## Subgroup Results for the Nation and the States

This chapter presents the NAEP 2000 science results for various subgroups of students at both the national and state levels. National average scale score and achievement-level results are presented by six demographic characteristics: gender, race/ethnicity, parents' education level, type
 of school, school location, and eligibility for the federal free/reduced-price school lunch program. State results at grades 4 and 8 are presented for gender, race/ethnicity, and eligibility for the free/ reduced-price school lunch program. Additional information by subgroup for each jurisdiction that participated in the 2000 science assessment is available on the NAEP web site at http:// nces.ed.gov/nationsreportcard.
The differences that are reported in this chapter for demographic subgroups are based on statistical tests that consider both the magnitude of the difference between group average scores or percentages and the standard error of those statistics. Differences between groups and between assessment years are discussed only if they have been determined to be statistically significant. Within the sections summarizing achievement level results, only significant differences detected at or above Basic and Proficient are discussed in the text. Significant differences detected within achievement levels are not discussed, although they are shown in the figures. The reader should bear in mind that differences in science performance most
likely reflect a range of socioeconomic and educational factors that are not addressed in this report or by NAEP.

## National Results: <br> Performance of Selected Subgroups

## Gender

Gender differences in science achievement on large-scale school assessments have been examined at the international, national, and state level. The Third International Mathematics and Science Study (TIMSS) that was conducted in 1995 reported that, at the fourth-grade level, males outperformed females in about one-half of the countries that participated including the U.S. At the eighth-grade level, while many of the countries that participated showed males outperforming females, this was not true for the U.S.; no difference in performance was seen. ${ }^{1}$ At the twelfth-grade level, however, where mathematics and science literacy were tested, males outperformed females in most countries including the U.S. ${ }^{2}$ A repeat of TIMSS at the eighthgrade in 1999 (TIMSS-R) showed that males outperformed females in nearly half of the 38 countries, including the United States. ${ }^{3}$

In addition to international data about the performance of male and female students on science assessments, national studies such as NAEP also show male and female differences. For example, the 1990 NAEP science assessment reported that males outperformed females at grade 8 and 12 ; but found no difference at grade $4 .{ }^{4}$ In 1996, when a new NAEP science assessment was administered, these results showed that males outperformed females at the twelfth-grade level only. ${ }^{5}$ The NAEP science assessment administered in 1996 was also administered in 2000; thus a measure of performance by males and females on the same assessment can be obtained.

Figure 3.1 presents the average science scores in 1996 and 2000 for male and female students at grades 4,8 , and 12 . While average scores for males at grade 8 were higher in 2000 than in 1996, average scores for twelfth-grade males were lower in 2000 . None of the apparent changes across years in females' average scores were statistically significant at any grade. In 2000, males had higher scores than females at grades 4 and 8 , but the apparent difference between male and female students at grade 12 was not statistically significant.

$\star$ Significantly different from 2000.
SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

Figure 3.2 provides a display of the science score gap between male and female students in 1996 and 2000. Even though the individual changes in average scores for male and female students at grade 4 were not statistically significant, taken together they created a significant difference favoring males over females. The increase in average scores among male students at grade 8 contributed to the creation of a similar difference favoring males at this grade level. Although the apparent narrowing of the gap between male and female twelfth-graders' science scores was not
statistically significant, their average scores in 2000 did not differ significantly as they did in 1996.

These score gaps, and the score gaps presented in the following section between selected racial/ethnic subgroups, should be interpreted with caution. The average score of a selected subgroup does not represent the entire range of performance within that group. Furthermore, differences between groups of students cannot be attributed solely to group identification, as a variety of educational and social factors can affect student performance.

# Male Score Minus Female Score 

$\star$ Significantly different from 2000.
NOTE: Score differences are calculated based on differences between unrounded average scale scores. SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

Another way of looking at student performance is to examine the percentages of male and female students at or above each science achievement level. These results are presented in figure 3.3. At grade 4, none of the apparent changes between 1996 and 2000 in the percentages of male or female students at or above any of the achievement levels was statistically significant. At grade 8, the percentage of male students at or above Proficient increased
from 31 percent in 1996 to 36 percent in 2000 . At grade 12 , the percentage of male students at or above Basic decreased from 60 percent in 1996 to 54 percent in 2000.

Comparing the performance of males and females on the 2000 assessment shows a higher percentage of males than females at or above Proficient at all three grade levels, and a higher percentage of males at or above Basic at grades 4 and 8 .

## Race/Ethnicity

NAEP assessments in all subject areas consistently report student achievement by race/ethnicity as well as by differences in performances among various racial/ethnic groups.

The differences provide important information about the progress being made to ensure that all students are making progress in a particular subject area. In order to collect data for this analysis, students who participated in the assessment were asked to indicate which of the following racial/ethnic subgroups best described them:White, Black, Hispanic, Asian/Pacific Islander, or American Indian (including Alaskan Native). Figure 3.4 presents average scale scores for students by these subgroups at grades 4,8 , and 12 . Data for Asian/Pacific Islander students were not reported for the 2000 science assessment at grade 4 because special analyses raised concerns about the accuracy and precision of these results. ${ }^{6}$

At grade 4, none of the apparent changes between 1996 and 2000 in the average scores of each racial/ethnic subgroup were
statistically significant. At grade 8 , American Indian students' average scores declined. At grade 12 , White students had lower average scores in 2000 than in 1996.

When students' performance in 2000 was compared across subgroups, differences in average scores were found at all three grade levels. At grade 4, White students scored higher, on average, than American Indian, Hispanic, or Black students. In addition, American Indian students scored higher on average than Hispanic or Black students. At grade 8 , White students had higher average scores than any of the other subgroups. Eighth-grade Asian/Pacific Islanders scored higher, on average, than American Indian, Hispanic, or Black students. American Indian and Hispanic eighth-graders scored higher on average than Black eighth-graders. At grade 12, White and Asian/Pacific Islander students both had higher average scores than American Indian, Hispanic, or Black students. American Indian students had a higher average score than that of either Hispanic or Black students.

SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

The average score gaps between White and Black students and between White and Hispanic students are shown in figure 3.5. Unlike the small gaps seen between male and female students, the size of the score
gaps between these racial/ethnic subgroups are much larger. None of the apparent differences in these gaps between 1996 and 2000 were found to be statistically significant.

## Figure 3.5 Differences in average science scale scores by race/ethnicity, grades 4, 8, and 12: 1996 and 2000 <br> National Scale Score <br> Differences by Race/ <br> Ethnicity

NOTE: Score differences are calculated based on differences between unrounded average scale scores.
SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

Achievement-level results for the racial/ ethnic groups are presented in figure 3.6. Although White twelfth-graders did show a decline in the percentage of students at or above Basic between 1996 and 2000, none of the apparent changes in the percentages of other racial/ethnic subgroups at or above the Basic or Proficient levels were
found to be statistically significant. When the performance of students in different racial/ethnic subgroups was compared in 2000, a higher percentage of White and Asian/Pacific Islander students were found to be at or above Basic and Proficient, compared to the other subgroups. This finding was consistent across the three grades.

## Parents' Highest Level of Education

It has been documented that, in general, higher levels of parental education are associated with higher levels of student performance. ${ }^{7}$ This has been noted not only in the U.S., but also in a number of other countries around the world. ${ }^{8}$

Students who participated in the NAEP science assessment were asked to indicate the highest level of education completed by each parent. Four levels of education were identified: did not finish high school, graduated from high school, some education after high school, and graduated from college. Students could also choose the response, "I don't know." For this analysis, the highest education level reported for either parent was used. Data are presented for students in grades 8 and 12 only. Data were not collected at grade 4 because in previous NAEP assessments fourth-graders' responses about their parents' education were highly variable and contained a large percentage of "I don't know" responses.

