## Asthma During Pregnancy Evidence Tables

Table 1. **Effects of bronchodilators—beta-agonists on maternal health and fetal outcomes when used to treat asthma during pregnancy.**

Citation/ Study Type	Population	Study Characteristics				Findings			Comments
		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3	
<b>Citation 1:</b> Alexander, Mather, Dines 1997  Preclinical inhalation exposure system to test metered-dose aerosol reformulation, HFA-134a (1,1,1,2- tetrafluoroethane), and to determine if this is an acceptable method for conducting inhalation teratology studies	<b>x Animal</b>  New Zealand white rabbits  <u>Age:</u> At least 15 weeks old on day 1 of pregnancy  <u>Gestation:</u> 8 days at time of exposure  Animals removed if negative progesterone assay at day 8	<b>Purpose/Objective:</b> To develop a snout-only inhalation exposure system as part of a developmental program for testing metered-dose pharmaceutical aerosol reformulations with HFA-134a (1,1,1,2-tetrafluoroethane), a potential replacement propellant for metered-dose inhalers; to determine if exposure using this technique is an acceptable method for conducting inhalation teratology studies to meet the regulatory requirements for preclinical safety evaluation.				<u>Maternal:</u>  Only maternal effects were reported.  Both drugs were absorbed into systemic circulation; plasma concentration was within normal biological variation.  <u>Fetal:</u>  Fetal effects were not described.	Only minor effects on body weight were reported; reduced body weight during acclimatization, reversed following completion of exposure.	No maternal findings at necropsy related to the method of exposure or to treatment with drugs.  Data confirm that the technique is an acceptable method for conducting inhalation teratology studies to meet regulatory requirements for preclinical safety evaluation.	Doses are estimated inhaled doses calculated by:  $RMV \times T \times C / BW$ where  RMV = respired minute volume T = time of exposure C = chamber concentration BW = body weight
		<b>Arm 1: Salbutamol</b> A. Air control B. HFA-134a control C. Low dose (115 µg/kg) D. Intermediate dose (223 µg/kg) E. High dose (625 µg/kg)	<u>Total: 25</u> 5 5 5 5	<u>Total: 18</u> 4 4 3 4	13 days acclimatization prior to exposure  Exposure 1 hour/day on days 8–20 of pregnancy				
<b>Arm 2: Salmeterol</b> F. Air control G. HFA-134a control H. Low dose (29.1 µg/kg) I. Intermediate dose (127 µg/kg) J. High dose (317 µg/kg)	<u>Total: 25</u> 5 5 5 5	<u>Total: 19</u> 4 4 3 4							
<b>Citation 2:</b> Baker and Flanagan 1997  Case report	<b>x Human</b>  <u>Age:</u> 34 years  <u>Race/Ethnicity:</u> Not specified  <u>Pregnancy Trimester:</u> 3rd (33 weeks)  <u>Severity:</u> Hospital admission for pneumonia	<b>Purpose/Objective:</b> Not specified				<u>Fetal:</u>  Fetal tachycardia (>200 beats/minute) was detected 3 hours after last dose.  Biophysical profile score = 8 of 8.  Fetal atrial flutter at 420 beats/minute with 2.1 conduction and rare 1:1 and 3:1 conduction.  Spontaneous conversion to normal rate 8 hours after detection of fetal dysrhythmia.			Albuterol MDI inadvertently continued after initiation of albuterol nebulizer treatments on day 3; both treatments continued for 24 hours.  Over that 24-hour period, the patient received 5 albuterol MDI doses and 5 albuterol nebulizer doses.  Albuterol administration was stopped upon detection of fetal tachycardia.  No further incidences of tachycardia were detected during the remainder of pregnancy after return to normal rhythm.  Full-term infant was delivered, HR = 130–150 beats per minute; there were 2 normal ECGs during 4 days of monitoring during hospitalization.
<b>Arm 1: Albuterol</b> <ul style="list-style-type: none"> <li>• MDI: two 90-µg inhalations q4–6h</li> <li>• Nebulizer: 2.5 mg q4h</li> </ul>	1	1	Days 1–3  Day 3 for 24 hours						

Key:

BW = body weight C = chamber concentration CI = confidence interval FEV <sub>1</sub> = forced expiratory volume in 1 second HFA = hydrofluoroalkane HR = heart rate	D = incidence density LMP = last menstrual period MDI = metered dose inhaler OR = odds ratio RMV = respired minute volume T = time of exposure

Evidence Tables**

Table 1. **Effects of bronchodilators—beta-agonists on maternal health and fetal outcomes when used to treat asthma during pregnancy (continued).**

Citation/ Study Type	Population	Study Characteristics				Findings			Comments	
		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3		
<b>Citation 3:</b> Bracken, Triche, Belanger, et al. 2003  Prospective study	<b>x Human</b>  <u>Age:</u> ≤24–≥35 years  <u>Race/Ethnicity:</u> White/Asian: 1,496 (67.8%) African American: 209 (9.5%) Hispanic: 406 (18.4%) Other: 89 (4.0%)  <u>Pregnancy Trimester:</u> ≤24 weeks  <u>Eligibility:</u> Pregnant women ≤24 weeks gestation with history of physician- diagnosed asthma and random sample of nonasthmatic, pregnant women	<b>Purpose/Objective:</b> To examine whether asthma, asthma symptoms, or asthma therapy influences pregnancy outcomes (specifically, preterm delivery, intrauterine growth restriction [IUGR], gestational age, or birth weight) while controlling for other known risk factors.				Preterm delivery (adjusted associations):	IUGR (adjusted associations):		Exclusion criteria included being more than 24 weeks pregnant at interview, having insulin-dependent diabetes mellitus, not speaking English or Spanish, and intending to terminate pregnancy.	
		<b>Arm 1: Asthma diagnosis</b>				Length of study: 4/97–6/00  Length of treatment: Not specified	Not significantly associated with diagnosis of asthma.	Risk increased in symptomatic women (symptom steps 2 and 3) with NO diagnosis of asthma; linear trend OR = 31% (95% CI 4%, 65%).  Risk also increased with severity (severity steps 3 and 4) in women with NO diagnosis of asthma; linear trend OR = 30% (95% CI 4%, 62%).		Asthma symptoms were classified using the modified Global Initiative for Asthma (GINA) guidelines.  Asthma treatment was classified using modified GINA guidelines.  Asthma severity was determined by cross-classifying with the 2002 GINA grid on symptom and medication steps to derive 4 severity categories: intermittent, mild persistent, moderate persistent, and severe persistent.
		Asthmatic		872	872					
		Symptoms or medications		778	778					
No symptoms or medications		98	98							
Nonasthmatic		1,333	1,333							
Symptoms or medications		449	449							
No symptoms or medications		884	884							
<b>Arm 2: Asthma symptoms</b>					Not significantly associated with asthma symptoms.	Risk increased for women with daily symptoms (OR = 2.25, 95% CI 1.25, 4.06).  Linear trend suggested increased risk (25% for each symptom step [95% CI 5%, 47%]).		Gestational age was calculated as completed days from first day of LMP or doctor's estimated date of delivery if LMP was uncertain.  Preterm delivery was defined as delivery before 37 weeks gestation.  Fetal growth restriction was defined as below 10th percentile of birth weight for gestational age.		
0 (no symptoms)										
Step 1		992	992							
Step 2		750	750							
Steps 3 and 4		305	305							
		158	158							
<b>Arm 3: Asthma severity</b>					Not significantly associated with asthma severity.	IUGR was associated with moderate persistent severity (OR = 2.01, 95% CI 1.11, 3.65).  Risk declined in highest severity group, but overall linear trend was significant (20% increase for each step in severity [95% CI 4%, 38%]).		Women with asthma symptoms but no asthma diagnosis are at particular risk of undermedication and of delivering IUGR infants.		
0 (no symptoms, no medications)		978	978							
Step 1		711	711							
Step 2		289	289							
Step 3		147	147							
Step 4		80	80

