169

170

171 **P.1 REPORT MOTIVATION AND GUIDANCE FOR USING THIS SYNTHESIS**

172 **AND ASSESSMENT REPORT**

173 The core mission of the U.S. Climate Change Science Program (CCSP) is to “Facilitate

174 the creation and application of knowledge of the Earth’s global environment through

175 research, observations, decision support, and communication.” Toward accomplishing

176 this goal, the CCSP has commissioned 21 Synthesis and Assessment products to

177 summarize current knowledge and evaluate the extent and development of this

178 knowledge for future scientific explorations and policy planning.

179

180 These products fall within five goals, namely:

- 181 1) Improve knowledge of the Earth's past and present climate and environment,
182 including its natural variability, and improve understanding of the causes of
183 observed variability and change;
- 184 2) Improve quantification of the forces bringing about changes in the Earth's climate
185 and related systems;
- 186 3) Reduce uncertainty in projections of how the Earth's climate and environmental
187 systems may change in the future;
- 188 4) Understand the sensitivity and adaptability of different natural and managed
189 ecosystems and human systems to climate and related global changes; and
- 190 5) Explore the uses and identify the limits of evolving knowledge to manage risks
191 and opportunities related to climate variability and change.

192 CCSP Synthesis and Assessment Product 5.3 (CCSP 5.3) is one of three products to be
193 developed for the final goal.

194

195 This product directly addresses decision support experiments and evaluations that have
196 used seasonal forecasts and observational data, and is expected to inform (1) decision
197 makers about the experiences of others who have experimented with these forecasts and
198 data in resource management; (2) climatologists, hydrologists and social scientists on
199 how to advance the delivery of decision-support resources that use the most recent
200 forecast products, methodologies, and tools; and (3) science and resource managers as
201 they plan for future investments in research related to forecasts and their role in decision
202 support.

203

204 **P.2 BACKGROUND**

205 Gaining a better understanding of how to provide better decision support to decision and
206 policy makers is of prime importance to the CCSP, and it has put considerable effort and
207 resources towards achieving this goal. For example, within its Strategic Plan, the CCSP
208 identifies decision support: as one of its four core approaches to achieving its mission¹.
209 The plan endorses the transfer of knowledge gained from science in a format that is
210 usable and understandable and which indicates levels of uncertainty and confidence.
211 CCSP expects that the resulting tools will promote the development of new models, tools
212 and methods that will improve current economic and policy analyses as well as advance
213 environmental management and decision making.
214 CCSP has also encouraged the authors of the 21 synthesis and assessment products to
215 support informed decision making on climate variability and change. Most of the
216 Synthesis and Assessment Products' Prospectuses have outlined efforts to involve
217 decision makers including a broad group of stakeholders, policymakers, resource
218 managers, media, and the general public as either writers or have encouraged their
219 participation through special workshops/meetings. Inclusion of decision makers in the
220 Synthesis and Assessment reports also helps to fulfill the requirements of the Global
221 Change Research Act (GCRA) of 1990 (P.L. 101-606, section 106), which directs the
222 program to "produce information readily usable by policymakers attempting to formulate
223 effective strategies for preventing, mitigating, and adapting to the effects of global
224 change" and to undertake periodic science "assessments".

225

¹ The four core approaches of CCSP include science, observations, decision support, and communications.

226 Finally, in November 2005, the CCSP held a workshop to address the potential of those
227 working in the climate sciences to inform decision and policy makers. The workshop
228 included discussions about decision-maker needs for scientific information on climate
229 variability and change, as well as future steps, including the completion of this product,
230 for research and assessment activities that are necessary for sound resource management,
231 adaptive planning, and policy formulation. The conference was well received as over 260
232 abstracts were submitted and approximately 700 individuals from the U.S. and abroad
233 attended. The audience included representatives from academia; governments at the state,
234 local and national levels; non-governmental organizations (NGO); decision makers,
235 including resource managers and policy developers; Congress; and the private sector.

236

237 **P.3 FOCUS OF THIS SYNTHESIS AND ASSESSMENT PRODUCT**

238 In response to the 2003 Strategic Plan for the Climate Change Science Program Office,
239 which recommended the creation of a series of Synthesis and Assessment product
240 reports, the National Oceanic and Atmospheric Administration (NOAA) took
241 responsibility for this product. An interagency group comprised of representatives from
242 NOAA, National Aeronautic and Space Administration, Environmental Protection
243 Agency, U.S. Geological Survey and National Science Foundation wrote the Prospectus²
244 for this product and recommended that this synthesis and assessment product should
245 concentrate on the water resource management sector. This committee felt that focusing
246 on a single sector would allow for a detailed synthesis of lessons learned in decision-
247 support experiments within that sector. These lessons in turn would be relevant,

² The Prospectus is posted on the Climate Change Science Program website at:
<http://www.climatescience.gov>.

248 transferable, and essential to other climate-sensitive resource management sectors. Water
 249 resource management was chosen, as it was the most relevant of the sectors proposed and
 250 would be of interest to all agencies participating in this process. The group wrote a
 251 Prospectus and posed a series of questions that they felt the CCSP 5.3 report authors
 252 should address in this report. Table P.1 lists these questions and provides the location
 253 within the Synthesis and Assessment Report where the authors addressed them.

254

255 **Table P.1 Questions To Be Addressed in Synthesis and Assessment Product 5.3**

Prospectus Question	Report Location where Question is Addressed
What seasonal to interannual (<i>e.g.</i> , probabilistic) forecast information do decisionmakers need to manage water resources?	2.1
What are the seasonal to interannual forecast/data products currently available and how does a product evolve from a scientific prototype to an operational product?	2.2
What is the level of confidence of the product within the science community and within the decision making community, who establishes these confidence levels and how are they determined?	2.2
How do forecasters convey information on climate variability and how is the relative skill and level of confidence of the results communicated to resource managers?	2.3
What is the role of probabilistic forecast information in the context of decision support in the water resources sector?	2.3
How is data quality controlled?	2.3
What steps are taken to ensure that this product is needed and will be used in decision support?	2.5
What types of decisions are made related to water resources?	3.2
What is the role that seasonal to interannual forecasts play and could play?	3.2
How does climate variability influence water resource management?	3.2
What are the obstacles and challenges decision makers face in translating climate forecasts and hydrology information into integrated resource management?	3.2
What are the barriers that exist in convincing decision makers to consider using risk-based hydrology information (including climate forecasts)?	3.2
What challenges do tool developers have in finding out the needs of decision makers?	3.3
How much involvement do practitioners have in product development?	4.1
What are the measurable indicators of progress in terms of access to information and its effective uses?	4.3

Identify critical components, mechanisms, and pathways that have led to successful utilization of climate information by water managers.	4.4
Discuss options for (a) improving the use of existing forecasts/data products and (b) identify other user needs and challenges in order to prioritize research for improving forecasts and products.	4.4 and 5
Discuss how these findings can be transferred to other sectors.	5

256

257 **P.4 THE SYNTHESIS AND ASSESSMENT WRITING TEAM**

258 This study required an interdisciplinary team that was able to integrate scientific
259 understandings about forecast and data products with a working knowledge of the needs
260 of water resource managers in decision-making. As a result, the team included
261 researchers, decision makers, and Federal government employees with varied
262 backgrounds in the social sciences, physical sciences, and law. The authors were
263 identified based on a variety of considerations, including their past interests and
264 involvements with decision-support experiments and their knowledge of the field as
265 demonstrated by practice and/or involvement in research and/or publications in refereed
266 journals. In addition, the authors held a public meeting, in January 2007, in which they
267 invited key stakeholders to discuss their decision support experiments with the
268 committee. Working with authors and stakeholders with such varied backgrounds
269 presented some unique challenges including preconceived notions of other disciplines, as
270 well as the realization that individual words have different meanings in the diverse
271 disciplines.

272

273 The author team for this Product was constituted as a Federal Advisory Committee in
274 accordance with the Federal Advisory Committee Act of 1972 as amended, 5 U.S.C.
275 App.2. The full list of the Author Team, in addition to a list of lead authors provided at

276 the beginning of each Chapter, is provided on page 3 of this report. The Editorial Staff
277 reviewed the scientific and technical input and managed the assembly, formatting and
278 preparation of the Report.

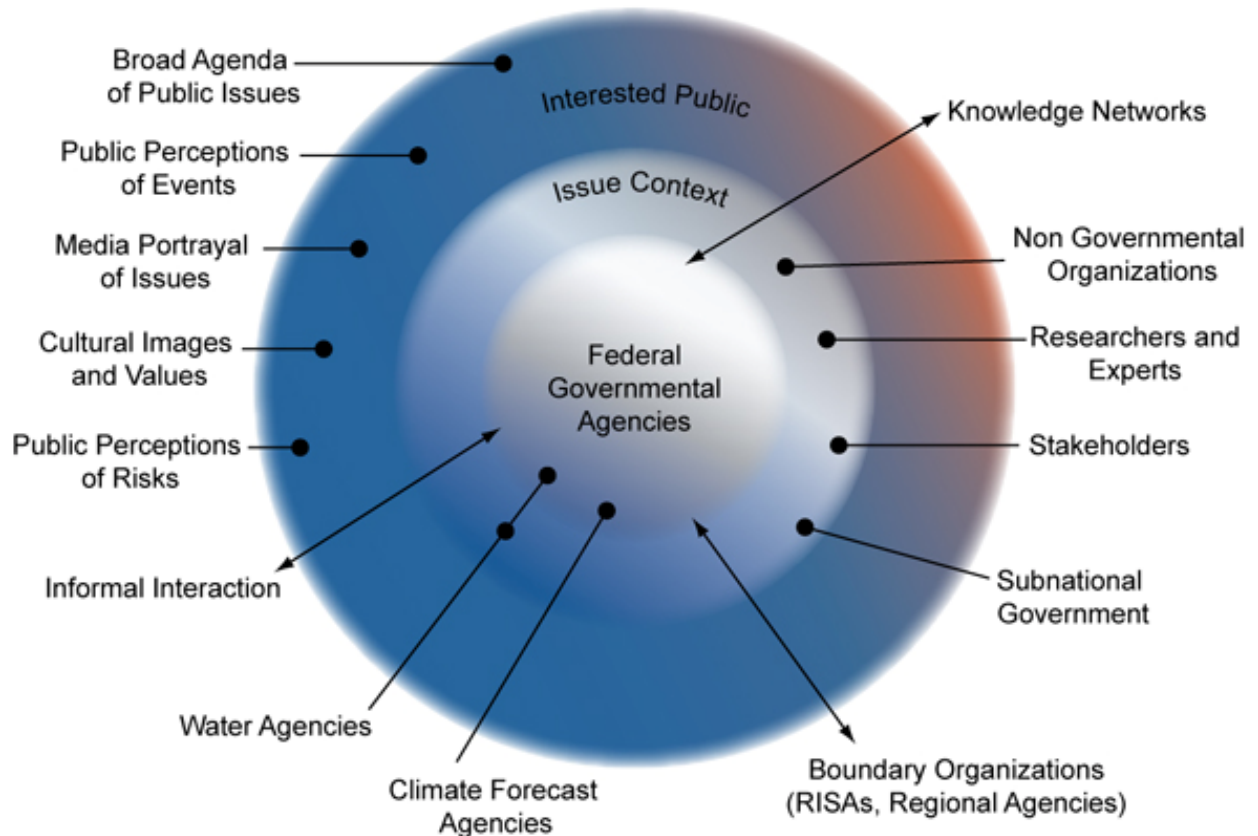

279

280 **P.5 HOW THIS SYNTHESIS AND ASSESSMENT PRODUCT IS ORGANIZED**
281 **AND WHY**

282 In discussions of how water resource management decisions are made within a climate
283 context the author team identified several major influences. Figure P.1 portrays the
284 different contexts that the authors of this product identified in which climate variation
285 and change information is considered.

286

Multiple and Interacting Contexts for Interpretation and Use of Seasonal to Interannual Forecasts and Observational Data

287

288 **Figure P.1** Contexts for interpretation and use of seasonal forecasts and observational data. The layers of
 289 the circle are described in the text below. Several organizations and approaches span multiple contexts,
 290 indicated by the arrows.
 291

292 The innermost circle contains federal climate and water related agencies, which provide
 293 the initial climate forecasts and climate and water resource operational data. As described
 294 in Chapter 2, climate forecasts are generally produced by national centers at larger scales
 295 in terms of space and time and are meant to serve a broad-range of uses. On the other
 296 hand, hydrologic forecasts are generally produced by regional and local agencies and
 297 tend to focus on water supplies.

298

299 The intermediate circle represents the context in which the forecasts and data are received
300 and interpreted. The same forecast in two different locations would be interpreted
301 according to the conditions and prevailing values of those locations. Factors such as the
302 public's perceptions of risk, cultural images and values, and even the media portrayal of
303 the event all influence the policy and decision makers' actions in response to these
304 forecasts and data. Chapters 3, 4 and 5 discuss the conditions necessary for uptake of new
305 information, and the knowledge-to-action networks that exist to provide information
306 dissemination to individuals and interest groups, equity implications of receiving and
307 using this information, and nature of science citizenship in participation of science-based
308 decision making.

309

310 The outer circle encompasses the attentive public and the interested actors for whom
311 climate information is of regular concern. Within the interested public are stakeholder
312 groups and entities concerned with climate in state and regional governmental entities.
313 Informal interaction and cooperation, as well as more formalized boundary organizations
314 are depicted as arrows going both inward and outward. This level of intermediate context
315 is described in Chapters 3 and 4. Decision support experiments within the water resource
316 management sector are also described in Chapters 3 and 4, as well as the barriers and
317 opportunities for better integrating these experiments into decision making. Chapter 5
318 discusses the lessons learned within decision support experiments and research areas that
319 are critical for progress.

320

321 Finally, some terms used in this Report may be unfamiliar to those not trained in the
322 physical or social sciences; a glossary and list of acronyms is included at the end of this
323 Report.

352 **Editor:** Anne M. Waple, STG, Inc.

353

354 **ES.1 WHAT IS DECISION SUPPORT AND WHY IS IT NECESSARY?**

355 Earth's climate is naturally varying and also changing in response to human activity. Our

356 ability to adapt and respond to climate variability and change depends, in large part, on

357 our understanding of the climate and how to incorporate this understanding into our

358 resource management decisions. Water resources in particular, are directly dependent on

359 the abundance of rain and snow and how we store and use the amount of water available.

360 With an increasing population, a changing climate and the expansion of human activity

361 into semi-arid regions of the United States, water management has unique and evolving

362 challenges. This report focuses on the connection between the scientific ability to predict

363 climate (on seasonal scales) and the opportunity to incorporate such understanding into

364 water resource management decisions. Reducing our societal vulnerability to changes in

365 climate depends upon our ability to bridge the gap between climate science, and the

366 implementation of scientific understanding in our management of critical resources –

367 arguably the most important of which, is water. It is important to note, however, that
368 while the focus of this report was on the water resources management sector, the findings
369 within this Synthesis and Assessment Product may be directly transferred to other
370 sectors.

371

372 The ability to predict many aspects of climate and hydrologic variability on seasonal to
373 interannual time scales is a significant success in earth systems science. Connecting the
374 improved understanding of this variability to water resources management is a complex
375 and evolving challenge. While much progress has been made, conveying climate and
376 hydrologic forecasts in a form useful to real world decision making introduces
377 complications that call upon the skills not only of climate scientists, hydrologists, and
378 water resources experts, but also social scientists with the capacity to understand and
379 work within the dynamic boundaries of organizational and social change.

380

381 Up until recent years, the provision of climate and hydrologic forecast products has been
382 a producer-driven rather than a user-driven process. The momentum in product
383 development has been largely skill-based rather than a response to demand from water
384 managers. It is now widely accepted that there is considerable potential for increasing the
385 use and utility of climate information for decision-support in water resources
386 management even without improving the skill level of climate and hydrologic forecasts.
387 The outcomes of “experiments” intended to deliver climate-related decision support
388 through ‘knowledge-to-action networks’ in water resource related problems are very
389 encouraging.

390

391 Linkages between climate and hydrologic scientists are getting stronger as they now more
392 frequently collaborate to create forecast products. A number of complex factors influence
393 the rate at which seasonal water supply forecasts and climate-driven hydrologic forecasts
394 are improving in terms of skill level. Mismatches between needs and information
395 resources continue to occur at multiple levels and scales. There is currently substantial
396 tension between providing tools at the space and time scales useful for water resources
397 decisions that are also scientifically accurate, reliable, and timely.

398 The concept of decision support has evolved over time. Early in the development of
399 climate information tools, *decision support* meant the translation and delivery of climate
400 science information into forms believed to be useful to decision makers. With experience
401 it became clear that climate scientists very often did not know what kind of information
402 would be useful to decision makers. Further, decision makers who had never really
403 considered the possibility of using climate information were not yet in a position to
404 articulate what they needed. It became obvious that user groups had to be involved at the
405 point at which climate information began to be developed. Making climate science useful
406 to decision makers involves a process in which climate scientists, hydrologists, and the
407 potential users of their products engage in an interactive process during which trust and
408 confidence is built at the same time that climate information is exchanged.

409

410 The institutional framework in which decision-support experiments are developed has
411 important effects. Currently there is a disconnect between agency-led operational
412 forecasts and experimental hydrologic forecasts being carried out in universities.

413 However, as shown by the experiments highlighted in this Product, it is possible to
414 develop decision-support tools, processes and institutions that are relevant to different
415 geographical scales and are sufficiently flexible to serve a diversity of users. Such tools
416 and processes can reveal commonalities of interests and shared vulnerabilities that are
417 otherwise obscure. Well designed tools, institutions and processes can clarify necessary
418 trade-offs of short term and long term gains and losses to potentially competing values
419 associated with water allocation and management.

420

421 Evidence suggests that many of the most successful applications of climate information
422 to water resource problems occur when committed leaders are poised and ready to take
423 advantage of unexpected opportunities. In evaluating the ways in which science-based
424 climate information is finding its way to users, it is important to recognize that straight-
425 forward, goal-driven processes do not characterize the real world. We usually think of
426 planning and innovation as a linear process, but experience shows us that it is a nonlinear,
427 chaotic process with emergent properties. This is particularly true when working with
428 climate impacts and resource management. It is clear that we must address problems in
429 new ways and understand how to encourage diffusion of new innovations.

430

431 The building of knowledge networks is a valuable way to provide decision support and
432 pursue strategies to put knowledge to use. Knowledge networks require widespread
433 sustained human efforts that persist through time. Collaboration and adaptive
434 management efforts among resource managers and forecast producers with different
435 missions show that mutual learning informed by climate information can occur between

436 scientists with different disciplinary backgrounds and between scientists and managers.
437 The benefits of such linkages and relationships are much greater than the costs incurred
438 to create and maintain them, however, the incentives for these associations are often
439 neglected or discouraged. It is commonly the case that collaborations across
440 organizational, professional, disciplinary and other boundaries are not given high priority;
441 incentives and reward structures need to change to take advantage of this opportunity. In
442 addition, the problem of data overload for people at critical junctions of information
443 networks, and for people in decision making capacity such as those of resource managers
444 and climate scientists, generally is a serious impediment to innovation.

445

446 Decision-support experiments employing climate related information have had varying
447 levels of success in integrating their findings with the needs of water and other resource
448 managers.

449

450 **ES.2 CLIMATE AND HYDROLOGIC FORECASTS: THE BASIS FOR MAKING**
451 **INFORMED DECISIONS**

452 There are a wide variety of climate and hydrologic data and forecast products currently
453 available for use by decision-makers in the water resources sector. However, the use of
454 official seasonal to interannual (SI) climate and hydrologic forecasts generated by federal
455 agencies remains limited in this sector. Forecast skill, while recognized as just one of the
456 barriers to the use of seasonal to interannual climate forecast information, remains a
457 primary concern among forecast producers and users. Simply put, there is no incentive to
458 use SI climate forecasts when they are believed to provide little additional skill to

459 existing hydrologic and water resource forecast approaches. Not surprisingly, there is
460 much interest in improving the skill of hydrologic and water resources forecasts. Such
461 improvements can be realized by pursuing several research pathways, including:

- 462 • Improved monitoring and assimilation of real-time hydrologic observations in
463 land surface hydrologic models that leads to improved estimates for initial
464 hydrologic states in forecast models;
- 465 • Increased accuracy in SI climate forecasts; and,
- 466 • Improved bias corrections in existing forecast.

467

468 Another aspect of forecasts that serves to limit their use and utility is the challenge in
469 interpreting forecast information. For example, from a forecast producer's perspective
470 confidence levels are explicitly and quantitatively conveyed by the range of possibilities
471 described in probabilistic forecasts. From a forecast user's perspective, probabilistic
472 forecasts are not always well understood or correctly interpreted. Although structured
473 user testing is known to be an effective product development tool, it is rarely done.

474 Evaluation should be an integral part of improving forecasting efforts, but that evaluation
475 should be extended to factors that encompass use and utility of forecast information for
476 stakeholders. In particular, very little research is done on effective seasonal forecast
477 communication. Instead, users are commonly engaged only near the end of the product
478 development process.

479

480 Other barriers to the use of SI climate forecasts in water resources management have
481 been identified and those that relate to institutional issues and aspects of current forecast
482 products are discussed in chapters 3 and 4 of this report.

483

484 Pathways for expanding the use and improving the utility of data and forecast products to
485 support decision-making in the water resources sector are currently being pursued at a
486 variety of spatial and jurisdictional scales in the US. These efforts include:

- 487 • An increased focus on developing forecast evaluation tools that provide users
488 with opportunities to better understand forecast products in terms of their
489 expected skill and applicability;
- 490 • Additional efforts to explicitly and quantitatively link SI climate forecast
491 information with SI hydrologic and water supply forecasting efforts;
- 492 • An increased focus on developing new internet-based tools for accessing and
493 customizing data and forecast products to support hydrologic forecasting and
494 water resources decision-making; and,
- 495 • Further improvements in the skill of hydrologic and water supply forecasts.

496

497 Many of these pathways are currently being pursued by the federal agencies charged with
498 producing the official climate and hydrologic forecast and data products for the US, but
499 there is substantial room for increasing these activities.

500

501 Recent improvements in the use and utility of data and forecast products related to water
502 resources decision-making have come with an increased emphasis on these issues in

503 research funding agencies through programs like the National Oceanic and Atmospheric
504 Administration's RISA, SARP, TRACS and CPPA and the World Climate Research
505 Programme's GEWEX programs. Sustaining and accelerating future improvements in the
506 use and utility of official data and forecast products in the water resources sector rests in
507 part on sustaining and expanding federal support for programs focused on improving the
508 skill in forecasts, increasing the access to data and forecast products, and fostering
509 sustained interactions between forecast producers and consumers.

510

511 **ES.3 DECISION-SUPPORT EXPERIMENTS IN THE WATER RESOURCE**

512 **SECTOR**

513 Decision-support experiments that test the utility of SI information for use by water
514 resource decision-makers have resulted in a growing set of successful applications.

515 However, there is significant opportunity for expansion of applications of climate-related
516 data and decision-support tools, and for developing more regional and local tools that
517 support management decisions within watersheds. Among the constraints that limit tool
518 use are:

- 519 • The range and complexity of water resources decisions. This is compounded by
520 the numerous organizations responsible for making these decisions, and the
521 shared responsibility for implementing them.
- 522 • Inflexible policies and organizational rules that inhibit innovation. Government
523 agencies historically have been reluctant to change practices; in part because of
524 value differences, risk aversion, fragmentation and sharing of authority. This

525 conservatism impacts how decisions are made as well as whether to use newer,
526 scientifically generated information, including SI forecasts and observational data.

527 • Different spatial and temporal frames for decisions. Spatial scales for decision-
528 making range from local, state, and national levels to international. Temporal
529 scales range from hours to multiple decades impacting policy, operational
530 planning, operational management, and near real-time operational decisions.
531 Resource managers often make multi-dimensional decisions spanning various
532 spatial and temporal frames.

533 • Lack of appreciation of the magnitude of potential vulnerability to climate
534 impacts. Communication of the risks differs among scientific, political, and mass
535 media elites – each systematically selecting aspects of these issues that are most
536 salient to their conception of risk, and thus, socially constructing and
537 communicating its aspects most salient to a particular perspective.

538

539 Decision-support systems are not often well integrated into planning and management
540 activities, making it difficult to realize the full benefits of these tools. Because use of
541 many climate products requires special training or access to data that are not easily
542 available, decision-support products may not equitably reach all audiences. Moreover,
543 over-specialization and narrow disciplinary perspectives make it difficult for information
544 providers, decision-makers, and the public to communicate with one another. Three
545 lessons stem from this:

- 546 • Decision-makers need to understand the types of predictions that can be made,
547 and the tradeoffs between longer-term predictions of information at the local or
548 regional scale on the one hand, and potential decreases in accuracy on the other.
- 549 • Decision-makers and scientists need to work together in formulating research
550 questions relevant to the spatial and temporal scale of problems the former
551 manage.
- 552 • Scientists should aim to generate findings that are accessible and viewed as
553 useful, accurate and trustworthy by stakeholders.

554

555 **ES.4 MAKING DECISION-SUPPORT INFORMATION USEFUL, USEABLE,**
556 **AND RESPONSIVE TO DECISION-MAKER NEEDS**

557 Decision-support experiments that apply SI climate variability information to basin and
558 regional water resource problems serve as test beds that address diverse issues faced by
559 decision-makers and scientists. They illustrate how to identify user needs, overcome
560 communication barriers, and operationalize forecast tools. They also demonstrate how
561 user participation can be incorporated in tool development.

562

563 Five major lessons emerge from these experiments and supporting analytical studies:

- 564 • The effective integration of SI climate information in decisions requires long-term
565 collaborative research and application of decision-support through identifying
566 problems of mutual interest. This collaboration will require a critical mass of
567 scientists and decision-makers to succeed and there is currently an insufficient
568 number of “integrators” of climate information for specific applications.

- 569 • Investments in long-term research-based relationships between scientists and
570 decision-makers must be adequately funded and supported. In general, progress
571 on developing effective decision-support systems is dependent on additional
572 public and private resources to facilitate better networking among decision-
573 makers and scientists at all levels as well as public engagement in the fabric of
574 decision-making.
- 575 • Effective decision-support tools must wed national production of data and
576 technologies to ensure efficient, cross-sector usefulness with customized products
577 for local users. This requires that tool developers engage a wide range of
578 participants, including those who generate tools and those who translate them, to
579 ensure that specially-tailored products are widely accessible and are immediately
580 adopted by users insuring relevancy and utility.
- 581 • The process of tool development must be inclusive, interdisciplinary, and provide
582 ample dialogue among researchers and users. To achieve this inclusive process,
583 professional reward systems that recognize people who develop, use and translate
584 such systems for use by others are needed within water management and related
585 agencies, universities and organizations. Critical to this effort, further progress in
586 boundary spanning – the effort to translate tools to a variety of audiences –
587 requires considerable organizational skills.
- 588 • Information generated by decision-support tools must be implementable in the
589 short term for users to foresee progress and support further tool development.
590 Thus, efforts must be made to effectively integrate public concerns and elicit
591 public information through dedicated outreach programs.

592 **ES.5 LOOKING TOWARD THE FUTURE; RESEARCH PRIORITIES**

593 A few central themes emerge from this report, which are summarized here. Then some
594 key research priorities are also highlighted.

595

596 **ES.5.1 Key Themes**

597 *1) The “Loading Dock Model” of Information Transfer is Unworkable.*

598 Skill is a necessary ingredient in perceived forecast value, yet more forecast skill by itself
599 does not imply more forecast value. Lack of forecast skill and/or accuracy may be one of
600 the impediments to forecast use, but there are many other barriers. Such improvements
601 must be accompanied by better communication and stronger linkages between forecasters
602 and potential users. In this report we have stressed that forecasts flow through knowledge
603 networks and across disciplinary and occupational boundaries. Thus, forecasts need to be
604 useful and relevant in the full range from observations to applications, or “end-to-end
605 useful.”

606

607 *2) Decision-Support is a Process Rather Than a Product.*

608 As knowledge systems have come to be better understood, providing decision support has
609 come to be understood not only as information products but instead as a communications
610 process that links scientists with users

611

612 *3) Equity May Not Be Served.*

613 Information is power in global society, and unless it is widely shared, the gaps between
614 the rich and the poor, and the advantaged and disadvantaged may widen.

615

616 *4) Science Citizenship Plays an Important Role in Developing Appropriate Solutions.*

617 Some scholars observe that a new paradigm in science is emerging, one that emphasizes

618 science-society collaboration and production of knowledge tailored more closely to

619 society's decision making needs. Concerns about climate impacts on water resource

620 management are among the most pressing problems that require close collaboration

621 between scientists and decision makers.

622

623 *5) Trends and Reforms in Water Resources Provide New Perspectives.*

624 Since the 1980s – some researchers suggest – a “new paradigm” or frame for federal

625 water planning has occurred, although no clear change in law has brought this change

626 about. This new paradigm appears to reflect the ascendancy of an environmental

627 protection ethic among the general public. The new paradigm emphasizes greater

628 stakeholder participation in decision-making; explicit commitment to environmentally-

629 sound, socially just outcomes; greater reliance upon drainage basins as planning units;

630 program management via spatial and managerial flexibility, collaboration, participation,

631 and sound, peer-reviewed science; and, embracing of ecological, economic, and equity

632 considerations

633

634 *6) Useful Evaluation of Applications of Climate Variation Forecasts Requires Innovative*635 *Approaches.*

636 There can be little argument that SI forecast applications must be evaluated just as are
637 most other programs that involve substantial public expenditures. This report also
638 illustrates many of the difficulties of using standard evaluation techniques.

639

640 **ES.5.2 Research Priorities**

641 As a result of the findings in this report, we suggest that a number of research priorities
642 should constitute the focus of attention for the foreseeable future. These priorities are:

- 643 • Improved vulnerability assessment
- 644 • Improved climate and hydrologic forecasts
- 645 • Enhanced monitoring to better link climate and hydrologic forecasts
- 646 • Better integration of SI climate science into decision making
- 647 • Better balance between physical science and social science research related to the
648 use of scientific information in decision making
- 649 • Better understanding of the implications of small-scale, specially-tailored tools,
650 and
- 651 • Sustained long-term scientist-decision-maker interactions and collaborations and
652 development of science citizenship.

670

671 **1.1 INTRODUCTION**

672 Increasingly frequent headlines such as “UN Calls Water Top Priority” (*The Washington*

673 *Post, January 25, 2008*), “Drought-Stricken South Facing Tough Choices (*The New York*

674 *Times, Oct 15, 2007*), “The Future is Drying Up” (*The New York Times, October 21,*

675 *2007*), coupled with the realities of less available water, have helped to alert decision

676 makers, from U.S. governors and mayors to individual farmers, that climate information

677 is crucial in future planning. The past quarter-century has also seen significant advances

678 in the ability to monitor and predict important aspects of seasonal to interannual

679 variations in climate, especially those associated with variations of the El Niño Southern

680 Oscillation (ENSO) cycle. Predictions of climate variability on seasonal to interannual

681 time scales are now routine and operational, and consideration of these forecasts in

682 making decisions has become more commonplace. Some water resources decision
683 makers have already begun to use seasonal, interseasonal, and even longer-time scale -
684 climate forecasts and observational data in assessing future options, while others are just
685 beginning to realize the potential of these resources. This report is meant to show how
686 climate and hydrologic forecast and observational data are being used, or neglected, by
687 water resources decision makers and suggests future pathways for increased use.

688

689 The Climate Change Science Program (CCSP) included a chapter in their 2003 Strategic
690 Plan that described the critical role of decision support in climate science; it was included
691 because previous assessment analyses and case studies had highlighted the importance of
692 assuring that climate information and data would be used by decision makers and not be
693 produced in a vacuum. Since that time, there has been an increase in interest and research
694 in decision support science including for organizations using seasonal to interannual
695 forecasts and observational data in future planning. Five years since the release of the
696 Strategic Plan, one of the main purposes of CCSP continues to be to “provide information
697 for decision-making through the development of decision-support resources¹.” (2008 Our
698 Changing Planet) As a result, CCSP has charged this author group to produce a Synthesis
699 and Assessment report that directly addresses decision support experiments and
700 evaluations in the water resources sector.

701

702 The authors of this product have concentrated their efforts on discussing seasonal to
703 interannual forecasts and data products, though in some cases, longer-range forecasts are

¹ According to this same document, “Decision-support resources, systems, and activities are climate-related products or processes that directly inform or advise stakeholders to help them make decisions.”

704 discussed because they have simply become a part of the decision making process and
705 separating them would cloud the examples given. We have provided a range of domestic
706 case study examples, referred to as “experiments and/or evaluations”, but have provided
707 some international examples, where appropriate.

708

709 **1.2 INCREASING STRESS AND COMPLEXITY IN WATER RESOURCES**

710 Under conditions of global warming and with an ever-accelerating demand for abundant
711 water supplies, the management of water may become increasingly politically charged
712 throughout the world in the coming century. Emerging challenges in water quantity,
713 quality, pricing, and seasonal climate fluctuations may all increase as the demand
714 continues to rise. Though it may well be the case that the total volume of water on the
715 planet is sufficient for societies’ needs, the largest portion of this water is geographically
716 remote, misallocated, wasted, or degraded by pollution (Whiteley *et al.*, 2008). At the
717 same time, there are shifts in the use to which it is put, the value given by society to
718 natural systems, and the changing laws that govern management of the resource.
719 Accordingly, the impact of climate on water resource management and the needs of
720 people has far-reaching implications for everyone from the farmer who may need to
721 change the timing of crop planting/harvesting or the crop type itself to citizens that may
722 have to move because their potable water supply has disappeared.

723

724 In the U.S., water resource decisions are made at multiple levels of government and
725 increasingly by the private sector. There is no national water policy, but rather a
726 patchwork of policies, amended by degree over decades. “Water” is

727 controlled/guided/governed by a gamut of Federal agencies overseeing various aspects
728 from quality (U.S. Environmental Protection Agency [EPA]) to quantity (U.S. Geological
729 Survey [USGS], Bureau of Land Management [BLM]). This is complicated by state,
730 regional, and jurisdictional boundaries and responsibilities. Defining a “decision maker”
731 is equally difficult given the complexity of water’s use and the types of information that
732 can be used to make decisions. Our challenge in writing this report is to reflect the
733 diverse models under which water is managed and the diverse character of decisions that
734 comprise water management. To illustrate: the term “water management” encompasses
735 decisions by a municipal water entity about when to impose outdoor water restrictions;
736 decisions by a federal agency about how to operate a storage facility; decisions by the
737 Congress about funding of recovery efforts for an endangered species; and decisions by a
738 state government about water purchases necessary to ensure compact compliance.

739

740 These types of decisions may be based on multiple factors, such as cost, climate (past
741 trends and future forecasts), community preferences, political advantage, strategic
742 concerns for future water decisions, *etc.* Further, water reflects many different values
743 including economic, security, opportunity, environmental quality, lifestyle, and a sense of
744 place (Blatter and Ingram, 2005). Information about climate variability can be expected
745 to affect some of these decisions and moderate some of these values; for others it may be
746 of remote interest or viewed as entirely irrelevant.

747

748 The rapidly-closing gap between usable supplies and rising demand is being narrowed by
749 a myriad of factors, some of the most important include:

- 750 • Demand for water is increasing with population growth in terms of potable
751 drinking water, agricultural/food requirements, energy needs, *etc.*
- 752 • Recreational and environmental interests in rivers have received greater
753 representation in the political processes, with attendant success in protecting
754 stream waters.
- 755 • Groundwater development enabled the expansion of western agriculture and is the
756 basis for the development of several urban regions. As groundwater reserves are
757 mined, pressure increases on other water sources.
- 758 • Water quality is a problem that persists, despite decades of regulations and
759 planning.

760

761 Most well-documented of these pressures is population growth, which is occurring in the
762 U.S. as a whole, and especially in the sunbelt states where water resources are also
763 among the scarcest. Because water sources were developed and rights created in much
764 earlier time periods, new uses must search for additional supplies. Las Vegas, Nevada is a
765 case study of the measures required to provide water in the desert, but Phoenix,
766 Albuquerque, Denver, Los Angeles and a host of other western cities provide comparable
767 examples. In the Southeastern United States, rapid growth of cities, such as Atlanta,
768 combined with growing environmental concerns that require water to sustain habitat, and
769 poor management, have all lead to serious shortages.

770

771 Recreational and environmental interests also have a direct stake in how waters are
772 managed. For example, fishing and boating have increased with importance as the
773 economic basis of our economy has changed.

774

775 Groundwater mining is a wild card in national water policy. Water resource allocation is
776 generally a matter of state, not federal control, and each state has different policies with
777 respect to groundwater. Some have no regulation; others permit mining (also referred to
778 as groundwater overdrafting). Because groundwater is not visible, it was less likely to be
779 regulated than surface water use. The effects of groundwater mining become evident
780 when regions must search for alternative sources of water.

781

782 These increasing demands for water are not likely to be met with the development of
783 major additional sources of water supply, although some additional storage likely will be
784 developed. The nation engaged in an extended period of construction (cite USGS on
785 dams and reservoirs) in which most of the appropriate sites for construction were utilized.
786 Further, as rivers are fully appropriated, or over appropriated, there is no longer “surplus”
787 water available for development. Environmental and recreational issues are implicated in
788 further development of rivers, making these alternatives more susceptible to challenge.

789

790 In response to these challenges, jurisdictions are developing alternatives such as water
791 reuse utilizing groundwater storage and recovery, which avoids reservoir siting issues;
792 conservation and improved efficiency, which has contributed to steady declines in per
793 capita consumption; desalinization of water, and conjunctive management of ground and

794 surface water. Pipelines, which have been used for decades, are suggested as the solution
795 to one region's water shortages, only to be met by resistance from the area of origin.

796

797 The most appealing water management solutions, then, are the most modest. Water
798 conservation, which may rely on incentives or regulation, often is the least expensive way
799 of meeting demand. Water pricing has been heralded by generations of economists as the
800 means of ensuring that water choices are wisely made. Transfers of water from one use to
801 another, commonly from agricultural to urban uses in the western U.S., are becoming
802 more common as a means of adjusting to changing economic realities. However, these
803 modest solutions that have lead to more efficient water allocation have also reduced
804 flexibility to adapt to climate variation and change.

805

806 The mosaic of water use may be viewed through another lens, which is the relative
807 flexibility of each demand. Municipal and industrial demands can be moderated through
808 conservation or temporary restrictions on use, but these demands are relatively fixed. In
809 contrast, agricultural uses, which still comprise the largest users by volume, can be
810 restricted in times of drought. The increasing connection between water and energy may
811 limit this flexibility. For example, greater reliance on biofuels both increase competition
812 for scarce water supplies and divert irrigated agriculture from the production of food to
813 the production of oilseeds such as soybeans, corn, rapeseed, sunflower seed, and
814 sugarcane among other crops. While parts of China and India have already breached the
815 limit of sustainable water use, without the added strain of trying to grow significant
816 quantities of biofuels, to a lesser but still serious extent, the reliance upon growing corn

817 for ethanol has changed the pattern of agricultural water use also in the U.S (Whiteley *et*
818 *al.*, 2008).

819

820 Rationalization of U.S. policies concerning water has been a goal for many decades.

821 Emergent issues of increased climate variability and change may be the agents of

822 transformation for U.S. water policies as many regions of the country are forced to

823 examine the long term sustainability of water related management decisions.

824

825 **1.2.1 The Evolving Context: The Importance of Issue Frames**

826 In order to fully understand the context in which a decision is made, those in the decision

827 support sciences often look at the “issue frame” or the factors influencing the decision

828 makers including the general frame of mind of society at the time. A common

829 denominator for conceptualizing a frame is the notion that a problem can be understood

830 or conceptualized in different ways (Dewulf *et al.*, 2005). For the purpose of this report,

831 an issue frame can be considered a tool that allows us to understand the importance of a

832 problem (Weick, 1995). Thus, salience is important part of framing. It is fair to categorize

833 most water resources decisions in previous decades as low salience issues, the kind that

834 do not attract much public notice. This low visibility is associated with the widespread

835 perception that the adequate delivery of acceptable water is within the realm of experts

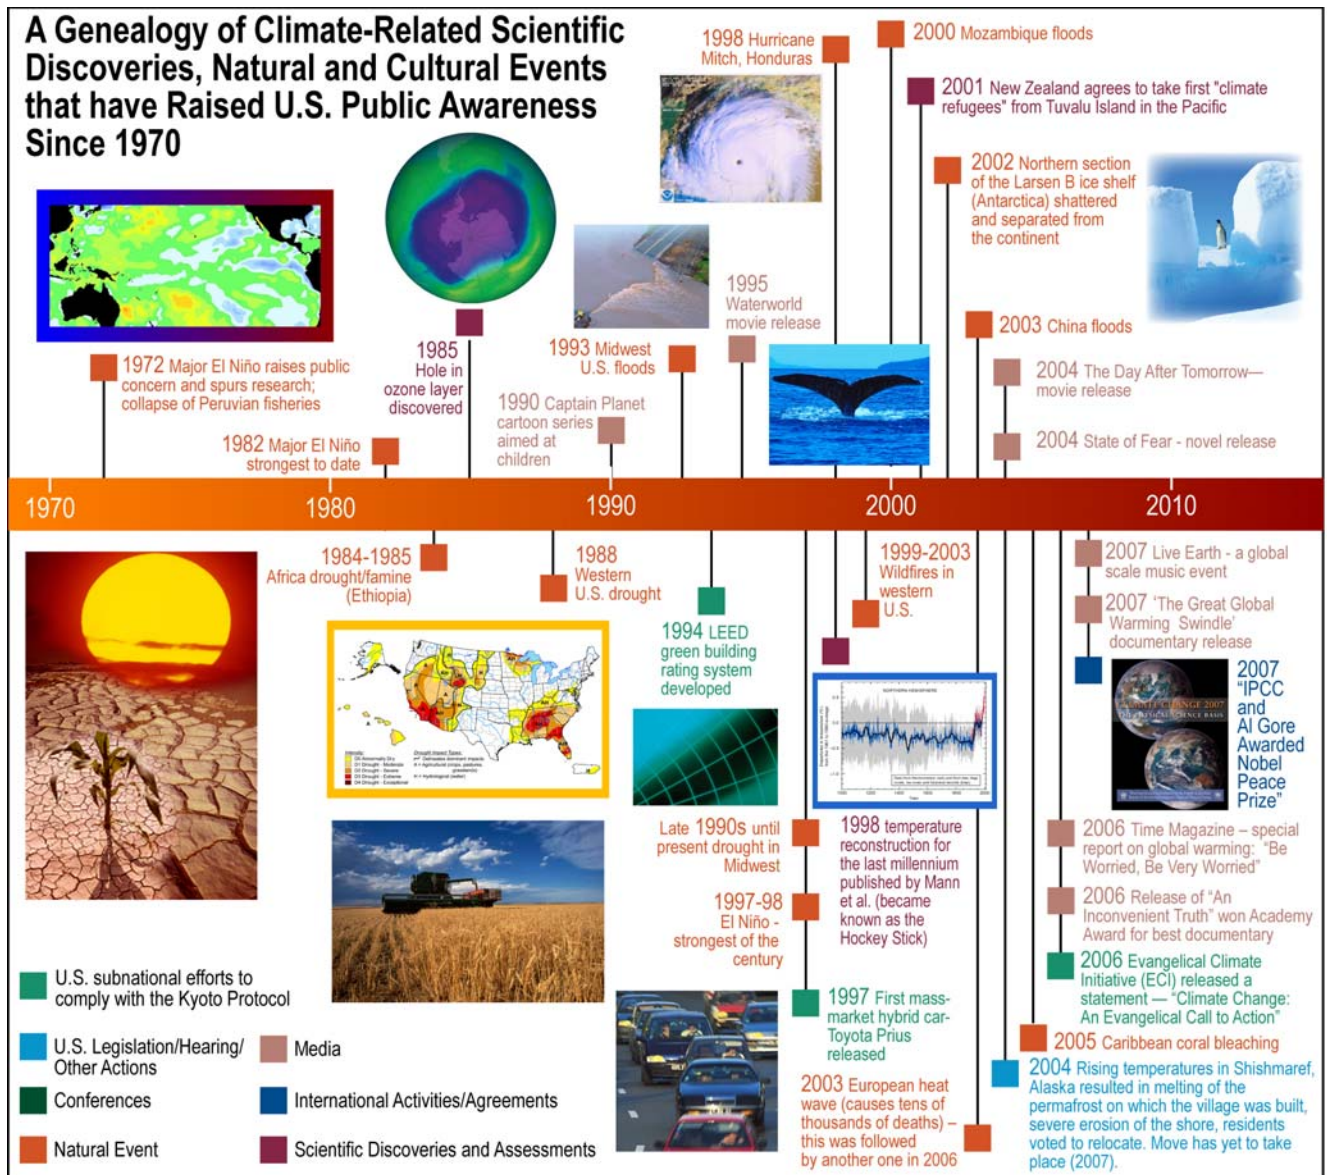

836 and that an adequate understanding and contribution to decisions takes time,

837 commitment, and knowledge that few possess or seek to acquire as water appears to be

838 plentiful and is available when needed. It is understood that considerable variations in

839 water supply and quality can occur, but it is accepted that the water resources

840 establishment knows how to handle variation.
841
842 A series of events and disclosures of scientific findings have profoundly changed the
843 framing of water issues and the interaction between such framing and climate variability
844 and change. As illustrated in Figure 1.1, natural disasters, including Hurricane Katrina
845 and recent sustained droughts in diverse sections of the United States, have disturbed the
846 public perception of well-being. Such events raise awareness of the vulnerability of
847 society to flood, drought, and degradation of water quality. Such extreme events come in
848 addition to mounting evidence in professional journals and the popular press that water
849 quantity and quality, fundamental components of ecological sustainability in many
850 geographical areas, are threatened. The February 2007 Intergovernmental Panel on
851 Climate Change, Working Group 1, report reinforced the high probability of significant
852 future climate change and more extreme climate variation affecting many sectors,
853 including water resources. The report received high press coverage and generated
854 increased concern among the public and policy makers. Instead of being low visibility
855 issue, the issue frame for water resources has become that of attention-grabbing risk and
856 uncertainty about such matters as rising sea levels, altered water storage in snow packs,
857 and less favorable habitats for endangered fish species sensitive to warmer water
858 temperatures. Thus, global warming has been an emerging issue-frame for water
859 resources management.
860

861

862

863 **Figure 1.1** Timeline from 1970 to present of key natural and cultural events contributing to a widespread
 864 change in context for increasing awareness of climate issues
 865

866

867 **Figure 1.2** Timeline from 1970 to present of key policy events contributing to a widespread change in
 868 context for increasing awareness of climate issues
 869

870 Along with higher visibility of water and climate issues has come greater political and
 871 public involvement. At the same time, with an increase in discovery and awareness of
 872 climate impacts there has been a deluge of new reports and passage of climate-related
 873 agreements and legislation. See Figure 1.2. As is the case with most high salience issues,
 874 politicians must compete with one another for status as policy leaders facilitating

875 governmental and private actions to reduce societal vulnerability to climate related
876 variability, although water has up until now taken a back seat to energy in terms of
877 salience. Higher visibility of climate and water variability has put pressure on water
878 managers to behave proactively to respond to expected negative effects of climate
879 variability and change (Hartmann, *et al.*, 2002; Carbone and Dow, 2005). Specifically, in
880 the case of water managers in the U.S., perception of risk has been found as a critical
881 variable for the adoption of innovative management in the sector (O'Connor *et al.*, 2005).

882

883 Frames encompass expectations about what can happen and what should be done if
884 certain predictions do occur (Minsky, 1980). The emergent issue frame water resource
885 management is that new knowledge (about climate change and variability) is being
886 created that warrants management changes. Information and knowledge about climate
887 variability experienced over the recent historical past is no longer as valuable as once it
888 was, and new knowledge must be sought and put to use (Milly *et al.*, 2008).

889 Organizational and individuals face a context today where perceived failure to respond to
890 climate variation and change is more risky than maintaining the status quo.

891

892 **1.2.2 Climate Forecasting Innovations and Opportunities in Water Resources**

893 Only in the last decade or so have climate scientists achieved the important innovation of
894 being able to predict aspects of future climate variations one to a few seasons in advance
895 with better skill than can be achieved by simply using historical averages for those
896 seasons. This is a scientific advance fundamentally new in human history (NRC SARP
897 Report, 2007).

898

899 **BOX 1.1: Seasonal to Interannual Climate Forecasts**

900 *Weather forecasts* seek to predict the exact state of the atmosphere for a specific time and place at lead-
901 times ranging from nowcasts (*e.g.* severe weather warnings) out to a maximum of two weeks. The accuracy
902 of weather forecasts depends crucially on observations that can be used to accurately characterize the initial
903 state of the atmosphere. In contrast, seasonal to interannual *climate forecasts* seek to predict the statistics of
904 the atmosphere for a region over a specified window of time, typically from one month to a few seasons in
905 advance.

906

907 The accuracy of climate forecasts depend crucially on observations of the slowly varying boundary
908 conditions on the atmosphere, including upper ocean temperatures, snow cover, and soil moisture. Climate
909 forecasts can also address the expected probabilities for extreme events (floods, freezes, blizzards,
910 hurricanes, *etc.*), and for the expected range of climate variability. Much of the skill in seasonal to
911 interannual climate forecasts for the U.S. derives from an ability to monitor and accurately predict the
912 future evolution of ENSO, however the actual skill demonstrated is not yet high As a general principal, all
913 climate forecasts are probabilistic. They are probabilistic both in the future state of ENSO and in the
914 consequences of ENSO for remotely influenced regions like the US. For example, a typical ENSO-related
915 climate forecast for the Pacific Northwest region of the U.S. might be presented as follows:

916

917 *Based on expectations for continued El Niño conditions in the tropical*
918 *Pacific, we expect increased likelihoods for above average winter and*
919 *spring temperatures with below average precipitation, with small but*
920 *non-zero odds for the opposite conditions (i.e., below average*
921 *likelihoods for below average winter and spring temperatures and*
922 *above average precipitation) in the Pacific Northwest (PNW).*

923

924 At lead times of a few decades to centuries, *climate change scenarios* are based on scenarios for changes in
925 the emissions and concentrations of atmospheric greenhouse gases and aerosols that are important for the
926 Earth's energy budget. Climate change scenarios do not require real-time observations needed to accurately
927 initialize the atmosphere or slowly-evolving boundary conditions (upper ocean temperatures, snow cover,
928 *etc.*).

929 *****END BOX*****

930

931 It is important to emphasize that seasonal to interannual climate forecasting skill is still
932 quite limited, and varies considerably depending on lead time, geographic scale, target
933 region, time of year, status of the ENSO cycle, and many other issues that are the subject
934 of chapter 2. Even so, the potential usefulness of this new scientific capability is
935 enormous, particularly in the water resources sector, and this potential is being harvested
936 through a variety of experiments and evaluations, some of which appear in this product.
937 For instance, reservoir management changes in the Columbia River Basin in response to
938 seasonal to interannual climate forecast information have the potential to generate an
939 average of \$150 million per year more hydropower with little or no loss to other

940 management objectives (Hamlet *et al.*, 2002). Table 1.1 illuminates the potential of SI
 941 climate forecasts to affect a wide range of water related decisions, potentially providing
 942 great economic, security, environmental quality, and other gains.

943

944 **Table 1.1** Examples of Water Resource Decisions Related to seasonal to interannual Climate Forecasts

Decision/topic	Agency/organization responsible	Activities affected	Climate Forecast information relevance
Dam and reservoir management and reservoir allocation	<ul style="list-style-type: none"> • US Army Corps of Engineers • US D.O.I., Bureau of Reclamation • Tennessee Valley Authority • FERC and its licensed projects • Federal power marketing agencies • State, local, regional water management entities and utilities, irrigation districts 	Distribution of inflows and outflows for: <ul style="list-style-type: none"> • Agriculture • public supply • industry • power • flood control • navigation • instream flow maintenance • protecting reserved waters for resources/ other needs 	<ul style="list-style-type: none"> • Total reservoir inflow • Long-range precipitation • Long-range temperature • Flow data • Snow melt data • Flood forecasts • Shifts in “phase” in decadal cycles
Irrigation/water allocation for agriculture/aqua culture	<ul style="list-style-type: none"> • Federal, state and regional facility operators • Irrigation districts • Agricultural cooperatives • Farmers 	How much water and when and where to allocate it.	<ul style="list-style-type: none"> • Long/short-range precipitation • Long-range temperature •
Ecosystem protection/ecosystem services	Federal and state resource agencies, <i>e.g.</i> , <ul style="list-style-type: none"> • US D.O.I., Fish and Wildlife Service • US D.O.A., Forest Service, US D.O.I., Park Service, US D.O.I., BLM, US D.O.C., NMFS, <i>etc.</i> • State, regional and watershed- based protected areas NGOs, <i>e.g.</i> , <ul style="list-style-type: none"> • Nature Conservancy, Local and regional land trusts 	<ul style="list-style-type: none"> • Instream flow management • Riverine/riparian management • Wildlife management 	<ul style="list-style-type: none"> • Climate cycles • Long-term climate predictions

Public water supply/wastewater management*	<ul style="list-style-type: none"> • Municipalities • Special water districts • Private water utilities • Water supply/wastewater utilities/utility districts 	Needs for new reservoirs, dams, wastewater treatment facilities, pumping stations, groundwater management areas, distribution systems; Needs for long term water supply and demand management plans; Drought planning.	Changes in temperature/precipitation effect water demand; reduction in base-flows, increased demands, and greater evaporation rates (Gleick <i>et al.</i> , 2000; Clarkson and Smerdon, 1989). Predictive information at multiple scales and multiple time frames.
Coastal zones	<ul style="list-style-type: none"> • Regional Coastal zone management agencies • Corps of Engineers • NMFS, other federal agencies • Local/regional flood control agencies • Public supply utilities 	Impacts to tidal deltas, low lying coastal plans Changes to fish production/coastal food systems, salt water intrusion Erosion; deterioration of marshes Flood control, water supply and sewage treatment implications	Predicted sea level rise & land subsidence; fluctuation in surface water temperature; tropical storm predictions; change to precipitation patterns; wind & water; storm surges and flood flow circulation patterns (Davidson, 1997).
Navigation	<ul style="list-style-type: none"> • Harbor managers • River system and reservoir managers, barge operators 	<ul style="list-style-type: none"> • River and harbor channel depth; flow 	<ul style="list-style-type: none"> • Stream flow, seasonality, flooding potential
Power production	<ul style="list-style-type: none"> • Federal water and power agencies; FERC; private utilities with licensed hydropower projects; private utilities using power from generation facilities 	<ul style="list-style-type: none"> • Water for hydropower • Water for steam generation in fossil fuel and nuclear plants • Water for cooling 	<ul style="list-style-type: none"> • Temperature (and relationships to demand for power) • Precipitation • Stream flow and runoff
Flooding/floodplain management	<ul style="list-style-type: none"> • Floodplain managers; flood zone agencies; insurance companies; risk managers, land use planners 	<ul style="list-style-type: none"> • Infrastructure needs planning • Emergency management 	Short and long-term runoff predictions, esp. long term trends in intensity of precipitation, storm surges, <i>etc.</i>

945

946 Besides the potential applications suggested in Table 1.1, there are other overarching
 947 opportunities for use of seasonal to interannual climate and hydrologic forecasts recently
 948 introduced to the water resources sector. Adaptive Management and Integrated Water
 949 Resources Management are examples of reforms that are still in relative infancy (see
 950 chapters 3 and 4) and could gain considerable traction through fostering continuous
 951 feedback from forecasts to changes in practice and improved performance. Adaptive

952 management embraces the need for continuous monitoring and feedback; information
953 provided by forecasts can prompt real time adaptations by public and private agencies
954 and water users. Integrated Water Resources Management is based around the concepts
955 of flexibility and adaptability, using measures that can be easily reversed or are robust to
956 changing circumstances (IPCC Report, 2007 3.6.5). Such potential flexibility and
957 adaptability extends not just to water agencies, but also to the citizenry generally.
958 Advances in climate forecast skill and their application provides an opportunity to convey
959 to the public, all of whom use water in one way or another, a deeper understanding than
960 currently exists about the relationship of climate variability to increased risk,
961 vulnerability, and uncertainty related to water that now tends to be perceived in static
962 terms. In addition, more finely tuning water management to real time climate prediction
963 allows for cutting down the lead time for response to climate variation.

964

965 **1.2.3 Organizational Dynamics and Innovation**

966 The flow of information among agencies and actors in a complex organizational field like
967 climate forecasting and water resources is not at all like water itself that is ruled by
968 gravity and flows downhill. Even as skill levels of climate and hydrologic forecasts have
969 improved, resistance to their use in water resources management both exists and persists
970 (O'Conner *et al.*, 1999; Rayner *et al.*, 2005; Yarnal *et al.*, 2006). Such resistance to
971 innovation is to be expected according to organizational and management literature that
972 addresses the management of information across boundaries of various kinds that include
973 organizations, disciplines, fields, practices and the like (Carlisle, 2004; Feldman *et al.*,
974 2006). The same specialization that makes organizations effective in delivery of

975 organizational goals can make them resistant to innovation (Weber, 1947). Creating a
976 product or service requires differences in experience, terminologies, tools, and incentives
977 that are embedded in a specific organization. Because knowledge takes investment such
978 as time, resources, and opportunity costs, it constitutes a kind of “stake”, and significant
979 costs are associated with giving it up and acquiring new knowledge (Carlisle, 2002).
980 Further, if the kind of knowledge that needs to be coordinated across boundaries may be
981 so different in kind that a bridge of a common language must be created that allows
982 translation to take place. Finally, the sort of demands made by sharing information across
983 boundaries may be so novel that a fundamental readjustment is needed that challenges the
984 organization to rethink what it knows and how.

985

986 Figure 1.3, adapted from Carlisle (2004) portrays the different level, challenge, or gap
987 that must be filled for sharing knowledge across boundaries, and helps convey the
988 challenge of innovation through information sharing across different organizations, levels
989 of government, and public and private actors. At the lowest level of the inverted triangle
990 information transfer is relatively simple such as exists between different climate
991 forecasters located in different organizations. Forecasters have common knowledge and
992 know each others’ levels of expertise and respect it regardless of organizational ties.
993 Because a common lexicon exists, knowledge transfer is relatively simple. The usual
994 barriers to smooth information flow apply, including information overload, availability of
995 storage and retrieval technologies and other information processing challenges.
996 Unfortunately, agencies prefer their own terminology and trust information that comes
997 from inside the organization more than information from outside, the adoption of

998 seasonal to interannual climate forecast information in the water resource sector hardly
999 ever fits this simple transfer profile.

1000

1001 At the second or translation level of managing information, shared meanings or
1002 resolution of discrepancy of meaning are necessary. This level of information sharing
1003 probably typifies the relationships between climate forecasters and water resource
1004 forecasters who have long predicted water futures using data such as snowpack, soil
1005 moisture, basin and watershed models and the like. This involves a large expenditure of
1006 effort that has to be justified within the organization and may well encounter resistance
1007 unless offset by some considerable pay off. A common lexicon may need to be invented
1008 with common definitions. Effort must be expended to develop shared methodologies,
1009 create cross-organizational teams, engage in strategies such as collocation of offices, and
1010 employ individuals who can act as translators or brokers. Sometimes translation requires
1011 making tacit knowledge explicit, and translation becomes more difficult when
1012 information is related to practices that may be very different on either side of boundaries.

1013 This level of information sharing probably typifies the relationships between climate
1014 forecasters and water resource forecasters who have long predicted water futures using
1015 data such as snowpack, soil moisture, basin and watershed models and the like.

1016

1017 The third or transformation level of managing information requires considerable change
1018 in the ways in which organizations presently process and use information, such as
1019 moving toward co-production of knowledge with outside organizations, interests and
1020 entities. These costs negatively impact the willingness of organizations to make such

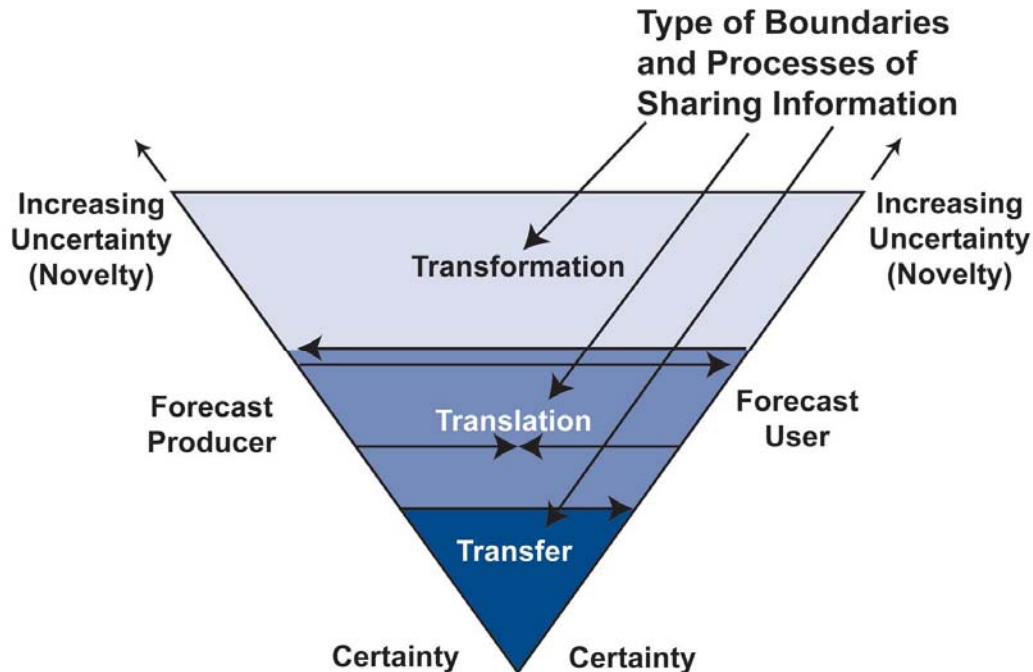

1021 transformational changes and help to explain why organizations continue to follow “path
1022 dependent” or business-as-usual practices despite evidence that innovation would be
1023 beneficial. For instance, the very large challenges presented to climate forecasters to
1024 involve users in the production of climate products explains why they continue to follow
1025 what has been termed the “loading dock” model, or simply putting forecasts out with
1026 little notion of whether or not they will be picked up (Cash *et al.*, 2006). Knowledge at
1027 this level is a transformed mixture of knowledge that is determined to still be of value and
1028 the knowledge that is of consequence given new insight on climate variability.

1029

1030 Knowledge at this third level must be created collaboratively rather than delivered and
1031 must be salient, credible and legitimate to all engaged actors. Salience or decision
1032 relevance is changing, as the context for decisions is changing as discussed above.
1033 However, information is likely to be more salient if it comes from known and trusted
1034 sources (NRC, 1984, 1989, 2002; Sarp Report, 2006). Credibility is not just credibility of
1035 scientists, but also to users. Information is more credible if it recognizes and treats
1036 multiple perspectives. Legitimacy relates to even handedness and the absence of narrow
1037 organizational or political agendas (Cash *et al.*, 2003; NRC SARP Report, 2006). Almost
1038 all of the important applications of seasonal to interannual climate forecasts involve
1039 information management at level three.

1040

1041

1042

1043

1044 **Figure 1.3** Illustration of the processes of information sharing. At the tip of the triangle forecast producers
 1045 and forecast users are sharing a common syntax and framework and therefore knowledge is simply
 1046 transferred. As the products and uses become increasingly different and novel, a process of learning has to
 1047 occur for information to be translated (middle of triangle). Finally, information will need to be transformed
 1048 in order for knowledge to be accessible to very different parties. Adapted from Carlile, 2003.
 1049

1050 **1.2.4 Decision Support, Knowledge Networks, Boundary Organizations, and** 1051 **Boundary Objects**

1052 A recent National Academy of Sciences Report (2006) observes that decision support is
 1053 widely used but definitions vary. Following the lead of this report, decision support is
 1054 defined here as creating conditions that foster the appropriate use of information. This
 1055 definition presumes that the climate scientists who generate seasonal to interannual
 1056 climate forecasts often do not know what information they could provide to water
 1057 resources managers that the managers would find useful, and that water managers do not
 1058 necessarily know how they could use seasonal to interannual climate forecasts and related

1059 information (NAS, 2006). The primary objective of decision support activities is to foster
1060 transformative information exchange that will both change the kind of information that is
1061 produced and the way it is used (NRC 1989, 1996, 1999, 2005, 2006).

1062

1063 Decision support involves engaging effective two-way communication between the
1064 producers and users of climate information (Jacobs *et al.*, 2005; 2006; Lemos and
1065 Morehouse, 2005; NRC, 1999, 2006) rather than just the development of tools and
1066 products that may also be useful though less fundamental. This conception of decision
1067 support brings into focus human relationships and networks in information utilization.
1068 The test of transformed information is that it is trusted and considered reliable, and is
1069 fostered by familiarity and repeated interaction between information collaborators and the
1070 working and reworking of relationships. A knowledge network is built through such
1071 human interactions across organizational boundaries and creating and conveying
1072 information that is end to end useful for all participants ranging from scientists to
1073 multiple decision makers.

1074

1075 A variety of mechanisms can be employed to foster the creation of knowledge networks
1076 and the coproduction of knowledge that transcends that otherwise available. Among such
1077 mechanisms are boundary organizations that play an intermediary role between different
1078 organizations, specializations, disciplines, practices, and functions including science and
1079 policy (Cash, 2001; Clark *et al.*, 2002; Guston, 2001) These organizations can play a
1080 variety of roles in decision support that include convening, collaboration, mediation and
1081 the production of boundary objects. A boundary object is a prototype, model or other

1082 artifact upon which collaboration can occur across different kinds of boundaries during
1083 which such collaboration participants may come to appreciate the contribution of other
1084 kinds of knowledge, perspectives, expertise or practice and how it may augment, help or
1085 modify their own knowledge (Star,1989). A fish ladder is a kind of boundary object since
1086 it is an add-on to a dam structure and must be part of structural design. At the same time
1087 it serves fish species and needs the insight of biologists for it to work.

1088

1089 **1.3 OUTLINE OF THE REPORT AND WHERE PROSPECTUS QUESTIONS**
1090 **ARE ADDRESSED**

1091 This Chapter addresses what types of seasonal interannual forecasts related decisions are
1092 made in the water community and what role could such forecasts play. It describes the
1093 general contextual opportunities and limitations to innovations such as the use of seasonal
1094 to interannual forecast information would entail.

1095

1096 Chapter 2 answers the question: what are seasonal and interannual forecast products and
1097 how do they evolve from a scientific prototype to an operational product? It also
1098 addresses the issue of skill and the impediments to progress in improving skill, and the
1099 steps that are taken to ensure that a product is needed and will be used in decision
1100 support. It describes the level of confidence about seasonal to interannual forecast
1101 products in the science and decision-making communities.

1102

1103 Chapter 3 focuses on the obstacles, impediments, and challenges in fostering close
1104 collaboration between scientists and decision makers in terms of theory and observation.

1105 The real world barriers encountered in translation of climate variation forecasting
1106 information is explained by a theoretically grounded body of knowledge on why and how
1107 resource decision makers use information. Chapter 3 addresses the following kinds of
1108 questions: How are hazards and risks related to climate variability perceived and
1109 managed? What are the challenges related to finding out and serving the needs of
1110 decision makers? It emphasizes the importance of reliability and trust. It suggests how
1111 decision support could leverage scientific and technological advances.

1112

1113 Chapter 4 provides examples of a range of decision support experiments in the context of
1114 seasonal and interannual forecast information. It describes the limitations on the kinds of
1115 information available and the need to employ logical inference. It also discusses how
1116 decision support tools can be improved.

1117

1118 Chapter 5 provides an overview of this report, especially identifying overarching themes.
1119 It suggests the kinds of research and action needed to improve progress in this area.
1120 Finally, it addresses how the knowledge gained in water resources might be useful to
1121 other sectors.

1122

1123 The Prospectus for this study contained a series of questions that the Climate Change
1124 Science Program Office directed this group to answer within this product. Table 1.2
1125 summarizes the questions and where they are addresses in the report.

1126

1127

1128

1129 **Table 1.2** Questions To Be Addressed in Synthesis and Assessment Product 5.3
 1130

Prospectus Question	Report Location where Question is Addressed
What seasonal to interannual (<i>e.g.</i> , probabilistic) forecast information do decision makers need to manage water resources?	2.1
What are the seasonal to interannual forecast/data products currently available and how does a product evolve from a scientific prototype to an operational product?	2.2
What is the level of confidence of the product within the science community and within the decision making community, who establishes these confidence levels and how are they determined?	2.2
How do forecasters convey information on climate variability and how is the relative skill and level of confidence of the results communicated to resource managers?	2.3
What is the role of probabilistic forecast information in the context of decision support in the water resources sector?	2.3
How is data quality controlled?	2.3
What steps are taken to ensure that this product is needed and will be used in decision support?	2.5
What types of decisions are made related to water resources?	3.2
What is the role that seasonal to interannual forecasts play and could play?	3.2
How does climate variability influence water resource management?	3.2
What are the obstacles and challenges decision makers face in translating climate forecasts and hydrology information into integrated resource management?	3.2
What are the barriers that exist in convincing decision makers to consider using risk-based hydrology information (including climate forecasts)?	3.2
What challenges do tool developers have in finding out the needs of decision makers?	3.3
How much involvement do practitioners have in product development?	4.1
What are the measurable indicators of progress in terms of access to information and its effective uses?	4.3
Identify critical components, mechanisms, and pathways that have led to successful utilization of climate information by water managers.	4.4
Discuss options for (a) improving the use of existing forecasts/data products and (b) identify other user needs and challenges in order to prioritize research for improving forecasts and products.	4.4 and 5
Discuss how these findings can be transferred to other sectors.	5

1336

1337 **KEY FINDINGS**

1338 There are a wide variety of climate and hydrologic data and forecast products currently
1339 available for use by decision-makers in the water resources sector. However, the use of
1340 official seasonal to interannual (SI) climate and hydrologic forecasts generated by federal
1341 agencies remains limited in the water resources sector. Forecast skill, while recognized as
1342 just one of the barriers to the use of SI climate forecast information, remains a primary
1343 concern among forecast producers and users. Simply put, there is no incentive to use SI
1344 climate forecasts when they are believed to provide little additional skill to existing
1345 hydrologic and water resource forecast approaches. Not surprisingly, there is much
1346 interest in improving the skill of hydrologic and water resources forecasts. Such
1347 improvements can be realized by pursuing several research pathways, including:

- 1348 • Improved monitoring and assimilation of real-time hydrologic observations in
1349 land surface hydrologic models that leads to improved estimates for initial
1350 hydrologic states in forecast models;
- 1351 • Increased accuracy in SI climate forecasts; and,
- 1352 • Improved bias corrections in existing forecast.