The average science score results for all levels of student-reported parent education are presented in figure 3.7. Almost one-half of both eighth-graders and twelfth-graders
(47 and 48 percent, respectively) reported that at least one parent had graduated from college, whereas only 6 percent of both eighth- and twelfth-graders reported that their parents had not graduated from high school. Additional information on the percentages of students reporting different levels of parents' education is available in appendix B.

Comparisons of average scores by parental education across years show a decline between 1996 and 2000 among twelfth-grade students whose parents' highest level of education was high school graduation or some education after high school. Comparing students' performance by level of parents' education in 2000 showed that eighth- and twelfth-graders whose parents graduated from college had higher scores, on average, than their peers whose parents had lower levels of education. In general, students who reported higher levels of parental education had higher average scores than their peers who reported lower levels of parental education. These results are consistent with the results from other studies.

[^2]Average science scale scores by student-reported parents' highest level of education, grades 8 and 12: 1996 and 2000

- Graduated college
$\square$ Some education after high school
- Graduated high school

Achievement-level results across years by level of parental education are presented in figure 3.8 and show patterns similar to those found for average scale scores. None of the apparent changes between 1996 and 2000 in percentages of eighth-grade students attaining achievement levels were statistically significant at any level of parental education. Among twelfth-graders, however, a drop in performance is evident at the two highest levels of parental education. The percentage of twelfth-graders at
or above Basic decreased between 1996 and 2000 among those students whose parents' highest level of education was some education after high school and among those students with at least one parent who graduated from college.

Comparing students' performance by parents' level of education in 2000 shows a consistent pattern at grades 8 and 12. At both grades, the level of parents' education had a positive relationship to the percentage of students at or above Basic and Proficient.

## Type of School

The schools that participate in the NAEP assessment are classified as either public or nonpublic. ${ }^{9}$ Differences in performance on NAEP science assessments between students attending public and nonpublic schools typically show students attending nonpublic schools outperforming their public school peers, on average. ${ }^{10}$ It is worth noting, however, that results from a special study of twelfth-grade students taking advanced science courses showed that the performance of twelfth-graders in public schools who were enrolled in an advanced science course was not found to be significantly different from that of twelfth-graders taking advanced science courses in nonpublic schools. ${ }^{11}$ Despite the general pattern of nonpublic school students outperforming public school students, readers are cautioned to consider the possibility that socioeconomic and sociological factors related to type of school enrollment may affect student performance. These factors are not accounted for in the NAEP assessment results.

Nine out of ten students who participated in the 2000 NAEP science assessment attended public schools (89 percent at grade 4,90 percent at grade 8 , and 91 percent at grade 12). Additional information on the percentages of students attending public and nonpublic schools can be found in appendix B. Figure 3.9 presents the average science scores by type of school. None of the apparent changes between 1996 and 2000 in average scores of fourth- and eighth-graders attending either public or nonpublic schools were statistically significant. At grade 12 , however, average scores for students attending nonpublic schools increased from 155 in 1996 to 161 in 2000, while scores for students attending public schools decreased from 149 to 145.

A comparison of students' average score by type of school attended in 2000 continues the trend found in other NAEP assessments; fourth- eighth-, and twelfth-graders who attended nonpublic schools had higher scores, on average, than their peers who attended public schools.

## - Nonpublic <br> Public

$\star$ Significantly different from 2000.
SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

Achievement-level results by school type are presented in figure 3.10. At grades 4 and 8 , none of the apparent changes between 1996 and 2000 in percentages of either public or nonpublic school students at or above Basic, at or above Proficient, or at Advanced were statistically significant. At grade 12, however, the results for public school and nonpublic school students show opposite trends in attainment of the Basic and Proficient achievement levels. Between 1996 and 2000, the percentage of public
school twelfth-graders at or above Basic and at or above Proficient decreased, while the percentages of their nonpublic school peers attaining these achievement levels increased.

Comparing students' performance by type of school in 2000 shows a consistent pattern at grades 4,8 , and 12 . At all three grades, a greater percentage of nonpublic school students than public school students were at or above Basic, at or above Proficient, or at Advanced.

## Type of Location

The schools from which NAEP draws its samples of students are classified according to their type of location. Based on Census Bureau definitions of metropolitan statistical areas, including population size and density, the three mutually exclusive categories are: central city, rural/small town, and urban fringe/large town. Because of slight changes by the Census Bureau in the definitions of these categories, schools were not classified in exactly the same way in 2000 as in previous years in terms of location type. Therefore, comparisons to previous years are not possible, and only
the data for the 2000 assessment are reported. More information on the definitions of the 2000 assessment classifications of location type is given in appendix A.

Average science scale scores for fourth-, eighth-, and twelfth-grade students attending schools in the three different types of location are presented in table 3.1. At grades 4 and 8 , students in central city locations had lower average scores than students in urban fringe/large town or rural/small town locations. At grade 12, there was no statistically significant relationship between school location and student performance.

Table 3.1 National Scale Score Results by Type of Location
Average science scale scores by type of location, grades 4, 8, and 12:2000

|  | Central city | Urban fringe/large town | Rural/small town |
| :---: | :---: | :---: | :---: |
| Grade 4 | 140 | 155 | 152 |
| Grade 8 | 142 | 156 | 152 |
| Grade 12 | 144 | 149 | 145 |

[^4]Percentages of students within and at or above each achievement level by type of school location are presented in figure 3.11. At grades 4 and 8 , the percentages of students at or above Basic and Proficient were higher in urban fringe/large town and rural/small town locations than central city locations. The percentage of fourth-
graders at Advanced was also higher among students in urban fringe locations than in central cities. At grade 12, there were no statistically significant differences in the percentages of students at or above Basic or Proficient or at Advanced based on the school's location.

## Free/Reduced-Price School Lunch Eligibility

Funded by the U.S. Department of Agriculture (USDA) as part of the National School Lunch program, the free/reducedprice school lunch program is designed to assure that children at, near, or below the poverty line receive nourishing meals. Eligibility guidelines for the lunch program are based on the Federal income poverty guidelines and are stated by household size. ${ }^{12}$ NAEP began collecting data on student eligibility for this program in 1996.

As shown in figure 3.12, average science scores for students who were not eligible for the free/reduced-price school lunch program (i.e., those above the poverty guidelines) were higher than the scores for students who were eligible for the program. Since information on eligibility is not
available for a substantial percentage of the students at each grade, scale score averages for this group of students are also provided. It should be noted that students for whom the information was not available (which included students from schools that did not offer free/reduced-price school lunches) also had higher average scores at each of the three grades than the students who were eligible for the free/reduced-price school lunch program.

Comparisons across years show lower average scores in 2000 than in 1996 among eighth-graders who were eligible for the program and higher scores among students who were not eligible. At grade 12, students who were not eligible for the program had lower average scores in 2000 than in 1996.

Achievement-level results by students' eligibility for the free/reduced-price school lunch program are displayed in figure 3.13. At grade 4, there were no statistically significant changes between 1996 and 2000 in the percentages of students at or above achievement levels among students who were either eligible or not eligible for the free/reduced-price school lunch program. At grade 8, the percentage of students at or above Proficient increased between 1996 and 2000 for those students who were not
eligible for the free/reduced-price school lunch program. At grade 12, the percentages of students at or above Basic decreased between 1996 and 2000 for those students who were not eligible for the free/reducedprice school lunch program. Similar to the pattern observed for scale score results in 2000 , there were higher percentages of fourth-, eighth-, and twelfth-graders at or above Basic and Proficient among those students who were not eligible for the program than among those who were.