Citation/ Study Type	Population	Study Characteristics				Findings			Comments																		
		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3																			
<b>Citation 6:</b> Wilton, Pearce, Martin, et al. 1998  Postmarketing surveillance; noninterventional observational cohort study using prescription event monitoring	<b>x Human</b>  <u>Age:</u> 14–48 years  <u>Race/Ethnicity:</u> Not specified  <u>Pregnancy Trimester:</u> 1st  <u>Eligibility:</u> Exposure to newly marketed drugs during 1st trimester	<b>Purpose/Objective:</b> To determine proportion and nature of congenital anomalies in babies born to women exposed to newly marketed drugs during 1st trimester.				Live births: 547 (70.1%) • Full-term: 513 (93.8%) – Single: 504 – Multiple: 9 • Premature: 34 (6.2%) – Single: 33 – Multiple: 1	Anomalies: 14 (1.8%) • Full-term: 12 (85.7%) – Single: 12 – Multiple: 0 • Premature: 2 (14.3%) – Single: 2 – Multiple: 0	Nonviable outcomes: 233 (29.9%) • Ectopic: 10 • Spontaneous abort: 94 • Missed abortion: 5 • Legal abortion: 120 • Intrauterine death: 4	Percentages were based on number of evaluable pregnancies.  Conditions for which drugs prescribed were not reported.  Mothers of 7 infants born with congenital anomalies had epilepsy and all were on multiple therapies; in 6 of these women, treatment included newer anti-epileptic drugs.  Specific data on the 2 respiratory anti-asthmatics, salmeterol and nedocromil, are as follows: <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th></th> <th>Salmeterol</th> <th>Nedocromil</th> </tr> </thead> <tbody> <tr> <td>Number of pregnancies</td> <td>93</td> <td>84</td> </tr> <tr> <td>Number stopped before LMP</td> <td>22</td> <td>44</td> </tr> <tr> <td>1st trimester exposure</td> <td>65</td> <td>35</td> </tr> <tr> <td>2nd/3rd trimester exposure</td> <td>3</td> <td>3</td> </tr> <tr> <td>Unknown exposure time</td> <td>3</td> <td>2</td> </tr> </tbody> </table> For the 2 infants born with congenital anomalies in the respiratory drug class, in the first case (baby born with congenital heart disease), the mother was prescribed a new drug, nedocromil (along with aminophylline, steroids, and salbutamol); in the second case (baby born with Aarskog syndrome), the mother was prescribed a new drug, salmeterol.  Three additional minor (nonreportable) anomalies were reported in live-born infants for an overall percentage rate of 2.2% (17 of 780) (article reports 2.5%); all were full-term births. No mother in this group was taking respiratory agents. **Key:**

A = pregnant women with asthma not receiving theophylline  
 AT = pregnant women with asthma receiving theophylline  
 BA = boric acid  
 C = pregnant controls—no asthma, no theophylline  
 EG = ethylene glycol  
 EGME = ethylene glycol methyl ether

ER = emergency room  
 FEV = forced expiratory volume  
 FEV<sub>1</sub> = forced expiratory volume in 1 second  
 GD = gestation day  
 GR = growth rate  
 LBW = low birth weight

NOAELs = no observable adverse effect levels  
 OR = odds ratio  
 RACB = reproductive assessment by continuous breeding  
 PEFr = peak expiratory flow rate  
 s.c. = subcutaneous  
 SD = study day  
 TH = theophylline

<b>Citation 5:</b> León, Albasanz, Ruiz, et al. 2002  Preclinical study	<b>x Animal</b> Female Wistar rats  Age: Not specified  Gestational Age: Day 2 at time of 1st exposure	<b>Purpose/Objective:</b> To determine the effect of caffeine or theophylline administration throughout pregnancy on maternal and fetal brain adenosine A <sub>1</sub> receptors.							Assuming that 10 mg/kg caffeine/theophylline in rats corresponds to ~ 3.5 mg/kg in humans because of difference in metabolic body weight and half-lives, then the daily intake in study is equivalent to 2–3 cups of coffee per day in humans.  B <sub>max</sub> is an indicator of the number of receptors; K <sub>d</sub> is an indicator of receptor affinity for caffeine or theophylline; K <sub>i</sub> is an indicator of competitive binding affinity.  Binding assays indicated a 30% decrease in total receptor numbers in maternal brain plasma membranes and a 50% decrease in fetal brain membranes. This was accompanied by a decrease in receptor affinity in maternal membranes; however, a significant increase in receptor affinity was detected in fetal membranes. This increase was associated with an increase in mRNA coding of the A <sub>1</sub> receptor in fetal brain membranes, but not in maternal membranes.  Results suggest that maternal caffeine or theophylline intake modulates adenosine A <sub>1</sub> receptor in both mothers and fetuses.

<b>Citation 6:</b> Lindström, Morrissey, George, et al. 1990  Preclinical teratology study	<b>x Animal</b> Sprague-Dawley (CD) rats; Swiss (CD-1) mice  Age: Not specified  Gestational Age: Day 6 at 1st exposure	<b>Purpose/Objective:</b> To determine the toxic and teratogenic effects of theophylline in rodents at several dose levels through oral administration during the period of organogenesis.  Arm 1: <b>Theophylline in rats</b> (percent admin in feed) • 0% (0 mg/kg/day) • 0.15% (124 mg/kg/day) • 0.20% (218 mg/kg/day) • 0.40% (259 mg/kg/day)	<u>Treated</u>  27 26 27 29	<u>Pregnant</u>  21 20 21 21	<u>Length of study:</u> From 1 day prior to mating through GD 20 (rats) or GD 17 (mice)  <u>Length of treatment:</u> GD 6 to 15	<u>Maternal weight measures:</u> • Gestational weight gain, weight gain during treatment, and corrected body weight significantly decreased at 0.40% doses. • Gravid uterine weight and liver weight showed decreasing trend with increasing concentrations.	<u>Maternal food and water consumption:</u> • Food consumption decreased significantly in 0.40% group. • Water consumption increased significantly in all treatment groups.	<u>Fetal parameters:</u> • No differences in number of implantation sites/litter or number of implantation losses. • No significant changes in number of litters with resorptions or percent resorptions/litter. • Average male and female body weight/litter significantly decreased at 0.30 and 0.40% doses. • No increase in percent of fetuses malformed or in incidence of external, visceral, or skeletal malformations.	The corrected body weight gain equals weight at pregnancy termination minus initial weight and gravid uterine weight.  Theophylline treatment was not associated with an increase in a particular malformation or group of malformations.  There were developmental effects in rats at a dose (0.30%) that did not produce overt maternal toxicity, but adverse developmental effects in mice were observed at doses causing reduced maternal water consumption and body weight gain.  It is possible that water deprivation contributed to the effects seen in mice.  For maternal toxicity, the NOAELs were at 218 mg/kg/day for rats and 282 mg/kg/day for mice.  For developmental toxicity, NOAELs were 124 mg/kg/day in rats and 282 mg/kg/day in mice.  These NOAELs are approximately 10- to 30-fold greater than doses required to maintain clinically useful serum theophylline concentrations in humans.

