SAW 47 Working Paper 11 (TOR 6) – Modeling Environmental Factors

September 5, 2007

Modeling environmental factors and summer flounder recruitment success

by
Mark Terceiro
NOAA Fisheries NEFSC

A Report to the Northeast Regional (NER) Stock Assessment Workshop (SAW)
Southern Demersal Working Group (SDWG)

INTRODUCTION

There is interest among scientists, managers, and fishermen in exploring the relationship between environmental processes and summer flounder recruitment. Such processes might include the influence of physical parameters such as water temperature and salinity, and biological ones such as the density of prey (e.g., zooplankton and small fish) or the density of predators (e.g., spiny dogfish, bluefish, or striped bass). The most recent stock assessments for summer flounder (Terceiro 2006a, b; SDWG 2007) indicate that over the last 25 years recruitment has varied annually by a factor of about seven (Table 1, Figure 1). The weak year class that recruited to the stock in 2005, which was spawned by the largest spawning stock biomass (SSB) of summer flounder since the 1970s, brought increased focus to the influence of environmental factors on the success of summer flounder recruitment.

Evidence from several studies suggests that low water temperatures could negatively impact summer flounder recruitment. Summer flounder spawning occurs during an annual offshore migration from coastal areas to the continental shelf from August through December, and is generally considered to peak around November 1 (O'Brien et al. 1993). Summer flounder eggs have been collected as early as September in the northern Mid-Atlantic Bight and as late as January off Cape Hatteras, NC, with peak egg concentrations in October and November (Smith 1973, Able et al. 1990). Summer flounder eggs in the wild are tolerant to a wide range of temperatures between about 9 and 22^{o}C, with most occurring in temperatures of about 13-17^{o}C (Smith 1973). Summer flounder larvae have been collected over an even wider range of temperatures (0-23^{o}C; Smith 1973). Laboratory studies suggest that summer flounder eggs and larvae are tolerant to relatively high temperatures (Johns and Howell 1980, Johns at al. 1981),

but that both eggs and larvae are susceptible to shock exposure to low temperatures of about 0°C (Hoss et al. 1974).

Summer flounder larvae undergo metamorphosis during the late autumn and early winter months as they enter the estuarine zone along the mid-Atlantic coast (Able et al. 1990). Szedlmayer et al. (1992) investigated the first year growth and effects of water temperature on survival for summer flounder juveniles migrating into New Jersey estuaries in the winter of 1988-1989, and found that the survival of metamorphosing larvae decreased drastically when water temperatures dropped below 2°C. Keefe and Able (1992) found that the survival of metamorphosing larvae was lower at laboratory water temperatures of 4°C than at 10°C, and concluded that estuarine summer flounder larvae suffer increased mortality based on both the duration and severity of cold water temperatures. Malloy and Targett (1991) conducted laboratory experiments on juvenile summer flounder and found 100% survival above 3°C, suggesting that the juveniles were able to survive most winter water temperatures encountered in the Mid-Atlantic Bight. However, Malloy and Targett (1994) found 42% mortality of juveniles at 2°C and concluded that mortality in the wild from acute exposure to low water temperatures probably occurred during one 2 to 4 week period each winter, and that summer flounder recruitment success in the north/central Mid-Atlantic Bight may be lower in years with late winter cold periods due to increased exposure to lethal temperatures.

Over the last decade, persistent significant relationships have been found between environmental factors and recruitment success for a variety of fish species around the world. Daskalov (1999) used General Additive Modeling (GAM; Hastie and Tibshirani 1990) to document significant correlations between the recruitment success of Black Sea anchovy, whiting, sprat, and horse mackerel and environmental factors including sea surface temperature, wind speed, wind stress, mixing, atmospheric pressure, and river run-off. Williams and Quinn (2000) used correlation analyses to identify significant environmental factors affecting Pacific herring recruitment success. Beentjes and Renwick (2001) used correlation analysis to identify a significant relationship between New Zealand red cod recruitment success and sea surface temperature. Chen and Ware (1999), Chen at al. (2000), Chen (2001), and Dreyfus-Leon and Chen (2007) used neural network, fuzzy logic, and genetic algorithm models to explore the relationships between environmental factors and recruitment success of Pacific herring stocks. Megrey et al. (2005) examined the utility of linear and non-linear regression, Generalized Additive Models (GAMs), and Artificial Neural Network (ANN) models in identifying relationships between recruitment and the environment for both simulated and real Norwegian herring stock-recruit data. Brodziak and O'Brien (2005) used randomization methods and the GAM approach to evaluate the response of New England groundfish recruit-spawner ratios to environmental variables such as the North Atlantic Oscillation (NAO) index, water temperature, windstress, and shelf water volume anomalies. This work explores the relationships between water temperature anomalies, NAO indices and metrics of summer flounder recruitment success by applying some of the approaches of Brodziak and O'Brien (2005) and Megrey et al. (2005) to summer flounder spawner-recruit data and relevant environmental data.