## State Results: Performance of Selected Subgroups

Results for public schools in participating states and jurisdictions are presented in this section by gender, race/ethnicity, and eligibility for free/reduced-price school lunch. Complete data for participating jurisdictions are available on the NAEP web site at http://nces.ed.gov/ nationsreportcard.

Nonpublic schools were not included in the state NAEP assessments for 2000, but were included in the national samples. While the national results shown in the previous sections of this chapter repre-
sented both public and nonpublic school students combined, the national data shown for comparison at the top of the following state tables are based on the national sample-not on aggregated state samplesof students from public schools only.

In addition to results from the 2000 state assessment, results are also available from 1996 for many of the jurisdictions at grade 8. Not all jurisdictions, however, met minimum school participation guidelines in every NAEP assessment. (See appendix A for details on the participation and reporting guidelines.) In 2000, results for grades 4 and 8 in Wisconsin and grade 8 in
the Virgin Islands are not included in the relevant tables because they did not meet the criteria.

The state results presented here were obtained by assessing a representative sample of students in each state under conditions that did not permit accommodations for special-needs students. These were the same conditions under which results were obtained in previous state assessments. Consequently, it is possible to report changes in student performance across the assessment years at grade 8. In 2000, a separate representative sample was assessed in each participating jurisdiction for which accommodations were offered to special-needs students. Those results are presented in chapter 4, along with a comparison of"accommodations-permitted" and "accommodations-not-permitted" results in each state. Subgroup "accommo-dations-permitted" results by state are available on the NAEP web site.

In examining the state results presented in this section, it should be noted that schools participating in the NAEP assessments under these conditions are permitted to exclude those students who cannot be assessed meaningfully without accommodations. Exclusion rates vary considerably across years in many jurisdictions. In 2000, in the sample that did not permit accommodations, the pattern in most jurisdictions was for more special-needs students to be excluded from the assessment than in 1996.

In addition to changes across years in exclusion rates for a particular jurisdiction, there is considerable variation in exclusion rates across jurisdictions. Comparisons of assessment results across jurisdictions and within jurisdictions across years should be
made with caution. No adjustments have been made for differing exclusion rates across jurisdictions or across years. Thus, a comparison within a jurisdiction across years or between two jurisdictions may be based on samples with exclusion rates that differ considerably. The exclusion rates for each jurisdiction are presented in appendix A. Tables presenting state-level results at grade 8 indicate statistically significant changes across years when examining only one jurisdiction at a time ( $\star$ ), and when using a multiple comparison procedure based on all the jurisdictions that participated ( $\ddagger$ ). Only those differences based on the multiple comparison procedure are discussed.

## Gender Results by State

Table 3.2 presents the results for the grade 4 male and female average science scores for each jurisdiction that participated in the 2000 assessment. Since this was the first time the assessment was given at the state level, there are no comparisons to other years. At grade 4, the average score of male students was higher than that of female students in 7 states and other jurisdic-tions-Connecticut, Georgia, Maine, North Dakota, Utah, Wyoming, and the Department of Defense Dependents Schools (Overseas) (DoDDS).

Table 3.3 presents the results for the grade 8 male and female average science scores for each jurisdiction that participated in the 2000 assessment. For both males and females the 2000 average score is compared to scores from 1996, where available. The following discussion of changes in subgroup performance within jurisdictions is based only on results of the statistical testing using a multiple-comparison procedure. At grade 8 , in 2000 , the average score

* Significantly different from 2000 if only one jurisdiction or the Nation is being examined.
$\ddagger$ Significantly different from 2000 when examining only one jurisdiction and when using a multiple comparison procedure based on all jurisdictions that participated both years.
$\dagger$ Indicates that the jurisdiction did not meet one or more of the guidelines for school participation in 2000
- Indicates that the jurisdiction did not participate.

NOTE: Comparative performance results may be affected by changes in exclusion rates for students with disabilities and limited English proficient students in the NAEP samples. DDESS: Department of Defense Domestic Dependent Elementary and Secondary Schools.
DoDDS: Department of Defense Dependents Schools (Overseas).
SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.
of male students was higher than that of female students in 23 jurisdictions. Between 1996 and 2000 gains were evident for males in three jurisdictions-Kentucky, Missouri, and the Department of Defense Dependents School (Overseas) (DoDDS). Gains were made by females in only one jurisdiction between 1996 and 2000-the Department of Defense Domestic Dependent Elementary and Secondary Schools (DDESS).

Tables 3.4 and 3.5 present the percentage of males and females at or above Proficient for the participating jurisdictions at grades 4 and 8 respectively. At grade 4, the percentage of students at or above Proficient in 2000 was higher for male students than for female students in

7 jurisdictions-Connecticut, Maine, North Dakota, Rhode Island, Utah, Wyoming, and the Department of Defense Dependents School (Overseas). At grade 8, the percentage of students at or above Proficient in 2000 was higher for male students than for female students in 29 jurisdictions. When results from 1996 were compared to those of 2000 , the percentage of male students at or above Proficient was higher in 2000 in 4 jurisdictions-Kentucky, Missouri, West Virginia, and the Department of Defense Dependents School (Overseas) (DoDDS). There were no statistically significant changes between 1996 and 2000 among female eighthgraders in any of the jurisdictions.

## Race/Ethnicity Results by State

Tables 3.6 and 3.7 display the average science scores for each of the racial/ethnic groups by jurisdiction in 2000 for grade 4, and in 1996 and 2000 for grade 8. In every state and other jurisdiction where sample sizes were large enough for reliable statisti-
cal comparisons, White students outperformed Black and Hispanic students at both grades. There were no statistically significant differences detected between 1996 and 2000 in any state or jurisdiction in the average scores of eighth-graders in the different racial/ethnic subgroups.

[^8]The percentages of students in the different racial/ethnic subgroups across jurisdictions who were at or above Proficient are presented in table 3.8 (grade 4) and table 3.9 (grade 8). The patterns seen in the grade 4 results are very similar to those found in the average score results. White students outperformed Black and Hispanic students in jurisdictions where sample sizes were large enough for reliable statistical comparisons.

At grade 8, the percentage of White students in most states and jurisdictions at or above Proficient was on average higher than the percentage of Black or Hispanic students in jurisdictions where a comparison was possible. There were no statistically significant changes between 1996 and 2000 in any state or jurisdiction in the percentages of eighth-graders in the different racial/ethnic subgroups who were at or above Proficient.

## Table 3.8 State Proficient Level Achievement Results by Race/Ethnicity, Grade 4

State percentages of students at or above the Proficient level in science by race/ethnicity for grade 4 public schools: 2000

## Scale Score Differences Between Selected Subgroups by State

Similar to results for the nation, changes in the score differences or "gaps" between male and female students were relatively small across states, and were not found to be significantly different across assessment years at grade 8 . Also similar to the national data, the score gaps between male and female students are generally much smaller than those seen between racial/ethnic subgroups. None of the apparent changes in racial/ethnic score gaps across years at grade 8 were statistically significant. The gender and racial/ethnic score gap results for jurisdictions are provided in appendix B.

## Free/Reduced-Price School Lunch Eligibility Results by State

NAEP collects data on students' eligibility for the federal free/reduced-price school lunch program as an indicator of economic status in both the national and state (or jurisdiction) samples. Tables 3.10 and 3.11 present the results by state and jurisdiction for grades 4 and 8 , respectively. As previously noted, comparison data for grade 4 do not exist because the science assessment was only offered state-by-state at the eighth-grade level in 1996.

At grade 4, in all jurisdictions where sample sizes were large enough for reliable statistical comparisons, students who were not eligible for the free/reduced-price school lunch program outperformed students who were. A similar result was seen at grade 8 . When data were compared across years, eighth-graders in five jurisdictions who were not eligible for the program had higher average scores in 2000 than in 1996. They are: Louisiana, Missouri, Vermont, West Virginia, and DoDDS.