<b>Citation 7:</b> Shibata, Wachi, Kawaguchi, et al. 2000  Preclinical teratology and toxicity study	x <b>Animal</b> Mated female Kbl: JW rabbits  Age: 18 weeks  Gestational Age: 6 days at 1st exposure	<b>Purpose/Objective:</b> To investigate the teratogenic and fetal toxicity of theophylline after i.v. administration to pregnant rabbits and the relationship to maternal plasma drug concentrations.			<b>Length of study:</b> 29 days  <b>Length of treatment:</b> Days 6 through 18 of gestation	<b>Maternal toxicity:</b> <ul style="list-style-type: none"> <li>• Significant decrease in food intake GD 7-21 (p &lt;0.05).</li> </ul> <ul style="list-style-type: none"> <li>• A few animals showed polyuria following dosing.</li> </ul> <ul style="list-style-type: none"> <li>• Significant decreases in body weight from GD 11 (p &lt;0.01).</li> <li>• Significant decrease in food intake GD 7-23 (p &lt;0.01).</li> <li>• Most exhibited sluggish startle reaction.</li> <li>• All exhibited dilation of auricular vessels and accelerated respiration during or following dosing; recovery within day.</li> <li>• Little or no feces in all animals, persisting 10 days or more in ½ the animals.</li> </ul>	<b>Fetal development:</b> <ul style="list-style-type: none"> <li>• Number of anomalies: 0</li> </ul> <ul style="list-style-type: none"> <li>• Number of anomalies: 2 (1 multiple, 1 cleft palate)</li> <li>• 14 occurrences of sutural bone vs. 3 in controls (p &lt;0.05)</li> </ul> <ul style="list-style-type: none"> <li>• Number of anomalies: 8 (8 cleft palate)</li> <li>• 74 fetuses with skeletal variations vs. 52 in controls, including 9 sutural bone occurrences and 63 occurrences of 13th rib (p &lt;0.05 for all)</li> <li>• Significant increase in number of late deaths (11.9 ± 16.3%) vs. 3.8 ± 13.3% in controls (p &lt;0.05)</li> </ul>	<b>Maternal plasma theophylline concentrations:</b> <ul style="list-style-type: none"> <li>• GD 6: 29.16 ± 1.16 µg/mL</li> <li>• GD 18: 30.45 ± 3.96 µg/mL</li> </ul> <ul style="list-style-type: none"> <li>• GD 6: 56.95 ± 6.52 µg/mL</li> <li>• GD 18: 54.76 ± 1.57 µg/mL</li> </ul> <ul style="list-style-type: none"> <li>• GD 6: 104.89 ± 8.68 µg/mL</li> <li>• GD 18: 106.39 ± 4.10 µg/mL</li> </ul>	There were no statistically significant differences in the number of corpora lutea, implantations, live fetuses, implantation index, or sex ratio.  No abnormalities were observed in the condition or appearance of amniotic fluid or placentas.  There were no significant differences in incidence of visceral or skeletal anomalies or ossification.  Maternal plasma theophylline levels on GD 18 were almost the same as those on day 6, indicating that there were differences due neither to gestational age nor to effects of 13 repeated administrations.  Plasma theophylline concentrations GD 6-18 were ~ 106 µg/mL in the 60 mg/kg/day group in which teratogenic effects were observed; concentrations were ~ 56 µg/mL for the 30 mg/kg/day group where incidence of teratogenic effects were no greater than controls.  It is suggested that the risk of teratogenic and fetal toxicity is dependent on dosage and that maternal (and fetal) plasma theophylline concentrations of 106 µg/mL and above may induce toxicity.

		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3																							
<b>Citation 10 (continued)</b>									It was expected that beclomethasone would be more efficacious because of greater anti-inflammatory effects, but possible explanation is that theophylline is bronchodilator + anti-inflammatory. Also, there are newer inhaled corticosteroids (e.g., fluticasone propionate and budesonide) that are more potent, require fewer puffs/day, and have less systemic absorption than beclomethasone; studies are needed to compare theophylline to these newer inhaled corticosteroids during pregnancy.																						
<b>Citation 11:</b> Neff and Leviton 1990  Prospective cohort study; review of data from Collaborative Perinatal Project	<b>x Human</b>  <u>Age:</u> Not specified  <u>Race/Ethnicity:</u> Not specified  <u>Pregnancy Trimester:</u> Not specified  <u>Eligibility:</u> Singleton pregnancies and data available on asthma status, theophylline administration, and stillbirth outcomes	<b>Purpose/Objective:</b> To assess to what extent theophylline receipt by pregnant women increases their risk of stillbirth.							Theophylline ingested by pregnant women does not appear to increase their risk of delivering a stillborn infant. This applies both to women who had a diagnosis of asthma and to those who were not so labeled. Overall stillbirth rate was 1.8% (952/51,830). Power of 6 analyses ranged from 48.0% to 57.7%.  <u>Three limitations of the study:</u> 1. The approximate 50% power is a consequence of a low incidence of stillbirth. 2. Details of theophylline dosage were not available to study. 3. Information on why a total of 157 women without a diagnosis of asthma received theophylline was not available to the study.  Findings led to the conclusion that theophylline does not compromise fetal well-being and is not associated with any increased risk of stillbirth.

<b>Citation 1:</b> Bracken, Triche, Belanger, et al. 2003  Prospective study	<b>x Human</b>  <u>Age:</u> ≤24–≥35 years  <u>Race/Ethnicity:</u> White/Asian: 1,496 (67.8%) African American: 209 (9.5%) Hispanic: 406 (18.4%) Other: 89 (4.0%)  <u>Pregnancy Trimester:</u> ≤24 weeks  <u>Eligibility:</u> Pregnant women ≤24 weeks gestation with history of physician- diagnosed asthma and random sample of nonasthmatic, pregnant women	<b>Purpose/Objective:</b> To examine whether asthma, asthma symptoms, or asthma therapy influence pregnancy outcomes (specifically, preterm delivery, intrauterine growth restriction [IUGR], gestational age, or birth weight) while controlling for other known risk factors.							Exclusion criteria included being more than 24 weeks pregnant at interview, having insulin-dependent diabetes mellitus, not speaking English or Spanish, and intending to terminate pregnancy.  Asthma symptoms were classified using the modified Global Initiative for Asthma (GINA) guidelines.  Asthma treatment was classified using modified GINA guidelines.  Asthma severity was determined by cross-classifying with the 2002 GINA grid on symptom and medication steps to derive 4 severity categories: intermittent, mild persistent, moderate persistent, and severe persistent.  Gestational age was calculated as completed days from first day of LMP or doctor's estimated date of delivery if LMP was uncertain.  Preterm delivery was defined as delivery before 37 weeks gestation.  Fetal growth restriction was defined as below 10th percentile of birth weight for gestational age.  Women with asthma symptoms but no asthma diagnosis are at particular risk of undermedication and of delivering IUGR infants.