1353

1354 Another aspect of forecasts that serves to limit their use and utility is the challenge in
1355 interpreting forecast information. For example, from a forecast producer's perspective
1356 confidence levels are explicitly and quantitatively conveyed by the range of possibilities
1357 described in probabilistic forecasts. From a forecast user's perspective, probabilistic
1358 forecasts are not always well understood or correctly interpreted. Although structured
1359 user testing is known to be an effective product development tool, it is rarely done.

1360 Evaluation should be an integral part of improving forecasting efforts, but that evaluation
1361 should be extended to factors that encompass use and utility of forecast information for
1362 stakeholders. In particular, very little research is done on effective seasonal forecast
1363 communication. Instead, users are commonly engaged only near the end of the product
1364 development process.

1365

1366 Other barriers to the use of SI climate forecasts in water resources management have
1367 been identified and those that relate to institutional issues and aspects of current forecast
1368 products are discussed in chapters 3 and 4 of this report.

1369

1370 Pathways for expanding the use and improving the utility of data and forecast products to
1371 support decision-making in the water resources sector are currently being pursued at a
1372 variety of spatial and jurisdictional scales in the United States. These efforts include:

- 1373 • An increased focus on developing forecast evaluation tools that provide users
1374 with opportunities to better understand forecast products in terms of their
1375 expected skill and applicability;
- 1376 • Additional efforts to explicitly and quantitatively link SI climate forecast
1377 information with SI hydrologic and water supply forecasting efforts;
- 1378 • An increased focus on developing new internet-based tools for accessing and
1379 customizing data and forecast products to support hydrologic forecasting and
1380 water resources decision-making; and,
- 1381 • Further improvements in the skill of hydrologic and water supply forecasts.

1382

1383 Many of these pathways are currently being pursued by the federal agencies charged with
1384 producing the official climate and hydrologic forecast and data products for the United
1385 States, but there is substantial room for increasing these activities.

1386

1387 An additional important finding is that recent improvements in the use and utility of data
1388 and forecast products related to water resources decision-making have come with an
1389 increased emphasis on these issues in research funding agencies through programs like
1390 GEWEX, NOAA's RISA, SARP, TRACS and CPPA programs. Sustaining and
1391 accelerating future improvements in the use and utility of official data and forecast
1392 products in the water resources sector rests in part on sustaining and expanding federal
1393 support for programs focused on improving the skill in forecasts, increasing the access to
1394 data and forecast products, and fostering sustained interactions between forecast
1395 producers and consumers.

1396

1397 **2.1 INTRODUCTION**

1398 In the past, water resource managers relied heavily on observed hydrologic conditions
1399 such as snowpack and soil moisture to make seasonal to interannual (SI) water supply
1400 forecasts to support management decisions. Within the last decade, researchers have
1401 begun to link SI climate forecasts with hydrologic models (*e.g.*, Kim *et al.*, 2000,
1402 Kyriakidis *et al.*, 2001) or statistical distributions of hydrologic parameters (*e.g.*,
1403 Dettinger *et al.*, 1999, Sankarasubramanian and Lall 2003) to improve hydrologic and
1404 water resources forecasts. Efforts to incorporate SI climate forecasts into water resources
1405 forecasts have been prompted in part by our growing understanding of the effects of

1406 global-scale climate phenomena, like El Niño Southern Oscillation (ENSO), on U.S.
1407 climate, and the expectation that SI forecasts of hydrologically-significant climate
1408 variables like precipitation and temperature provide a basis for predictability that is not
1409 currently being exploited. To the extent that climate variables like temperature and
1410 precipitation can be forecasted seasons in advance, hydrologic and water-supply forecasts
1411 can also be made skillfully well before the end, or even beginning, of the water year¹.

1412

1413 This chapter focuses on a description and evaluation of hydrologic and climate forecast
1414 and data products that support decision-making for water resource managers. Because the
1415 focus of this CCSP product is on using SI forecasts and data for decision-support in the
1416 water resources sector, we frame this chapter around key forecast and data products that
1417 contribute towards improved hydrologic and water supply forecasts. As a result, this
1418 product does not contain a comprehensive review and assessment of the entire national SI
1419 climate and hydrologic forecasting effort. In addition, the reader should note that, even
1420 today, hydrologic and water supply forecasting efforts in many places are still not
1421 inherently linked with the SI climate forecasting enterprise.

1422

1423 Surveys identify a variety of barriers to the use of climate forecasts (Pulwarty and
1424 Redmond, 1997; Callahan *et al.*, 1999;. Hartmann *et al.*,2002), but insufficient accuracy
1425 is always mentioned as a barrier. It is also well established that an accurate forecast is, in
1426 and of itself, not sufficient to make it useful or usable for decision-making in
1427 management applications (see Table 2.1). Chapters 3 and 4 provide extensive reviews,

¹ The *water year*, or hydrologic year, is October 1st through September 30th. This reflects the natural cycle in many hydrologic parameters such as the seasonal cycle of evaporative demand, and of the snow accumulation, melt, and runoff periods in many parts of the US.

1428 case studies, and analyses that provide insights into pathways for lowering or overcoming
1429 barriers to the use of SI climate forecasts in water resources decision-making.

1430

1431 It is almost impossible to discuss the perceived value of forecasts without also discussing
1432 issues related to forecast skill. Many different criteria have been used to evaluate forecast
1433 skill (see Wilks, 1995 for a comprehensive review). Some measures focus on aspects of
1434 deterministic skill (*e.g.*, correlations between predicted and observed seasonally averaged
1435 precipitation anomalies), while many others are based on categorical forecasts (*e.g.*,
1436 Heidke skill scores for categorical forecasts of “wet,” “dry,” or “normal” conditions). The
1437 most important measures of skill vary with different perspectives. For example,
1438 Hartmann *et al.*, (2002) argue that forecast performance criteria based on “hitting” or
1439 “missing” associated observations offer users conceptually easy entry into discussions of
1440 forecast quality. In contrast, some research scientists and water supply forecasters may be
1441 more interested in correlations between the ensemble average of predictions and observed
1442 measures of water supply like seasonal runoff volume.

1443

1444 Forecast skill remains a primary concern among many forecast producers and users. Skill
1445 in hydrologic forecast systems derives from various sources, including the quality of the
1446 simulation models used in forecasting, the ability to estimate the initial hydrologic state
1447 of the system, and the ability to skillfully predict the statistics of future weather over the
1448 course of the forecast period. Despite the significant resources expended to improve SI
1449 climate forecasts over the past 15 years, few water resource related agencies have been

1450 making quantitative use of climate forecast information in their water supply forecasting
 1451 efforts (Pulwarty and Redmond 1997; Callahan *et al.*, 1999).

1452

1453

1454 **Table 2.1 Barriers to the use of climate forecasts and information for resource managers in the**
 1455 **Columbia River Basin**

1456 (Reproduced from Pulwarty and Redmond, 1997).

- a. Forecasts not “accurate” enough.
- b. Fluctuation of successive forecasts (“waffling”).
- c. The nature of what a forecast is, and what is being forecast (*e.g.*, types of El Niño and La Niña impacts, non-ENSO events, what are “normal” conditions?).
- d. Nonweather/climate factors are deemed to be more important (*e.g.*, uncertainty in other arenas, such as freshwater and ocean ecology [for salmon productivity]).
- e. Low importance is given to climate forecast information because its role is unclear or impacts are not perceived as important enough to commit resources.
- f. Other constraints deny a flexible response to the information (*e.g.*, meeting flood control or Endangered Species Act requirements).
- g. Procedures for acquiring knowledge and making and implementing decisions, which incorporate climate information, have not been clearly defined.
- h. Events forecast may be too far in the future for a discrete action to be engaged.
- i. Availability and use of locally specific information may be more relevant to a particular decision.
- j. “Value” may not have been demonstrated by a credible reliable organization or competitor.
- k. Desired information not provided (*e.g.*, number of warm days, regional detail).
- l. There may be competing forecasts or other conflicting information.
- m. Lack of “tracking” information; does the forecast appear to be verifying?
- n. History of previous forecasts not available. Validation statistics of previous forecasts not available.

1457

1458 In Section 2.2 of this chapter, we review hydrologic data and forecasts products. Section
 1459 2.3 provides a parallel discussion of the climate data and forecast products that support
 1460 hydrologic and water supply forecasting efforts in the United States. In Section 2.4, we
 1461 provide a more detailed discussion of pathways for improving the skill and utility in
 1462 hydrologic and climate forecasts and data products.

1463

1464 Section 2.5 contains a brief review of operational considerations and efforts to improve
 1465 the utility of forecast and data products through efforts to improve the forecast evaluation
 1466 and development process. These efforts include cases in which forecast providers and

1467 users have been engaged in sustained interactions to improve the use and utility of
1468 forecast and data products, and have led to many improvements and innovations in the
1469 data and forecast products generated by national centers. In recent years, a small number
1470 of water resource agencies have also developed end-to-end forecasting systems that
1471 utilize climate forecasts to directly inform hydrologic and water resources forecasts.

1472

1473 BOX 2.1: Agency Support

1474

1475 Federal support for research supporting improved hydrologic forecasts and applications through the use of
1476 climate forecasts and data has received increasing emphasis since the mid-1990s. The World Climate
1477 Research Program's Global Energy and Water Cycle Experiment (GEWEX) was among the first attempts
1478 to integrate hydrology/land surface and atmosphere models in the context of trying to improve hydrologic
1479 and climate predictability.

1480

1481 There have been two motivations behind this research: understanding scientific issues of land surface
1482 interactions with the climate system, and the development or enhancement of forecast applications, *e.g.*, for
1483 water, energy and hazard management. Early on, these efforts were dominated by the atmospheric (and
1484 related geophysical) sciences.

1485

1486 In the past, only two U.S. programs have been very relevant to hydrologic prediction: the NOAA Climate
1487 Prediction Program for the Americas (CPPA) and NOAA predecessors GEWEX Continental-scale
1488 International Project (GCIP) and GEWEX Americas Prediction Project (GAPP) and the NASA Terrestrial
1489 Hydrology Program. The hydrologic prediction and water management focus of NOAA and NASA has
1490 slowly expanded over time. Presently, the NOAA Climate Dynamics and Experimental Prediction (CDEP),
1491 Transition of Research Applications to Climate Services (TRACS) and Sectoral Applications Research
1492 Program (SARP) programs, and the Water Management program within NASA, have put a strong
1493 emphasis on the development of both techniques and community linkages for migrating scientific advances
1494 in climate and hydrologic prediction into applications by agencies and end use sectors. The longer-standing
1495 NOAA Regional Integrated Sciences and Assessments (RISA) program has also contributed to improved
1496 use and understanding of climate data and forecast products in water resources forecasting and decision-
1497 making. Likewise, the recently initiated postdoctoral fellowship program under the Predictability,
1498 Predictions, and Applications Interface (PPAI) panel of U.S. CLIVAR aims to grow the pool of scientists
1499 qualified to transfer advances in climate science and climate prediction into climate-related decision
1500 frameworks and decision tools.

1501

1502 Still, these programs are not well funded in comparison to current federally funded science-focused
1503 initiatives, and are only just beginning to make inroads into the vast arena of effectively increasing the use
1504 and utility of climate and hydrologic data and forecast products.

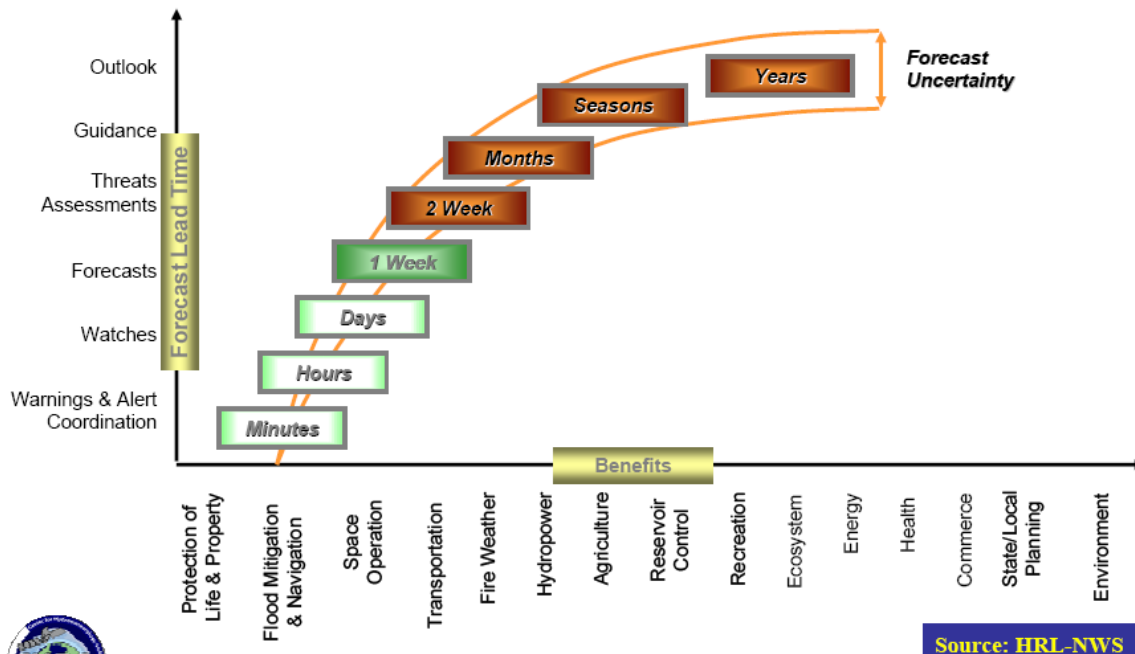

1505

1506 end BOX 2.1

1507

1508 2.2 HYDROLOGIC AND WATER RESOURCES: MONITORING AND**1509 PREDICTION**

1510 The uses of hydrologic monitoring and prediction products, and specifically those that are
 1511 relevant for water, hazard and energy management vary depending on the forecast lead
 1512 time (Figure 2.1). The shortest climate and hydrologic lead time forecasts, from minutes
 1513 to hours, are applied to such uses as warnings for floods and extreme weather, wind
 1514 power scheduling, aviation, recreation, and wild fire response management. In contrast, at
 1515 lead times of years to decades predictions are used for strategic planning purposes rather
 1516 than operational management of resources. At SI lead times, climate and hydrologic
 1517 forecast applications span a wide range that includes the management of water, fisheries,
 1518 hydropower and agricultural production, navigation and recreation. Table 2.1 lists aspects
 1519 of forecast products at these time scales that are relevant to decision-makers.
 1520

1521

Source: HRL-NWS

1522 **Figure 2.1** The correspondence of climate and hydrologic forecast lead time to user sectors in which
 1523 forecast benefits are realized (from HRL-NWS). The focus of this product is on climate and hydrologic
 1524 forecasts with lead times greater than 2 weeks and up to approximately one year.
 1525

1526 **2.2.1 Prediction Approaches**

1527 The primary climate and hydrologic prediction approaches used by operational and
1528 research centers fall into four categories: statistical, dynamical, statistical-dynamical
1529 hybrid, and consensus. The first three approaches are objective in the sense that the inputs
1530 and methods are formalized, outputs are not modified on an ad hoc basis, and the
1531 resulting forecasts are potentially reproducible by an independent forecaster using the
1532 same inputs and methods. The fourth major category of approach, which might also be
1533 termed blended knowledge, requires subjective weighting of results from the other
1534 approaches. These types of approaches are discussed in Box 2.2.

1535

1536 BOX 2.2: Forecast Approaches

1537

1538 *Dynamical:* Computer models designed to represent the physical features of the oceans, atmosphere and
1539 land surface, at least to the extent possible given computational constraints, form the basis for dynamical
1540 predictions. These models have at their core a set of physical relationships describing the interactions of the
1541 Earth's energy and moisture states. Inputs to the models include estimates of the current moisture and
1542 energy conditions needed to initialize the state variables of the model (such as the moisture content of an
1543 atmospheric or soil layer), and of any physical characteristics (called parameters -- one example is the
1544 elevation of the land surface) that must be known to implement the relationships in the model's physical
1545 core. In theory, the main advantage of dynamical models is that influence of any one model variable on
1546 another is guided by the laws of nature as we understand them. As a result, the model will correctly
1547 simulate the behavior of the earth system even under conditions that may not have occurred in the period
1548 during which the model is verified, calibrated and validated. The primary disadvantages of dynamical
1549 models, however, are that their high computational and data input demands require them to approximate
1550 characteristics of the Earth system in ways that may compromise their realism and therefore performance.
1551 For example, the finest computational grid resolution that can be practically achieved in most atmospheric
1552 models (on the order of 100~200 km per cell) is still too coarse to support a realistic representation of
1553 orographic effects on surface temperature and precipitation. Dynamical hydrologic models can be
1554 implemented at much finer resolutions (down to 10 meters per cell, for catchment-scale models) because
1555 they are typically applied to much smaller geographic domains than are atmospheric models. While there
1556 are many aspects that distinguish one model from another, only a subset of those (listed in Table 1.1) is
1557 appreciated by the forecast user, as opposed to the climate modeler, and is relevant in describing the
1558 dynamical forecast products.

1559

1560 *Statistical:* Statistical forecast models use mathematical models to relate observations of an earth system
1561 variable that is to be predicted to observations of one or more other variables (and/or of the same variable at
1562 a prior time) that serve as predictors. The variables may describe conditions at a point location (*e.g.*, flow
1563 along one reach of a river) or over a large domain, such as sea surface temperatures along the equator. The
1564 mathematical models are commonly linear relationships between the predictors and the predictand, but also
1565 may be formulated as more complex non-linear systems.

1566

1567 Statistical models are often preferred for their computational ease relative to dynamical models. In many
1568 cases, statistical models can give equal or better performance to dynamical models due in part to the
1569 inability of dynamical models to represent fully the physics of the system (often as a result of scale or data

1570 limitations), and in part to the dependence of predictability in many systems on predominantly linear
 1571 dynamics (Penland and Magorian, 1993; van den Dool, 2007). The oft-cited shortcomings of statistical
 1572 models, on the other hand, include their lack of representation of physical causes and effects, which in
 1573 theory compromise their ability to respond to unprecedented events in a fashion that is consistent with the
 1574 physical constraints of the system. In addition, statistical models may require a longer observational record
 1575 for “training” than dynamical models, which are helped by their physical structure.
 1576

1577 **Objective hybrids:** Statistical and dynamical tools can be combined using objective approaches. A primary
 1578 example is a weighted merging of the tools’ separate predictions into a single prediction (termed an
 1579 objective consolidation; van den Dool, 2007). A second example is a tool that has dynamical and statistical
 1580 subcomponents, such as a climate prediction model that links a dynamical ocean submodel to a statistical
 1581 atmospheric model. A distinguishing feature of these hybrid approaches is that an objective method exists
 1582 for linking the statistical and dynamical schemes so as to produce a set of outputs that are regarded as
 1583 “optimal” relative to the prediction goals. This objectivity is not preserved in the next consensus approach.
 1584

1585 **Blended Knowledge or Subjective consensus:** Some forecast centers release operational predictions, in
 1586 which expert judgment is subjectively applied to modify or combine outputs from prediction approaches of
 1587 one or more of the first three types, thereby correcting for perceived errors in the objective approaches to
 1588 form a prediction that has skill superior to what can be achieved by objective methods alone. The process
 1589 by which the NOAA Climate Prediction Center (CPC) and International Research Institute for Climate and
 1590 Society (IRI) constructs their monthly and seasonal outlooks for example, includes subjective weighting of
 1591 the guidance provided by different climate forecast tools. The weighting is often highly sensitive to recent
 1592 evolution and current state of the tropical ENSO, but other factors like decadal trends in precipitation and
 1593 surface temperature also have the potential to influence the final official climate forecasts.
 1594

1595 end BOX 2.2
 1596

1597 **Table 2.1 Aspects of forecast products that are relevant to users**

Forecast Product Aspect	Description / Examples
Forecast product variables	Precipitation, temperature, humidity, windspeed, atmospheric pressure
Forecast product spatial resolution	Grid cell longitude by latitude, climate division
Domain	Watershed, river basin, regional, national, global
Product time step (temporal resolution)	Hourly, sub-daily, daily, monthly, seasonal
Range of product lead times	1 to 15 days, 1 to 13 months
Frequency of forecast product update	every 12 hours, every month
Lag of forecast product update	The length of time from the forecast initialization time before forecast products are available: <i>e.g.</i> , 2 hours for a medium range forecast, one day for a monthly to seasonal forecast
Existence of historical climatology	Many users require a historical climatology showing forecast model performance to use in bias-correction, downscaling, and/or verification.
Deterministic or probabilistic	Deterministic forecasts have a single prediction for each future lead time. Probabilistic forecasts frame predicted values within a range of uncertainty, and consist either of an ensemble of forecast sequences spanning all lead times, or of a distinct forecast distribution for each future lead time.
Availability of skill / accuracy information	Published or otherwise available information about the performance of forecasts is not always available, particularly for forecasts that are steadily evolving. In principle, the spread of probabilistic forecasts contains such information about the median of the forecast; but the skill characteristics pertaining to the spread of the forecast are not usually available.

1598

1599 Other aspects of dynamical prediction schemes related to model physical and
1600 computational structure are important in distinguishing one model or model version from
1601 another. These aspects are primary indicators of the sophistication of an evolving model,
1602 relative to other models, but are not of much interest to the forecast user community.
1603 Examples include the degree of coupling of model components, model vertical
1604 resolution, cloud microphysics package, nature of data assimilation approaches, and of
1605 the data assimilated, and the ensemble generation scheme, among many other forecast
1606 system features.

1607

1608 **2.2.2 Forecast Producers and Products**

1609 Hydrologic forecasts are produced by many federal, regional, state, and local agencies, as
1610 well as by private sector companies such as utilities. In contrast to climate forecasts,
1611 hydrologic forecast products more directly target end use sectors -- *e.g.*, water, energy,
1612 natural resource or hazard management -- and are often region-specific. Prediction
1613 methods and forecast products vary from region to region and are governed by many
1614 factors, but depend in no small measure on the hydro-climatology, institutional traditions
1615 and sectoral concerns in each region. A representative sampling of typical forecast
1616 producers and products is given in Appendix A.1. Forecasting activities at the federal,
1617 state, regional, and local scales are discussed in the following subsections.

1618

1619 **2.2.2.1 Federal**

1620 The primary federal streamflow forecasting agencies at SI lead times are the NOAA
1621 National Weather Service (NWS) and the U.S. Department of Agriculture,(USDA)

1622 National Resource Conservation Service (NRCS) National Water and Climate Center
1623 (NWCC). The NWCC's four forecasters produce statistical forecasts of summer runoff
1624 volume in the western U.S. using multiple linear regression to estimate future streamflow
1625 from current observed snow water equivalent, accumulated water year precipitation,
1626 streamflow, and in some locations, using ENSO indicators such as the Niño3.4 index
1627 (Garen, 1992; Ref: Pagano and Garen, 2005). Snowmelt runoff is critical for a wide
1628 variety of uses (water supply, irrigation, navigation, recreation, hydropower,
1629 environmental flows) in the relatively dry summer season. The regression approach has
1630 been central in the NRCS since the mid-1930s, before which similar snow-survey based
1631 forecasting was conducted by a number of smaller groups. Forecasts are available to
1632 users both in the form of tabular summaries (Figure 2.2) that convey both the central
1633 tendency of the forecasts and estimates of uncertainty, and maps showing the median
1634 forecast anomaly for each river basin area for which the forecasts are operational (Figure
1635 2.3). Until 2006, the NWCC's forecasts were released once a month, near the first of the
1636 month, for summer flow periods such as April through July or April through September.
1637 In 2006, the NWCC began to develop automated daily updates to these forecasts, and the
1638 daily product is likely to become more prevalent as development and testing matures. The
1639 NWCC also has begun to explore the use of physically-based hydrologic models as a
1640 basis for forecasting, but this effort has barely begun.

1641

1642 NWCC water supply forecasts are coordinated subjectively with a parallel set of forecasts
1643 produced by the western U.S. NWS River Forecast Centers (RFCs), and with forecasts
1644 from Environment Canada's BC Hydro. The NRCS-NWS joint, official forecasts are of

1645 the subjective consensus type described earlier, meaning that the final forecast products
 1646 are subjective combinations of information from different sources, in this case objective
 1647 statistical tools (*i.e.*, regression-models informed by observed snow water equivalent,
 1648 accumulated water year precipitation, and streamflow) and model based forecast results
 1649 from the RFCs.
 1650

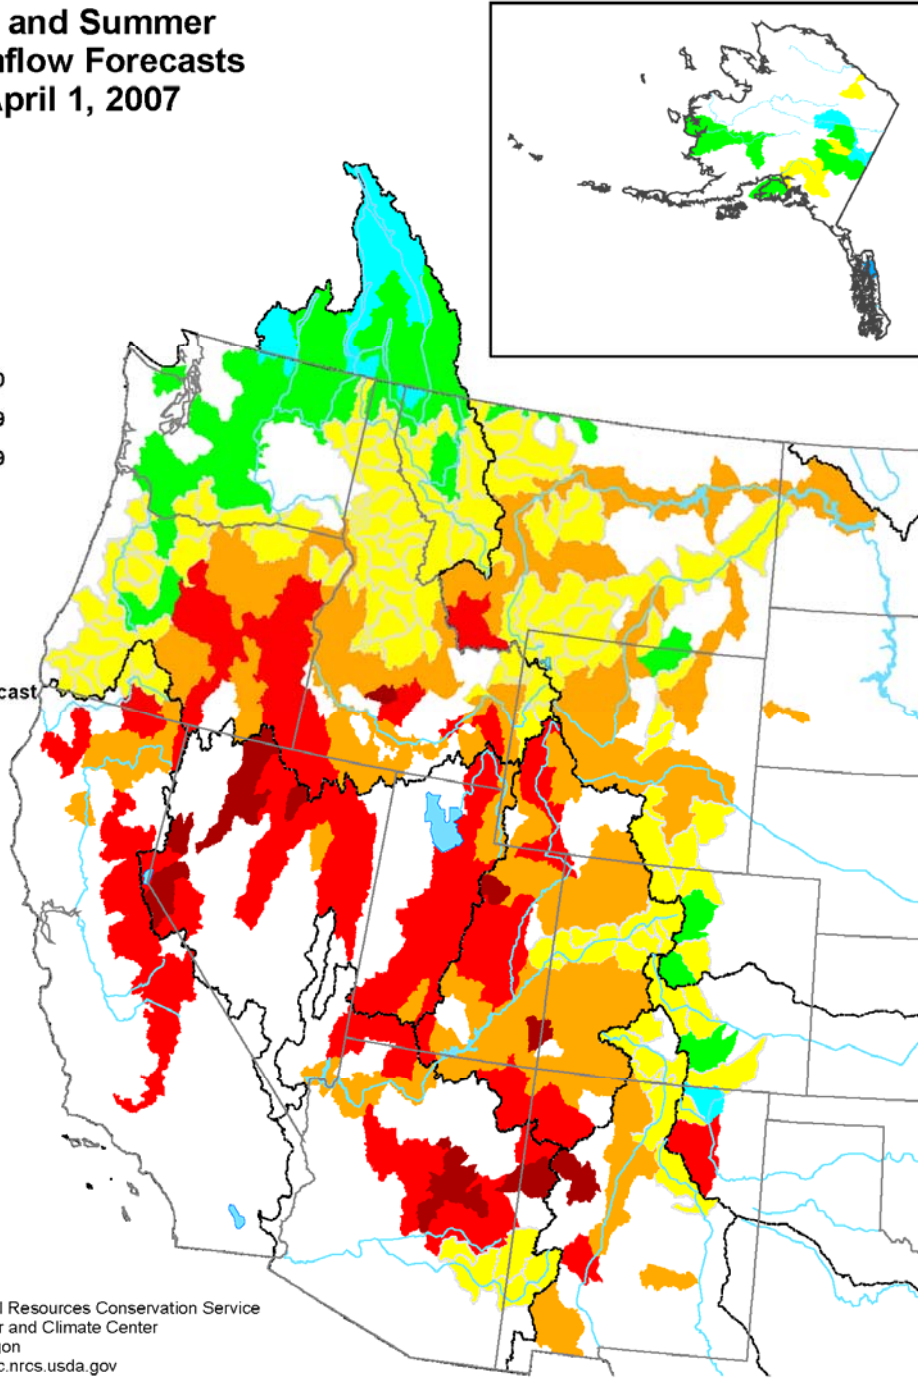

Stream and Station	Forecast Period	Forecasts This Year			30 Year '71-'00 Average Runoff kaf

1651

1652 **Figure 2.2** Example of NRCS tabular summer runoff (streamflow) volume forecast summary, showing
 1653 median (“most probable”) forecasts and probabilistic confidence intervals, as well as climatological flow
 1654 averages. Flow units are thousand-acre-feet (KAF), a runoff volume for the forecast period. This table was
 1655 downloaded from <http://www.wcc.nrcs.usda.gov/wsf/wsf.html>.
 1656

1657 The NWS surface water supply forecast program began in the 1940s in the Colorado
1658 Basin. It has since expanded to include seasonal forecasts (of volume runoff during the
1659 spring—summer snow melt period) for most of the snowmelt dominated basins important
1660 to water management in the western United States. These forecasts rely on two primary
1661 tools: Statistical Water Supply (SWS), based on multiple-linear regression, and
1662 Ensemble Streamflow Prediction (ESP), a technique based on hydrologic modeling
1663 (Schaake, 1978; Day, 1985). Results from both approaches are augmented by forecaster
1664 experience and the coordination process with other forecasting entities. In contrast to the
1665 western RFCs, RFCs in the eastern U.S. are more centrally concerned with short to
1666 medium-range flood risk and drought-related water availability out to about a three
1667 month lead time. At some eastern RFC websites, the seasonal forecast is linked only to
1668 the CPC Drought Outlook rather than an RFC-generated product (Box 2.3).
1669

**Spring and Summer
Streamflow Forecasts
as of April 1, 2007**

Prepared by
 USDA, Natural Resources Conservation Service
 National Water and Climate Center
 Portland, Oregon
<http://www.wcc.nrcs.usda.gov>

1670

1671 **Figure 2.3** Example of NRCS spatial summer runoff (April-September streamflow) volume forecast
 1672 summary, showing median runoff forecasts as an anomaly (percent of average).
 1673

1674 The streamflow prediction services of the RFCs have a national presence, and as such are
1675 able to leverage a number of common technological elements, including models,
1676 databases and software for handling meteorological and hydrological data, and for
1677 making, assessing and disseminating forecasts; *i.e.*, website structure. Nonetheless, the
1678 RFCs themselves are regional entities with regional concerns.

1679

1680 The NWS's ESP approach warrants further discussion. In the mid 1970s, the NWS
1681 developed the hydrologic modeling, forecasting and analysis system – NWS River
1682 Forecast System (NWSRFS) – the core of which is the Sacramento soil moisture
1683 accounting scheme coupled to the Snow-17 temperature index snow model, for ESP-
1684 based prediction (Anderson, 1972, 1973; Burnash *et al.*, 1973). The ESP approach uses a
1685 deterministic simulation of the hydrologic state during a model spin-up (initialization)
1686 period leading up to the forecast start date to estimate current hydrologic conditions, and
1687 then uses an ensemble of historical meteorological sequences as model inputs (*e.g.*,
1688 temperature and precipitation) to simulate hydrology in the future (or forecast) period.
1689 Until several years ago, the RFC dissemination of ESP-based forecasts for streamflows at
1690 SI lead times was rare, and the statistical forecasts were the accepted standard. Now, as
1691 part of the NWS Advanced Hydrologic Prediction Service (AHPS) initiative, ESP
1692 forecasts are being aggressively implemented for basins across the United States (Figure
1693 2.4) at lead times from short to SI (McEnery *et al.*, 2005).

1694

1695

1696 **Figure 2.4** Areas covered by the NWS Advanced Hydrologic Prediction Service (AHPS) initiative
1697 (McEnery *et al.*, 2005).
1698

1699 At the seasonal lead times, several western RFCs use graphical forecast products for the
1700 summer period streamflow forecasts that convey the probabilistic uncertainty of the
1701 forecasts. A unified web based suite of applications that became operational in 2008
1702 provides forecast users with a number of avenues for exploring the RFC water supply
1703 forecasts. For example, Figure 2.5 shows (in clockwise order from top left) (a) a western
1704 U.S. depiction of the median water supply outlook for the RFC forecast basins, (b) a
1705 progression of forecasts (median and bounds) during the water year together with flow
1706 normals and observed flows; (c) monthly forecast distributions, with the option to display
1707 individual forecast ensemble members (*i.e.*, single past years) and also select ENSO-
1708 based categorical forecasts (ESP subsets); and (d) various skill measures, such as mean
1709 absolute error, for the forecasts based on hindcast performance. Access to raw ensemble
1710 member data is also provided from the same website.

1711

1712

1713 **Figure 2.5** A graphical forecast product from the NWS River Forecast Centers, showing a forecast of
 1714 summer (April—July) period streamflow on the Colorado River, Colorado-Arizona. These figures were
 1715 obtained from <http://www.nwrfc.noaa.gov/westernwater>.

1716

1717 The provision of a service which assists hydrologic forecast users in either customizing a

1718 selection of ESP traces to reflect, perhaps, the users interest in past years that they

1719 perceive as analogues to the current year, or the current ENSO state, is a notable advance

1720 from the use of “climatological” ESP (*i.e.*, using all traces from a historical period) in the

1721 prior ESP-related seasonal forecast products. Some western RFCs have also

1722 experimented with using the CPC seasonal climate outlooks as a basis for adjusting the

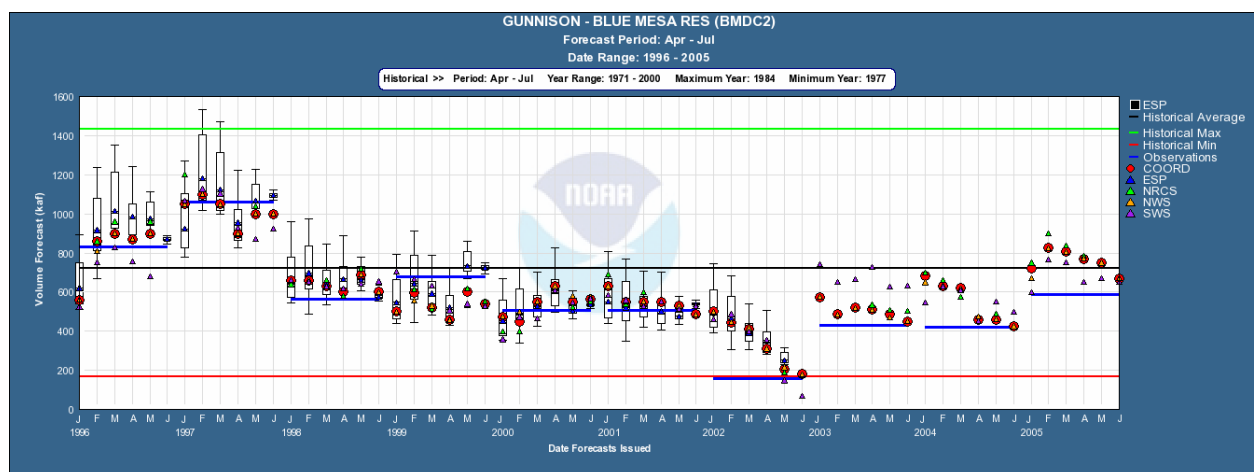

1723 precipitation and temperature forcings used in climatological ESP, but found that the
1724 CPC outlook anomalies were generally too small to produce a distinct forecast from the
1725 climatological ESP (Hartmann *et al.*, 2002). In some RFCs, NWS statistical water supply
1726 forecasts have also provided perspective (albeit more limited) on the effect of future
1727 climate assumptions on future runoff by including results from projecting 50, 75, 100,
1728 125 and 150 percent of normal precipitation in the remaining water year. At times, the
1729 official NWS statistical forecasts have adopted such assumptions, *e.g.*, that the first
1730 month following the forecast date would contain other than 100% of expected
1731 precipitation – based on forecaster judgment and consideration of a range of factors,
1732 including ENSO state and CPC climate predictions.

1733

1734 Figure 2.6 shows the performance of summer streamflow volume forecasts from both the
1735 NWS and NRCS over a recent 10-year period; this example is also part of the suite of
1736 forecast products that the western RFC designed to improve the communication of
1737 forecast performance and provide verification information. Despite recent literature
1738 (Welles *et al.*, 2007) that has underscored a general scarcity of such information from
1739 hydrologic forecast providers, the NWS has recently codified verification approaches and
1740 developed verification tools, and is in the process of disbursing them throughout the RFC
1741 organization (NWS, 2005, “River Forecast Verification Plan”). The existence in digitized
1742 form of the retrospective archive of seasonal forecasts is critical for the verification of
1743 forecast skill. The 10-year record shown in Figure 2.6, which is longer than the record
1744 available (internally or to the public) for many public agency forecast variables, is of
1745 inadequate length for some types of statistical assessment, but is an undeniable advance

1746 in forecast communication relative to the services that were available previously. Future
 1747 development priorities include a climate change scenario application, which would
 1748 leverage climate change scenarios from IPCC or similar to produce inputs for future
 1749 water supply planning exercises. In addition, forecast calibration procedures (*e.g.*, Seo *et*
 1750 *al.*, 2006; Wood and Schaake, 2008) are being developed for the ensemble forecasts to
 1751 remove forecast biases. The current NOAA/NWS web service Internet web address is:
 1752 (<http://www.nwrfc.noaa.gov/westernwater>)

1753

1754

1755 **Figure 2.6** Comparing ESP and statistical forecasts from the NRCS and NWS for a recent 10-year period.
 1756 The forecasts are for summer (April—July) period streamflow on the Gunnison River, Colorado.
 1757

1758 A contrast to these probabilistic forecasts is the deterministic 5-week forecast of lake
 1759 elevation in Lake Lanier, GA, produced by the U.S. Army Corps of Engineers (USACE)
 1760 based on probabilistic inflow forecasts from the NWS southeastern RFC. Given that the
 1761 lake is a managed system and the forecast has a subseasonal lead time, the single-valued
 1762 outlook may be justified by the planned management strategy. In such a case, the lake
 1763 level is a constraint that requires transferring uncertainty in lake inflows to a different
 1764 variable in the reservoir system, such as lake outflow. Alternatively, the deterministic

1765 depiction may result from an effort to simplify probabilistic information in the
 1766 communication of the lake outlook to the public.

1767

1768 Figure 2.7 A deterministic 5-week forecast of reservoir levels in Lake Lanier, Georgia, produced by
 1769 USACE. <http://water.sam.usace.army.mil/lanfc.htm>.

1770

1771 **2.2.2.2 State and Regional**

1772 Regionally-focused agencies such as the U.S. Bureau of Reclamation (USBR), the
 1773 Bonneville Power Administration (BPA), the Tennessee Valley Authority (TVA), and the
 1774 Great Lakes Environmental Research Laboratory (GLERL) also produce forecasts
 1775 targeting specific sectors within their priority areas. Figure 2.7 shows an example of an SI
 1776 lead forecast of lake levels produced by GLERL. GLERL was among the first major
 1777 public agency to incorporate climate forecast information into operational forecasts
 1778 hydrologic and water management variables. Forecasters use coarse-scale climate
 1779 forecast information to adjust climatological probability distribution functions (PDFs) of
 1780 precipitation and temperature that are the basis for generating synthetic ensemble inputs

1781 to hydrologic and water management models, the outputs of which include lake level as
1782 shown in the figure. In this case, the climate forecast information is from the CPC
1783 seasonal outlooks (method described in Croley, 1996).

1784

1785 The Bonneville Power Administration, which helps manage and market power from the
1786 Columbia River reservoir system, is both a consumer and producer of hydrologic forecast
1787 products. The BPA generates their own ENSO-state conditioned ESP forecasts of
1788 reservoir system inflows as input to management decisions, a practice supported by
1789 research into the benefits of ENSO information for water management (Hamlet and
1790 Lettenmaier, 1999).

1791

1792 A number of state agencies responsible for releasing hydrologic and water resources
1793 forecasts also make use of climate forecasts in the process of producing their own
1794 hydrologic forecasts. The South Florida Water Management District (SFWMD) predicts
1795 lake (*e.g.*, Okeechobee) and canal stages, and makes drought assessments, using a
1796 decision tree in which the CPC seasonal outlooks play a role. SFWMD follows GLERL's
1797 lead in using the Croley (1996) method for translating the CPC seasonal outlooks to
1798 variables of interest for their system.

1799

1800

1801

1802 **Figure 2.7** Probabilistic forecasts of future lake levels disseminated by GLERL (from:
 1803 <http://www.glerl.noaa.gov/wr/ahps/curfcst/>).
 1804

1805 **2.2.2.3 Local**

1806 At an even smaller scale, some local agencies and private utilities may also produce
 1807 forecasts or at least derive applications-targeted forecasts from the more general climate
 1808 or hydrology forecasts generated at larger agencies or centers. Seattle Public Utilities
 1809 (SPU; see CASE STUDY IN Chapter 4) for example, operates a number of reservoirs for
 1810 use primarily in municipal water supply. SPU makes SI reservoir inflow forecasts using
 1811 statistical methods based on observed conditions in their watersheds (*i.e.*, snow and
 1812 accumulated precipitation), and on the current ENSO state, in addition to consulting the

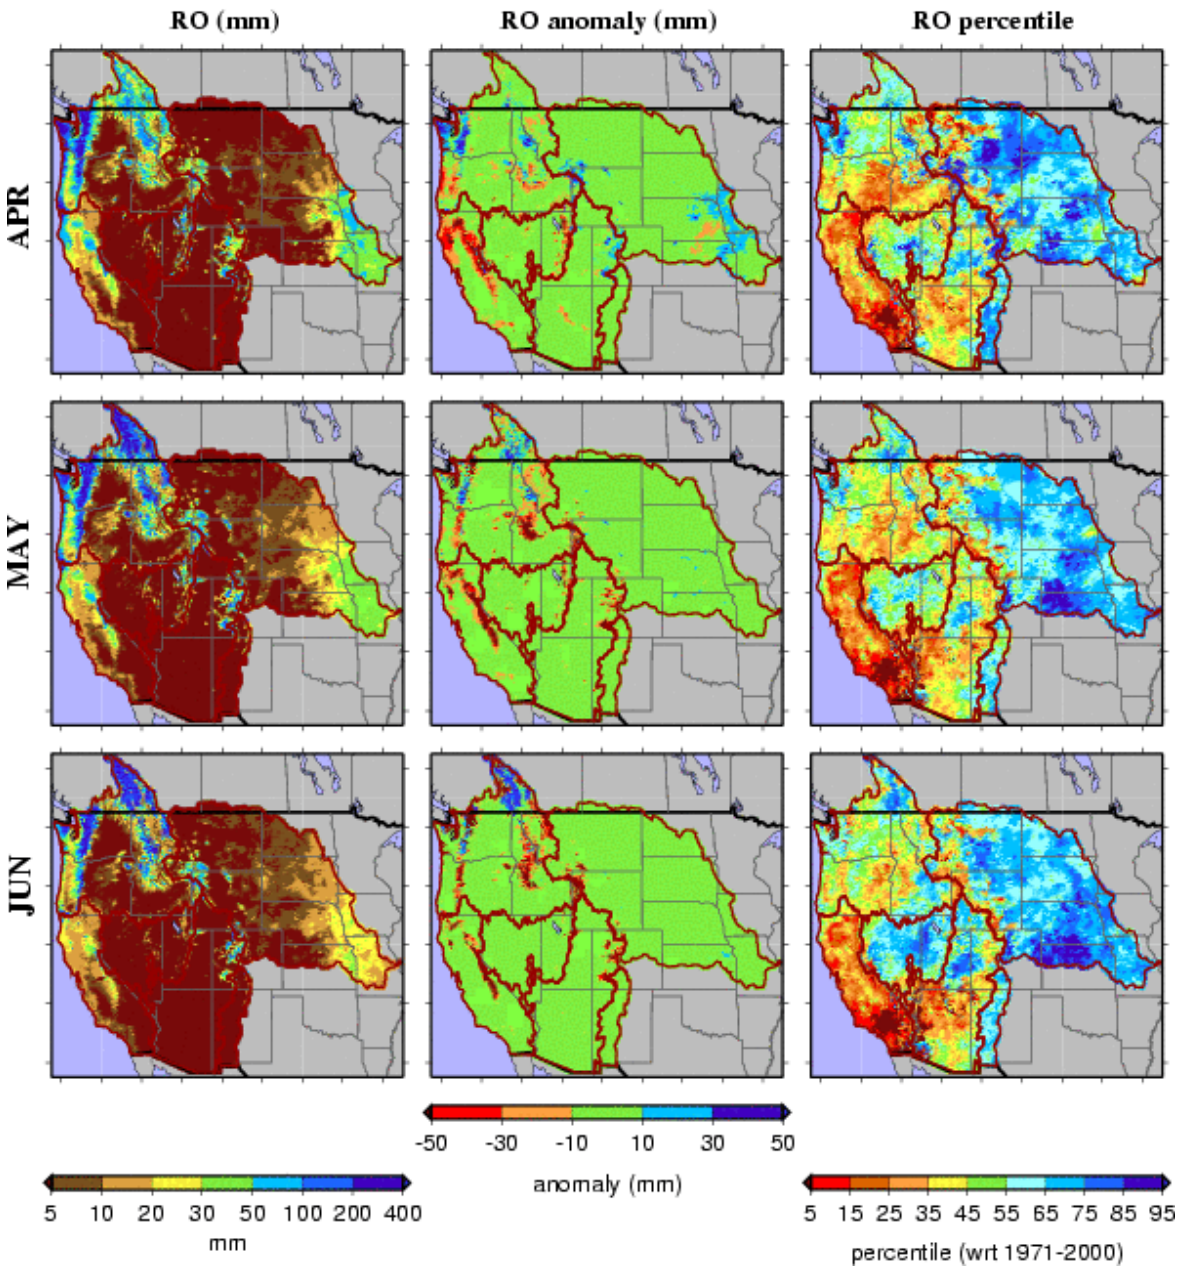

1813 NWRFC volume runoff forecasts. The SPU forecasts are made and used internally rather
1814 than disseminated to the public.

1815

1816 **2.2.2.4 Research**

1817 Research institutions such as universities also produce hydrologic forecasts of a more
1818 experimental nature. A prime example is the Integrated Forecast and Reservoir
1819 Management (INFORM) project housed at the Hydrologic Research Center (HRC),
1820 which produces not only streamflow forecasts in the state of California, but also reservoir
1821 system forecasts; this project is discussed at greater length in Chapter 4 (Georgakakos *et*
1822 *al.*, 2005). At the University of Washington and Princeton University, approximately five
1823 years ago, researchers launched an effort to produce operational hydrologic and
1824 streamflow predictions using distributed land surface models that were developed by an
1825 interagency effort called the Land Data Assimilation System (LDAS) project (Mitchell *et*
1826 *al.*, 2004; Wood and Lettenmaier, 2006); Figure 2.8 shows an example that is based on
1827 the use of CPC climate outlooks. In addition to generating SI streamflow forecasts in the
1828 western and eastern United States, the project also generates forecasts for land surface
1829 variables such as runoff, soil moisture, and snow water equivalent. These forecasts, like
1830 the NWS ESP predictions, are also physically-based, dynamical and objective. The effort
1831 is supported primarily by NOAA, and like the INFORM project collaborates with public
1832 forecast agencies in developing research-level prediction products. The federal funding is
1833 provided with the intent of migrating operational forecasting advances that arise in the
1834 course of these efforts into the public agencies, a topic discussed briefly in Section 2.1.

Runoff (RO) Forecasts (April 1, 2007)

1835

1836 **Figure 2.8** Ensemble median forecasts of monthly runoff from an experimental hydrologic model based on
 1837 CPC climate outlooks. The hydrologic prediction project has run operationally since 2004 at the University
 1838 of Washington, and has a partner effort at Princeton University. Other variables, not shown, include soil
 1839 moisture, snow water equivalent and streamflow. This map was obtained from
 1840 <http://cse.washington.edu/cig/fpt/waterfc/weststreamflowfc.shtml>.
 1841

1842 2.2.3 Skill in SI Hydrologic and Water Resource Forecasts

1843 This section focuses on the skill of hydrologic forecasts; section 2.5 includes a discussion
1844 of forecast utility. Forecasts are statements about events expected to occur at specific
1845 times and places in the future. They can be either deterministic, single-valued predictions
1846 about specific outcomes, or probabilistic descriptions of likely outcomes that typically
1847 take the form of ensembles, distributions, or weighted scenarios.

1848

1849 The hydrologic and water resources forecasts made for water resources management
1850 reflect three components of predictability: the seasonality of the hydrologic cycle,
1851 predictability associated with large-scale climate teleconnections, and persistence of
1852 anomalies in hydrologic initial conditions. Evapotranspiration, runoff (*e.g.*, Pagano *et al.*,
1853 2004) and ground-water recharge (*e.g.*, Earman *et al.*, 2006) all depend on soil moisture
1854 and (where relevant) snowpack conditions one or two seasons prior to the forecast
1855 windows, so that these moisture conditions, directly or indirectly, are key predictors to
1856 many hydrologic forecasts with lead times up to six months. Although hydrologic initial
1857 conditions impart only a few months of predictability to hydrologic systems, during their
1858 peak months of predictability, the skill that they contribute is often paramount. This is
1859 particularly true in the western U.S., where much of the year's precipitation falls during
1860 the cool season, as snow, and then accumulates in relatively easily observed form, as
1861 snowpack, until it predictably melts and runs off in the warm-season months later.

1862 Information about large-scale climatic influences, like the current and projected state of
1863 ENSO, are valued because some of the predictability that they confer on water resources
1864 has influence even before snow begins to accumulate or soil-recharging fall storms

1865 arrive. ENSO, in particular, is strongly synchronized with the annual cycle, so that, in
1866 many instances, the first signs of an impending warm (El Niño) or cold (La Niña) ENSO
1867 event may be discerned toward the end of the summer before the fluctuation reaches its
1868 maturity and peak of influence on the U.S. climate, in winter. This advanced warning for
1869 important aspects of water year climate allows forecasters, in some locations, to
1870 incorporate the expected ENSO influences into hydrologic forecasts before or near the
1871 beginning of the water year (*e.g.*, Hamlet and Lettenmaier, 1999).

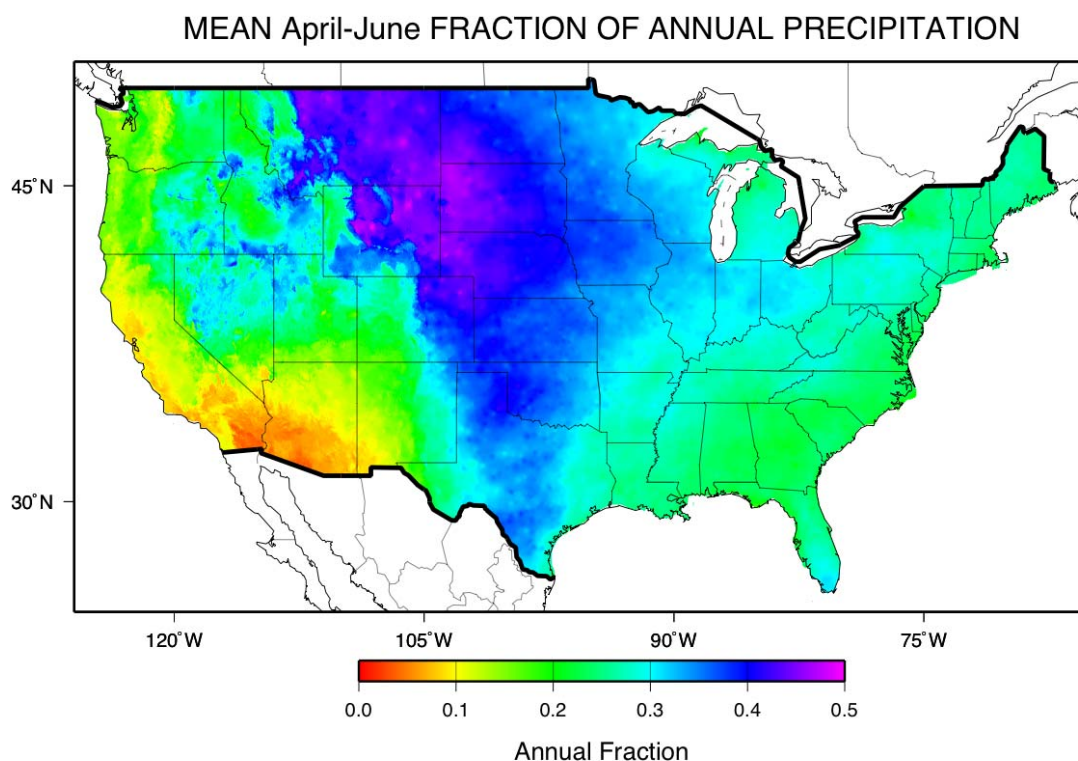

1872

1873 These large-scale climatic influences, however, rarely provide the high level of skill that
1874 can commonly be derived later in the water year from estimates of land surface moisture
1875 state, *i.e.*, from precipitation accumulated during the water year, snow water equivalent or
1876 soil moisture, as estimated indirectly from streamflow. Finally, the unpredictable, random
1877 component of variability remains to limit the skill of all real-world forecasts. The
1878 unpredictable component reflects a mix of uncertainties and errors in the observations
1879 used to initialize forecast models, and errors in the models, and the chaotic complexities
1880 in forecast model dynamics and in the real world.

1881

1882 Many studies have shown that the single greatest source of forecast error is unknown
1883 precipitation after the forecast issue date. Schaake and Peck (1985) estimate that for the
1884 1947-1984 forecasts for inflow to Lake Powell, almost 80% of the January 1st forecast
1885 error is due to unknown future precipitation; by April 1st, Schaake and Peck find that
1886 future precipitation still accounts for 50% of the forecast error. Forecasts can perform
1887 poorly specifically in years with extreme spring precipitation (*e.g.*, 1983 above), or

1888 generally, they can do poorly if spring precipitation is normally a significant component
1889 of the annual cycle. For example, in California, the bulk of the moisture falls from
1890 January-March and rarely does it rain in spring, meaning that April 1 forecasts of spring-
1891 summer streamflow are generally very accurate. In comparison (see Figure 2.9), in
1892 eastern Wyoming and the front range of Colorado, April-through-June is the wettest time
1893 of year and by April 1 the forecaster can only guess at future precipitation events because
1894 of an inability to skillfully forecast springtime precipitation in this region one season in
1895 advance.

1896

1897 **Figure 2.9** Mean percentages of annual precipitation that fall from April through June, 1971-2000 (based
1898 on 4-km PRISM climatologies). This figure was obtained from <http://www.prism.oregonstate.edu/>.
1899

1900 Pagano *et al.* (2004) discovered that the second greatest factor influencing skill is how
1901 much influence snowmelt has on the hydrology of the basin and how warm it is during

1902 the winter. For example, in basins high in the mountains of Colorado, the temperature
1903 remains below freezing for most of the winter. Streamflow is generally low through April
1904 until temperatures rise and the snow starts to melt. The stream then receives a major pulse
1905 of snowmelt over the course of several weeks. Spring precipitation may supplement the
1906 streamflow, but any snow that falls in January is likely to remain in the basin until April
1907 when the forecast target season starts. In comparison, in western Oregon, warm rain-
1908 producing storms can be interspersed with snow-producing winter storms. Most of the
1909 runoff occurs during the winter and it is possible for a large snowpack in February to be
1910 wasted away by March rains. For the forecaster, attempting to predict April-to-July
1911 streamflow is difficult to anticipate, particularly the quantity of water is going to “escape”
1912 before the target season begins.

1913

1914 Some element of forecast accuracy depends on the variability of the river itself. It would
1915 be easy to incur a 100% forecast error on, for example, the San Francisco River in
1916 Arizona, whose observations vary between 17% of average to over 750% of average. It
1917 would be much more difficult to do so on a river such as the Stehekin River in
1918 Washington, where the streamflow ranges only between 60% and 150% of average. A
1919 user may be interested in this aspect of accuracy (*e.g.*, percent of normal error), but most
1920 forecasters use skill scores (*e.g.*, correlation) that would normalize for this effect and
1921 make the results from these two basins more comparable. As noted by Hartmann *et al.*
1922 (2002), consumers of forecast information may be more interested in measures of
1923 forecast skill other than correlations.

1924

1925 **2.2.3.1 Skill of current seasonal hydrologic and water-supply forecasts**

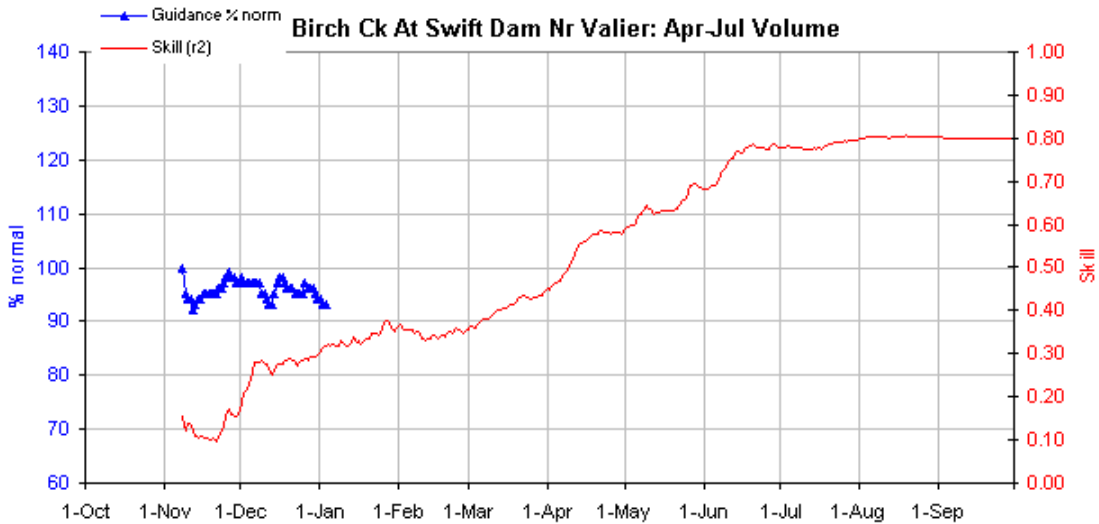

1926 As previously indicated, hydrologic and streamflow forecasts that extend to a 9 -month
1927 lead time are made for western U.S. rivers, primarily during the winter and spring,
1928 whereas in other parts of the United States, where seasonality of precipitation is less
1929 pronounced, the forecasts either link to CPC drought products, are qualitative (the NWS
1930 Southeastern RFC, for instance, provides water supply related briefings from their
1931 website) or in other regards are less amenable to skill evaluation. For this reason, the
1932 following discussion of water supply forecast skill focused mostly on western U.S.
1933 streamflow forecasting, and in particular water supply (*i.e.*, runoff volume) forecasts, for
1934 which most published material relating to SI forecasts exists.

1935

1936 In the western U.S., the skill of operational forecasts generally improves progressively
1937 during the winter and spring months leading up to the period being forecasted, as
1938 increasing information about the year's land surface water budget are observable (*i.e.*,
1939 reflected in snowpack, soil moisture, streamflow and the like). An example of the long-
1940 term average seasonal evolution of NWCC operational forecast skill at a particular stream
1941 gage is shown in Figure 2.10. The flow rates that are judged to have a 50% chance of not
1942 being exceeded (*i.e.*, the 50th percentile or median) are shown by the blue curve for the
1943 early part of 2007. The red curve shows that early in the water year, the April-July
1944 forecast has little skill, measured by the regression coefficient of determination (r^2 or
1945 correlation squared), with only about 10% of historical variance captured by the forecast
1946 equations. By about April 1, the forecast equations predict about 45% of the historical
1947 variance, and at the end of the season, the variance explained is about 80%. This measure

1948 of skill does not reach 100% because the observations available for use as predictors do
 1949 not fully explain the observed hydrologic variation.

1950

1951

1952 **Figure 2.10** Recent operational NWCC forecasts of April-July 2007 streamflow volume in Birch Creek at
 1953 Swift Dam near Valier, showing daily median-forecast values of percentages of long-term average
 1954 streamflow total for summer 2007 (blue) and the long-term estimates of correlation-based forecast skill
 1955 corresponding to each day of the year. (Figure obtained from the National Water and Climate Center
 1956 (NWCC) -- <http://www.wcc.nrcs.usda.gov/>).

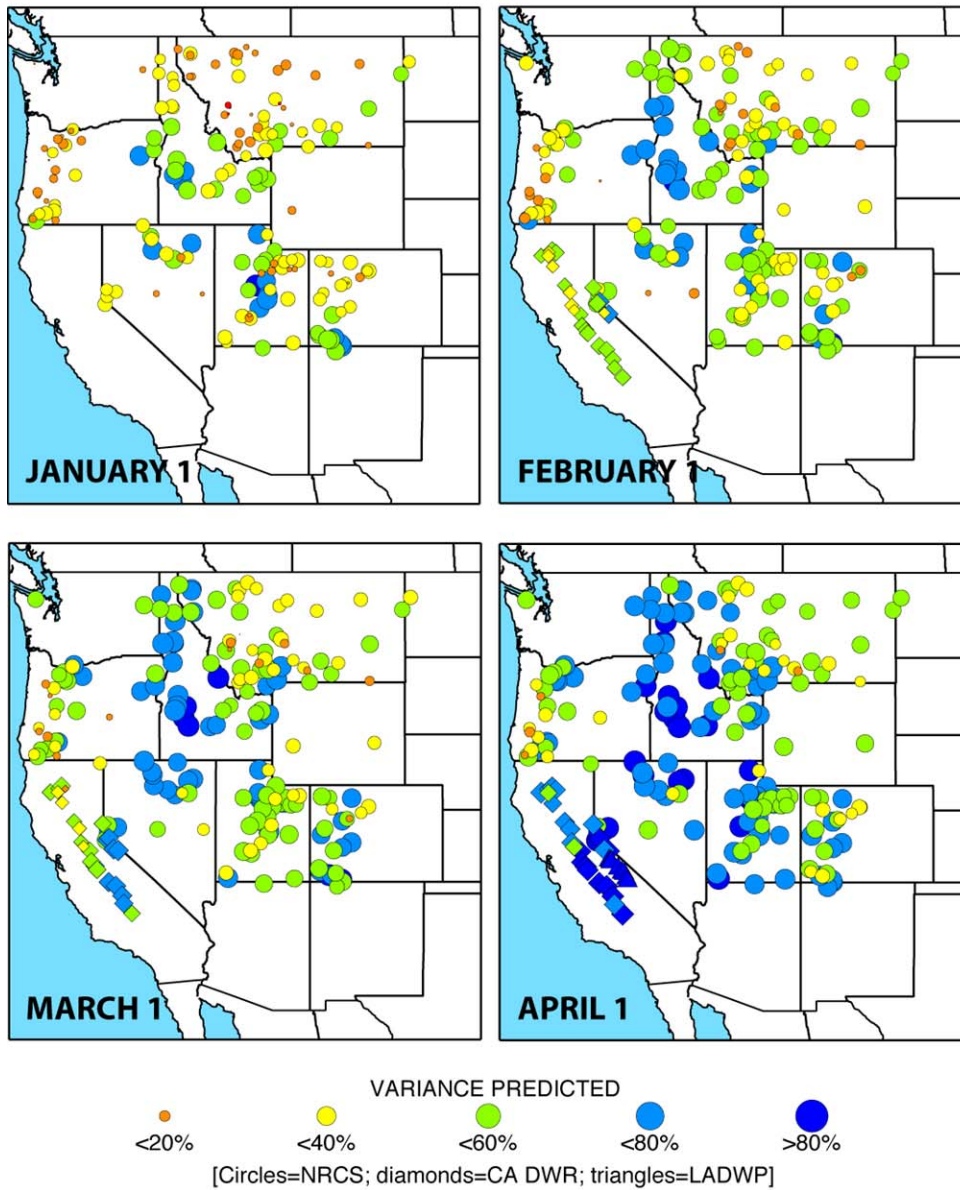

1957

1958 Comparisons of “hindcasts”—seasonal flow estimates generated by applying the
 1959 operational forecast equations to a few decades (lengths of records differ from site to site)
 1960 of historical input variables at each location with observed flows provide estimates of the
 1961 expected skill of current operational forecasts. The actual skill of the forecast equations
 1962 that are operationally used at as many as 226 western stream gages are illustrated in
 1963 Figure 2.11, in which skill is measured by correlation of hindcast median with observed
 1964 values.

1965

1966 The symbols in the various panels of Figure 2.11 become larger and bluer in hue as the
1967 hindcast dates approach the start of the April-July seasons being forecasted. They begin
1968 with largely unskillful beginnings each year in the January 1 forecast; by April 1 the
1969 forecasts are highly skillful by the correlation measures (predicting as much as 80% of
1970 the year-to-year fluctuations) for most of the California, Nevada, and Idaho rivers and
1971 many stations in Utah and Colorado.

**HISTORICAL CORRELATION SKILLS
FOR APRIL-JULY FLOW VOLUMES**

1972

1973 **Figure 2.11** Skills of forecast equations used operationally by NRCS, California Department of Water
 1974 Resources, and Los Angeles Department of Water and Power, for predicting April-July water supplies
 1975 (streamflow volumes) on selected western rivers, as measured by correlations between observed and
 1976 hindcasted flow totals over each station's period of forecast records. Figure provided by Tom Pagano,
 1977 USDA NRCS.

1978

1979 The general increases in skill and thus in numbers of stations with high (correlation) skill

1980 scores as the April 1 start of the forecast period approaches is shown in Figure 2.12.

1981

1982

1983 **Figure 2.12** Percentages of stations with various correlation skill scores in the various panels (forecast
 1984 dates) of Figure 2.11.

1985

1986 A question not addressed in this report relates to the probabilistic skill of the forecasts.

1987 That is, how reliable are the confidence limits around the median forecasts that are

1988 provided by the published forecast quantiles (10th and 90th percentiles, for example). In

1989 a reliable forecast, the frequencies with which the observations fall between various sets

1990 of confidence bounds matches the probability interval set by those bounds. That is, 80%

1991 of the time, the observed values fall between the 10th and 90th percentiles of the forecast.

1992 Among the few analyses that have been published focusing on the probabilistic

1993 performance of U.S. operational streamflow forecasts, Franz *et al.* (2003) evaluated

1994 Colorado River basin ESP forecasts using a number of probabilistic measures and found

1995 reliability deficiencies for many of the streamflow locations considered.

1996

1997 **2.2.3.2 The implications of decadal variability and long term change in climate for**
1998 **seasonal hydrologic prediction skill**

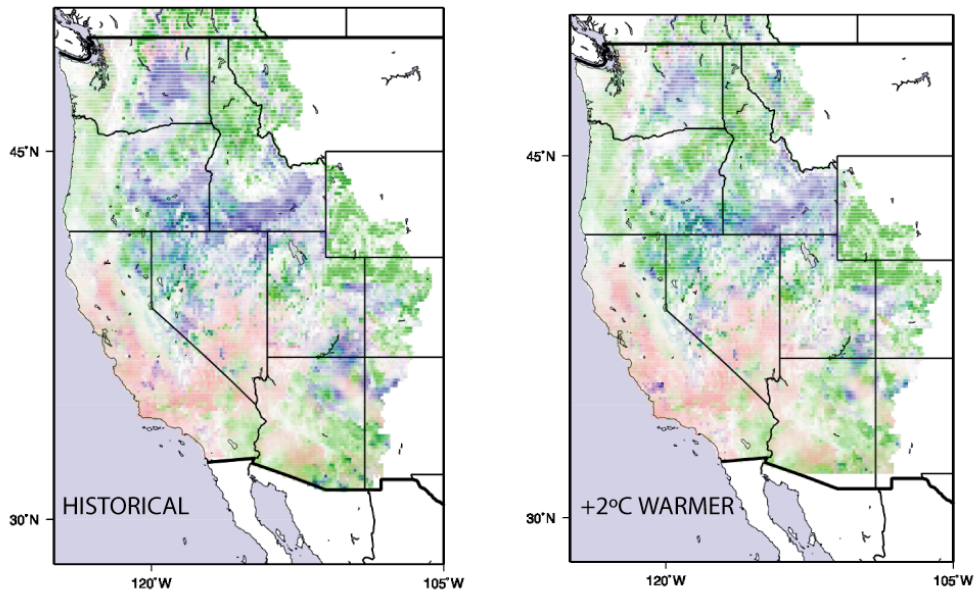

1999 In the earlier discussion of sources of water-supply forecast skill, we highlighted the
2000 amounts and sources of skill provided by snow, soil moisture, antecedent runoff
2001 influences. IPCC projections of global and regional warming, with its expected strong
2002 effects on western U.S. snowpacks (Stewart *et al.*, 2004; Barnett *et al.*, 2008) raises the
2003 concern that prediction methods such as regression that depend on a consistent
2004 relationship between these predictors and future runoff may not perform as expected if
2005 the current climate system is being altered in ways that then alters these hydro-climatic
2006 relationships. Decadal climate variability, particularly in precipitation (*e.g.*, Mantua *et al.*,
2007 1997; McCabe and Dettinger, 1999), may also represent a challenge to such methods,
2008 although some researchers suggest that knowledge of decadal variability can be
2009 beneficial for streamflow forecasting (*e.g.*, Hamlet and Lettenmaier, 1999). One view
2010 voiced in the literature (*e.g.*, Wood and Lettenmaier, 2006) is that hydrologic model-
2011 based forecasting may be more robust to the effects of climate change and variability due
2012 to the physical constraints of the land surface models, but this thesis has not been
2013 comprehensively explored.