The percentage of students at or above Proficient by free/reduced-price school lunch eligibility in 2000 are presented for participating jurisdiction in tables 3.12 and 3.13 for grades 4 and 8 , respectively. There were higher percentages of eighth-graders who were not eligible for the program at or above Proficient in 2000 than in 1996 in Lousiana, Missouri, and West Virginia. Additional data for these subgroups are included in appendix B.

## 4

## Becoming a More Inclusive National Assessment

Legislation at the federal level now mandates the inclusion of all students in large-scale academic assessments. ${ }^{1}$ As a consequence, most states have assessment programs that must make provisions for special-needs students-those with disabilities or limited English proficient students-that include the allowance of testing accommodations when appropriate. Assessing as representative a sample of the nation's students as possible is particularly important for NAEP's mission to serve as a key indicator of the academic achievement of the nation's students. This

## Chapter Focus

How would the NAEP results differ if
accommodations were permitted for special-needs students? mission can be satisfactorily accomplished only if the assessment results include data gathered from all groups of students, including those classified as having special needs.

Although the intent of NAEP has consistently been to include special-needs students in its assessments to the fullest degree possible, the implementation of the assessment has always resulted in some exclusion of students who could not be assessed meaningfully without accommodations. Participating schools have been permitted to exclude certain students who have been classified as having a disability under the Individuals with Disabilities Education Act, based upon their Individualized Education Programs (IEP) and Section 504 of the Rehabilitation Act of 1973.

[^12]Similarly, schools have been permitted to exclude some students they identify as being limited-English proficient. Exclusion decisions are made in accordance with explicit criteria provided by the NAEP program.

In order to move the NAEP assessments toward more inclusive samples, the NAEP program began to explore the use of accommodations with special-needs students during the 1996 science assessment. An additional impetus for this change was the attempt to keep NAEP consistent with state and district testing policies that increasingly offered accommodations so that more special-needs students could be assessed. In 1996, the national NAEP sample was split so that some of the schools sampled were permitted to provide accommodations to special-needs students and the other schools were not. This sample design made it possible to study the effects on NAEP results of including special-needs students in the assessments under alternate testing conditions. Technical research papers have been published with the results of these comparisons. ${ }^{2}$ Based on the outcomes of these analyses, the 1998 results of those NAEP assessments that used new test frameworks (writing and civics), and hence also began new trend lines, were reported with the inclusion of data from accommodated special-needs students.

The results presented in the NAEP 1996 science report card included the performance of those students with disabilities (SD) or limited English proficient students (LEP) who were assessed without the possibility of accommodations. They did not include results on the performance of students for whom accommodations were permitted. However, in both the 1996 and 2000 science assessments, NAEP used the split-sample design so that changes in students' science achievement could be reported across the two assessment years and, at the same time, the program could continue to examine the effects of including students assessed with accommodations.

## Two Sets of 2000 NAEP Science Results

This report card is the first to display two different sets of NAEP science results based on the split-sample design: 1) those that reflect the performance of regular and special-needs students when accommodations were not permitted, and 2) those that reflect the performance of regular and special-needs students-both those who were accommodated and those who were tested without accommodations-when accommodations were permitted. It should be noted that accommodated students make up a small proportion of the total weighted number of students assessed (see table A.9, in appendix A for details). Mak-

Lutkus, A. D., \& Mazzeo, J. Including special-needs students in the NAEP 1998 reading assessment: Part I, comparison of overall results with and without accommodations. Washington, DC: U.S. Department of Education, Institute of Education Sciences, National Center for Education Statistics (forthcoming).
Lutkus, A. D. Including special-needs students in the NAEP 1998 reading assessment: Part II, results for students with disabilities and limited English proficient students. Washington, DC: U.S. Department of Education, Institute of Education Sciences, National Center for Education Statistics (forthcoming).
ing accommodations available may change the overall assessment results in subtle and different ways. For example, when accommodations are permitted, there may be some occurrences of students being accommodated who might have taken the test under standard conditions if accommodations were not permitted. This could lead to an overall increase in the average assessment results, if accommodations were to increase special-needs students' performance. Conversely, when accommodations are permitted, many special-needs students who could not have been tested without accommodations could be included in the sample. Assuming that these are generally lower-performing students, their inclusion in the sample-even with accommoda-tions-could result in an overall lower average score.

Chapters 1, 2, 3, and 5 of this report are based on the first set of results (i.e., no accommodations offered). This chapter presents an overview of the second set of results-those that include students who were provided with accommodations during the assessment administration. By including these results, the NAEP program begins a phased transition toward a more inclusive reporting sample. Future assessment results will be based solely on student and school samples in which accommodations are permitted.

The two sets of results presented in this chapter were obtained by administering the assessment to a nationally representative sample of students and schools. In one part of the schools sampled, no accommodations were permitted: all students were assessed under the same conditions that were the basis for reporting results from the 1996 NAEP science assessments. In another part of the schools sampled, accommoda-
tions were permitted for SD and LEP students who normally receive accommodations in their district or state assessment programs. Most accommodations that schools routinely provide for their own testing programs were permitted. Such permitted accommodations included, but were not limited to the following:

- one-on-one testing,
- bilingual dictionary,
- large print book,
- small-group testing,
- extended time,
- oral reading of directions, and
- use of an aide for transcribing responses.
(See appendix A, table A.11, for greater detail on the numbers and percentages of students accommodated by accommodation type in the 1996 and 2000 science assessments.)

Figure 4.1 provides a visual representation of how the two sets of results were based on the two samples in 1996 and 2000. Included in both sets of results (accommodations not permitted and accommodations permitted) are those students from both samples of schools who were not identified as either SD or LEP. In addition, the first set of results (accommodations not permitted) includes SD and LEP students from the sample of schools where accommodations were not permitted (see middle portion of figure 4.1). This is the set of results that allowed for comparisons to 1996 and that are presented in the other chapters of this report.

The second set of results, accommodations permitted (see bottom portion of figure 4.1), includes SD and LEP students from the sample of schools where accommodations were permitted. This is the set

Figure 4.1 Split-Sample Design

## The two sets of NAEP results based on a split-sample design

| Sample with no <br> accommodations permitted | Sample with <br> accommodations permitted |
| :---: | :---: |
| Non-SD/LEP <br> students | Non-SD/LEP <br> students |
| SD/LEP |  |
| Students | SD/LEP |
| Students |  |

## Split-sample design

The national sample was split. In part of the schools, accommodations were not permitted for students with disabilities (SD) and limited English proficient students (LEP). In the other schools, accommodations were permitted for SD and LEP students who routinely received them in their school assessments.

## Accommodations-not-permitted results

The accommodations-not-permitted results include the performance of students from both samples who were not classified as SD or LEP and the performance of SD and LEP students from the sample in which no accommodations were permitted.

## Accommodations-permitted results

The accommodations-permitted results also include the performance of students from both samples who were not classified as SD or LEP; however, the SD and LEP students whose performance is included in this set of results were from the sample in which accommodations were permitted. Since students who required testing accommodations could be assessed and represented in the overall results, it was anticipated that these results would include more special-needs students and reflect a more inclusive sample.
of results that form the new, more inclusive baseline for future reporting of trend comparisons for the NAEP science assessment.