DATA AND MODELING APPROACH

Data

Spawning stock biomass (SSB) and recruitment estimates (VPA0) for summer flounder were taken from a version of the 2007 assessment update Virtual Population Analysis (VPA)

F07_ALL sensitivity run (includes all available survey indices; SDWG 2007), which has historically exhibited a milder retrospective pattern and more precise estimates of stock size (a "degrees of freedom" phenomenon) than the F07_1 final run used to determine the official status of the stock. Because no accepted parametric stock-recruit relationship was available (Terceiro 2006b), the RSAs were computed as the difference between the observed annual RS ratio values and the mean RS ratio value for the 1983-2006 year classes (Table 1, Figure 1).

NEFSC research survey surface and bottom water temperature anomalies for the Mid-Atlantic Bight North (MABN; Nantucket Shoals to Hudson Canyon) and South regions (MABS; Hudson Canyon to Cape Hatteras) were obtained from the NEFSC database (http://www.nefsc.noaa.gov/epd/ocean/MainPage/ioos) following the methods developed by Mountain (2004). Seasonal temperatures anomalies were computed for the two regions for winter/spring (season 1; January-June) and fall (July-December) for both surface and bottom water temperatures (Figure 2). Fall season anomalies are forward lagged to the next calendar year for correspondence with summer flounder age-0 year class designation (because summer flounder are born during September-March, and appear in fishery and research survey catches from 9-16 months after birth, a fish spawned in fall 1990 by the 1990 SSB may not appear in fishery and catches until late fall/early winter 1991 – but it is classified as a age 0 fish even though it may be up to 15 months old, since the abundance of the year class is estimated as of January 1, 1991).

North Atlantic Oscillation (NAO) climate index monthly values were obtained from the University of East Anglia database (http://www.cru.uea.ac.uk/cru/climon/monthly) and winter (December-March) and fall (September- November) indices were computed as per Jones et al. (1997)(Figure 3). NAO indices were also forward lagged one and two years because the NAO can produce both contemporary local and time-lagged broad-scale physical changes in the climate that could influence recruitment success (Brodziak and O'Brien 2005).

Modeling Approach

The works cited in the Introduction set the foundation for the hypothesis that relatively cold water temperature, or some mechanism associated with cold and/or severe weather, is correlated with poor recruitment success for summer flounder. Aspects of the current work follow the general approach of Brodziak and O'Brien (2005), who examined relationships between environmental indices and summer flounder Recruit-Spawner Anomalies (RSAs), considered a measure of summer flounder recruitment success that is independent of the size of the Spawning Stock Biomass (SSB). Brodziak and O'Brien (2005) found that the NAO2 index (NAO winter index forward lagged by two years) was a significant predictor of summer flounder RS ratios, with positive NAO anomalies (wet and mild winters) correlating with positive RSAs (high recruit survival rate). This work also follows aspects of the work of Megrey et al. (2005), by considering the absolute estimates of recruitment (VPA0) as another measure of recruitment success, which may or may not be subject to strong influence of the magnitude of SSB.

Correlation analyses among the environmental factors and RSAs and absolute estimates of recruitment (VPA0) were performed first to identify potentially significant relationships. The GAM approach to modeling (Hastie and Tibshirani 1990), suggested by Daskalov (1999), Megrey et al. (2005), and Brodziak and O'Brien (2005) as an effective tool for modeling biological responses to environmental factors, was then used to model relationships for environmental (predictive) factors initially identified by the correlation analysis as significant at the $p = 0.10$ level. The GAM approach is a nonparametric regression technique that relaxes error

distribution assumptions in modeling the relationships between independent predictive variables and dependent response variables. The initial null predictive model in the GAM framework used smoothing splines with 3 degress of freedom for each predictive factor. Following the procedures suggested by Brodziak and O'Brien (2005), a stepwise model-selection process was applied to eliminate predictive factors from the model if they had a *p*-value <= 0.20, with the step repeated until only predictive factors with $p <= 0.20$ were included in the model. Finally, the time series of the environmental factors with best fitting GAM models were used in an exercise to investigate their performance as potential VPA recruitment calibration indices.