2014
2015 The maps shown in Figure 2.13 are based on hydrologic simulations of a physically-
2016 based hydrologic model, the Variable Infiltration Capacity (VIC) model (Liang *et al.*,
2017 1994), in which historical temperatures are uniformly increased by +2°C. These figures
2018 show that the losses of snowpack and the tendencies for more precipitation to fall as rain
2019 rather than snow in a warmer world reduce overall forecast skill, shrinking the areas

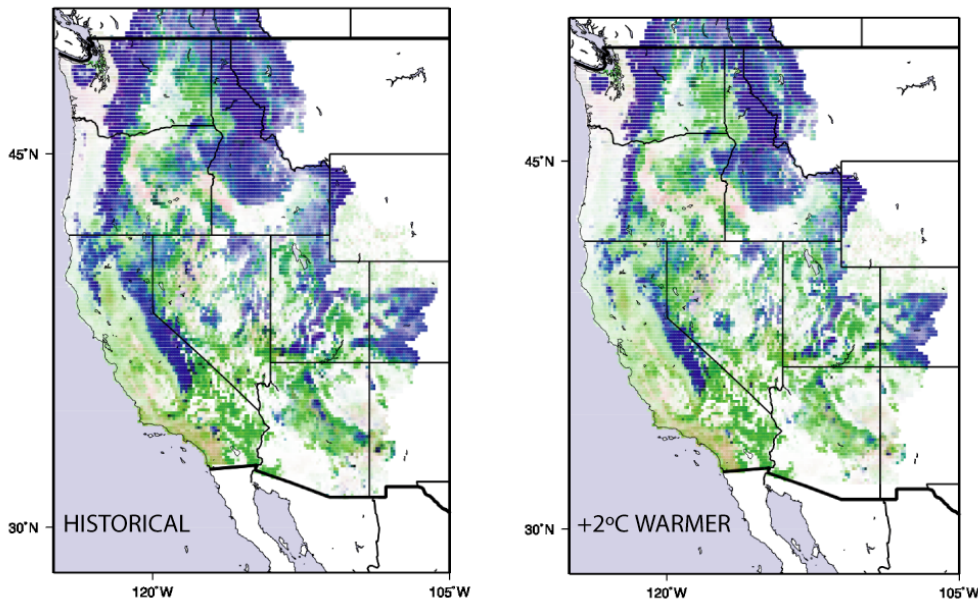

2020 where snowpack contributes strong predictability and also making antecedent runoff a
2021 less reliable predictor. Thus many areas where warm-season runoff volumes are
2022 accurately predicted historically are likely to lose some forecast skill along with their
2023 snowpacks. Overall, the average skill declines by about 2% (out of a historical average of
2024 35%) for the January-March volumes and by about 4% out of a historical average of 53%
2025 for April-July. More importantly, though, are the declines in skill at grid cells where
2026 historical skills are greatest, nearly halving the occurrence of high-end (>0.8) January-to-
2027 March skills and reducing high-end April-to-July skills by about 15% (Figure 2.14).
2028

CHANGES IN CONTRIBUTIONS OF FORECAST SKILL FOR SEASONAL RUNOFF IN RESPONSE TO +2°C WARMING

JANUARY-MARCH RUNOFF FROM DECEMBER PREDICTORS

APRIL-JULY RUNOFF FROM MARCH PREDICTORS

2029

2030

2031

2032

2033

2034

2035

Figure 2.13 Potential contributions of antecedent snowpack conditions, runoff, and Niño 3.4 sea-surface temperatures to seasonal forecast skills in hydrologic simulations under historical, 1950-99, meteorological conditions (left panels) and under those same conditions but with a +2°C uniform warming imposed. (Dettinger, 2007)

2036

2037 **Figure 2.14** Distributions of overall fractions of variance predicted, in Fig. 2.13, of January-March
 2038 (curves) and April-July (histograms) runoff volumes under historical (black) and +2°C warmer conditions.
 2039 (Dettinger, 2007)

2040

2041 This enhanced loss among the most skillful grid cells reflects the strong reliance of those
 2042 grid cells on historical snowpacks for the greater part of their skill, snowpacks which
 2043 decline under the imposed +2°C warmer conditions. Overall, skills associated with
 2044 antecedent runoff are more strongly reduced for the April-to-July runoff volumes, with
 2045 reductions from an average contribution of 24% of variance predicted (by antecedent
 2046 runoff) historically to 21% under the +2°C warm conditions; for the January-to-March
 2047 volumes, skill contributed by antecedent runoff only declines from 18.6% to 18.2% under
 2048 the imposed warmer conditions. The relative declines in the contributions from snowpack
 2049 and antecedent runoff make antecedent runoff (or, more directly, soil moisture, for which
 2050 antecedent runoff is serving as a proxy here) a more important predictor to monitor in the
 2051 future.

2052

2053 It is worth noting that the changes in skill contributions illustrated in Figure 2.13 are best-
2054 case scenarios. The skills shown are skills that would be provided by a complete
2055 recalibration of forecast equations to the new (imposed) warmer conditions, based on 50
2056 years of runoff history. In reality, the runoff and forecast conditions are projected to
2057 gradually and continually trend towards increasingly warm conditions, and fitting new,
2058 appropriate forecast equations (and models) will always be limited by having only a brief
2059 reservoir of experience with each new degree of warming. Consequently, we must expect
2060 that regression-based forecast equations will tend to be increasingly and perennially out
2061 of date in a world with strong warming trends. This problem with the statistics of forecast
2062 skill in a changing world suggests development and deployment of more physically
2063 based, less statistically based forecast models should be a priority in the foreseeable
2064 future.

2065

2066 **2.2.3.3 Skill of climate forecast-driven hydrologic forecasts**

2067 The extent to which the ability to forecast United States precipitation and temperature
2068 seasons in advance can be translated into long-lead hydrologic forecasting has been
2069 evaluated by Wood *et al.* (2005). That evaluation compared hydrologic variables in the
2070 major river basins of the western conterminous U.S. as simulated by the VIC hydrologic
2071 model (Liang *et al.*, 1994), forced by two different sources of temperature and
2072 precipitation data: (1) observed historical meteorology (1979-1999); and (2) by hindcast
2073 climate-model-derived 6-month-lead climate forecasts.

2074

2075 The Wood *et al.* (2005) assessment quantified and reinforced an important aspect of the
2076 hydrologic forecasting community’s intuition about the current levels of hydrologic
2077 forecast skill using long-lead climate forecasts generated from various sources. The
2078 analysis first underscored the conclusions that, depending on the season, knowledge of
2079 initial hydrologic conditions conveys substantial forecast skill. A second finding was that
2080 the additional skill available from incorporating current (at the time) long-lead climate
2081 model forecasts into hydrologic prediction is limited when all years are considered, but
2082 can improve streamflow forecasts relative to climatological ESP forecasts in extreme
2083 ENSO years. If performance in all years is considered, the skill of current climate
2084 forecasts (particularly, of precipitation) is inadequate to provide readily extracted
2085 hydrologic-forecast skill at monthly to seasonal lead times. This result is consistent with
2086 findings for North American climate predictability (Saha *et al.*, 2006). During El Niño
2087 years, however, the climate forecasts have high enough skill for temperatures, and mixed
2088 skill for precipitation, so that hydrologic forecasts for some seasons and some basins
2089 (especially California, the Pacific Northwest and the Great Basin) provide measurable
2090 improvements over the ESP alternative.

2091

2092 The authors of that assessment concluded “climate model forecasts presently suffer from
2093 a general lack of skill, [but] there may be locations, times of year and conditions (*e.g.*,
2094 during El Niño or La Niña) for which they improve hydrologic forecasts relative to ESP”
2095 (Wood *et al.*, 2005). However, their conclusion was that improvements to hydrologic
2096 forecasts based on other forms of climate forecasts, *e.g.*, statistical or hybrid methods that

2097 are not completely reliant on a single climate model may prove more useful in the near
2098 term, presumably until pure climate-model forecasts have improved considerably.

2099

2100 **2.3 CLIMATE DATA AND FORECAST PRODUCTS**

2101 **2.3.1 A Sampling of SI Climate Forecast Products of Interest to Water Resource**

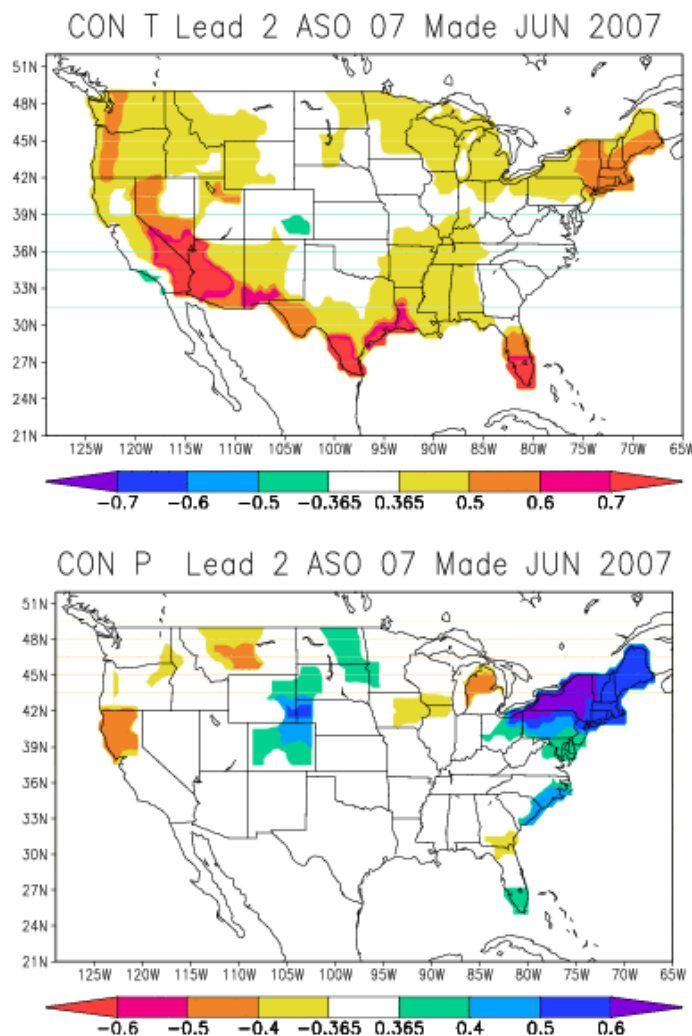

2102 **Managers**

2103 At SI lead times, a wide array of dynamical prediction products exists. A representative
2104 sample of SI climate forecast products is listed in Appendix A.1. The current dynamical
2105 prediction scheme used by NCEP, for example, is a system of models comprising
2106 individual models of the oceans, global atmosphere and continental land surfaces. These
2107 models were developed and originally run for operational forecast purposes in an
2108 uncoupled, sequential mode, an example of which is the so-called “Tier 2” framework in
2109 which the ocean model runs first, producing ocean surface boundary conditions that are
2110 prescribed as inputs for subsequent atmospheric model runs. Since 2004, a “Tier 1”
2111 scheme was introduced in which the models, together called the Coupled Forecast
2112 System (CFS; Saha *et al.*, 2006), were fully coupled to allow dynamic exchanges of
2113 moisture and energy across the interfaces of the model components.

2114

2115 At NCEP, the dynamical tool, CFS, is complemented by a number of statistical forecast
2116 tools, three of which, Screening Multiple Linear Regression (SMLR), Optimal Climate
2117 Normals (OCN), and Canonical Correlation Analysis (CCA), are merged with the CFS to
2118 form an objective consolidation forecast product (Figure 2.15). While the consolidated
2119 forecast exceeds the skill of the individual tools, the official seasonal forecast from CPC

2120 involves a subjective merging of it with forecast and nowcast information sources from a
 2121 number of different sources, all accessible to the public at CPC’s monthly briefing. The
 2122 briefing materials comprise 40 different inputs regarding the past, present and expected
 2123 future state of the land, oceans and atmosphere from sources both internal and external to
 2124 CPC, that are posted online at:
 2125 (<http://www.cpc.ncep.noaa.gov/products/predictions/90day/tools/briefing/>).

2126

2127 **Figure 2.15** CPC objective consolidation forecast for precipitation and temperature for the three month
 2128 period Aug-Sep-Oct 2007, made June 2007 (lead 2 months). Figure obtained from
 2129 <http://www.cpc.ncep.noaa.gov>.
 2130

2131 The resulting official forecast briefing has CPC’s primary presentation of climate forecast
2132 information each month. Forecast products are accessible directly from CPC’s root level
2133 home page in the form of maps of the probability anomalies for precipitation and
2134 temperature in three categories, or “terciles”, representing below-normal, normal and
2135 above-normal values; a two-category scheme (above and below normal) is also available.
2136 This framework is used for the longer lead outlooks (Figure 2.16). The seasonal forecasts
2137 are also available in the form of maps of climate anomalies in degrees Celsius for
2138 temperature and inches for precipitation (Figure 2.17). The forecasts are released
2139 monthly, have a time-step of three months, and have a spatial unit of the climate division
2140 (Figure 2.18). For users desiring more information about the probabilistic forecast than is
2141 given in the map products, a probability of exceedence (POE) plot, with associated
2142 parametric information, is also available for each climate division (Figure 2.19). The
2143 POE plot shows the shift of the forecast probability distribution from the climatological
2144 distribution for each lead-time of the forecast.

2151

Anomaly (Inches) of the Mid-value of the 3-Month Precipitation Outlook Distribution for ASO 2007

Dashed lines are the median 3-month precipitation (inches) based on observations from 1971–2000. Shaded areas indicate whether the anomaly of the mid-value is positive (green) or negative (brown) compared to the 1971–2000 average. Non-shaded regions indicate that the absolute value of the anomaly of the mid-value is less than 0.1. For a given location, the mid-value of the outlook may be found by adding the anomaly value to the 1971–2000 average. There is an equal 50–50 chance that actual conditions will be above or below the mid-value. Please note that this product is a limited representation of the official forecast, showing the anomaly of the mid-value, but not the width of the range of possibilities. For more comprehensive forecast information, please see our additional forecast products.

2152

 2168 &var=p.
 2169

2170 In addition to NCEP, a few other centers, (e.g., the International Research Institute for
 2171 Climate and Society (IRI)) produce similar consensus forecasts and use a similar map-
 2172 based, tercile-focused framework for exhibiting their results. A larger number of centers
 2173 run dynamical forecast tools, and the NOAA Climate Diagnostics Center, which
 2174 produces monthly climate outlooks internally using statistical tools, also provides
 2175 summaries of climate forecasts from a number of major sources, both in terms of
 2176 probabilities or anomalies, for selected surface and atmospheric variables. The

2177 Experimental Climate Prediction Center (ECPC) at Scripps Institute provides monthly
2178 and seasonal time step forecasts of both climate and land surface variables at a national
2179 and global scale, from dynamical models. Using these model outputs, ECPC also
2180 generates forecasts for derived variables that target wildfire management – *e.g.*, soil
2181 moisture, the Fireweather Index (See Chapter 4 for a more detailed description of Water
2182 Resource Issues in Fire-Prone U.S. Forests and the use of this index) . The CPC has
2183 similar efforts in the form of the Hazards Assessment, a short to medium range map
2184 summary of hazards related to extreme weather (such as flooding and wildfires), and the
2185 CPC Drought Outlook (Box 2.3), a subjective consensus product focusing on the
2186 evolution of large-scale droughts, that is released once a month, conveying expectations
2187 for a 3-month outlook period.

2188

2189 The foregoing is a brief survey of climate forecast products from major centers in the
2190 United States, and as such is far from a comprehensive presentation of the available
2191 sources. It does, however, provide examples from which the following observations about
2192 the general nature of climate prediction in the U.S. may be drawn. First, that operational
2193 SI climate forecasting is conducted at a relatively small number of federally-funded
2194 centers, and forecast products are national to global in scale. These products tend to have
2195 a coarse resolution in space and time, and are typically for basic earth system variables
2196 (*e.g.*, temperature, precipitation, atmospheric and surface pressure) that are of general
2197 interest to many sectors. Forecasts are nearly always probabilistic, and the major products
2198 attempt to convey the inherent uncertainty via maps or data detailing forecast

2199 probabilities, although deterministic reductions (such as forecast variable anomalies) are
2200 also available.

2201

2202 **2.3.2 Sources of Climate-Forecast Skill**

2203 Much as with hydrologic forecasts, the skill of forecasts of climate variables (notably,
2204 temperature and precipitation) varies from region to region, varies with forecast season
2205 and lead time, is limited by the chaotic and uncertain character of the climate system, and
2206 derives from a variety of sources. While initial conditions are an important source for
2207 skill in SI hydrologic forecasts, the initial conditions of an atmospheric forecast are
2208 effectively forgotten after about 8-10 days and have no influence on SI climate forecast
2209 skill (Molteni *et al.*, 1996). SI forecasts are actually forecasts of those variations of the
2210 climate system that reflect predictable changes in boundary conditions, like sea-surface
2211 temperatures (SSTs), or in external ‘forcings’, disturbances in the radiative energy budget
2212 of the Earth’s climate system. At time scales of decades to centuries, potential skill rests
2213 in predictions for slowly varying components of the climate system like the atmospheric
2214 concentrations of CO₂ that influence the greenhouse effect, or slowly evolving changes
2215 in ocean circulation that can alter SSTs and thereby change the boundary conditions for
2216 the atmosphere. Not all possible sources of SI climate-forecast skill have been identified
2217 or exploited, but contributors that have been proposed and pursued include a variety of
2218 large-scale air-sea connections (*e.g.*, Redmond and Koch, 1991; Cayan and Webb, 1992;
2219 Mantua *et al.*, 1997; Enfield *et al.*, 2001; Hoerling and Kumar, 2003), snow and sea ice
2220 patterns (*e.g.*, Cohen and Entekhabi, 1999; Clark and Serreze, 2000; Lo and Clark, 2002;

2221 Liu *et al.*, 2004), and soil moisture and vegetation regimes (*e.g.*, Koster and Suarez, 1995,
2222 2000; Ni-Meister *et al.*, 2005).

2223

2224 In operational practice, however, most of the forecast skill provided by current forecast
2225 systems (especially, including climate models) derives from our ability to predict the
2226 evolution of ENSO events on time scales of 6 to 12 months, coupled with the

2227 “teleconnections” from the events in the tropical Pacific to many areas of the globe.

2228 Barnston *et al.* (1994), in their explanation of the advent of the first operational long-lead
2229 forecasts from the NOAA Climate Prediction Center, stated that “while some

2230 extratropical processes probably develop independently of the Tropics..., much of the

2231 skill of the forecasts for the extratropics comes from anomalies of ENSO-related tropical

2232 sea-surface temperatures.” Except for the changes associated with diurnal cycles,

2233 seasonal cycles, and possibly the (30-60 day) Madden-Julian Oscillation of the tropical

2234 ocean-atmosphere system, “ENSO is the most predictable climate fluctuation on the

2235 planet” (McPhaden *et al.*, 2006). Diurnal cycles and seasonal cycles are predictable on

2236 time scales of hours-to-days and months-to-years, respectively, whereas ENSO mostly

2237 provides predictability on SI time scales (*e.g.*, Figure 2.19b, from a potential

2238 predictability study by Collins 2002). Notice, in Figure 2.19a, that temperatures over the

2239 tropical oceans and lands, and extratropical oceans are much more correlated from season

2240 to season than are conditions on the extratropical continents. To the extent that they can

2241 anticipate the slow evolution of the tropical oceans, indicated by these correlations, SCFs

2242 in the extratropics that harken to the tropical oceans are provided a basis for prediction

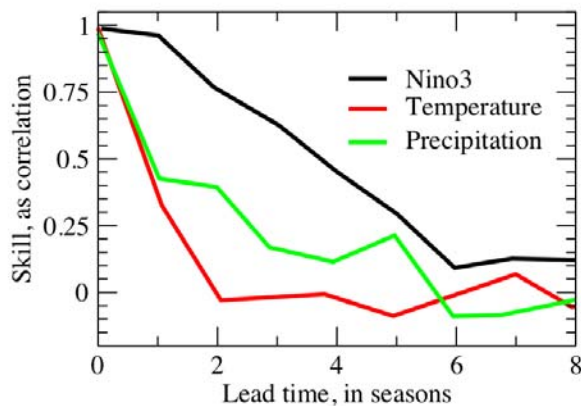

2243 skill; to the extent that the multiseasonal long-term potential predictability of the ENSO

2244 episodes (Figure 2.19b) can be drawn upon in certain regions at certain times of year, the
 2245 relatively meager predictabilities of North American temperatures and precipitation can
 2246 be extended.

2247

2248

2249

2250 **Figure 2.19** (a) Map of correlations between surface-air temperatures in each season and the following
 2251 season in 600 years of historical climate simulation by the HadCM3 model (Collins 2002); (b) Potential
 2252 predictability of a common ENSO index (Niño3 SST, the average of SSTs between 150°W and 90W, 5°S
 2253 and 5°N), average temperatures over the United States and Canada, and average precipitation over the
 2254 United States and Canada, with skill measured by anomaly correlations and plotted against the forecast lead
 2255 times; results extracted from Collins (2002), who estimated these skills from the reproducibility among
 2256 multiple simulations of 30yrs of climate by the HadCM3 coupled ocean-atmosphere model. Correlations
 2257 below about 0.3 are not statistically significant at 95% level.
 2258

2259 The scattered times between ENSO events drastically limits skillful prediction of events
2260 until, at least, the first faltering steps towards the initiation of an ENSO event have been
2261 observed. ENSO events, however, are frequently (but not always) phase-locked
2262 (synchronized) with aspects of the seasonal cycle (Neelin *et al.*, 2000), so that (a)
2263 forecasters know when to look most diligently for those “first faltering steps” and (b) the
2264 first signs of the initiation of an event are often witnessed 6-9 months prior to ENSO’s
2265 largest expressions in the tropics and Northern Hemisphere (*e.g.*, Penland and
2266 Sardeshmukh, 1995). Thus ENSO influences, however irregular and unpredictable they
2267 are on multiyear time scales, regularly provide the basis for SI climate forecasts over
2268 North America. ENSO events generally begin their evolution sometime in late (northern)
2269 spring or early summer, growing and maturing until they most often reach full strength
2270 (measured by either their SST expressions in the tropical Pacific or by their influences on
2271 the Northern Hemisphere) by about December – March (*e.g.*, Chen and van den Dool
2272 1997). An ENSO event’s evolution in the tropical ocean and atmosphere during the
2273 interim period is reproducible enough that relatively simple climate indices that track
2274 ENSO-related SST and atmospheric pressure patterns in the tropical Pacific provide
2275 predictability for North American precipitation patterns as much as two seasons in
2276 advance. Late summer values of the Southern Oscillation Index (SOI), for instance, are
2277 significantly correlated with a north-south see-saw pattern of wintertime precipitation
2278 variability in western North America (Redmond and Koch 1991).

2279

2280 **2.4 IMPROVING WATER RESOURCES FORECAST SKILL AND PRODUCTS**

2281 Although forecast skill is only one measure of the value that forecasts provide to water
2282 resources managers and the public, it is an important measure and current forecasts are
2283 generally understood to fall short of the maximum possible skill on SI time scales (*e.g.*,
2284 http://www.clivar.org/organization/wgsip/spw/spw_position.php). Schaake *et al.* (2007)
2285 describe the SI hydrologic prediction process for model-based prediction in terms of
2286 several components: (i) development, calibration and/or downscaling of SI climate
2287 forecasts; (ii) estimation of hydrologic initial conditions, with or without data
2288 assimilation; (iii) SI hydrologic forecasting models and methods; and (iv) calibration of
2289 the resulting forecasts. Notable opportunities for forecast skill improvement in each area
2290 are discussed here.

2291

2292 **2.4.1 Improving SI Climate Forecast Use for Hydrologic Prediction**

2293 SI climate forecast skill is a function of the skill of climate system models, the efficacy of
2294 model combination strategies if multiple models are used, the accuracy of climate system
2295 conditions from which the forecasts are initiated, and the performance of post processing
2296 approaches applied to correct systematic errors in numerical model outputs.

2297 Improvements are sought in all of these areas.

2298

2299 **2.4.1.1 Climate forecast use**

2300 Many researchers have found that SI climate forecasts must be downscaled,
2301 disaggregated and statistically calibrated to be suitable as inputs for applied purposes
2302 (*e.g.*, hydrologic prediction, as in Wood *et al.*, 2002). Downscaling is the process of
2303 bridging the spatial scale gap between the climate forecast resolution and the

2304 application’s climate input resolution, if they are not the same. If the climate forecasts are
2305 from climate models, for instance, they are likely to be at a grid resolution of several 100
2306 km, whereas the application may require climate information at a point (*e.g.*, station
2307 location). Disaggregation is similar to downscaling, but in the temporal dimension – *e.g.*,
2308 seasonal climate forecasts may need to be translated into daily or subdaily temperature
2309 and precipitation inputs for a given application (as described in Kumar, 2008). Forecast
2310 calibration is a process by which the statistical properties (such as bias and spread errors)
2311 of a probabilistic forecast are corrected to match their observed error statistics (*e.g.*,
2312 Atger, 2003; Hamill *et al.*, 2006). These procedures may be distinct from each other, or
2313 they may be inherent parts of a single approach (such as the analogue techniques of
2314 Hamill *et al.*, 2006). These steps do not necessarily improve the signal to noise ratio of
2315 the climate forecast, but done properly, they do correct bias and reliability problems that
2316 would otherwise render impossible their use in applications. For shorter lead predictions,
2317 corrections to forecast outputs have long been made based on (past) model output
2318 statistics (MOS; Glahn and Lowry, 1972). MOS are sets of statistical relations (*e.g.*,
2319 multiple linear regression (MLR)) that effectively convert numerical model outputs into
2320 unbiased, best climate predictions for selected areas or stations, where “best” relates to
2321 past performance of the model in reproducing observations. MOS corrections are widely
2322 used in weather prediction (Dallavalle and Glahn 2005). Corrections may be as simple as
2323 removal of mean biases indicated by historical runs of the model, with the resulting
2324 forecasted anomalies superimposed on station climatology. More complex methods
2325 specifically address spatial patterns in climate forecasts based on specific inadequacies of

2326 the models in reproducing key teleconnection patterns or topographic features (*e.g.*,
2327 Landman and Goddard 2002, Tippett *et al.*, 2003).

2328

2329 A primary limitation on calibrating SI forecasts is the relatively small numbers of
2330 retrospective forecasts available for identifying biases. Weather predictions are made
2331 every day and thus even a few years' of forecasts provide a large number of examples
2332 from which to learn. SI forecasts, in contrast, are comparatively infrequent and even
2333 several decades' worth may not provide an adequate resource with which to develop
2334 model-output corrections (Kumar, 2007). This limitation is exacerbated when the
2335 predictability and biases themselves vary between years and states of the global climate
2336 system. Thus there is a clear need to expand current "reforecast" practices for fixed SI
2337 climate models over long historical periods to provide both for quantification (and
2338 verification) of the evolution of SI climate forecast skills and for post-processing
2339 calibrations to those forecasts.

2340

2341 **2.4.1.2 Development of objective multi-model ensemble approaches**

2342 The accuracy of SI climate forecasts has been shown to increase when forecasts from
2343 groups of models are combined into multi-model ensembles (*e.g.*, Krishnamurti *et al.*,
2344 2000; Palmer *et al.*, 2004; Tippett *et al.*, 2007). Multi-model forecast ensembles yield
2345 greater overall skill than do any of the individual forecasts included, in principle, as a
2346 result of cancellation of errors between ensemble members. Best results thus appear to
2347 accrue when the individual models are of similar skill and when they exhibit errors and
2348 biases that differ from model to model. In part, these requirements reflect the current

2349 uncertainties about the best strategies for choosing among models for inclusion in the
2350 ensembles used and, especially for weighting and combining the model forecasts within
2351 the ensembles. Many methods have been proposed and implemented (*e.g.*, Rajagopalan *et*
2352 *al.*, 2002; Yun *et al.*, 2005), but strategies for weighting and combining ensemble
2353 members are still an area of active research (*e.g.*, Doblas-Reyes *et al.*, 2005; Coelho *et*
2354 *al.*, 2004). Multi-model ensemble forecast programs are underway in Europe
2355 (DEMETER, Palmer *et al.*, 2004) and in Korea (APEC; *e.g.*, Kang and Park, 2007). In
2356 the United States, IRI forms an experimental multi-model ensemble forecast, updating
2357 monthly, from seasonal forecast ensembles run separately at 7 centers, a 'simple multi-
2358 model' approach that compares well with centrally organized efforts such as DEMETER
2359 (Doblas-Reyes *et al.*, 2005). The NOAA Climate Test Bed Science Plan also envisions
2360 such a capability for NOAA (Higgins *et al.*, 2006).

2361

2362 **2.4.1.3 Improving climate models, initial conditions, and attributions**

2363 Improvements to climate models used in SI forecasting efforts should be a high priority.
2364 Several groups of climate forecasters have identified the lack of key aspects of the
2365 climate system in current forecast models as important weaknesses, including
2366 underrepresented linkages between the stratosphere and troposphere (Baldwin and
2367 Dunkerton 1999), limited processes and initial conditions at land surfaces (Beljaars *et al.*,
2368 1996; Dirmeyer *et al.*, 2006; Ferranti and Viterbo, 2006), and lack of key biogeochemical
2369 cycles like carbon dioxide.

2370

2371 Because climate prediction is, by most definitions, a problem determined by boundary
2372 condition rather than an initial condition, specification of atmospheric initial conditions is
2373 not the problem for SI forecasts that it is for weather forecasts. However, SI climate
2374 forecast skill for most regions comes from knowledge of current SSTs or predictions of
2375 future SSTs, especially those in the tropics (Shukla *et al.*, 2000; Goddard and Dilley,
2376 2005; Rosati *et al.*, 1997). Indeed, forecast skill over land (worldwide) increases directly
2377 with the strength of an ENSO event (Goddard and Dilley, 2005). Thus an important
2378 determinant of recent improvements in SI forecast skill has been the quality and
2379 placement of tropical ocean observations, like the TOGA/TAO network of buoys that
2380 monitors the conditions that lead up to and culminate in El Niño and La Niña events
2381 (Trenberth *et al.*, 1998; McPhaden *et al.*, 1998; Morss and Batistti, 2004). More
2382 improvements in all of the world's oceans are expected from the broader Array for Real-
2383 time Geostrophic Oceanography (ARGO) upper-ocean monitoring arrays and Global
2384 Ocean Observing System (GOOS) programs (Nowlin *et al.*, 2001). In many cases, and
2385 especially with the new widespread ARGO ocean observations, ocean-data assimilation
2386 has improved forecast skill (*e.g.*, Zheng *et al.*, 2006). Data assimilation into coupled
2387 ocean-atmosphere-land models is a difficult and unresolved problem that is an area of
2388 active research (*e.g.*; Ploshay, 2002; Zheng *et al.*, 2006). Land-surface and cryospheric
2389 conditions also can influence the seasonal scale dynamics that lend predictability to SI
2390 climate forecasting, but incorporation of these initial boundary conditions into SI climate
2391 forecasts is in an early stage of development (Koster and Suarez, 2001; Lu and Mitchell,
2392 2004; Mitchell *et al.*, 2004). Both improved observations and improved avenues for

2393 including these conditions into SI climate models, especially with coupled ocean-
2394 atmosphere-land models, are needed.
2395
2396 Finally, a long-standing but little explored approach to improving the value of SI climate
2397 forecasts is the attribution of the causes of climate variations. The rationale for an
2398 attribution effort is that forecasts have greater value if we know why the forecasted event
2399 happened, either before or after the event, and why a forecast succeeded or failed, after
2400 the event. The need to distinguish natural from human-caused trends, and trends from
2401 fluctuations, is likely to become more and more important as climate change progresses.
2402 SI forecasts are always likely to fail from time to time, or to realize less probable ranges
2403 of probabilistic forecasts; knowing that forecasters understand the failures (in hindsight)
2404 and have learned from them will help to build increasing confidence through time among
2405 users. Attempts to attribute causes to important climate events began as long ago as the
2406 requests from Congress to explain the 1930s Dust Bowl. Recently NOAA has initiated a
2407 Climate Attribution Service (<http://www.cdc.noaa.gov/CSI/>) that will combine historical
2408 records, climatic observations, and many climate model simulations to infer the principle
2409 causes of important climate events of the past and present. Forecasters can benefit from
2410 knowledge of causes and effects of specific climatic events as well as improved
2411 feedbacks as to what parts of their forecasts succeed or fail. Users will also benefit from
2412 knowing the reasons for prediction successes and failures.

2413

2414 **2.4.2 Improving Initial Hydrologic Conditions for Hydrologic and Water Resource**
2415 **Forecasts**

2416 Operational hydrologic and water resource forecasts at SI time scales derive much of
2417 their skill from hydrologic initial conditions, with the particular sources of skill
2418 depending on seasons and locations. Thus better estimation of hydrologic initial
2419 conditions will in some seasons lead to improvements in SI hydrologic and consequently
2420 water resources forecast skill. The four main avenues for progress in this area are: (1)
2421 augmentation of climate and hydrologic observing networks; (2) improvements in
2422 hydrologic models (*i.e.*, physics and resolution); (3) improvements in hydrologic model
2423 calibration approaches; and (4) data assimilation.

2424

2425 **2.4.2.1 Hydrologic observing networks**

2426 As discussed previously (in section 2.2), hydrologic and hydroclimatic monitoring
2427 networks provide crucial inputs to hydrologic and water resource forecasting models at SI
2428 time scales. Continuous or regular measurements of streamflow, precipitation and snow
2429 water contents provide important indications of the amount of water that entered and left
2430 river basins prior to the forecasts and thus provide directly or indirectly the initial
2431 conditions for model forecasts.

2432

2433 Observed snow water contents are particularly important sources of predictability in most
2434 of the western half of the United States, and have been measured regularly at networks of
2435 snow courses since the 1920s and continually at SNOTELs (automated and telemetered
2436 snow instrumentation sites) since the 1950s. Snow measurements can contribute as much
2437 as 3/4 of the skill achieved by warm-season water supply forecasts in the West. However,
2438 recent studies have shown that measurements made at most SNOTELs are not

2439 representative of overall basin water budgets, so that their value is primarily as indexes of
2440 water availability rather than as true monitors of the overall water budgets (Molotch and
2441 Bales 2005). The discrepancy arises because most SNOTELs are located in clearings, on
2442 flat terrain, and at moderate altitudes, rather than (historically) sampling snow conditions
2443 throughout the complex terrains and micrometeorological conditions found in most river
2444 basins. The discrepancies limit some of the usefulness of SNOTEL measurements as the
2445 field of hydrologic forecasting moves more and more towards physically-based, rather
2446 than empirical-statistical models. To remedy this situation and to provide the sorts of
2447 more diverse and more widespread inputs required by most physically-based models,
2448 combinations of remotely sensed snow conditions (to provide complete areal coverage)
2449 and extensions of at least some SNOTELs to include more types of measurements and
2450 measurements at more nearby locations will likely be required (Bales *et al.*, 2006).

2451

2452 Ground-water level measurements are made at thousands of locations around the country,
2453 but only recently have they been made available for widespread use in near-real time
2454 (<http://ogw01.er.usgs.gov/USGSGWNetworks.asp>). Few operational surface-water
2455 resource forecasts have been designed to use ground-water measurements. Similarly
2456 climate-driven SI ground-water resource forecasts are rarely made, if at all. However,
2457 surface-water and groundwater are interlinked in nearly all cases and, in truth, constitute
2458 a single resource (Winter *et al.*, 1998). Thus, with the growing availability of real-time
2459 groundwater data dissemination, opportunities for improving water resource forecasts by
2460 better integration and use of surface- and ground-water data resources may develop.

2461 Groundwater level networks already are contributing to drought monitors and response
2462 plans in many states.
2463
2464 Similarly, long-term soil-moisture measurements have been relatively uncommon until
2465 recently. Soil moisture is an important control on the partitioning of water between
2466 evapotranspiration, groundwater recharge and runoff, and thus plays an important (but
2467 largely unaddressed) role in the quantities addressed by water resource forecasts. Soil
2468 moisture varies rapidly from place to place (Vinnikov *et al.*, 1996; Western *et al.*, 2004)
2469 so that networks that will provide representative measurements have always been
2470 difficult to design (Wilson *et al.*, 2004). Nonetheless, the Illinois State Water Survey has
2471 monitored soil moisture at about 20 sites in Illinois for many years
2472 (<http://www.sws.uiuc.edu/warm/soilmoist/ISWSSoilMoistureSummary.pdf>), but for most
2473 of that time was alone in monitoring soil moisture at the state scale. As the technologies
2474 for monitoring soil moisture have become less troublesome, more reliable, and less
2475 expensive in recent years, more and more agencies are beginning to install soil-moisture
2476 monitoring stations (*e.g.*, the NRCS is augmenting many of its SNOTELs with soil-
2477 moisture monitors and has established a national Soil Climate Analysis Network (SCAN;
2478 <http://www.wcc.nrcs.usda.gov/scan/SCAN-brochure.pdf>); Oklahoma's Mesonet
2479 micrometeorological network includes soil-moisture measurements at its sites; California
2480 is on the verge of implementing a state-scale network at both high and low altitudes).
2481 With the advent of regular remote sensing of soil-moisture conditions (Wagner *et al.*,
2482 2007), many of these *in situ* networks will be provided context so that their geographic
2483 representativeness can be assessed and calibrated (Famligietti *et al.*, 1999). As with

2484 ground water, soil moisture has not often been an input to water resource forecasts on the
2485 SI time scale, instead, if anything, being simulated rather than measured, where values
2486 were required. Increased monitoring of soil moisture, both remotely and *in situ*, will
2487 provide important checks on the models of soil-moisture reservoirs that underlie nearly
2488 all of our water resources and water resource forecasts, making hydrological model
2489 improvements possible.

2490

2491 Augmentation of real-time stream gauging networks is also a priority, a subject discussed
2492 in SAP 4.3 (CCSP, 2008).

2493

2494 **2.4.2.2 Improvements in hydrologic modeling techniques**

2495 Efforts to improve hydrologic simulation techniques have been pursued in many areas
2496 since the inception of hydrologic modeling in the 1960s and 1970s when the Stanford
2497 Watershed Model (Crawford and Linsley, 1966), the Sacramento Model (Burnash *et al.*,
2498 1973) and others were created. More recently, physically-based, distributed and semi-
2499 distributed hydrologic models have been developed, both at the watershed scale (*e.g.*,
2500 Wigmosta *et al.*, 1994; Boyle *et al.*, 2000) to account for terrain and climate
2501 inhomogeneity, and at the regional scale (Liang *et al.*, 1994 among others). The latter
2502 category, macroscale models, were motivated in part by the need to improve land surface
2503 representation in climate system modeling approaches (Mitchell *et al.*, 2004), but these
2504 models have also been found useful for hydrologic applications related to water
2505 management (*e.g.*, Hamlet and Lettenmaier, 1999; Maurer and Lettenmaier, 2004; Wood
2506 and Lettenmaier, 2006). The NOAA North American Land Data Assimilation Project

2507 (Mitchell *et al.*, 2004 and NASA Land Information System (Kumar *et al.*, 2006) projects
2508 are leading agency-sponsored research efforts that are focused on advancing the
2509 development and operational deployments of the regional, physically based models.
2510 These efforts include research to improve the estimation of observed parameters (*e.g.*, use
2511 of satellite remote sensing for vegetation properties and distribution), the accuracy of
2512 meteorological forcings, model algorithms and computational approaches. Progress in
2513 these areas has the potential to improve the ability of hydrologic models to characterize
2514 land surface conditions for forecast initialization, and to translate future meteorology and
2515 climate into future hydrologic response.

2516

2517 Aside from improving hydrologic models and inputs, strategies for hydrologic model
2518 implementation are also important. Model calibration – *i.e.*, the identification of optimal
2519 parameter sets for simulating particular types of hydrologic output (single or multiple) –
2520 has arguably been the most extensive area of research toward improving hydrologic
2521 modeling techniques (Wagener and Gupta, 2005 is but one article from a broad
2522 literature). This body of work has yielded advances in the understanding of the model
2523 calibration problem from both practical and theoretical perspectives. The work has been
2524 conducted using models at the watershed scale to a greater extent than the regional scale,
2525 and the potential for applying these techniques to the regional scale models not been
2526 much explored.

2527

2528 Data assimilation is also an area of active research (*e.g.*, Andreadis and Lettenmaier
2529 2006; Reichle *et al.*, 2002; Vrugt *et al.*, 2005; Seo *et al.*, 2006). Data assimilation is a

2530 process in which verifying observations of model state or output variables are used to
2531 adjust the model variables as the model is running, thereby correcting simulation errors
2532 on the fly. The primary types of observations that can be assimilated include snow water
2533 equivalent and snow covered area, land surface skin temperature, remotely sensed or *in*
2534 *situ* soil moisture, and streamflow. NWSRFS has the capability to do objective data
2535 assimilation; in practice NWS (and other agencies) perform a qualitative data
2536 assimilation, in which forecaster judgment is used to adjust model states and inputs to
2537 reproduce variables such as streamflow, snow line elevation and snow water equivalent
2538 prior to initializing an ensemble forecast.

2539

2540 **2.4.3 Calibration of Hydrologic Model Forecasts**

2541 Even the best real-world hydrologic models have biases and errors when applied to
2542 specific gages or locations. Statistical models often are tuned well enough so that their
2543 biases are relatively small, but physically-based models often exhibit significant biases.
2544 In either case, further improvements in forecast skill can be obtained, in principle, by
2545 post-processing model forecasts to remove or reduce any remaining systematic errors, as
2546 detected in the performance of the models in hindcasts. Very little research has been
2547 performed on the best methods for such post processing (Schaake *et al.*, 2007), which is
2548 closely related to the calibration corrections regularly made to weather forecasts. Seo *et*
2549 *al.* (2006), however, describe an effort being undertaken by the National Weather Service
2550 for short lead hydrologic forecasts, a practice that is more common than for longer lead
2551 hydrologic forecasts. Other examples include work by Hashino *et al.* (2007) and
2552 Krzysztofowicz (1999). At least one example of an application for SI hydrologic

2553 forecasts is given in Wood & Schaake (2008); but as noted earlier, a major limitation for
2554 such approaches is the limited sample sizes available for developing statistical
2555 corrections.

2556

2557 2.5 Improving Products: Forecast and related information Packaging and delivery

2558 The value of SI forecasts can depend on more than their forecast skill. The context that is
2559 provided for understanding or using forecasts can contribute as much or more to their
2560 value to forecast users. Several avenues for re-packaging and providing context for SI
2561 forecasts are discussed in the following paragraphs.

2562

2563 Probabilistic hydrologic forecasts typically represent summaries of collections of
2564 forecasts, forecasts that differ from each other due to various representations of the
2565 uncertainties at the time of forecast or likely levels of climate variation after the forecast
2566 is made, or both (Schaake *et al.*, 2007). For example, the “ensemble streamflow
2567 prediction” methodology begins its forecasts (generally) from a single best estimate of
2568 the initial conditions from which the forecasted quantity will evolve, driven by copies of
2569 the historical meteorological variations from each year in the past (Franz *et al.*, 2003).

2570 This provides ensembles of as many forecasts as there are past years of appropriate
2571 meteorological records, with the ensemble scatter representing likely ranges of weather
2572 variations during the forecast season. Sometimes deterministic forecasts are extended to
2573 represent ranges of possibilities by directly adding various measures of past hydrologic or
2574 climatic variability. More modern probabilistic methods are based on multiple climate
2575 forecasts, multiple initial conditions or multiple parameterization (including multiple

2576 downscalings) (Clark *et al.*, 2004; Schaake *et al.*, 2007). However accomplished, having
2577 made numerous forecasts that represent ranges of uncertainty or variability, the
2578 probabilistic forecaster summarizes the results in terms of statistics of the forecast
2579 ensemble and presents the probabilistic forecast in terms of selected statistics, like
2580 probabilities of being more or less than normal.

2581

2582 In most applications, it is up to the forecast user to interpret these statistical descriptions
2583 in terms of their particular data needs, which frequently entails (1) application of various
2584 corrections to make them more representative of their local setting and (2), in some
2585 applications, essentially a deconvolution of the reported probabilities into plausible
2586 examples that might arise during the future described by those probabilities. Forecast
2587 users in some cases may be better served by provision of historical analogs that closely
2588 resemble the forecasted conditions, so that they can analyze their own histories of the
2589 results during the analogous (historical) weather conditions. Alternatively, some forecast
2590 users may find that elements from the original ensembles of forecasts would provide
2591 useful examples that could be analyzed or modeled in order to more clearly represent the
2592 probabilistic forecast in concrete terms. The original forecast ensemble members are the
2593 primary source of the probabilistic forecasts and can offer clear and definite examples of
2594 what the forecasted future COULD look like (but not specifically what it WILL look
2595 like). Thus, along with the finished forecasts—which should remain the primary forecast
2596 products, other representations of what the forecasts are and how they would appear in
2597 the real world could be a useful and more accessible complements for some users, and
2598 would be a desirable addition to the current array of forecast products.

2599

2600 Another approach to providing context (and, potentially, examples) for the SI water
2601 resource forecasts involves placing the SI forecasts in context of paleo-climate
2602 reconstructions. The 20th century has, by and large, been climatically benign in much of
2603 the nation, compared to previous centuries (Hughes and Brown, 1992; Cook *et al.*, 1999).
2604 As a consequence, the true likelihood of various forecasted, naturally occurring climate
2605 and water resource anomalies may best be understood in the context of longer records,
2606 which paleoclimatic reconstructions can provide. At present, approaches to incorporating
2607 paleoclimatic information into responses to SI forecasts are uncommon and only
2608 beginning to develop, but eventually they may provide a clearer framework for
2609 understanding and perfecting probabilistic SI water resource forecasts. One approach that
2610 is being investigated is the statistical synthesis of examples (scenarios) that reflect both
2611 the long-term climate variability identified in paleorecords AND time-series-based
2612 deterministic long-lead forecasts (Kwon *et al.*, 2007).

2613

2614 **2.5 THE EVOLUTION OF PROTOTYPES TO PRODUCTS AND THE ROLE OF** 2615 **EVALUATION IN PRODUCT DEVELOPMENT**

2616 Studies of what makes forecasts useful have identified a number of common
2617 characteristics in the process by which forecasts are generated, developed, and taught to
2618 and disseminated among users (Cash and Buizer, 2005). These characteristics include:
2619 ensuring that the problems that forecasters address are themselves driven by forecast
2620 users; making certain that knowledge-to-action networks (the process of interaction
2621 between scientists and users which produces forecasts) are end-to-end inclusive;

2622 employing “boundary organizations” (groups or other entities that bridge the
2623 communication void between experts and users) to perform translation and mediation
2624 functions between the producers and consumers of forecasts; fostering a social learning
2625 environment between producers and users (*i.e.*, emphasizing adaptation); and providing
2626 stable funding and other support to keep networks of users and scientists working
2627 together.

2628

2629 This section begins by providing a review of recent processes used to take a prototype
2630 into an operational product, with specific examples from the NWS. The section then
2631 reviews a few examples of interactions between forecast producers and users that have
2632 lead to new forecast products, and concludes by describing a vision of how user-centric
2633 forecast evaluation could play a role in setting priorities for improving data and forecast
2634 products in the future.

2635

2636 **2.5.1 Transitioning Prototypes to Products**

2637 During testimony for this report, heads of federal operational forecast groups all painted a
2638 relatively consistent picture of how most in-house innovations currently begin and
2639 evolve. Although formal and quantitative innovation planning methodologies exist (see
2640 Appendix A.3: TRANSITIONING NWS RESEARCH INTO OPERATIONS and How
2641 the Weather Service Prioritizes the Development of Improved Hydrologic Forecasts), for
2642 the most part, the operational practice is often relatively ad-hoc and unstructured except
2643 for the larger and longer-term projects. The Seasonal Drought Outlook is an example of a

2644 product that was developed under a less formal process than that used by the NWS (Box
 2645 2.3).

2646

2647 **BOX 2.3: The CPC Seasonal Drought Outlook**

2648

2649 The CPC Drought Outlook (DO) is a categorical prediction of drought evolution for the 3 months forward
 2650 from the forecast date. The product, which is updated once per month, comprises a map that is
 2651 accompanied by a text discussion of the rationale for the categories depicted on the map.

2652

2653 The starting conditions for the DO are given by the current Drought Monitor (DM) (a United States map
 2654 that is updated weekly showing the status of drought nationwide located:
 2655 <http://www.drought.unl.edu/DM/monitor.html>), and the DO shows likely changes in and adjacent to the
 2656 current DM drought areas. The DO is a subjective consensus forecast that is assembled each month by a
 2657 single author (rotating between CPC and NDMC) with feedback from a panel of geographically distributed
 2658 agency and academic experts. The basis for estimating future drought evolution includes a myriad of
 2659 operational climate forecast products: from short and medium range weather forecasts to seasonal
 2660 predictions from the CPC climate outlooks and the NCEP CFS outputs; consideration of climate tendencies
 2661 for current ENSO state; regional hydroclimatology; and medium range to seasonal soil moisture and runoff
 2662 forecasts from a variety of sources.

2663

2664 The DO thus makes use of the most advanced objective climate and hydrologic prediction products
 2665 currently available, including not only operational, but experimental products, although the merging of the
 2666 different inputs is based on expert judgment rather than an objective system. The DO is verified by
 2667 comparing the DM drought assessments at the start and end of the DO forecast period; verification skill
 2668 scores have been tracked for the last 7 years. The DO is the primary drought-related agency forecast
 2669 produced in the United States, and is widely used by the drought management and response community
 2670 from local to regional scales.

2671

2672 The DO was developed in the context of new drought assessment partnerships between the CPC, USDA
 2673 and the National Drought Mitigation Center following the passage of the National Drought Policy Act of
 2674 1998. The DM had been released as an official product in August, 1999, with the expectation that a weekly

2675

2693

2694 was informal and lasted about six months. In November 2000, the first Drought Monitor Forum was held,
 2695 at which producers and users (agency, state, private, academic) came together to evaluate the DM in its first

or seasonal drought forecast capacity would be added in the future. A drought on the eastern seaboard in the fall of 1999 required briefings for the press and the U.S. administration; internal discussions between DM participants at the CPC led to the formation of the first version of the DO (maps and text) for these briefings. These were released informally to local, state and federal agency personnel throughout the winter of 1999-2000, and received positive feedback.

The CPC decided to make the products official, provided public statements and developed product specifications, and made the product operational in March 2000. The initial development process

2696 year and plan for its second, providing in addition a venue for discussion of the DO. This forum still meets
2697 bi-annually, focusing on both DM and DO-relevant issues. Developmental efforts for the DO are internal at
2698 CPC or within NCEP, and the primary avenues for feedback are the website and at presentations by DO
2699 authors at workshops and conferences. The DO authors also interact with research efforts funded by the
2700 NOAA Climate Program Office and other agency funding sources, and with NOAA research group efforts
2701 (such as at NCEP), as part of the ongoing development effort. (URL:
2702 http://www.cpc.noaa.gov/products/expert_assessment/drought_assessment.shtml)
2703

2704 **end BOX 2.3*******
2705

2706 Climate and water resource forecasters are often aware of small “fixes” or tweaks to
2707 forecasts that would make their jobs easier; these are often referred to as “forecasts of
2708 opportunity.” A forecaster may be aware of a new dataset or method or product that
2709 he/she believes could be useful. Based on past experience, production of the forecast may
2710 seem feasible and it could be potentially skillful. Especially in climate forecasting, where
2711 there is very high uncertainty in the forecasts themselves and there is marginal user
2712 adoption of existing products, the operational community often focuses more on potential
2713 forecast skill than likely current use. The belief is that if a product is skillful, a user base
2714 could be cultivated. If there is no skill, even if user demand exists, forecasting would be
2715 futile.

2716

2717 Attractive projects may also develop when a new method comes into use by a colleague
2718 of the forecaster (someone from another agency, alumni, friend or prior collaborator on
2719 other projects). For example, Redmond and Koch (1991) published the first major study
2720 of the impacts of ENSO on western U.S. streamflow. At the time the study was being
2721 done, a NRCS operational forecaster was one of Koch’s graduate students. The student
2722 put Koch's research to operational practice at the NRCS after realizing that forecast skill
2723 could be improved.

2724

2725 Efficiency is also often the inspiration for an innovation. A forecaster may be looking for
2726 a way to streamline or otherwise automate an existing process. For example, users
2727 frequently call the forecaster with a particular question; if it is possible to automate the
2728 answering of that question with a new Internet-based product, the forecaster's time may
2729 be freed up to work on other tasks. While most forecasters can readily list several
2730 bottlenecks in the production process, this knowledge often comes more from personal
2731 experience than any kind of structured system review.

2732

2733 At this stage, many ideas exist for possible innovations, although only some small subset
2734 of them will be pursued. The winnowing process continues with the forecaster and/or
2735 peers evaluating the feasibility of the innovation: Is the method scientifically defensible?
2736 Are the data reliably available to support the product? Are the computers powerful
2737 enough to complete the process in a reasonable time? Can this be done with existing
2738 resources, would it free up more resources than it consumes, or is the added value worth
2739 the added operational expense? In other words, is the total value of the advance worth the
2740 effort? Is it achievable and compatible with legacy systems or better than the total worth
2741 of the technology, installed base and complementary products?

2742

2743 If it is expected to be valuable, some additional questions may be raised by the forecaster
2744 or by management about the appropriateness of the solution. Would it conflict with or
2745 detract from another product, especially the official suite (*i.e.*, destroy competency)?
2746 Would it violate an agency policy? For example, a potential product may be technically
2747 feasible but not allowed to exist because the agency's webpage does not permit

2748 interactivity because of increasingly stringent congressionally-mandated cyber-security
2749 regulations. In this case, to the agency as a whole, the cost of reduced security is greater
2750 than the benefit of increased interactivity. It is important to note that if security and
2751 interactivity in general are not at odds, the issue may be that a particular form of
2752 interactivity is not compatible with the existing security architecture. If a different
2753 security architecture is adopted or a different form of interactivity used (*e.g.*, written in a
2754 different computer language), then both may function together, assuming one has the
2755 flexibility and ability to change.

2756

2757 Additionally, an agency policy issue can sometimes be of broader, multi-organizational
2758 scope and would require policy decisions to settle. For example, currently no agency
2759 produces water quality forecasts. Which agency should be responsible for this? The
2760 USDA, Environmental Protection Agency, USGS or NWS? What of soil moisture
2761 forecasts? Should it be the first agency to develop the technical proficiency to make such
2762 forecasts? Or should it be established by a more deliberative process to prevent “mission
2763 creep”? Agencies are also concerned about whether innovations interfere with the
2764 services provided by the private sector.

2765

2766 If appropriate, the forecaster may then move to implement the solution on a limited test
2767 basis, iteratively developing and adapting to any unforeseen challenges. After a
2768 successful functional prototype is developed, it is tested in-house using field personnel
2769 and/or an inner circle of sophisticated customers and gradually made more public as
2770 confidence in the product increases. In these early stages, many of the “kinks” of the

2771 process are smoothed out, developing the product format and look and feel, adapting to
2772 initial feedback (e.g., “please make the map labels larger”) but for the most part the initial
2773 vision remains intact.

2774

2775 There is no consistent formal procedure across agencies for certifying a new method or
2776 making a new product official. A product may be run and labeled “experimental” for 1-2
2777 years in an evaluation period. The objectives and duration of the evaluation period are
2778 sometimes not formalized and one must just assume that if a product has been running for
2779 an extended period of time with no obvious problems, then it succeeds and the
2780 experimental label removed. Creating documentation of the product and process is often
2781 part of the transition from experimental to official, either in the form of an internal
2782 technical memo, conference proceedings or peer-reviewed journal article, if appropriate.

2783

2784 If the innovation involves using a tool or technique that supplements the standard suite of
2785 tools, some of the evaluation may involve running both tools in parallel and comparing
2786 their performance. Presumably ease of use and low demand on resources are criteria for
2787 success (although the task of running models in parallel can, by itself, be a heavy demand
2788 on resources). Sometimes an agency may temporarily stretch its resources to
2789 accommodate the product for the evaluation period and if additional resources are not
2790 acquired by the end of the evaluation (for one of a number of reasons, some of which
2791 may not be related to the product but rather due to variability in budgets), the product
2792 may be discontinued.

2793

2794 Sometimes skill is used to judge success, but this can be a very inefficient measure. This
2795 is because seasonal forecast skill varies greatly from year to year, primarily due to the
2796 variability of nature. Likewise, individual tools may perform better than other tools in
2797 some years but not others. In the 1-2 years of an evaluation period the new tool may be
2798 lucky (or unlucky) and artificially appear better (or worse) than the existing practice.

2799

2800 If the agency recognizes that a tool has not had a fair evaluation, more emphasis is placed
2801 on “hindcasting,” using the new tool to objectively and retrospectively generate realistic
2802 “forecasts” for the last 20-30 years and comparing the results to hindcasts of the existing
2803 system and/or official published forecasts. The comparison is much more realistic and
2804 effective, although hindcasting has its own challenges. It can be very operationally
2805 demanding to produce the actual forecasts each month (*e.g.*, the agency may have to
2806 compete for the use of several hours of an extremely powerful computer to run a model),
2807 much less do the equivalent of 30 years worth at once. These hindcast datasets, however,
2808 have their own uses and have proven to be very valuable (*e.g.*, Hamill *et al.*, 2006 for
2809 medium range weather forecasting and Franz *et al.*, 2003 for seasonal hydrologic
2810 forecasting). Often times, testbeds are better suited for operationally realistic hindcasting
2811 experiments (Box 2.4).

2812

2813 **BOX 2.4: What Role Can a “Testbed” Play in Innovation?**

2814

2815 For an innovation to be deemed valuable, it must be able to stand on its own and be better than the entire
2816 existing system, or marginally better than the existing technology if it is compatible with the rest of the
2817 framework of the existing system. If the innovation is not proven or believed likely to succeed, its adoption
2818 is less likely to be attempted. However, who conducts the experiments to measure this value? And who has
2819 the resources to ensure backwards-compatibility of the new tools in an old system?

2820

2821 Later sections of this report will describe in more detail what is sometimes referred to as the “loading dock”
2822 model of forecast delivery (*i.e.*, the producer creates something, leaves it on the loading dock where the

2823 user seeks it out, picks it up, drives off and uses it; if this process fails, the loading dock mostly comes to
2824 serve as a metaphorical storage facility). This model lacks any direct communication between user and
2825 producer and leaves out the necessary support structure to help users make the most of the product (Cash *et*
2826 *al.*, 2006). Similarly, testbeds are designed as an alternative to the “loading dock” model of transferring
2827 research to operations.

2828
2829 Previously, a researcher may get a short-term grant to develop a methodology, and conduct an idealized,
2830 focused study of marginal operational realism. The results may be presented at research conferences or
2831 published in the scientific literature. While a researcher's career may have a unifying theme, for the most
2832 part, this specific project may be finished when publication is accomplished and the grant finishes.
2833 Meanwhile, the operational forecaster is expected to seek out the methodology and attempt to implement it,
2834 although often times the forecaster does not have the time, resources or expertise to use the results. Indeed,
2835 the forecaster may not be convinced of the incremental advantage of the technique over existing practices if
2836 it has not endured a realistic operational test and been compared to the results of the official system.

2837
2838 Testbeds are intermediate activities, a hybrid mix of research and operations, serving as a conduit between
2839 the operational, academic and research communities. A testbed activity may have its own resources to
2840 develop a realistic operational environment. However, the testbed would not have real-time operational
2841 responsibilities and instead, would be focused on introducing new ideas and data to the existing system and
2842 analyzing the results through experimentation and demonstration. The old and new system may be run in
2843 parallel and the differences quantified. The operational system may even be deconstructed to identify the
2844 greatest sources of error and use that as the motivation to drive new research to find solutions to operations-
2845 relevant problems. The solutions are designed to be directly integrated into the mock-operational system
2846 and therefore should be much easier to directly transfer to actual production.

2847
2848 NOAA has many testbeds currently in operation: Hydrometeorological (floods), Hazardous Weather
2849 (thunderstorms and tornadoes), Aviation Weather (turbulence and icing for airplanes), Climate (ENSO,
2850 seasonal precipitation and temperature) and Hurricanes. The Joint Center for Satellite Data Assimilation is
2851 also designed to facilitate the operational use of new satellite data. A testbed for seasonal streamflow
2852 forecasting does not exist. Generally, satisfaction with testbeds has been high, rewarding for operational
2853 and research participants alike.

2854
2855 **end BOX 2.4 *******
2856

2857 During the evaluation period, the agency may also attempt to increasingly
2858 “institutionalize” a process by identifying and fixing aspects of a product or process that
2859 do not conform to agency guidelines. For example, if a forecasting model is demonstrated
2860 as promising but the operating system or the computer language it is written in does not
2861 match the language chosen by the agency, a team of contract programmers may rewrite
2862 the model and otherwise develop interfaces that make the product more user-friendly for
2863 operational work. A team of agency personnel may also be assembled to help transfer the
2864 research idea to full operations, from prototype to project. For large projects, many
2865 people may be involved, including external researchers from several other agencies.

2866

2867 During this process of institutionalization, the original innovation may change in
2868 character. There may be uncertainty at the outset and the development team may
2869 consciously postpone certain decisions until more information is available. Similarly,
2870 certain aspects of the original design may not be feasible and an alternative solution must
2871 be found. Occasionally, poor communication between the inventor and the developers
2872 may cause the final product to be different than the original vision. Davidson *et al.* (2002)
2873 found success in developing a hydrologic database using structured, iterative
2874 development involving close communication between users and developers throughout
2875 the life of the project. This model is in direct contrast to that of the inventor generating a
2876 ponderous requirements document at the outset, which is then passed on to a separate
2877 team of developers who execute the plan in isolation until completion.

2878

2879 **2.5.2 Evaluation of Forecast Utility**

2880 As mentioned in Section 2.1, there are many ways to assess the usefulness of forecasts,
2881 one of which is forecast skill. While there are inherent limitations to skill (due to the
2882 chaotic nature of the atmosphere), existing operational systems also fall short of their
2883 potential maximum skill for a variety of reasons. Section 2.4 highlights ways to improve
2884 operational skill, such as by having better models of the natural system or denser and
2885 more detailed climate and hydrologic monitoring networks. Other factors, such as
2886 improved forecaster training or better visualization tools, also play a role. This section
2887 addresses the role of forecast evaluation in driving the technology development agenda.

2888

2889 Understanding the current skill of forecast products is a key component to ensuring the
2890 effectiveness of programs to improve the skill of these products. There are several
2891 motivations for verifying forecasts including administrative, scientific and economic
2892 (Brier and Allen, 1951). Evaluation of very recent forecasts can also play a role in
2893 helping operational forecasters make mid-course adjustments to different components of
2894 the forecast system before issuing an official product.

2895

2896 Of particular interest to forecasting agencies is administrative evaluation because of its
2897 ability to describe the overall skill and efficiency of the forecast service in order to
2898 inform and guide decisions about resource allocation, research directions and
2899 implementation strategies (Welles 2005). For example, the development of numerical
2900 weather prediction (NWP) forecasting models is conducted by numerous, unaffiliated
2901 groups following different approaches, with the results compared through objective
2902 measures of performance. In other words, the forecasts are verified, and the research is
2903 driven, not by ad hoc opinions postulated by subject matter experts, but by the actual
2904 performance of the forecasts as determined with objective measures (Welles *et al.*, 2007).

2905 The most important sources of error are identified quantitatively and systematically and
2906 are paired with objective measures of the likely improvement resulting from an
2907 innovation in the system.

2908

2909 Recently the NWS adopted a broad national-scale administrative initiative of hydrologic
2910 forecast evaluation. This program defines a standard set of evaluation measures,
2911 establishes a formal framework for forecast archival and builds flexible tools for access

2912 to results. It is designed to provide feedback to local forecasters and users on the
2913 performance of the regional results, but also to provide an end-to-end assessment of the
2914 elements of the entire system (HVSRT, 2006). Welles *et al.* add that these activities
2915 would be best served by cultivating a new discipline of “hydrologic forecast science” that
2916 engages the research community to focus on operational-forecast-specific issues.

2917

2918 While administrative evaluation is an important tool for directing agency resources,
2919 ultimately innovation should be guided by the anticipated benefit to forecast users. Some
2920 hydrologists would prefer not to issue a forecast that they suspect the user could not use
2921 or would misinterpret (Pielke Jr, 1999). Additionally, these evaluations should be
2922 available and understandable to users. Uncertainty about the accuracy of forecasts
2923 precludes users from making more effective use of them (Hartmann *et al.*, 2002). Users
2924 want to know how good the forecasts are so they know how much confidence to place in
2925 them. Agencies want to focus on the aspects of the forecast that are most important to
2926 users. Forecast evaluation should be more broadly defined than skill, it should also
2927 include measures of communication and understandability, relevance and so on. In
2928 determining these critical aspects, Agencies must make a determination of the key
2929 priorities to address given the number and varied interest of potential forecast users; the
2930 Agencies can not satisfy all users. The Advanced Hydrologic Prediction System (AHPS)
2931 of the NWS provides a nice case study of product development and refinement in
2932 response to user-driven feedback (Box 2.5).

2933

2934 **BOX 2.5: The Advanced Hydrologic Prediction Service**
2935

2936 Short to medium range forecasts (those with lead times of hours to days) of floods are a critical component
2937 of NWS hydrological operations and these services generate nearly \$2 billion of benefits annually (NHWC,
2938 2002). In 1997 the NWS Office of Hydrologic Development began the Advanced Hydrologic Prediction
2939 Service (AHPS) program to advance technology for hydrologic products and forecasts. This 16-year multi-
2940 million dollar program seeks to enhance the agency's ability to issue and deliver specific, timely, and
2941 accurate flood forecasts. One of its main foci is the delivery of probabilistic and visual information through
2942 an Internet based interface. One of its seven stated goals is also to "Expand outreach and engage partners
2943 and customers in all aspects of hydrologic product development." (NWS, 2004)
2944

2945 Starting in 2004, the National Research Council reviewed the AHPS program and also analyzed the extent
2946 that users were actually playing in the development of products and setting of the research agenda
2947 (National Research Council, 2006). The study found that AHPS had largely a top-down structure with
2948 technology being developed at a national center to be delivered to regional and local offices. Although
2949 there was a wide range of awareness, understanding and acceptance of AHPS products inside and outside
2950 the NWS, little to no research was being done in early 2004 on effective communication of information,
2951 and some of the needs of primary customers were not being addressed. From the time the NRC team
2952 carried out its interviews, the NWS started acting on the perceived deficiencies, so that, by the time the
2953 report was issued in late 2006, the NWS had already made some measurable progress. This progress
2954 included a rigorous survey process in the form of focus groups, but also a more engaged suite of outreach,
2955 training, and educational activities that have included presentations at the national floodplain and
2956 hydrologic manager's conferences, the development of closer partnerships with key users, committing
2957 personnel to education activities, conducting local training workshops, and awarding a research grant to
2958 social scientists to determine the most effective way to communicate probabilistic forecasts to emergency
2959 and floodplain managers.

2960
2961 **end BOX 2.5**
2962

2963 There is another component to forecast skill beyond the assessment of how the forecast
2964 quantities are better (or worse) than a reference forecast. Thinking of forecast assessment
2965 more broadly, the forecasts should be evaluated for their 'skill' communicating their
2966 information content in ways that can be correctly interpreted both easily and reliably --
2967 *i.e.*, no matter what the quantity (*e.g.*, wet, dry, or neutral tercile) in the forecast is, the
2968 user can still correctly interpret it (Hartmann *et al.*, 2002).

2969
2970 Finally, it seems important to stress that agencies should provide for user-centric forecast
2971 assessment as part of the process for moving prototypes to official products. That would
2972 include access to user tools for assessing forecast skill (*i.e.*, the Forecast Evaluation Tool,
2973 which is linked to by the NWS Local 3-month Temperature Outlook (Box 2.6), and field
2974 testing of the communication effectiveness of the prototype products. Just as new types of

2975 forecasts should show (at least) no degradation in predictive skill, they should also show
2976 no degradation in their communication effectiveness.

2977

2978 **BOX 2.6: NWS Local 3-Month Outlooks for Temperature and Precipitation**

2979

2980 In January 2007, the NWS made operational the first component of a new set of climate forecast products
2981 called Local 3-Month Outlooks (L3MO). Accessible from the NWS Weather Forecast Offices (WFO),
2982 River Forecast Centers (RFC) and other NWS offices, the Local 3-Month Temperature Outlook (L3MTO)
2983 is designed to clarify and downscale the national-scale CPC Climate Outlook temperature forecast product.
2984 The corresponding local product for precipitation is still in development as of the writing of this report.
2985 The local outlooks were motivated by ongoing NOAA NWS activities focusing on establishing a dialog
2986 with NWS climate product users (<http://www.nws.noaa.gov/directives/>),. In particular, a 2004 NWS
2987 climate product survey (conducted by Claes Fornell International for the NOAA Climate Services Division)
2988 found that a lack of climate product clarity lowered customer satisfaction with NWS CPC climate outlook
2989 products; and presentations and interactions at the annual Climate Prediction Application Science
2990 Workshop (CPASW) highlighted the need for localized CPC climate outlooks in numerous and diverse
2991 applications.

2992 In response to these user-identified issues, CSD collaborated with the NWS Western Region Headquarters,
2993 CPC and the National Climatic Data Center (NCDC) to develop localized outlook products. The
2994 collaboration between the four groups, which linked several line offices of NOAA (*e.g.*, NCDC, NWS),
2995 took place in the context of an effort that began in 2003 to build a climate services infrastructure within
2996 NOAA. The organizations together embarked on a structured process that began with a prototype
2997 development stage, which included identifying resources, identifying and testing methodologies, and
2998 defining the product delivery method. To downscale the CPC climate outlooks (which are at the climate
2999 division scale) to local stations, the CSD and WR development team assessed and built on internal, prior
3000 experimentation at CPC that focused on a limited number of stations. To increase product clarity, the team
3001 added interpretation, background information, and a variety of forecast displays providing different levels
3002 of data density. A NWS products and services team made product mockups that were reviewed by all 102
3003 WFOs, CPC and CSD representatives and a small number of non-agency reviewers. After product
3004 adjustments based on the reviews, CSD moved toward an experimental production stage by obtaining union
3005 approval, providing NWS staff with training and guidelines, releasing a public statement about the product
3006 and writing product description documentation. Feedback was solicited via the experimental product
3007 website beginning in August 2006, and the products were again adjusted. Finally, the products were
3008 finalized, the product directive was drafted and the product moved to an operational stage with official
3009 release. User feedback continues via links on the official product website
3010 (<http://www.weather.gov/climate/l3mto.php>).

3011

3012 In general, the L3MO development process exhibited a number of strengths. Several avenues existed for
3013 user needs to reach developers, and user-specified needs determined the objectives of the product
3014 development effort. The development team spanning several parts of the agency then drew on internal
3015 expertise and resources to propose and to demonstrate tentative products responding to those needs. The
3016 first review stage of the process gave mostly internal (*i.e.*, agency) reviewers an early opportunity for
3017 feedback, but this was followed by an opportunity for a larger group of users in the experimental stage,
3018 leading to the final product. An avenue for continued review is built into the product dissemination
3019 approach.

3425

3426 **KEY FINDINGS**

3427 Decision-support experiments that test the utility of SI information for use by water
3428 resource decision-makers have resulted in a growing set of successful applications.

