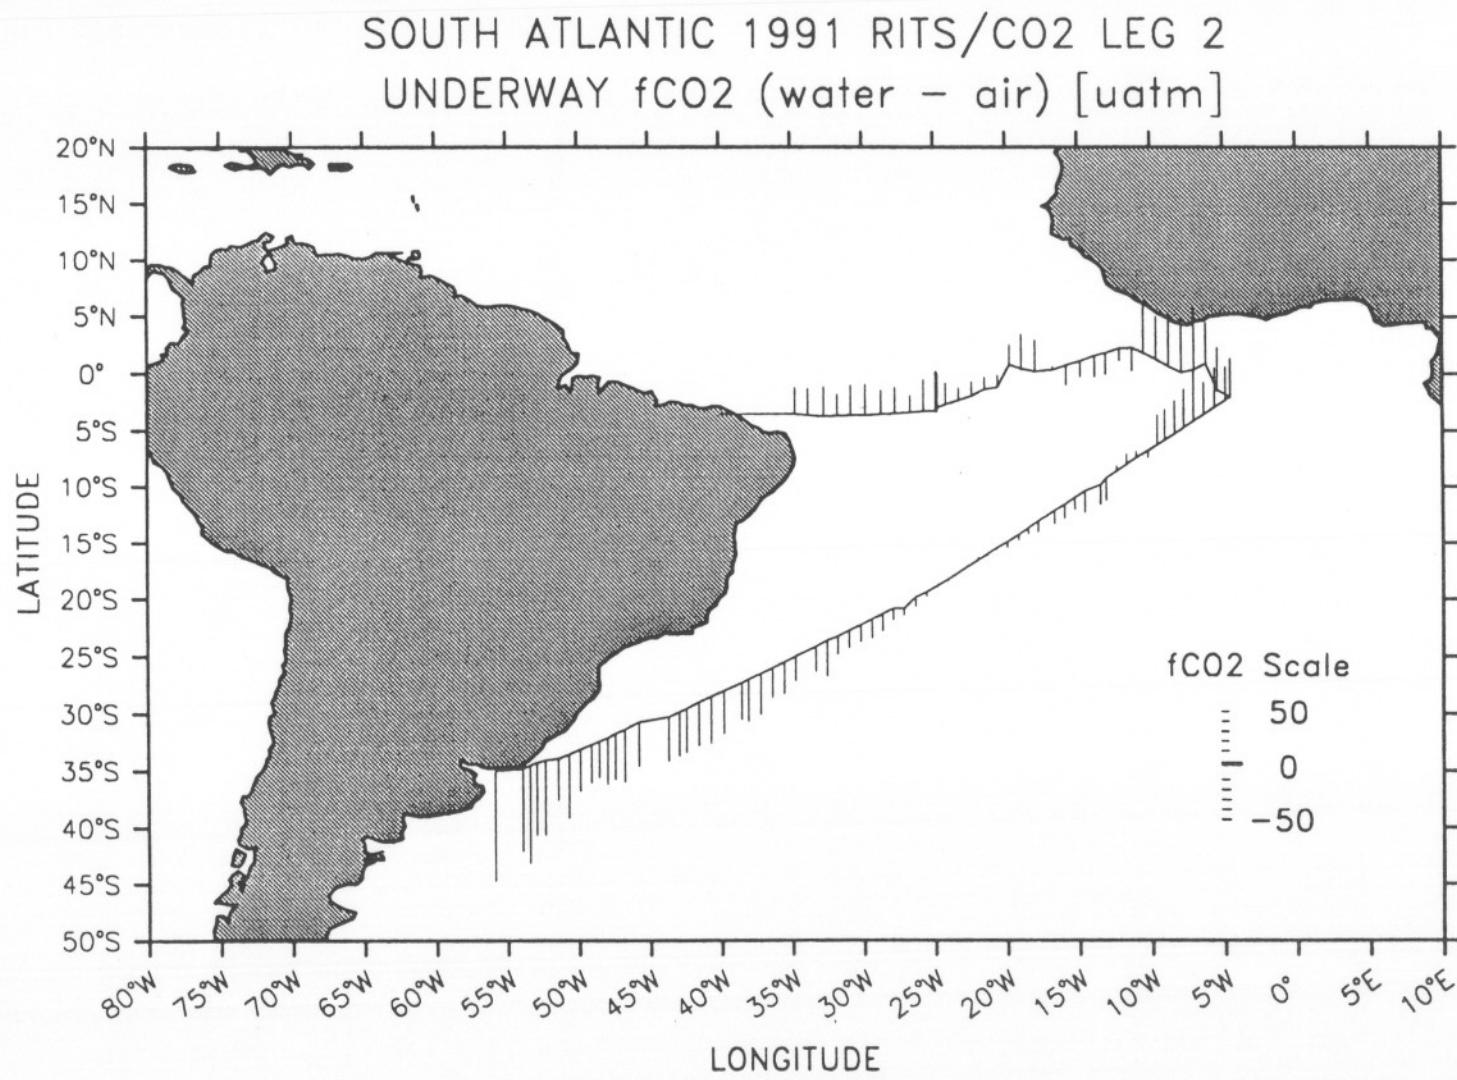

Figure 10: Underway fCO<sub>2</sub>(w-a) measurements from Leg 2. Stick height above track line equals fCO<sub>2</sub>(w-a). Negative fCO<sub>2</sub>(w-a) values appear below the track line.