In the NAEP 2000 national sample where accommodations were not permitted, 14 percent of fourth-graders, 14 percent of eighth-graders, and 9 percent of twelfth-graders, were identified by their schools as having special needs (i.e., either as SD or LEP students). In the other national sample where accommodations were offered, 16 percent of fourth-graders, 13 percent of eighth-graders, and 9 percent of twelfth-graders were identified as having special needs. In the sample where accommodations were not permitted, 48 percent of the special-needs students at fourth and twelfth grade, and 49 percent at eighth grade (between 4 and 7 percent of all students-see appendix A, table A.7) were excluded from NAEP testing by their schools. In the sample where accommodations were offered, 28 percent of the special-needs students at each of the three grade levels were excluded from the assessment (between 2 and 4 percent of the total sample).

The focus of this chapter is a comparison of data from the two sets of results: 1) accommodations not permitted, and 2) accommodations permitted. Because the split-sample design was used in both 1996 and 2000 for the NAEP national science assessment, both sets of results are presented for both years. The split-sample design was first used in the NAEP state science assessment in 2000 . Overall results
are provided for the nation and for participating states and other jurisdictions. In addition, national results are presented by gender and by race/ethnicity. These results are discussed in terms of statistically significant differences between the two sets of results in each year, changes between assessment years, and differences between subgroups of students within each set of results. Throughout this chapter, the assessment results that include SD and LEP students for whom accommodations were not permitted will be referred to as the "accommodations-not-permitted" results. The set of results that includes SD and LEP students for whom accommodations were permitted will be referred to as the "ac-commodations-permitted" results.

## Results for the Nation Accommodations Not Permitted and Accommodations Permitted

Table 4.1 displays the average science scale scores for the nation in 1996 and 2000 for two sets of results: 1) accommodations not permitted, and 2) accommodations permitted. At grade 4, the accommodationspermitted average score in 2000 was two points lower than the accommodations-not-permitted average score. The small difference between the two sets of results in 1996 was not statistically significant. At grades 8 and 12 the apparent differences between the two average scores in either 1996 or 2000 were not found to be statistically significant. The decline in the average twelfth-grade score between 1996 and 2000 is evident in both sets of results.

Table 4.1 Comparison of Two Sets of National Scale Score Results
National average science scale scores by type of results, grades 4, 8, and 12: 1996 and 2000

SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

As noted in the introduction to this chapter, NAEP has always sought to include special-needs students proportionate to their representation in the U.S. population. Offering accommodations tends to reduce exclusion rates for special-needs students and therefore allows NAEP to offer a fairer and more accurate picture of the status of American education. Because special-needs students are typically classified as eligible for special educational services after having shown some difficulty in the regular learning environment, the academic achievement of special-needs students might be expected to be lower than that of students without such needs. This only appeared to be the case in the observed difference between the two sets of grade 4 science results in 2000, where the accommodations-permitted results, which included slightly more special-needs
students because of the availability of accommodations, were lower than the accommodations-not-permitted results. It is important to examine the percentages of students attaining the NAEP achievement levels, however, to see if there were higher percentages at the lower achievement levels (i.e., below Basic and Basic), when students were assessed with accommodations.

Table 4.2 shows the percentages of students attaining each of the achievement levels. The percentages are similar across the two sets of 1996 results for grades 8 and 12: apparent differences between the accom-modations-not-permitted and the accom-modations-permitted results were not found to be significantly different. At grade 4, however, the percentage of students below Basic in both years was higher when accommodations were permitted than when they were not.

## Table 4.2 Comparison of Two Sets of National Achievement-Level Results

## National Results by Gender Accommodations Not Permitted and Accommodations Permitted

The average science scale scores by gender for both sets of results in 1996 and 2000 are provided in table B. 67 in appendix B. In 2000, male students at grade 4 had higher science scores when accommodations were not permitted than when accommodations were permitted.

At grades 4 and 8, male students outperformed female students in 2000 regardless of whether or not accommodations were permitted. At grade 12, the apparent difference in scores between male and
female students was not statistically significant in either set of results.

There was no variation in the two sets of results with respect to differences in the performance of male and female students between 1996 and 2000. In both sets of results, male students had higher average scores in 2000 than in 1996 at grade 8 , and lower average scores in 2000 at grade 12. The performance among female students also remained stable between 1996 and 2000 at all three grades, with no statistically significant differences observed over time in either set of results.

The percentages of male and female students attaining the Basic, Proficient, and Advanced levels are provided in table B. 68 in appendix B. Comparing the two sets of results both in 1996 and 2000, a higher percentage of fourth-grade males were below Basic when accommodations were permitted in 2000 than when they were not. No statistically significant differences were found in the percentages of students attaining each of the achievement levels at grades 8 or 12 .

## National Results by <br> Race/Ethnicity <br> Accommodations Not Permitted and Accommodations Permitted

NAEP assessments across academic subjects have typically reported large score differences between different racial and ethnic subgroups. If students with disabilities (SD) or limited English proficient (LEP) students are overrepresented in a particular racial or ethnic group, that group's assessment scores may decrease. Table B. 69 in appendix B provides the average science scale scores for each of the race/ethnicity categories for the two sets of results in 1996 and in 2000. There were no statistically significant differences observed between the average scores when accommodations were not permitted and when accommodations were permitted for any of the race/ethnicity categories in either 1996 or 2000.

As noted in chapter 3, a pattern of performance differences by race/ethnicity can be seen in the accommodations-notpermitted results in 2000. Similar patterns were observed in the accommodationspermitted results with three exceptions. American Indian eighth-graders scored higher than Hispanic eighth-graders when accommodations were permitted, while the apparent difference was not statistically
significant when accommodations were not permitted. Hispanic twelfth-graders scored higher than Black twelfth-graders when accommodations were permitted but not significantly different from each other when accommodations were not permitted. Finally, the difference in average science scores between Asian/Pacific Islander and American Indian twelfthgraders was not significantly different when accommodations were permitted, while Asian/Pacific Islander students outperformed American Indian students when accommodations were not permitted.

At grade 8, American Indian students scored lower in 2000 than in 1996 when accommodations were not permitted, while the apparent decrease was not statistically significant when accommodations were permitted.

The percentages of students in each race/ethnicity category who attained the Basic, Proficient, and Advanced levels are provided in table B. 70 in appendix B. No statistically significant differences were found between the accommodations-notpermitted results and the accommodationspermitted results for the percentages of students attaining any of the achievement levels at any of the grade levels in 1996 and 2000.

## State Results <br> Accommodations Not Permitted and Accommodations Permitted

While the split-sample design was used for both the 1996 and 2000 national assessments, it was used for the first time in the state assessment of science in 2000 . The two sets of average scale scores for the jurisdictions that participated in 2000 are presented in tables 4.3 and 4.4 for grades 4 and 8 , respectively. As with the presentation of results for jurisdictions in previous
chapters, two types of statistical tests are indicated in these tables-one that involves a multiple-comparison procedure based on all jurisdictions that participated, and one that examines each jurisdiction separately. The following discussion of differences between the accommodations-not-permitted results and the accommodationspermitted results is based solely on the multiple-comparison procedure.

None of the apparent differences between the accommodations-not-permitted results and the accommodations-permitted results for either grade 4 or grade 8 were found to be statistically significant.

Figures 4.3 and 4.4 show comparisons of scale scores across states when accommodations were permitted for fourth- and eighth-grade students, respectively. Six states were included among the highestperforming jurisdictions at grade 4: Iowa,

Maine, Massachusetts, Montana, North Dakota and Vermont. These states were also included among the highest-performing jurisdictions when accommodations were not permitted. At grade 8, a cluster of highperforming jurisdictions when accommodations were permitted included Department of Defense Dependents Schools (Overseas), Idaho, Maine, Massachusetts, Michigan, Minnesota, Nebraska, North Dakota, Ohio, and Vermont. This cluster of 10 states was outperformed only by Montana. Most of these states were also among the higher-performing jurisdictions when accommodations were not permitted. Michigan had lower average scores than Massachusetts, Vermont, and North Dakota, and scores in Nebraska were lower than in Vermont and North Dakota when accommodations were not permitted. A listing of these jurisdictions by type of results is presented in figure 4.2.