3429 However, there is significant opportunity for expansion of applications of climate-related
3430 data and decision support tools, and for developing more regional and local tools that

3431 support management decisions within watersheds. Among the constraints that limit tool
3432 use are:

- 3433 • the range and complexity of water resources decisions. This is compounded by
3434 the numerous organizations responsible for making these decisions, and the
3435 shared responsibility for implementing them.
- 3436 • inflexible policies and organizational rules that inhibit innovation. Government
3437 agencies historically have been reluctant to change practices; in part because of
3438 value differences, risk aversion, fragmentation and sharing of authority. This
3439 conservatism impacts how decisions are made as well as whether to use newer,
3440 scientifically generated information, including SI forecasts and observational data.
- 3441 • different spatial and temporal frames for decisions. Spatial scales for decision-
3442 making range from local, state, and national levels to international. Temporal
3443 scales range from hours to multiple decades impacting policy, operational
3444 planning, operational management, and near real-time operational decisions.
3445 Resource managers often make multi-dimensional decisions spanning various
3446 spatial and temporal frames.
- 3447 • lack of appreciation of the magnitude of potential vulnerability to climate impacts.
3448 Communication of the risks differs among scientific, political, and mass media
3449 elites – each systematically selecting aspects of these issues that are most salient
3450 to their conception of risk, and thus, socially constructing and communicating its
3451 aspects most salient to a particular perspective.
- 3452
- 3453 Decision-support systems are not often well integrated into planning and management
3454 activities, making it difficult to realize the full benefits of these tools. Because use of
3455 many climate products requires special training or access to data that are not easily

3456 available, decision-support products may not equitably reach all audiences. Moreover,
3457 over-specialization and narrow disciplinary perspectives make it difficult for information
3458 providers, decision-makers, and the public to communicate with one another. Three
3459 lessons stem from this:

3460

3461 • Decision-makers need to understand the types of predictions that can be made, and
3462 the tradeoffs between longer-term predictions of information at the local or regional
3463 scale on the one hand, and potential decreases in accuracy on the other.

3464

3465 • Decision-makers and scientists need to work together in formulating research
3466 questions relevant to the spatial and temporal scale of problems the former manage.

3467

3468 • Scientists should aim to generate findings that are accessible and viewed as useful,
3469 accurate and trustworthy by stakeholders.

3470 **3.1 INTRODUCTION**

3471

3472 Over the past century, the U. S. has built a vast and complex infrastructure
3473 to provide clean water for drinking and for industry, dispose of wastes,
3474 facilitate transportation, generate electricity, irrigate crops, and reduce the
3475 risks of floods and droughts. . . . To the average citizen, the nation's dams,
3476 aqueducts, reservoirs, treatment plants, and pipes are . . . taken for granted.
3477 Yet they help insulate us from wet and dry years and moderate other
3478 aspects of our naturally variable climate. Indeed they have permitted us to
3479 almost forget about our complex dependences on climate. We can no
3480 longer ignore these close connections. – From: Peter Gleick and Briane
3481 Adams, *Water: The Potential Consequences of Climate Variability and*
3482 *Change for the Water Resources of the United States* (2000), p. 1.

3483

3484 This chapter synthesizes and distills lessons for the water resources management sector
3485 from efforts to apply decision-support experiments and evaluations using *seasonal to*

3486 *inter-annual forecasts* and observational climate data. Its thesis is that, while there is a
3487 growing, theoretically-grounded body of knowledge on how and why resource decision-
3488 makers use information, there is little research on barriers to use of decision-support
3489 products in the water management sector. Much of what we know about these barriers
3490 comes from case studies on the application of seasonal to inter-annual forecast
3491 information and by efforts to span organizational boundaries dividing scientists and users.
3492 Research is needed on factors that can be generalized beyond these single cases in order
3493 to develop a strong, theoretically-grounded understanding of the processes that facilitate
3494 information dissemination, communication, use, and evaluation – and to predict effective
3495 methods of boundary spanning between decision-makers and information generators.

3496

3497 Decision support is a three-fold process that encompasses: (i) the generation of climate
3498 science products; (ii) the translation of those products into forms useful for decision-
3499 makers; and, (iii) the processes that facilitate the dissemination, communication, and use
3500 of climate science products, information, and tools (NRC, 2007). As shall be seen,
3501 because users include many private and small, as well as public and large users serving
3502 multiple jurisdictions and entities, effective decision support is difficult to achieve.

3503

3504 Section 3.2 describes the range of major decisions water users make, their decision
3505 support needs, and the role decision support systems can play in meeting them. We
3506 examine the attributes of water resource decisions, their spatial and temporal
3507 characteristics, and the implications of complexity, political fragmentation, and shared
3508 responsibility on forecast use. We also discuss impediments to forecast information use

3509 by decision-makers, including mistrust, uncertainty, and lack of agency coordination, and
3510 discuss four cases – whose problem foci range from severe drought to flooding – where
3511 efforts to address these impediments are being undertaken with mixed results.

3512

3513 Section 3.3 examines challenges in fostering closer collaboration between scientists and
3514 decision-makers in order to communicate, translate, and operationalize climate forecasts
3515 and hydrology information into integrated water management decisions. We review what
3516 the social and decision sciences have learned about barriers in interpreting, deciphering,
3517 and explaining climate forecasts and other meteorological and hydrological models and
3518 forecasts to decision-makers, including issues of relevance, accessibility, organizational
3519 constraints on decision-makers, and compatibility with users' values and interests. Case
3520 studies reveal how these issues manifest themselves in decision-support applications.
3521 Chapter 4 – which is a continuation of these themes in the context of how to surmount
3522 these problems – examines how impediments to effectively implementing decision-
3523 support systems can be overcome in order to make them more useful, useable, and
3524 responsive to decision-maker needs.

3525

3526 **3.2 WHAT DECISIONS DO WATER USERS MAKE, WHAT ARE THEIR**
3527 **DECISION-SUPPORT NEEDS, AND WHAT ROLES CAN DECISION-SUPPORT**
3528 **SYSTEMS PLAY IN MEETING THESE NEEDS?**

3529

3530 This section reviews the range and attributes of water resource decisions, including
3531 complexity, political fragmentation, shared decision-making, and varying spatial scale.

3532 We also discuss the needs of water resource managers for climate variability forecast
3533 information, and the multi-temporal and multi-spatial dimensions of these needs. Finally,
3534 we examine how climatic variability affects water supply and quality. Embedded in this
3535 examination is discussion of the risks, hazards, and vulnerability of water resources (and
3536 human activities dependent on them) from climatic variability.

3537

3538 **3.2.1 Range and Attributes of Water Resource Decisions**

3539 As discussed in Chapter 1, and as illustrated in Table 1.1, decisions regarding water
3540 resources in the U.S. are many and varied, and involve public and private sector decision-
3541 makers. Spatial scales for decision-making range from local, state, and national levels to
3542 international political jurisdictions – the latter with some say in the way U.S. water
3543 resources are managed (Hutson *et al.*, 2004; Sarewitz and Pielke, 2006; Gunaji, 1993;
3544 Wagner, 1995. These characteristics dictate that information must be tailored to the
3545 particular roles, responsibilities, and concerns of different decision-makers to be useful.
3546 Chapter 1 also suggests that the way water issues are framed – a process determined
3547 partly by organizational commitments and perceptions, and in part by changing demands
3548 imposed by external events and actors – determines how information must be tailored to
3549 optimally impact various decision-making constituencies – and how it will likely be used
3550 once tailored. Here we focus on the implications of this multiple-actor, multi-
3551 jurisdictional environment for delivery of climate variability information.

3552

3553 **3.2.1.1 Institutional Complexity, Political Fragmentation, and Shared Decision-** 3554 **Making: Impacts on Information Use**

3555 The range and complexity of water resource decisions, the numerous organizations
3556 responsible for making these decisions, and the shared responsibility for implementing
3557 them affect how water resource decision-makers use climate variability information in
3558 five ways: (1) a tendency toward institutional conservatism by water agencies, (2) a
3559 decision-making climate that discourages innovation, (3) a lack of national-scale
3560 coordination of decisions, (4) difficulties in providing support for decisions at varying
3561 spatial and temporal scales due to vast variability in “target audiences” for products, and
3562 (5) growing recognition that rational choice models that attempt to explain information
3563 use as a function of decision-maker needs for “efficiency” are overly simplistic. These
3564 are discussed in turn.

3565

3566 First, institutions that make water resource decisions, particularly government agencies,
3567 operate in domains where they are beholden to powerful constituencies. These
3568 constituencies have historically wanted public works projects for flood control,
3569 hydropower, water supply, navigation, and irrigation. They also have worked hard to
3570 maximize their benefits within current institutional structures, and are often reluctant to
3571 change practices that appear antiquated or inefficient to observers.

3572

3573 The success of these constituencies in leveraging federal resources for river and harbor
3574 improvements, dams, and water delivery systems is in part due to mobilizing regional
3575 development interests. Such interests commonly resist change and place a premium on
3576 engineering predictability and reliability (D. Feldman, 1995; D. Feldman, 2007; Ingram
3577 and Fraser, 2006; Merritt, 1979: 48; Holmes, 1979). This conservatism not only affects

3578 how these agencies and organizations make decisions, it also impacts how they employ,
3579 or do not employ, scientifically generated information, including that related to seasonal
3580 and inter-annual climate variability. Information that conflicts with their mandates,
3581 traditions, or roles may not be warmly received, as surveys of water resource managers
3582 has shown (*e.g.*, O'Connor *et al.*, 1999 and 2005; Yarnal *et al.*, 2006; Dow *et al.*, 2007)
3583

3584 Second, the decision-making culture of U.S. water resources management has
3585 traditionally *not* embraced innovation. It has long been the case that value differences,
3586 risk aversion, fragmentation, and sharing of authority has produced a decision-making
3587 climate in which innovation is discouraged. When innovations have occurred, they have
3588 usually resulted from, or been encouraged through, outside influences on the decision-
3589 making process, including extreme climate events or mandates from higher-level
3590 government entities (Hartig *et al.*, 1992; Landre and Knuth, 1993; Cortner and Moote,
3591 1994; Water in the West, 1998; May *et al.*, 1996).

3592
3593 Third, throughout the history of U.S. water resources management there have been
3594 various efforts to seek greater synchronization of decisions at the national level, in part,
3595 to better respond to environmental protection, economic development, water supply, and
3596 other goals. These efforts hold many lessons for understanding the role of climate change
3597 information and its use by decision-makers, as well how to bring about communication
3598 between decision-makers and climate information producers. While there has been
3599 significant investment of federal resources to provide for water infrastructure
3600 improvements, there has been little national-scale coordination over decisions, or over the

3601 use of information employed in making them (Kundell, DeMeo, and Myszewski, 2001).
3602 The system does not encourage connectivity between the benefits of the federal
3603 investments and those who actually pay for them, which leaves little incentive for
3604 improvements in efficiency and does not reward innovation.

3605

3606 **3.2.1.2 Implications of the federal role in water management**

3607 In partial recognition of the need to coordinate across state boundaries to manage
3608 interstate rivers, in the 1960s groups of Northeastern states formed the Delaware River
3609 Basin Commission (DRBC) and the Susquehanna River Basin Commission (SRBC) to
3610 pave the way for conflict resolution. These early federal interstate commissions
3611 functioned as boundary organizations that mediated communication between supply and
3612 demand functions for water and climate information (Sarewitz and Pielke, 2007). They
3613 relied on frequent, intensive, face-to-face negotiations; coordination among politically-
3614 neutral technical staffs; sharing of study findings among partners; willingness to sacrifice
3615 institutional independence when necessary; and commission authority to implement
3616 decisions so as to transcend short-term pressures to act expediently (Cairo, 1997; Weston,
3617 1995)¹.

3618

3619 An ambitious effort to coordinate federal water policy occurred in 1965 when Congress
3620 established the Water Resources Council (WRC), under the Water Resources Planning

¹ Compact entities were empowered to allocate interstate waters (including groundwater and inter-basin diversions), regulate water quality, and manage interstate bridges and ports. DRBC includes numerous federal partners such as the Interior Department and Corps of Engineers officials (DRBC, 1998; DRBC, 1960; Weston, 1999; Weston, 1995; Cairo, 1997). One of the forces giving rise to DRBC was periodic *drought* that helped exacerbate conflict between New York City and other political entities in the basin. This led to DRBC's empowerment, as the nation's first federal interstate water commission, in all matters relating to the water resources of its basin, ranging from flooding to fisheries to water quality.

3621 Act, to coordinate federal programs. Due to objections to federal intervention in water
3622 rights issues by some states, and the absence of vocal defenders for the WRC, Congress
3623 de-funded WRC in 1981 (Feldman, 1995). Its demise points out the continued frustration
3624 in creating a national framework to coordinate water management, especially for optimal
3625 management in the context of climate variability. Since termination of the WRC,
3626 coordination of federal programs, when it has occurred, has come variously from the
3627 Office of Management and Budget, White House Council on Environmental Quality, and
3628 *ad hoc* bodies (*e.g.*, Task Force on Floodplain Management)².

3629

3630 Fourth, the physical and economic challenge in providing decision support due to the
3631 range of “target audiences” (*e.g.*, Naim, 2003) and the controversial role of the federal
3632 government in such arenas is illustrated by efforts to improve the use of seasonal to inter-
3633 annual climate change information for managing water resources along the U.S.-Mexico
3634 border, as well as the U.S.-Canadian border. International cross-boundary water issues in
3635 North America bring multiple additional layers of complexity, in part because the federal
3636 governments of Canada, Mexico and the U.S. often are ill equipped to respond to local
3637 water and wastewater issues. Bringing the U.S. State Department into discussions over
3638 management of treatment plants, for example, may not be an effective way to resolve
3639 technical water treatment or supply problems.

3640

²Today the need for policy coordination, according to one source, “stems from the . . . environmental and social crises affecting the nation’s rivers” (Water In the West, 1998: xxvii). In nearly every basin in the West, federal agencies are responding to tribal water rights, growing urban demands, endangered species listings, and Clean Water Act lawsuits. Climate change is expected to exacerbate these problems.

3641 In the last decade, climate-related issues that have arisen between Mexico and the U.S.
3642 regarding water revolve around disagreements among decision-makers on how to define
3643 extraordinary drought and how to allocate shortages – and over how to cooperatively
3644 prepare for climate extremes. These issues have led to renewed efforts to better consider
3645 the need for predictive information and ways to use it to equitably distribute water under
3646 drought conditions. Continuous monitoring of meteorological data, consumptive water
3647 uses, calculation of drought severity, and detection of longer-term climate trends could,
3648 under the conditions of these agreements, prompt improved management of the cross
3649 boundary systems (Gunaji, 1995; Mumme, 2003; Mumme, 1995; Higgins, Chen and
3650 Douglas, 1999). The 1906 Rio Grande Convention and 1944 Treaty between the U.S. and
3651 Mexico – the latter established the *International Boundary Water Commission* – contain
3652 specific clauses related to “extraordinary droughts.” These clauses prescribe that the U.S.
3653 government appraise Mexico of the onset of drought conditions as they develop, and
3654 adjust water deliveries to both U.S. and Mexican customers accordingly (Gunaji, 1995).
3655 However, there is some reluctance to engage in conversations that could result in
3656 permanent reduced water allocations or reallocations of existing water rights.

3657

3658 For the U.S. and Canada, a legal regime similar to that between the U.S. and Mexico has
3659 existed since the early 1900s. The anchor of this regime is the 1909 Boundary Waters
3660 Treaty that established an *International Joint Commission* with jurisdiction over threats
3661 to water quality, anticipated diversions, and protection of instream flow and water supply
3662 inflow to the Great Lakes – the latter being a region in which climate change-related
3663 concerns have grown in recent years due, especially, to questions arising over calls to

3664 treat its water resources as a marketable commodity, as well as concerns over what
3665 criteria to use to resolve disputes over these and other questions (Wagner, 1995;
3666 International Joint Commission, 2000).

3667

3668 **3.2.1.3 Institutions and decision-making**

3669 Fifth, there is growing recognition of the limits of so-called *rational choice models* of
3670 information use, which assume that decision-makers deliberately focus on optimizing
3671 organizational performance when they use climate variability or other water resource
3672 information. This recognition is shaping our understanding of the impacts of institutional
3673 complexity on use of climate information. An implicit assumption in much of the
3674 research on probabilistic forecasting of seasonal and inter-annual variation in climate is
3675 that decision makers on all levels will value and use improved climate predictions,
3676 monitoring data, and forecast tools that can predict changes to conditions affecting water
3677 resources (*e.g.*, Nelson and Winter, 1960). *Rational choice* models of decision-making
3678 are predicated on the assumption that decision makers seek to make optimal decisions
3679 (and perceive that they have the flexibility and resources to implement them).

3680

3681 A widely-cited study of four water management agencies in three locations – the
3682 Columbia River system in the Pacific Northwest, Metropolitan Water District of Southern
3683 California, and Potomac River Basin and Chesapeake Bay in the greater Washington,
3684 D.C. area - examined the various ways water agencies at different spatial scales use
3685 probabilistic climate forecast information. The study found that not only the multiple
3686 geographic scales at which these agencies operate – but the complexity of their decision-

3687 making systems – dramatically influences how, and to what extent, they use probabilistic
3688 climate forecast information. An important lesson is that the complexity of these systems’
3689 sources of supply and infrastructure, and the stakeholders they serve are important
3690 influences on their capacity to use climate information. Decision-systems may rely on
3691 multiple sources of data, support the operation of various infrastructure components,
3692 straddle political (and hydrological) boundaries, and serve stakeholders with vastly
3693 different management objectives (Rayner, Lach, and Ingram, 2005). Thus, science is only
3694 one of an array of potential elements influencing decisions.

3695

3696 The cumulative result of these factors is that water system managers and operations
3697 personnel charged with making day-to-day decisions tend toward an overall institutional
3698 conservatism when it comes to using complex meteorological information for short-to
3699 medium term decisions. Resistance to using new sources of information is affected by the
3700 complexity of the institutional setting within which managers work, dependency on craft
3701 skills and local knowledge, and a hierarchy of values and processes designed to ensure
3702 their political invisibility. Their goal is to smooth out fluctuations in operations and keep
3703 operational issues out of the public view (Rayner, Lach, and Ingram, 2005).

3704 In sum, the use of climate change information by decision makers is constrained by a
3705 politically fragmented environment, a regional economic development tradition that has
3706 inhibited – at least until recently – the use of innovative information (*e.g.*, conservation,
3707 integrated resource planning), and multiple spatial and temporal frames for decisions. All
3708 this makes the target audience for climate information products vast and complex.

3709

3710 The interplay of these factors, particularly the specific needs of target audiences and the
3711 inherently conservative nature of water management, is shown in the case of how
3712 Georgia has come to use drought information to improve long-term water supply
3713 planning. As shall be seen later (section 3.3.1), while the good news in this case is that
3714 information is beginning to be used by policymakers, the downside is that *some*
3715 information use is being inhibited by institutional impediments – namely, inter-state
3716 political conflicts over water.

3717

3718 Box 3.1: Georgia Drought

3719

3720 Background

3721 Two apparent physical causes of the 2007-08 Southeast drought include a lack of tropical storms and
3722 hurricanes, which usually can be counted on to replenish declining reservoirs and soil moisture, and the
3723 development of a La Niña episode in the tropical Pacific, which continues to steer storms to the north of the
3724 region (see Figure 3.1). Drought risk is frequently modeled as a function of hazard (*e.g.*, lack of
3725 precipitation) and vulnerability (*i.e.*, susceptibility of society to the hazard) using a multiplicative formula,
3726 $\text{risk} = \text{hazard} * \text{vulnerability}$ (Hayes *et al.*, 2004). In 2007, Atlanta, Georgia received only 62% of its
3727 average annual precipitation, the second driest calendar year on record; moreover, streamflows were among
3728 the lowest recorded levels on several streams. By June 2007, the National Climatic Data Center reported
3729 that December-May precipitation totals for the Southeast were at new lows. Spring wildfires spread
3730 throughout southeastern Georgia which also recorded its worst pasture conditions in 12 years. Georgia's
3731 Governor Purdue extended a state of emergency through June 30; however, the state's worst drought
3732 classification, accompanied by a ban on outdoor water use, was not declared until late September.

3733

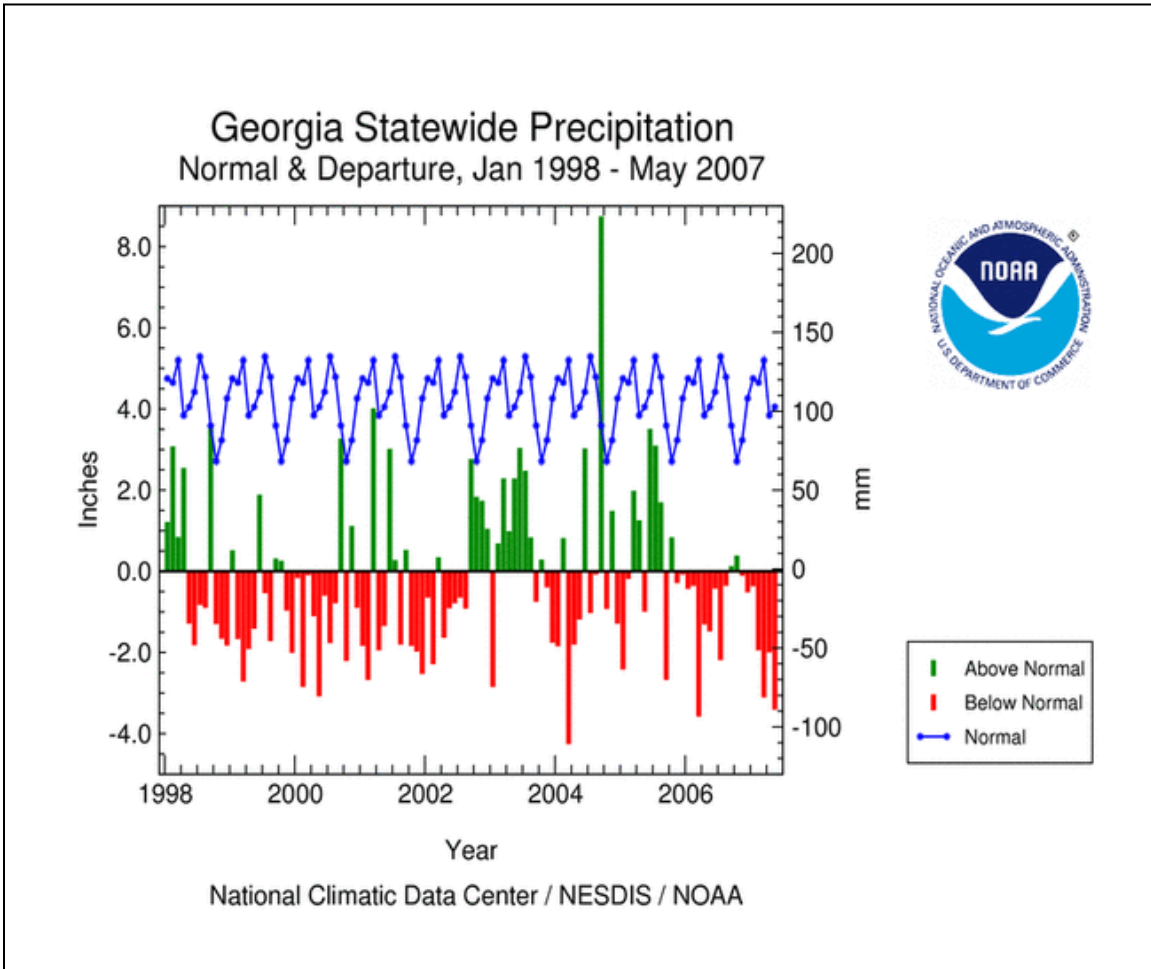

3734 While progressive state drought plans, such as Georgia's (which was adopted in March, 2003), emphasize
3735 drought preparedness and mitigation of impacts through mandatory restrictions in some water use sectors,
3736 they do not commonly factor in the effect of population growth on water supplies. Moreover, conservation
3737 measures in a single state cannot address water allocation factors affecting large, multi-state watersheds,
3738 such as the Apalachicola- Chattahoochee-Flint (ACF), which encompasses parts of Georgia, Alabama, and
3739 Florida.

3740

3741 Institutional barriers and problems

3742 The source of water woes in this Southeastern watershed dates back to a 1987 decision by the Army Corps
3743 of Engineers to reallocate 20% of power generation flow on the Chattahoochee River to municipal supply
3744 for Atlanta, which sits near the headwaters of the river. Alabama and Florida soon demanded an assessment
3745 of the environmental and economic effects of that decision, which set off a series of on-again, off-again
3746 disputes and negotiations between the three states, known as the "Tri- State Water Wars," that have not
3747 been resolved (as of January, 2008). At the heart of the disputes is a classic upstream-downstream water
3748 use and water rights dispute, pitting municipal water use for the rapidly expanding Atlanta metropolitan
3749 region against navigation, agriculture, fishing, and environmental uses downstream in Alabama and
3750 Georgia. The situation is further complicated by water quality concerns, as downstream users suffer
3751 degraded water quality, due to polluted urban runoff and agricultural waste, pesticide, and fertilizer
3752 leaching. Despite the efforts of the three states and Congress to create water compacts, by engaging in joint
3753 water planning and developing and sharing common data bases, the compacts have never been

3754 implemented as a result of disagreements over what constitutes equitable water allocation formulae
 3755 (Feldman, 2007).
 3756
 3757 Political and sectoral disputes continue to exacerbate lack of coordination on water-use priorities, and there
 3758 is a continuing need to include climate forecast information into these activities, as underscored by
 3759 continuing drought in the Southeast. The result is that water management decision-making is constrained,
 3760 and there are few opportunities to insert effective decision support tools, aside from the kinds of multi-
 3761 stakeholder shared-vision modeling processes developed by the Army Corps of Engineers Institute for
 3762 Water Resources.

3763 **Figure Box 3.1 Georgia statewide precipitation: 1998-2007**
 3764
 3765 (end box)

3768 ***Spatial scale of decisions***

3769 In addition to the challenges created by institutional complexity, the spatial scale of
 3770 decisions made by water management organizations ranges from small community water
 3771 systems to large, multi-purpose metropolitan water service and regional water delivery

3772 systems (Rayner, Lach, and Ingram, 2005). Differences in spatial scale of management
3773 also affect information needed – an issue discussed in chapter 4 when we analyze
3774 Regional Integrated Science Assessment (RISA) experiences. These problems of diverse
3775 spatial scale are further compounded by the fact that most water agencies do not conform
3776 to hydrological units. While some entities manage water resources in ways that conform
3777 to hydrological constraints (*i.e.*, watershed, river basin, aquifer or other drainage basin –
3778 Kenney and Lord, 1994; Cairo, 1997), basin-scale management is not the most common
3779 U.S. management approach. Because most hydrologic tools focus on watershed
3780 boundaries, there is a disconnect between the available data and the decision context.
3781
3782 Decision-makers often *share* authority for decisions across local, state, and national
3783 jurisdictions. In fact, the label “decision maker” embraces a vast assortment of elected
3784 and appointed local, state, and national agency officials, as well as public and private
3785 sector managers with policy-making responsibilities in various water management areas
3786 (Sarewitz and Pielke, 2007). Because most officials have different management
3787 objectives while sharing authority for decisions, it is likely that their specific seasonal to
3788 inter-annual climate variability information needs will vary not only according to spatial
3789 scale, but also according to institutional responsibilities and agency or organization goals.
3790 Identifying who the decision makers are is equally challenging. The Colorado River basin
3791 illustrates the typical array of decision-makers on major U.S. streams. A recent study in
3792 Arizona identified an array of potential decision makers affected by water shortages
3793 during drought, including conservation groups, irrigation districts, power providers,
3794 municipal water contractors, state water agencies, several federal agencies, two regional

3795 water project operators (the Central Arizona and Salt River projects), tribal
3796 representatives, land use jurisdictions, and individual communities (Garrick, Jacobs,
3797 Garfin, 2006). This layering of agencies with water management authority is also found
3798 at the national level.

3799

3800 There is no universally agreed-upon classification system for defining *water users*.
3801 Taking as one point of departure the notion that water users occupy various “sectors”
3802 (*i.e.*, activity areas distinguished by particular water uses), the U.S. Geological Survey
3803 monitors and assesses water use for eight user categories: public supply, domestic use,
3804 irrigation, livestock, aquaculture, industrial, mining, and thermo-electric power. These
3805 user categories share freshwater supplies withdrawn from streams and/or aquifers and,
3806 occasionally, from saline water sources as well (Hutson *et al.*, 2004). However, the
3807 definitions of these classes of users vary from state to state.

3808

3809 One limitation in this user-driven classification scheme in regards to identifying
3810 information needs for seasonal to inter-annual climate forecasts is that it inadvertently
3811 excludes in-stream water users – those who do not remove water from streams or
3812 aquifers. Instream uses are extremely important, as they affect aquatic ecosystem health,
3813 recreation, navigation, and public health (Gillilan and Brown, 1997; Trush and McBain,
3814 2000; Rosenberg *et al.*, 2000; Annear *et al.*, 2002). Moreover, instream uses and wetland
3815 habitats have been found to be among the most vulnerable to impacts of climate
3816 variability and change (USGCRP, 2001)³.

³In general, federal law protects instream uses only when an endangered species is affected. Protection at the state level varies, but extinction of aquatic species suggests the relatively low priority given to

3817

3818 Finally, decision-makers' information needs are also influenced by the time frame for
3819 decisions – and to a greater degree than scientists. For example, while NOAA researchers
3820 commonly distinguish between weather prediction information, produced on an hours-to-
3821 weeks time frame, and climate predictions, which may be on a seasonal to inter-annual
3822 time frame, many managers make decisions based on annual operating requirements or
3823 on shorter time frames that may not match the products currently produced.

3824

3825 Two important points stem from this. First, as longer-term predictions gain skill, use of
3826 longer-term climate information is likely to expand, particularly in areas with economic
3827 applications. Second, short-term decisions may have long-term consequences. Thus,
3828 identifying the information needed to make better decisions in all time frames is
3829 important – especially since it can be difficult to get political support for research that
3830 focuses on long-term, incremental increases in knowledge that are the key to significant
3831 policy changes (Kirby, 2000). This poses a challenge for decision-makers concerned
3832 about adaptation to global change.

3833

3834 Multi-decadal climate-hydrology forecasts and demand forecasts (including population
3835 and economic sector forecasts and forecasts of water and energy demand) are key inputs
3836 for policy decisions. Changes in climate that affect these hydrology and water demand
3837 forecasts are particularly important for policy decisions, as they may alter the anticipated

protecting flow and habitat. Organizations with interests in the management of instream flows are diverse, ranging from federal land management agencies to state natural resource agencies and private conservation groups, and their climate information needs widely vary (Pringle, 2000; Restoring the Waters, 2000).

3838 streams of benefits and impacts of a proposal. Information provided to the policy
3839 planning process is best provided in the form of tradeoffs assessing the relative
3840 implications, hazards, risks, and vulnerabilities associated with each policy option⁴.

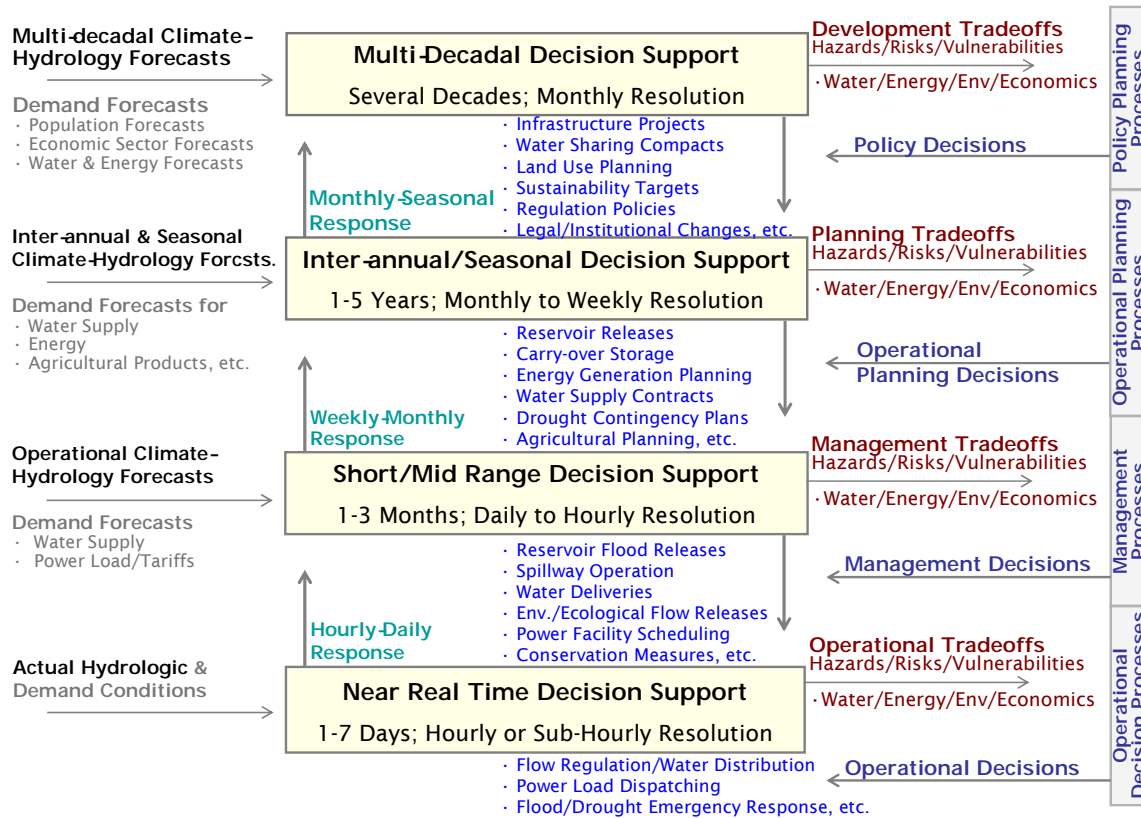

3841

3842 **3.2.2 Decision-support Needs of Water Managers for Climate Information**

3843 As we have noted, the decision-support needs of water resource decision-makers for
3844 information on climate variability depend upon the temporal and spatial scale of the
3845 decisions that they make. The complexity of the decision process is graphically illustrated
3846 in Figure 3.2 (Georgakakos, 2006a; HRC-GWRI, 2006). This figure includes *four*
3847 temporal scales ranging from multiple decades to hours. The *first* decision level includes
3848 *policy decisions* pertaining to multi-decadal time scales and involving infrastructure
3849 changes (*e.g.*, storage projects, levee systems, energy generation facilities, waste water
3850 treatment facilities, inter-basin transfer works, sewer/drainage systems, well fields, and
3851 monitoring networks), as well as water sharing compacts, land use planning,
3852 environmental sustainability requirements and targets, regulations, and other legal and
3853 institutional requirements. Policy decisions may also encompass many political entities.
3854 Decisions pertaining to trans-boundary water resources are particularly challenging, as
3855 noted in section 3.2.1.1, because they aim to reconcile benefits and impacts measured and
3856 interpreted by different standards, generated and accrued by stakeholders of different

⁴ Ideally, the purpose of the participatory planning processes is to formulate policies benefiting stakeholders. The process is highly interactive and iterative with stakeholder groups formulating policy options for assessment by the decision support systems and experts, in turn, interpreting the assessment results for the stakeholders who evaluate and refine them. It is acknowledged, however, that water resource decisions are often contentious, and stakeholder decision processes may fail to reach consensus.

3857 nations, and regulated under different legal and institutional regimes (Naim, 2003;
 3858 Mumme, 2003; Mumme, 1995; Higgins, Chen and Douglas, 1999).
 3859

3860

3861 **Figure 3.2** Water Resources Decisions: Range and Attributes

3862

3863 The second decision level involves *operational planning decisions pertaining to inter-*
 3864 *annual and seasonal time scales.* These and other lower level decisions are made within
 3865 the context set by the policy decisions and pertain to inter-annual and seasonal reservoir
 3866 releases, carry-over storage, hydro-thermal energy generation plans, agreements on
 3867 tentative or final water supply and energy contracts, implementation of drought
 3868 contingency plans, and agricultural planning decisions, among others. The relevant
 3869 spatial scales for operational planning decisions may be as large as those of the policy

3870 decisions, but are usually associated with individual river basins as opposed to political
3871 jurisdictions. Inter-annual and seasonal hydro-climatic and demand forecasts (for water
3872 supply, energy, and agricultural products) are critical inputs for this decision level.

3873

3874 The third decision level pertains to *operational management decisions associated with*
3875 *short and mid range time scales of 1-3 months*. Typical decisions include reservoir
3876 releases during flood season, spillway operations, water deliveries to urban, industrial, or
3877 agricultural areas, releases to meet environmental and ecological flow requirements,
3878 power facility operation, and drought conservation measures. The benefits and impacts of
3879 these decisions are associated with daily and hourly system response (high resolution).

3880 This decision level requires operational hydro-climatic forecasts and forecasts of water
3881 and power demand and pricing. The decision process is similar to those of the upper
3882 decision layers, although, as a practical matter, general stakeholder participation is
3883 usually limited, with decisions taken by the responsible operational authorities. This is an
3884 issue relevant to several cases discussed in chapter 4.

3885

3886 The final decision level pertains to *near real time operations* associated with hydrologic
3887 and demand conditions. Typical decisions include regulation of flow control structures,
3888 water distribution to cities, industries, and farms, operation of power generation units,
3889 and implementation of flood and drought emergency response measures. Data from real
3890 time monitoring systems are important inputs for daily to weekly operational decisions.
3891 Because such decisions are made frequently, stakeholder participation may be

3892 impractical, and decisions may be limited to government agencies or public sector
3893 utilities according to established operational principles and guidelines.

3894 While the above illustration addresses water resources complexity (*i.e.*, multiple temporal
3895 and spatial scales, multiple water uses, multiple decision makers), it cannot be
3896 functionally effective (*i.e.*, create the highest possible value) unless it exhibits
3897 consistency and adaptiveness. *Consistency* across the decision levels can be achieved by
3898 ensuring that (1) lower level forecasts, decision support systems, and stakeholder
3899 processes operate within the limits established by upper levels (as represented by the
3900 downward pointing feedback links in Figure 1, and (2) upper decision levels capture the
3901 benefits and impacts associated with the high resolution system response (as represented
3902 by the upward pointing feedback links in Figure 3.2). *Adaptiveness*, as a number of
3903 studies indicate, requires that decisions are continually re-visited as system conditions
3904 change and new information becomes available, or as institutional frameworks for
3905 decision-making are amended (Holling, 1978; Walters, 1986; Lee, 1993).

3906 **3.2.3 How Does Climate Variability Affect Water Management?**

3907 Water availability is essential for human health, economic activity, ecosystem function,
3908 and geophysical processes. Climate variability can have dramatic seasonal and inter-
3909 annual effects on precipitation, drought, snow-pack, runoff, seasonal vegetation, water
3910 quality, groundwater, and other variables. Much recent research on climate variability
3911 impacts on water resources is linked to studies of long-term climate change, necessitating
3912 some discussion of the latter. In fact there is a relative paucity of information on the
3913 potential influence of climate change on the underlying patterns of climate variability

3914 (*e.g.*, CCSP, 2007). At the close of this section, we explore one case – that of drought in
3915 the Colorado River basin – exemplifying several dimensions of this problem, including
3916 adaptive capacity, risk perception, and communication of hazard.

3917

3918

3919 According to the Intergovernmental Panel on Climate Change, while total annual
3920 precipitation is increasing in the northern latitudes, and average precipitation over the
3921 continental U.S. has increased, the southwestern U.S. (and other semi-tropical areas
3922 worldwide) appear to be tending towards reduced precipitation, which in the context of
3923 higher temperatures, results in lower soil moisture and a substantial effect on runoff in
3924 rivers (IPCC, 2007b). The observed trends are expected to worsen due to continued
3925 warming over the next century. Observed impacts on water resources from changes that
3926 are thought to have already occurred include increased surface temperatures and
3927 evaporation rates, increased global precipitation, an increased proportion of precipitation
3928 received as rain rather than snow, reduced snowpack, earlier and shorter runoff seasons,
3929 increased water temperatures and decreased water quality (IPCC, 2007a, b).

3930

3931 Additional effects on water resources result from sea level rise of approximately 10-20
3932 cm since the 1890s (IPCC, 2007a)⁵, an unprecedented rate of mountain glacier melting,
3933 seasonal vegetation emerging earlier in the spring and a longer period of photosynthesis,
3934 and decreasing snow and ice cover with earlier melting. Climate change is also likely to
3935 produce increases in intensity of extreme precipitation events (*e.g.*, floods, droughts, heat
3936 waves, violent storms) that could “exhaust the social buffers that underpin” various

⁵ According to the IPCC 2007 Fourth Assessment Report, sea level has risen an average of 1.8 mm per year over the period 1961-2003 (IPCC, 2007: 5).

3937 economic systems such as farming; foster dynamic and interdependent consequences
3938 upon other resource systems (*e.g.*, fisheries, forests); and generate “synergistic” outcomes
3939 due to simultaneous multiple human impacts on environmental systems (*i.e.*, an
3940 agricultural region may be simultaneously stressed by degraded soil and changes in
3941 precipitation caused by climate change) (Homer-Dixon, 1999).

3942

3943 Studies have concluded that changes to runoff and stream flow would have considerable
3944 regional-scale consequences for economies as well as ecosystems, while effects on the
3945 latter are likely to be more severe (Milly *et al.*, 2005). If elevated aridity in the western
3946 U.S is a natural response to climate warming, then any trend toward warmer temperatures
3947 in the future could lead to serious long-term increase in droughts - highlighting both the
3948 extreme vulnerability of the semi-arid west to anticipated precipitation deficits caused by
3949 global warming, and the need to better understand long term drought variability and its
3950 causes (Cook *et al.*, 2004).

3951

3952 The impacts of climate variability are largely regional, making the spatial and temporal
3953 scale of information needs of decision-makers likewise regional. This is why we focus
3954 (section 3.2.3.1) on specific regional hazards, risks, and vulnerabilities of climate
3955 variability on water resources). TOGA and RISA studies focus on the regional scale
3956 consequences of changes to runoff and stream flow on economies as well as ecosystems
3957 (Milly *et al.*, 2005).

3958

3959 **3.2.3.1 Hazards, risks, and vulnerabilities of climate variability**

3960 A major purpose of decision-support tools is to reduce the risks, hazards, and
3961 vulnerabilities to water resources from seasonal to inter-annual climate variation, as well
3962 as to related resource systems, by generating climate science products and *translating*
3963 these products into forms useful to water resource managers (NRC, 2008). In general,
3964 what water managers need help in translating is *how* changes resulting from weather and
3965 seasonal to inter-annual climate variation can affect the functioning of the systems they
3966 manage. Numerous activities are subject to risk, hazard, and vulnerability, including fires,
3967 navigation, flooding, preservation of threatened or endangered species, and urban
3968 supplies. At the end of this section, we focus on three less visible but nonetheless
3969 important challenges: water quality, groundwater depletion, and energy production.
3970 Despite their importance, hazard, risk, and vulnerability can be confusing concepts. A
3971 *hazard* is an event that is potentially damaging to people or to things they value. Floods
3972 and droughts are two common examples of hazards that affect water resources. *Risk*
3973 indicates the probability of a particular hazardous event occurring. Hence, while the
3974 hazard of drought is a concern to all water managers, drought risk varies considerably
3975 with physical geography, management context, infrastructure type and condition, and
3976 many other factors so that some water resource systems are more at-risk than others
3977 (Stoltman *et al.*, 2004; Stern and Fineberg, 1996; Wilhite, 2004).
3978
3979 A related concept—vulnerability—is more complex and can cause further confusion⁶.
3980 Although experts dispute precisely what the term means, most agree that vulnerability
3981 considers the likelihood of harm to people or things they value and it entails a physical as

⁶ Much of this discussion on vulnerability is modified from Yarnal (in press). See also Polsky *et al.*, and Dow *et al.*, (in press) for definitions of vulnerability, especially in relation to water resource management.

3982 well as social dimension (*e.g.*, Cutter 1996; Schröter *et al.*, 2005; Handmer, 2004).
3983 Physical vulnerability has to do with exposure to harmful events, while social
3984 vulnerability entails the factors affecting a system's sensitivity and capacity to respond to
3985 exposure. Moreover, experts accept some descriptions of vulnerability more readily than
3986 others. One commonly accepted description considers vulnerability to be a function of
3987 exposure, sensitivity, and adaptive capacity (Schneider and Sarukhan, 2001). Exposure is
3988 the degree to which people and the places or things they value, such as their water supply,
3989 are likely to be impacted by a hazardous event, such as a flood. The "things they value"
3990 include not only economic value and wealth but also cultural, spiritual, and personal
3991 values. This concept also refers to physical infrastructure (*e.g.*, water pipelines and dams)
3992 and social infrastructure (*e.g.*, water management associations and the Army Corps of
3993 Engineers). Valued components include intrinsic values like water quality and other
3994 outcomes of water supply availability such as economic vitality.

3995

3996 *Sensitivity* is the degree to which people and the things they value can be harmed by
3997 exposure. Some water resource systems, for example, are more sensitive than others
3998 when exposed to the same hazardous event. All other factors being equal, a water system
3999 with old infrastructure will be more sensitive to a flood or drought than one with new
4000 state-of-the-art infrastructure; in a century, the newer infrastructure will be considerably
4001 more sensitive to a hazardous event than it is today because of aging.

4002

4003 *Adaptive capacity* is the least explored and most controversial aspect of vulnerability.
4004 The understanding of adaptive capacity favored by the climate change research

4005 community is the degree to which people can mitigate the potential for harm—that is,
4006 reduce vulnerability—by taking action to reduce exposure or sensitivity, both before and
4007 after the hazardous event. The physical, social, economic, spiritual, and other resources
4008 they possess, including such resources as educational level and access to technology,
4009 determine the capacity to adapt. For instance, all things being equal, a community water
4010 system that has trained managers and operators with and up-to-date computer technology
4011 will be less vulnerable than a neighboring system with untrained volunteer operators and
4012 limited access to computer technology⁷.

4013

4014 Some people or things they value can be highly vulnerable to low-impact events because
4015 of high sensitivity or low adaptive capacity. Others may be less vulnerable to high-impact
4016 events because of low sensitivity or high adaptive capacity. A hazardous event can result
4017 in a patchwork pattern of harm due to variation in vulnerability over short distances
4018 (Rygel *et al.*, 2006). Such variation means that preparing for or recovering from flood or
4019 drought may require different preparation and recovery efforts from system to system.

4020

4021 **3.2.3.2 Perceptions of risk and vulnerability – Issue frames and risk communication**

4022 Much of the research on vulnerability of water resources to climate variability has
4023 focused on *physical vulnerability*, *i.e.*, the exposure of water resources and water resource
4024 systems to harmful events. Cutter *et al.*, (2002) and many others have noted, however,

⁷ A slightly different view of adaptive capacity favored by the hazards and disaster research community is that it consists of two subcomponents: coping capacity and resilience. The former is the ability of people and systems to endure the harm; the latter is the ability to bounce back after exposure to harmful events. In both cases, water resource systems can take measures to increase their ability to cope and recover, again depending on the physical, social, economic, spiritual, and other resources they possess or have access to.

4025 that *social vulnerability*—the social factors that affect a system’s sensitivity to exposure,
4026 and that influence its capacity to respond and adapt in order to lessen its exposure or
4027 sensitivity—can often be more important than physical vulnerability. Understanding the
4028 social dimensions of vulnerability and related risks is therefore crucial to determining
4029 how climate variation and change will affect water resources.

4030

4031 The perception of risk is perhaps the most-studied of the social factors relating to climate
4032 information and the management of water resources. At least three barriers stemming
4033 from their risk perceptions prevent managers from incorporating weather and climate
4034 information in their planning; each barrier has important implications for communicating
4035 climate information to resource managers and other stakeholders (Yarnal *et al.*, 2005). A
4036 fourth barrier relates to the underlying public perceptions of the severity of climate
4037 variability and change – and thus, implicit public support for policies and other actions
4038 that might impel managers to incorporate climate variability into decisions.

4039

4040 The first conceptual problem is that managers who find climate forecasts and projections
4041 to be reliable appear in some cases no more likely to use them than managers who find
4042 them to be unreliable (O’Connor *et al.*, 1999 and 2005)⁸. Managers most likely to use
4043 weather and climate information may have experienced weather and climate problems in
4044 the recent past – their heightened feelings of vulnerability are the result of negative

⁸ Based on findings from two surveys of community water system managers (N>400 in both studies) in Pennsylvania’s Susquehanna River Basin. The second survey compared Pennsylvania community water system managers to their counterparts in South Carolina (N>250) and found that managers who find climate forecasts and projections to be reliable are no more likely to use them than are those who find them to be unreliable. Thus, unless managers feel vulnerable (vulnerability being a function of whether they have had adverse experience with weather or climate), they are statistically less likely to use climate forecasts.

4045 experiences with weather or climate. The implication of this finding is that simply
4046 delivering weather and climate information to potential users may be insufficient in those
4047 cases in which the manager does not perceive climate to be a hazard – at least in humid,
4048 water rich regions of the U.S. that we have studied⁹. Purveyors of weather and climate
4049 information may need to convince potential users that, despite the absence of recent
4050 adverse events, their water resources have suffered historically from—and therefore are
4051 vulnerable to—weather and climate.

4052

4053 The second barrier is that managers' perceptions about the usefulness of climate
4054 information varies not only with their exposure to adverse events, but also with the
4055 financial, regulatory, and management contexts of their decisions (Yarnal *et al.*, 2006;
4056 Dow *et al.*, 2007). The implication of this finding is that assessments of weather and
4057 climate vulnerability and of climate information needs must consider the institutional
4058 contexts of the resource systems and their managers. Achieving a better understanding of
4059 these contexts and of the informational needs of resource managers requires working with
4060 them directly.

4061

4062 The third barrier is that managers expect more difficulties to come from associated
4063 financial and water quality impacts of climate challenges associated with floods and
4064 droughts than from their ability to find water and supply it to their customers (Yarnal *et*
4065 *al.*, 2006; Dow *et al.*, 2007). Combined with the second barrier, the implication is that
4066 managers view weather and climate forecasts as more salient when put into the context of

⁹Additional research on water system manager perceptions is needed, in regions with varying hydro-meteorological conditions, to discern if this finding holds true in other regions.

4067 system operations and management needs. Presenting managers with a climate forecast
4068 for the United States showing the regional probability of below-normal precipitation for
4069 the coming season may not generate much interest; presenting those managers with a
4070 Palmer Drought Severity Index tailored to their state that suggests a possible drought
4071 watch, warning, or emergency will grab their attention (Carbone and Dow, 2005). The
4072 Southwest drought case discussed at the end of this section exemplifies how this salience
4073 worked to prod decision-makers to partner closely with water managers, and how the
4074 latter embraced climate knowledge in improving forecasts and demand estimates.

4075

4076 The fourth barrier is the way climate variability and change are framed as public policy
4077 issues, and how their risks are publically communicated. Regardless of the “actual” (if
4078 indeterminate) risks from climate change and variability, communication of the risks
4079 differs among scientific, political, and mass media elites – each systematically selecting
4080 aspects of these issues that are most relevant to their conception of risk, and thus, socially
4081 constructing and communicating its aspects most salient to a particular perspective. Thus,
4082 climate variability can be viewed as: a phenomenon characterized by probabilistic and
4083 consequential uncertainty (science); an issue that imposes fiduciary or legal responsibility
4084 on government (politics); or, a sequence of events that may lead to catastrophe unless
4085 immediate action is taken (Weingart *et al.*, 2000).

4086

4087 Related to this is considerable research which suggests that when risk information – such
4088 as that characteristic of climate change or variability modeling and forecasting – is
4089 generated by select groups of experts who work in isolation from the public (or from

4090 decision-makers) – the risks presented may sometimes be viewed as untrustworthy or as
4091 not fully warranting a reposing of credibility. This research also suggests that building
4092 trust requires the use of public forums designed to facilitate open risk communication that
4093 is clear, succinct, and jargon-free, and that affords groups ample opportunity for
4094 questions, discussion, feedback, and reaction (*e.g.*, Freudenburg and Rursch, 1994;
4095 Papadakis, 1996; Jasanoff, 1987; Covello, Donovan and Slavick, 1990; NRC, 1989).

4096

4097 Research on these barriers also shows that personal experience has a powerful influence
4098 on perceptions of risk and vulnerability. They suggest that socioeconomic context is
4099 important in shaping perceptions, and, thus, the perceptions they produce are very
4100 specific. They also show that climate information providers must present their
4101 information in ways salient to potential users, necessitating customizing information for
4102 specific user groups. Finally, they suggest ways that perceptions can be changed.

4103

4104 Research on the influence of climate science on water management in western Australia
4105 (Power *et al.*, 2005) suggests that water resource decision-makers can be persuaded to act
4106 on climate variability information if a strategic program of research in support of specific
4107 decisions (*e.g.*, extended drought) can be wedded to a dedicated, timely risk
4108 communication program. In this instance, affected western Australian states formed a
4109 partnership between state agencies representing economic interests affected by drought,
4110 national research institutions engaged in meteorology and hydrology modeling, and water
4111 managers. This partnership succeeded in influencing decision-making by: being sensitive
4112 to the needs of water managers for advice that was seen as “independent,” in order to

4113 assure the public that water use restrictions were actually warranted; providing timely
4114 products and services to water users in an accessible way; and, directly involving water
4115 managers in the process of generating forecast information. The Georgia drought case
4116 (section 3.2.1) also illustrates the need to be sensitive and responsive to decision-maker
4117 needs. As in Australia, ensuring scientific “independence” facilitated the efforts of
4118 managers to consider climate science in their decisions, and helped ensure that climate
4119 forecast information was “localized” through presentation at public meetings and other
4120 fora so that residents could apply it to local decisions (Power *et al.*, 2005). In sum, to
4121 overcome barriers to effective climate information communication, information must be
4122 specific to the sectoral context of managers and enhance their ability to realize
4123 management objectives threatened by weather and climate.

4124

4125 We now examine three particularly vulnerable areas to climate variability: water quality,
4126 groundwater depletion, and energy production. Following this discussion, we feature a
4127 case study on *drought responses in the Southwest U.S.* which is instructive about the role
4128 that perceived vulnerability has played in adaptive responses.

4129

4130 **Water Quality:** Assessing the vulnerability of water *quality* to climate variability and
4131 change is a particularly challenging task, not only because quality is a function – partly –
4132 of water quantity, but because of the myriad physical, chemical and biological
4133 transformations that non-persistent pollutants undergo in watersheds and water bodies.
4134 One of the most comprehensive literature reviews of the many ways in which water

4135 quality can be impacted by climate variability and change was undertaken by Murdoch *et*
 4136 *al.* (2000). A synopsis of their major findings is depicted in Table 3.1.

4137

4138

4139 **Table 3.1 Water Quality, Climate Variability, and Climate Change***
 4140

<p><u>Impacts associated with increases in temperature alone</u></p> <ul style="list-style-type: none"> • Decreased oxygen-holding capacity due to higher surface-water temperatures • In arctic regions, the melting of ice and permafrost resulting in increased erosion, runoff, and <i>cooler</i> stream temperatures. • Changes in the seasonal timing and degree of stratification of temperate lakes. • Increased biomass productivity leading to increased rates of nutrient cycling, eutrophication and anoxia. • Increased rates of chemical transformation and bioaccumulation of toxins. • Changes in the rates of terrestrial nutrient cycling and the delivery of nutrients to surface waters.
<p><u>Impacts associated with drought and decreases in streamflow</u></p> <ul style="list-style-type: none"> • Increased concentration of pollutants in streams, but decreased total export of those pollutants to the receiving water body. • Decreases in the concentration of pollutants that are derived from the flushing of shallow soils and by erosion. • Increases in the concentration of pollutants that are derived from deeper flow paths and from point sources. • Decreased stratification and increased mixing in estuaries and other coastal waters, leading to decreased anoxia of bottom waters and decreased nutrient availability (and eutrophication). • Movement of the freshwater-saltwater boundary up coastal river and intrusion of saltwater into coastal aquifers—impacts which would be exacerbated by sea-level rise. <p><u>Impacts associated with flooding and increases in streamflow</u></p> <ul style="list-style-type: none"> • In general, mitigation of the impacts associated with drought and decreases in streamflow • Increases in the spatial extent of source areas for storm flow, leading to the increased flushing of pollutants from both point and non-point sources of pollution. • Increased rates of erosion • Increased rates of leaching of pollutants to groundwater • Greater dilution of pollutants being countervailed by decreased rates of chemical and biological transformations owing to shorter residence times in soils, groundwater and surface waters.
<p>* From Murdoch, <i>et. al.</i>, 2003</p>

4141

4142 One conclusion to be drawn from Table 3.1 is that climate variability and change can
 4143 have both negative and positive impacts on water quality. In general, warmer surface-
 4144 water temperatures and lower flows tend to have a negative impact through decreases in
 4145 dissolved oxygen (DO). In contrast, decreased flows to receiving water bodies—
 4146 especially estuaries and coastal waters—can improve water quality, while increased
 4147 flows can degrade water quality of the receiving water bodies, particularly if they carry

4148 increased total loads of nutrients and sediments. In healthy watersheds that are relatively
4149 unimpacted by disturbances to the natural vegetation cover, increased stream flow may
4150 increase water quality in the given stream by increasing dilution and DO.

4151

4152 Increased runoff and flooding in urbanized areas can lead to increased loads of nonpoint-
4153 source pollutants (Kirshen *et al.*, 2008) such as pesticides and fertilizer from landscaped
4154 areas, and point-source pollutants, from the overflow of combined sewer systems (Furlow
4155 2006). In addition to increasing pesticide and nutrient loads (Chang *et al.*, 2001), increase
4156 in runoff from agricultural lands can lead to greater sediment loads from erosion and
4157 pathogens from animal waste (Dorner *et al.*, 2006). Loads of non-point pollution may be
4158 especially large during flooding if the latter occurs after a prolonged dry period in which
4159 pollutants have accumulated in the watershed.

4160

4161 The natural vegetation cover that is integral to a healthy watershed can be disturbed not
4162 only by land-use but by the stresses of climate extremes directly (*e.g.*, die off during
4163 drought and blow down of trees during tropical storms and hurricanes) and climate-
4164 sensitive disturbances indirectly (*e.g.*, pest infestations and wildfire). Climate change and
4165 variability can also lead to both adaptive human changes in land use and land cover that
4166 can impact water quality (*e.g.* for example changes in cropping patterns and fertilizer
4167 use), as well as to mitigative ones (*e.g.*, increased production of bio-fuels.) Hence there is
4168 a tight and complex coupling between land use changes and the potential impacts of
4169 climate variability and change on water quality.

4170

4171 Water quality can also be indirectly impacted by climate variability and change through
4172 changes in water-use. Withdrawals from streams and reservoirs may increase during a
4173 drought thereby degrading stream water quality through lower in-stream flows, polluted
4174 return flows, or both. Under the water rights system of the western United States, junior
4175 agricultural users may be cut off during drought thereby actually reducing return flows
4176 from agricultural lands, further lowering in-stream flows.

4177

4178 Perhaps the most common water-quality-related, climate-sensitive decisions undertaken
4179 by water-resource managers in the U.S. are in relation to the regulation of dams and
4180 reservoirs. Very often, reservoir releases are made to meet low flow requirements or
4181 maintain stream temperatures in downstream river reaches. Releases can also be made to
4182 improve water quality in downstream reservoirs, lakes and estuaries. Any operating
4183 decisions based on water quality usually occur in the context of the purpose(s) for which
4184 the dam and reservoir were constructed—typically some combination of hydropower,
4185 flood control, recreation, and storage for municipal supply and irrigation. Thus decision
4186 support systems for reservoir operation that include water quality usually do so in a
4187 multi-objective framework (*e.g.*, Westphal *et al.*, 2003).

4188

4189 Municipal water providers would also be expected to respond to water quality
4190 degradation forecasts. Some decisions they might undertake include stockpiling treatment
4191 chemicals, enhanced treatment levels, *ad hoc* sediment control, preparing to issue water
4192 quality alerts, increasing water quality monitoring, and securing alternative supplies (see
4193 Denver and New York City case studies in Miller and Yates (2005) for specific examples

4194 of climate-sensitive water-quality decision-making by water utilities). Managers of
4195 coastal resources such as fisheries and beaches also respond to water-quality forecasts.
4196
4197 Decision-making with regards to point sources will necessarily occur within the context
4198 of the permitting process under the National Pollution Discharge Elimination System and
4199 the in-stream water quality standards mandated by the Clean Water Act (Jacoby, 1990).
4200 Regulation of non-point sources falls entirely to the states and is therefore highly variable
4201 across the nation, but is in general done to a lesser degree than the regulation of point
4202 sources. Examples of actions—either voluntary or mandatory—that could be taken in
4203 response to a seasonal forecast of increased likelihood of flooding include: decreased
4204 fertilizer and pesticide application by farmers, measures for greater impoundment of
4205 runoff from feedlots, and protection of treatment ponds of all kinds from overflow.
4206
4207 **Groundwater Depletion:** The vulnerability of groundwater resources to climate
4208 variability and change is very much dependent on the hydrogeologic characteristics of the
4209 given aquifer. In general, the larger and deeper the aquifer, the less inter-annual climate
4210 variability will impact groundwater supplies. On the other hand, shallow aquifers that are
4211 hydraulically connected to surface waters tend to have shorter residence times and
4212 therefore respond more rapidly to climate variability. The vulnerability of such aquifers
4213 should be evaluated within the context of their *conjunctive use* with the surface waters.
4214
4215 Seasonal and inter-annual variability in water-table depths are a function of natural
4216 climate variability as well as variations in human exploitation of the resource. During

4217 periods of drought, water tables in unconfined aquifers may drop because of both reduced
4218 recharge and increased rates of pumping. Reduced hydraulic head at well intakes then
4219 decreases the potential yield of the given well or well field and increases the energy
4220 required for pumping. In extreme cases the water table may drop below the well intake,
4221 resulting in complete drying of the well. Municipal supply and irrigation wells tend to be
4222 developed in larger aquifers and at depths greater than wells supplying individual
4223 domestic users. Therefore, they are in general less vulnerable to interannual climate
4224 variability. In addition to the reduction in the yield of water-supply wells, drops in water
4225 table depths during droughts may result in the drying of springs and worsening of low
4226 flow conditions in streams. Greater withdrawals may result because of the shifting of
4227 usage from depleted surface waters, as well as because of an overall increase in demand
4228 due to lower precipitation and greater evapotranspirative demand from the land surface
4229 and water bodies. Morehouse *et al.* (2002) find this to be the case in southern Arizona. To
4230 the extent that climate change reduces surface water availability in the Southwest U.S. it
4231 can be anticipated that pressure on groundwater supplies will increase as a result.

4232

4233 When long-term average pumping rates exceed recharge rates the aquifer is said to be in
4234 *overdraft*. Zekster *et al.* (2005) identify four major impacts associated with groundwater
4235 extraction and overdraft: (1) reduction of stream flow and lake levels, (2) reduction or
4236 elimination of vegetation, (3) land subsidence, and (4) seawater intrusion. Additional
4237 impacts include changes in water quality due to pumping from different levels in aquifers
4238 and increased pumping costs. The karst Edwards Aquifer in south-central Texas, which
4239 supplies over 2 million people in the San Antonio metropolitan area, is identified by

4240 Loáiciga (2003) as particularly vulnerable to climate change and variability because it is
4241 subject to highly variable rates of recharge and has undergone a steady increase in
4242 pumping rates over the last century. While groundwater overdraft is most common in the
4243 arid and semi-arid western U.S. (Roy *et al.*, 2005; Hurd *et al.*, 1999), it is not uncommon
4244 in the more humid East. Lyon *et al.* (2005) study the causes of the three drought
4245 emergencies that have been declared in Rockland County, New York since 1995. 78% of
4246 the county's public water supply is from small regional aquifers. Rather than increased
4247 frequency or intensity of meteorological or hydrologic drought, the authors attribute
4248 drought emergencies to development and population growth overtaxing local supplies
4249 and to failure of aging water-supply infrastructure. The former is an example of *demand-*
4250 *driven* drought. The Ipswich River Basin in northeast Massachusetts is another example
4251 in the east where population growth is taxing groundwater resources. Because of reliance
4252 on ground water and in-stream flows for municipal and industrial supply, summer low
4253 flows in the Ipswich frequently reach critical levels (Zarriello and Ries, 2000).

4254

4255 A few researchers have studied the potential application of seasonal-to-interannual
4256 climate forecasting to forecasting of groundwater recharge and its implications for water
4257 management. For example, using U.S. Geological Survey recharge estimates for the
4258 Edwards Aquifer from 1970-1996, Chen *et al.* (2005) find that recharge rates during La
4259 Niña years average about twice those during El Niño years. Using a stochastic dynamic
4260 programming model, they show that optimal water use and allocation decision-making
4261 based on ENSO forecasts could result in benefits of \$1.1 to \$3.5 million per year, mainly
4262 to agricultural users as a result of cropping decisions.

4263

4264 Hanson and Dettinger (2005) evaluate the seasonal-to-interannual predictability of
4265 groundwater levels in the Santa Clara-Calleguas Basin in coastal Southern California
4266 using a regional groundwater model (RGWM) as driven by a general circulation model
4267 (GCM). In agreement with other studies, they find a strong association between
4268 groundwater levels and the Pacific Decadal Oscillation (PDO) and ENSO. Their results
4269 lead them to conclude that coupled GCM-RGWM modeling is useful for planning and
4270 management purposes, particularly with regard to conjunctive use of surface and ground
4271 water and the prevention of saltwater intrusion. They also suggest that GCM forecast skill
4272 may at times be strong enough to predict groundwater levels. Forecasts of greater surface
4273 water availability may allow utilities to reduce reliance on over-utilized and expensive
4274 groundwater resources. Bales *et al.* (2004) note that a forecast for heavy winter snowpack
4275 during the 1997/1998 El Niño led the Salt River Project in Arizona to reducing
4276 groundwater pumping in the fall and winter in favor of greater releases from reservoirs,
4277 thereby saving about \$1 million.

4278

4279 **Water Supply and Energy Production:** Adequate water supplies are an essential part of
4280 energy production, from energy resource extraction (mining) to electric-power generation
4281 (DOE, 2006). Water withdrawals for cooling and scrubbing in thermoelectric generation
4282 now exceed those for agriculture in the U.S. (Hutson *et al.*, 2004), and this difference
4283 becomes much greater when hydropower uses are considered. Emerging energy sources,
4284 such as biofuels, synfuels, and hydrogen, will add to future water demands. Another new
4285 energy-related stress on water resource systems will be the integration of hydropower

4286 with other intermittent renewables, such as wind and solar, at the power system level.
4287 Hydropower is a very flexible, low-cost generating source that can be used to balance
4288 periods when other renewables are not available (*e.g.*, times of calm winds) and thus
4289 maintain electricity transmission reliability. As more non-hydro renewables are added to
4290 transmission grids, calls for fluctuating hydropower operation may become more frequent
4291 and economically valuable, and may compete with other water demands. If electricity
4292 demand increases by 50% in the next 25 years, as predicted by the Energy Information
4293 Administration, then energy-related water uses can also be expected to expand greatly –
4294 an ominous trend, especially where available water resources are already over allocated.
4295
4296 The Climate Change Science Program’s Synthesis and Analysis Product 4.5 examined
4297 how climate change will affect the energy sector (CCSP, 2007). Some of the most direct
4298 effects of climate change on the energy sector will occur via water cycle processes
4299 (CCSP, 2007). For instance, changes in precipitation could affect prospects for
4300 hydropower, either positively or negatively at different times and locations. Increases in
4301 storm intensity could threaten further disruptions of the type experienced in 2005 with
4302 Hurricane Katrina. Also, average warming can be expected to increase energy needs for
4303 cooling and reduce those for warming. Concerns about climate change impacts could
4304 change perceptions and valuations of energy technology alternatives. Any or all of these
4305 types of effects could have very real meaning for energy policies, decisions, and
4306 institutions in the U.S., affecting discussions of courses of action and appropriate
4307 strategies for risk management and energy’s water demands will change accordingly.
4308

4309 The energy-related decisions in water management are especially complex, because they
4310 usually involve both water quality and quantity aspects, and they often occur in the
4311 context of multiple-use river basins. The Tennessee Valley is a good example of these
4312 complexities. The Tennessee Valley Authority (TVA) operates an integrated power
4313 system of nuclear, coal, and hydropower projects along the full length of the Tennessee
4314 River. TVA's river operations include upstream storage reservoirs and mainstem locks
4315 and dams, most of which include hydropower facilities. Cold water is a valuable resource
4316 that is actively stored in the headwater reservoirs and routed through the river system to
4317 maximize cooling efficiencies of the downstream thermoelectric plants. Reservoir
4318 releases are continuously optimized to produce least-cost power throughout the river
4319 basin, with decision variables of both water quantity and quality.

4320

4321 **Case Study: Southwest drought – climate variability, vulnerability, and water**
4322 **management**

4323 **Introduction**

4324 Climate variability affects water supply and management in the Southwest through
4325 drought, snowpack runoff, groundwater recharge rates, floods, and temperature-driven
4326 water demand. The region sits at a climatic crossroads, at the southern edge of reliable
4327 winter storm tracks and at the northern edge of summer North American monsoon
4328 penetration (Sheppard *et al.*, 2002). This accident of geography, in addition to its
4329 continental location, drives the region's characteristic aridity. Regional geography also
4330 sets the region up for extreme vulnerability to subtle changes in atmospheric circulation
4331 and the impacts of temperature trends on snowmelt, evaporation, moisture stress on
4332 ecosystems, and urban water demands. The instrumental climate record provides ample
4333 evidence of persistent regional drought during the 1950s (Sheppard *et al.*, 2002; Goodrich
4334 and Ellis, 2006), and its influence on Colorado River runoff (USGS, 2004); in addition
4335 the impact of the 1950s drought on regional ecosystems is well documented (Allen and

4336 Breshears, 1998; Swetnam and Betancourt, 1998). Moreover, it has been well known for
4337 close to a decade that interannual and multi-decade climate variations, forced by
4338 persistent patterns of ocean-atmosphere interaction, lead to sustained wet periods and
4339 severe sustained drought (Andrade and Sellers, 1988; D'Arrigo and Jacoby, 1991; Cayan
4340 and Webb, 1992; Meko *et al.*, 1995; Mantua *et al.*, 1997; Dettinger *et al.*, 1998).

4341

4342 **Sources of vulnerability**

4343 Despite this wealth of information, interest in the effects of climate variability on
4344 southwestern water supplies has been limited by dependence on seemingly unlimited
4345 groundwater resources, which are largely buffered from inter-annual climate fluctuations.
4346 Evidence of extensive groundwater depletion in Arizona and New Mexico, from a
4347 combination of rapid urban expansion and sustained pumping for irrigated agriculture,
4348 has forced changes in water policy, resulting in a greater reliance on renewable surface
4349 water supplies (Holway, 2007; Anderson and Woosley, Jr., 2005; Jacobs and Holway,
4350 2004). The distance between southwest urban water users and the sparsely-populated
4351 mountain sources of their surface water in Wyoming, Utah, and Colorado, reinforces a
4352 lack of interest in the impacts of climate variations on water supplies (Rango, 2006;
4353 Redmond, 2003). Until Southwest surface water supplies were substantially affected by
4354 sustained drought, beginning in the late 1990s, water management interest in climate
4355 variability seemed to be focused on the increased potential for flood damage during El
4356 Niño episodes (Rhodes *et al.*, 1984; Pagano *et al.*, 2001).