introduction of the ambient air into the equilibrator chamber during sampling of the headspace results in an error in the determination of the equilibrated head space composition no greater than one micro atmosphere. The total time required to fully replace equilibrator air through the ambient air intake/vent line is 213 minutes. The headspace equilibration time, as determined by return to equilibrium after perturbation by adding nitrogen to the head space, is approximately 2.5 minutes. The intake/vent line also assures that the pressure in the head space of the equilibrator remains at atmospheric value.

During underway sampling operations ambient air is drawn through 100 m of 0.37 cm OD Dekoron™ tubing from the bow mast of the ship at a rate of 6 to 8 L/min. During 22 minutes of each hour, ambient air mixing ratios are measured in the IR analyzer by teeing off the air line at a flow rate of 75 mL/min. Compressed gas standards with nominal mixing ratios of 300, 350, and 400 ppm (parts per million by volume) flow through the IR analyzer for five minutes each hour at 75 mL/min for calibration. The 300 ppm standard flows continuously at 50 mL/min through the reference side of the IR analyzer (detector) as well. All reference tanks undergo a pre- and post-cruise calibration at CMDL against standards certified by the World Meteorological Organization (WMO).

The IR analyzer/detector's voltage output is measured once per second with a Keithley™ (model 195 A) digital multimeter; 1-minute averages are calculated and stored on the hard disk of an MS-DOS computer. The MFC's connected to the reference and sample inlet of the IR, the MFM's measurement of the intake rate of ambient air and recirculation rate of the headspace of the equilibrator, the back pressure in the air and equilibrated air lines, and two thermistors readings of the water temperature in the equilibrator are all logged at 1-minute intervals as well.

#### *fCO<sub>2</sub> Calculations*

The mixing ratios of ambient air and equilibrated headspace air are calculated by fitting a second-order polynomial fit through the response of the detector versus mixing ratio of the standards. Due to the need for sufficient time to flush the sample cell and lines leading to the IR from the previous gas, the first three minutes of each analysis run are not used in the calculations. The subsequent one-minute readings for each analysis are averaged, yielding one 19-minute average ambient air mixing ratio and one 20-minute average equilibrated headspace mixing ratio per hour. Typical standard deviations for air values are  $\pm 0.1$  ppm and for equilibrated headspace  $\pm 0.3$  ppm.

Mixing ratios of dried equilibrated headspace and air must be converted to fugacity of CO<sub>2</sub> in water and water saturated air in order to determine the driving force for the air-sea CO<sub>2</sub> flux. For ambient air, assuming 100% water vapor content, the conversion is:

$$f\text{CO}_2\text{a} = \text{XCO}_2\text{a} (\text{P}-\text{pH}_2\text{O}) \exp(\text{B11} + 2 \delta_{12}) \text{ P/RT} \quad (1)$$

where pH<sub>2</sub>O is the water vapor pressure at the sea surface temperature, and P is the atmospheric pressure. The exponential term is the fugacity correction where B11 is the second virial coefficient of pure CO<sub>2</sub> ( $B11 = -1636.75 + 12.0408 T - 0.0327957 T^2 + 3.16528 \times 10^{-5} T^3$ ) and  $\delta_{12}$  ( $= 57.7 - 0.118 T$ ) is the correction for an air-CO<sub>2</sub> mixture (Weiss,

1974). The calculation for the fugacity in water includes an empirical temperature correction term for the increase of  $f\text{CO}_2$  due to heating ( $\text{dfCO}_2\text{w/dT} = 4.23\%/\text{ }^\circ\text{C}$ , D. Chipman and T. Takahashi, personal communication), of the water from passing through the pump and through 5 cm ID PVC tubing within the ship. The water in the equilibrator is typically  $0.3\text{ }^\circ\text{C}$  warmer than sea surface temperature. The fugacity in water is calculated according to:

$$f\text{CO}_2\text{w} =$$

$$\text{XCO}_2\text{w} (\text{P}-\text{pH}_2\text{Oeq}) (\exp[(\text{Tsw} - \text{Teq}) 0.0428]) \exp(\text{B11} + 2 \sigma_{12}) \text{ P/RT} \quad (2)$$

where  $\text{pH}_2\text{Oeq}$  is the water vapor pressure at the temperature of the water in the equilibrator,  $\text{Tsw}$  is the temperature of the surface seawater,  $\text{Teq}$  is the temperature of the water in the equilibrator.