TA 1 time/day on days 12,13, and 14 of gestation (study group)</p>	<p>14 rats producing 158 fetuses</p>	<p>Same</p>	<p><u>Length of study:</u> Days 1-21 of gestation</p>	<p><u>Fetal:</u> Cleft palate: 69/80</p>	<p><u>Various weight parameters:</u></p> <p><u>Maternal weight:</u> Initial loss in body weight was found, then a slower increase than in controls.</p> <p><u>Fetal weight:</u> Modest gain was found between days 15 and 17, then an increase between days 18 and 21, but less than controls (to ~ 60% of control weights).</p> <p><u>Placental weight:</u> Weight increased throughout period, but less than in controls.</p> <p><u>Amniotic fluid weight:</u> Little increase was found.</p>	<p><u>Fetal pulmonary effects:</u> <u>Peripheral airway count:</u> Increased exponentially with gestational age; was significantly higher than controls on days 17-18 (p &lt;0.001).</p> <p><u>Pole to pole:</u> Increased exponentially with gestational age; was significantly lower than controls days 17-18 (p &lt;0.05 on day 17, p &lt;0.001 on day 18).</p> <p><u>Ratio dry lung weight/body weight:</u> 0.025 (evidence of pulmonary hypoplasia).</p> <p><u>Branching morphology:</u> Diminished monopodial branching from segmental airways was found; but dichotomous branching increased.</p> <p><u>Histology:</u> Accelerated differentiation of peripheral airway epithelium resulted in increased tissue maturation and increased cellular differentiation of peripheral airspaces.</p>	

**Key:**

AA = arachidonic acid  
 B = bifurcation  
 b.i.d. = twice per day  
 BA = inhaled steroid treatment at various times  
 C = cross  
 CI = confidence interval  
 D = division  
 df = degrees of freedom

ER = emergency room  
 FEV = forced expiratory volume  
 FEV<sub>1</sub> = forced expiratory volume in 1 second  
 g = grams  
 ICU = intensive care unit  
 i.m. = intramuscular  
 IS = inhaled steroid treatment  
 L-656,224 = a benzofuran-class orally active lipoxigenase inhibitor

LBW = low birth weight  
 LMP = last menstrual period  
 MDI = metered dose inhaler  
 NICU = neonatal intensive care unit  
 NIS = no inhaled steroid treatment  
 NS = not significant  
 OR = odds ratio  
 PCD = postcoital day

PEF = peak expiratory flow  
 q4h = every four hours  
 q8h = every eight hours  
 s.c. = subcutaneous  
 Sh = shortness  
 Su = supernumerary  
 TA = triamcinolone acetonide  
 vol = volume  
 χ<sup>2</sup> = chi<sup>2</sup>

Citation/ Study Type	Population	Study Characteristics				Findings			Comments
		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3	
<b>Citation 2 (continued)</b>		<b>Arm 4:</b> Untreated controls; embryos were analyzed on day 15.	5	5 mice producing 75 embryos		<b>Crown-rump length:</b> 14.1 ± 0.5 mm	<b>Number of variant palatal rugae:</b> 10 embryos (11.2%) showing 12 variant rugae	<b>Variant rugae types:</b> B: 0 (0.0%) D: 6 (50.0%) Su: 3 (25.0%) Sh: 3 (25.0%) C: 0 (0.0%)	Authors speculated that formation of variant rugae was associated with disturbance of normal epithelial-mesenchymal interaction.  The relationship between increased appearance of variant rugae and failure of palatal shelf elevation was examined, but no direct evidence was obtained.
<b>Citation 3:</b> Wise, Vetter, Anderson, et al. 1991  Preclinical randomized controlled study	<b>x Animal</b>  Nulliparous Sprague-Dawley rats  <u>Age:</u> ~ 11 weeks on day 1 of pregnancy  <u>Gestational Age:</u> 11 or 14 days at time of 1st exposure	<b>Purpose/Objective:</b> To examine effects of arachidonic-acid-cascade inhibitors in rats; if agents cause decreases in anogenital distance in association with hypospadias, this is significant for future developmental toxicity studies of agents that could affect the cascade.  <b>Arm 1:</b> • TA: 0.05 mg/kg s.c. once/day • TA: 0.10 mg/kg s.c. once/day • Control 1: TA-vehicle 2 mL/kg s.c. 1 time/day • Aspirin: 75 mg/kg oral gavage vol 5 mL/kg once/day • Aspirin: 150 mg/kg oral gavage vol 5 mL/kg once/day • L-656,224: 1,000 mg/kg oral gavage vol 5 mL/kg once/day • L-656,224: 2,000 mg/kg oral gavage vol 5 mL/kg once/day • Control 2: aspirin/L-656,224 vehicle oral gavage vol 5 mL/kg once/day	10 rats per treatment group	Same	<b>Length of study:</b> Day 11 of gestation to day 58 postpartum  <b>Length of treatment:</b> Rats were exposed to treatments on days 11–19 of gestation	<b>Fetal:</b> <b>Congenital anomalies:</b> • Anomalous external genitalia were found in all pups in both TA treatment groups (0.05 mg/kg and 0.10 mg/kg) on PCD 23: genital tubercle flattened; thinned, glossy strip of flattened skin between tubercle and anus. • Malformations were found in 12 of 90 pups examined in the TA 0.10 mg/kg group (2 cleft palate; 10 omphalocele) vs. 0–1 malformations in all other groups of 123–150 pups each. • Male anogenital distance on PCD 23 was reduced 11% below control for the TA 0.05 mg/kg group (p <0.01) and 19% for the TA 0.10 mg/kg group (p <0.001).	<b>Prewaning pups:</b> • 4.7 live pups/litter (45.3%) were born in TA 0.10 mg/kg treatment group vs. 12.1–14.8 live pups/litter (93.3–100%) for all other treatment groups (p <0.001). • On PCD 23, pup weight was reduced by 35.4% and 46.2% below controls in females treated with TA 0.05 mg/kg and TA 0.10 mg/kg, respectively (p <0.001). • On PCD 23, pup weight was reduced by 35.7% and 45.7% in males treated with TA 0.05 mg/kg and TA 0.10 mg/kg, respectively (p <0.001). – There was slight, but not significant, decrease in PCD 23 pup weight for males and females in both LCD-656,224 treatment groups (1,000 mg/kg and 2000 mg/kg).	<b>Postweaning pups:</b> <b>Anatomic:</b> (Examination of pups was from culled litters in TA 0.05 mg/kg, control 1, control 2, aspirin 150 mg/kg, and L-656,224 2000 mg/kg groups.) • Vaginal canalization in TA 0.05 mg/kg group was slightly decreased compared with control group 1 (64% vs. 83%) on postnatal day 37. • No evidence was found of irreversible alterations of external genitalia or testes descent for pups in any treatment group examined at 8 weeks.	L-656,224 (7-chloro-2-[(4-methoxyphenyl)methyl]-3-methyl-5-propyl-4-benzofuranol) is a benzofuran-class orally active lipoxygenase inhibitor.  Data indicate that Sprague-Dawley rats are much less sensitive to the effects of aspirin and glucocorticoids on anogenital distance; therefore, prostaglandins are unlikely to be primary mediators of androgen-initiated external masculinization in this rat strain.