4357

4358 Observed vulnerability of Colorado River and Rio Grande water supplies to recent
4359 sustained drought, has generated profound interest in the effects of climate variability on
4360 water supplies and management (*e.g.*, Sonnett *et al.*, 2006). In addition, extensive
4361 drought-driven stand-replacing fires in Arizona and New Mexico watersheds have
4362 brought to light indirect impacts of climate variability on water quality and erosion
4363 (Neary *et al.*, 2005; Garcia *et al.*, 2005; Moody and Martin, 2001). Prompted by these
4364 recent dry spells and their impacts, New Mexico and Arizona developed their first
4365 drought plans (NMDTF, 2006; GDTF, 2004); in fact, repeated drought episodes,
4366 combined with lack of effective response, compelled New Mexico to twice revise its

4367 drought plan (NMDTF, 2006; note, these workshops are discussed in chapter 4 in case
4368 study H). Colorado River Basin water managers have commissioned tree-ring
4369 reconstructions of streamflow, in order to revise estimates of record droughts, and to
4370 improve streamflow forecast performance (Woodhouse and Lukas, 2006; Hirschboeck
4371 and Meko, 2005). These reconstructions and others (Woodhouse *et al.*, 2006; Meko *et al.*,
4372 2007) reinforce concerns over surface water supply vulnerability, and the effects of
4373 climate variability and trends (*e.g.*, Cayan *et al.*, 2001; Stewart *et al.*, 2005) on
4374 streamflow.

4375

4376 **Decision-support tools**

4377 Diagnostic studies of the associations between El Niño-Southern Oscillation (ENSO)
4378 teleconnections, multi-decade variations in the Pacific Ocean-atmosphere system, and
4379 Southwest climate demonstrate the potential predictability of seasonal climate and
4380 hydrology in the Southwest (Cayan *et al.*, 1999; Gutzler, *et al.*, 2002; Hartmann *et al.*,
4381 2002; Hawkins *et al.*, 2002; Clark *et al.*, 2003; Brown and Comrie, 2004; Pool, 2005).
4382 ENSO teleconnections currently provide an additional source of information for
4383 ensemble streamflow predictions by the National Weather Service Colorado Basin River
4384 Forecast Center (Brandon *et al.*, 2005). The operational use of ENSO teleconnections as a
4385 primary driver in Rio Grande and Colorado River streamflow forecasting, however, is
4386 hampered by high variability (Dewalle *et al.*, 2003), and poor skill in the headwaters of
4387 these rivers (Udall and Hoerling, 2005; FET, 2008).

4388

4389 **Future prospects**

4390 Current prospects for forecasting beyond ENSO time-scales, using multi-decade “regime
4391 shifts” (Mantua, 2004) and other information (McCabe *et al.*, 2004) are limited by lack of
4392 spatial resolution, the need for better understanding of land-atmosphere feedbacks, and
4393 global atmosphere-ocean interactions (Dole, 2003; Garfin *et al.*, 2007). Nevertheless,
4394 Colorado River and Rio Grande water managers, as well as managers of state
4395 departments of water resources have embraced the use of climate knowledge in
4396 improving forecasts, preparing for infrastructure enhancements, and estimating demand
4397 (Fulp, 2003; Shamir *et al.*, 2007). Partnerships among water managers, forecasters, and

4398 researchers hold the most promise for reducing water supply vulnerabilities and other
4399 water management risks through the incorporation of climate knowledge (Wallentine and
4400 Matthews, 2003).

4401

4402 **3.2.4 Institutional Factors that Inhibit Information Use in Decision-Support Systems**

4403 In section 3.1, decision-support was defined as a process that generates climate science
4404 products *and* translates them into forms useful for decision-makers through dissemination
4405 and communication. This process, when successful, leads to institutional *transformation*
4406 (NRC, 2008). Five factors are cited as impediments to optimal use of decision-support
4407 systems' information: (1) lack of integration of systems with expert networks; (2) lack of
4408 institutional coordination; (3) insufficient stakeholder engagement in product
4409 development; (4) insufficient cross-disciplinary interaction; and, (5) expectations that the
4410 expected "payoff" from forecast use may be low. The *Red River flooding and flood*
4411 *management case* following this discussion exemplifies some of these problems, and
4412 promising efforts being expended in overcoming them.

4413

4414 Some researchers (Georgakakos *et al.*, 2005) note that because water management
4415 decisions are subject to gradual as well as rapid changes in data, information, technology,
4416 natural systems, uses, societal preferences, and stakeholder needs, effective decision-
4417 support processes regarding climate variability information must be adaptive and include
4418 self-assessment and improvement mechanisms in order to be kept current (Fig.3.3).

4419

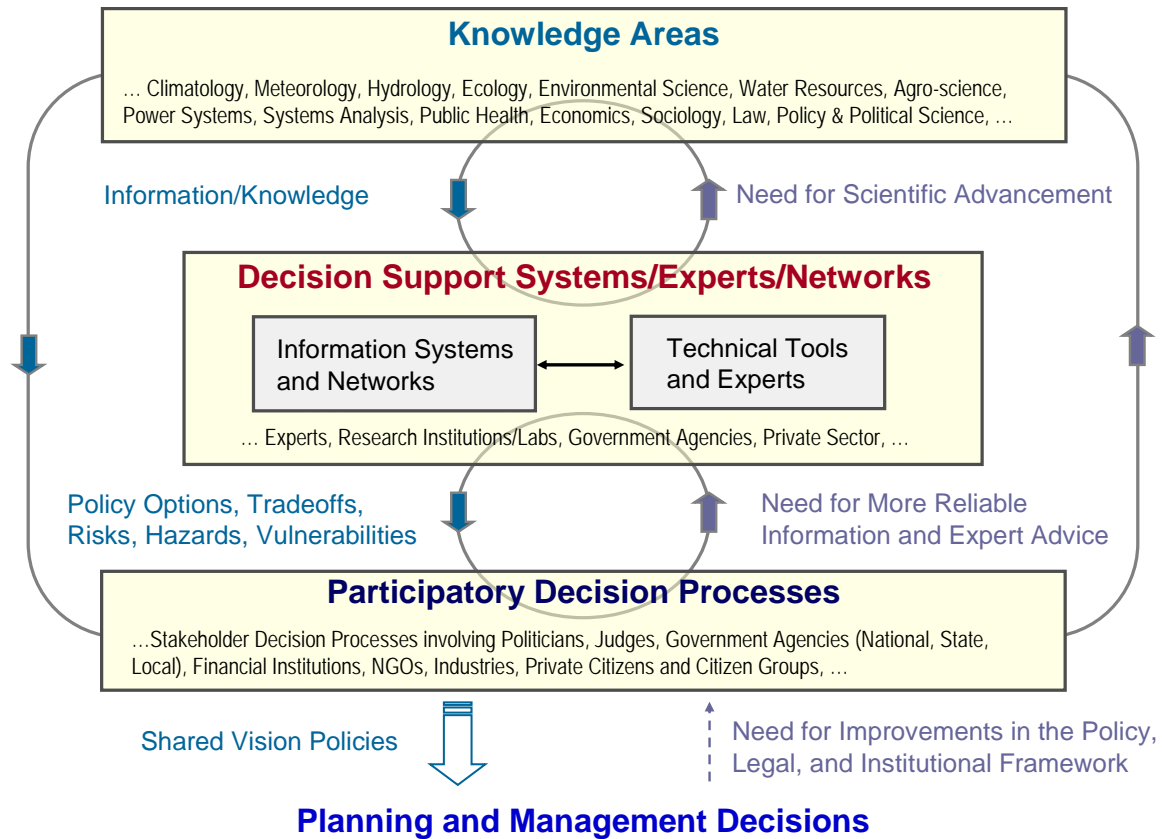

4420 These assessment and improvement mechanisms, which produce transformation, are
4421 denoted by the upward-pointing feedback links shown in Figure 3.3, and begin with

4422 monitoring and evaluating the impacts of previous decisions. These evaluations ideally
4423 identify the need for improvements in the effectiveness of policy outcomes and/or legal
4424 and institutional frameworks. They also embrace assessments of the quality and
4425 completeness of the data and information generated by decision support systems and the
4426 validity and sufficiency of current knowledge. Using this framework as a point of
4427 departure makes discussing our five barriers to information use easier to comprehend.

4428

4429 First, the lack of integrated decision support systems and expert networks to support
4430 planning and management decisions means that decision-support experts and relevant
4431 climate information are often not available to decision-makers who would otherwise use
4432 this information. This lack of integration is due to several factors, including resources
4433 (*e.g.*, large agencies can better afford to support modeling efforts, consultants, and large-
4434 scale data management efforts than can smaller, less-well funded ones), organizational
4435 design (expert networks and support systems may not be well-integrated administratively
4436 from the vantage point of connecting information with users' "decision routines"), and
4437 opportunities for interaction between expert system designers and managers (the strength
4438 of communication networks to permit decisions and the information used for them to be
4439 challenged, adapted, or modified – and event to frame scientific questions). This
4440 challenge embraces users and producers of climate information, as well as the boundary
4441 organizations that can serve to translate information (Hartmann, 2001; National Research
4442 Council, 1996; Sarewitz and Pielke, 2007; NRC, 2008).

4443

4444
4445
4446
4447
4448
4449
4450
4451
4452
4453
4454

Figure 3.3 Water Resources Decision Processes

Second, the lack of coordination of institutions responsible for water resources management means that information generated by decision support networks must be communicated to various audiences in ways relevant to their roles and responsibilities (see section 3.2.1). Figure 3.3 – and discussion of the factors that led to development of better decision-support for flood hazard alleviation on the *Red River of the North* – reveal how extreme environmental conditions compounds the challenge in conveying information to different audiences given the dislocation and conflict that may arise.

4455 Third, limited stakeholder participation and political influence in decision making
4456 processes – a problem discussed in chapter 1 in the context of the typically low public
4457 interest in water policy given the traditional, technical framing of water issues in
4458 American society – means that decision support products may not equitably penetrate to
4459 all relevant audiences. It also means that because water issues typically have low
4460 visibility for most of the public, the economic and environmental dislocations caused by
4461 climate variability events (*e.g.*, drought, floods), or even climate change, may exacerbate
4462 these inequities and draw sudden, sharp attention to the problems resulting from failure to
4463 properly integrate decision-support models and forecast tools, since disasters often strike
4464 disadvantaged populations disproportionately (*e.g.*, Hurricane Katrina on 2005)
4465 (Hartmann, *et al.*, 2002; Carbone and Dow, 2005; Subcommittee on Disaster Reduction,
4466 2005; Leatherman and White, 2005).

4467

4468 Fourth, the lack of adequate cross-disciplinary interaction between science, engineering,
4469 public policy-making, and other knowledge and expertise sectors – across agencies,
4470 academic institutions, and private sector organizations – exacerbates these problems by
4471 making it difficult for decision support information providers to communicate with one
4472 another. It also exacerbates the problem of information overload by inhibiting use of
4473 incremental additional the sources and benefits of which are unclear to the user. In short,
4474 certain current decision support services are often narrowly focused, developed by over-
4475 specialized professionals working in a “stovepipe” system of communication within their
4476 organizations. While lack of integration can undermine the effectiveness of decision

4477 support tools and impede optimal decisions, it may create *opportunities* for design,
4478 development and use of effective decision support services.

4479

4480 **Case Study: Red River of the North – Flooding and Water Management**

4481 **Overview**

4482 This case study of climate variability information use focuses on flooding. Model outputs
4483 to better encompass seasonal precipitation, snowmelt and other factors, are increasingly
4484 being incorporated into operations decisions. Lessons include how to translate complex
4485 data into useable warning and alert systems for decision-making and, are deterministic
4486 forecasts an effective mechanism for communicating information for use water resource
4487 planning and management?

4488 **Background and Context**

4489 Flooding on the Red River of the North in April 1997 resulted in losses estimated to be
4490 four billion dollars. The Red River crested about 5 feet higher than the maximum flood
4491 height of 49 feet predicted by the NOAA National Weather Service North Central River
4492 Forecast Center (NCRFC) and the public outcry was that the NWS had failed to render a
4493 correct forecast (Pielke, 1999). With snowmelt as the dominant contributor to spring
4494 flooding, in February 1997, the NCRFC had issued an outlook assuming average
4495 temperatures and no additional precipitation for the next few months of 47.5 feet and a
4496 second outlook assuming average temperature and precipitation of 49 feet. In early April
4497 1997, there was a record snowfall in the region, which neither outlook scenario
4498 anticipated. On April 14, 1997, a crest forecast of 50 feet was issued for East Grand
4499 Forks to occur in the April 19-22 time period; the river actually crested at 54 feet on
4500 April 19, breaching levees. A critical issue identified in the NOAA Office of Hydrology
4501 1999 report is that the previous record flood stage height was 48.8 feet and NWS
4502 outlooks were based on extrapolations of the rating curves and there was no way to know
4503 that experimental rating curves being developed by the Army Corps of Engineers would
4504 have been more accurate.

4505

4506 Although the NWS outlooks contained a disclaimer that there was a 50 percent chance of
4507 the forecast stage height being equaled or exceeded, they provided no measure of
4508 uncertainty, and were interpreted as either an exact or maximum estimate of expected
4509 river crest height. The communication and interpretation of these rather precise flood
4510 outlooks, with no updates prior to mid-April, led local officials to assume they were
4511 prepared to deal with worse-case flood scenarios.

4512

4513 In fall 2006, the NRC released a report entitled “Completing the Forecast: Characterizing
4514 and Communicating Uncertainty for Better Decisions Using Weather and Climate
4515 Forecasts,” noting that all predictions are inherently uncertain, and that effective
4516 communication of uncertainty information in weather, seasonal climate, and hydrological
4517 forecasts benefits users’ decisions (*e.g.*, AMS, 2002; NRC, 2003b). The chaotic character
4518 of the atmosphere, coupled with inevitable inadequacies in observations and computer
4519 models, results in forecasts that always contain uncertainties. These uncertainties
4520 generally increase with forecast lead time and vary with weather situation and location.
4521 Uncertainty is thus a fundamental characteristic of weather, seasonal climate, and
4522 hydrological prediction, and no forecast is complete without a description of its
4523 uncertainty. Nonetheless, for decades, users of weather, seasonal climate, and
4524 hydrological (collectively called “hydrometeorological”) forecasts have not provided
4525 complete information about the certainty or likelihood of a particular event.

4526

4527 Users became comfortable with single-valued forecasts and applied their own experience
4528 in determining how much confidence to place in the forecast. The evolution of the media
4529 as the primary vehicle for conveying weather information in the United States
4530 compounded this trend. The inclusion of uncertainty information in a forecast was
4531 viewed by some as a weakness or disadvantage instead of supporting a more
4532 scientifically sound and useful product.

4533

4534 Most forecast products from the weather and climate enterprise including those from the
4535 National Oceanic and Atmospheric Administration’s (NOAA’s) National Weather
4536 Service (NWS), continue this deterministic legacy. Decisions by users at all levels, but

4537 perhaps most critically those associated directly with protection of life and property, are
4538 being made without the benefit of knowing the uncertainties of the forecasts upon which
4539 they rely.

4540

4541 The complex hydraulic characteristics of the Red River of the North at Grand Forks and
4542 East Grand Forks were difficult to model with the NWS forecast methods in place during
4543 the April 1997 flood. This was the primary reason for the forecast error at that location.

4544

4545 **Lessons learned**

4546 As the NWS RFC move to develop probabilistic forecasts, making sure that these climate
4547 variability forecasts are of use to decision makers will be critical. In this regard, a number
4548 of useful lessons emanate from this case, including: incorporating the latest rating curves
4549 for flooding to reflect recent data, conducting inter-agency review of available data that
4550 might be applicable to future flooding, moving toward real-time forecasting to the extent
4551 that dynamic routing procedures permit, warning decision-makers when a forecast
4552 exceeds the top of the rating curve – so that appropriate risk responses can be better
4553 contemplated, modeling the impact of temporary meltwater storage on flood hazard,
4554 supporting aerial snow cover surveys, incorporating user feedback to improve
4555 communication of forecast information, and conducting post-flooding technical
4556 assessment workshops among relevant agencies to assess how , and how effectively
4557 climate forecast information was used.

4558

4559 **3.2.5 Reliability and Trustworthiness as Problems in Collaboration**

4560 The collaborative process for decision-support must be believable and trustworthy, with
4561 benefits to all engaged in it. One of the challenges in ensuring that information is
4562 perceived by decision-makers as trustworthy is that trust is the result of an interactive
4563 process of long-term, sustained effort by scientists to respond to, work with, and be
4564 sensitive to the needs of decision-makers and users, and of decision-makers becoming

4565 sensitive to – and informed about – the process of research. In part, trust is also a matter
4566 of the perceived credibility of the outcomes generated by decision-support systems.

4567

4568 The *Red River Flood warning case* (section 3.2.4) provides an excellent example of this
4569 problem – users are becoming comfortable with single-valued forecasts and applied their
4570 own experience in determining how much confidence to place in them. Coupled with the
4571 dependence on media as the tool for conveying weather information, the inclusion of
4572 uncertainty information in a forecast was viewed by some as a weakness, or
4573 disadvantage, in providing adequate warning of impending flood conditions, instead of an
4574 advantage in ensuring a more sound and useful forecast product.

4575

4576 Two other case vignettes featured below – *the Yakima and Upper Colorado River basins*
4577 – reveal the inverse dimensions of this problem. In effect, what happens if forecast
4578 information proves to be incorrect in its predictions, because predictions turned out to be
4579 technically-flawed, overly (or not sufficiently) conservative in their estimate of hazards,
4580 contradictory in the face of other information, or simply insufficiently sensitive to the
4581 audiences to whom forecasts were addressed?

4582

4583 As these cases suggest, given the different expectations and roles of scientists and
4584 decision-makers, what constitutes credible information to a scientist involved in climate
4585 prediction or evaluation may differ from what is considered credible information by a
4586 decision-maker. To a decision-maker forecast credibility is often unfortunately perceived
4587 as hinging upon its *certainty*. The more certain and exact a forecast, in other words, the

4588 more trusted it will be by decision-makers, and the more trustworthy the developers of
4589 that information will be perceived. As shown below, improvements in forecast
4590 interpretation and translation, communication and institutional capacity to adjust to
4591 changing information and its consequences, are essential to addressing this problem. A
4592 basic characteristic of much forecast information is that even the best forecasts rarely
4593 approach close to absolute certainty of prediction – we discuss this issue in section 3.3.2.
4594

4595 **Case Study: Credibility and the Use of Climate Forecasts: Yakima River Basin/El**
4596 **Nino and Colorado Basin Case Studies**

4597 **Yakima Case – Background**

4598 Establishing credibility is essential to fostering the use of climate forecasts in water
4599 management decisions. Although daily weather forecasts, relied upon by millions of
4600 people, can be extremely accurate the majority of the time, the most memorable forecasts
4601 are ones that miss the mark. This is especially true where operational risk tolerance is
4602 low, and the consequences are costly, such as the case of the Yakima River basin in 1977
4603 (Glantz, 1982). At risk in this well documented case were the livelihoods of hundreds in a
4604 heavily irrigated agricultural region in the lee of Washington’s Cascade Mountains.
4605

4606 **The Problem – Relating Forecast to Allocation Decisions**

4607 Low snowpack in the late winter of 1977 prompted the U.S. Bureau of Reclamation to
4608 issue a forecast for summer runoff below the threshold established in a legal precedent
4609 (U.S. District Court, 1945), with the consequence that junior water rights holders would
4610 receive irrigation allocations as low as 6% of normal. In fact, the forecast issued by
4611 Reclamation was exceedingly conservative, well below runoff estimates by the National
4612 Weather Service and Soil Conservation Service. As noted by Glantz (1982), such low
4613 allocations “were noted by all observers as insufficient to protect perennial plants and
4614 trees from drought-related destruction. The loss of perennial plants and trees could mean
4615 a loss of production for up to eight years...[with] replacement costs...on the order of \$7-
4616 \$8000 per acre.” Orchardists and others were forced to pursue expensive tactics to protect

4617 their investments, including well digging and deepening, leasing water rights, and
4618 transplanting crops. As it turned out, Reclamation's forecast suffered from technical
4619 deficiencies: calculations failed to include return flows and treated some reservoir storage
4620 as flow. In addition, changes in operations that differed from Reclamation policy within
4621 memory of Yakima basin farmers, and poor communications, left water users and the
4622 public frustrated and uninformed. The aftermath of the forecast, actions taken by
4623 agriculturalists, and subsequent investigations, resulted in animosity between senior and
4624 junior water rights holders, a loss of confidence in Reclamation, and lawsuits against the
4625 agency (Allen Orchards *et al.*, 1980).

4626

4627 **Lessons**

4628 Glantz surmises that greater transparency in forecast methods, including issuing forecast
4629 confidence limits, better communication between agencies and the public, and
4630 consideration of the consequences of potential actions taken by users in the event of an
4631 erroneous forecast, would have improved the value of the forecast and the actions taken
4632 by Reclamation. Twenty years later, NOAA made a similar error when issuing a *perfectly*
4633 *confident* forecast of intensifying drought conditions for the Midwestern U.S. in 2000
4634 (Changnon, 2002). Based on the forecasts, state water officials took actions they felt were
4635 needed anyway, and were not harmed by the lack of predictive skill and over-confidence
4636 in the forecast; however, agricultural producers may have sustained losses on the order of
4637 \$1 billion, depending on the extent to which they employed particular pricing strategies.
4638 The upshot of this case of a failed forecast, once again, was increased skepticism in long-
4639 term climate forecasts and government institutions (Changnon, 2002).

4640

4641 **El Nino and the Lower Colorado River basin**

4642 **Background**

4643 Incorporating probabilistic climate forecast information into water management actions is
4644 more difficult than most climate researchers expect. Pagano *et al.* (2001; 2002)
4645 documented Arizona water and emergency management use of climate forecasts during
4646 the 1997-98 El Niño. Studies determined that issues in interpretation of the NOAA
4647 Climate Prediction Center's three category probabilistic forecasts presented a major

4648 barrier to forecast use (Pagano *et al.*, 2002). Despite the fact that the climate forecasts
4649 expressed a 50% probability of seasonal precipitation totals being in the wettest one-third
4650 of the 1961-90 distribution of precipitation, agencies prepared for an array of outcomes
4651 ranging from "business as usual," to 100% above normal precipitation. Some
4652 stakeholders, such as the U.S. Bureau of Reclamation, took action, by reducing reservoir
4653 levels, in order to avoid potential structural damage. The 1982-83 El Niño events
4654 threatened to undermine Glen Canyon dam (Rhodes *et al.*, 1984), and the memory of
4655 nearly losing the dam was still fresh in the Bureau's institutional memory.

4656

4657 **Problem: Conflicting predictions**

4658 Another noteworthy barrier to forecast use was noted in the 1997-98 ENSO event, when
4659 ENSO-based climate forecasts contradicted historical regression-based water supply
4660 outlooks, and it became difficult for stakeholders to reconcile differences between the
4661 forecasts. One stakeholder noted "the man with two watches never knows what time it is"
4662 (Pagano *et al.*, 2001). Salt River Project (SRP), the major surface water manager in the
4663 Phoenix metropolitan area, relied upon in-house research and a history of tracking ENSO
4664 in their decision to shift from groundwater to surface water supplies in anticipation of the
4665 1997-98 El Nino. However, SRP chose to [correctly] ignore forecasts for an East Pacific
4666 hurricane to track across their region of interest, based on a greater perceived margin of
4667 error in such forecasts (Pagano *et al.*, 2001). These examples resonate, in part, with the
4668 Yakima, 1977, case study, because they demonstrate decision-makers' ability to
4669 substitute their own judgment after previously relying on information with a poor track
4670 record or insufficient interpretation of potential outcomes.

4671

4672 **Lessons**

4673 The Arizona examples illustrate the need for capacity building to promote understanding
4674 of uncertainty in forecasts, and to avoid the outcome of "once burned, twice shy,"
4675 identified by Adeel and Glantz (2001), especially where agencies or operations have little
4676 capacity to recover from poor decisions based on "blown" (*i.e.*, failed) forecasts.

4677

4678 **3.2.5.1 Other Reliability and Trustworthiness Issues: The Need for High Resolution**
4679 **Data**

4680 Research on the information needs of water decision-makers has increasingly brought
4681 attention to the fact that use of climate-related decision support tools is partly a function
4682 of the extent to which they can be made relevant to site-specific conditions and specific
4683 managerial resource needs, such as flow needs of aquatic species; the ability to forecast
4684 the impact of climate variability on orographic precipitation; and, the ability to fill in
4685 gaps in hydrologic monitoring (Proceedings of the Western Governors Association,
4686 2007). In effect, proper integration of climate information into a water resource
4687 management context means developing high-resolution outputs able to be conveyed at
4688 the watershed level. It also means predicting changes in climate forecasts through the
4689 season and year, and regularly updating predictions. Specificity of forecast information
4690 can be as important as reliability for decision-making at the basin and watershed level
4691 (Proceedings of the Western Governors Association, 2007). The Southwest drought case
4692 discussed in section 3.2.3 illustrates this importance of information specificity in the
4693 context of water managers' responses, particularly within the Colorado River basin.
4694

4695 **3.2.5.2 Uncertainty in the regulatory process**

4696 While uncertainty is an inevitable part of the water resource decision-makers' working
4697 environment, one source of lack of trust revolves around multi-level, multi-actor
4698 governance (see section 3.2.1). Shared governance for water management, coupled with
4699 the risk-averse character of traditional public works-type water agencies in particular,
4700 leads to situations where – while parties may act together for purposes of shared

4701 governance, “they may not have common goals or respond to common incentives” (NRC,
4702 2008). Moreover, governance processes that cross various agencies, jurisdictions, and
4703 stakeholder interests are rarely straightforward, linear, or predictable because different
4704 actors are asked to provide information or resources peripheral to their central functions.
4705 In the absence of clear lines of authority, trust among actors and open lines of
4706 communication are essential (NRC, 2008).

4707

4708 As shown in chapter 4 in the discussion of the *South Florida water management* case,
4709 one regulatory change introduced to guide water release decisions helped increase
4710 certainty and trust in the water allocation and management process. The South Florida
4711 water management district uses a Water Supply and Environment (WSE) schedule for
4712 Lake Okeechobee that employs seasonal and multi-seasonal climate outlooks as guidance
4713 for regulatory releases (Obeysekera, 2007). The WSE schedule, in turn, uses ENSO and
4714 Atlantic Multi-decadal Oscillation (AMO; Enfield *et al.*, 2001) to estimate net inflow.
4715 While uncertainty in regional hydrology remains and is attributable to natural climatic
4716 variation, long-term global climate change, changes in precipitation patterns associated
4717 with drainage and development, and rainfall-runoff relationships altered by infrastructure
4718 change, the overall decision-making process is effective (Obeysekera, 2007).

4719

4720 **3.2.5.3 Data problems**

4721 Lack of information about geographical and temporal variability in climate processes is
4722 one of the primary barriers to adoption and use of specific products. An important
4723 dimension of this lack of information problem – relevant to discussions of reliability and

4724 trust – revolves around how decision-makers make decisions when they have poor, no, or
4725 little data. Decision research from the social and behavioral sciences suggests that when
4726 faced with such problems, individual decision makers typically omit or ignore key
4727 elements of good decision processes. This leads to decisions that are often ineffective in
4728 bringing about the results they intended (Slovic, Fischhoff, and Lichtenstein, 1977).
4729 Furthermore, decision-makers, such as water managers responsible for making flow or
4730 allocation decisions based on incomplete forecast data, may respond to complex tasks by
4731 employing professional judgment to simplify them in ways that seem adequate to the
4732 problem at hand – sometimes adopting “heuristic rules” that presume different levels of
4733 risk are acceptable based on their prior familiarity with a similar set of problems (Tversky
4734 and Kahneman, 1974; Payne *et al.*, 1993).
4735
4736 Decision-makers and the public also may respond to probabilistic information or
4737 questions involving uncertainty with predictable biases that ignore or distort important
4738 information (Kahneman, Slovic, and Tversky, 1982) or exclude alternative scenarios and
4739 possible decisions (*e.g.*, Keeney, 1992; NRC, 2005). El Nino/Southern Oscillation
4740 (ENSO) forecasts illustrate some of these problems¹⁰. Operational ENSO-based forecasts
4741 have only been made since the late 1980s – while ENSO-related products that provide
4742 information about which forecasts are likely to be most reliable for what time periods, in
4743 which areas – have an even shorter history. Thus, decision-maker experience in their use
4744 has been limited. Essential knowledge for informed use of ENSO forecasts includes

¹⁰ El Ninos tend to bring higher than average winter precipitation to the U.S. Southwest and Southeast while producing below-average precipitation in the Pacific Northwest. By contrast, La Ninas produce drier than average winter conditions in the Southeast and Southwest while increasing precipitation received in the Pacific Northwest.

4745 understanding of the temporal and geographical domain of ENSO impacts. Yet making a
4746 decision based *only* on this information may expose a manager unnecessarily to
4747 consequences from that decision.

4748

4749 **3.2.5.4 Changing environmental, social and economic conditions**

4750 Over the past three decades, a combination of economic changes (*e.g.*, reductions in
4751 federal spending for large water projects), environmental conditions (*e.g.*, demands for
4752 more non-structural measures to address water problems, and heightened emphasis on
4753 environmental restoration practices), and public demands for greater participation in
4754 water resource management have led to new approaches to water management. In
4755 Chapter 4 we address two of these approaches – adaptive management and integrated
4756 resource management. These approaches emphasize explicit commitment to
4757 environmentally-sound, socially just outcomes; greater reliance upon drainage basins as
4758 planning units; program management via spatial and managerial flexibility, collaboration,
4759 participation, and peer-reviewed science (Hartig *et al.*, 1992; Landre and Knuth, 1993;
4760 Cortner and Moote, 1994; Water in the West, 1998; May *et al.*, 1996; McGinnis, 1995;
4761 Miller *et al.*, 1996; Cody, 1999; Bormann *et al.*, 1993; Lee, 1993). As shall be seen, these
4762 approaches place added demands on water managers regarding use of climate variability
4763 information, including adding new criteria to decision processes such as: managing in-
4764 stream flows/low flows, climate variability impacts on runoff, water quality, fisheries,
4765 and water uses.

4766

4767 **3.2.5.5 Public perception and politics may outweigh facts and professional judgment**

4768 Climate variability and its risks are viewed through perceptual frames that affect not only
4769 decision-makers and other policy elites, but members of the general public. Socialization
4770 and varying levels of education contribute to a social construction of risk information that
4771 may lead the public to view extreme climate variability as a sequence of events that may
4772 lead to catastrophe unless immediate action is taken (Weingart *et al.*, 2000). Extreme
4773 events may heighten the influence of sensational reporting, impede reliance upon
4774 professional judgment, lead to sensationalized reporting, and a sudden rise in public
4775 attention that may even shut off political discussion of the issue (Weingert *et al.*, 2000:
4776 7).

4777

4778 **3.2.5.6 Decision-makers may be vulnerable when they use information**

4779 Decision-makers can lose their jobs, livelihoods, stature, or reputation by relying on
4780 forecasts that are wrong. Likewise, similar consequences can come about from untoward
4781 outcomes of decisions based on *correct* forecasts. This fact tends to make decision-
4782 makers risk averse, and sometimes politically over-sensitive when using information, as
4783 noted in section 4. As Jacobs (2005) notes in her review, much has been written on the
4784 reasons why decision-makers and scientists rarely develop the types of relationships and
4785 information flows necessary for full integration of scientific knowledge into the decision-
4786 making process (Kirby, 2000; Pagano *et al.*, 2001; Pulwarty and Melis, 2001 Rayner,
4787 Lach and Ingram, 2005). The primary reasons are problems with relevance (are the
4788 scientists asking and answering the right questions?), accessibility of findings (are the
4789 data and the associated value-added analysis available to and understandable by the
4790 decision-makers?), acceptability (are the findings seen as accurate and trustworthy?)

4791 conclusions being drawn from the data (is the analysis adequate?) and context (are the
4792 findings useful given the constraints in the decision process?)

4793

4794 Scientists have some authority to overcome some of these sources of uncertainty that
4795 result in distrust (*e.g.*, proper diagnosis of a problem, providing adequate data, regularly
4796 updating forecasts, and drawing correct forecast conclusions). Other constraints on
4797 uncertainty, however, may be largely out of their control. Sensitivity to these sources of
4798 uncertainty – and their influence upon decision-makers, is important.

4799

4800 The *Yakima case*, discussed earlier in the context of forecast credibility, further illustrates
4801 how decision-makers can become vulnerable by relying on information that turns out to
4802 be inaccurate, or a poor predictor of future climate variability events. It underscores the
4803 need for trust-building mechanisms to be built into forecast translation projects, such as
4804 issuing forecast confidence limits, communicating better with the public and agencies,
4805 and considering the consequences of potential actions taken by users in the event of an
4806 erroneous forecast. The next section discusses particular challenges related to translation.

4807

4808 **3.3 WHAT ARE THE CHALLENGES IN FOSTERING COLLABORATION** 4809 **BETWEEN SCIENTISTS AND DECISION-MAKERS?**

4810 This section examines problems in translating climate forecasts and hydrology
4811 information into integrated water management decisions, forecast communication, and
4812 operationalizing decision-support systems. This discussion focuses on translation of
4813 scientific information into forms useful and useable by decision-makers.

4814

4815 **3.3.1 General Problems in Fostering Collaboration**

4816 The social and decision sciences have learned a great deal about the obstacles,
4817 impediments, and challenges in translating scientific information, especially forecasts, for
4818 decision makers generally, and resource managers in particular. Simply “doing research”
4819 on a problem does not assure in any way that the research results can or will contribute to
4820 solving a societal problem; likewise “more research does not necessarily lead to better
4821 decisions” (*e.g.*, Cash *et al.*, 2003; Jacobs *et al.*, 2005; Sarewitz and Pielke, 2007;
4822 Rayner, Lach, and Ingram, 2005). Among the principal reasons information may not be
4823 used by decision makers are the following:

4824

4825 The information may be viewed as irrelevant to the user or inappropriate to the decision
4826 context: While scientists’ worldviews are strongly influenced and affected by the
4827 boundaries of their own research and disciplines, decision-makers’ worldviews are
4828 conditioned by the “decision space” (Jacobs *et al.*, 2005). Decision space refers to the
4829 range of realistic options available to a given decision maker to resolve a particular
4830 problem. While a new scientifically derived tool or source of information may have
4831 obvious applications when viewed from a theoretical perspective, a decision maker may
4832 be constrained from using these tools and information by external factors.

4833

4834 External constraints such as laws and regulations may limit the range of options available
4835 to the decision-maker: Policies, procedures, and precedents relevant to a given decision –
4836 including decisional rules and protocols, expectations imposed by decision makers

4837 through training and by peer and supervisory expectations, sufficiency of resources (*e.g.*,
4838 time and money) within organizations to properly integrate information and tools into
4839 decision-making, and the practicality of implementing various options prescribed by tools
4840 and/or information given the key questions the decision-maker must manage on a daily
4841 basis – are all factors that limit decision-makers use of information. These factors can
4842 also limit the range of options available to decision-makers.

4843

4844 Political scientists who study administrative organizations cite three principal ways the
4845 rule-making culture of administrative organizations hinders information use, ranging
4846 from the nature of policy “attentiveness” in administrative organizations in which cues
4847 awareness of alternatives are often driven by demands of elected officials instead of
4848 newly available information (*e.g.*, Kingdon, 1995), to organizational goals and objectives
4849 which often frame or restrict the flow of information and “feedback.” Another set of
4850 reasons revolves around the nature of indirect commands within organizations – that
4851 evolve through trial and error. Over time, these commands take the form, of rules and
4852 protocols which guide and prescribe appropriate and inappropriate ways of using
4853 information in bureaucracies (Stone, 1997; Torgerson, 2005).

4854

4855 The following case, relating to the translation of drought information in the Southeastern
4856 U.S., describes the influence of institutional constraints on information use. In this
4857 instance, the problem of drought is nested within a larger regional water dispute among
4858 three states. By describing the challenges in incorporating drought and water shortage
4859 information into basin wide water planning – this case also helps clarify a number of

4860 salient problems faced by water managers working with complex information in a
4861 contentious political or legal context. In short, information usefulness is determined in
4862 part by social and political context or “robustness.” To be “socially robust,” information
4863 must be valid outside, as well as inside the laboratory where it is developed; and, involve
4864 an extended group of experts, including lay ‘experts’ (Gibbons, 1999).

4865

4866 **Case Study: The Southeast Drought: Another Perspective on Water Problems in the**
4867 **Southeastern U.S.**

4868 **Introduction and context**

4869 As mentioned earlier, drought risk consists of a hazard component (*e.g.*, lack of
4870 precipitation, along with direct and indirect effects on runoff, lake levels and other
4871 relevant parameters) and a vulnerability component. Some aspects of vulnerability
4872 include the condition of physical infrastructure, economics, awareness and preparedness,
4873 institutional capability and flexibility, policy, demography, access to technology (Wilhite
4874 *et al.*, 2000). Thus, there are clearly non-climatic factors that can enhance or decrease the
4875 likelihood of drought impacts. Laws, institutions, policies, procedures, precedents and
4876 regulations, for instance, may limit the range of options available to the decision-maker,
4877 even if armed with a perfect forecast.

4878

4879 In the case of the ongoing drought in the southeastern United States, the most recent
4880 episode (beginning in 2006 and intensifying in 2007, see Figure 3.1), impacts to
4881 agriculture, fisheries, and municipal water supplies were likely exacerbated by a lack of
4882 action on water resources compacts between Georgia, Alabama, and Florida (Feldman,
4883 2007). The hazard component was continuously monitored at the state, regional, and
4884 national level by a variety of institutions, including state climatologists, the Southeast
4885 Regional Climate Center, the Southeast Climate Consortium, the USGS, the National
4886 Weather Service, the U.S. Drought Monitor and others. In some cases, clear decision
4887 points were specified by state drought plans (Steinemann and Cavalcanti, 2006; Georgia
4888 DNR, 2003). (Florida lacks a state drought plan.) During spring 2007, as record

4889 precipitation deficits mounted, water supplies declined, and drought impacts, including
4890 record-setting wildland fires accumulated (Georgia Forestry Commission, 2007). Georgia
4891 decision-makers faced the option of relying on a forecast for above-average Atlantic
4892 hurricane frequency, or taking more cautious, but decisive, action to stanch potentially
4893 critical water shortages. Public officials allowed water compacts to expire, because they
4894 could not agree on water allocation formulae; hence, unresolved conflicts regarding the
4895 relative priorities of upstream and downstream water users, such as streamflows intended
4896 to preserve endangered species and enrich coastal estuaries, versus reservoir holdings
4897 intended to drought-proof urban water uses, impeded the effective application of climate
4898 information to mitigate potential impacts.

4899

4900 **The Apalachicola-Chattahoochee-Flint River basin compact negotiations**

4901 The Apalachicola-Chattahoochee-Flint (ACF) River Basin Compact was formed to
4902 address the growing demands for water in the region's largest city, Atlanta, while at the
4903 same time balancing off-stream demands of other users against in-stream needs to
4904 support fisheries and minimum flows for water quality (Hull, 2000). While the basin is
4905 rapidly urbanizing, farming – and the rural communities that depend upon it – remain
4906 important parts of the region's economy. Conflicts between Georgia, Florida, and
4907 Alabama over water rights in the basin began in the late 1800s. Today, metro Atlanta
4908 currently draws more than 400 million gallons of water per day from the river and
4909 discharges into it more than 300 million gallons of wastewater each day.

4910

4911 Following protracted drought in the region in the 1990s, decision-makers in Alabama,
4912 Florida, and Georgia dedicated themselves to avoiding lengthy and expensive litigation
4913 that likely would have led to a decision that would have pleased no one. In 1990, the
4914 three states began an 18-month negotiation process that resulted, first, in a *Letter of*
4915 *Agreement* (April, 1991) to address short term issues in the basin and then, in January
4916 1992, a *Memorandum of Agreement* that, among other things, stated that the three states
4917 were in accord on the need for a study of the water needs of the three states. The three
4918 states' governors also agreed to initiate a comprehensive study by the Corps of Engineers
4919 (Kundell and Tetens, 1998).

4920

4921 At the conclusion of the 1998 compact summit chaired by former Representative
4922 Gingrich, the three states agreed to: protect federal regulatory discretion and water rights;
4923 assure public participation in allocation decisions; consider environmental impacts in
4924 allocation and, develop specific allocation numbers – in effect, guaranteeing volumes “at
4925 the state lines.” Water allocation formulas were to be developed and agreed upon by
4926 December 31, 1998. However, negotiators for the three states requested at least a one-
4927 year extension of this deadline in November of 1998, and several extensions and requests
4928 for extensions have subsequently been granted over the past dozen years – often at the
4929 11th hour of stalemated negotiations.

4930

4931 Opportunities for a breakthrough came in 2003. Georgia’s chief negotiator claimed that
4932 the formulas posted by Georgia and Florida, while different, were similar enough to
4933 allow the former to “accept Florida’s numbers (and to work to resolve language
4934 differences in the terms and conditions of the formula.” Alabama representatives
4935 concurred that the numbers were workable and that differences could be resolved.
4936 Nonetheless, within days of this tentative settlement, negotiations broke off once again
4937 (Georgia Environmental Protection Division, 2002a). In August 2003, Governors Riley,
4938 Bush, and Perdue from Alabama, Florida, and Georgia, respectively, actually signed a
4939 memorandum of understanding detailing the principles for allocating water for the ACF
4940 over the next 40 years; however, as of this writing, Georgia has lost an appeal in the
4941 Appellate Court of the District of Columbia to withdraw as much water as it had planned
4942 to do – lending further uncertainty to this dispute (Goodman, 2008).

4943

4944 **Policy impasse**

4945 Three issues appear to be paramount in the failure to reach accord. First, various demands
4946 imposed on the river system may be incompatible, such as protecting in-stream flow
4947 while permitting varied off-stream uses. Second, many of the prominent user conflicts
4948 facing the three states are really up- versus down-stream disputes. For example, Atlanta is
4949 a major user of the Chattahoochee. However, it is also a “headwaters” metropolis. The
4950 same water used by Atlanta for water supply and wastewater discharge is used by “up-

4951 streamers” for recreation and to provide shoreline amenities such as high lake levels for
4952 homes (true especially along the shoreline of Lake Lanier) – and provides downstream
4953 water supply to other communities. Without adequate drawdown from Lanier, for
4954 example, water supplies may be inadequate to provide for all of Atlanta’s needs.
4955 Likewise, water quality may be severely degraded because of the inability to adequately
4956 dilute pollution discharges from point and non-point sources around Atlanta. This is
4957 especially true *if* in-stream water volumes decline due to growing off-stream demands.

4958
4959 Finally, the compact negotiating process itself lacks robustness – technically, the compact
4960 does not actually take effect *until* an allocation formula can be agreed upon. Thus, instead
4961 of agreeing on an institutional framework that can collect, analyze, translate, and use
4962 information to reach accord over allocation limits and water uses – the negotiations have
4963 been targeted on first determining a formula for allocation based on need (Feldman,
4964 2007). As we have seen in the previous case on drought management in Georgia, climate
4965 forecast information is being used to enhance drought preparedness and impact
4966 mitigation. Nevertheless, as noted in that case, conservation measures in one state alone
4967 cannot mitigate region-wide problems affecting large, multi-state watersheds. The same
4968 holds true for regional water supply dispute-resolution. Until a cooperative decision-
4969 making platform emerges whereby regional climate forecast data can be used for conjoint
4970 drought planning, water allocation prescriptions, and incorporation of regional population
4971 and economic growth (not currently done on an individual state-level), effective use of
4972 decision-support information (i.e., transformation) will remain an elusive goal.

4973
4974 **3.3.1.1 Researchers often develop products and tools that they believe will be useful,
4975 and make them available for use without verifying whether they are needed:**

4976 This is sometimes referred to as the “loading dock” phenomenon (Sarewitz and Pielke,
4977 2005), and generally results from one-way communication, without sufficient evaluation
4978 of the needs of stakeholders. As seen below in the case of northeast *Brazil*, this challenge
4979 in integrating information and tools into decision-making is a problem endemic to all

4980 societies – but in the case of climate variability and water management is exacerbated by
4981 sufficiency of resources in developing nation contexts.

4982

4983 **Case Study: Policy learning and seasonal climate forecasting application in**
4984 **Northeast Brazil – integrating information into decisions**

4985 **Introduction**

4986 The story of climate variability forecast application in the state of Ceará (N.E. Brazil)
4987 chronicles a policy process in which managers have deployed seasonal climate
4988 forecasting experimentally for over ten years for water and agriculture, and have slowly
4989 learned different ways in which seasonal forecasting works, does not work, and could be
4990 improved for decision making (Lemos *et al.*, 2002; Lemos, 2003 Lemos and Oliveira,
4991 2004; Taddei 2005; Pfaff *et al.*, 1999).

4992

4993 The *Hora de Plantar* (“Time to Plant”) Program, begun in 1988, aimed at distributing
4994 high-quality, selected seed to poor subsistence farmers in Ceará and at maintaining a
4995 strict planting calendar to decrease rain-fed farmers sensitivity to climate variability
4996 (Lemos, 2003). In exchange for selected seeds, farmers “paid” back the government with
4997 grain harvested during the previous season or received credit to be paid the following
4998 year. The rationale for the program was to provide farmers with high quality seeds (corn,
4999 beans, rice, and cotton), but to distribute them only when planting conditions were
5000 appropriate. Because farmers tend to plant with the first rains (sometimes called the “pre-
5001 season”) and often have to replant, the goal of this program was to use a simplified
5002 soil/climate model, developed by the state meteorology agency (FUNCEME) to orient
5003 farmers with regard to the actual onset of the rainy season (Andrade, 1995).

5004

5005 While the program was deemed a success (Golnaraghi and Kaul, 1995), a closer look
5006 revealed many drawbacks. First, it was plagued by a series of logistical and enforcement
5007 problems (transportation and storage of seed, lack of enough distribution centers, poor
5008 access to information and seeds by those most in need, fraud, outdated client lists, etc)
5009 (Lemos *et al.*, 1999). Second, local and lay knowledge accumulated for years to inform

5010 its design was initially ignored. Instead the program relied on a model of knowledge use
5011 that privileged the use of technical information imposed on the farmers in a exclusionary
5012 and insulated form that alienated stakeholders and hampered buying in from clients
5013 (Lemos, 2003). Third, farmers strongly resented *Hora de Plantar's* planting calendar and
5014 its imposition over their own best judgment. Finally, there was the widespread perception
5015 among farmers (and confirmed by a few bank managers) that a “bad” forecast negatively
5016 affected the availability of rural credit (Lemos *et al.*, 1999). And while many of the
5017 reasons farmers disliked the program had little to do with climate forecasting, the overall
5018 perception was that FUNCEME was to blame for its negative impact on their livelihoods
5019 (Lemos *et al.*, 2002; Lemos, 2003; Meinke *et al.*, 2006). As a result, there was both a
5020 backlash against the program and a relative discredit of FUNCEME as a technical agency
5021 and of the forecast by association. The program is still active, although by 2002, the strict
5022 coupling of seed distribution and the planting calendar had been phased out (Lemos,
5023 2003).

5024

5025 In 1992, as part of Ceará’s modernizing government administration, and in response to a
5026 long period of drought, the state enacted Law 11.996 that defined its policy for water
5027 resources management. This new law created several levels of water management,
5028 including watershed Users’ Commissions, Watershed Committees and a state level Water
5029 Resources Council. The law also defined the watershed as the planning unit of action;
5030 spelled out the instruments of allocation of water permits and fees for the use of water
5031 resources; and regulated further construction in the context of the watershed (Lemos and
5032 Oliveira, 2004; Formiga-Johnsson and Kemper, 2005; Pfaff *et al.*, 1999).

5033

5034 **Innovation – Using Information More Effectively**

5035 One of the most innovative aspects of water reform in Ceará was creation of an
5036 interdisciplinary group within the state water management agency (COGERH) to develop
5037 and implement reforms. The inclusion of social and physical scientists within the agency
5038 allowed for the combination of ideas and technologies that critically affected the way the
5039 network of *técnicos* and their supporters went about implementing water reform in the

5040 state. From the start, COGERH sought to engage stakeholders, taking advantage of
5041 previous political and social organization within the different basins to create new water
5042 organizations (Lemos and Oliveira, 2005). In the Lower Jaguaribe-Banabuiú river basin,
5043 for example, the implementation of participatory councils went further than the suggested
5044 framework of River Basin Committees to include the Users Commission to negotiate
5045 water allocation among different users directly (Garjulli, 2001; Lemos and Oliveira,
5046 2004; Taddei, 2005; Pfaff *et al.*, 1999). COGERH *técnicos* specifically created the
5047 Commission independently of the “official” state structure to emphasize their autonomy
5048 vis-à-vis the state (Lemos and Oliveira, 2005). This agenda openly challenged a pattern
5049 of exclusionary water policymaking prevalent in Ceará and was a substantial departure
5050 from the top-down, insulated manner of water allocation in the past (Lemos and Oliveira,
5051 2004). The ability of these *técnicos* to implement the most innovative aspects of the
5052 Ceará reform can be explained partly by their insertion into policy networks that were
5053 instrumental in overcoming the opposition of more conservative sectors of the state
5054 apparatus and their supporters in the water user community (Lemos and Oliveira, 2004).

5055

5056 The role of knowledge in building adaptive capacity in the system was also important
5057 because it helped democratize decision-making. In Ceará, the organization of stakeholder
5058 councils and the effort to use technical knowledge, especially reservoir scenarios to
5059 inform water release, may have enhanced the system’s adaptive capacity to climate
5060 variability as well as improved water resources sustainability (Formiga-Johnson and
5061 Kemper, 2005; Engle, 2007). In a recent evaluation of the role of governance institutions
5062 in influencing adaptive capacity building in two basins in NE Brazil (Lower Jaguaribe in
5063 Ceará and Pirapama in Pernambuco), Engle (2007) found that water reform played a
5064 critical role in increasing adaptive capacity across the two basins. And while the use of
5065 seasonal climate knowledge has been limited so far (the scenarios assume zero inflows
5066 from future rainfall), there is great potential that use of seasonal forecasts could affect
5067 several aspects of water management and use in the region and increase forecast value.

5068

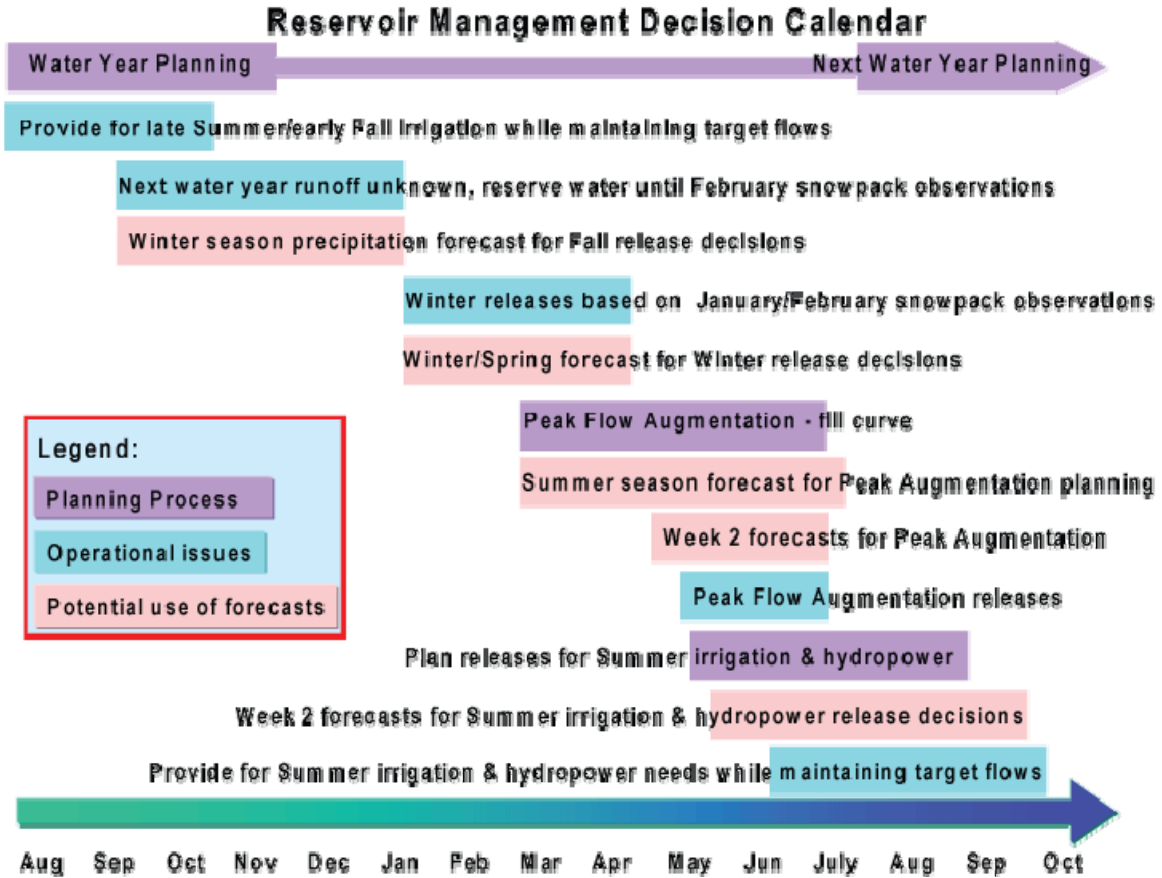

5069 In the context of Ceará’s Users Commissions, the advantages are twofold. First, by
5070 making simplified reservoir models available to users, COGERH is not only enhancing
5071 public knowledge about the river basin but also is crystallizing the idea of collective risk.
5072 While individual users may be willing to “free-ride”, collective decision-making
5073 processes may be much more effective in curbing overuse. Second, information can play
5074 a critical role in democratization of decision-making at the river basin level by training
5075 users to make decisions, and dispelling the widespread distrust that has developed as a
5076 result of previous applications of climate information. Finally, the case suggests that
5077 incorporating social science into processes that are being designed to optimize the use of
5078 climate forecast tools in specific water management contexts can enhance outcomes by
5079 helping poorer communities better adapt to, and build capacity for managing climate
5080 variability impacts on water resources.

5081

5082 **3.3.1.2 Information may not be available at the time it could be useful**

5083 It is well established in the climate science community that information must be timely in
5084 order to be useful to decision makers. This requires that researchers understand and be
5085 responsive to the time frames during the year for which specific types of decisions are
5086 made. Pulwarty and Melis (2001) and Ray and Webb (2000) have developed the concept
5087 of “decision calendars” in the context of the Western Water Assessment in Boulder,
5088 Colorado (see figure 3.4). Failure to provide information at a time when it can be inserted
5089 into the annual series of decisions made in managing water levels in reservoirs, for
5090 example, may result in the information losing virtually all of its value to the decision-
5091 maker. Likewise, decision-makers need to understand the types of predictions that can be
5092 made and tradeoffs between longer-term predictions of information at the local or
5093 regional scale and potential decreases in accuracy. They also need to help scientists in
5094 formulating research questions.

5095

5096

5097

5098 **Figure 3.4** An example of a decision calendar for reservoir management planning. Shaded bars indicate the
 5099 timing of information needs for planning and operational issues over the year. (Source: Ray and Webb,
 5100 2000)

5101

5102 The importance of leadership in initiating change cannot be overestimated (see chapter
 5103 4), and its importance in facilitating information exchange is also essential – particularly
 5104 with regard to making connections with on-the-ground operational personnel and data
 5105 managers are also important to facilitate information exchange. The presence of a
 5106 “champion” within stakeholder groups or agencies may make the difference in successful
 5107 integration of new information. Identifying people with leadership qualities and working

5108 through them will facilitate adoption of new applications and techniques. Recently hired
5109 water managers have been found to be more likely to take risks and deviate from
5110 precedent and “craft skills” that are unique to a particular water organization (Rayner, *et*
5111 *al.*, 2005).

5112

5113 The following vignette on the Advanced Hydrologic Prediction System (AHPS),
5114 established in 1997, exemplifies a conscious effort by the National Weather Service to
5115 respond to many of these chronic relational problems in a decisional context. AHPS is an
5116 effort to go beyond traditional river stage forecasts which are short-term (1-3 days), and
5117 are the product of applied historical weather data, stream gage data, channel cross-section
5118 data, water supply operations information, and hydrologic model characteristics
5119 representing large regions. It is an effort that has worked, in part, because it has many
5120 “champions” – however, questions remain over how extensively the initiative has been
5121 supported with resources.

5122

5123 AHPS responds directly to the problem of timely information availability by: trying to
5124 provide forecasting information sooner, particularly on potential flooding – linking it
5125 directly to local decision-makers, providing the information in a visual format; and,
5126 perhaps most of all, providing a dedicated program within NOAA (and the National
5127 Weather Service) that has the capacity to work directly with the user community and
5128 monitor ongoing, evolving decision-support needs.

5129

5130 **Vignette: AHPS – Advantages over conventional forecasting**

5131 Applying the same hydrologic data used in current methods, AHPS also employs
5132 advanced hydrologic models with characteristics *specific to local watersheds and*
5133 *tributaries*. These advanced, localized hydrologic models increase forecast accuracy by
5134 20% over existing models. Its outputs are more accurate, detailed, and visually oriented –
5135 and are able to provide decision-makers and the public with information on, among other
5136 variables: how high a river will rise, when it will reach its peak, where properties will be
5137 subject to flooding, and how long a flood event will continue. It is estimated that national
5138 implementation of AHPS will save at least \$200 million per year in reduced flood losses
5139 and contribute an additional \$400 million a year in economic benefits to water resource
5140 users (Advanced Hydrologic Prediction Service/
5141 http://www.state.nj.us/drbc/Flood_Website/AHPS.htm).

5142 **Benefits and application**

5143 AHPS provides greater-detailed products in an improved format. Because it is visually
5144 oriented, it provides information in a format that is easier to understand and use by the
5145 general public as well as planners and scientists. AHPS depicts the magnitude and
5146 probability of hydrologic events, and gives users an idea of worst case scenario
5147 situations. Finally, AHPS provides forecasts farther in advance of current methods,
5148 allowing people additional time to protect themselves, their families, and their property
5149 from floods.

5150 Following the Great Flood of 1993 in the Midwest, the Des Moines River Basin in Iowa
5151 was selected to be the first phase toward national implementation of AHPS. Residents,
5152 via the Internet, can now access interactive maps displaying flood forecast points.
5153 Selecting any of the flood forecast points on the map allows Internet users to obtain river
5154 stage forecast information for the point of interest. Available information includes: river
5155 flood stages, flow and volume probabilities, site maps, and damage tables projecting
5156 areas are likely to be subject to flooding.

5157 **Status and assessment**

5158 A 2006 MRC report found AHPS to be an ambitious climate forecast program that
5159 promises to provide services and products that are timely and necessary. However, it

5160 expressed concerns about “human and fiscal resources” – recommending that there is a
5161 need for trained hydrologic scientists to conduct hydrologic work in the NWS. Regarding
5162 fiscal resources, “the budgetary history and current allocation seem misaligned with the
5163 ambitious goals of the program.” Thus, the program’s goals and budget should be
5164 brought into closer alignment (NRC, 2006).

5165

5166 **3.3.2 Scientists Need to Communicate Better and Decision-Makers Need a Better**
5167 **Understanding of Uncertainty – It Is Embedded In Science.**

5168 Discussions of uncertainty are at the center of many debates about forecast information
5169 and its usefulness. Uncertainties result from: the relevance and reliability of data, the
5170 appropriateness of theories used to structure analyses, the completeness of the
5171 specification of the problem, and in the “fit” between a forecast and the social and
5172 political matters of fact on the ground (NRC, 2005). While few would disagree that
5173 uncertainties are inevitable, there is less agreement as to how to improve ways of
5174 describing uncertainties in forecasts to provide widespread benefits (NRC, 2005).

5175 It is important to recognize that expectations of certainty are unrealistic in regards to
5176 climate variability. Weather forecasts are only an estimate; the risk tolerance (sect. 3.2.3)
5177 of the public is often unrealistically low. As we have seen in multiple cases, one mistaken
5178 forecast (*e.g.*, the Yakima basin case) can have an impact out of proportion to the gravity
5179 of its consequences. Some starting points from the literature include helping decision-
5180 makers understand that uncertainty does not make a forecast scientifically flawed – only
5181 imperfect. Along these lines, decision-makers must understand the types of predictions
5182 that can be made and tradeoffs between predictions of information at the local or regional

5183 scale that are less accurate than larger scale predictions (Jacobs, 2005). They also need to
5184 help scientists formulate research questions that result in relevant decision support tools.

5185

5186 Second, uncertainty is not only inevitable, but necessary and desirable. It helps to
5187 advance and motivate scientific efforts to refine data, analysis, and forecaster skills;
5188 replicate research results; revise previous studies – especially through peer review
5189 discussed below, and improve observation. As one observer has noted, “(un)certainty is
5190 not the hallmark of bad science, it is the hallmark of honest science (when) we know
5191 enough to act is inherently a policy question, not a scientific one” (Brown, 1997).

5192

5193 Finally, the characterization of uncertainty should consider the decision relevance of
5194 different aspects of the uncertainties. Failure to appreciate such uncertainties results in
5195 poor decisions, misinterpretation of forecasts, and to diminish trust of analysts.

5196 Considerable work on uncertainty in environmental assessments and models make this
5197 topic ripe for progress (*e.g.*, National Research Council, 1999a).

5198

5199 **Vignette: Interpreting Climate Forecasts – uncertainties and temporal variability**

5200 **Introduction**

5201 Lack of information about geographical and temporal variability in climate processes is
5202 one of the primary barriers to adoption and use of specific products. El Niño/Southern
5203 Oscillation (ENSO) forecasts are an excellent example of this issue. While today El Niño
5204 and La Niña are part of the public vocabulary, operational ENSO-based forecasts have
5205 only been made since the late 1980s. Yet making a decision based only on the forecasts
5206 themselves may expose a manager to unanticipated consequences. Additional information
5207 can mitigate such risk. ENSO-related ancillary products, such as those illustrated in
5208 Figures 3.5 and 3.6, can provide information about which forecasts are likely to be most

5209 reliable for what time periods, in which areas. As Figure 3.5 shows, informed use of
5210 ENSO forecasts requires understanding of the temporal and geographical domain of
5211 ENSO impacts. El Niño (EN) events tend to bring higher than average winter
5212 precipitation to the U.S. Southwest and Southeast while producing below-average
5213 precipitation in the Pacific Northwest. La Niña (LN) events (*e.g.*, the El Niño Lower
5214 Colorado Basin case discussed earlier). Further, not all ENs or LNs are the same with
5215 regard to the amount of precipitation they produce. As illustrated in Figure 3.7, which
5216 provides this kind of information for Arizona, the EN phase of ENSO tends to produce
5217 above-average winter precipitation less dependably than the LN phase produces below-
5218 average winter precipitation.

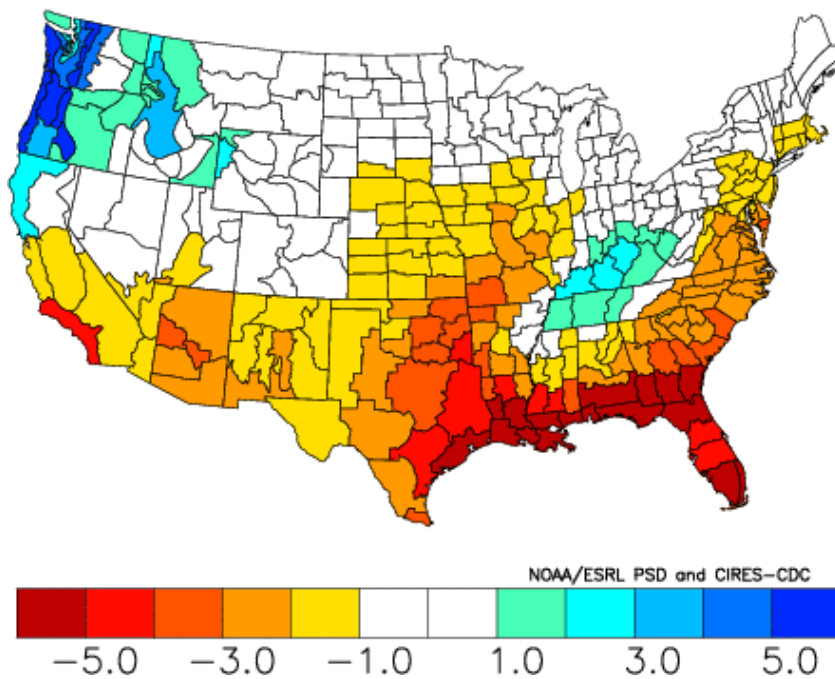

5219
5220 An example of the value of combining ENSO forecasts with information about how
5221 ENSO tended to affect local systems arose during the 1997-98 ENSO event. In this case,
5222 the Arizona-based Salt River Project (SRP) made a series of decisions based on the 1997-
5223 98 EN forecast plus analysis of how ENs tended to affect their system of rivers and
5224 reservoirs. Knowing that ENs tended to produce larger streamflows late in the winter
5225 season, SRP managers reduced groundwater pumping in August 1997 in anticipation of a
5226 wet winter. Their contingency plan called for resuming groundwater pumping if
5227 increased streamflows did not materialize by March 1, 1998. As the winter progressed, it
5228 became apparent that the EN had produced a wet winter and plentiful water supplies in
5229 SRP's reservoirs. The long-lead decision to defer groundwater pumping in this instance
5230 saved SRP \$1 million (Pagano *et al.*, 2001). SRP was uniquely well positioned to take
5231 this kind of risk because the managers making the decisions had the support of upper-
5232 level administrators and because the organization had unusually straightforward access to
5233 information. First, a National Weather Service office is co-located in the SRP
5234 administrative headquarters, and second, key decision makers had been interacting
5235 regularly with climate and hydrology experts associated with the NOAA-funded Climate
5236 Assessment for the Southwest (CLIMAS) project, located at the University of Arizona.
5237 Relatively few decision makers have this level of support for using climate forecasts and
5238 associated information. The absence of such support systems may increase managers'
5239 exposure to risk, in turn generating a strong disincentive to use climate forecasts.

5250 Nina, and Neutral, for Arizona climate division 6. Note the greater variation in El Nino precipitation
5251 (blue) than in La Nina precipitation (red).
5252

5253 **3.4 Summary**

5254 Decision-support systems are not often well integrated into policy networks to support
5255 planning and management, making it difficult to convey information. Among the reasons
5256 for this are a tendency toward institutional conservatism by water agencies, a decision-
5257 making climate that discourages innovation, lack of national-scale coordination of
5258 decisions, difficulties in providing support for decisions at varying spatial and temporal
5259 scales due to vast variability in “target audiences” for products, and growing recognition
5260 that rational choice models of information transfer are overly simplistic. The case of

5261 information use in response to Georgia’s recent drought brings to light problems that
5262 students of water decision-making have long predicated about resistance to innovation.
5263
5264 The use of climate products requires special training or access to data that are not easily
5265 available, making access to decision-support products challenging. As we have seen,
5266 equity of access is partly a function of the fact that decision-support tools are intended to
5267 translate risks, hazards, and vulnerabilities to water resources from seasonal to inter-
5268 annual climate variation. These factors are themselves subject to socially constructed
5269 processes of trust, confidence, and perceived credibility, reliability and certainty. Sources
5270 of distrust – including uncertainties that lead to wrong forecasts are underscored in the
5271 Yakima and upper Colorado basin cases, while the problems of drought and water supply
5272 along the Colorado and Rio Grande basins in the Southwest illustrate the challenges
5273 afforded by reliability and uncertainty. For their part, institutional factors that inhibit
5274 access to decision-support service to, for example, prevent flooding, are revealed by the
5275 Red River of the North case. In some respects, the discussion of the Advanced
5276 Hydrologic Prediction System is the reverse of this discussion – by showing how
5277 scientists and decision-makers can design a dedicated decision-support enterprise that
5278 incorporates useful information, in near real time, and which utilizes platforms accessible
5279 to the public - and generates information salient to the public and local decision-makers.
5280
5281 Ensuring information relevance requires overcoming the barriers of over-specialization
5282 by encouraging inter-disciplinary collaboration in product and tool development.
5283 Decision-makers need to learn to appreciate the inevitability and desirability of forecast

5284 uncertainties regional scale on the one hand, and potential decreases in accuracy on the
5285 other. Scientists must understand both internal institutional impediments (agency rules
5286 and regulations) as well as external ones (*e.g.*, political-level conflicts over water
5287 allocation as exemplified in the Southeast U.S., asymmetries in information access in the
5288 case of Northeast Brazil) as factors constraining decision-support translation and decision
5289 transformation. Decision-makers and scientists must conjointly formulate research
5290 questions relevant to the spatial and temporal scale of problems the former manage and to
5291 ensure accessibility of information, while scientists should aim to generate findings
5292 viewed as accurate and trustworthy, contextually specific, and peer reviewed. While the
5293 nine cases discussed here have been useful and instructive, more generalizable findings
5294 are needed in order to develop a strong, theoretically-grounded understanding of
5295 processes that facilitate information dissemination, communication, use, and evaluation –
5296 and to predict effective methods of boundary spanning between decision-makers and
5297 information generators. We discuss this set of problems in Chapter 4.

5933

5934

5935

5936

5937

5938

5939

5940 **KEY FINDINGS**

5941 Decision-support experiments that apply seasonal and interannual climate variability
5942 information to basin and regional water resource problems serve as test beds that address
5943 diverse issues faced by decision-makers and scientists. They illustrate how to identify
5944 user needs, overcome communication barriers, and operationalize forecast tools. They
5945 also demonstrate how user participation can be incorporated in tool development.