## Comparisons of average science scale scores for grade 4 public schools: 2000 sample where accommodations were permitted

Instructions: Read down the column directly under a jurisdiction name listed in the heading at the top of the figure. Match the shading intensity surrounding a jurisdiction's abbreviation to the key below to determine whether the average science scale score of this jurisdiction is higher than, the same as, or lower than the jurisdiction in the column heading. For example, in the column under Indiana, Indiana's score was lower than Maine, Massachusetts, Vermont, North Dakota, Montana, and lowa, about the same as all the states from Minnesota through Nebraska, and higher than the remaining states down the column.

Jurisdiction has statistically significantly higher average scale score than the jurisdiction listed at the top of the figure.

No statistically significant difference detected from the jurisdiction listed at the top of the figure.

Jurisdiction has statistically significantly lower average scale score than the jurisdiction listed at the top of the figure.

The between jurisdiction comparisons take into account sampling and measurement error and that each jurisdiction is being compared with every other jurisdiction. Significance is determined by an application of a multiple comparison procedure (see appendix A).
++Indicates that the jurisdiction did not satisfy one or more of the guidelines for school participation rates (see appendix A).
DDESS: Department of Defense Domestic Dependent
Elementary and Secondary Schools.
DoDDS: Department of Defense Dependents Schools (Overseas). NOTE: Differences between states and jurisdictions may be partially explained by other factors not included in this figure.
SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 2000 Science Assessment.

Figure 4.4 Cross-State Scale Score Comparisons for Accommodations-Permitted Results, Grade 8
Comparisons of average science scale scores for grade 8 public schools: 2000 sample where accommodations were permitted
Instructions: Read down the column directly under a jurisdiction name listed in the heading at the top of the figure. Match the shading intensity surrounding a jurisdiction's abbreviation to the key below to determine whether the average science scale score of this jurisdiction is higher than, the same as, or lower than the jurisdiction in the column heading. For example, in the column under Ohio, Ohio's score was lower than Montana, about the same as all the states from North Dakota through Michigan, and higher than the remaining states down the column.

Jurisdiction has statistically significantly higher average scale score than the jurisdiction listed at the top of the figure.
listed at the top of the figure.
Jurisdiction has statistically significantly lower average scale score than the jurisdiction listed at the top of the figure.

The between jurisdiction comparisons take into account sampling and measurement error and that each jurisdiction is being compared with every other jurisdiction. Significance is determined by an application of a multiple comparison procedure (see appendix A).
++Indicates that the jurisdiction did not satisfy one or more of the guidelines for school participation rates (see appendix A).

Tables 4.5 and 4.6 show the percentages of students in each jurisdiction who were at or above the Proficient level when accommodations were not permitted and when accommodations were permitted. Again, no statistically significant differences were observed between the two sets of results at both grades 4 and 8 .

Figures 4.5 and 4.6 indicate whether differences in the percentages of students at or above Proficient between pairs of participating jurisdictions were statistically significant when accommodations were permitted. At grade 4, the cluster of four states with the highest percentage at or above the

Proficient level included Maine, Massachusetts, Montana, and Vermont. The same four states were also included among the jurisdictions clustered at the top when accommodations were not permitted (see chapter 2). At grade 8, Massachusetts, Minnesota, Montana, North Dakota, Ohio, and Vermont, had the highest percentages of students at or above Proficient when accommodations were permitted. Only four of these six states were among those with the highest percentage at or above the Proficient level (Massachusetts, Minnesota, Montana, and Ohio), in the accommodations-notpermitted results for grade 8 .

## Table 4.5 Comparisons of Two Sets of State Proficient Level Results, Grade 4

Jurisdiction has statistically significantly higher percentage than the jurisdiction listed at the top of the figure.

No statistically significant difference detected from the jurisdiction listed at the top of the figure.

Jurisdiction has statistically significantly lower percentage than the jurisdiction listed at the top of the figure.

The between jurisdiction comparisons take into account sampling and measurement error and that each jurisdiction is being compared with every other jurisdiction. Significance is determined by an application of a multiple comparison procedure (see appendix A).
++ Indicates that the jurisdiction did not satisfy one or more of the guidelines for school participation rates (see appendix A).
DDESS: Department of Defense Domestic Dependent Elementary and Secondary Schools
DoDDS: Department of Defense Dependents Schools (Overseas).
NOTE: Differences between states and jurisdictions may be partially explained by other factors not included in this figure.

## Figure 4.6 Cross-State ProficientLevel Comparisons for Accommodations-Permitted Results, Grade 8

Comparisons of percentage of students at or above Proficient in science for grade 8 public schools: 2000 sample where accommodations were permitted
Instructions: Read down the column directly under a jurisdiction name listed in the heading at the top of the figure. Match the shading intensity surrounding a jurisdiction's abbreviation to the key below to determine whether the percentage of students at or above Proficient in this jurisdiction is higher than, the same as, or lower than the jurisdiction in the column heading. For example, in the column under Maine, the percentage of students at or above Proficient in Maine was lower than Montana and Minnesota, about the same as all the states from Ohio through Department of Defense Domestic Dependent Elementary and Secondary Schools (DD), and higher than the remaining states down the column.

## Teaching and Learning Science

During the past 15 to 20 years science education has undergone a number of reforms that were spurred on initially by the 1983 report entitled $A$ Nation at Risk. This report raised the concern that national student achievement across core subjects was eroding. ${ }^{1}$ Publications by organizations such as the American Association for the Advancement of Science (AAAS), the National Research Council of the Academy of Sciences (NRC), and the National Science Teachers Association helped focus attention on a number of critical issues in science education that ranged from what science content to teach to how learning should be assessed. ${ }^{2}$ These publications, especially Benchmarks for Science Literacy and The National Science Education Standards, have been extensively used by some states as they have revised or created new science standards. ${ }^{3}$ Some recent publications written by the AAAS and NRC build on the information contained in Benchmarks and the National Standards, addressing in more detail such topics as curriculum design, how learning should be assessed, and how inquiry-based learning

[^16]helps students learn science content. ${ }^{4}$ However, the fact that a wealth of information on science teaching and learning is available to teachers does not necessarily mean that teachers incorporate such information into their daily classroom activities. Furthermore, there is a lack of information concerning the efficacy of certain teaching and learning strategies as they relate to what students know and can do in science. Thus, the results of the NAEP science assessment are very important since they give valuable information about teacher practices in the classroom, and may help to elucidate the relationship between those practices and student achievement.

This chapter considers school factors related to teaching and learning, as reported by teachers and students and examines their relationship to students' average scale scores on the NAEP 2000 science assessment. The information is based on responses to questionnaires answered both by teachers of students who participated in the assessment and by the students who took the assessment. Data based on teachers' responses are presented for grades 4 and 8 only. Grade 12 teachers were not administered a questionnaire because it is difficult to link students to teachers across the many different science courses taught at this grade level.

The information presented in this chapter may help readers interpret some of the findings found in earlier chapters of
this report. The contexts for teaching and learning explore two areas: computer availability and use, and students' coursetaking practices. As with all NAEP data, the unit of analysis in this chapter is the student. Although some of the data reported here are based on teachers' responses to the questionnaires, the results are reported in terms of percentages of students whose teachers responded to each question in a particular manner. The results for each of the factors described in this chapter include the percentages of students and their corresponding average scale scores. Results from the 2000 assessment are compared to 1996 for those questions that were asked of students or teachers in both assessment years. In some cases, data are available only from the 2000 assessment.