		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3	
<b>Citation 4:</b> Alexander, Dodds, Armson 1998  Population-based retrospective cohort study	<b>x Human</b>  <u>Age:</u> Nonasthmatic pregnant women: 28.4 ± 5.1 years  Asthmatic pregnant women, no medication: 26.1 ± 5.7 years  Asthmatic pregnant women, using β-agonists only: 26.7 ± 5.5 years  Asthmatic pregnant women, using steroids, with or without other medications: 28.9 ± 5.9 years  <u>Race/Ethnicity:</u> Not specified  <u>Pregnancy            Trimester:</u> Not specified  <u>Eligibility:</u> All women living in the county delivering at city hospital	<b>Purpose/Objective:</b> To determine whether adverse perinatal outcome is associated with asthma or asthma medication use during pregnancy.				<u>Maternal hemorrhage:</u>	<u>Maternal hypertension:</u>	<u>Infant complications:</u>	Overall, 5.8% of pregnant women were identified as being asthmatic; the prevalence increased each year, from 4.8% in 1991 to 6.9% in 1993.  Study groups differed significantly according to maternal age: mean age at delivery among nonasthmatic pregnant women was higher than that in the asthmatic, no medication use and the asthmatic, β-agonist use groups.  Risk of antepartum and postpartum hemorrhage increased in asthmatic women, independent of medication usage.  Increased incidence of neonatal hyperbilirubinemia and borderline increased risk of pregnancy-induced hypertension may be complications of steroid use or may be related to poorly controlled asthma.  Did not differentiate oral from inhaled corticosteroid use.

<b>Citation 5:</b> Bracken, Triche, Belanger, et al. 2003  Prospective study	<b>x Human</b>  <u>Age:</u> ≤24–≥35 years  <u>Race/Ethnicity:</u> White/Asian: 1,496 (67.8%) African American: 209 (9.5%) Hispanic: 406 (18.4%) Other: 89 (4.0%)  <u>Pregnancy Trimester:</u> ≤24 weeks  <u>Eligibility:</u> Pregnant women ≤24 weeks gestation with history of physician- diagnosed asthma and random sample of nonasthmatic, pregnant women	<b>Purpose/Objective:</b> To examine whether asthma, asthma symptoms, or asthma therapy influence pregnancy outcomes (specifically, preterm delivery, intrauterine growth restriction [IUGR], gestational age, or birth weight) while controlling for other known risk factors.							Exclusion criteria included being more than 24 weeks pregnant at interview, having insulin-dependent diabetes mellitus, not speaking English or Spanish, and intending to terminate pregnancy.  Asthma symptoms were classified using the modified Global Initiative for Asthma (GINA) guidelines.  Asthma treatment was classified using modified GINA guidelines.  Asthma severity was determined by cross-classifying with the 2002 GINA grid on symptom and medication steps to derive 4 severity categories: intermittent, mild persistent, moderate persistent, and severe persistent.  Gestational age was calculated as completed days from first day of LMP or doctor's estimated date of delivery if LMP was uncertain.  Preterm delivery was defined as delivery before 37 weeks gestation.  Fetal growth restriction was defined as below 10th percentile of birth weight for gestational age.  Women with asthma symptoms but no asthma diagnosis are at particular risk of undermedication and of delivering IUGR infants.

<b>Citation 7 (continued)</b>									It was expected that beclomethasone would be more efficacious because of greater anti-inflammatory effects, but possible explanation is that theophylline is bronchodilator plus anti-inflammatory. Also, there are newer inhaled corticosteroids (e.g., fluticasone propionate and budesonide) that are more potent, require fewer puffs/day, and have less systemic absorption than beclomethasone; studies needed to compare theophylline to these newer inhaled corticosteroids during pregnancy.

Citation/ Study Type	Population	Study Characteristics				Findings			Comments
		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3	
<b>Citation 9 (continued)</b>	Eligibility: Pregnant asthmatic and nonasthmatic women from prenatal clinic	Arm 2: Subjects were grouped by inhaled glucocorticoid use (control, nil, low, moderate, high)	Control: 25 Nil: 30 Low: 16 Moderate: 32 High: 24	Same		<b>Birth weight centile:</b> • Was significantly lower in nil group compared to control (p <0.05). • Corresponds to a 25% reduction in birth weight centile vs. controls and 17% reduction vs. infants from mothers who used inhaled glucocorticoids at all.	<b>Fetal cortisol:</b> • Significantly increased in nil use group compared to control (p <0.05); dose- dependent restoration to control with increased concentration of inhaled glucocorticoid intake.  <b>Fetal estriol:</b> • Significantly reduced in nil group compared to control and glucocorticoid users (p <0.05). • Inversely correlated with fetal cortisol in all groups (p <0.005).	<b>11β-HSD2 activity:</b> • Significant reduction in enzyme activity occurred in subjects in the nil-use category compared with control and low-use (p <0.02) and moderate- and high-use subjects (p <0.01). • Mean 11β-HSD2 protein levels in the nil and high-use subjects were significantly higher than in controls (p <0.05).	Oral glucocorticoid intake was not quantified.  Inhaled glucocorticoid intake for treatment of asthma was associated with improved placental function and fetal outcome, suggesting that inflammatory factors associated with asthma may be detrimental to fetal growth and development in these pregnancies.
<b>Citation 10: Norjavaara and de Verdier 2003</b>	<b>x Human</b>  Age: Not specified  Race/Ethnicity: Not specified  Pregnancy Trimester: “Early pregnancy”  Eligibility: Pregnant asthmatic subjects	<b>Purpose/Objective:</b> To investigate whether reported use of inhaled budesonide during pregnancy influences birth outcome.	298,880 total newborns; mothers in following groups:	Study population of newborns = 293,948	Length of study: 1995–1998	<b>Maternal:</b>  Cesarean births in study population:  Girls                      Boys Number    %    Number    % 16,132    11.3    18,487    12.2	<b>Newborns:</b>  Average birth weight (g) in study population:  Girls                      Boys 3,500 ± 530    3,630 ± 570	<b>Newborns:</b>  Birth weight <1,000g in study population:  Girls                      Boys Number    %    Number    % 205    0.1    216    0.1	Mothers who reported use of inhaled budesonide during pregnancy gave birth to babies of normal gestational age, birth weight, and length, with no increased rate of stillbirths or multiple births.  Doses of budesonide reported in the current study were probably less than recommended doses, as real-life use tends to be lower than prescribed.  Asthma severity is a possible confounding effect: inadequate control of asthma is associated with adverse outcomes such as higher prematurity rates, intrauterine growth retardation, low birth weight, perinatal death, and preeclampsia.  Results of the current study on concomitant use of oral glucocorticoids were probably confounded by a severity of maternal asthma that necessitated use of both budesonide and oral glucocorticoids.