5946

5947 Five major lessons emerge from these experiments and supporting analytical studies:

- 5948 • The effective integration of seasonal to interannual climate information in
5949 decisions requires long-term collaborative research and application of decision-
5950 support through identifying problems of mutual interest. This collaboration will
5951 require a critical mass of scientists and decision-makers to succeed and there is
5952 currently an insufficient number of “integrators” of climate information for
5953 specific applications.
- 5954 • Investments in long-term research-based relationships between scientists and
5955 decision-makers must be adequately funded and supported. In general, progress
5956 on developing effective decision-support systems is dependent on additional
5957 public and private resources to facilitate better networking among decision-
5958 makers and scientists at all levels as well as public engagement in the fabric of
5959 decision-making.
- 5960 • Effective decision-support tools must wed national production of data and
5961 technologies to ensure efficient, cross-sector usefulness with customized products
5962 for local users. This requires that tool developers engage a wide range of

5963 participants, including those who generate tools and those who translate them, to
5964 ensure that specially-tailored products are widely accessible and are immediately
5965 adopted by users insuring relevancy and utility.

5966 • The process of tool development must be inclusive, interdisciplinary, and provide
5967 ample dialogue among researchers and users. To achieve this inclusive process,
5968 professional reward systems that recognize people who develop, use and translate
5969 such systems for use by others are needed within water management and related
5970 agencies, universities and organizations. Critical to this effort, further progress in
5971 boundary spanning – the effort to translate tools to a variety of audiences – re
5972 quires considerable organizational skills.

5973 • Information generated by decision-support tools must be implementable in the
5974 short term for users to foresee progress and support further tool development.
5975 Thus, efforts must be made to effectively integrate public concerns and elicit
5976 public information through dedicated outreach programs.

5977

5978 **4.1 INTRODUCTION**

5979 This chapter examines a series of decision-support experiments that explore how
5980 information on seasonal to interannual climate variability is being used, and how various
5981 water management contexts serve as test beds for implementing decision-support outputs.

5982 We describe how these experiments are implemented and how seasonal to interannual
5983 climate information is used to assess potential impacts of and responses to climate
5984 variability and change. We also examine characteristics of effective decision-support

5985 systems, involving users in forecast and other tool development, and incorporating
5986 improvements.

5987

5988 Section 4.2 discusses a series of experiments from across the nation, and in a variety of
5989 contexts. Special attention is paid to the role of key leadership in organizations to
5990 empower employees, take risks, and promote inclusiveness. The role of organizational
5991 culture in building pathways for innovation related to boundary-spanning approaches is
5992 also considered, with a special focus on boundary-spanning approaches.

5993

5994 Section 4.3 examines approaches to building user knowledge and enhancing capacity
5995 building. We discuss the role of two-way communication among multiple forecast and
5996 water resource sectors, and the importance of translation and integration skills, as well as
5997 operations staff incentives for facilitating such integration.

5998

5999 Section 4.4 discusses the development of measurable indicators of progress in promoting
6000 climate information access and effective use – including process measures such as
6001 consultations between agencies and potential forecast user communities. The role of
6002 efforts to enhance dialogue and exchange among researchers and users is emphasized.

6003

6004 Finally, section 4.5 summarizes major findings, directions for further research, and
6005 recommendations, including: needs for better understanding of the role of decision-maker
6006 context for tool use, how to assess vulnerability to climate, communicating results to
6007 users, bottom-up as well as top-down approaches to boundary-spanning innovation, and

6008 applicability of lessons from other resource management sectors (*e.g.*, forestry, coastal
6009 zone management, hydropower) on decision-support use and decision-maker/scientist
6010 collaboration.

6011

6012 We conclude that, at present, the weak conceptual grounding afforded by cases from the
6013 literature necessitates that we base measures to improve decision-support for the water
6014 resources management sector, as it pertains to inclusion of climate forecasts and
6015 information, on best judgment extrapolated from case experience. Additional research is
6016 needed on effective models of boundary spanning in order to develop a strong,
6017 theoretically-grounded understanding of the processes that facilitate information
6018 dissemination, communication, use, and evaluation so that it is possible to generalize
6019 beyond single cases, and to have predictive value.

6020

6021 **4.2 DECISION-SUPPORT TOOLS FOR CLIMATE FORECASTS: SERVING**
6022 **END-USER NEEDS, PROMOTING USER-ENGAGEMENT AND**
6023 **ACCESSIBILITY**

6024 This section examines a series of decision-support experiments from across the U.S. that
6025 involve the use of information on seasonal to interannual climate variability to manage a
6026 wide range of water resource problems. Our objective is to learn how the barriers to
6027 optimal decision-making – including impediments to trust, user confidence,
6028 communication of information, product translation, operationalization of decision-
6029 support tools, and policy transformation discussed in Chapter 3 can be overcome. As
6030 shall be seen, all of these experiments share one characteristic: users have been involved,

6031 to some degree, in tool development – through active elicitation of their needs,
6032 involvement in tool design, evaluation of tool effectiveness (and feedback into product
6033 refinement as a result of tool use), or some combination of factors.

6034

6035 **4.2.1 Decision-Support Experiments on Seasonal to Interannual Climate Variability**

6036 The following seven cases are important test beds that examine how, and how effectively,
6037 decision-support systems have been used to manage diverse water management needs,
6038 including ecological restoration, riparian flow management, urban water supply,
6039 agricultural water availability, coastal zone issues, and fire management. They exemplify
6040 the uses of seasonal to interannual climate forecast information at diverse spatial scales:
6041 from cities and their surrounding urban concentrations (New York, Seattle), to regions
6042 (Northern California, South Florida, Inter-mountain West), a comprehensively-managed
6043 river basin (CALFED), and a resource (forest lands) scattered over parts of the West and
6044 Southwest U.S. They also illustrate efforts to rely on temporally diverse information (*i.e.*,
6045 predictions of future variability in precipitation, sea-level rise, and drought as well as past
6046 variation) in order to validate trends.

6047

6048 Most importantly, these experiments represent the use of different ways of integrating
6049 information into water management to enable better decisions to be made, including
6050 neural networks in combination with El Niño-Southern Oscillation (ENSO) forecasting;
6051 temperature, precipitation and sea-level rise prediction; probabilistic risk assessment;
6052 integrated weather, climate and hydrological models producing short- and longer-term
6053 forecasts; weather and stream-flow station outputs; paleoclimate records of streamflow

6054 and hydro-climatic variability; and the use of climate change information on precipitation
6055 and sea level rise to manage shorter-term weather variability.

6056

6057 ***Experiment 1:***

6058 ***How the South Florida Water Management District Uses Climate Information***

6059 ***The Experiment***

6060 In an attempt to restore the Everglades ecosystem of South Florida, a team of state and
6061 federal agencies is engaged in the world's largest restoration program (FL Department of
6062 Environmental Protection and South Florida Water Management District, 2007). A
6063 cornerstone of this effort is the understanding that seasonal to interannual climate
6064 variability (as well as climate change) could have significant impacts on the region's
6065 hydrology over the program's 50-year lifetime. The South Florida Water Management
6066 District (SFWMD) is actively involved in conducting and supporting climate research to
6067 improve the prediction and management of South Florida's complex water system
6068 (Obeysekera, 2007). The SFWMD is significant because it is one of the few cases in
6069 which decade-scale climate variability information is being used in water resource
6070 modeling, planning, and operation programs.

6071

6072 ***Background/Context***

6073 Research relating climatic indices to South Florida climate started at SFWMD more than
6074 a decade ago (South Florida Water Management District, 1996). Zhang and Trimble
6075 (1996), Trimble *et al.* (1997), and Trimble and Trimble (1998) used neural network
6076 models to develop a better understanding of how ENSO and other climate factors
6077 influence net inflow to Lake Okeechobee. From that knowledge, Trimble *et al.* (1998)
6078 demonstrated the potential for using ENSO and other indices to predict net inflow to
6079 Lake Okeechobee for operational planning. Subsequently, SFWMD was able to apply
6080 climate forecasts to its understanding of climate-water resources relationships in order to
6081 assess risks associated with seasonal and multi-seasonal operations of the water
6082 management system and to communicate the projected outlook to agency partners,
6083 decision makers, and other stakeholders (Cadavid *et al.*, 1999).

6084

6085 *Implementation/Application*

6086 SFWMD later established the Water Supply and Environment (WSE), a regulation
6087 schedule for Lake Okeechobee that formally uses seasonal and multi-seasonal climate
6088 outlooks as guidance for regulatory release decisions (Obeysekera, 2007). The WSE
6089 schedule uses states of ENSO and the Atlantic Multidecadal Oscillation (AMO; Enfield
6090 *et al.*, 2001) to estimate the Lake Okeechobee net inflow outlook for the next six to 12
6091 months. A decision tree with a climate outlook is a unique component of the WSE
6092 schedule and is considered a major advance over traditional hydrologic rule curves
6093 typically used to operate large reservoirs (Obeysekera, 2007). Evaluation of the WSE
6094 revealed that considerable uncertainty in regional hydrology remains and is attributable to
6095 some combination of natural climatic variation, long-term global climate change, changes
6096 in South Florida precipitation patterns associated with drainage and development, and
6097 rainfall-runoff relationships altered by infrastructure changes (Obeysekera, 2007).

6098

6099 *Lessons Learned*

6100 From its experience with climate information and research, SFWMD has learned that to
6101 improve its modeling capabilities and contributions to basin management, it must
6102 improve its ability to: differentiate trends and discontinuities in basin flows associated
6103 with climate variation from those caused by water management; gauge the skill gained in
6104 using climate information to predict basin hydroclimatology; improve management;
6105 account for management uncertainties caused by climate variation and change; and
6106 evaluate how climate change projections may affect facility planning and operation of the
6107 SFWMD (Bras, 2006; Obeysekera, 2007).

6108

6109 The district has also learned that, given the decades needed to restore the South Florida
6110 ecosystem, adaptive management is an effective way to incorporate seasonal to
6111 interannual climate variation into its modeling and operations decision-making processes,
6112 especially since longer term climate change is likely to exacerbate operational challenges.
6113 This experiment is also unique in being the only one that has been identified in which
6114 decadal climate status (*e.g.*, state of the Atlantic Multidecadal Oscillation) is being used

6115 in a decision-support context.

6116

6117 ***Experiment 2:***

6118 ***Long-Term Municipal Water Management Planning – New York City***

6119 ***The Experiment***

6120 Projections of long-term climate change, while characterized by uncertainty, generally
6121 agree that coastal urban areas will, over time, be increasingly threatened by a unique set
6122 of hazards. These include sea level rise, increased storm surges, and erosion. Two
6123 important questions facing decision-makers are: 1) how will long-term climate change
6124 increase these threats, which are already of concern to urban planners who incorporate
6125 gradual changes in seasonal to interannual climate conditions in their management
6126 decisions? And, 2) can information on the likely changes in recurrence intervals of
6127 extreme events (*e.g.*, tropical storms) be used in long term municipal water management
6128 planning and decision making?

6129

6130 ***Background and Context***

6131 Water management in coastal urban areas faces unique challenges due to vulnerabilities
6132 of much of the built water supply and treatment infrastructure to storm surges, coastal
6133 erosion, coastal subsidence, and tsunamis (Jacobs *et al.*, 2007). Not only are there risks
6134 due to extreme events under current and evolving climate conditions, but many urban
6135 areas rely on aging infrastructure that was built in the late 19th and early 20th centuries.
6136 These vulnerabilities will only be amplified by the addition of global warming-induced
6137 sea-level rise due to thermal expansion of ocean water and the melting of glaciers,
6138 mountain ice caps and ice sheets (IPCC, 2007). For example, observed global sea-level
6139 rise was ~1.8 mm per year from 1961 – 2003, whereas from 1993 – 2003 the rate of sea
6140 level rise was ~3.1 mm per year (IPCC, 2007). IPCC projections for the 21st century
6141 (IPCC, 2007) are for an “increased incidence of extreme high sea level” which they
6142 define as the highest 1% of hourly values of observed sea level at a station for a given
6143 reference period. The New York City Department of Environmental Protection
6144 (NYCDEP) is one example of an urban agency that is adapting strategic and capital
6145 planning to take into account the potential effects of climate change—sea level rise,

6146 higher temperature, increases in extreme events, and changing precipitation patterns - on
6147 the city's water systems. NYCDEP, in partnership with local universities and private
6148 sector consultants, is evaluating climate change projections, impacts, indicators, and
6149 adaptation and mitigation strategies to support agency decision-making (Rosenzweig *et*
6150 *al.*, 2007).

6151

6152 *Implementation/Application*

6153 In New York City (NYC) as in many coastal urban areas, many of the wastewater
6154 treatment plants are at elevations of 2–6 m above present sea level and thus within the
6155 range of current surges for tropical storms and hurricanes and extra-tropical cyclones
6156 (*e.g.* Nor'easters) (Rosenzweig and Solecki, 2001; Jacobs, 2001). Like many U.S. cities
6157 along the Atlantic Coast, New York City's vulnerability to storm surges is predominantly
6158 from extra-tropical cyclones ("Nor'easters") that occur largely between late November
6159 and March, and tropical storms and hurricanes that typically strike between July and
6160 October. Based on global warming-induced sea-level rise inferred from IPCC TAR,
6161 studies suggest that the recurrence interval for the 100-year storm flood (probability of
6162 occurring in any given year = 1/100) may decrease to 60 years or, under extreme
6163 changes, a recurrence interval as little as 4 years (Rosenzweig and Solecki, 2001; Jacob *et*
6164 *al.*, 2007).

6165

6166 Increased incidence of high sea levels and heavy rains can cause sewer back-up and
6167 overflow water treatment plants. Activities to address current and future concerns include
6168 using sea-level rise forecasts as input to storm surge and elevation models to analyze the
6169 impact of flooding on NYC coastal water resource-related facilities. Other concerns
6170 include potential water quality impairment from heavy rains that can increase pathogen
6171 levels and turbidity with the possible effects magnified by "first-flush" storms: heavy
6172 rains after weeks of dry weather. NYC water supply reservoirs have not been designed
6173 for rapid releases and any changes to operations to limit downstream damage through
6174 flood control measures will reduce water supply. In addition, adding filtration capacity to
6175 the water supply system would be a significant challenge.

6176

6177 Planners in New York City have begun to consider these issues by defining risks through
6178 probabilistic climate scenarios, and categorizing potential adaptations as related to (1)
6179 operations/management; (2) infrastructure; and (3) policy (Rosenzweig *et al.*, 2007).
6180 NYCDEP is examining the feasibility of relocating critical control systems to higher
6181 floors/ground in low lying buildings, building protective flood walls, modifying design
6182 criteria to reflect changing hydrologic processes, and reconfiguring outfalls to prevent
6183 sediment build-up and surging. Significant strategic decisions and capital investments for
6184 NYC water management will continue to be challenged by questions such as: How does
6185 NYC utilize projections in ways that are robust to uncertainties? And, when designing
6186 infrastructure in the face of future uncertainty, how to make infrastructure more robust
6187 and adaptable to changing climate, regulatory mandates, zoning, and population
6188 distribution?

6189

6190 *Lessons Learned*

6191 When trends and observations clearly point to increasing risks, decision-makers need to
6192 build support for adaptive action despite inherent uncertainties. The extent and
6193 effectiveness of adaptive measures will depend on building awareness of these issues
6194 among decision makers, fostering processes of interagency interaction and collaboration,
6195 and developing common standards (Zimmerman, 2001).

6196

6197 New plans for regional capital improvements can be designed to include measures that
6198 will reduce vulnerability to the adverse effects of sea level rise. Wherever plans are
6199 underway for upgrading or constructing new roadways, airport runways, or wastewater
6200 treatment plants, which may already include flood protection, projected sea-level rise
6201 needs to be considered.

6202

6203 In order to incorporate new sources of risk into engineering analysis, the meteorological
6204 and hydrology communities need to define and communicate current and increasing risks
6205 clearly, and convey them coherently, with explicit consideration of the inherent
6206 uncertainties. Research needed to support regional stakeholders include: further reducing
6207 uncertainties associated with sea level rise, providing more reliable predictions of

6208 changes in frequency and intensity of tropical and extra-tropical storms, and determining
 6209 how saltwater intrusion will impact freshwater. Finally, regional climate model
 6210 simulations and statistical techniques being used to predict long-term climate change
 6211 impacts could be down-scaled to help manage projected seasonal to interannual climate
 6212 variability. This could be especially useful for adaptation planning.

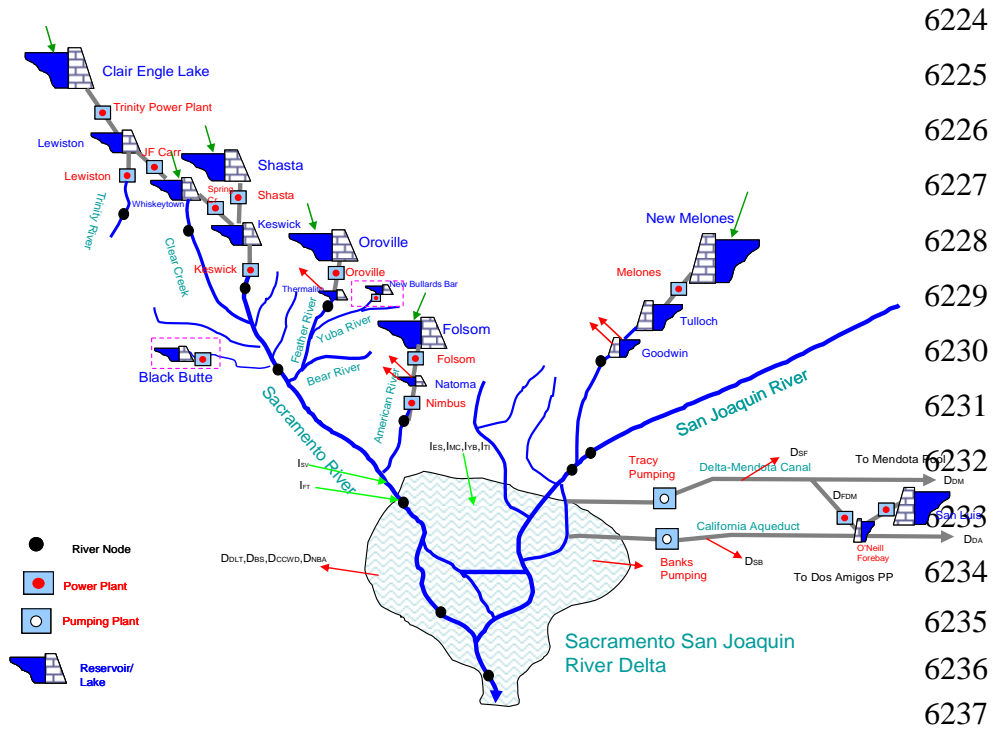

6213

6214 **Experiment 3:**

6215 **Integrated Forecast and Reservoir Management (INFORM) - Northern California**

6216 **The Experiment**

6217 The Integrated Forecast and Reservoir Management (INFORM) project aims to
 6218 demonstrate the value of climate, weather, and hydrology forecasts in reservoir
 6219 operations. Specific objectives are to: (a) implement a prototype integrated forecast-
 6220 management system for the Northern California river and reservoir system in close
 6221 collaboration with operational forecasting and management agencies, and (b) demonstrate
 6222 the utility of meteorological/climate and hydrologic forecasts through near-real-time tests
 6223 of the integrated system with actual data and management input.

6238 Map of Sacramento and San Joaquin River Delta

6232
6233
6234
6235 **Figure**
6236 **re**
6237 **4.1**

6239

6240 *Background and Context*

6241 The Northern California river system (Figure 4.1) encompasses the Trinity, Sacramento,
6242 Feather, American, and San Joaquin river systems, and the Sacramento-San Joaquin
6243 Delta (see experiment 7: CALFED). Major regulation and hydropower projects on this
6244 system include the Clair Eagle Lake (Trinity Dam) and Whiskeytown Lake on the Trinity
6245 River, the Shasta-Keswick Lake complex on the upper Sacramento River, the Oroville-
6246 Thermalito complex on the Feather River, the Folsom-Nimbus complex on the American
6247 River, and several storage projects along the tributaries of the San Joaquin River,
6248 including New Melones. The Sacramento and San Joaquin Rivers join to form an
6249 extensive Delta region and eventually flow out into the Pacific Ocean. The Oroville-
6250 Thermalito complex comprises the State Water Project (SWP), while the rest of the
6251 system facilities are federal and comprise the Central Valley Project (CVP).

6252

6253 The Northern California river and reservoir system serves many vital water uses,
6254 including providing two-thirds of the state's drinking water, irrigating 7 million acres of
6255 the world's most productive farmland, and providing habitat to hundreds of species of
6256 fish, birds, and plants. In addition, the system protects Sacramento and other major cities
6257 from flood disasters and contributes significantly to the production of hydroelectric
6258 energy. The Sacramento-San Joaquin Delta provides a unique environment and is
6259 California's most important fishery habitat. Water from the Delta is pumped and
6260 transported through canals and aqueducts south and west serving the water needs of many
6261 more urban, agricultural, and industrial users.

6262

6263 An agreement between the U.S. Department of the Interior, Bureau of Reclamation, and
6264 California Department of Water Resources provides for the coordinated operation of the
6265 SWP and CVP facilities (Agreement of Coordinated Operation-COA). The agreement
6266 aims to ensure that each project obtains its share of water from the Delta and protects
6267 other beneficial uses in the Delta and the Sacramento Valley. Coordination is structured
6268 around the necessity to meet in-basin use requirements in the Sacramento Valley and the
6269 Delta, including Delta outflow and water quality requirements.

6270

6271 *Implementation/Application*

6272 The INFORM Forecast-Decision system consists of a number of diverse elements for
6273 data handling, model runs, and output archiving and presentation. It is a distributed
6274 system with on-line and off-line components. The system routinely captures real-time
6275 National Center for Environmental Predictions (NCEP) ensemble forecasts and uses both
6276 ensemble synoptic forecasts from NCEP's Global Forecast System (GFS) and ensemble
6277 climate forecasts from NCEP's Climate Forecast System (CFS). The former produces
6278 real-time short-term forecasts, and the latter produce longer-term forecasts as needed.
6279 Detailed descriptions of system operations and components are in the first phase final
6280 report for INFORM (HRC-GWRI, 2006).

6281

6282 The INFORM DSS is designed to support the decision-making process, which includes
6283 multiple decision makers, objectives, and temporal scales. Toward this goal, INFORM
6284 DSS includes a suite of interlinked models that address reservoir planning and
6285 management at multi-decadal, interannual, seasonal, daily, and hourly time scales. The
6286 DSS includes models for each major reservoir in the INFORM region, simulation
6287 components for watersheds, river reaches, and the Bay Delta, and optimization
6288 components suitable for use with ensemble forecasts. The decision software runs off-line,
6289 as forecasts become available, to derive and assess planning and management strategies
6290 for all key system reservoirs. DSS is embedded in a user-friendly, graphical interface that
6291 links models with data and helps visualize and manage results.

6292

6293 Development and implementation of the INFORM Forecast-Decision system was carried
6294 out by the Hydrologic Research Center (in San Diego) and the Georgia Water Resources
6295 Institute (in Atlanta), with funding from NOAA, CALFED, and the California Energy
6296 Commission. Other key participating agencies included U.S. National Weather Service
6297 California-Nevada River Forecast Center, the California Department of Water Resources,
6298 the U.S. Bureau of Reclamation Central Valley Operations, and the Sacramento District
6299 of the U.S. Army Corps of Engineers. Other agencies and regional stakeholders (*e.g.*, the
6300 Sacramento Flood Control Authority, SAFCA, and the California Department of Fish and

6301 Game) participated in project workshops and, indirectly, through comments conveyed to
6302 the INFORM Oversight and Implementation Committee.

6303

6304 *Lessons Learned*

6305 The INFORM approach demonstrates the value of advanced forecast-decision methods
6306 for water resource decision-making, attested to by participating agencies who took part in
6307 designing the experiments and who are now proceeding to incorporate the INFORM tools
6308 and products in their decision-making processes.

6309

6310 From a technical standpoint, INFORM served to demonstrate the following important
6311 aspects of integrated forecast-decision systems: seasonal climate and hydrologic forecasts
6312 benefit reservoir management, provided that they are used in connection with adaptive
6313 dynamic decision methods that can explicitly account for and manage forecast
6314 uncertainty, and ignoring forecast uncertainty in reservoir regulation and water
6315 management decisions leads to costly failures, and. By contrast, static decision rules
6316 cannot take full advantage of and handle forecast uncertainty information. The extent to
6317 which forecasts benefit the management process depends on their reliability, range, and
6318 lead time, in relation to the management systems' ability to regulate flow, water
6319 allocation, and other factors.

6320

6321 ***Experiment 4:***

6322 ***How Seattle Public Utility District Uses Climate Information to Manage Reservoirs***

6323 *The Experiment*

6324 Seattle Public Utilities (SPU) provides drinking water to 1.4 million people living in the
6325 central Puget Sound region of Washington. SPU also has instream (*i.e.*, river flow),
6326 resource management, flood control management and habitat responsibilities on the
6327 Cedar and South Fork Tolt rivers located on the west slopes of the Cascade Mountains.
6328 Over the past several years SPU has taken numerous steps to improve the incorporation
6329 of climate, weather, and hydrologic information into the real-time and seasonal to
6330 interannual management of its mountain water supply system.

6331

6332 *Implementation/Application*

6333 Through cooperative relationships with agencies such as NOAA's National Weather
6334 Service, Natural Resource Conservation Service, and the U.S. Geological Survey, SPU
6335 has secured real-time access to numerous Snotel sites¹, streamflow gages and weather
6336 stations in and around Seattle's watersheds. SPU continuously monitors weather and
6337 climate data across the maritime Pacific derived from all these above sources. Access to
6338 this information has helped to reduce the uncertainty associated with making real-time
6339 and seasonal tactical and strategic operational decisions, and enhanced the inherent
6340 flexibility of management options available to SPU's water supply managers as they
6341 adjust operations for changing weather and hydrologic conditions, including abnormally
6342 low levels of snowpack or precipitation.

6343

6344 Among the important consequences of this synthesis of information has been SPU's
6345 increasing ability to undertake reservoir operations with higher degrees of confidence
6346 than in the past. As an example, SPU was well served by this information infrastructure
6347 during the winter of 2005 when the lowest snowpack on record was realized in its
6348 watersheds. The consequent reduced probability of spring flooding, coupled with their
6349 ongoing understanding of local and regional climate and weather patterns, enabled SPU
6350 water managers to safely capture more water in storage earlier in the season than normal.
6351 As a result of SPU's ability to continuously adapt its operations, Seattle was provided
6352 with enough water to return to normal supply conditions by early summer despite the
6353 record low snowpack.

6354

6355 SPU is also using conclusions from a SPU-sponsored University of Washington (UW)
6356 study that examined potential impacts of climate change on SPU's water supply. To
6357 increase the rigor of the study a set of fixed reservoir operating rules was used and no
6358 provisions were made to adjust these to account for changes projected by the study's
6359 climate change scenarios. From these conclusions, SPU has created two future climate
6360 scenarios, one for 2020 and one for 2040, to examine how the potential impacts of
6361 climate change may affect decisions about future supply. While these scenarios indicated

¹ The snotel network of weather stations is a snowfall depth monitoring network established by USGS.

6362 a reduction in yield, SPU's existing sources of supply were found to be sufficient to meet
6363 official demand forecasts through 2053.

6364

6365 *Lessons Learned*

6366 SPU has actually incorporated seasonal climate forecasts into their operations and is
6367 among the leaders in considering climate change. SPU is a 'receptive audience' for
6368 climate tools in that it has a wide range of management and long-term capital investment
6369 responsibilities that have clear connections to climate conditions. Further, SPU is
6370 receptive to new management approaches due to public pressure and the risk of legal
6371 challenges related to the protection of fish populations who need to move upstream to
6372 breed.

6373

6374 Specific lessons include:

- 6375 • Access to skillful seasonal forecasts enhances credibility of using climate
6376 information in the Pacific Northwest, even with relatively long lead times, due to
6377 strong warming trends and ENSO.
- 6378 • Monitoring of snowpack moisture storage and mountain precipitation is essential
6379 for effective decision making and for detecting long-term trends that can affect
6380 water supply reliability.
- 6381 • While SPU has worked with the research community and other agencies, it also
6382 has significant capacity to conduct in-house investigations and assessments. This
6383 provides confidence in the use of information.

6384

6385 *Experiment 5:*

6386 *Using Paleo-climate Information to Examine Climate Change Impacts*

6387 *The Experiment*

6388 Can an expanded estimate of the range of natural hydrologic variability from tree-ring
6389 reconstructions of stream-flow – a climate change research tool – be used effectively as a
6390 decision-support resource for better understanding seasonal to interannual climate
6391 variability and water resource planning? Incorporation of tree-ring reconstructions of

6392 streamflow into decision making was accomplished through partnerships between
6393 researchers and water managers in the inter-mountain West.

6394

6395 *Background and Context*

6396 Although water supply forecasts in the intermountain west have become increasingly
6397 sophisticated in recent years, water management planning and decision making have
6398 generally depended on instrumental gage records of flow, most of which are less than 100
6399 years in length. Drought planning in the intermountain west has been based on the
6400 assumption that the 1950s drought, as the most severe drought in the instrumental record,
6401 adequately represents the full range of natural variability and thus a likely worst-case
6402 scenario.

6403

6404 The recent prolonged drought in the western U.S. prompted many water managers to
6405 consider that the observational gage records of the 20th century may not contain the full
6406 range of natural hydroclimatic variability possible. Gradual shifts in recent decades to
6407 more winter precipitation as rain and less as snow, earlier spring runoff, higher
6408 temperatures, and unprecedented population growth have resulted in an increase in
6409 vulnerability of limited water supplies to a variable and changing climate. The
6410 paleoclimate records of streamflow and hydroclimatic variability provide an extended
6411 record (based on more than 1000 years of record from tree rings in some key watersheds)
6412 for assessing the potential impact of a more complete range of natural variability as well
6413 as for providing a baseline for detecting possible regional impacts of global climate
6414 change.

6415

6416 *Implementation/Application*

6417 Several years of collaborations between scientists and water resource partners have
6418 explored possible applications of tree-ring reconstructed flows in water resource
6419 management to assess the potential impacts of drought on water systems. Extended
6420 records of hydroclimatic variability from tree-ring based reconstructions reveal a wider
6421 range of natural variability than in gage records alone, but how to apply this information
6422 in water management planning has not been obvious. The severe western drought that

6423 began in 2000 and peaked in 2002 provided an excellent opportunity to work with water
6424 resource providers and agencies on how to incorporate paleoclimate drought information
6425 in planning and decision-making. These partnerships with water resource managers have
6426 lead to range of applications evolving from a basic change in thinking about drought, to
6427 the use of tree-ring reconstructed flows to run a complex water supply model to assess
6428 the impacts of drought on water systems.

6429

6430 The extreme 2002-year drought, and the 5-year drought that developed motivated water
6431 managers to ask these questions: How unusual was 2002, or the 2000-2004 drought?
6432 How often do years or droughts like this occur? What is the likelihood of it happening
6433 again in the future (should we plan for it or is there too low a risk to justify infrastructure
6434 investments)? And, from a long term perspective, is the 20th/21st century record an
6435 adequate baseline for drought planning?

6436

6437 The first three questions could be answered with reconstructed streamflow data for key
6438 gages, but to address planning, a critical step is determining how tree-ring streamflow
6439 reconstruction could be incorporated into water supply modeling efforts. The tree ring
6440 streamflow reconstructions have annual resolution, whereas most water system models
6441 required weekly or daily time steps, and reconstructions are generated for a few gages,
6442 while water supply models typically have multiple input nodes. The challenge has been
6443 spatially and temporally disaggregating the reconstructed flow series into the time steps
6444 and spatial scales needed as input into models. A variety of analogous approaches have
6445 successfully addressed the temporal scale issue, while the spatial challenges have been
6446 addressed statistically using nearest neighbor or other approaches.

6447

6448 Another issue addressed has been that the streamflow reconstructions explain only a
6449 portion of the variance in the gage record, and the most extreme values are often not fully
6450 replicated. Other efforts have focused on characterizing the uncertainty in the
6451 reconstructions, the sources of uncertainty, and the sensitivity of the reconstruction to
6452 modeling choices. In spite of these many challenges, expanded estimates of the range of
6453 natural hydrologic variability from tree ring reconstructions have been integrated into

6454 water management decision support and allocation models to evaluate operating policy
6455 alternatives for efficient management and sustainability of water resources, particularly
6456 during droughts in California and Colorado.

6457

6458 *Lessons Learned*

6459 Roadblocks to incorporating tree-ring reconstructions into water management policy and
6460 decision making were overcome through prolonged, sustained partnerships with
6461 researchers working to make their scientific findings relevant, useful, and usable to users
6462 for planning and management, and water managers willing to take risk and invest time to
6463 explore the use of non-traditional information outside of their comfort zone. The
6464 partnership focused on formulating research questions that led to applications addressing
6465 institutional constraints within a decision process addressing multiple timescales.

6466

6467 Workshops requested by water managers have resulted in expansion of application of the
6468 tree-ring based streamflow reconstructions to drought planning and water management
6469 <<http://wwa.colorado.edu/resources/paleo/>>. In addition, an online resource called
6470 TreeFlow (<http://wwa.colorado.edu/resources/paleo/data.html>) was developed to provide
6471 water managers interested in using tree ring streamflow reconstructions access to gage
6472 and reconstruction data and information, and a tutorial on reconstruction methods for
6473 gages in Colorado and California.

6474

6475 *Experiment 6*

6476 *Climate, Hydrology, and Water Resource Issues in Fire-Prone U.S. Forests*

6477 *The Experiment*

6478 Improvements in ENSO-based climate forecasting, and research on interactions between
6479 climate and wildland fire occurrence, have generated opportunities for improving use of
6480 seasonal to interannual climate forecasts by fire managers. They can now better anticipate
6481 annual fire risk, including potential damage to watersheds over the course of the year.

6482 The experiment, consisting of annual workshops to evaluate the utility of climate
6483 information for fire management, were initiated in 2000 to inform fire managers about
6484 climate forecasting tools and to enlighten climate forecasters about the needs of the fire

6485 management community. These workshops have evolved into an annual assessment of
6486 conditions and production of pre-season fire-climate forecasts.

6487

6488 *Background and Context*

6489 Large wildfire activity in the U.S. West and Southeast has increased substantially since
6490 the mid-1980s, an increase that has largely been attributed to shifting climate conditions
6491 (Westerling *et al.*, 2006). Recent evidence also suggests that global or regional warming
6492 trends and a positive phase of the Atlantic Multidecadal Oscillation (AMO) are likely to
6493 lead to an even greater increase in risk for ecosystems and communities vulnerable to
6494 wildfire in the western U.S. (Kitzberger *et al.*, 2007). Aside from the immediate impacts
6495 of a wildfire (*e.g.*, destruction of biomass, substantial altering of ecosystem function), the
6496 increased likelihood of high sediment deposition in streams and flash flood events can
6497 present post-fire management challenges including impacts to soil stability on slopes and
6498 mudslides (*e.g.*, Bisson *et al.*, 2003). While the highly complex nature and substantially
6499 different ecologies of fire-prone systems precludes one-size-fits-all fire management
6500 approaches (Noss *et al.*, 2006), climate information can help managers plan for fire risk
6501 in the context of watershed management and post-fire impacts, including impacts on
6502 water resources. One danger is inundation of water storage and treatment facilities with
6503 sediment-rich water, creating potential for significant expense for pre-treatment of water
6504 or facilities repair. Post-fire runoff can also raise nitrate concentrations to levels that
6505 exceed the federal drinking water standard (Meixner and Wohlgemuth, 2004).

6506

6507 Work by Kuyumjian (2004), suggests that coordination among fire specialists,
6508 hydrologists, climate specialists, and municipal water managers may produce useful
6509 warnings to downstream water treatment facilities about significant ash- and sediment-
6510 laden flows. For example, in the wake of the 2000 Cerro Grande fire in the vicinity of
6511 Los Alamos, New Mexico, catastrophic floods were feared, due to the fact that 40 percent
6512 of annual precipitation in northern New Mexico is produced by summer monsoon
6513 thunderstorms (*e.g.*, Earles *et al.*, 2004). Concern about water quality and about the
6514 potential for contaminants carried by flood waters from the grounds of Los Alamos
6515 Nuclear Laboratory to enter water supplies prompted a multi-year water quality

6516 monitoring effort (Gallaher and Koch, 2004). In the wake of the 2002 Bullock Fire and
6517 2003 Aspen Fire in the Santa Catalina Mountains adjacent to Tucson Arizona, heavy
6518 rainfall produced floods that destroyed homes and caused one death in Canada del Oro
6519 wash in 2003 (Ekwurzel, 2004), destroyed structures in the highly popular Sabino
6520 Canyon recreation area and deposited high sediment loads in Sabino Creek in 2003
6521 (Desilets *et al.*, 2006). A flood in 2006 wrought a major transformation to the upper
6522 reaches of the creek (Kreutz, 2006). Residents of Summerhaven, a small community
6523 located on Mt. Lemmon, continue to be concerned about the impacts of future fires on
6524 their water resources. In all of these situations, climate information can be helpful in
6525 assessing vulnerability to both flooding and water quality issues.

6526

6527 *Implementation/Application*

6528 Little published research exists that specifically targets interactions among climate, fire,
6529 and watershed dynamics. However, publications on fire-climate interactions provide a
6530 useful entry point for examining needs for and uses of climate information in decision
6531 processes involving water resources. A continuing effort to produce fire-climate outlooks
6532 was initiated through a workshop held in Tucson, Arizona, in late winter 2000. One of the
6533 goals of the workshop was to identify the climate information uses and needs of fire
6534 managers, fuel managers, and other decision makers. Another was to actually produce a
6535 fire-climate forecast for the coming fire season. The project was initiated through
6536 collaboration involving researchers at the University of Arizona, the NOAA-funded
6537 Climate Assessment for the Southwest Project (CLIMAS), the Center for Ecological and
6538 Fire Applications (CEFA) at the Desert Research Institute in Reno, Nevada and the
6539 National Interagency Fire Center (NIFC) located in Boise, Idaho (Morehouse, 2000).
6540 Now called the National Seasonal Assessment Workshop (NSAW), the process continues
6541 to produce annual fire-climate outlooks (*e.g.*, Crawford *et al.*, 2006). The seasonal fire-
6542 climate forecasts produced by NSAW have been published through NIFC since 2004.
6543 During this same time period Westerling *et al.* (2002) developed a long-lead statistical
6544 forecast product for area burned in western wildfires.

6545

6546 *Lessons Learned*

6547 The experimental interactions between climate scientists and fire managers clearly
6548 demonstrated the utility of climate information for managing watershed problems
6549 associated with wildfire. Climate information products used in the most recently
6550 published NSAW Proceedings (Crawford *et al.*, 2006), for example, include the
6551 following:

6552

6553 NOAA Climate Prediction Center (CPC) seasonal temperature and precipitation
6554 outlooks:

- 6555 • Historical temperature and precipitation data, *e.g.*, High Plains Regional Climate
6556 Center
- 6557 • National drought conditions, from National Drought Mitigation Center
- 6558 • 12-month standardized precipitation index
- 6559 • Spring and summer streamflow forecasts
- 6560 • Departure from average greenness

6561

6562 Based on extensive interactions with fire managers other products are also used by some
6563 fire ecologists and managers, including:

- 6564 • Climate history data from instrumental and paleo (especially tree-ring) records
- 6565 • Hourly to daily and weekly weather forecasts, (*e.g.*, temperature, precipitation,
6566 wind, relative humidity)

6567

6568 Products identified as potentially improving fire management (*e.g.*, Morehouse, 2000,
6569 Garfin and Morehouse, 2001) include:

- 6570 • Improved monsoon forecasts and training in how to use them
- 6571 • Annual to decadal (Atlantic Multidecadal Oscillation, Pacific Decadal
6572 Oscillation) projections
- 6573 • Decadal to centennial climate change model outputs, downscaled to regional/finer
6574 scales
- 6575 • Dry lightning forecasts

6576

6577 This experiment is one of the most enduring we have studied – it is now part of accepted
6578 practice by agencies, and has produced spin-off activities managed and sustained by the
6579 agencies and new participants. The use of climate forecast information in fire
6580 management began because decision-makers within the wildland fire management
6581 community were open to new information, due to legal challenges, public pressure, and a
6582 “landmark” wildfire season in 2000. The National Fire Plan (2001) and its associated 10-
6583 year Comprehensive Strategy reflected a new receptiveness for new ways of coping with
6584 vulnerabilities, calling for a “proactive, collaborative, and community-based approach to
6585 reducing wildland fires” rather than prior approaches entered on internal agency
6586 activities.

6587
6588 Annual workshops became routine fora for bringing scientists and decision makers
6589 together to continue to explore new questions and opportunities, as well as involve new
6590 participants, new disciplines and specialties, and to make significant progress in
6591 important areas (*e.g.*, lightning climatologies, and contextual assessments of specific
6592 seasons), quickly enough to fulfill the needs of agency personnel.

6593

6594 ***Experiment 7:***

6595 ***The CALFED – Bay Delta Program: Implications of Climate Variability***

6596 ***The Experiment***

6597 The Sacramento-San Joaquin River Delta, which flows into San Francisco Bay, is the
6598 focus of a broad array of environmental issues relating to endangered fish species, land
6599 use, flood control and water supply. After decades of debate about how to manage the
6600 Delta to export water supplies to southern California while managing habitat and water
6601 supplies in the region, and maintaining endangered fish species, decision makers are
6602 involved in making major long-term decisions about rebuilding flood control levees and
6603 rerouting water supply networks through the region. Incorporating the potential for
6604 climate change impacts on sea level rise and other regional changes are important to the
6605 decision-making process (see, for example, Hayhoe *et al.*, 2004; Knowles *et al.*, 2006;
6606 Lund *et al.*, 2007).

6607

6608 *Background and Context*

6609 Climate considerations are critical for the managers of the CALFED program, which
6610 oversees the 700,000 acres in the Sacramento-San Joaquin Delta. 400,000 acres have
6611 been subsiding due to microbial oxidation of peat soils that have been used for
6612 agriculture. A significant number of the islands are below sea level, and protected from
6613 inundation by dikes that are in relatively poor condition. Continuing sea-level rise and
6614 regional climate change are expected to have additional major impacts such as flooding
6615 and changes in seasonal precipitation patterns. There are concerns that multiple islands
6616 would be inundated in a “10- year storm event” – this represents extreme local
6617 vulnerability to flooding.

6618

6619 In the central delta there are five county governments in addition to multiple federal and
6620 state agencies and non-governmental organizations whose perspectives need to be
6621 integrated into the management process, which is one of the purposes of the CALFED
6622 program. A key decision being faced is whether Delta interests should invest in trying to
6623 build up and repair levies to protect subsided soils. What are the implications for other
6624 islands when one island floods? Knowing the likelihood of sea level rise of various
6625 magnitudes will significantly constrain the answers to these questions. For example, if the
6626 rise is greater than 1 foot in next 50 – 100 years, that could end the debate about whether
6627 to use levee improvements to further protect these islands. Smaller amounts of sea level
6628 rise will make this decision less clear-cut. Answers are needed in order to support
6629 decisions about the delta in the next year and a half.

6630

6631 *Implementation/Application*

6632 Hundreds of millions of dollars of restoration work has been done in the Delta and
6633 associated watersheds, and more investment is required. Where money should be
6634 invested for effective long term impact? There is a need to invest in restoring lands at
6635 intertidal and higher elevations so that wetlands can evolve uphill while tracking rising
6636 sea level (estuarine progression). Protecting only “critical” Delta islands (those with
6637 major existing infrastructure) to endure a 100-year flood will cost around \$2.6 billion.

6638

6639 Another way that climate change-related information is critical to Delta management is in
6640 estimating volumes and timing of runoff from the Sierra Nevada mountain range (see
6641 Knowles *et al.*, 2006). To the extent that snowpack will be diminished and snowmelt
6642 runoff occurs earlier, there are implications for flood control, water supply and
6643 conveyance, and seawater intrusion – all of which affect habitat and land use decisions.
6644 One possible alternative approach is more aggressive management of reservoirs to
6645 maximize water supply benefits, thereby possibly increasing flood risk. The State Water
6646 Project is now looking at a 10% failure rate operating guideline at Oroville rather than a
6647 5% failure rate operating guideline -- this would provide much more water supply
6648 flexibility.

6649

6650 *Lessons Learned*

6651 Until recently the implications of climate change and sea level rise were not considered in
6652 the context of solutions to the Bay Delta problem – particularly in the context of climate
6653 variability. These implications are currently considered to be critical factors in
6654 infrastructure planning, and the time horizon for future planning has been extended to
6655 200 years (see California Department of Water Resources Delta Risk Management
6656 Strategy effort for details). The relatively rapid shift in perception of the urgency of
6657 climate change impacts was not predicted, but does demand renewed consideration of
6658 adaptive management strategies in the context of step-wise changes in understanding (as
6659 opposed to gradual increases in accumulation of new facts, which is the dominant
6660 paradigm in adaptive management).

6661

6662 **4.2.2 Organizational and Institutional Dimensions of Decision-Support Experiments**

6663 These seven experiments illuminate the need for effective two-way communication
6664 among tool developers and users, and the importance of organizational culture in
6665 fostering collaboration. An especially important lesson they afford is in underscoring the
6666 significance of boundary-spanning entities to enable decision-support transformation.

6667 Boundary spanning, discussed in section 4.3, refers to the activities of special

6668 scientific/stakeholder committees, agency coordinating bodies, or task forces that
6669 facilitate the bringing together of tool developers and users to exchange information,
6670 promote communication, propose remedies to problems, foster frequent engagement, and
6671 jointly develop decision-support systems to address user needs. In the process, they
6672 provide incentives for innovation – frequently noted in the literature - that facilitate the
6673 use of climate science information in decisions (*e.g.*, NRC, 2007; Cash and Buizer, 2005;
6674 Sarewitz and Pielke, 2007). Before outlining how these seven experiments illuminate
6675 boundary spanning, it is important to consider problems identified in recent research.

6676

6677 While there is widespread agreement that decision support involves translating the
6678 products of climate science into forms useful for decision makers and disseminating the
6679 translated products, there is disagreement over precisely what constitutes translation
6680 (NRC, 2008). One view is that climate scientists know which products will be useful to
6681 decision makers and that potential users will make appropriate use of decision-relevant
6682 information once it is made available. Adherents of this view typically emphasize the
6683 importance of developing “decision-support tools:” models, maps, and other technical
6684 products intended to be relevant to certain classes of decisions which, when created,
6685 completes the task of decision-support. This approach, also called a “translation model,”
6686 (NRC, 2008) has not proved useful to many decision-makers – underscored by the fact
6687 that in our seven cases, greater weight was given to “creating conditions that foster the
6688 appropriate use of information” rather than to the information itself (NRC, 2008).

6689

6690 A second view is that decision-support activities should enable climate information
6691 producers and users to communicate better with one another to ensure that the
6692 information produced addresses users' needs – also called “co-production” of information
6693 or reconciling information “supply and demand” (National Research Council, 1989,
6694 1996, 1999a, 2006; McNie, 2007; Sarewitz and Pielke, 2007; Lemos and Morehouse,
6695 2005). Our seven cases clearly delineate the presumed advantages of the second view.

6696

6697 In the SFWMD case, an increase in user trust was a powerful inducement to introduce,
6698 and then continue, experiments leading to development of a Water Supply and
6699 Environment (WSE) schedule employing seasonal and multi-seasonal climate outlooks as
6700 guidance for regulatory releases. As this tool began to help reduce operating system
6701 uncertainty, decision-maker confidence in the use of model outputs increased, as did
6702 further cooperation between scientists and users – facilitated by SFWMD's
6703 communication and agency partnership networks.

6704

6705 In the case of INFORM, participating agencies in California worked in partnership with
6706 scientists to design experiments that would introduce forecast methods that helped adapt
6707 to uncertainties in reservoir regulation. Not only did this set of experiments demonstrate
6708 the practical value of such tools, but they built support for adaptive measures to manage
6709 risks, and reinforced the use, by decision-makers, of tool output in their decisions.

6710 Similar to the SFWMD case, through demonstrating how forecast models could reduce
6711 operating uncertainties – especially as regards increasing reliability and lead time for
6712 crucial decisions – cooperation among partners seems to have been strengthened.

6713

6714 Because the New York City and Seattle cases share in common the use of decision-
6715 support information in urban settings, they amplify another set of boundary-spanning
6716 factors: the need to incorporate public concerns and develop communication outreach
6717 methods, particularly about risk, that are clear and coherent. While conscientious efforts
6718 to support stakeholder needs for reducing uncertainties associated with sea-level rise and
6719 infrastructure relocation are being made, the New York case highlights the need for
6720 further efforts to refine communication, tool dissemination and evaluation efforts to
6721 deliver information on potential impacts of climate change more effectively. It also
6722 illustrates the need to incorporate new risk-based analysis into existing decision
6723 structures related to infrastructure construction and maintenance. Seattle public utilities
6724 has had success in conveying the importance of employing seasonal to interannual
6725 climate forecasts in operations, and is considered a national model for doing so, in part
6726 because of a higher degree of established public support due to: 1) litigation over
6727 protection of endangered fish populations, and 2) a greater in-house ability to test forecast
6728 skill and evaluate decision tools. Both served as incentives for collaboration. Access to
6729 highly-skilled forecasts in the region also enhanced prospects for forecast use.

6730

6731 Although not an urban case, the CALFED experiment's focus on climate change, sea-
6732 level rise, and infrastructure planning has numerous parallels with the Seattle and New
6733 York City cases. In this instance, the public and decision-makers were prominent in these
6734 cases, and their involvement enhanced the visibility and importance of these issues and

6735 probably helped facilitate the incorporation of climate information by water resource
6736 managers in generating adaptation policies.

6737

6738 The other cases represent variations of boundary spanning whose lessons are also worth
6739 noting. The tree-ring reconstruction case – which generated a new data source, not
6740 surprisingly documents impediments to incorporation into water planning due to its
6741 novelty. This impediment was overcome through prolonged and sustained partnerships
6742 between researchers and users that helped ensure that scientific findings were relevant,
6743 useful, and usable for water resources planning and management, and water managers
6744 who were willing to take some risk. Likewise, the case of fire-prone forests represented a
6745 different set of impediments that also required novel means of boundary spanning to
6746 overcome. In this instance, an initial workshop held among scientists and decision-
6747 makers itself constituted an experiment on how to: identify topics of mutual interest
6748 across the climate and wildland fire management communities; provide a forum for
6749 exploring new questions and opportunities; and constitute a vehicle for inviting diverse
6750 agency personnel, disciplinary representatives, and operation, planning, and management,
6751 personnel to facilitate new ways of thinking about an old set of problems.

6752

6753 Before turning to analytical studies on the importance of such factors as the role of key
6754 leadership in organizations to empower employees, organizational climate that
6755 encourages risk and promote inclusiveness, and the ways organizations encourage
6756 boundary innovation (section 4.3), it is important to note another distinguishing feature of
6757 the above experiments: they underscore the importance of process as well as product

6758 outcomes in assessing collaborative success in developing, disseminating and using
6759 information. We return to this issue when we discuss evaluation in Section 4.4.

6760

6761 **4.3 APPROACHES TO BUILDING USER KNOWLEDGE AND ENHANCING** 6762 **CAPACITY BUILDING**

6763 The previous section demonstrated a variety of contexts where decision-support
6764 innovations are occurring. This section analyzes six factors that are essential for building
6765 user knowledge and enhancing capacity in decision-support systems for integration of
6766 seasonal to interannual climate variability information, and which are highlighted in the
6767 seven cases above: 1) boundary spanning, 2) knowledge-action systems through inclusive
6768 organizations, 3) decision-support needs are user driven, 4) proactive leadership that
6769 champions change; 5) adequate funding and capacity building, and, 6) adaptive
6770 management.

6771

6772 **4.3.1 Boundary-Spanning Organizations as Intermediaries Between Scientists and** 6773 **Decision Makers**

6774 As noted in 4.2.2, boundary spanning organizations link different social and
6775 organizational worlds (*e.g.*, science and policy) in order to foster innovation across
6776 boundaries, provide two-way communication among multiple sectors, and integrate
6777 production of science with user needs. More specifically, these organizations perform
6778 translation and mediation functions between producers of information and their users
6779 (Guston, 2001; Ingram and Bradley, 2006 Jacobs, *et al.*, 2005). Such activities include

6780 convening forums that provide common vehicles for conversations and training, and for
6781 tailoring information to specific applications.

6782

6783 Ingram and Bradley (2006) suggest that boundary organizations span not only disciplines,
6784 but different conceptual and organizational divides (*e.g.*, science and policy),
6785 organizational missions and philosophies, levels of governance, and gaps between
6786 experiential and professional ways of knowing. This is important because effective
6787 knowledge transfer systems cultivate individuals and/or institutions that serve as
6788 intermediaries between nodes in the system, most notably between scientists and decision
6789 makers. In the academic community and within agencies, knowledge, including that
6790 involved in the production of climate forecast information, is often produced in “stove-
6791 pipes” isolated from neighboring disciplines or applications.

6792

6793 Evidence for the importance of this proposition – and for the importance of boundary
6794 spanning generally – is provided by those cases – particularly in Chapter 3 (*e.g.*, the
6795 Apalachicola-Chattahoochee-Flint river basin dispute) where the absence of a boundary
6796 spanning entity created a void that made the deliberative consideration of various
6797 decision-maker needs all but impossible to negotiate. Because the compact organization
6798 charged with managing water allocation among the states of Alabama, Florida, and
6799 Georgia would not actually take effect until an allocation formula was agreed upon, the
6800 compact could not actually serve to bridge the divides between decision-making and
6801 scientific assessment of flow, meteorology, and riverine hydrology in the region.

6802

6803 Boundary spanning organizations are important to decision-support system development
6804 in three ways. First, they “mediate” communication between supply and demand
6805 functions for particular areas of societal concern. Sarewitz and Pielke (2007) suggest, for
6806 example, that the IPCC serves as a boundary organization for connecting the science of
6807 climate change to its use in society – in effect, satisfying a “demand” for science
6808 implicitly contained in such international processes for negotiating and implementing
6809 climate treaties as the U.N. Framework Convention on Climate Change and Kyoto
6810 Protocol. In the U.S., local irrigation district managers and county extension agents often
6811 serve this role in mediating between scientists (hydrological modelers) and farmers (Cash
6812 *et al.*, 2003). In the various cases we explored in section 4.2.1 – and in chapter 3 (*e.g.*,
6813 coordinating committees, post-event “technical sessions” after the Red River floods, and
6814 comparable entities), we saw other boundary spanning entities performing mediation
6815 functions.

6816

6817 Second, boundary organizations enhance communication among stakeholders. Effective
6818 tool development requires that affected stakeholders be included in dialogue, and that
6819 data from local resource managers (blended knowledge) be used to ensure credible
6820 communication. Successful innovation is characterized by two-way communication
6821 between producers and users of knowledge, as well as development of networks that
6822 allow close and ongoing communication among multiple sectors. Likewise, networks
6823 must allow close communication among multiple sectors (Sarewitz and Pielke, 2007).

6824

6825 Third, boundary organizations contribute to tool development by serving the function of
6826 translation more effectively than is conceived in the loading-dock model of climate
6827 products. In relations between experts and decision-makers, understanding is often
6828 hindered by jargon, language, experiences, and presumptions; *e.g.*, decision makers often
6829 want deterministic answers about future climate conditions, while scientists can often
6830 only provide probabilistic information, at best. As noted in chapter 3, decision-makers
6831 often mistake probabilistic uncertainty as a kind of epistemological failure – even though
6832 uncertainty is a characteristic of science (Brown, 1997).

6833

6834 One place where boundary spanning can be important with respect to translation is in
6835 providing a greater understanding of uncertainty and its source. This includes better
6836 information exchange between scientists and decision-makers on, for example, the
6837 decisional-relevance of different aspects of uncertainties, and methods of combining
6838 probabilistic estimates of events through simulations, in order to reduce decision-maker
6839 distrust, misinterpretation of forecasts, and mistaken interpretation of models (National
6840 Research Council, 2005).

6841

6842 Effective boundary organizations facilitate the co-production of knowledge—generating
6843 information or technology through the collaboration of scientists/engineers and
6844 nonscientists who incorporate values and criteria from both communities. This is seen,
6845 for example, in the collaboration of scientists and users in producing models, maps, and
6846 forecast products. Boundary organizations have been observed to work best when
6847 accountable to the individuals or interests on both sides of the boundary they bridge, in

6848 order to avoid capture by either side and to align incentives such that interests of actors
6849 on both sides of the boundary are met.
6850
6851 Jacobs (2003) suggests that universities can be good locations for the development of
6852 new ideas and applications, but they may not be ideal for sustained stakeholder
6853 interactions and services, in part because of funding issues and because training cycles
6854 for graduate students, who are key resources at universities, do not always allow a long-
6855 term commitment of staff. Many user groups and stakeholders either have no contact with
6856 universities or may not encourage researchers to participate in or observe decision-
6857 making processes. University reward systems rarely recognize inter-disciplinary work,
6858 outreach efforts, and publications outside of academic journals. This limits incentives for
6859 academics to participate in real-world problem solving and collaborative efforts. Despite
6860 these limitations, many successful boundary organizations are located within universities.
6861
6862 In short, boundary organizations serve to make information from science useful and to
6863 keep information flowing (in both directions) between producers and users of the
6864 information. They foster mutual respect and trust between users and producers. Within
6865 such organizations there is a need for individuals simultaneously capable of translating
6866 scientific results for practical use and framing the research questions from the perspective
6867 of the user of the information. These key intermediaries in boundary organizations need
6868 to be capable of integrating between disciplines and defining the research question
6869 beyond that which focuses on the disciplines. Table 4.1 depicts a number of boundary

6870 organization examples for climate change decision-support tool development. Section
6871 4.3.2 considers the type of organizational leaders who facilitate boundary spanning.

6872

6873 **Table 4.1 Examples of Boundary Organizations for Decision-Support tool development**

6874

Cooperative Extension Services: housed in land-grant universities in the U.S., they provide large networks of people who interact with local stakeholders and decision-makers within certain sectors (not limited to agriculture) on a regular basis. In other countries this agricultural extension work is often done with great effectiveness by local government (*e.g.*, Department of Primary Industries, Queensland, Australia).

Watershed Councils: in some U.S. states, watershed councils and other local planning groups have developed, and many are focused on resolving environmental conflicts and improved land and water management (particularly successful in the State of Oregon).

Natural Resource Conservation Districts: within the U.S. Department of Agriculture, these districts are highly networked within agriculture, land management, and rural communities.

Non-governmental organizations (NGOs) and public interest groups: focus on information dissemination and environmental management issues within particular communities. They are good contacts for identifying potential stakeholders, and may be in a position to collaborate on particular projects. Internationally, a number of NGOs have stepped forward and are actively engaged in working with stakeholders to advance use of climate information in decision-making (*e.g.*, Asian Disaster Preparedness Center (ADPC), in Bangkok, Thailand).

Federal agency and university research activities: expanding the types of research conducted within management institutions and local and state governments is an option to be considered—the stakeholders can then have greater influence on ensuring that the research is relevant to their particular concerns

6875

6876 An oft-cited model of the type of boundary-spanning organization needed for the transfer
6877 and translation of decision-support information on climate variability is the “Regional
6878 Integrated Science and Assessment (RISA) teams supported by NOAA. These teams
6879 “represent a new collaborative paradigm in which decision-makers are actively involved
6880 in developing research agendas” (Jacobs, 2003). The nine RISA teams, located within
6881 universities and often involving partnerships with NOAA laboratories throughout the
6882 U.S, are focused on stakeholder-driven research agendas and long-term relationships
6883 between scientists and decision-makers in specific regions. RISA activities are
6884 highlighted in the sidebar below. This is followed by another sidebar on comparative

6885 examples of boundary spanning which emphasizes the “systemic” nature of boundary
6886 spanning – that boundary organizations produce reciprocity of benefits to various groups.

6887

6888 **4.3.2 Regional Integrated Science and Assessment Teams (RISAs) – An Opportunity**
6889 **for Boundary Spanning, and a Challenge**

6890 A true dialog between end users of scientific information and those who generate data
6891 and tools is rarely achieved. The nine Regional Integrated Science and Assessment
6892 (RISA) teams that are sponsored by NOAA and activities sponsored by the
6893 Environmental Protection Agency’s Global Change Research Program are among the
6894 leaders of this experimental endeavor, and represent a new collaborative paradigm in
6895 which decision-makers are actively involved in developing research agendas. RISAs
6896 explicitly seek to work at the boundary of science and decision making.

6897

6898 There are five principal approaches RISA teams have learned that facilitate engagement
6899 with stakeholders and design of climate-related decision-support tools for water
6900 managers. First, RISAs employ a “stakeholder-driven research” approach that focuses on
6901 performing research on both the supply side (*i.e.*, information development) and demand
6902 side (*i.e.*, the user and her/his needs). Such reconciliation efforts require robust
6903 communication in which each side informs the other with regard to decisions, needs, and
6904 products – this communication cannot be intermittent; it must be robust and ongoing.

6905 Second, some RISAs employ an “information broker” approach. They produce little new
6906 scientific information themselves, due to resource limitations or lack of critical mass in a

6907 particular scientific area. Rather, the RISAs' primary role is providing a conduit for
6908 information and facilitating the development of information networks.

6909

6910 Third, RISAs generally utilize a "participant/advocacy" or "problem-based" approach,
6911 which involves focusing on a particular problem or issue, and engaging directly in
6912 solving that problem. They see themselves as part of a learning system and promote the
6913 opportunity for joint learning with a well-defined set of stakeholders who share the
6914 RISA's perspective on the problem and desired outcomes.

6915

6916 Fourth, some RISAs utilize a "basic research" approach in which the researchers
6917 recognize particular gaps in fundamental knowledge that are necessary as a prerequisite
6918 to the production of context sensitive, policy-relevant information. Any RISA may utilize
6919 many or most of these approaches at different times depending upon the particular
6920 context of the problem. The more well-established RISAs have had more formal
6921 processes and procedures in place to identify stakeholder needs and design appropriate
6922 responses, as well as to evaluate the effectiveness of decision-support tools that are
6923 developed.

6924

6925 Finally, a critical lesson for climate science policy from RISAs is that, despite knowing
6926 what is needed to produce, package, and disseminate useful climate information – and the
6927 well-recognized success of the regional partnerships with stakeholders, While RISA
6928 lessons have been criticized as not having had large influence on the federal climate
6929 science policy community outside of the RISAs in the past, progress has been made in

6930 recent years. Improving feedback between RISA programs and the larger research
6931 enterprise need to be enhanced so lessons learned can inform broader climate science
6932 policy decisions – not just those decisions made on the local problem-solving level
6933 (McNie, *et al.*, 2007).

6934

6935 In April, 2002, the House Science Committee held a hearing to explore the connections
6936 of climate science and the needs of decision makers. One question it posed was the
6937 following: “Are our climate research efforts focused on the right questions?”

6938 (http://www.house.gov/science/hearings/full02/apr17/full_charter_041702.htm)

6939 The Science Committee found that the RISA program is a promising means to connect
6940 decision-making needs with the research prioritization process, because “(it) attempts to
6941 build a regional-scale picture of the interaction between climate change and the local
6942 environment from the ground up. By funding research on climate and environmental
6943 science focused on a particular region, [the RISA] program currently supports
6944 interdisciplinary research on climate-sensitive issues in five selected regions around the
6945 country. Each region has its own distinct set of vulnerabilities to climate change, *e.g.*,
6946 water supply, fisheries, agriculture, *etc.*, and RISA's research is focused on questions
6947 specific to each region.”

6948

6949 *****BOX 4.1: Comparative Examples of Boundary Spanning – Australia and the U.S**

6950

6951 In Australia, forecast information is actively sought both by large agribusiness and government
6952 policymakers planning for drought because “the logistics of handling and trading Australia’s grain
6953 commodities, such as wheat, are confounded by huge swings in production associated with climate
6954 variability. Advance information on likely production and its geographical distribution is sought by many
6955 industries, particularly in the recently deregulated marketing environment” (Hammer, *et al.*, 2001).
6956 Forecast producers have adopted a systems approach to the dissemination of seasonal forecast information
6957 that includes close interaction with farmers, use of climate scenarios to discuss the incoming rainfall season
6958 and automated dissemination of seasonal forecast information through the RAINMAN interactive software.

6959
6960 In the U.S. Southwest, forecast producers organized stakeholder workshops that refined their understanding
6961 of potential users and their needs. Because continuous interaction with stakeholder was well funded and
6962 encouraged, producers were able to ‘customize’ their product—including the design of user friendly and
6963 interactive Internet access to climate information—to local stakeholders with significant success
6964 (Hartmann, *et al.*, 2002; Pagano, *et al.*, 2002; Lemos and Morehouse, 2005). Such success stories seem to
6965 depend largely on the context in which seasonal climate forecasts were deployed—in well-funded policy
6966 systems, with adequate resources to customize and use forecasts, benefits can accrue to the local society as
6967 a whole. From these limited cases, it is suggested that where income, status, and access to information are
6968 more equitably distributed in a society, the introduction of seasonal forecasts may create winners; in
6969 contrast, when pre-existing conditions are unequal, the application of seasonal climate forecasts may create
6970 more losers by exacerbating those inequities (Lemos and Dilling, 2007). The consequences can be costly
6971 both to users and seasonal forecast credibility.

6972 ***END BOX*****

6973

6974 **4.3.3 Developing Knowledge-Action Systems – a Climate for Inclusive Management**

6975 Research suggests that decision makers do not always find seasonal-to-interannual
6976 forecast products, and related climate information, to be useful for the management of
6977 water resources – this is a theme central to this entire report. As our case study
6978 experiments suggest, in order to ensure that information is useful, decision makers must
6979 be able to affect the substance of climate information production and the method of
6980 delivery so that information producers know what are the key questions to respond to in
6981 the broad and varied array of decisional needs different constituencies require (Sarewitz
6982 and Pielke, 2007: 7; Callahan, *et al.*, 1999; NRC, 1999a), and this is likely the most
6983 effective process by which true decision-support activities can be made useful.

6984

6985 Efforts to identify factors that improve the usability of seasonal to interannual climate
6986 information have found that effective “knowledge-action” systems focus on promoting
6987 broad, user driven risk management objectives (Cash and Buizer, 2005: 9). These
6988 objectives, in turn, are shaped by the decision context, which usually contains multiple
6989 stresses and management goals. Research on water resource decision-making suggests
6990 that goals are defined very differently by agencies or organizations dedicated to

6991 managing single-issue problems in particular sectors (*e.g.*, irrigation, public supply) when
6992 compared to decision-makers working in political jurisdictions or watershed-based
6993 entities designed to comprehensively manage and coordinate several management
6994 objectives simultaneously (*e.g.*, flood control and irrigation, power generation, and in-
6995 stream flow). The latter entities face the unusual challenge of trying to harmonize
6996 competing objectives, are commonly accountable to numerous users, and require
6997 “regionally and locally tailored solutions” to problems (Water in the West, 1998; also,
6998 Kenney and Lord, 1994; Grigg, 1996).

6999

7000 Effective knowledge-action systems should be designed for learning rather than knowing
7001 – the difference being that the former emphasizes the process of exchange between
7002 decision-makers and scientists, constantly evolving in an iterative fashion – rather than
7003 aiming for a one-time only completed product. Learning requires that knowledge-action
7004 systems have flexibility of processes and institutions in order to effectively produce and
7005 apply climate information (Cash and Buizer, 2005), encourage diffusion of boundary-
7006 spanning innovation, are themselves innovative and responsive, and are able to develop
7007 “operating criteria that measure responsiveness to changing conditions and external
7008 advisory processes” (Cash and Buizer, 2005). Often, nontraditional institutions that
7009 operate outside of “normal” channels, such as nongovernmental organizations (NGOs) or
7010 regional coordinating entities are less constrained by tradition or legal mandate and thus
7011 more able to innovate.

7012

7013 To encourage climate forecast and information producers and end-users to better
7014 communicate with one another, they need to be engaged in a long-term dialogue about
7015 one another's needs and capabilities. To achieve this, knowledge producers must be
7016 committed to establishing opportunities for joint learning. When such communication
7017 systems have been established, the result has been the gaining of knowledge by users.
7018 The discovery that climate information must be part of a larger suite of information can
7019 help producers understand the decision context, and better appreciate that users "manage
7020 a broad array of risks." Lead innovators within the user community can lay the
7021 groundwork for broader participation of other users and greater connection between
7022 producers and users (Cash and Buizer, 2005).

7023

7024 Such tailoring or conversion of information requires organizational settings that foster
7025 communication and exchange of ideas between users and scientists. For example, a
7026 particular user might require a specific type of precipitation forecast or even a different
7027 type of hydrologic model to generate a credible forecast of water supply volume. This
7028 producer-user dialogue must be long-term; allow users to independently verify the utility
7029 of forecast information; and, provide opportunities for verification results to feed back
7030 into new product development (Cash and Buizer, 2005; Jacobs *et al.*, 2005).

7031

7032 Studies of this connection refer to it as an "end-to-end" system to suggest that knowledge
7033 systems need to engage a range of participants including those who generate scientific
7034 tools and data, those who translate them into predictions for use by decision-makers, and
7035 the decision-makers themselves. A forecast innovation might combine climate factor

7036 observations, analyses of climate dynamics, and seasonal/interannual forecasts. In turn,
7037 users might be concerned with varying problems and issues such as planting times,
7038 instream flows to support endangered species, and reservoir operations.

7039

7040 As Cash and Buizer note, “Often entire systems have failed because of a missing link
7041 between the climate forecast and these ultimate user actions. Avoiding the missing link
7042 problem varies according to the particular needs of specific users (Cash and Buizer,
7043 2005). Users want useable information more than they want answers – they want an
7044 understanding of things that will help them explain, for example, the role of climate in
7045 determining underlying variation in the resources they manage. This includes a broad
7046 range of information needed for risk management; not just forecasting particular threats.

7047

7048 Organizational measures to hasten, encourage, and sustain these knowledge-action
7049 systems must include practices that empower people to use information through
7050 providing adequate training and outreach – as well as sufficient professional reward and
7051 development opportunities. Three measures are essential. First, organizations must
7052 provide incentives to produce boundary objects, such as decisions or products that reflect
7053 the input of different perspectives. Second, they must involve participation from actors
7054 across boundaries. And finally, they must have lines of accountability to the various
7055 organizations spanned (Guston, 2001).

7056

7057 Introspective evaluations of the organization’s ability to learn and adapt to the
7058 institutional and knowledge-based changes around them should be combined with

7059 mechanisms for feedback and advice from clients, users, and community leaders.
7060 However, it is important that a review process not become an end in itself or be so
7061 burdensome as to affect the ability of the organization to function efficiently. This
7062 orientation is characterized by a mutual recognition on the part of scientists and decision-
7063 makers of the importance of social learning – that is, learning by doing or by experiment,
7064 and refinement of forecast products in light of real-world experiences and previous
7065 mistakes or errors – both in forecasts and in their application. This learning environment
7066 also fosters an emphasis on adaptation and diffusion of innovation (*i.e.*, social learning,
7067 learning from past mistakes, long-term funding).