Readers of this report are reminded that the relationship between a contextual variable and science performance is not necessarily causal, and that different interpretations may apply to a given finding of association between a variable and average science scores. For example, one finding reported in this chapter is that twelfthgraders who used computers to collect data at least once a month outperformed their peers who did so less frequently. One possible interpretation of this finding is that the experience of using a computer in this manner for science learning may help students achieve in science. Conversely, it may also be possible that teachers of students who are already high achievers

[^17]may be more likely to allow their students to spend time collecting data with computers than are teachers of lower-achieving students. Without further study, the exact cause for the relationship between this instructional practice and students' average science scores cannot be determined.

## Technology Use: <br> Availability of Computers for Science Classes

How to best use computers for teaching and learning is an ongoing discussion among educators. There are many issues associated with effective use of technology in the classroom that range from computer access to teachers' expertise in building the tools computers offer into their teaching and learning plans. ${ }^{5}$ This multitude of factors makes it difficult to assess the effectiveness of computers vis-à-vis student learning. While the data on computers that were collected as part of the NAEP 2000 science assessment do not pretend to answer the questions these issues raise, the data do give an indication of how teachers are using computers. The following section reports some of these findings. Other data about computer availability and use can be found on the NAEP web site at http://nces.ed.gov/nationsreportcard.

Teachers of students in grades 4 and 8 were asked which best described the availability of computers for use by their science students. The response options are shown in table 5.1, together with the percentage of students whose teachers chose each response option and students' average science scores. In 2000, only 11 percent of fourth-graders and 10 percent of eighth-graders were taught by teachers who reported that no computers were available for use by the science students. Approximately 24 percent of fourthgraders and 41 percent of eighth-graders were taught by teachers who indicated that, although computers were available in a laboratory, they may not have had computers in their classrooms. Between 1996 and 2000 , none of the apparent changes in the availability of computers at grades 4 and 8 were found to be statistically significant.

At both grades 4 and 8 in 2000, students who could access computers in laboratories scored higher, on average, than their peers who had no access at all to computers. Regardless of the number of computers teachers reported having in their classrooms, there was no statistically significant difference detected in the average scores of students who had no access to computers and those who had one or more computers available in their classrooms.

[^19]
## Technology Use: Computers for Instruction in Science, Grades 4 and 8

Teachers whose students participated in the science assessment were asked how they used the computer for instruction in science. Since they could identify more than one type of computer use, the results are reported in terms of a "yes" or "no response" for each type of computer use. Table 5.2 shows the percentages and average scores of students whose teachers reported using the computer for drill and practice, playing science/learning games, simulations and modeling, data analysis and other applications, and word processing. It also provides the data for students whose teachers stated that they did not use computers for science instruction. It is important to note that any apparent relationship between computer use and student performance may reflect the influence of factors other than the type of computer use in and of itself.

In 2000, 43 percent of fourth-graders and 26 percent of eighth-graders had teachers who did not use computers for science instruction. At grade 4, students whose teachers indicated that they did not use computers for science instruction scored lower, on average, than did students whose teachers did use computers. (Note that a "no response" to this option in the table indicates that computers were used by teachers for science instruction.)

In 2000, fourth-graders whose teachers indicated that they used computers for playing science/learning games scored higher, on average, than fourth-graders whose teachers indicated that they did not use computers in this manner during science instruction. Eighth-graders whose teachers indicated using computers for simulations and modeling, and data analysis and other applications scored higher, on average, than eighth-graders whose teachers did not indicate doing so.

The results presented in table 5.2 also indicate an overall increase between 1996 and 2000 in the percentage of both fourthand eighth-graders whose teachers reported using computers for science instruction. The percentage of students whose teachers indicated using computers increased from 47 to 57 percent at grade 4, and from 54 to 74 percent at grade 8 . Also at grade 8 , there was an increase in the percentage of students whose teachers said they used computers for data analysis and other applications, and for word processing, as a part of science instruction.

The percentage of students is listed first with the corresponding average scale score presented below.

* Significantly different from 2000. Although not marked in the table, the difference in the percentage of students not responding in 1996 is significantly different from 2000 in all instances where the corresponding percentage of students responding yes is significantly different.
NOTE: Percentages may not add to 100 due to rounding.
SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

## Technology Use: Computers for Instruction in Science, Grade 12

In 2000, twelfth-grade students were asked how frequently they used computers in their science classes for collecting data using lab equipment that interfaces with computers; downloading data and related information from the Internet; analyzing data using the computer; and using the Internet to exchange information with other students or scientists about science experiments or investigations. The results are shown in table 5.3.

Thirty-four percent of twelfth-graders reported that they were not taking a science course, and between 42 and 54 percent of students stated that they never used computers to do the listed activities. The remaining percentage of students were fairly evenly split between those who indicated that they used the computer for each of the listed activities at least once a month and those who did so less than once a month.

With one exception, students who reported that they were not taking a science course were outperformed by their peers who were, even when their peers were not using computers for the listed activities. Average scores for students who reported using the Internet to exchange information with other students once a month or more were not found to be significantly different from those of students who were not taking science. Twelfth-graders who reported collecting data and who reported analyzing data with computers at least once a month outperformed their peers who reported doing so less frequently. Students who said they never downloaded data and related information from the Internet scored lower, on average, than their peers who indicated doing so at least sometimes.

## Student Coursework: Grade 4 Science Courses

Students in grade 4 tend to take a science course that incorporates a mixture of topics in science. While increasing emphasis on state standards and state assessments may have led to the topics covered in the early grades becoming more formalized, the topics taught in fourth-grade science classes are not necessarily unified across the nation. ${ }^{6}$ Since the instructional information that can be collected from teachers on a questionnaire is somewhat limited, information collected by NAEP on science course work for fourth-graders was confined to asking teachers how much time was spent on the broad domains of life science, Earth science, and physical science. Teachers responding to this question could choose from the options "a lot," "some," "little," and "none." It is important to note that the responses did not refer to minutes or hours spent on the domain, but rather to time spent in relation to the other areas. Thus, teachers may have spent only 10 minutes a week on life science and still have indicated that they devoted "a lot" of time to this domain. The results for this question are presented in table 5.4.

In 2000, teachers of 31 percent of fourth-graders reported spending a lot of time on life science and Earth science, and teachers of 22 percent of fourth-graders reported spending a lot of time on physical science. A very small percentage of fourthgraders were taught by teachers who said they actually devoted no time to any of these three science domains-only 1 to 2 percent. The amount of time teachers devoted to life science and to Earth science displayed a fairly positive relationship with average NAEP science scores. In both cases, students whose teachers indicated that they devoted a lot or some time on these science domains outperformed their peers whose teachers indicated spending little time.

The percentage of students whose teachers reported spending a lot of time on Earth science increased from 19 percent in 1996 to 31 percent in 2000. At the same time, the percentage of students whose teachers reported spending only some time on the Earth science domain decreased from 76 to 62 percent.

## Student Coursework: Grade 8 Science Courses

By the time students reach middle school, science is being taught as a core content area. There is, however, no consensus as to the order in which the key domains should be taught. ${ }^{7}$ As part of the NAEP science assessment, eighth-grade teachers were asked the same question that was asked of teachers of fourth-graders, namely to indicate how much time they spent on certain science domains. Readers are reminded that the NAEP assessment surveys the content domains of Earth, physical, and life science; thus, if students are to do well on NAEP, breadth of coverage may be important in middle school.

Table 5.5 presents the percentages of eighth-graders and their average scores by teachers' reports on how much time they spent on various science domains. In 2000, 45 and 47 percent of eighth-graders were
taught by teachers who spent a lot of time on Earth science and physical science, respectively. Twenty-one percent of eighth-graders were taught by teachers who indicated spending a lot of time on life science. None of the apparent changes between 1996 and 2000 in eighth-grade teachers' reports of amount of time devoted to any of the science domains were statistically significant.