<b>Citation 12 (continued)</b>		<b>Arm 2:</b> Effect of acute asthma on maternal health in 504 pregnant women with asthma	47 acute attack  457 nonacute attack  237 pregnant nonasthmatic controls				<b>Maternal complications:</b>  No significant differences were found in incidence of preeclampsia, intrahepatic cholestasis of pregnancy, or gestational diabetes between acute attack patients and nonacute attack patients or controls.  No significant differences were found in incidence of pregnancy complications between acute attack patients and nonacute attack or control groups.	<b>Newborn outcomes:</b>  No significant differences were found in the incidence of congenital malformations, perinatal death, hypoglycemia, treatment in newborn ICU, or jaundice between births in acute attack patients and those in nonacute attack or controls.  No significant differences were found in perinatal deaths, Apgar scores, or relative birth weights between births in acute attack patients and those in nonacute attack patients or control groups.	
<b>Citation 13:</b> Wendel, Ramin, Barnett-Hamm, et al. 1996  Prospective randomized controlled trial	<b>x Human</b>  <u>Age:</u> 22 ± 5 years  <u>Race/Ethnicity:</u> • Hispanic: 46% • African American: 42% • White: 10%  <u>Pregnancy Trimester:</u> 2nd–3rd (22.7 ± 9.1 weeks)  <u>Eligibility:</u> • Asthma exacerbation prompting visit to ER or prenatal clinic and requiring inhaled bronchodilator therapy • FEV <70% predicted after initial therapy	<b>Purpose/Objective:</b> To study the effect of inhaled corticosteroids on asthma exacerbations in pregnancy.  <b>Arm 1: Outpatient group</b> (FEV >70% predicted after initial isoetharine therapy); patients discharged with no other therapy indicated  Outpatient followup only  <b>Arm 2:</b> Data for Arm 2 are shown at Bronchodilators—theophylline citation #15  <b>Arm 3: Inpatient group 2</b> (FEV <70% predicted after initial isoetharine therapy) • Albuterol MDI q4h • IV methylprednisolone 1 mg/kg q8h; maximum single dose = 80 mg	40 exacerbations (number of subjects not specified)	33 exacerbations (number of subjects not specified)	Duration: through delivery			<b>Maternal:</b>  <b>All patient groups (n = 72):</b>  <b>Obstetric complications:</b> • Pregnancy hypertension (n = 12) increased 13% over general population. • Cesarean sections (n = 21) increased 17% over general population. • Other complications were not outside the range of those in the general population.	Initially, 84 pregnant women were enrolled in the study; 12 patients overall were lost to followup. However, data (except for obstetric complications) are recorded in numbers of exacerbations, and the number of women experiencing exacerbations in each of the groups is not specified.  Patients in inpatient groups 1 and 2 underwent a second randomization at discharge into groups A and B.  Obstetric complications relate to all patients, both those in initial outpatient group and those in both inpatient groups.  The general population appears to refer to the obstetric population at the institution where the study was performed.

Table 5. Effects of oral steroids on maternal health and fetal outcomes when used to treat asthma during pregnancy.

Citation/ Study Type	Population	Study Characteristics				Findings			Comments																																					
		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3																																						
<b>Citation 1:</b> Abbott, Diliberto, Birnbaum 1992  Preclinical developmental toxicity study	<b>x Animal</b>  Pregnant C57BL/6N mice  Maternal Age: Not specified  Gestational Age: 10 days at 1st exposure	<b>Purpose/Objective:</b> To examine mechanisms of cleft palate induction by exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), retinoic acid (RA) + TCDD, and hydrocortisone (HC) + TCDD; to determine the effects of these exposures on the proliferation and differentiation of palatal cells and the relationship of these effects to those on growth factor expression.							Effects on growth factor expression varied: • TCDD increased TGF- $\beta_1$ peptide levels in the absence of altered mRNA expression. • HC and HC + TCDD strongly induced both TGF- $\beta_1$ peptide and mRNA. • Increase in EGF after HC and HC + TCDD was not accompanied by increased mRNA.  A palatal organ culture was used on medial epithelial cells; comparisons were made with cultured F344 rat and human palatal cultures.  Induction of medial cell responses with 1% FBS-containing medium suggests that serum factor plays a role in <i>in vitro</i> activity.  It remains to be seen if altered growth factor expression is a consequence of direct effects or is secondary to TCDD transcriptional regulation at other sites or posttranscriptional effects. Synergism between TCDD and RA or HC implies action through these pathways.

<b>Citation 2:</b> Abbott, Harris, Birnbaum 1992  Preclinical randomized, controlled teratology study	<b>x Animal</b>  Female C57BL/6N mice  <u>Maternal Age:</u> 8–10 weeks at mating  <u>Gestational Age:</u> 10 days at 1st exposure	<b>Purpose/Objective:</b> To extend the range of doses at which hydrocortisone (HC) and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) interaction occurs and to compare the morphological, cellular, and molecular responses of palates to HC vs. HC + TCDD.							Extreme sensitivity, indicated by teratogenic effects at very low doses, suggests involvement of a receptor-mediated mechanism, possibly resulting in altered regulation of gene expression.  Interaction between HC and TCDD results in a small palate resembling that induced by HC alone rather than the morphology typical of TCDD-induced clefting.  Both compounds inhibited programmed cell death of medial epithelium, which instead differentiated into oral-like epithelium.  Synergism between HC and TCDD may involve similar and potentially additive effects on regulators of proliferation and differentiation in the palate.

<b>Citation 4:</b> Abbott, Schmid, Brown, et al. 1999  Preclinical randomized, controlled teratology study	<b>x Animal</b>  Pregnant C57BL/6N mice  <u>Maternal Age:</u> Not specified  <u>Gestational Age:</u> 12 days at time of exposure	<b>Purpose/Objective:</b> To provide quantitative observations of glucocorticoid receptor (GR) and aryl hydrocarbon receptor (AhR) expression.							CYP1A1 is capable of biotransforming xenobiotics, such as polycyclic hydrocarbons and halogenated aromatic hydrocarbons, into carcinogenic or mutagenic compounds.  ARNT is considered to mediate effects of dioxin-like pollutants and aryl hydrocarbon signaling and toxicity by dimerizing with the ligand-activated AhR, forming a complex that binds specific DNA elements and alters transcription of target genes.  The relative overall expression of genes was AhR >ARNT >GR; within individuals, expression of AhR and/or ARNT highly correlated with GR level.
		<b>Arm 1:</b> TCDD 24 µg/kg, oral dose	4 fetuses from each of 3 litters	Same	<u>Length of treatment:</u>  Dams dosed at GD 12; fetuses collected at 4, 12, and 24 hours postexposure	<u>AhR expression:</u> <ul style="list-style-type: none"> <li>TCDD did not significantly alter expression.</li> <li>Expression was similar at 4 and 12 hours but increased significantly at 24 hours (p &lt; 0.05) for both TCDD groups and controls.</li> </ul>	<u>CYP1A1 expression:</u> <ul style="list-style-type: none"> <li>Significant rise 2–4 hours (p = 0.02); plateau 4–48 hours.</li> </ul>