7068

7069 **4.3.4 The Value of User-Driven Decision Support**

7070 Studies of what makes climate forecasts useful have identified a number of common
7071 characteristics in the process by which forecasts are generated, developed, and taught to –
7072 and disseminated among – users (Cash and Buizer, 2005). These characteristics include:

- 7073 • Ensuring that the problems forecasters address are themselves driven by forecast
7074 users;
- 7075 • Making certain that knowledge-action systems (the process of interaction between
7076 scientists and users which produces forecasts) are end-to-end inclusive;
- 7077 • Employing “boundary organizations” (groups or other entities that bridge the
7078 communication void between experts and users) to perform translation and
7079 mediation functions between the producers and consumers of forecasts;
- 7080 • Fostering a social learning environment between producers and users (*i.e.*,
7081 emphasizing adaptation); and

- 7082 • Providing stable funding and other support to keep networks of users and
7083 scientists working together.

7084

7085 As noted earlier, “users” encompass a broad array of individuals and organizations,
7086 including farmers, water managers, and government agencies; while “producers” include
7087 scientists and engineers and those “with relevant expertise derived from practice” (Cash
7088 and Buizer, 2005). Complicating matters is that some “users” may – over time – become
7089 “producers” as they translate, repackage, or analyze climate information for use by
7090 others.

7091

7092 In effective user-driven information environments, the agendas of analysts, forecasters,
7093 and scientists who generate forecast information are at least partly set by the users of the
7094 information. Moreover, the collaborative process is grounded in appreciation for user
7095 perspectives regarding the decision context in which they work, the multiple stresses
7096 under which they labor, and their goals so users can integrate climate knowledge into risk
7097 management. Most important, this user-driven outlook is reinforced by a systematic
7098 effort to link the generation of forecast information with needs of users through soliciting
7099 advice and input from the latter at every step in the generation of information process.

7100

7101 Effective knowledge-action systems do not allow particular research or technology
7102 capabilities (*e.g.*, ENSO forecasting) to drive the dialogue. Instead, effective systems
7103 ground the collaborative process of problem definition in user perspectives regarding the
7104 decision context, the multiple stresses bearing on user decisions, and ultimate goals that

7105 the knowledge-action system seeks to advance. For climate change information, this
7106 means shifting the focus toward “the promotion of broad, user-driven risk-management
7107 objectives, rather than advancing the uptake of particular forecasting technologies” (Cash
7108 and Buizer, 2005; Sarewitz and Pielke, 2007).

7109

7110 In sum, there is an emerging consensus in the field of climate forecast information that
7111 the utility of information intended to make possible sustainable environmental decisions
7112 depends on the “dynamics of the decision context and its broader social setting” (Jasanoff
7113 and Wynne, 1998; Pielke *et al.*, 2000; Sarewitz and Pielke, 2007). Usefulness is not
7114 inherent in the knowledge generated by forecasters – the information generated must be
7115 “socially robust.” Robustness is determined by how well it meets three criteria: 1) it is
7116 valid outside, as well as inside the laboratory; (2) validity is achieved through involving
7117 an extended group of experts, including lay ‘experts;’ and 3) because society as-a-whole
7118 has participated in the generation of forecast models, the information derived from them
7119 is less likely to be contested (Gibbons, 1999).

7120

7121 Finally, a user-driven information system relies heavily on two-way communication.
7122 Such communication can help bridge gaps between what is produced and what is likely to
7123 be used, thus ensuring that scientists produce products that are recognized by the users,
7124 and not just the producers, as useful. Effective user-oriented two-way communication can
7125 increase users’ understanding of how they could use climate information and enable them
7126 to ask questions about information that is uncertain or in dispute. It also affords an
7127 opportunity to produce “decision-relevant” information that might otherwise not be

7128 produced because scientists may not have understood completely what kinds of
7129 information would be most useful to water resource decision makers (NRC, 2008).
7130
7131 In conclusion, user-driven information as regards to seasonal to interannual climate
7132 variability for water resources decision-making must be salient (*e.g.*, decision-relevant
7133 and timely), credible (viewed as accurate, valid, and of high quality), and legitimate
7134 (uninfluenced by pressures or other sources of bias) (see NRC, 2008; NRC, 2005). In the
7135 words of a recent National Research Council report, broad involvement of “interested and
7136 affected parties” in framing scientific questions helps ensure that the science produced is
7137 useful (“getting the right science”) by ensuring that decision-support tools are explicit
7138 about any simplifying assumptions that may be in dispute among the users, and
7139 accessible to the end-user (NRC, 2008).

7140

7141 **4.3.5 Pro-Active Leadership – Championing Change**

7142 Organizations – public, private, scientific, and political – have leaders: individuals
7143 charged with authority, and span of control, over important personnel, budgetary, and
7144 strategic planning decisions, among other venues. Boundary organizations require a kind
7145 of leadership called inclusive management practice by its principal theorists (Feldman
7146 and Khademian, 2001). Inclusive management is defined as management that seeks to
7147 incorporate the knowledge, skills, resources, and perspectives of several actors.

7148

7149 While there is an enormous literature on organizational leadership, synthetic studies –
7150 those which take various theories and models about leaders and try to draw practical,

7151 even anecdotal, lessons for organizations – appear to coalesce around the idea that
7152 inclusive leaders have context-specific skills that emerge through a combination of tested
7153 experience within a variety of organizations, and a knack for judgment (Bennis, 2003;
7154 Tichy and Bennis, 2007). These skills evolve through trial and error and social learning.
7155 Effective “change-agent” leaders have a guiding vision which sustains them through
7156 difficult times, a passion for their work and an inherent belief in its importance, and a
7157 basic integrity toward the way in which they interact with people and approach their jobs
7158 (Bennis, 2003).

7159

7160 While it is difficult to discuss leadership without focusing on individual leaders – and
7161 difficult to disagree with such claims about virtuous leadership, inclusive management
7162 also embraces the notion of process accountability – that leadership is embodied in the
7163 methods by which organizations make decisions, and not in charismatic personality
7164 alone. Process accountability comes not from some external elected political principle or
7165 body that is hierarchically superior, but instead infuses through processes of deliberation
7166 and transparency. All of these elements make boundary organizations capable of being
7167 solution focused and integrative and, thus, able to span the domains of climate knowledge
7168 production and climate knowledge for water management use.

7169

7170 Adaptive and inclusive management practices are essential to fulfilling these objectives.
7171 These practices must empower people to use information through providing adequate
7172 training and outreach – as well as sufficient professional reward and development
7173 opportunities, and they must overcome capacity-building problems within organizations

7174 to ensure that these objectives are met, including adequate user support. The cases
7175 discussed below – on the California Department of Water Resources’ role in adopting
7176 climate variability and change into regional water management, and the efforts of the
7177 Southeast consortium and its satellite efforts – are examples of inclusive leadership which
7178 illustrate how both scientists as well agency managers can be proactive leaders. In the
7179 former case, decision-makers consciously decided to develop relationships with other
7180 western states’ water agencies and partnership (through a Memorandum of
7181 Understanding [MOU]) with NOAA. In the latter, scientists ventured into collaborative
7182 efforts – across universities, agencies, and states – because they shared a commitment to
7183 exchanging information in order to build institutional capacity among the users of the
7184 information themselves

7185

7186 ***Case Study A:***

7187 ***Leadership in the California Department of Water Resources***

7188 The deep drought in the Colorado River Basin that began with the onset of a La Niña
7189 episode in 1998 has awakened regional water resources managers to the need to
7190 incorporate climate variability and change into their plans and reservoir forecast models.
7191 Paleohydrologic estimates of streamflow, which document extended periods of low flow
7192 and demonstrate greater streamflow variability than that found in the gage record, have
7193 been particularly persuasive examples of the non-stationary behavior of the hydroclimate
7194 system (Woodhouse *et al.*, 2006; Meko *et al.*, 2007). Following a 2005 scientist-
7195 stakeholder workshop on the use of paleohydrologic data in water resource management
7196 (http://www.climas.arizona.edu/calendar/details.asp?event_id=21), NOAA RISA and
7197 California Department of Water Resources (CDWR) scientists developed strong
7198 relationships oriented toward improving the usefulness and usability of science in water
7199 management. Since the 2005 workshop, CDWR, whose mission in recent years includes
7200 preparation for potential impacts of climate change on California’s water resources, has

7201 led western states' efforts in partnering with climate scientists to co-produce
7202 hydroclimatic science to inform decision-making. CDWR led the charge to clarify
7203 scientific understanding of Colorado River Basin climatology and hydrology, past
7204 variations, projections for the future, and impacts on water resources, by calling upon the
7205 National Academy of Sciences to convene a panel to study the aforementioned issues
7206 (NRC, 2007). This occurred, and in 2007, CDWR developed a Memorandum of
7207 Agreement with NOAA, in order to better facilitate cooperation with scientists in
7208 NOAA's RISA program and research laboratories (CDWR, 2007).

7209

7210 ***Case Study B:***

7211 ***Cooperative extension services, watershed stewardship: the Southeast Consortium***

7212 Developing the capacity to use climate information in resource management decision-
7213 making requires both outreach and education, frequently in an iterative fashion that leads
7214 to two-way communication and builds partnerships. The Cooperative Extension Program
7215 has long been a leader in facilitating the integration of scientific information into decision
7216 maker of practice in the agricultural sector. Cash (2001) documents an example of
7217 successful Cooperative Extension leadership in providing useful water resources
7218 information to decision-makers confronting policy changes in response to depletion of
7219 groundwater in the High Plains aquifer. Cash notes the Cooperative Extension's history of
7220 facilitating dialogue between scientists and farmers, encouraging the development of
7221 university and agency research agendas that reflect farmers' needs, translating scientific
7222 findings into site-specific guidance, and managing demonstration projects that integrate
7223 farmers into researchers' field experiments.

7224

7225 In the High Plains aquifer example, the Cooperative Extension's boundary spanning work
7226 was motivated from a bottom-up need of stakeholders for credible information on
7227 whether water management policy changes would affect their operations. By acting as a
7228 liaison between the agriculture and water management decision-making communities,
7229 and building bridges between many levels of decision-makers, Kansas Cooperative
7230 Extension was able to effectively coordinate information flows between university and
7231 USGS modelers, and decision-makers. The result of their effort was collaborative

7232 development of a model with characteristics needed by agriculturalists (at a sufficient
7233 spatial resolution) and that provided credible scientific information to all parties. Kansas
7234 Cooperative Extension effectiveness in addressing groundwater depletion and its impact
7235 on farmers sharply contrasted with the Cooperative Extension efforts in other states
7236 where no effort was made to establish multi-level linkages between water management
7237 and agricultural stakeholders.

7238

7239 The Southeast Climate Consortium RISA (SECC), a confederation of researchers at six
7240 universities in Alabama, Georgia, and Florida, has used more of a top-down approach to
7241 developing stakeholder capacity to use climate information in the Southeast's \$33 billion
7242 agricultural sector (Jagtap *et al.*, 2002). Early in its existence, SECC researchers
7243 recognized the potential to use knowledge of the impact of the El Niño-Southern
7244 Oscillation on local climate to provide guidance to farmers, ranchers, and forestry sector
7245 stakeholders on yields and changes to risk (*e.g.*, frost occurrence). Through a series of
7246 needs and vulnerability assessments (Hildebrand *et al.*, 1999, Jagtap *et al.*, 2002), SECC
7247 researchers determined that the potential for producers to benefit from seasonal forecasts
7248 depends on factors that include the flexibility and willingness to adapt farming operations
7249 to the forecast, and the effectiveness of the communication process – and not merely
7250 documenting the effects of climate variability and providing better forecasts (Jones *et al.*,
7251 2000). Moreover, Fraisse *et al.* (2006) explain that climate information is only valuable
7252 when both the potential response and benefits of using the information are clearly
7253 defined. SECC's success in championing integration of new information is built upon a
7254 foundation of sustained interactions with agricultural producers in collaboration with
7255 extension agents. Extension specialists and faculty are integrated as members of the
7256 SECC research team. SECC engages agricultural stakeholders through planned
7257 communication and outreach, such as monthly video conferences, one-on-one meetings
7258 with extension agents and producers, training workshops designed for extension agents
7259 and resource managers to gain confidence in climate decision tool use and to identify
7260 opportunities for their application, and by attending traditional extension activities (*e.g.*,
7261 commodity meetings, field days) (Fraisse *et al.*, 2005). SECC is able to leverage the trust
7262 engendered by Cooperative Extension's long service to the agricultural community and

7263 Extension's access to local knowledge and experience, in order to build support for its
7264 AgClimate online decision-support tool (<http://www.agclimate.org>) (Fraisie *et al.*, 2006).
7265 This direct engagement with stakeholders provides feedback to improve the design of the
7266 tool and to enhance climate forecast communication (Breuer *et al.*, 2007).

7267

7268 Yet another Cooperative Extension approach to integrating scientific information into
7269 decision-making is the Extension's Master Watershed Steward (MWS) programs. MWS
7270 was first developed at Oregon State University
7271 <<http://seagrant.oregonstate.edu/wsep/index.html>>. In exchange for 40 hours of training
7272 on aspects of watersheds that range from ecology to water management, interested citizen
7273 volunteers provide service to their local community through projects, such as drought and
7274 water quality monitoring, developing property management plans, and conducting
7275 riparian habitat restoration. Arizona's MWS program includes training in climate and
7276 weather (Garfin and Emanuel, 2006); stewards are encouraged to participate in drought
7277 impact monitoring through Arizona's Local Drought Impact Groups (GDTF, 2004;
7278 Garfin, 2006). MWS enhances the capacity for communities to deploy new climate
7279 information and to build expertise for assimilating scientific information into a range of
7280 watershed management decisions.

7281

7282 **4.3.6 Funding and Long-Term Capacity Investments Must Be Stable and**

7283 **Predictable**

7284 Provision of a stable funding base, as well as other investments, can help to ensure
7285 effective knowledge-action systems for climate change. Stable funding promotes long-
7286 term stability and trust among stakeholders because it allows researchers to focus on user
7287 needs over a period of time, rather than having to train new participants in the process.
7288 Given that these knowledge-action systems produce benefits for entire societies, as well
7289 as for particular stakeholders in a society, it is not uncommon for these systems to be
7290 thought of as producing both public and private goods, and thus, needing both public and

7291 private sources of support (Cash and Buizer, 2005). Private funders could include, for
7292 example, farmers whose risks are reduced by the provision of climate information (as is
7293 done in Queensland, Australia – where the individual benefits of more profitable
7294 production are captured by farmers who partly support drought-warning systems). In less
7295 developed societies, by contrast, it would not be surprising for these systems to be
7296 virtually entirely supported by public sources of revenue (Cash and Buizer, 2005).

7297

7298 Experience suggests that a public-private funding balance should be shaped on the basis
7299 of user needs and capacities to self-tailor knowledge-action systems. More generic
7300 systems that could afterwards be tailored to users' needs might be most suitable for
7301 public support, while co-funding with particular users can then be pursued for developing
7302 a collaborative system that more effectively meets users' needs. Funding continuity is
7303 essential to foster long-term relationship building between users and producers. The key
7304 point here is that – regardless of who pays for these systems, continued funding of the
7305 social and economic investigations of the use of scientific information is essential to
7306 ensure that these systems are used and are useful (Jacobs, *et al.*, 2005).

7307

7308 Other long-term capacity investments relate to user training – an important component
7309 that requires drawing upon the expertise of “integrators.” Integrators are commonly self-
7310 selected managers and decision-makers with particular aptitude or training in science, or
7311 scientists who are particularly good at communication and applications. Training may
7312 entail curriculum development, career and training development for users as well as
7313 science integrators, and continued mid-career in-stream retraining and re-education.

7314 Many current integrators have evolved as a result of doing interdisciplinary and applied
7315 research in collaborative projects, and some have been encouraged by funding provided
7316 by NOAA’s Climate Programs Office (formerly Office of Global Programs) (Jacobs, *et*
7317 *al.*, 2005).

7318

7319 **4.3.7 Adaptive Management for Water Resources Planning – Implications for**
7320 **Decision Support**

7321 Since the 1970s an “adaptive management paradigm” has emerged that emphasizes
7322 greater public and stakeholder participation in decision-making; an explicit commitment
7323 to environmentally-sound, socially just outcomes; greater reliance upon drainage basins
7324 as planning units; program management via spatial and managerial flexibility,
7325 collaboration, participation, and sound, peer-reviewed science; and, embracing of
7326 ecological, economic, and equity considerations (Hartig, *et al.*, 1992; Landre and Knuth,
7327 1993; Cortner and Moote, 1994; Water in the West, 1998; May *et al.*, 1996; McGinnis,
7328 1995; Miller, *et al.*, 1996; Cody, 1999; Bormann, *et. al.*, 1993; Lee, 1993). Adaptive
7329 management traces its roots to a convergence of intellectual trends and disciplines,
7330 including industrial relations theory, ecosystems management, ecological science,
7331 economics, and engineering. It also embraces a constellation of concepts such as social
7332 learning, operations research, environmental monitoring, precautionary risk avoidance,
7333 and many others (NRC, 2004).

7334

7335 Adaptive management can be viewed as an alternative water resource decision-making
7336 paradigm that seeks insights into the behavior of ecosystems utilized by humans. In

7337 regards to climate variability and water resources, adaptive management compels
7338 consideration of questions such as the following: what are the decision-support needs
7339 related to managing in-stream flows/low flows? How does climate variability affect
7340 runoff, degraded water quality due to higher temperatures, impacts on cold-water
7341 fisheries lower dissolved oxygen levels, and other environmental quality parameters
7342 related to endangered or threatened species? And, what changes to runoff and flow will
7343 occur in the future, and how will these changes affect water uses among future
7344 generations unable to influence the causes of these changes today? What makes these
7345 questions particularly challenging is that they are inter-disciplinary in nature².
7346
7347 While a potentially important concept, applying adaptive management to improving
7348 decision-support requires that we deftly avoid a number of false and sometimes
7349 uncritically accepted suppositions. For example, adaptive management does not postpone
7350 actions until “enough” is known about a managed ecosystem, but supports actions that
7351 acknowledge the limits of scientific knowledge, “the complexities and stochastic
7352 behavior of large ecosystems,” and the uncertainties in natural systems, economic
7353 demands, political institutions, and ever-changing societal social values (NRC, 2004;
7354 Lee, 1999). In short, an adaptive management approach is one that is flexible and subject
7355 to adjustment in an iterative, social learning process (Lee, 1999). If treated in such a

² Underscored by the fact that scholars concur adaptive management entails a broad range of processes to avoid environmental harm by imposing modest changes on the environment, acknowledging uncertainties in predicting impacts of human activities on natural processes, and embracing social learning (*i.e.*, learning by experiment). In general, it is characterized by managing resources by learning, especially about mistakes, in an effort to make policy improvements using four major strategies that include, 1) modifying policies in the light of experience – and 2) permitting such modifications to be introduced in “mid-course, 3) allowing revelation of critical knowledge heretofore missing and analysis of management outcomes, and 4) incorporating outcomes in future decisions through a consensus-based approach that allows government agencies and NGOs to conjointly agree on solutions (Bormann, *et al.*, 1993; Lee, 1993; Definitions of Adaptive Management, 2000). .

7356 manner, adaptive management can encourage timely responses by encouraging
7357 protagonists involved in water management to bound disputes, discussing them in an
7358 orderly manner, investigating environmental uncertainties, continuing to constantly learn
7359 and improve the management and operation of environmental control systems, learning
7360 from error, and “reduc(ing) decision-making gridlock by making it clear that decisions
7361 are provisional, that there is often no “right” or “wrong” management decision, and that
7362 modifications are expected” (NRC, 2004).

7363

7364 The four cases discussed below illustrate varying applications, and context specific
7365 problems, of adaptive management. The discussion of Integrated Water Resource
7366 Planning stresses the use of adaptive management in a variety of local political contexts
7367 where the emphasis is on reducing water use and dependence on engineered solutions to
7368 provide water supply. The key variables are the economic goals of cost savings coupled
7369 with the ability to flexibly meet water demands. The Arizona Water Institute case
7370 illustrates the use of a dynamic organizational training setting to provide “social learning”
7371 and decisional responsiveness to changing environmental and societal conditions. A key
7372 trait is the use of a boundary-spanning entity to bridge various disciplines.

7373

7374 The Glen Canyon and Murray-Darling basin cases illustrate operations-level decision-
7375 making aimed at addressing a number of water management problems that, over time,
7376 have become exacerbated by climate variability: namely, drought, stream-flow, salinity,
7377 and regional water demand. On one hand, adaptive management has been applied to “re-
7378 engineer” a large reservoir system. On the other, a management authority that links

7379 various stakeholders together has attempted to instill a new set of principles into regional
7380 river basin management.

7381

7382 **4.3.8 Integrated Water Resources Planning – Local Water Supply and Adaptive**
7383 **Management**

7384 A significant innovation in U.S. water resources management that affects climate
7385 information use is occurring in the local water supply sector – the growing use of
7386 integrated water resource planning (or IWRP) as an alternative to conventional supply-
7387 side approaches for meeting future demands. IWRP is gaining acceptance in chronically
7388 water-short regions such as the Southwest and portions of the Midwest – including
7389 Southern California, Kansas, Southern Nevada, and New Mexico (*e.g.*, Beecher, 1995;
7390 Warren, *et al.*, 1995; Fiske and Dong, 1995; Wade, 2001).

7391

7392 IWRP’s goal is to “balanc(e) water supply and demand management considerations by
7393 identifying feasible planning alternatives that meet the test of least cost without
7394 sacrificing other policy goals” (Beecher, 1995). This can be variously achieved through
7395 depleted aquifer recharge, seasonal groundwater recharge, conservation incentives,
7396 adopting growth management strategies, wastewater reuse, and applying least-cost
7397 planning principles to large investor-owned water utilities. The latter may encourage
7398 IWRP by demonstrating the relative efficiency of efforts to reduce demand as opposed to
7399 building more supply infrastructure. A particularly challenging alternative is the need to
7400 enhance regional planning among water utilities in order to capitalize on the resources of

7401 every water user, eliminate unnecessary duplication of effort, and avoid the cost of
7402 building new facilities for water supply (Atwater and Blomquist, 2002: 1201).
7403
7404 In some cases, short term least cost may increase long-term project costs, especially when
7405 environmental impacts, resource depletion, and energy and maintenance costs are
7406 included. The significance of least-cost planning is that it underscores the importance of
7407 long and short-term costs (in this case, of water) as an influence on the value of certain
7408 kinds of information for decisions. Models and forecasts that predict water availability
7409 under different climate scenarios can be especially useful to least-cost planning and make
7410 more credible efforts to reducing demand. Specific questions IWRP raises for decision-
7411 support-generated climate change information include: how precise must climate
7412 information be to enhance long term planning? How might predicted climate change
7413 provide an incentive for IWRP strategies? And, what climate information is needed to
7414 optimize decisions on water pricing, re-use, shifting from surface to groundwater use, and
7415 conservation?

7416

7417 ***Case Study C:***

7418 ***Approaches to building user knowledge and enhancing capacity building – the Arizona***
7419 ***Water Institute***

7420 The Arizona Water Institute was initiated in 2006 to focus the resources of the Arizona
7421 state university system on the issue of water sustainability. Because there are 400 faculty
7422 members in the three Arizona universities who work on water-related topics, it is clear
7423 that asking them and their students to assist the state in addressing the major water
7424 quantity and quality issues should make a significant contribution. This is particularly
7425 relevant given that the state budget for supporting water resources related work is
7426 exceedingly small by comparison to many other states, and the fact that Arizona is one of

7427 the fastest-growing states in the U.S. In addition to working towards water sustainability,
7428 the Institute’s mission includes water-related technology transfer from the universities to
7429 the private sector to build economic opportunities, as well as capacity building to enhance
7430 the use of scientific information in decision-making.

7431

7432 The Institute was designed from the beginning as a “boundary organization” to build
7433 pathways for innovation between the universities and state agencies, communities, Native
7434 American tribal representatives, and the private sector. In addition, the Institute is
7435 specifically designed as an experiment in how to remove barriers between groups of
7436 researchers in different disciplines and across the universities. All of the Institute’s
7437 projects involve faculty members from more than one of the universities, and all involve
7438 true engagement with stakeholders. The faculty is provided incentives to engage both
7439 through small grants for collaborative projects and through the visibility of the work that
7440 the Institute supports. Further, the Institute’s structure is unique, in that there are high
7441 level Associate Directors of the Institute whose assignment is to build bridges between
7442 the universities and the three state agencies that are the Institute’s partners: Water
7443 Resources, Environmental Quality, and Commerce. These Associate Directors are
7444 physically located inside the state agencies that they serve. The intent is to build trust
7445 between university researchers who are often viewed as “out of touch with reality” by
7446 agency employees, and researchers who often believe that state workers have no interest
7447 in innovative ideas. Physical proximity of workspaces and daily engagement has been
7448 shown to be an ingredient of trust building.

7449

7450 A significant component of the Institute’s effort is focused on capacity building: on
7451 training students through engagement in real-world water policy issues, on providing
7452 better access to hydrologic data for decision-makers, on assisting them in visualizing the
7453 implications of the decisions that they make, on workshops and training programs for
7454 tribal entities, on joint definition of research agendas between stakeholders and
7455 researchers, and on building employment pathways to train students for specific job
7456 categories where there is an insufficient supply of trained workers, such as water and
7457 wastewater treatment plant operators. Capacity-building in interdisciplinary planning

7458 applications such as combining land use planning and water supply planning to focus on
7459 sustainable water supplies for future development is emerging as a key need for many
7460 communities in the state.

7461

7462 The Institute is designed as a “learning organization” in that it will regularly revisit its
7463 structure and function, and redesign itself as needed to maintain effectiveness in the
7464 context of changing institutional and financial conditions.

7465

7466 ***Case Study D:***

7467 ***Murray-Darling Basin – sustainable development and adaptive management***

7468 The Murray-Darling Basin Agreement (MDBA), formed in 1985 by New South Wales,
7469 Victoria, South Australia and the Commonwealth, is an effort to provide for the
7470 integrated and conjoint management of the water and related land resources of the
7471 world’s largest catchment system. The problems initially giving rise to the agreement
7472 included rising salinity and irrigation-induced land salinisation that extended across state
7473 boundaries (SSCSE, 1979; Wells, 1994). However, embedded in its charter was a
7474 concern with using climate variability information to more effectively manage drought,
7475 runoff, riverine flow and other factors in order to meet the goal of “effective planning
7476 and management for the equitable, efficient and sustainable use of the water, land and
7477 environmental resources (of the basin)” (MDBC, 2002).

7478

7479 Some of the more notable achievements of the MDBA include programs to promote the
7480 management of point and non-point source pollution; balancing consumptive and in-
7481 stream uses (a decision to place a cap on water diversions was adopted by the
7482 commission in 1995); the ability to increase water allocations – and rates of water flow –
7483 in order to mitigate pollution and protect threatened species (applicable in all states
7484 except Queensland); and an explicit program for “sustainable management.” The latter
7485 hinges on implementation of several strategies, including a novel human dimension
7486 strategy adopted in 1999 that assesses the social, institutional and cultural factors
7487 impeding sustainability; as well as adoption of specific policies to deal with salinity,
7488 better manage wetlands, reduce the frequency and intensity of algal blooms by better

7489 managing the inflow of nutrients, reverse declines in native fisheries populations (a plan
7490 which, like that of many river basins in the U.S., institutes changes in dam operations to
7491 permit fish passage), and preparing floodplain management plans.

7492

7493 Moreover, a large-scale environmental monitoring program is underway to collect and
7494 analyze basic data on pressures upon the basin's resources as well as a "framework for
7495 evaluating and reporting on government and community investment" efforts and their
7496 effectiveness. This self-evaluation program is a unique adaptive management innovation
7497 rarely found in other basin initiatives. To support these activities, the Commission funds
7498 its own research program and engages in biophysical and social science investigations. It
7499 also establishes priorities for investigations based, in part, on the severity of problems,
7500 and the knowledge acquired is integrated directly into commission policies through a
7501 formal review process designed to assure that best management practices are adopted.

7502

7503 From the standpoint of adaptive management, the Murray-Darling Basin Agreement
7504 seeks to integrate quality and quantity concerns in a single management framework, has a
7505 broad mandate to embrace social, economic, environmental and cultural issues in
7506 decisions, and, has considerable authority to supplant, and supplement, the authority of
7507 established jurisdictions in implementing environmental and water development policies.
7508 While water quality policies adopted by the Basin Authority are recommended to states
7509 and the federal government for approval, generally, the latter defer to the commission and
7510 its executive arm. The MDBA also promotes an integrated approach to water resources
7511 management. Not only does the Commission have responsibility for functions as widely
7512 varied as floodplain management, drought protection, and water allocation, but for
7513 coordinating them as well. For example, efforts to reduce salinity are linked to strategies
7514 to prevent waterlogging of floodplains and land salinisation on the Murray and
7515 Murrumbidgee valleys (MDBC, 2002). Also, the basin commission's environmental
7516 policy aims to utilize water allocations not only to control pollution and benefit water
7517 users, but to integrate its water allocation policy with other strategies for capping
7518 diversions, governing in-stream flow, and balancing in-stream needs and consumptive

7519 (*i.e.*, agricultural irrigation) uses. Among the most notable of MDBC’s innovations is its
7520 community advisory effort.

7521

7522 In 1990, the ministerial council for the MDBC adopted a Natural Resources Management
7523 Strategy that provides specific guidance for a community-government partnership to
7524 develop plans for integrated management of the Basin's water, land and other
7525 environmental resources on a catchment basis. In 1996 the ministerial council put in
7526 place a Basin Sustainability Plan that provides a planning, evaluation and reporting
7527 framework for the Strategy, and covers all government and community investment for
7528 sustainable resources management in the Basin.

7529

7530 According to Newson, while the policy of integrated management has “received wide
7531 endorsement,” progress towards effective implementation has fallen short – especially in
7532 the area of floodplain management. This has been attributed to a “reactive and
7533 supportive” attitude as opposed to a proactive one (Newson, 1997). Despite such
7534 criticism, it is hard to find another initiative of this scale that has attempted adaptive
7535 management based on community involvement.

7536

7537 ***Case Study E:***

7538 ***Adaptive management in Glen Canyon, Arizona and Utah***

7539 Glen Canyon Dam was constructed in 1963 to provide hydropower, water for irrigation,
7540 flood control, and public water supply – and to ensure adequate storage for the upper
7541 basin states of the Colorado River Compact (*i.e.*, Utah, Wyoming, New Mexico, and
7542 Colorado). Lake Powell, the reservoir created by Glen Canyon Dam, has a storage
7543 capacity equal to approximately two-years flow of the Colorado River. Critics of Glen
7544 Canyon Dam have insisted that its impacts on the upper basin have been injurious almost
7545 from the moment it was completed. The flooding of one of the West’s most beautiful
7546 canyons under the waters of Lake Powell; increased rates of evapo-transpiration and
7547 other forms of water loss (*e.g.*, seepage of water into canyon walls); and eradication of
7548 historical flow regimes are the most frequently cited problems. The latter has been the
7549 focus of recent debate. Prior to Glen Canyon’s closure, the Colorado River was highly

7550 variable with flows ranging from 120,000 cubic feet per second (cfs) to less than 1,000
7551 cfs.

7552

7553 When the dam's gates were closed in 1963, the Colorado River above and below Glen
7554 Canyon was altered by changes in seasonal variability. Once characterized by muddy,
7555 raging floods, the river became transformed into a clear, cold stream. Annual flows were
7556 stabilized and replaced by daily fluctuations by as much as 15 feet. A band of exotic
7557 vegetation colonized a river corridor no longer scoured by spring floods; five of eight
7558 native fish species disappeared; and the broad sand beaches of the pre-dam river eroded
7559 away. Utilities and cities within the region came to rely on the dam's low cost power and
7560 water, and in-stream values were ignored (Carothers and Brown, 1991).

7561

7562 Attempts to abate or even reverse these impacts came about in two ways. First, in 1992
7563 under pressure from environmental organizations, Congress passed the Grand Canyon
7564 Protection Act that mandated Glen Canyon Dam's operations coincide with protection,
7565 migration, and improvement of the natural and cultural resources of the Colorado River.
7566 Second, in 1996 the Bureau of Reclamation undertook an experimental flood to restore
7567 disturbance and dynamics to the river ecosystem. Planners hoped that additional sand
7568 would be deposited on canyon beaches and that backwaters – important rearing areas for
7569 native fish – would be revitalized. They also hoped the new sand deposits would stabilize
7570 eroding cultural sites while high flows would flush some exotic fish species out of the
7571 system (Moody, 1997; Restoring the Waters, 1997). The 1996 flood created over 50 new
7572 sandbars, enhanced existing ones, stabilized cultural sites, and helped to restore some
7573 downstream sport fisheries. What made these changes possible was a consensus
7574 developed through a six-year process led by the Bureau that brought together diverse
7575 stakeholders on a regular basis. This process developed a new operational plan for Lake
7576 Powell, produced an EIS for the project, and compelled the Bureau (working with the
7577 National Park Service) to implement an adaptive management approach that encouraged
7578 wide discussion over all management decisions.

7579

7580 While some environmental restoration has occurred, improvement to backwaters has
7581 been less successful. Despite efforts to restore native fisheries, the long-term impact of
7582 exotic fish populations on the native biological community, as well as potential for long-
7583 term recovery of native species, remains uncertain (Restoring the Waters, 1997). The
7584 relevance for climate variability decision-support in the Glen Canyon case is as that
7585 continued drought in the Southwest is placing increasing stress on the water resources of
7586 the region. Efforts to restore the river to conditions more nearly approximating the era
7587 before the dam was built will require changes in the dam's operating regime that will
7588 force a greater balance between instream flow considerations and power generation and
7589 offstream water supply. This will also require imaginative uses of forecast information to
7590 ensure that these various needs can be balanced.

7591

7592 **4.3.9 Measurable Indicators of Progress to Promote Information Access and Use**

7593 These cases, and our previous discussion about capacity building, point to four basic
7594 measures that should be used to evaluate progress in providing equitable access to
7595 decision-support generated information. First, the overall process of tool development
7596 must be inclusive. Over time, it should be possible to document the development of such
7597 an inclusive process. This could be measured by the propensity of groups to continue to
7598 participate and to be consulted and involved. Participants should view the process of
7599 collaboration as fair and effective – this could be gauged by elicitation of feedback from
7600 process participants.

7601

7602 Second, there must be progress in developing an inter-disciplinary and inter-agency
7603 environment of collaboration, documented by the presence of dialogue, discussion, and
7604 exchange of ideas among different professions – in other words, documented boundary-
7605 spanning progress. One documentable measure of inter-disciplinary, boundary-spanning

7606 collaboration is the growth, over time, of professional reward systems within
7607 organizations that reward and recognize people who develop, use, and translate such
7608 systems for use by others.

7609

7610 Third, the collaborative process must be viewed by participants as credible. This means
7611 that participants feel it is believable and trustworthy, that there are no hidden agendas,
7612 and that there are benefits to all who engage in it. Again, this can be documented by
7613 elicitation of feedback from participants. Finally, outcomes of decision-support tools
7614 must be implementable in the short term – as well as longer-term. It is necessary to see
7615 progress in assimilating and using such systems in a short period of time in order to
7616 sustain the interest, effort, and participatory conviction of decision-makers in the process.

7617 Table 4.2 suggests some specific, discrete measures that can be used to assess progress
7618 toward effective information use.

7619

7620 **Table 4.2 Promoting Access to Information and its Use Between Scientists and Decision-Makers – A**
7621 **Checklist (adopted from: Jacobs, 2003)**

7622

Information Integration

- Was information received by stakeholders and integrated into decision-makers' management framework or world view?
- Was capacity built? Did the process lead to a result where institutions, organizations, agencies, officials can use information generated by decision-support experts? Did experts who developed these systems rely upon the knowledge and experience of decision-makers – and respond to their needs in a manner that was useful?
- Will stakeholders continue to be invested in the program and participate in it over the long-term?
- Stakeholder Interaction/Collaboration
- Were contacts/relationships sustained over time and did they extend beyond individuals to institutions?
- Did stakeholders invest staff time or money in the activity?
- Was staff performance evaluated on the basis of quality or quantity of interaction?
- Did the project take on a life of its own, become at least partially self-supporting after the end of the project?
- Did the project result in building capacity and resilience to future events/conditions rather than focus on mitigation?

- Was quality of life or economic conditions improved due to use of information generated or accessed through the project?
- Did the stakeholders claim or accept partial ownership of final product?
- Tool Salience
- Are the tools actually used to make decisions; are they used by high-valued uses and users?
- Is the information generated/provided by these tools accurate/valid?
- Are important decisions made on the basis of the tool?
- Does the use of these tools reduce vulnerabilities, risks, and hazards?
- Collaborative Process Efficacy
- Was the process representative (all interests have a voice at the table)?
- Was the process credible (based on facts as the participants knew them)?
- Were the outcomes implementable in a reasonable time frame (political and economic support)?
- Were the outcomes disciplined from a cost perspective (*i.e.*, there is some relationship between total costs and total benefits)?
- Were the costs and benefits equitably distributed, meaning there was a relationship between those who paid and those who benefited?

7623

7624 **4.3.10 Monitoring Progress**

7625 An important element in the evaluation of process outcomes is the ability to monitor
 7626 progress. A recent National Academy report (NRC, 2008) on NOAA's Sectoral
 7627 Applications Research Program (SARP), focusing on climate-related information to
 7628 inform decisions, encourages the identification of process measures that can be recorded
 7629 on a regular basis, and of outcome measures tied to impacts of interest to NOAA and
 7630 others which can also be recorded on a comparable basis.

7631

7632 These metrics can be refined and improved on the basis of research and experience –
 7633 while consistency is maintained to permit time-series comparisons of progress (NRC,
 7634 2008). An advantage of such an approach includes the ability to document learning (*e.g.*,
 7635 Is there progress on the part of investigators in better project designs? Should there be a
 7636 re-direction of funding toward projects that show a large payoff in benefits to decision-
 7637 makers?)

7638

7639 Finally, the ability to consult with agencies, water resource decision-makers, and a host
7640 of other potential forecast user communities can be an invaluable means of providing
7641 “mid-course” or interim indicators of progress in integrating forecast use in decisions.
7642 The Transition of Research Applications to Climate Services Program (TRACS), also
7643 within the NOAA Climate Program Offices, has as one of its mandates to support users
7644 of climate information and forecasts at multiple spatial and geographical scales – the
7645 transitioning of “experimentally mature climate information tools, methods, and
7646 processes, including computer related applications (*e.g.* web interfaces, visualization
7647 tools), from research mode into settings where they may be applied in an operational and
7648 sustained manner” (TRACS, 2008). While TRACS primary goal is to deliver useful
7649 climate information products and services to local, regional, national, and even
7650 international policy makers, it is also charged with learning from its partners how to
7651 better accomplish technology transition processes. NOAA’s focus is to infer the
7652 effectiveness of how effectively transitions of research applications (*i.e.* experimentally
7653 developed and tested, end-user-friendly information to support decision making), and
7654 climate services (*i.e.* the routine and timely delivery of that information, including via
7655 partnerships) are actually occurring.

7656

7657 While it is far too early to conclude how effectively this process of consultation has
7658 advanced, NOAA has established criteria for assessing this learning process, including
7659 clearly identifying decision makers, research, operations and extension partners, and
7660 providing for post audit evaluation (*e.g.*, validation, verification, refinement,
7661 maintenance) to determine at the end of the project if the transition of information has

7662 been achieved and is sustainable – according to the partners, and focusing on developing
7663 means of communication and feedback, and on deep engagement with the operational
7664 and end-user communities (TRACS, 2008).

7665

7666 The Southeast Climate Consortium case discussed below illustrates how a successful
7667 process of ongoing stakeholder engagement can be developed through the entire cycle
7668 (from development, introduction, and use) of decision-support tools. This experiment
7669 affords insights into how to elicit user community responses in order to refine and
7670 improve climate information products, and how to develop a sense of decision-support
7671 ownership through participatory research and modeling. The Potomac River case focuses
7672 on efforts to resolve a long-simmering water dispute and the way collaborative processes
7673 can themselves lead to improved decisions. Finally, the Upper San Pedro Partnership
7674 exemplifies the kind of sustained partnering efforts that are possible when adequate
7675 funding is made available, politicization of water management questions is prevalent, and
7676 climate variability has become an important issue on decision-makers' agenda, while the
7677 series of fire prediction workshops illustrate the importance of a highly-focused problem
7678 – one that requires improvements to information processes, as well as outcomes, to foster
7679 sustained collaboration.

7680

7681 ***Case Study F:***

7682 ***Southeast Climate Consortium capacity building, tool development***

7683 The Southeast Climate Consortium is a multidisciplinary, multi-institutional team, with
7684 members from Florida State University, University of Florida, University of Miami,
7685 University of Georgia, University of Auburn and the University of Alabama-Huntsville.
7686 A major part of the Southeast Climate Consortium's (SECC) effort is directed toward

7687 developing and providing climate and resource management information through
7688 AgClimate (<http://www.agclimate.org/>), a decision-support system (DSS) introduced for
7689 use by Agricultural Extension, agricultural producers, and resource managers in the
7690 management of agriculture, forests, and water resources. Two keys to SECC's progress in
7691 promoting the effective use of climate information in agricultural sector decision-making
7692 are (1) iterative ongoing engagement with stakeholders, from project initiation to
7693 decision-support system completion and beyond (further product refinement,
7694 development of ancillary products, *etc.*) (Breuer *et al.*, 2007; Cabrera *et al.*, 2007), and
7695 (2) co-developing a stakeholder sense of decision-support ownership through
7696 participatory research and modeling (Meinke and Stone, 2005; Breuer *et al.*, 2007;
7697 Cabrera *et al.*, 2007).

7698

7699 The SECC process has begun to build capacity for the use of climate information with a
7700 rapid assessment to understand stakeholder perceptions and needs regarding application
7701 of climate information that may have benefits (*e.g.*, crop yields, nitrogen pollution in
7702 water) (Cabrera *et al.*, 2006). Through a series of engagements, such as focus groups,
7703 individual interviews, research team meetings (including stakeholder advisors), and
7704 prototype demonstrations, the research team assesses which stakeholders are most likely
7705 adopt the decision-support system and communicate their experience with other
7706 stakeholders (Roncoli *et al.*, 2006), as well as stakeholder requirements for decision
7707 support (Cabrera *et al.*, 2007). Among the stakeholder requirements gleaned from more
7708 than six years of stakeholder engagements, are: present information in an uncomplicated
7709 way (often deterministic), but allow the option to view probabilistic information; provide
7710 information timed to allow users to take *ex ante* action; include an economic component
7711 (because farmer survival, *i.e.* cost of practice adoption, takes precedence over
7712 stewardship concerns); and allow for confidential comparison of model results with
7713 proprietary data.

7714

7715 The participatory modeling approach used in the development of DyNoFlo, a whole-farm
7716 decision-support system to decrease nitrogen leaching while maintaining profitability
7717 under variable climate conditions (Cabrera *et al.*, 2007), engaged federal agencies,

7718 individual producers, cooperative extension specialists, and consultants (who provided
7719 confidential data for model verification). Cabrera *et al.* (2007) report that the dialogue
7720 between these players, as co-equals, was as important as the scientific underpinning and
7721 accuracy of the model in improving adoption. They emphasize that the process, including
7722 validation that is defined as occurring when researchers and stakeholders agree the model
7723 fits real or measured conditions adequately, is a key factor in developing stakeholder
7724 sense of ownership and desire for further engagement and decision-support system
7725 enhancement. These findings concur with recent examples of the adoption of climate
7726 data, predictions and information to improve water supply model performance by
7727 Colorado River basin water managers (Woodhouse and Lukas, 2006; B. Udall, personal
7728 communication).

7729

7730 ***Case Study G:***

7731 ***The Potomac River Basin***

7732 Water Wars, traditionally seen in the West, are spreading to the Midwest, East and South.
7733 The “Water Wars” report (Council of State Governments, 2003) underlines the stress a
7734 growing resident population is imposing on a limited natural resource, and how this stress
7735 is triggering water wars in areas formerly plentiful of water. An additional source of
7736 concern would be the effect on supply and the increase in demand due to climate
7737 variability and change. Although the study by Hurd *et al.* in 1999 indicated that the
7738 Northeastern water supply would be less vulnerable to the effect of climate change, the
7739 Interstate Commission on the Potomac River Basin (ICPRB) periodically studies the
7740 impact of climate change on the supply reliability to the Washington metropolitan area
7741 (WMA).

7742

7743 The ICPRB was created in 1940 by the States of Maryland and West Virginia, the
7744 Commonwealths of Virginia and Pennsylvania, and the District of Columbia. The ICPRB
7745 was recognized by the US Congress, which provided also a presence in the Commission.
7746 The ICPRB’s purpose is "Regulating, controlling, preventing, or otherwise rendering
7747 unobjectionable and harmless the pollution of the waters of said Potomac drainage area
7748 by sewage and industrial and other wastes."

7749

7750 The Potomac River constitutes the primary source of water for the WMA. Out of the five
7751 reservoirs in the WMA, three are in the Potomac River Basin. The largest of the
7752 reservoirs, Jennings Randolph Reservoir, holds 13.4 billion gallons (BG) of water
7753 available to the WMA water suppliers. This reservoir is about 200 miles upstream of the
7754 water supply intakes. It takes more than a week for the releases to reach those intakes
7755 during low flow periods. The second reservoir, Little Seneca Reservoir holds 3.8 BG of
7756 water, and is only about one day's water travel time from the most downstream intake.
7757 This allows a joint operation of these two reservoirs, with the Jennings Randolph
7758 Reservoir being operated in a more strategic fashion, and the Little Seneca Reservoir in a
7759 tactical (day-to-day) mode. The third reservoir on the Potomac watershed is the Savage
7760 Reservoir, in the headwaters of the basin near the Jennings Randolph Reservoir, and
7761 owned by the Upper Potomac River Commission. This reservoir is operated under
7762 guidance from the U.S. Army Corps of Engineers and is used for water quality releases.
7763 From April, 1990 and every five years, the Commission evaluates the adequacy of the
7764 different sources of water supply to the Metropolitan Washington area. The latest report,
7765 (Kame'enui *et al.*, 2005), includes a report of a 1997 study by Steiner *et al.* of the
7766 potential effects of climate variability and change on the reliability of water supply for
7767 that area.

7768

7769 The ICPRB inputs temperature, precipitation from five general circulation models
7770 (GCMs), and soil moisture capacity and retention, to a water balance model, to produce
7771 monthly average runoff records. The computed Potential Evapotranspiration (PET) is
7772 also used to estimate seasonal water use in residential areas.

7773

7774 The results of the 2005 study indicated that, depending on the climate change scenario,
7775 the demand in the Washington metropolitan area could increase in 2030 between 74 and
7776 138 percent greater than the 1990 demand values. According to the report, "resources
7777 were significantly stressed or deficient" at that point. The water management component
7778 of the model helped determined that, with aggressive plans in conservation and operation
7779 policies, existing resources would be sufficient through 2030. In consequence, the study

7780 recommended “that water management consider the need to plan for mitigation of
7781 potential climate change impacts.” (Kame’enui *et al.*, 2005, Steiner *et al.*, 1997).

7782

7783 ***Case Study H:***

7784 ***Fire prediction workshops as a model for a climate science-water management process***
7785 ***to improve water resources decision support***

7786 Fire suppression costs the United States ~ \$1 billion each year. Almost two decades of
7787 research into the associations between climate and fire (*e.g.*, Swetnam and Betancourt,
7788 1998), demonstrate a high potential to predict various measures of fire activity, based on
7789 direct influences, such as drought, and indirect influences, such as growth of fine fuels
7790 such as grasses and shrubs (*e.g.*, Westerling *et al.*, 2002; Roads *et al.*, 2005; Preisler and
7791 Westerling, 2007). Given strong mutual interests in improving the range of tools
7792 available to fire management, with the goals of reducing fire related damage and loss of
7793 life, fire managers and climate scientists have developed a long-term process to improve
7794 fire potential prediction (Garfin *et al.*, 2003; Ochoa and Wordell, 2006) and to better
7795 estimate the costs and most efficient deployment of fire fighting resources. The strength
7796 of collaborations between climate scientists, fire ecologists, fire managers, and
7797 operational fire weather forecasters, is based upon mutual learning and meshing both
7798 complementary knowledge (*e.g.*, atmospheric science and forestry science) and expertise
7799 (*e.g.*, dynamical modeling and command and control operations management) (Garfin,
7800 2005). The emphasis on process, as well as product, may be a model for climate science
7801 in support of water resources management decision-making. Another key facet in
7802 maintaining this collaboration and direct application of climate science to operational
7803 decision-making has been the development of strong professional relationships between
7804 the academic and operational partners. Aspects of developing these relationships that are
7805 germane to adoption of this model in the water management sector include:

- 7806 • Inclusion of climate scientists as partners in annual fire management strategic
7807 planning meetings;
- 7808 • Development of knowledge and learning networks in the operational fire
7809 management community;

- 7810 • Inclusion of fire managers and operational meteorologists in academic research
7811 projects and development of verification procedures (Corringham *et al.*, 2008)
7812 • Co-location of fire managers at academic institutions (Schlobohm, *et al.*, 2003).
7813

7814 ***Case Study I:***

7815 ***Incentives to Innovate – Climate Variability and Water Management along the San***
7816 ***Pedro River***

7817 The San Pedro River, though small in size, supports one of the few intact riparian
7818 systems remaining in the Southwest. Originating in Sonora, Mexico, the stream flows
7819 northward into rapidly urbanizing southeastern Arizona, eventually joining with the Gila
7820 River, a tributary of the Lower Colorado River. On the American side of the international
7821 boundary, persistent conflict plagues efforts to manage local water resources in a manner
7822 that supports demands generated at Fort Huachuca Army Base and the nearby city of
7823 Sierra Vista, while at the same time preserving the riparian area. Located along a major
7824 flyway for migratory birds and providing habitat for a wide range of avian and other
7825 species, the river has attracted major interest of an array of environmental groups that
7826 seek its preservation. Studies carried out over the past decade highlight the vulnerability
7827 of the river system to climate variability. Recent data indicate that flows in the San Pedro
7828 have declined significantly due in part to ongoing drought. More controversial is the
7829 extent to which intensified groundwater use is depleting water that would otherwise find
7830 its way to the river.

7831

7832 The highly politicized issue of water management in the upper San Pedro River Basin has
7833 led to establishment of the Upper San Pedro Partnership, whose primary goal is balancing
7834 water demands with water supply in a manner that does not compromise the region's
7835 economic viability, much of which is directly or indirectly tied to Fort Huachuca.

7836 Funding from several sources, including among others several NOAA programs and the
7837 Netherlands-based Dialogue on Climate and Water, has supported ongoing efforts to
7838 assess vulnerability of local water resources to climate variability on both sides of the
7839 border. These studies, together with experience from recent drought, point toward
7840 escalating vulnerability to climatic impacts, given projected increases in demand and

7841 likely diminution of effective precipitation over time in the face of rising temperatures
7842 and changing patterns of winter versus summer rainfall (IPCC, 2007). Whether recent
7843 efforts to reinforce growth dynamics by enhancing the available supply through water
7844 reuse or water importation from outside the basin will buffer impacts on the riparian
7845 corridor remain to be seen. In the meantime, climatologists, hydrologists, social
7846 scientists, and engineers continue to work with members of the Partnership and others in
7847 the area to strengthen capacity for an interest in using climate forecast products. A
7848 relatively recent decision to include climate variability and change in a decision-support
7849 model being developed by a University of Arizona engineer in collaboration with
7850 members of the Partnership constitutes a significant step forward in integrating climate
7851 into local decision processes.

7852

7853 The incentives for engagement in solving the problems in the San Pedro include both a
7854 “carrot” in the form of federal and state funding for the San Pedro Partnership, and a
7855 newly formed water management district, and a “stick” in the form of threats to the future
7856 of Fort Huachuca. Fort Huachuca represents a significant component of the economy of
7857 southern Arizona, and its existence is at least in part dependent on a showing that
7858 endangered species in the river, and the water rights of the San Pedro Riparian
7859 Conservation Area, are protected.

7860

7861 **4.4 SUMMARY FINDINGS AND CONCLUSIONS**

7862 The decision-support experiments discussed here and in chapter 3, together with the
7863 analytical discussion, have depicted several barriers to use of decision-support
7864 experiment information on seasonal to interannual climate information by water resource
7865 managers. The discussion has also pinpointed a number of ways to overcome these
7866 barriers and ensure effective communication, transfer, dissemination, and use of
7867 information. Our major findings are as follows.

7868

7869 Effective integration of climate information in decisions requires identifying topics of
7870 mutual interest to sustain long-term collaborative research and application of decision-
7871 support outcomes: Identifying topics of mutual interests – through forums and other
7872 means of formal collaboration – can lead to information penetration into agency (and
7873 stakeholder group) activities, and produce self-sustaining, participant-managed spin-off
7874 activities. Long-term engagement also allows time for the evolution of science-decision-
7875 maker collaboration, ranging from understanding the roles of various players to
7876 connecting climate to a range of decisions, issues, and adaptation strategies – and
7877 building trust.

7878

7879 Tools must engage a range of participants including those who generate them, those who
7880 translate them into predictions for decision-maker use, and the decision-makers
7881 themselves. Forecast innovations might combine climate factor observations, analyses of
7882 climate dynamics, and seasonal/interannual forecasts. In turn, users are concerned with
7883 varying problems and issues such as planting times, in-stream flows to support
7884 endangered species, and reservoir operations. While forecasts vary in their skill, multiple
7885 forecasts that examine various factors (*e.g.*, snow pack, precipitation, temperature
7886 variability) are most useful because they provide decision makers better information than
7887 might previously have been available.

7888

7889 A critical mass of scientists and decision-makers is needed for collaboration to succeed:
7890 Development of successful collaborations requires representation of multiple
7891 perspectives, including diversity of disciplinary and agency-group affiliation. For

7892 example, operations, planning, and management personnel should be involved in
7893 activities related to integrating climate information into decision systems; and there
7894 should be sound institutional pathways for information flow from researchers to decision-
7895 makers, including explicit responsibility for information use. Cooperative relationships
7896 that foster learning and capacity building within and across organizations, including
7897 restructuring organizational dynamics, are important, as is training of “integrators” who
7898 can assist stakeholders with using complex data and tools.

7899

7900 What makes a “critical mass critical?” Research on water resource decision-making
7901 suggests that agencies and other organizations define problems differently depending on
7902 whether they are dedicated to managing single-issue problems in particular sectors (*e.g.*,
7903 irrigation, public supply) as opposed to working in political jurisdictions or watershed-
7904 based entities designed to comprehensively manage and coordinate several management
7905 objectives simultaneously (*e.g.*, flood control and irrigation, power generation, and in-
7906 stream flow). The latter entities face the unusual challenge of trying to harmonize
7907 competing objectives, are commonly accountable to numerous users, and require
7908 “regionally and locally tailored solutions” to problems (Water in the West, 1998; also,
7909 Kenney and Lord, 1994; Grigg, 1996). A lesson that appears to resonate in our cases is
7910 that decision-makers representing the affected organizations should be incorporated into
7911 collaborative efforts.

7912

7913 Forums and other means of engagement must be adequately funded and supported:
7914 Discussions that are sponsored by boundary organizations and other collaborative

7915 institutions allow for co-production of knowledge, legitimate pathways for climate
7916 information to enter assessment processes, and a platform for building trust.
7917 Collaborative products also give each community something tangible that can be used
7918 within its own system (*i.e.*, information to support decision making, climate service, or
7919 academic research product). Experiments that effectively incorporate seasonal forecasts
7920 into operations generally have long term financial support, facilitated, in turn, by high
7921 public concern over potential adverse environmental and/or economic impacts. Such
7922 concern helps generate a “receptive audience” for new tools and ideas. Flexible and
7923 appropriate sources of funding must be found that recognize benefits received by various
7924 constituencies on the one hand, and ability to pay on the other. A combination of
7925 privately-funded, as well as publicly-supported revenue sources may be appropriate in
7926 many cases – both because of the growing demands on all sources of decision-support
7927 development, and because such a balance better satisfies demands that support for these
7928 experiments be equitably borne by all who benefit from them. Federal agencies within
7929 CCSP can help in this effort by developing a database of possible funding sources from
7930 all sectors – public and private (Proceedings: Western Governors Association, 2007).

7931

7932 There is a need to balance national decision-support tool production against
7933 customizable, locally specific needs: Given the diversity of challenges facing decision-
7934 makers, the diverse needs and aspirations of stakeholders, and the diversity of decision-
7935 making authorities, there is little likelihood of providing comprehensive climate services
7936 or “one-stop-shop” information systems to support all decision-making or risk
7937 assessment. Support for tools to help communities and other self-organizing groups

7938 develop their own capacity and conduct their own assessments within a regional context
7939 is essential.

7940

7941 There is a growing push for smaller scale products that are tailored to specific users but
7942 are expensive; as well as private sector tailored products (*e.g.*, “Weatherbug” and many
7943 reservoir operations proprietary forecasts have restrictions on how they share data).

7944 However, private sector products are generally available only to specific paying clients,

7945 and private observing systems generate issues related to trustworthiness of information

7946 and quality control. What are the implications of this push for proprietary vs. public

7947 domain controls and access? This problem is well-documented in policy studies of risk-

7948 based information in the fields of food labeling, toxic pollutants, medical and

7949 pharmaceutical information, and other forms of public disclosure programs (Graham,

7950 2002).

7951

7952 **4.5 FUTURE RESEARCH NEEDS AND PRIORITIES**

7953 Six major research needs are at the top of our list of priorities for investigations by

7954 government agencies, private sector organizations, universities, and independent

7955 researchers. These are:

7956 1) Better understanding the decision-maker context for tool use;

7957 2) Understanding decision-maker perceptions of climate risk and vulnerability;

7958 3) Improving the generalizability of case studies on decision-support experiments;

7959 4) Understanding the role of public pressures and networks in generating demands

7960 for climate information;

7961 5) Improving the communication of uncertainties; and

7962 6) Lessons for collaboration and partnering from other natural resource areas.

7963

7964 Better understanding of the decision-maker context for tool use is needed. While we
7965 know that decision-maker context has a powerful influence on the use of tools, we need
7966 to learn more about how to promote user interactions with researchers at all junctures
7967 within the tool development process.

7968

7969 The institutional and cultural circumstances of decision-makers and scientists are
7970 important to determining how well – and how likely – collaboration will be. Among the
7971 questions that need to be answered are the following:

- 7972 • there is much that remains to be learned in regards to organizations and
7973 experiments engaged in transferring and developing climate variability
7974 information;
- 7975 • the decision space occupied by decision-makers;
- 7976 • ways to encourage innovation within institutions; and
- 7977 • the economic status of decision makers.

7978

7979 Access to information is an equity issue – large water management agencies may be able
7980 to afford sophisticated modeling efforts, consultants to provide specialized information,
7981 and a higher quality of data management and analysis, while smaller or less wealthy
7982 stakeholders generally do not have the same access or the consequent ability to respond
7983 (Hartmann, 2001). Scientific information that is not properly disseminated can

7984 inadvertently result in windfall profits for some and disadvantage others (Pfaff *et al.*,
7985 1999; Broad and Agrawalla, 2000; Broad *et al.*, 2002). Access and equity issues also
7986 need to be explored in more detail.

7987

7988 **4.5.1 Understanding Decision-Makers' Perceptions of Climate Vulnerability**

7989 Much more needs to be known about how to make decision-makers aware of their
7990 possible vulnerability from climate variability impacts to water resources. Research on
7991 the influence of climate science on water management in western Australia, for example,
7992 (Power *et al.*, 2005) suggests that water resource decision-makers can be persuaded to act
7993 on climate variability information if a strategic program of research in support of specific
7994 decisions (*e.g.*, extended drought) can be wedded to a dedicated, timely risk
7995 communication program.

7996

7997 While we know based on research in specific applications that managers who find
7998 climate forecasts and projections to be reliable are no more likely to use them, those most
7999 likely to use weather and climate information are individuals who have experienced
8000 weather and climate problems in the recent past. The implication of this finding is that
8001 simply delivering weather and climate information to potential users may be insufficient
8002 in those cases in which the manager does not perceive climate to be a hazard – at least in
8003 humid, water rich regions of the U.S. that we have studied.³

8004

³Additional research on water system manager perceptions is needed, in regions with varying hydro-meteorological conditions, to discern if this finding is universally true. .

8005 We also need to know more about how the financial, regulatory, and management
8006 contexts influence perceptions of usefulness (Yarnal *et al.*, 2006; Dow *et al.*, 2007).
8007 Achieving a better understanding of these contexts and of the informational needs of
8008 resource managers will require more investigation of their working environments and
8009 intimate understanding of their organizational constraints, motivations, and institutional
8010 rewards. generate much interest; presenting those managers with a Palmer Drought
8011 Severity Index tailored to their state that suggests a possible drought watch, warning, or
8012 emergency will grab their attention (Carbone and Dow, 2005).

8013

8014 **4.5.2 Possible Research Methodologies**

8015 Case studies increase understanding of how decisions are made by giving specific
8016 examples of decisions and lessons learned. A unique strength offered by the case study
8017 approach is that “. . .only when we confront specific facts, the raw material on the basis
8018 of which decisions are reached – not general theories or hypotheses – do the limits of
8019 public policy become apparent (Starling, 1989).” In short, case studies put a human face
8020 on environmental decision-making by capturing – even if only in a temporal “snapshot,”
8021 the institutional, ethical, economic, scientific, and other constraints and factors that
8022 influence decisions.

8023

8024 One school suggests that a key to case study research that would make it more
8025 generalizable is adoption of a “grounded theory” approach. This approach discerns
8026 general patterns (or principles of behavior common to decisions – *e.g.*, the motives of
8027 decision-makers who collaborated on a common agreement). These patterns are not

8028 experimental – instead, they occur within real-world settings where decision-makers and
8029 the public relied on local knowledge. Thus, they produce more accurate insights into
8030 decision-making than theory building or deduction alone (Glaser and Strauss, 1967;
8031 Goffman, 1974; Fischer, 1995: 78-9). The use of grounded theory also helps us identify
8032 additional cases – at different geographic or temporal scales – to confirm or disconfirm
8033 initial findings, provides “feedback” on real world conditions, and allows us to rethink
8034 initial assumptions, thus providing a foundation for testing theories, as well drawing
8035 lessons for decision makers, citizens, and students about the those conditions that
8036 promote – and inhibit – sustainable development. Finally, cases permit researchers to
8037 reason from analogy; draw comparisons and render contrasts; and capture subtle changes
8038 in decision-maker perceptions, attitudes, or beliefs over time (Yin, 1984; Stone, 1997,
8039 Babbie, 1989).

8040

8041 **4.5.3 Public Pressures, Social Movements and Innovation**

8042 The extent to which public pressures can compel innovation in decision-support
8043 development and use is an important area of prospective research. As has been discussed
8044 elsewhere in this report, knowledge networks – which provide linkages between various
8045 individuals and interest groups that allow close, ongoing communication and information
8046 dissemination among multiple sectors of society involved in technological and policy
8047 innovations – can be one source of non-hierarchical movement to impel innovation
8048 (Sarewitz and Pielke, 2007; Jacobs, 2005). Such networks can allow continuous
8049 feedback between academics, scientists, policy-makers, and NGOs in at least two ways:
8050 1) by cooperating in seeking ways to foster new initiatives, and 2) providing means of

8051 encouraging common evaluative and other assessment criteria to advance the
8052 effectiveness of such initiatives.

8053

8054 Since the late 1980s, there has arisen an extensive array of local, state (in the case of the
8055 U.S.) and regional/sub-national climate change-related activities in an array of developed
8056 and developing nations. These activities are wide-ranging and embrace activities inspired
8057 by various policy goals – some of which are only indirectly related to climate variability.
8058 These activities include energy efficiency and conservation programs; land use and
8059 transportation planning; and regional assessment. In some instances, these activities have
8060 been enshrined in the “climate action plans” of so-called Annex I nations to the UN
8061 Framework Convention on Climate Change (UNCED, 1992; Rabe, 2004).

8062

8063 An excellent example of an important network initiative is the International Council of
8064 Local Environmental Initiatives, or ICLEI. ICLEI is a Toronto, Canada-based NGO
8065 representing local governments engaged in sustainable development efforts worldwide.
8066 Formed in 1990 at the conclusion of the World Congress of Local Governments
8067 involving 160 local governments, it has completed studies of urban energy use useful for
8068 gauging growth in energy production and consumption in large cities in developing
8069 countries (*e.g.*, Kugler, 2007; ICLEI, 2007). ICLEI is helping to provide a framework of
8070 cooperation to evaluate energy, transport, and related policies and, in the process, may be
8071 fostering a form of “bottom-up” diffusion of innovation process that functions across
8072 jurisdictions – and even entire nation-states (Feldman and Wilt, 1996; 1999). More
8073 research is needed on how – and how effectively networks actually function and whether

8074 their efforts can shed light on the means by which the diffusion of innovation can be
8075 improved and evaluated.

8076

8077 Another form of public pressure is social movements – hardly unknown in water policy
8078 (*e.g.*, Donahue and Johnston, 1998). Can public pressures through such movements
8079 actually change the way decision-makers look at available sources of information? Given
8080 the anecdotal evidence, much more research is warranted. One of the most compelling
8081 recent accounts of how public pressures can change such perceptions is that by the
8082 historian Norris Hundley on the gradual evolution on the part of city leaders in Los
8083 Angeles, California, as well as members of the public, water agencies, and state and
8084 federal officials – toward diversion of water from the Owens Valley.

8085

8086 After decades of protests – some violent – over efforts to, at first prevent and then later,
8087 roll back, the amount of water taken from the Owens River, growing pressures by
8088 environmental organizations throughout the state of California, and the nation as a whole
8089 – coupled with withering support by federal agencies that initially “looked the other way”
8090 led the city of Los Angeles to seek an out of court settlement over diversion; to look
8091 seriously at the reports of environmental degradation caused by the volumes of water
8092 transferred, and to compensate the valley for its damages (Hundley, 2001: 347ff). While
8093 Hundley’s chronicling of resistance has a familiar ring to students of water policy,
8094 remarkably little research has been done to seek to draw lessons – through the grounded
8095 theory approach discussed earlier – about the impacts of such social movements.

8096

8097 Communicating uncertainty to users of climate variability information: While uncertainty
8098 is an inevitable factor in regards to climate variability and weather information, the
8099 communication of uncertainty – as our discussion has shown – can be significantly
8100 improved. Better understanding of innovative ways to communicate uncertainty to users
8101 should draw on additional literatures from the engineering, behavioral and social, and
8102 natural science communities (*e.g.*, NRC 2005; NRC 2006). Research efforts are needed
8103 by various professional communities involved in the generation and dissemination of
8104 climate information to better establish how to define and communicate climate variability
8105 risks clearly and coherently – and in ways that are meaningful to water managers.
8106 Additional research is needed to determine the most effective communication,
8107 dissemination and evaluation tools to deliver information on potential impacts of climate
8108 variability, especially with regards to such factors as further reducing uncertainties
8109 associated with future sea level rise, more reliable predictions of changes in frequency
8110 and intensities of tropical and extra-tropical storms, and how saltwater intrusion will
8111 impact freshwater resources, and the frequency of drought. Much can be learned from the
8112 growing experience of RISAs and other decision-support partnerships and networks.
8113
8114 Research on lessons from other resource management sectors on decision-support use
8115 and decision-maker/researcher collaboration would be useful. While water issues are
8116 ubiquitous and connect to many other resource areas, a great deal of research has been
8117 done on the impediments to, and opportunities for collaboration in, other resource areas
8118 such as energy, forests, coastal zone and hydropower. This research suggests that there is
8119 much that water managers and those who generate seasonal to interannual information on

8120 climate variability could learn from this literature. Among the questions that need further
8121 investigation are those that revolve around innovation (Are there resource areas in which
8122 tool development and use is proceeding at a faster pace than in water management?);
8123 organizational culture and leadership (Are some organizations and agencies more
8124 resistant to change; more hierarchical in their decision-making; more formalized in their
8125 decisional protocols) than is the case in water management?; and collaborative style (Are
8126 some organizations in certain resource areas – or science endeavors better at
8127 collaborating with stakeholder groups in the generation of information tools, or other
8128 activities? (*e.g.*, Kaufman, 1967; Bromberg, 2000). Much can also be learned about
8129 public expectations and the expectations of user groups from their collaborations with
8130 such agencies that could be valuable to the water sector.

8630 **5.1 INTRODUCTION**

8631 The future context for decision support for seasonal to interannual climate forecasting-
8632 related decisions in water resources and other sectors will evolve in response to future
8633 climate trends and events, advances in monitoring, predicting and communicating
8634 information about hydrologically-significant aspects of climate, and social action.
8635 Climate related issues have a much higher profile among the public, media, and policy
8636 makers than they did even a few years ago. In water resources and other sectors, climate
8637 is likely to be only one of a number of factors affecting decision making, and the extent
8638 to which it is given priority will depend both on the experiences associated with
8639 “focusing events” such as major droughts, floods, hurricanes and heat waves, and on how
8640 strong knowledge networks have become. The utility of climate information will depend
8641 largely on how salient, credible, valuable and legitimate it is perceived to be. These
8642 qualities are imparted through knowledge networks that can be fostered and strengthened
8643 using decision-support tools. Increasingly climate forecasting and data have become
8644 integrated with water resources decisions at multiple levels, and some of the lessons
8645 learned in the water sector can improve the application of seasonal-to-interannual (SI)
8646 climate forecasts in other climate sensitive sectors. Better integration of climate
8647 forecasting science into water resources and other sectors will likely save and improve
8648 lives, reduce damages from weather extremes, and lower economic cost related to
8649 adapting to continued climate variability.

8650

8651 This chapter begins by highlighting a number of overarching themes that need to be
8652 emphasized as important to understanding the overall challenges facing decision support

8653 and its use. It then turns to research priorities that are critical to progress. The chapter
8654 concludes with some discussion of other sectors likely to be affected by climate variation
8655 that could profit from lessons in the water resources sector.