In 2000, the relationship between teachers' reports on the amount of time devoted to the various science domains and eighth-graders' average science scores was somewhat different than that observed at the fourth grade. For both life science and Earth science, the students whose teachers reported spending no time on these domains outperformed their peers whose teachers reported spending a lot or some time.

[^21]

## Student Coursework: Grade 12 Science Courses

Most states have science coursework requirements for graduation; however, in some states the requirements are determined at the local level. In 2000, according to a Council of Chief State School Officers report, 4 states required four credits for graduation, 15 states and the Department of Defense schools required three credits, 21 required two credits, and 2 required only one credit. ${ }^{8}$ The number of science credits required in the remaining states were either determined by a local board or were included as part of combined credits in mathematics and science. Some states required that students take specific courses such as life science and physical science, while other states made no such demands. Some states required that students take courses in specific areas such as life science and physical science. However, course requirements in life science and physical science can often be fulfilled without taking a core course in biology, chemistry, or physics. While seven states did require at least one of the core science courses, no state required all three for graduation. ${ }^{9}$

Twelfth-grade students in the NAEP science assessment responded to several questions about their science studies. They were asked whether they were currently taking a science class and then asked to indicate which courses they had taken from the eighth grade to the present. The list of courses included Earth and space science, life science (other than biology), physical science (other than physics and chemistry), general science, integrated science, biology, chemistry, physics, and science and technology. Students were also asked if they were currently enrolled in or had taken Advanced Placement courses in biology, chemistry, and physics. The data collected from these questions are presented on the following pages.

[^22]

The percentage of students is listed first with the corresponding average scale score presented below.
NOTE: Percentages may not add to 100 due to rounding.
SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

## Current Science Course Enrollment

Table 5.6 shows the percentages of students who were enrolled in a science course in 2000 and in 1996. As can be seen from the data, in 2000, 53 percent of students reported currently taking a science course, whereas 47 percent reported not taking one. This was similar to the results in 1996. Students who reported that they were currently taking a science course in 2000 outperformed their counterparts who reported that they were not taking a science course at the time of the assessment.

## Science Courses Taken Since Eighth Grade

Table 5.7 presents the results for a question that asked students in which grade they had taken certain science courses. The grades covered were 8 through 12 . Students were also asked to indicate if they had not taken a specific course. The actual list presented to students included more courses than are listed in the table; for example second year biology was included on the list that was presented to students, but is not presented in table 5.7. A complete listing can be found on the NAEP web site.

NOTE: Row percentages may not add to 100 because some students indicated taking a course in more than one grade.
SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 2000 Science Assessment.

The table shows that 26 percent of students reported not taking Earth and space science in grades 8 through 12. This does not mean that they never had a course in earth and space science. They may have taken it in grade 7 , or even in grade 6 . Almost one-half of the twelfth-grade student population did report taking the course during eighth grade. While almost
all students had taken biology at some point since the eighth grade, the most popular grade for taking the course was tenth. Two-thirds of twelfth-graders reported taking chemistry. Forty percent of students took the course in the eleventh grade. Thirty-six percent of twelfthgraders reported taking physics-most typically in the eleventh or twelfth grade.

## Enrollment in Advanced Placement Science Courses

Many schools offer higher-level courses that allow students to accumulate college credits. Table 5.8 displays the percentage of students in 2000 who reported that they were currently enrolled in or had taken an Advanced Placement course in the three core sciences-biology, chemistry, and physics. Students' average scores are also presented.

The results show that 10 percent of twelfth-graders had taken or were enrolled in biology, and that 6 and 5 percent had taken or were enrolled in chemistry and physics, respectively. Students who had taken or were enrolled in AP biology, chemistry, or physics scored higher, on average, than those students who said they had not taken and were not enrolled in these courses.

## Table 5.8

Percentage of twelfth-graders and average scale score by students' reports on whether they are currently enrolled in or have taken an Advanced Placement course: 2000

Twelfth-graders who had taken an AP course in biology, chemistry, or physics had higher average scores than twelfith-graders who had not taken one of these courses.

The percentage of students is listed first with the corresponding average scale score presented below.

[^6]:    $\dagger$ Indicates that the jurisdiction did not meet one or more of the guidelines for school participation.
    NOTE: Comparative performance results may be affected by changes in exclusion rates for students with disabilities and limited English proficient students in the NAEP samples. DDESS: Department of Defense Domestic Dependent Elementary and Secondary Schools.
    DoDDS: Department of Defense Dependents Schools (Overseas).
    SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 2000 Science Assessment.

[^7]:    **** Sample size is insufficient to permit a reliable estimate.
    $\dagger$ Indicates that the jurisdiction did not meet one or more of the guidelines for school participation.
    NOTE: Comparative performance results may be affected by changes in exclusion rates for students with disabilities and limited English proficient students in the NAEP samples.
    $\sim$ Special analyses raised concerns about the accuracy and precision of the National grade 4 Asian/Pacific Islander results in 2000. As a result, they are omitted from the body of this report. See appendix A for a more detailed discussion.
    DDESS: Department of Defense Domestic Dependent Elementary and Secondary Schools. DoDDS: Department of Defense Dependents Schools (Overseas)
    SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 2000 Science Assessment.

[^8]:    * Significantly different from 2000 if only one jurisdiction or the Nation is being examined.
    $* * * *$ Sample size is insufficient to permit a reliable estimate.
    $\dagger$ Indicates that the jurisdiction did not meet one or more of the guidelines for school participation in 2000.
    - Indicates that the jurisdiction did not participate.

    NOTE: Comparative performance results may be affected by changes in exclusion rates for students with disabilities and limited English proficient students in the NAEP samples.
    DDESS: Department of Defense Domestic Dependent Elementary and Secondary Schools.
    DoDDS: Department of Defense Dependents Schools (Overseas).
    SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

[^9]:    **** Sample size is insufficient to permit a reliable estimate.
    $\dagger$ Indicates that the jurisdiction did not meet one or more of the guidelines for school participation.
    NOTE: Comparative performance results may be affected by changes in exclusion rates for students with disabilities and limited English proficient students in the NAEP samples. DDESS: Department of Defense Domestic Dependent Elementary and Secondary Schools.
    DoDDS: Department of Defense Dependents Schools (Overseas).
    SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 2000 Science Assessment.

[^10]:    * Significantly different from 2000 if only one jurisdiction or the Nation is being examined.
    $\ddagger$ Significantly different from 2000 when examining only one jurisdiction and when using a multiple comparison procedure based on all jurisdictions that participated both years. **** Sample size is insufficient to permit a reliable estimate.
    $\dagger$ Indicates that the jurisdiction did not meet one or more of the guidelines for school participation in 2000.
    - Indicates that the jurisdiction did not participate.

    NOTE: Comparative performance results may be affected by changes in exclusion rates for students with disabilities and limited English proficient students in the NAEP samples. DDESS: Department of Defense Domestic Dependent Elementary and Secondary Schools. DoDDS: Department of Defense Dependents Schools (Overseas). SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 and 2000 Science Assessments.

[^11]:    **** Sample size is insufficient to permit a reliable estimate.
    $\dagger$ Indicates that the jurisdiction did not meet one or more of the guidelines for school participation.
    A Percentage is between 0.0 and 0.5 .
    NOTE: Comparative performance results may be affected by changes in exclusion rates for students with disabilities and limited English proficient students in the NAEP samples. DDESS: Department of Defense Domestic Dependent Elementary and Secondary Schools,
    DoDDS: Department of Defense Dependents Schools (Overseas).