<b>Citation 5:</b> Dodic, May, Wintour, et al. 1998  Preclinical controlled study	<b>x Animal</b>  Pregnant Merino ewes  <u>Maternal Age:</u> Not specified  <u>Gestational Age:</u> 22–29 days or 59–66 days	<b>Purpose/Objective:</b> To test the hypothesis that relatively brief prenatal treatment could have long-lasting deleterious consequences in a long-gestation mammal.							Pregnant ewes were transported from a farm to the study center, cannulated, treated, and returned to the farm, where they then lambed; control lambs were taken from sheep not exposed to stress of transportation or cannulation.  Prenatal treatment at end of first month, but not at end of second month of gestation, resulted in lambs which had significantly higher blood pressures from 4–19 months of age.
		<b>Arm 1: Dexamethasone</b> infusion at 0.28 mg/kg/day for 48 hours at GD 22–29 (prenatal treatment group 1 [PTG1])	8 ewes giving birth to 9 lambs, (6 F, 3 M, including 1 set of twins)	6 female lambs	<u>Length of treatment:</u>  48 hours  <u>Length of study:</u>  Up to 560 days postdelivery	<u>Basal mean arterial pressure in lambs:</u> <ul style="list-style-type: none"> <li>At 104–124 days, BP was significantly higher in PTG1 vs. controls (p &lt;0.05).</li> <li>At 285–323 days, BP was significantly higher in PTG1 vs. controls (p &lt;0.05).</li> <li>At 558–568 days, BP was significantly higher in PTG1 vs. controls (p &lt;0.05) and also vs. PTG2 (p &lt;0.05).</li> <li>BP changed significantly with age in controls (p &lt;0.05) and in PTG1 (p &lt;0.001), but not in PTG2.</li> </ul>	<u>BP responsiveness to NA, ANG II, and ACTH:</u> <ul style="list-style-type: none"> <li>At 104–124 days, BP responsiveness was similar across all groups.</li> <li>At 285–323 days, BP responsiveness was similar across all groups.</li> <li>At 558–568 days, BP responsiveness was similar across all groups.</li> </ul>		
		<b>Arm 2: Dexamethasone</b> infusion at 0.28 mg/kg/day for 48 hours at GD 59–66 (prenatal treatment group 2 [PTG2])	12 ewes giving birth to 11 lambs (7 F, 4 M)	7 female lambs					
		<b>Arm 3: Control</b>		7 female lambs					
<b>Citation 6:</b> Jobe, Wada, Berry, et al. 1998  Preclinical randomized controlled study	<b>x Animal</b>  Sheep  <u>Age:</u> Not specified  <u>Gestational Age:</u> 104 days at 1st exposure	<b>Purpose/Objective:</b> To evaluate the effects of a single dose or three repeated doses of maternal betamethasone on fetal growth at preterm and term delivery in sheep.							All pregnant ewes were given 150 mg medroxyprogesterone, i.m., at GD 97–102 to minimize the occurrence of preterm labor and abortion induced by glucocorticoids in sheep.  Sheep were divided into 2 groups: those delivered at 125 GD (preterm) and those delivered at 145 GD (term).  Decreases in length and head size were less pronounced than decreases in weight in the 3-dose group; therefore, the 3-dose group lost weight out of proportion to length and head size; this effect was not noted in 1-dose group.  The effect of a single dose at 104 GD, at both 125-day and 145-day delivery, and of 3 doses evaluated at term was proportionate to growth retardation in body size measurements, organ weights, organ DNA, and organ protein.
		<b>Arm 1: Betamethasone</b> 0.5 mg/kg i.m. <b>Citation 7:</b> Tangalakis, Lumbers, Moritz, et al. 1992  Preclinical randomized controlled study	<b>x Animal</b>  Merino ewes  <u>Age:</u> Not specified  <u>Gestational Age:</u> 103 days or 130 days at 1st exposure	<b>Purpose/Objective:</b> To test the potential pressor effect of exogenous cortisol in the ovine fetus between 100 and 120 days when endogenous cortisol production is minimal and after 130 days when endogenous plasma cortisol starts to rise.  <b>Arm 1: Cortisol</b> in immature (103–120 days of gestation) fetuses: 3-day schedule: day 1, control day; day 2, 24-hour infusion of 0.9% saline; day 3, 24-hour infusion of cortisol at 100 µg/hour	13	13	<u>Length of study:</u> Not specified  <u>Length of treatment:</u> 3 days	<u>Blood pressure (systolic/diastolic):</u>  Day 1: 50.8 ± 1.3/31.7 ± 1.3 Day 2: 51.7 ± 1.5/30.1 ± 1.2 Day 3: 59.1 ± 1.4/34.7 ± 1.7  Significant increase occurred in both systolic and diastolic pressures as a result of cortisol infusion (p <0.001).	<u>Effect of angiotensin II administered days 1–3:</u>  Day 1: No significant changes in blood pressure Day 2: No significant changes in blood pressure Day 3: Significant increase in systolic pressure (p <0.004)  Slope of dose-response curve was significantly steeper (p <0.001 for systolic, p <0.05 for diastolic pressure).	<u>Effect of noradrenaline administered days 1–3:</u>  Day 1: No significant changes in blood pressure Day 2: No significant changes in blood pressure Day 3: No significant changes in blood pressure	Angiotensin II and noradrenaline were administered randomly to the fetus in bolus i.v. doses of 0.2, 0.5, 1.0, and 2.0 µg on day 1 and following the 24-hour infusions on days 2 and 3. To let blood pressure and heart rate return to basal values, at least a 10-minute interval was allowed between consecutive doses.  No significant changes in fetal heart rate occurred in either regimen.  Basal blood pressure was higher in the mature group but did not increase further despite an increase in cortisol levels.  Vascular responsiveness to angiotensin II, but not to adrenaline, was significantly enhanced following cortisol infusion at both ages.