### 3. ACKNOWLEDGMENTS

The dedication and assistance of the officers and crew of the NOAA ship MALCOLM BALDRIGE is gratefully appreciated and hereby acknowledged. The authors also thank Ms. Betty Huss for her expertise and efforts in the processing of the initial data sets. This research was supported by the Climate and Global Change Program of NOAA.

## APPENDIX A: Index of Measurements and Units

### List of measurements

<u>Column heading or abbreviation</u>	<u>Explanation</u>
<i>Hydrography, Appendix B</i>	
TCO <sub>2</sub> (coul.)	dissolved inorganic carbon dioxide (coulometer)
TCO <sub>2</sub> (titr.)	dissolved inorganic carbon dioxide (titrated)
fCO <sub>2,20</sub>	fugacity of CO <sub>2</sub> at 20 degrees
TALK	total alkalinity
calc.	means the value has been calculated
coul.	coulometer.
DOC	dissolved organic carbon
<i>Productivity measurements, Appendix C</i>	
OPT_DEPTH	optical depth
PROD_RATE	organic carbon production rate
CARB_DAY	organic carbon production per day (= PROD_RATE*24)
CHLORO_A	chlorophyll a
CHLOR_DAY	chlorophyll production per day
TOT_PIGS	chlorophyll a + phaopigments
INCUB-TIME	incubation time for productivity measurements
<i>Underway measurements, Appendix D</i>	
Lat	latitude in decimal degrees
Lon	longitude in decimal degrees
XCO <sub>2,a</sub>	the volume fraction of CO <sub>2</sub> in air
XCO <sub>2,w</sub>	the volume fraction of CO <sub>2</sub> in equilibrator headspace
fCO <sub>2,w-a</sub>	fugacity of CO <sub>2</sub> (water value minus the air value)
SST	sea surface temperature
SST-Eq.T	sea surface Temperature-Equilibrator temperature
Sal(CTD)	salinity from CTD measurement at stations
Sal(TSG)	salinity measurement from thermosalinograph

### Hydrographic and Carbon System parameters, Appendix B

<u>Parameter</u>	<u>Units</u>	<u>Unit spelled out</u>
Depth	m	meters
Pres.	db	decibars
Temp.	°C	degrees centigrade
Pot. T.	°C	degrees centigrade
Salinity	(none)	salinity
Sigma theta	(none)	potential density
Oxygen	mL/L	milliliters per liter
NO <sub>2</sub>	umol/L	micro moles per liter
NO <sub>3</sub>	umol/L	micro moles per liter
SiO <sub>4</sub>	umol/L	micro moles per liter
TCO <sub>2</sub> (coul.)	umol/Kg	micro moles per kilogram
fCO <sub>2</sub> (20 deg.)	uatm	micro atmospheres at 20 °C
pH	(none)	
TALK	uEq/Kg	micro equivalents per kilogram
TCO <sub>2</sub> (titr.)	umol/Kg	micro moles per kilogram
DOC	umol/L	micro moles per liter

Productivity parameters, Appendix C

<u>Parameter</u>	<u>Units</u>	<u>Unit spelled out</u>
SALINITY	(none)	salinity
INCUB_TIME	HRS	hours

Pressure	mb	millibars
fCO <sub>2</sub> ,w	uatm	microatmospheres
fCO <sub>2</sub> ,w-a	uatm	microatmospheres

## **APPENDIX B: Station Data for Hydrography and Carbon Parameters**

Casts are presented by cruise leg and increasing cast number. The cruise leg number, the station number, geographic coordinates, operation number, date and bottom depth are shown at the top of each data table. Data values that are suspect for various reasons are italicized. A blank space is left when either no data was collected, or the value was known to be in error. See Appendix A for explanation of column headings and abbreviations. All coordinates are in fractional degrees with negative values indicating south or west.

## **APPENDIX C: Station Data for Productivity Casts**

Casts are presented by cruise leg and in increasing cast number. The cruise leg number, the productivity cast number, geographic coordinates, operation number, and date are shown at the top of each data table. Data values that are suspect for various reasons are italicized. A blank space is left when either no data was collected, or the value was known to be in error. All coordinates are in fractional degrees with negative values indicating south or west.

## **APPENDIX D: Data for Underway Measurements**

Casts are presented by cruise leg and in chronological order. Data values that are suspect for various reasons are italicized. A blank space is left when either no data was collected, or the value was known to be in error. All coordinates are in decimal degrees with negative values indicating south or west.