8656

8657 **5.2 OVERARCHING THEMES AND FINDINGS**

8658 **5.2.1 The “Loading Dock Model” of Information Transfer is Unworkable**

8659 Only recently have climate scientists come to realize that improving the skill and
8660 accuracy of climate forecasting products does not necessarily make them more useful or
8661 more likely to be adopted. Skill is a necessary ingredient in perceived forecast value, yet
8662 more forecast skill by itself does not imply more forecast value. Lack of forecast skill
8663 and/or accuracy may be one of the impediments to forecast use, but there are many other
8664 barriers. Such improvements must be accompanied by better communication and stronger
8665 linkages between forecasters and potential users. In this report we have stressed that
8666 forecasts flow through knowledge networks and across disciplinary and occupational
8667 boundaries. Thus, forecasts need to be useful and relevant in the full range from
8668 observations to applications, or “end-to-end useful.” End-to-end useful also implies a
8669 broader fabric of utility, created by multiple entities that adopt forecasts for their own
8670 reasons and adapt them to their own purposes by blending forecast knowledge with
8671 know-how, practices, and other sources of information more familiar to those
8672 participants. These network participants then pass the blended information along to other
8673 participants who in turn engage in the same process. By the end of the process of
8674 transfer, translation and transformation of information, forecast information may look
8675 very different from what scientists initially envisioned.

8676

8677 Skill and accuracy are only two of the values important to the use of climate knowledge.

8678 Relevance is of equal importance, and to be relevant the information must be timely as

8679 well. It almost goes without saying that the benefits of using the information should be

8680 larger than the costs, but it is worth remembering that many decision makers already

8681 operate with an overload of information and therefore relevance depends on salience to

8682 specific situations that they are concerned about. Also, benefits should not be thought of

8683 as primarily economic but need also to include political, organizational and professional

8684 advantages. Salience is a product of framing in the larger political community and in the

8685 professional circles in which different decision makers' travel. Information must be

8686 credible and come from a legitimate or trusted source that has a reputation for integrity.

8687 Novel ideas are difficult for organizations to adopt, and, therefore such ideas become

8688 more credible if they are blended with and tempered by already existing information

8689 channels and organizational routines.

8690

8691 5.2.2 Decision Support is a Process Rather Than a Product

8692 As knowledge systems have come to be better understood, providing decision support has

8693 come to be understood not only as information products but instead as a communications

8694 process that links scientists with users. While decision tools like models, scenarios, and

8695 other boundary objects that connect scientific forecasters to various stakeholder groups

8696 can be helpful, the notion of tools insufficiently conveys the relational aspects of

8697 networks. Relevance, credibility, and legitimacy are human perceptions built through

8698 repeated interactions. For this reason, decision support does not result in a product that

8699 can be shelved until needed or reproduced for different audiences. Clearly lessons from
8700 decisions support experience are portable from one area to another but only as the
8701 differences in context are interpreted, understood, and taken into account.

8702

8703 Governments are not the only producers of climate variability forecasts. Non-
8704 governmental actors including private businesses play a critical role in knowledge
8705 networks, particularly in tailoring climate forecast products to fit the needs of particular
8706 sectors and user groups. Nothing in this report should suggest that knowledge networks
8707 must be wholly or even for the most part in the public sector. Just as numerous
8708 entrepreneurs have taken National Weather Service forecasts and applied them to
8709 different sectors and user group needs, SI climate information transfer, translation and
8710 transformation may become functions largely provided by the private sector. However, as
8711 argued in the following section, there is clearly a role for the public sector because
8712 information access is related to economic and social outcomes that must be
8713 acknowledged.

8714

8715 Ensuring that information is accessible and relevant will require paying greater attention
8716 to the role of institutions in furthering the process of decision support – particularly
8717 *boundary spanning* activities that bring together tool developers and users to exchange
8718 information, promote communication, propose remedies to problems, foster stakeholder
8719 engagement, and conjointly develop decision-support systems to address user needs. An
8720 important facet of boundary spanning is that the co-production, transference,
8721 communication and dissemination of climate information to water decision makers

8722 requires partnerships among public and private sector entities. In short, to avoid the
8723 loading-dock model previously discussed, efforts to further boundary-spanning
8724 partnerships is essential to fostering a process of decision support (NRC, 2007; NRC,
8725 2008; Cash and Buizer, 2005; Sarewitz and Pielke, 2007).

8726

8727 **5.2.3 Equity May Not Be Served**

8728 Information is power in global society, and unless it is widely shared, the gaps between
8729 the rich and the poor, and the advantaged and disadvantaged may widen. Lack of
8730 resources is one of the causes of poverty, and resources are required to tap into
8731 knowledge networks so that in a vicious cycle, poverty can become its own cause.

8732 Unequal distribution of knowledge can insulate decision-making, facilitate elite capture
8733 of resources, and alienate disenfranchised groups. In contrast, an approach that is open,
8734 interactive and inclusionary can go a long way in supporting informed decisions that, in
8735 turn, can yield better outcomes from the perspective of fairness.

8736

8737 The emergence of seasonal climate forecasting initially raised great expectations of its
8738 potential role to decrease the vulnerability of poor farmers around the world to climate
8739 variability and the development and dissemination of forecasts have been justified in
8740 equity terms (Glantz, 1996; McPhaden *et al.*, 2006). However, ten years of empirical
8741 research on seasonal forecasting application and effect on agriculture, disaster response
8742 and water management have tempered these expectations (Klopper, 1999; Vogel, 2000;
8743 Valdivia *et al.*, 2000; Letson *et al.*, 2001; Hammer *et al.*, 2001; Lemos *et al.*, 2002; Patt
8744 and Gwata, 2002; Broad *et al.*, 2002; Archer, 2003; Lusenso *et al.*, 2003; Roncoli *et al.*,

8745 2006; Bharwani *et al.*, 2005; Meinke *et al.*, 2006; Klopper *et al.*, 2006). Examples of
8746 applications of SI climate forecasts show that not only are the most vulnerable often
8747 unable to benefit, but in some situations may be harmed (Broad *et al.*, 2002; Lemos *et al.*,
8748 2002; Patt and Gwata, 2002; Roncoli *et al.*, 2004; Roncoli *et al.*, 2006; O'Brien and
8749 Vogel, 2007). Some users have been able to benefit from this new information. For
8750 example, many Pacific island nations respond to El Niño forecasts and avoid potential
8751 disasters from water shortages. Similarly, agricultural producers in Australia have been
8752 better able to cope with swings in their commodity production associated with drought
8753 and water managers. In the United States Southwest, managers have been able to
8754 incorporate SI climate forecasts in their decision-making processes to respond to crisis –
8755 and this is even becoming true in more water-rich regions such as the United States
8756 Southeast that are now facing prolonged drought (Hammer, *et al.*, 2001; Hartmann, *et al.*,
8757 2002; Pagano *et al.*, 2002; Georgia DNR, 2003). But, unless greater effort is expended to
8758 rectify the differential impacts of climate information in contexts where the poor lack
8759 resources, SI climate forecasts will not contribute to global equity.

8760

8761 There are several factors that help to explain when and where equity goals are served in
8762 SI climate forecasting and when they are not (Lemos and Dilling, 2007). Understanding
8763 existing levels of underlying inequities and differential vulnerabilities is critical
8764 (Agrawala *et al.*, 2001). Forecasts are useful only when recipients of information have
8765 sufficient decision space or options to be able to respond to lower vulnerability and risk.
8766 Differential levels in the ability to respond can create winners and losers within the same
8767 policy context. For example, in Zimbabwe and northeastern Brazil, news of poor rainfall

8768 forecasts for the planting season influence bank managers who systematically deny
8769 credit, especially to poor farmers they perceive as high risk (Hammer, *et al.*, 2001;
8770 Lemos, *et al.*, 2002). In Peru, a forecast of El Niño and the prospect of a weak season
8771 gives fishing companies incentives to accelerate seasonal layoffs of workers (Broad, *et*
8772 *al.*, 2002). Some users (bankers, businesses) who were able to act based on forecasted
8773 outcomes (positive or negative) benefited while those who could not (farmers,
8774 fishermen), lost. Financial, social and human resources are often out of reach of the poor
8775 that lack education, money and time resources to engage forecast producers (Lemos and
8776 Dilling, 2007). Even when the information is available, however, differences in
8777 resources, social status, and empowerment limit hazard management options. As
8778 demonstrated by Hurricane Katrina, for example, the poor and minorities are reluctant to
8779 leave their homes for fear of becoming victims of crime and looting – and are simply not
8780 welcome as immigrants fleeing from disaster (*e.g.*, Hartmann, *et al.*, 2002; Carbone and
8781 Dow, 2005; Subcommittee on Disaster Reduction, 2005; Leatherman and White, 2005).
8782
8783 Native American farmers who are unable to move their farming enterprises as do
8784 agribusinesses, and can not lease their water rights strategically to avoid planting during
8785 droughts are disadvantaged because of their small decision space or lack of alternatives.
8786 Moreover, poorer groups often distrust experts who are in possession of risk information
8787 because the latter are often viewed as elitist; focused more on probabilities rather than on
8788 the consequences of disaster; or, unable to communicate in terms comprehensible to the
8789 average person (Jasanoff, 1987; Covello *et al.*, 1990). However, other research has found
8790 that resources, while desirable, are not an absolute constraint to poor peoples' ability to

8791 benefit from seasonal forecast use. In these cases, farmers have been able to successfully
8792 use seasonal climate forecasts by making small adjustments to their decision making
8793 process (Eakin, 2000; Ingram *et al.*, 2002; Patt *et al.*, 2005; Roncoli *et al.*, 2006).

8794

8795 A more positive future in terms of redressing inequity and reducing poverty can take
8796 place if application policies and programs create alternative types of resources, such as
8797 sustained relationships with information providers and web-based tools that can be easily
8798 tailored to specific applications; promotion of inclusionary dissemination practices; and
8799 paying attention to the context of information applications (Valdivia *et al.*, 2000; Archer,
8800 2003; Ziervogel and Calder, 2003; Roncoli *et al.*, 2006). Examples in the literature show
8801 that those who benefit from SI climate forecasts usually have the means to attend
8802 meetings or to access information through the media (at least through the radio). It is
8803 especially helpful if organizers of workshops where attendance is limited reach out to
8804 disadvantaged and vulnerable populations. For example, small farmers in Tamil Nadu,
8805 India (Huda *et al.*, 2004) and Zimbabwe (Patt and Gwata, 2002) benefited from climate
8806 information through a close relationship with forecast “brokers”¹ who spent considerable
8807 effort in sustaining communication and providing expert knowledge to farmers.

8808 However, the number of farmers targeted in these projects was very limited. For any real
8809 impact such efforts will need to be scaled up and sustained beyond research projects.

8810

8811 Equitable communication and access are critical to fairness with respect to potential
8812 benefit from forecast information, but such qualities often do not exist. Factors such as

¹ Researchers in the India case and researchers and extension agents in the Zimbabwe case.

8813 levels of education, access to electronic media such as the Internet, and expert knowledge
8814 critically affect the ability of different groups to take advantage of seasonal forecasts
8815 (Lemos and Dilling, 2007). While the adoption of participatory processes of
8816 communication and dissemination can defray some of these constraints, the number of
8817 positive cases documented is small (*e.g.* Patt *et al.*, 2005; Roncoli *et al.*, 2006; Vogel and
8818 O'Brien, 2006). And because forecasts are mostly disseminated in the language of
8819 probabilities, it may be difficult to assimilate by those who do not generally think
8820 probabilistically nor interpret probabilities easily, or those whose framing of
8821 environmental issues is formed through experience with extreme events, or a
8822 preoccupation with consequences due to the context in which they make decisions
8823 (Nicholls, 1999; Yarnal *et al.*, 2006; Dow *et al.*, 2007; Weingert *et al.*, 2000). In a
8824 situation where private enterprise is important for participants in knowledge networks,
8825 serving the poor may not be profitable, and for that reason they become marginalized.
8826
8827 Fostering inclusive, equitable access, therefore, will require a combination of
8828 organizational practices that empower employees, and engage agency clients, outside
8829 stakeholder groups, and the general public through providing training and outreach in
8830 tool use, and the infusion of trust in communication of risks. The latter will require use
8831 of public forums and other vehicles that provide opportunities for open, clear, jargon-free
8832 information as well as opportunity for discussion and public reaction (Freudenburg and
8833 Rursch, 1994; Papadakis, 1996; Jasanoff, 1987; Covello *et al.*, 1990; NRC, 1989). If
8834 climate science applications are to more clearly put vulnerable poor on an equal footing
8835 or to go further toward reducing inequality, decision support must target the vulnerable

8836 poor specifically. Time and funds must be invested in understanding the process through
8837 which decisions are made and resources allocated. Specific training and a concerted
8838 effort to “fit” the available information to local decision making patterns and culture can
8839 be a first step to enhance its relevance. Seasonal forecast producers and policy makers
8840 need to be aware of the broader sociopolitical context and the institutional opportunities
8841 and constraints presented by seasonal forecast use and understand potential users and
8842 their decision environment. A better fit between product and client can avoid situations
8843 in which forecast use may harm those it could help. Finally, as some of the most
8844 successful examples show, seasonal forecasting application should strive to be more
8845 transparent, inclusionary, and interactive as a means to counter power imbalances.

8846

8847 **5.2.4 Science Citizenship Plays an Important Role in Developing Appropriate**

8848 **Solutions**

8849 Some scholars observe that a new paradigm in science is emerging, one that emphasizes
8850 science-society collaboration and production of knowledge tailored more closely to
8851 society’s decision making needs (Gibbons, 1999; Nowotny *et al.*, 2001; Jasanoff, 2004a).
8852 The philosophy is that, through mobilizing both academic and pragmatic knowledge and
8853 experience, better solutions may be produced for pressing problems. Concerns about
8854 climate impacts on water resource management are among the most pressing problems
8855 that require close collaboration between scientists and decision makers. Examples of
8856 projects that are actively pursuing collaborative science to address climate-related water
8857 resource problems include the Semi-Arid Hydrology and Riparian Area (SAHRA) project
8858 (<http://www.sahra.arizona.edu>), funded by the National Science Foundation (NSF) and

8859 located at the University of Arizona and the NSF-funded Decision Center for a Desert
8860 City, located at Arizona State University (<http://dcdc.asu.edu>). The regional focus of
8861 NOAA's RISA program is likewise providing opportunities for collaborations between
8862 scientists and citizens to address climate impacts and information needs in different
8863 sectors, including water resource management. An examination of the Climate
8864 Assessment for the Southwest (CLIMAS), one of the RISA projects, provided insight into
8865 some of the ways in which co-production of science and policy is being pursued in a
8866 structured research setting (Lemos and Morehouse, 2005).

8867

8868 Collaborative efforts to produce knowledge and policy in synchrony not only expand the
8869 envelope of the scientific enterprise, but also change the terms of the relationship
8870 between scientists and citizens. This emergence of new forms of science-society
8871 interactions has been documented from various perspectives, including the place of local,
8872 counter-scientific, and non-scientific knowledge (Eden, 1996; Fischer, 2000), links with
8873 democracy and democratic ideals (Jasanoff, 1996; Harding, 2000; Durodié, 2003), and
8874 environmental governance and decision making (Jasanoff and Wynne, 1998; Bäckstrand,
8875 2003; Brunner *et al.*, 2005). These types of collaboration present opportunities to bridge
8876 the gaps between abstract scientific conceptualizations and knowledge needs generated
8877 by a grounded understanding of the nature and intensity of actual and potential risks and
8878 the specific vulnerabilities experienced by different populations, at different times and in
8879 different places.

8880

8881 Unlike the more traditional “pipeline” structure of knowledge transfer unidirectionally
8882 from scientists to citizens, processes involving coproduction of science and policy take a
8883 more circuitous form, one that requires experimentation and iteration (Lemos and
8884 Morehouse, 2005; Jasanoff and Wynne, 1998). This model of science-society interaction
8885 has a close affinity to concepts of adaptive management and adaptive governance
8886 (Pulwarty and Melis, 2001; Gunderson, 1999; Holling, 1978; Brunner *et al.*, 2005), for
8887 both of these concepts are founded on notions that institutional and organizational
8888 learning can be facilitated through careful experimentation with different decision and
8889 policy options. Such experimentation is, ideally, based on best available knowledge but
8890 allows for changes based on lessons learned, emergence of new knowledge, and/or
8891 changing conditions in the physical or social realms. The experiments described in this
8892 report offer examples of adaptive management and adaptive governance in practice.
8893
8894 Less extensively documented, but no less essential to bringing science to bear effectively
8895 on climate-related water resource management challenges is the notion of science
8896 citizenship (Jasanoff, 2004b), whereby the fruits of collaboration between scientists and
8897 citizens produces capacity to bring science-informed knowledge into processes of
8898 democratic deliberation, including network building, participation in policy-making,
8899 influencing policy interpretation and implementation processes, and even voting in
8900 elections. Science citizenship might, for example, involve participating in deliberations
8901 about how best to avert or mitigate the impacts of climate variability and change on
8902 populations, economic sectors, and natural systems vulnerable to reduced access to water.
8903 Indeed, water is fundamental to life and livelihood, and, as noted above, climate impacts

8904 research has revealed that deleterious effects of water shortages are unequally
8905 experienced: poorer and more marginalized segments of populations often suffer the most
8906 (Lemos, 2008). Innovative drought planning processes require precisely these kinds of
8907 input, as does planning for long-term reductions in water availability due to reduced
8908 snowpack—a problem that Seattle is beginning to plan for, as reflected in this report
8909 (Chapter 4). Issues such as these require substantial evaluation of how alternative
8910 solutions are likely to affect different entities at different times and in different places.
8911 For example, substantial reduction in snowpack, together with earlier snowmelt and
8912 longer periods before the onset of the following winter, will likely require serious
8913 examination of social values and practices as well as of economic activities throughout a
8914 given watershed and water delivery area. As these examples demonstrate, science
8915 citizenship clearly has a crucial role to play in building bridges between science and
8916 societal values in water resource management. It is likely that this will occur primarily
8917 through the types of knowledge networks and knowledge-to-action networks discussed
8918 earlier in this chapter.

8919

8920 **5.2.5 Trends and Reforms in Water Resources Provide New Perspectives**

8921 As noted in Chapters 1 and 4, since the 1980s a “new paradigm” or frame for federal
8922 water planning has occurred that appears to reflect the ascendancy of an environmental
8923 protection ethic among the general public. The new paradigm emphasizes greater
8924 stakeholder participation in decision-making; explicit commitment to environmentally-
8925 sound, socially-just outcomes; greater reliance upon drainage basins as planning units;
8926 program management via spatial and managerial flexibility, collaboration, participation,

8927 and sound, peer-reviewed science; and, embracing of ecological, economic, and equity
8928 considerations (Hartig, et. al., 1992; Landre and Knuth, 1993; Cortner and Moote, 1994;
8929 Water in the West, 1998; May *et al.*, 1996; McGinnis, 1995; Miller, et. al., 1996; Cody,
8930 1999; Bormann, et. al., 1994; Lee, 1993).

8931

8932 This “adaptive management” paradigm results in a number of climate-related SI climate
8933 information needs, including questions pertaining to the following: what are the decision-
8934 support needs related to managing in-stream flows/low flows? And, what changes to
8935 water quality, runoff and stream flow will occur in the future, and how will these changes
8936 affect water uses among future generations unable to influence the causes of these
8937 changes today? The most dramatic change in decision support that emerges from the
8938 adaptive management paradigm is the need for real-time monitoring and ongoing
8939 assessment of the effectiveness of management practices, and the possibility that
8940 outcomes recommended by decision-support tools be iterative, incremental and reversible
8941 if they prove unresponsive to critical groups, ineffective in managing problems, or both.
8942 What makes these questions particularly challenging is that they are interdisciplinary in
8943 nature².

8944

² Underscored by the fact that scholars concur adaptive management entails a broad range of processes to avoid environmental harm by imposing modest changes on the environment, acknowledging uncertainties in predicting impacts of human activities on natural processes, and embracing social learning (*i.e.*, learning by experiment). In general, it is characterized by four major strategies: 1) managing resources by learning, especially about mistakes, in an effort to make policy improvements, 2) modifying policies in the light of experience – and permitting such modifications to be introduced in “mid-course”, 3) allowing revelation of critical knowledge heretofore missing, as feedback to improve decisions, and 4) incorporating outcomes in future decisions through a consensus-based approach that allows government agencies and NGOs to conjointly agree on solutions (Bormann et. al., 1993; Lee, 1993; Definitions of Adaptive Management, 2000).

8945 Another significant innovation in United States water resources management that affects
8946 climate information use is occurring in the *local* water supply sector, as discussed in
8947 chapter 4, the growing use of integrated water resource planning (or IWRP) as an
8948 alternative to conventional supply-side approaches for meeting future demands. IWRP is
8949 gaining acceptance in chronically water-short regions such as the Southwest and portions
8950 of the Midwest – including Southern California, Kansas, Southern Nevada, and New
8951 Mexico (Beecher, 1995; Warren et. al., 1995; Fiske and Dong, 1995; Wade, 2001).
8952 IWRM supports the use of multiple sources of information like that of SI climate and
8953 water supply forecasts as well as feedback from experience and experiments.
8954
8955 IWRP’s goal is to “balance water supply and demand management considerations by
8956 identifying feasible planning alternatives that meet the test of least cost without
8957 sacrificing other policy goals” (Beecher, 1995). This can be variously achieved through
8958 depleted aquifer recharge, seasonal groundwater recharge, conservation incentives,
8959 adopting growth management strategies, wastewater reuse, and applying least-cost
8960 planning principles to large investor-owned water utilities. The latter may encourage
8961 IWRP by demonstrating the relative efficiency of efforts to reduce demand as opposed to
8962 building more supply infrastructure. A particularly challenging alternative is the need to
8963 enhance regional planning among water utilities in order to capitalize on the resources of
8964 every water user, eliminate unnecessary duplication of effort, and avoid the cost of
8965 building new facilities for water supply (Atwater and Blomquist, 2002).
8966

8967 In some cases, short term least cost planning may *increase* long-term project costs,
8968 especially when environmental impacts, resource depletion, and energy and maintenance
8969 costs are included. The significance of least-cost planning is that it underscores the
8970 importance of long and short-term costs (in this case, of water) as an influence on the
8971 value of certain kinds of information for decisions. The most dramatic change in decision
8972 support that emerges from the adaptive management paradigm is the need for real-time
8973 monitoring and ongoing assessment of the effectiveness of management practices, and
8974 the possibility that outcomes recommended by decision-support tools be iterative,
8975 incremental and reversible if they prove unresponsive to critical groups, ineffective in
8976 managing problems, or both. Models and forecasts that predict water availability under
8977 different climate scenarios can be especially useful to least-cost planning and make more
8978 credible efforts to reducing demand. Specific questions IWRP raises for decision-
8979 support-generated climate information include: how precise must climate information be
8980 to enhance long term planning? How might predicted climate change provide an
8981 incentive for IWRP strategies? And, what climate information is needed to optimize
8982 decisions on water pricing, re-use, shifting from surface to groundwater use, and
8983 conservation?

8984

8985 **5.2.6 Useful Evaluation of Applications of Climate Variation Forecasts Requires**

8986 **Innovative Approaches**

8987 There can be little argument that SI climate and hydrologic forecast applications must be
8988 evaluated just as are most other programs that involve substantial public expenditures.
8989 That said, this report has evidenced many of the difficulties of using standard evaluation

8990 techniques. While there have been some evaluations of programs, mostly from the
8991 vantage point of assessing the influence of Regional Integrated Science Assessments
8992 (RISAs) on federal climate science policy (*e.g.*, McNie *et al.*, 2007; Cash *et. al.*, 2006),
8993 there has been little formal systematic, standardized evaluation of whether they are
8994 optimally designed to learn from experience and incorporate user feedback. Evaluation
8995 works best on programs with a substantial history so that it is possible to compare present
8996 conditions with those that existed some years in the past. The effort to promote the use of
8997 SI climate forecasts is relatively new and has been a moving target, with new elements
8998 being regularly introduced, so that it is difficult to determine what features of those
8999 federal programs charged with collaborating with decision makers in the development,
9000 use, application and evaluation of climate forecasts have which consequences. As the
9001 effort to promote greater use of SI climate and hydrologic forecasts accelerates in the
9002 future, it is important to foster developments that facilitate evaluation. It is imperative
9003 that promoting forecast use have a clear causal model that includes the complete
9004 implementation chain with credible rationales or incentives for participants to take
9005 desired actions. Setting clear goals and priorities for allocation of resources among
9006 different elements is essential to any evaluation of program accomplishments (NRC,
9007 Research and Networks for Decision Support, 2008). It is especially difficult to measure
9008 the accomplishment of some kinds of goals important to adaptive management such as
9009 organizational learning. For this reason, we believe that consistent monitoring and
9010 regular evaluation of processes and tools at different time and spatial scales will be
9011 required to assess progress.
9012

9013 An NRC panel addressing a closely related challenge for standard evaluation
9014 recommended that the need for evaluation should be addressed through monitoring
9015 (NRC, SARP Rpt, 2008). The language of that report seems entirely applicable here:

9016 Monitoring requires the identification of process measures that
9017 could be recorded on a regular (for instance, annual) basis and of
9018 useful output or outcome measures that are plausibly related to the
9019 eventual effects of interest and can be feasibly and reliably
9020 recorded on a similar regular basis. Over time, the metrics can be
9021 refined and improved on the basis of research, although it is
9022 important to maintain some consistency over extended periods
9023 with regard to at least some of the key metrics that are developed
9024 and used.

9025
9026 There are signals of network building and collaborative forecaster-user interaction and
9027 collaboration that can be monitored. Meetings and workshops held, new contacts made,
9028 new organizations involved in information diffusion, websites, list serves, newsletters
9029 and reports targeted to new audiences are but a few of the many activities that are
9030 indicative of network creation activity.

9031

9032 **5.3 RESEARCH PRIORITIES**

9033 As a result of the findings in this report, we suggest that a number of research priorities
9034 should constitute the focus of attention for the foreseeable future. These priorities are: 1)
9035 improved vulnerability assessment, 2) improved climate and hydrologic forecasts, 3)
9036 enhanced monitoring to better link climate and hydrologic forecasts, 4) better integration
9037 of SI climate science into decision making, 5) better balance between physical science
9038 and social science research related to the use of scientific information in decision making,
9039 6) better understanding of the implications of small-scale, specially-tailored tools, and 7)
9040 sustained long-term scientist-decision-maker interactions and collaborations and

9041 development of science citizenship. The following discussion identifies each priority in
9042 detail, and recommends ways to implement them.

9043

9044 **5.3.1 A Better Understanding of Vulnerability is Essential**

9045 Case studies of the use of decision-support tools in water resources planning and
9046 management suggest that the research and policy-making communities need a far more
9047 comprehensive picture of the vulnerability of water and related resources to climate
9048 variability. This assessment must account for vulnerability along several dimensions.

9049

9050 As we have seen, there are many forms climate vulnerability may take – ranging from
9051 social and physical vulnerability to ecological fragmentation, economic dislocation, and
9052 even organizational change and turmoil. Vulnerability may also range across numerous
9053 temporal and spatial scales. Spatially, it can affect highly localized resources or spread
9054 over large regions. Temporally, vulnerability can be manifested as an extreme and/or
9055 rapid onset problem that lasts briefly, but imposes considerable impact on society (*e.g.*,
9056 intense tropical storms) or takes the form of a prolonged or slow-onset event, such as
9057 drought, which may produce numerous impacts for longer time periods.

9058

9059 In order to encompass these widely varying dimensions of vulnerability. We also need
9060 more research on how decision makers perceive the risks from climate variability and,
9061 thus, what variables incline them to respond proactively to threats and potential hazards.

9062 As in so many other aspects of decision-support information use, previous research
9063 indicates that merely delivering weather and climate information to potential users may

9064 be insufficient in those cases in which the manager does not perceive climate variability
9065 to be a hazard – at least in humid, water rich regions of the United States that we have
9066 studied (Yarnal *et al.*, 2006; Dow *et al.*, 2007). Are there institutional incentives to using
9067 risk information, or – conversely – not using it? And, in what decisional contexts (*e.g.*,
9068 protracted drought, sudden onset flooding hazards) are water managers most likely – or
9069 least likely – to be susceptible to employing climate variability hazard potential
9070 information?

9071

9072 **5.3.2 Improving Hydrologic and Climate Forecasts**

9073 Within the hydrologic systems, accurate measures and assimilation of the initial state are
9074 crucial for making skillful hydrologic forecasts; therefore, a sustained high-quality
9075 monitoring system tracking stream flow, soil moisture, snowpack, and evaporation,
9076 together with tools for real-time data assimilation, are fundamental to the hydrologic
9077 forecasting effort. In addition, watersheds with sparse monitoring networks, or relatively
9078 short historical data series are also prone to large forecast errors due to a lack of historical
9079 and real-time data and information about its hydrologic state.

9080

9081 Monitoring and assimilation are also essential for climate forecasting, as well as exercises
9082 of hindcasting to compare present experience with the historical record. Moreover,
9083 monitoring is critical for adaptive and integrated water resources management, and for
9084 the more effective adoption of strategies currently widely embraced by natural resources
9085 planners and managers.

9086 On-going improvements in the skill of climate forecasting will continue to provide
9087 another important avenue for improving the skill in SI hydrologic and water supply
9088 forecasts. For many river basins and in many seasons, the single greatest source of
9089 hydrologic forecast error is unknown precipitation after the forecast issue date. Thus,
9090 improvements in hydrologic forecasting are directly linked with improvements in
9091 forecasts for precipitation and temperature.

9092

9093 In addition, support for coordinated efforts to standardize and quantify the skill in
9094 hydrologic forecasts is needed. While there is a strong culture and tradition of forecast
9095 evaluation in meteorology and climatology, this sort of retrospective analysis of the skill
9096 of seasonal hydrologic forecasts has historically not been commonly disseminated.
9097 Hydrologic forecasts have historically tended to be more often deterministic than
9098 probabilistic with products focused on water supplies (stream flow, reservoir inflows,
9099 *etc.*). In operational settings, seasonal hydrologic forecasts have generally been taken
9100 with a grain of salt, in part because of limited quantitative assurance of how accurate they
9101 can be expected to be. In contrast, operational climate forecasts and many of today's
9102 experimental and newer operational hydrologic forecasts are probabilistic, and in this
9103 way contain quantitative estimates for the forecast uncertainty.

9104

9105 New efforts are needed to extend "forecasts of opportunity" beyond those years when
9106 anomalous ENSO conditions are underway. At present, the skill available from
9107 combining current seasonal-interannual climate forecasts with hydrologic models is
9108 limited when all years are considered, but can provide useful guidance in years having

9109 anomalous ENSO conditions. During years with substantial ENSO effects the climate
9110 forecasts have high enough skill for temperatures, and mixed skill for precipitation, so
9111 that hydrologic forecasts for some seasons and some basins provide measurable
9112 improvements over approaches that do not take advantage of ENSO information. In
9113 contrast, in years where the state of ENSO is near neutral, most of the skill in United
9114 States climate forecasts is due to decadal temperature trends, and this situation leads to
9115 substantially more limited skill in hydrologic forecasts. In order to improve this situation,
9116 additional sources of climate and hydrologic predictability must be exploited, and these
9117 sources likely include other patterns of ocean temperature change, sea ice, land cover,
9118 and soil moisture conditions.

9119

9120 Linkages between climate and hydrologic scientists are getting stronger as they
9121 collaboratively create forecast products. A great many complex factors influence the rate
9122 at which seasonal water supply forecasts and climate forecast-driven hydrologic forecasts
9123 are improving in terms of skill level. Mismatches between needs and information
9124 resources continue to occur at multiple levels and scales. There is currently substantial
9125 tension between providing tools at the space and time scales useful for water resources
9126 decisions and ensuring that they are also scientifically defensible, accurate, reliable, and
9127 timely. Further research is needed to identify ways to resolve this tension.

9128

9129 **5.3.3 Better integration of climate information into decision making**

9130 It cannot be expected that information that promises to lower costs or improve benefits
9131 for organizations or groups will simply be incorporated into decisions. Scholarly research

9132 on collaboration among organizations indicates that straightforward models of
9133 information transfer are not operative in situations where a common language between
9134 organizations has not been adopted, or more challenging, when organizations must
9135 transform their own perspectives and information channels to adjust to new information.
9136 It is often the case that organizations are path dependent, and will continue with decision
9137 routines even when they are suboptimal. The many case examples provided in this report
9138 indicate that the framing of issues is important, and that framing of many climate
9139 dependent natural resources issues that emphasizes the uncertainty and variability of
9140 climate and the need for adaptive action helps in integrating forecasting information.
9141 What is needed are not more case studies, however, but better case investigations
9142 employing grounded theory approaches to make possible discerning general
9143 characteristics of decision-making contexts and their factors that impeded, or provide
9144 better opportunity for, issue framing that is not path dependent, tradition-bound, or averse
9145 to collaborating with scientists and other tool developers. The construction of knowledge
9146 networks in which information is viewed as relevant, credible, and trusted is essential,
9147 and much can be learned from emerging experiences in climate-information networks
9148 being formed among local governments, environmental organizations, scientists, and
9149 others worldwide to exchange information and experiences, influence national policy-
9150 making agendas, and leverage international organization resources on climate variability
9151 and water resources – as well as other resource - vulnerability.

9152

9153 Potential barriers to information use that must be further explored include: the cultural
9154 and organizational context and circumstances of scientists and decision makers; the

9155 decision space allowed to decision makers and their real range of choice; opportunities to
9156 develop – and capacity to exercise – science citizenship; impediments to innovation
9157 within institutions; and solutions to information overload and the numerous conflicting
9158 sources of already available information. As our case studies have shown, there is often a
9159 relatively narrow range of realistic options open to decision makers given their roles,
9160 responsibilities, and the expectations placed upon them.

9161

9162 There are also vast differences in water laws and state-level scientific and regulatory
9163 institutions designed to manage aquifers and stream-flows in the United States And,
9164 information can be both transparent and yet opaque simultaneously. While scientific
9165 products can be precise, accurate, and lucid, they may still be inaccessible to those who
9166 most need them because of proprietary issues restricting access except to those who can
9167 pay, or due to agency size or resource base. Larger agencies and organizations, and
9168 wealthier users, can better access information in part because scientific information that
9169 is restricted in its dissemination tends to drive up information costs (Pfaff *et al.*, 1999;
9170 Broad and Agrawalla, 2000; Broad *et al.*, 2002; Hartmann, 2001). Access and equity
9171 issues also need to be explored in more detail. Every facet of tool use juncture needs to
9172 be explored.

9173

9174 Priority in research should be toward interdisciplinary projects that involve sufficient
9175 numbers and varieties of kinds of knowledge. To this end, NOAA's Sectoral Applications
9176 Research Program is designed to support these types of interactions between research and
9177 development of decision-support tools. Although this program is small, it is vital for

9178 provision of knowledge on impacts, adaptation, and vulnerability and should be
9179 supported especially as Federal agencies are contemplating a larger role in adaptation and
9180 vulnerability assessments and in light of pending legislation by Congress.

9181

9182 Regional Integrated Science Assessments (RISAs) are regarded as a successful model of
9183 effective knowledge-to-action networks because they have developed interdisciplinary
9184 teams of scientists working as (and/or between) forecasts producers while being actively
9185 engaged with resource managers. The RISAs have been proposed as a potentially
9186 important component of a national climate service (NCS), wherein the NCS engages in
9187 observations, modeling, and research nested in global, national, and regional scales with a
9188 user-centric orientation (Figure 1 of Miles *et al.*, 2007). The potential for further
9189 development of the RISAs and other boundary spanning organizations that facilitate
9190 knowledge-to-action networks deserves study. Further, as they are the most successful
9191 long-term effort by the federal government to integrate climate science in sectors and
9192 regions across the United States, they merit expanded financial and institutional support
9193

9194 **5.3.4 Better balance between physical science and social science**

9195 Throughout this report, the absence of systematic research on applications of climate
9196 variation forecasting information has required analysis to be based on numerous case
9197 study materials often written for a different purpose, upon the accumulated knowledge
9198 and wisdom of authors, and logical inference. The dearth of hard data in this area attests
9199 to the very small research effort afforded the study of use inspired social science
9200 questions. Five years ago a social science review panel recommended that NOAA should

9201 readjust its research priorities by additional investment in a wide variety of use-inspired
9202 social science projects (Anderson *et al.*, 2003). What was once the Human Dimensions
9203 of Climate Change Program within NOAA now exists only in the Sector Applications
9204 Research Program, an important and worthy endeavor, but one whose small staff and
9205 budget can hardly address these important research needs. Managers whose
9206 responsibilities may be affected by climate variability need detailed understanding of
9207 relevant social, economic, organizational and behavioral systems – as well as the ethical
9208 dilemmas faced in using, or not using information, including public trust, perceived
9209 competence, social stability and community well-being, and perceived social equity in
9210 information access, provision, and benefit. Much more needs to be known about the
9211 economic and other factors that shape demands for water, roads, and land conversion for
9212 residential and commercial development and shape social and economic resilience in
9213 face of climate variability.

9214

9215 A recent NRC Report (2008) set out five research topics that have direct relevance to
9216 making climate science information better serve the needs of various sectors: human
9217 influences on vulnerability to climate; communications processes; science produced in
9218 partnership with users; information overload; and innovations at the individual and
9219 organizational level necessary to make use of climate information. The last research
9220 topic is the particular charge of NOAA's Sectoral Applications Research Program and is
9221 of great relevance to the subject of this report. However, the lack of use theoretically-
9222 infused social science research is a clear impediment to making investments in physical
9223 sciences useful and used. Committed leadership that is poised to take advantage of

9224 opportunities is fundamental to future innovation, yet not nearly enough research has
9225 been done on the necessary conditions for recruitment, promotion and rewarding
9226 leadership in public organizations, particularly as that leadership serves in networks
9227 involving multiple agencies, both public and private, at different organizational levels.
9228

9229 **5.3.5 Better understanding of the implications of small-scale, tailored decision-**
9230 **support tools is needed**

9231 While there is almost universal agreement that specially tailored, small scale forecast
9232 tools are needed, concern is growing that the implications of such tools for
9233 trustworthiness, quality control, and ensuring an appropriate balance between proprietary
9234 vs. public domain controls have not been sufficiently explored.

9235
9236 There is a growing push for smaller scale products that are tailored to specific users but
9237 are expensive; as well as private sector tailored products (*e.g.*, “Weatherbug” and many
9238 reservoir operations proprietary forecasts have restrictions on how they share data with
9239 NOAA) – this also generates issues related to trustworthiness of information and quality
9240 control. What are the implications of this push for proprietary vs. public domain controls
9241 and access? This problem is well-documented in policy studies of risk-based information
9242 in the fields of food labeling, toxic pollutants, medical and pharmaceutical information,
9243 and other public disclosure or “right-to-know” programs but has not been sufficiently
9244 explored in the context of climate forecasting tool development.

9245

9246 Related to this issue of custom-tailoring forecast information is the fact that future
9247 progress in making climatic forecasts useful depends upon advancing our understanding
9248 of the incorporation of available knowledge into decisions in water related sectors, since
9249 there are already many useful applications of climate variation and change forecasts at
9250 present skill levels. Here, the issue is tailoring information to the *type* of user. Research
9251 related to specific river systems, and/or sectors such as energy production, flood plain
9252 and estuary planning and urban areas is important. Customizable products rather than
9253 generic services are the most needed by decision makers. The uptake of information is
9254 more likely when the form of information provided is compatible with existing practice.
9255 It makes sense to identify decision-support experiments where concerted efforts are made
9256 to incorporate climate information into decision-making. Such experimentation feeds into
9257 a culture of innovation within agencies that is important to foster at a time when
9258 historically conservative institutions are evolving more slowly than the pace of change in
9259 the natural and social systems, and where, in those instances when evolution is taking
9260 place relatively quickly – there are few analogues that can be used as reference points for
9261 how to accommodate these changes and ensure that organizations can adapt to stress – an
9262 important role of visionary leadership (Bennis, 2003; Tichy and Bennis, 2007)

9263

9264 Given the diversity of challenges facing decision makers, the diverse needs and
9265 aspirations of stakeholders, and the diverse array of decision-making authorities, there is
9266 little hope of providing comprehensive climate services or a “one-stop-shop” information
9267 system to support the decision-making or risk assessment needs of a wide audience of
9268 users. Development of products to help nongovernmental communities and groups

9269 develop their own capacity and conduct their own assessments is essential for future
9270 applications of climate information.
9271
9272 A seasonal *hydrologic forecasting and applications testbed program* would facilitate the
9273 rapid development of better decision-support tools for water resources planning.
9274 Testbeds, as described in Chapter 2, are intermediate activities, a hybrid mix of research
9275 and operations, serving as a conduit between the operational, academic and research
9276 communities. A testbed activity may have its own resources to develop a realistic
9277 operational environment. However, the testbed would not have real-time operational
9278 responsibilities and instead, would be focused on introducing new ideas and data to the
9279 existing system and analyzing the results through experimentation and demonstration.
9280 The old and new system may be run in parallel and the differences quantified (a good
9281 example of this concept is the INFORM program tested in various reservoir operations in
9282 California described in Chapter 4). Other cases that demonstrate aspects of this same
9283 parallelism are the use of paleo-climate data in the southwest (tree-ring data being
9284 compared to current hydrology) and the South Florida WMD (using decade-scale data
9285 together with current flow and precipitation information). The operational system may
9286 even be deconstructed to identify the greatest sources of error, and these findings can
9287 serve as the motivation to drive new research to find solutions to operations-relevant
9288 problems. The solutions are designed to be directly integrated into the mock-operational
9289 system and therefore should be much easier to directly transfer to actual production.
9290 While NOAA has many testbeds currently in operation, including testbeds focused on:
9291 Hydrometeorology (floods), Hazardous Weather (thunderstorms and tornadoes), Aviation

9292 Weather (turbulence and icing for airplanes), Climate (El Niño, seasonal precipitation
9293 and temperature) and Hurricanes, a testbed for seasonal stream flow forecasting does not
9294 exist. Generally, satisfaction with testbeds has been high, with the experience rewarding
9295 for operational and research participants alike.

9296

9297 **5.3.6 Understand impacts of climate variability and change on other resources**

9298 Research shows the close interrelationships among climate change, deep sustained
9299 drought, beetle infestations, high fuel load levels, and forest fire activity. Serious concern
9300 about the risks faced by communities in wild land-urban interface areas as well as about
9301 the long-term viability of the nation's forests is warranted. It is important to know more
9302 about climate-influenced changes in marine environments that have significant
9303 implications for the health of fisheries and for saltwater ecosystems. Potential changes in
9304 the frequency and severity of extreme events such as tropical storms, floods, droughts,
9305 and strong wind episodes threaten urban and rural areas alike and need to be better
9306 understood. Rising temperatures, especially at night, are already driving up energy use
9307 and contributing to urban heat island effects, and they pose alarming potential for heat
9308 wave-related deaths such as those experienced in Europe a few years ago. The poor and
9309 the elderly suffer most from such stresses. Clearly, climate conditions affect everyone's
9310 daily life. Long-term climate changes also impinge on the prospects for the next
9311 generation and generations yet unborn. Although it would be the height of hubris to say
9312 that humans are now totally in control of our biophysical and social universes, we can say
9313 that humans' responsibility to be good stewards of planet has grown enormously.

9314

9315 **5.4 THE APPLICATION OF LESSONS LEARNED FROM THIS PRODUCT TO**
9316 **OTHER SECTORS**

9317 “Climate” is gaining popularity in agencies throughout the federal government (*e.g.*, the
9318 Center for Disease Control has recently increased efforts concerning the impacts of
9319 climate on health), in national and boundary organizations across the nation (*e.g.*, there
9320 has been an increase in awareness and activity of mayors and their staffs that are
9321 members of the U.S. Conference of Mayors), and is beginning to become an important
9322 component to future planning in local jurisdictions (*e.g.*, King County, Washington has
9323 issued a guidebook for planners on adaptation to global warming). As these
9324 organizations become more aware of the potential of climate impacts on their
9325 constituents, they are responding by holding conferences, writing manuals, setting up
9326 climate-related offices to better understand the role that climate plays in their purview,
9327 and beginning to demand more of the Federal Government in terms of services in part, in
9328 the form of SI forecasts and observational data and new information about long-term
9329 climate change impacts. SI information would be helpful to a wide range of users from
9330 those in the transportation and urban realms with information on how much salt to buy
9331 for the next season’s snowstorms, to health officials as they prepare for the next season’s
9332 climate-influenced diseases such as those spread by mosquito or ticks, and to those
9333 employed in agriculture to help determine the type of seed, irrigation and fertilizer needs
9334 for the coming season. For some, the information they need already exists; they simply
9335 do not understand where to obtain the information or how to use it. For others, the
9336 delivery must be tweaked to provide the information in a format that would better suit

9337 their needs. For the more sophisticated user, refinements of present forecasts and data as
9338 well as more information about the data itself would satisfy their present needs.
9339

9340 The lessons learned and described in this report from the water sector are directly
9341 transferable to other sectors. The experiments described in Chapters 2, 3, and 4 are just
9342 as relevant to water resource managers as they are to farmers, energy planners or city
9343 planners. Of the overarching lessons described in this chapter, perhaps the most
9344 important to all sectors is that the climate forecast delivery system in the past, where
9345 climatologists and meteorologists produced forecasts and other data in a vacuum, can be
9346 improved. This report reiterates in each chapter that the loading dock model of
9347 information transfer is unworkable. Fortunately, this report highlights experiments where
9348 interaction between producers and users is successful. Similar examples can be found in
9349 other sectors such as the urban planning arena. Within New York City, a prototype
9350 information system was developed for transportation planners concerned about future
9351 climate impacts (<http://ccir.ciesin.columbia.edu/nyc>). The team first assessed the
9352 information needs of urban policy makers, analyzing both the ways that they obtain and
9353 use information and the kinds of information that they take into account in their work.
9354 The team gathered and organized existing climate forecast, policy, and scientific
9355 information and also tried to anticipate how urban climate change information would be
9356 maintained and used in the future. Representatives from key transportation planning
9357 groups in the area such as the Port Authority were involved in most aspects of this
9358 project.
9359

9360 This report has emphasized that decision support is a process rather than a product.
9361 Accordingly, we have learned that communication is key to delivering and using climate
9362 products. One example, where this is already working can be found is in the southwest
9363 with the Climate Assessment for the Southwest (RISA) project who are working with the
9364 University of Arizona Cooperative Extension to produce a newsletter that contains
9365 official and non-official forecasts, as well as other information relevant for a variety of
9366 decision makers in that area, particularly farmers
9367 (<http://www.climas.arizona.edu/forecasts/swoutlook.html>).

9368

9369 Equity is an issue that arises in other sectors as well. Emergency managers preparing for
9370 an ENSO-influenced season already understand that while some have access to
9371 information and evacuation routes, others, notably the elderly and those with financial
9372 difficulties might not have the same access. To compound this problem, information may
9373 also not be in a language understood by all citizens. While these managers already
9374 realize the importance of climate forecast information, improved climate forecast and
9375 data delivery and/or understanding will certainly help in assuring that the response to a
9376 potential climate disaster is performed equitably for all of their residents (Beller-Simms,
9377 2004).

9378

9379 Finally, science citizenship is and will be increasingly important in all sectors. Science
9380 citizenship clearly has a crucial role to play in building bridges between science and
9381 societal values in all resource management arenas and increased collaboration and
9382 production of knowledge between scientists and decision makers. The use of SI and

9383 climate forecasts and observational data will continue to be increasingly important in
9384 assuring that resource-management decisions bridge the gap between climate science,
9385 and the implementation of scientific understanding in our management of critical
9386 resources.

9643 Washington; Kelly Redmond, Western Regional Climate Center, Desert Research

9644 Institute

9645

9646 **Contributing Author:** Pedro Restrepo, NOAA

9647

9648

9649

9650

9651

9652

9653

9654

9655

9656

9657 (Adapted from the National Weather Service Instruction 10-103, June, 2007, available at:
9658 <http://www.weather.gov/directives/sym/pd01001003curr.pdf>)

9659

9660 Because of the operational nature of the National Weather Service’s mission, transition of
9661 research into operations is of particular importance. Transition of all major NOAA
9662 research into operations is monitored by the NOAA Transition Board. Within the NWS,
9663 two structured processes are followed to transition research into operations, in
9664 coordination with the NOAA Transition Board. A wider process, the Operations and
9665 Service Improvement Process (OSIP) is used to guide all projects, including non-
9666 hydrology projects, through field deployment within the Advanced Weather Interactive
9667 System (AWIPS). A similar process called Hydrologic Operations and Service
9668 Improvement Process (HOSIP) with nearly identical stages and processes as OSIP is used
9669 exclusively for the hydrology projects. For those hydrology projects that will be part of
9670 AWIPS, HOSIP manages the first two stages of hydrologic projects, and, upon approval,
9671 are moved to HOSIP. The OSIP process is described below.

9672

9673 OSIP consists of 5 stages. (Table A.1 below). For a project to advance from one stage to
9674 the next, it is necessary to pass a review process (a “gate”), which examines that the
9675 requirements for each gate are met and that the typical gate questions are satisfactorily
9676 answered.

9677

9678

9679

9680 **Table A.1 National Weather Service Transition of Research to Operations: Operational and Service**
 9681 **Improvement Process, OSIP.**

Stage	Major Activity	Typical Decision Point (Gate) Questions?
1	Collection and Validation of Need or Opportunity	Is this valid for the Weather Service? What is to be done next? (and who will do it)
2	Concept Exploration and Definition	Are the concept and high level requirements adequately defined or is research needed? What is to be done next? (and who will do it)
3	Applied Research and Analysis	What solutions are feasible, which is best? What is to be done next? (and who will do it)
4	Operational Development	Does developed solution meet requirements? Is there funding for deployment and subsequent activities? What is to be done next? (and who will do it)
5	Deploy, Maintain and Assess	Survey –How well did the solution meet the requirements?

9682

9683 Each gate requires that the project be properly documented up to that point. The first
 9684 stage, *Collection and Validation of Need or Opportunity*, allows people who have a need,
 9685 an idea, or opportunity (including people external to the NWS) to hold discussions with
 9686 an OSIP Submitting Authority to explore the merits of that idea, and to have that idea
 9687 evaluated. For this evaluation, the working team prepares two documents: 1) a Statement
 9688 of Need or Opportunity Form, which describes the Need or Opportunity for
 9689 consideration, and 2), the OSIP Project Plan, which identifies what is to be done next and
 9690 what resources will be needed. For Hydrology projects, the Statement of Need requires
 9691 the endorsement of a field office.

9692

9693 The *Concept Exploration and Definition* stage requires the preparation of the following
 9694 documents: 1) the Exploratory Research Results Document which, as required for
 9695 research projects, documents the results from exploratory research to determine
 9696 effectiveness, use or concept for associated need or opportunity, and documents the
 9697 availability of already-developed solutions that will meet the Statement of Need; 2), the
 9698 Concept of Operations and Operational Requirements Document, which describes how

9699 the system operates from the perspective of the user in terms that define the system
9700 capabilities required to satisfy the need, and 3), an updated OSIP Project Plan.
9701
9702 During the Applied Research and Analysis stage, the team conducts applied research,
9703 development, and analysis; identifies possible solutions; defines and documents the
9704 technical requirements; prepares a Business Case Analysis (BCA) to present a detailed
9705 comparison of the potential alternative solutions, with the recommendation of the
9706 working team as to which alternative is preferred. The BCA is a critical element in
9707 demonstrating to NWS, NOAA, and Department of Commerce management that a
9708 program is a prudent investment and will support and enhance the ability of the NWS to
9709 meet current and planned demand for its products and services. This stage requires the
9710 preparation of four documents: 1) the Applied Research Evaluation, which documents
9711 how the research was carried out, how the processes were validated, and the algorithm
9712 description for operational implementation; 2) the Technical Requirements document,
9713 which states what the operational system must explicitly address; 3) the Business case,
9714 which collects the business case analysis that describe how the system will be used, and
9715 4), an updated Project Plan.

9716
9717 During the Operational Development stage, the team performs the operational
9718 development activities summarized in the approved Project Plan and described in the
9719 Operational Development Plan. The purpose of this stage is to fully implement the
9720 previously selected solution, verifying that the solution meets the operational and
9721 technical requirements, to conduct preparations to deploy the solution to operations, and

9722 carry out the actions stated in the Training Plan. During this stage, the team prepares 1)
9723 the Deployment Decision Document, which summarizes the results of the development
9724 and verification activities and presents the results of preparations for deployment, support
9725 and training; 2) the Deployment, Maintenance and Assessment Plan, which is the plan for
9726 the final OSIP stage, Stage 5, and 3) an updated OSIP Project Plan and other
9727 documentation as needed.

9728

9729 During the final stage, Deploy, Maintain and Assess, the team performs the deployment
9730 activities summarized in the approved Project Plan and described in the Deployment,
9731 Assessment, and Lifecycle Support Plan. The primary purpose of this stage is to fully
9732 deploy the developed and verified solution.

9733

9734 The requirement process for Web page improvements include:

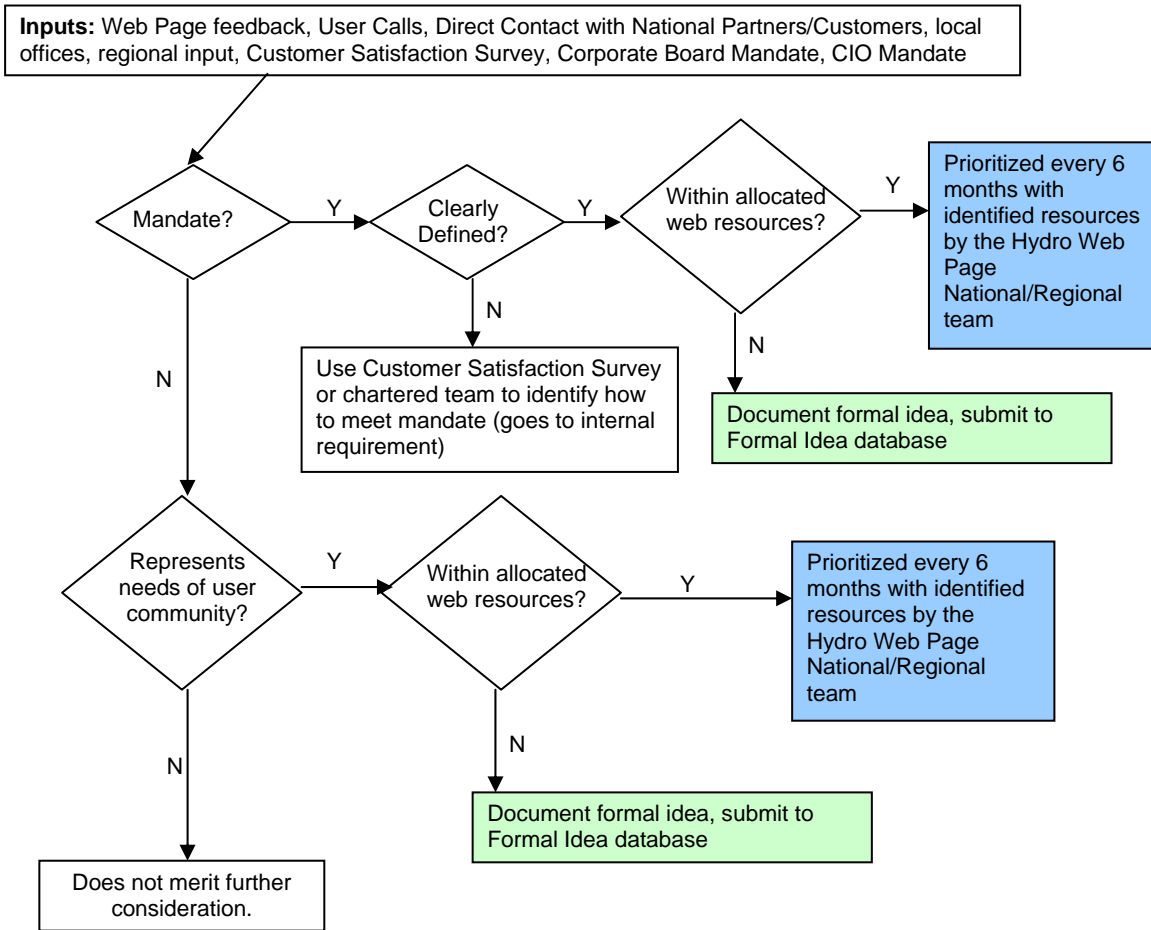

- 9735 • Requests arising from user feedback on the web
- 9736 • User calls
- 9737 • Direct contact with national partners/customers
- 9738 • Local NWS offices and NWS regions input
- 9739 • Customer satisfaction survey
- 9740 • Corporate Board Mandate
- 9741 • Chief Information Office Mandate

9742

9743 Figure A.1 shows the flow diagram for the web-page improvement requirement process.

9774

9775 (Adapted from Mary Mulluski's HSD Requirements Process: How to Solicit, Collect,
9776 Refine, and Integrate Formal Ideas into Funded Projects, NWS internal presentation,
9777 2008).

9778

9779 There are three sources of requirements towards the development of improved hydrologic
9780 forecasts at the National Weather Service: internal, external requirements for forecast
9781 improvements, and web-page information improvement. All improvements are
9782 coordinated by the National Weather Service Hydrologic Services Division (HSD).

9783

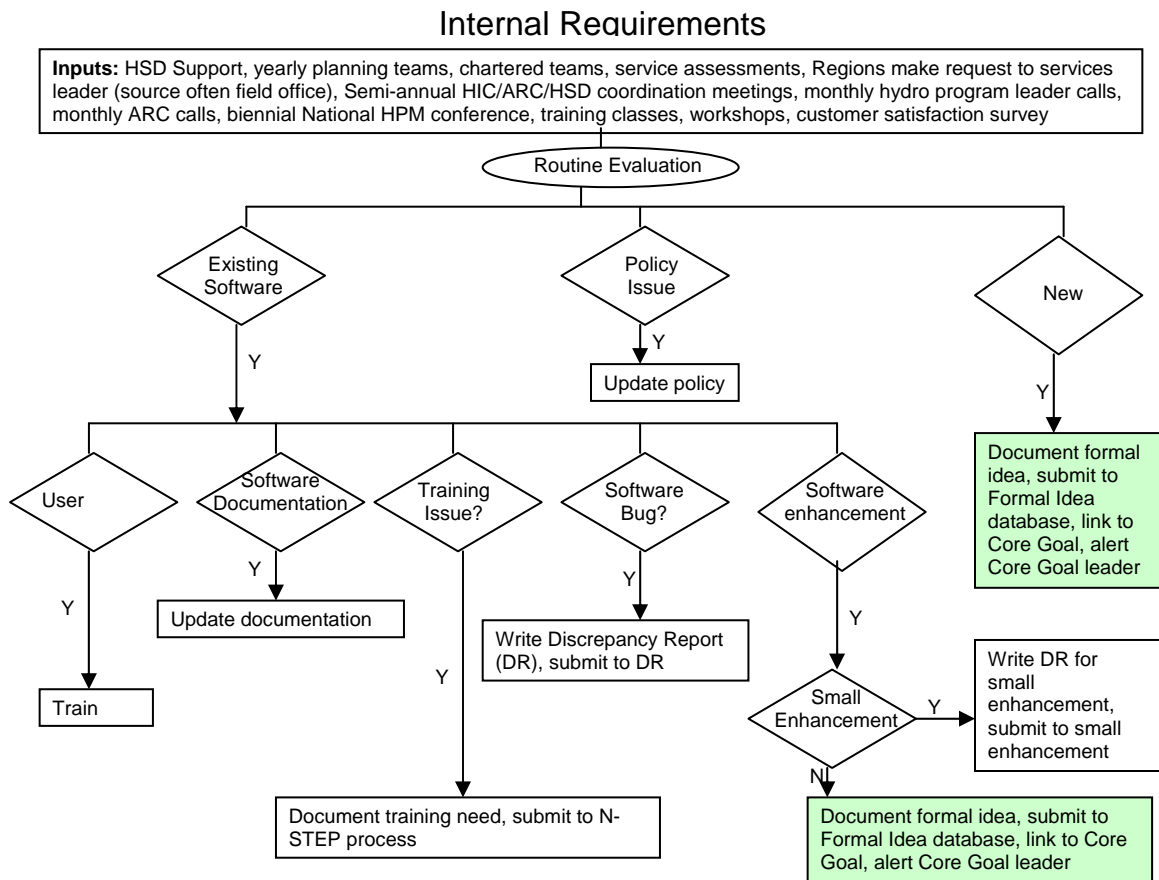

9784 The internal hydrologic forecast improvement requirements at the National Weather
9785 Service are a result of one of more of these sources:

- 9786 • HSD routine support
- 9787 • Proposed research and research-to-operations projects by annual planning teams,
9788 with the participation of HSD, the Office of Hydrologic Development (OHD) ,
9789 River Forecast Center and Weather Forecast Offices employees
- 9790 • Teams chartered to address specific topics
- 9791 • The result of service assessments
- 9792 • Solicitation by the NWS Regions of improved forecast requirements to services
9793 leaders
- 9794 • Semi-annual Hydrologists-in-charge, AHPS Review Committee (ARC), and HSD
9795 Chiefs coordination meetings
- 9796 • Monthly hydro program leader calls
- 9797 • Monthly ARC calls

- 9798 • Biennial National Hydrologic Program Manager’s Conference (HPM)
- 9799 • Training classes, workshops, and customer satisfaction surveys

9800

9801 A flow diagram of the internal hydrologic forecast process is shown in Figure B.1.

9802

9803 **Figure B.1** Hydrologic Forecast Improvement: Internal Requirements Process

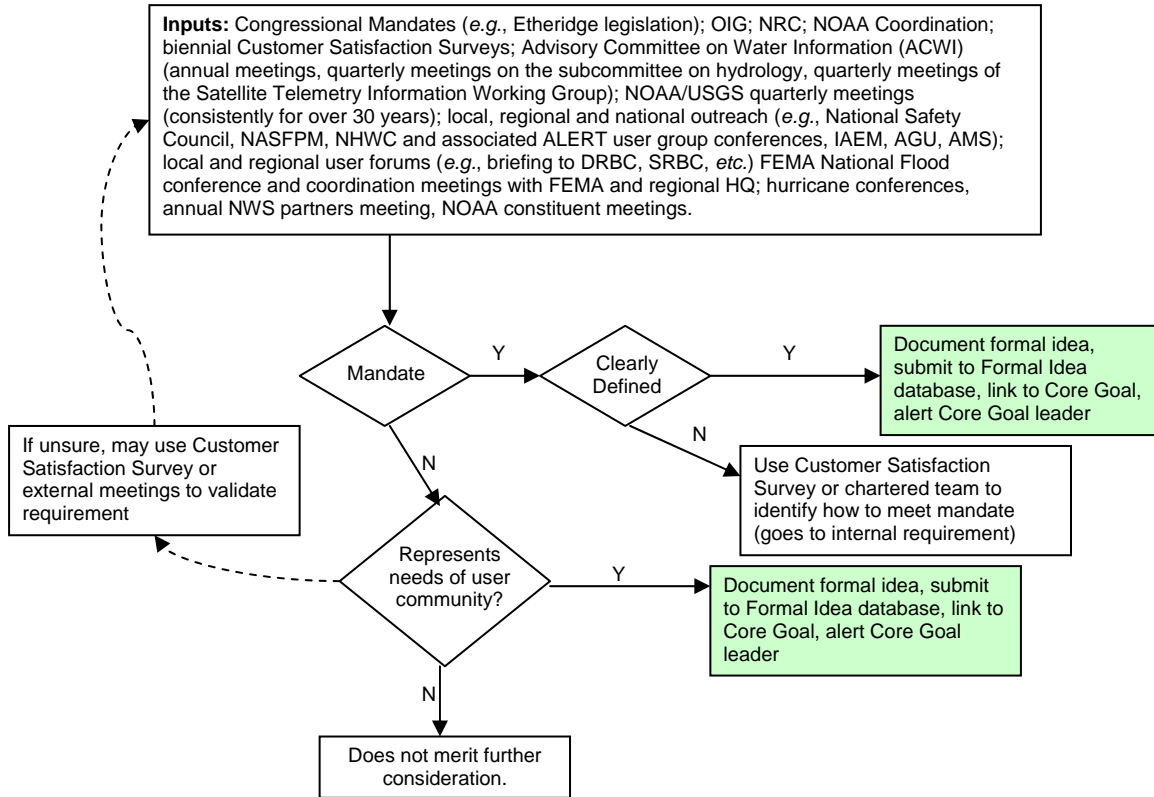

9804

9805 The external requirements for hydrologic forecast improvements are the results of:

- 9806 • Congressional mandates
- 9807 • Office of Inspector General requirements
- 9808 • National Research Council recommendations
- 9809 • NOAA Coordination

- 9810 • Biennial customer satisfaction surveys
- 9811 • Annual meetings, quarterly meetings on the subcommittee on hydrology,
- 9812 quarterly meetings of the Satellite Telemetry Information Working Group of the
- 9813 Advisory Committee on Water Information (ACWI)
- 9814 • NOAA/USGS quarterly meetings (consistently for over 30 years);
- 9815 • Local, regional and national outreach such as the National Safety Council,
- 9816 National Association of Flood Plain Managers, (NASFPM), National Hydrologic
- 9817 Warning Council (NHWC) and associated ALERT user group conferences,
- 9818 International Association of Emergency Managers, (IAEM), American
- 9819 Geophysical Union (AGU), American Meteorological Society (AMS);
- 9820 • Local and regional user forums (*e.g.*, briefing to DRBC, SRBC, *etc.*)
- 9821 • FEMA National Flood conference and coordination meetings with FEMA and
- 9822 regional HQ
- 9823 • Hurricane conferences, annual NWS partners meeting, NOAA constituent
- 9824 meetings
- 9825 A flow diagram of the external hydrologic forecast process is shown in Figure B.2
- 9826

External Requirements Process

9827

9828 **Figure B.2** Hydrologic Forecast Improvement: External Requirements Process

9829

9830

9831

9832

9833

9834

9835

9836

9837

9838

9839

9840 **Glossary and Acronyms**

9841

9842 **GLOSSARY**

9843

9844 **Adaptive capacity**

9845 The ability of people to mitigate or reduce the potential for harm, or their vulnerability to
9846 various hazards that can cause them harm, by taking action to reduce exposure or
9847 sensitivity, both before and after the hazardous event.

9848

9849 **Adaptive management**

9850 Approach to water resource management that emphasizes stakeholder participation in
9851 decisions; commitment to environmentally-sound, socially just outcomes; reliance upon
9852 drainage basins as planning units; program management via spatial and managerial
9853 flexibility, collaboration, participation, and sound, peer-reviewed science; and, embracing
9854 ecological, economic, and equity considerations.

9855

9856 **Boundary organizations**

9857 Entities that perform translation and mediation functions between producers (*i.e.*,
9858 scientists) and users (*i.e.*, policy makers) of information. These functions include
9859 convening forums to discuss information needs, provide training, assess problems in
9860 communication, and tailoring information for specific applications. Individuals within
9861 these organizations who lead these activities are often terms “integrators.”

9862

9863 **Conjunctive use**

9864 The conjoint use of surface and groundwater supplies within a region to supply various
9865 uses and permit comprehensive management of both sources. This requires co-
9866 management of a stream or system of streams and an aquifer system to meet several
9867 objectives such as conserving water supplies, preventing saltwater intrusion into aquifers,
9868 and preventing contamination of one supply source through polluting the other.

9869

9870 **Decision maker**

9871 In water resources, the term embraces a vast assortment of elected and appointed local,
9872 state, and national agency officials, as well as public and private sector managers with
9873 policy-making responsibilities in various water management areas.

9874

9875 **Decision-support experiments**

9876 Practical exercises where scientists and decision-makers explicitly set out to use decision-
9877 support tools – such as climate forecasts, hydrological forecasts and other – to aid in
9878 making decisions in order to address the impacts of climate variability and change upon
9879 various water issues.

9880

9881 **Disaggregation**

9882 Similar to downscaling, but in the temporal dimension – *e.g.*, seasonal climate forecasts
9883 may need to be translated into daily or subdaily temperature and precipitation inputs for a
9884 given application (as described in Kumar, 2008).

9885

9886 Downscaling

9887 The process of bridging the spatial scale gap between the climate forecast resolution and
9888 the application's climate input resolution, if they are not the same. If the climate
9889 forecasts are from climate models, for instance, they are likely to be at a grid resolution
9890 of several 100 km, whereas the application may require climate information at a point
9891 (*e.g.*, station location).

9892

9893 Dynamical forecasts

9894 Physics based forecasts that are developed from conservation equations.

9895

9896 Ensemble streamflow prediction (ESP)

9897 Uses an ensemble of historical meteorological sequences as model inputs (*e.g.*,
9898 temperature and precipitation) to simulate hydrology in the future (or forecast) period.

9899

9900 Hindcasts

9901 Simulated forecasts for periods in the past using present day tools and monitoring
9902 systems; hindcasts are often used to evaluate the potential skill of present day forecast
9903 systems.

9904

9905 Integrated Water Resource Planning

9906 Efforts to manage water by balancing supply and demand considerations through
9907 identifying feasible alternatives that meet the test of least cost without sacrificing other

9908 policy goals – such as depleted aquifer recharge, seasonal groundwater recharge,
9909 conservation, growth management strategies, and wastewater reuse.

9910

9911 **Knowledge-to-action networks**

9912 The interaction among scientists and decision-makers that results in decision-support
9913 system development. It begins with basic research, continues through development of
9914 information products, and concludes with end use application of information products.

9915 What makes this process a “system” is that scientists and users discuss what’s needed as
9916 well as what can be provided; learn from one another’s perspectives; and try to
9917 understand one another’s roles and professional constraints.

9918

9919 **Objective hybrid forecasts**

9920 Forecasts that objectively use some combination of objective forecast tools (typically a
9921 combination of dynamical and statistical approaches).

9922

9923 **Physical vulnerability**

9924 The hazard posed to, *e.g.*, water resources and water resource systems by exposure to
9925 harmful, natural or technological events such as pollution, flooding, sea level rise, or
9926 temperature change.

9927

9928 **Sensitivity**

9929 The degree to which people and the things they value can be harmed by exposure. Some
9930 water resource systems, for example, are more sensitive than others when exposed to the

9931 same hazardous event. All other factors being equal, a water system with old
9932 infrastructure will be more sensitive to a flood or drought than one with new state-of-the-
9933 art infrastructure.

9934

9935 **Social vulnerability**

9936 The social factors (*e.g.*, level of income, knowledge, institutional capacity, disaster
9937 experience) that affect a system's sensitivity to exposure, and that also influences its
9938 capacity to respond and adapt in order to reduce the effects of exposure.

9939

9940 **Statistical Forecasts**

9941 Objective forecasts based on empirically determined relationships between observed
9942 predictors and predictands.

9943

9944 **Subjective consensus forecasts**

9945 Forecasts in which expert judgement is subjectively applied to modify or combine outputs
9946 from other forecast approaches.

9947

9948 **Water year** or hydrologic year

9949 October 1st through September 30th. This reflects the natural cycle in many hydrologic
9950 parameters such as the seasonal cycle of evaporative demand, and of the snow
9951 accumulation, melt, and runoff periods in many parts of the US.