Citation/ Study Type	Population	Study Characteristics				Findings			Comments
		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3	
<b>Citation 7 (continued)</b>		<b>Arm 2: Cortisol</b> in mature (130–137 days of gestation) fetuses: 3-day schedule: day 1, control day; day 2, 24-hour infusion of 0.9% saline; day 3, 24-hour infusion of cortisol at 100 µg/hour	10	10		Day 1: 55.6 ± 0.8/34.7 ± 1.3 Day 2: 53.9 ± 1.4/34.3 ± 1.6 Day 3: 57.0 ± 1.6/34.9 ± 2.0  No significant increase in blood pressure occurred as a result of cortisol infusion.	Day 1: No significant changes in blood pressure Day 2: No significant changes in blood pressure Day 3: Increase in blood pressure  Slope of the dose-response curve was significantly steeper (p <0.01 for systolic, p <0.05 for diastolic pressure).	Day 1: No significant changes in blood pressure Day 2: No significant changes in blood pressure Day 3: No significant changes in blood pressure	Exogenous cortisol contributes to regulation of fetal blood pressure in the immature fetus when other mechanisms have not developed. Cortisol might achieve this effect, in part, by enhancing vascular sensitivity to angiotensin II.
<b>Citation 8:</b> Uno, Eisele, Sakai, et al. 1994  Preclinical longitudinal study	<b>x Animal</b>  Female rhesus monkeys  <u>Age:</u> Not specified  <u>Gestational Age:</u> 132 days at 1st exposure	<b>Purpose/Objective:</b> To examine longitudinal postnatal sequelae of prenatal brain damage resulting from exposure to dexamethasone in utero.							This paper also reviews the authors' earlier studies that examined the effects of prenatal glucocorticoids on hippocampal neurons.  Four consecutive images of hippocampal formations, coronal segments posterior from uncus, were selected for examination.  Familiarity between the caretaker and the mother- infant monkey pairs was established for 4 months prior to the study; thereafter, all handling and blood collections were done by the same caretaker.  Stress blood samples were taken after the infant was separated from the mother and kept in small, dark cage for 30 minutes. The infant was returned to its mother after the sample was drawn.  Results suggest that the hippocampus mediates negative feedback of cortisol release: lack or deficiency of hippocampal neurons attenuates this feedback, resulting in hypercortisolemia.
		<b>Arm 1: Dexamethasone</b> 5 mg/kg, multiple-doses	5	5	<u>Length of study:</u> 20 months  <u>Length of treatment:</u> GD 132–133	<u>Hippocampal MRI in 19- to 20-month-old infants:</u> • Both average area and volume of hippocampal segments were reduced 20–30% from those in vehicle-treated animals. • Total brain volume of the two groups showed no significant difference, although female brains were ~ 10% smaller in volume compared to male brains in same age groups.	<u>Plasma cortisol levels in 10-month-old infants (µg/dL):</u> • 10 a.m.: 30.1 ± 2.5 • 2 p.m.: 23.3 ± 2.6 • 2:30 p.m. (post-stress): 51.4 ± 3.4 • 3:30 p.m.: 49.5 ± 5.6 • 4:30 p.m.: 28.7 ± 2.9

<b>Citation 10:</b> Bracken, Triche, Belanger, et al. 2003  Prospective study	<b>x Human</b>  <u>Age:</u> <24–≥35 years  <u>Race/Ethnicity:</u> White/Asian: 1,496 (67.8%) African American: 209 (9.5%) Hispanic: 406 (18.4%) Other: 89 (4.0%)  <u>Pregnancy Trimester:</u> <24 weeks  <u>Eligibility:</u> Pregnant women <24 weeks gestation with history of physician- diagnosed asthma and random sample of nonasthmatic, pregnant women	<b>Purpose/Objective:</b> To examine whether asthma, asthma symptoms, or asthma therapy influence pregnancy outcomes (specifically, preterm delivery, intrauterine growth restriction [IUGR], gestational age, or birth weight) while controlling for other known risk factors.							Exclusion criteria included being more than 24 weeks pregnant at interview, having insulin-dependent diabetes mellitus, not speaking English or Spanish, and intending to terminate pregnancy.	
		<b>Arm 1: Asthma diagnosis</b>  (See Bronchodilators— β-agonists citation #3 for complete description of study arms)			<u>Length of study:</u> 4/97–6/00  <u>Length of treatment:</u> Not specified	<u>Preterm delivery</u> (adjusted associations):  (See Bronchodilators— β-agonists citation #3 for complete description of outcomes)	<u>IUGR:</u>  (See Bronchodilators— β-agonists citation #3 for complete description of outcomes)			Asthma symptoms were classified using the modified Global Initiative for Asthma (GINA) guidelines.  Asthma treatment was classified using modified GINA guidelines.
		<b>Arm 2: Asthma symptoms</b>  (See Bronchodilators— β-agonists citation #3 for complete description of study arms)								Asthma severity was determined by cross-classifying with the 2002 GINA grid on symptom and medication steps to derive 4 severity categories: intermittent, mild persistent, moderate persistent, and severe persistent.
		<b>Arm 3: Asthma severity</b>  (See Bronchodilators— β-agonists citation #3 for complete description of study arms)								Gestational age was calculated as completed days from first day of LMP or doctor's estimated date of delivery if LMP was uncertain.
		<b>Arm 4: Asthma treatment</b>  0 (no medication use) Step 1 Step 2 Step 3 Step 4	1,657 402 108 28 10	1,657 402 108 28 10		Preterm delivery increased with each increasing treatment step.  OR for 2 controller medications = 3.67 (95% CI 1.11, 12.16).  OR for 3 controller medications = 4.57 (95% CI 0.75, 24.63).  Overall, 32% increased risk (95% CI 0%, 76%) for every increase in treatment step.  Oral steroids use increased risk by 11% (95% CI 3%, 18%).  Oral steroids used daily across pregnancy reduced gestation 2.22 weeks (p = 0.001).	No increased risk by treatment step or for any specific medication type			Preterm delivery was defined as delivery before 37 weeks gestation.  Fetal growth restriction was defined as below 10th percentile of birth weight for gestational age.
	<u>Exposure:</u> • Oral steroids	52	52		<u>Specific exposure risks:</u> • Oral steroids: OR 1.11 (95% CI 1.03, 1.18)	<u>Specific exposure risks:</u> • Oral steroids: OR 0.99 (95% CI 0.93, 1.05)		Women with asthma symptoms but no asthma diagnosis are at particular risk of undermedication and delivering IUGR infants.

		Arm	Number Enrolled	Number Evaluable	Treatment Duration	Outcome 1	Outcome 2	Outcome 3		
<b>Citation 16:</b> Rodríguez-Pinilla and Martínez-Frías 1998  Case-control study	<b>x Human</b>  Age: Not specified  Race/Ethnicity: Not specified  Pregnancy Trimester: 1st  Eligibility: All infants born with congenital anomalies in ~ 75 participating hospitals and controls	<b>Purpose/Objective:</b> To present the results of a large case-control study, conducted by the Spanish Collaborative Study of Congenital Malformations (ECEMC), on the use of corticosteroids during pregnancy and the presence of oral clefts in the newborn (nonsyndromic).							<b>Maternal illness for steroids:</b> <ul style="list-style-type: none"> <li>• Addison's disease</li> <li>• Thrombocytopenia</li> <li>• Ulcerative colitis</li> <li>• Chronic sinusitis</li> </ul> <b>Key:</b> Case 4: CL, CP+ = cleft lip + cleft palate, diaphragmatic hernia, and hypoplasia of left kidney  Case 5: CL, CP+ = cleft lip + cleft palate, dysplastic ears, posterior fontanel, hemivertebra, ventricular hypertrophy, absent parathyroid gland, hypoplastic ovary, postaxial polydactyly, talipes  Researchers cannot rule out that case 5 is trisomy 13, because karyotype could not be performed.  Results of analysis were controlled for potential confounder factors such as maternal smoking, maternal hyperthermia, first-degree malformed relatives with cleft lip with or without cleft palate, and maternal treatment with antiepileptics, benzodiazepines, metronidazole, or sex hormones during first trimester of pregnancy.  The safety of oral steroids in first trimester is controversial.  The authors believe that corticosteroids in the first trimester should be restricted to life-threatening situations, diseases without any other safe alternative, or cases with replacement therapy.