RESULTS AND DISCUSSION

The most prominent features of the summer flounder absolute recruitment series (VPA0) are the strong year class that recruited in 1983, and the two weak year classes that recruited in 1988 and 2005 (Table 1, Figure 1). The most prominent features of the summer flounder recruit-spawner anomaly (RSA) series are the generally positive anomalies before 1996, and the uniformly negative anomalies since. The strong negative RSAs in 1988 and 2005 correspond to the weak absolute magnitude of recruitments (VPA0) in those years. The pattern of relatively low (negative) RSA since 1995 is one that would be expected for a fish stock exhibiting a Beverton-Holt (1957) asymptotic stock-recruitment relationship as that stock grows toward SSB_{MSY} (Terceiro 2006b).

Visual inspection of the temperature anomaly and climate index series indicates a few instances of prominent environmental factors that correspond with the metrics of recruitment success. For example, a) the relatively high MAS_ST2 and MAS_BT2 (Mid-Atlantic South region Fall surface and bottom) temperature anomalies in 1983 correlate with the strong 1983 year class (VPA0) and positive 1983 RSA, b) the negative MAS_BT2 anomaly correlates with the weak 2005 year class and negative 2005 RSA, and c) the slightly negative MAS_ST1 anomaly in 1988 is the strongest correlate with the weak 1998 year class/negative 1988 RSA (Figure 2). For the NAO climate indices, the unlagged positive NAO_WIN climate indices in the early 1990s correlate with the positive RSAs during that period; the positive 1983 NAO_FAL index correlates with the strong 1983 year class and positive 1983 RSA (Figure 3). The lagged NAO indices likewise have a positive correspondence with positive RSAs in the early 1990s (Figures 3-4), but do not appear to correlate strongly with any of the prominent recruitment success features (i.e., 1983, 1998, or 2005 year classes or RSAs).

Several of the regional, seasonal temperature anomalies exhibit significant statistical correlation over the time series. The strongest positive correlations were between annual values of the Mid-Atlantic North region winter-spring surface (MAN_ST1) and bottom (MAN_BT1) anomalies ($r = 0.50$) and the MAN_BT1 and MAS_BT2 ($r = 0.57$) anomalies, both significant at the $p = 0.01$ level. None of the correlations between NAO indices were significant at the $p = 0.10$ level. The strongest relationships between temperature anomalies and NAO indices were negative correlations between the MAN_BT1 anomaly and NAO_WIN index ($r = -0.42$; $p = 0.03$) and the MAS_ST1 anomaly and the NAO_FAL index ($r = -0.41$; $p = 0.04$).

The strongest statistical correlations between the metrics of recruitment success and environmental factors (Table 2) were between the RSA and the NAO_WIN index ($r = 0.59$; $p < 0.01$), the RSA and the MAN_BT1 anomaly ($r = -0.43$; $p = 0.04$), the VPA0 and the MAS_BT2 anomaly ($r = 0.38$; $p = 0.08$), the VPA0 and the NAO_FAL_1 index ($r = 0.35$; $p = 0.09$), and the VPA0 and the NAO_FAL index ($r = 0.34$; $p = 0.09$). Correlations of this magnitude are of about

the same statistical significance as the highest correlations between the F07_ALL absolute recruitment estimates (VPA0) and research survey VPA calibration indices (e.g., MDDNR r = 0.53, $p < 0.01$; CTDEP r = 0.45, p = 0.03; RIDFW r = 0.35, p = 0.09; VIMS r = 0.34, p = 0.09; NEFSC r = 0.33, p = 0.10; SDWG 2007).

Based on the combined results of the correlation analyses, the initial GAMs related either absolute recruitment (VPA0) or recruitment survival rate (RSA) to the MAN_BT1 and MAS_BT2 temperature anomalies and the NAO_FAL, NAO_FAL_1, and NAO_WIN climate indices. The final GAM relating RSA to the predictive factors included only the NAO_WIN index (i.e., $p <= 0.20$). The estimated effect of the NAO_WIN index (predictive factor; x-axis) on summer flounder recruit-spawner anomaly (RSA; y-axis) is presented in Table 3 and Figure 4 (GAM 1). Comparison of the observed NAO_WIN index and estimated RSA indicates a positive and fairly strong predicative relationship, in line with the results of the correlation analysis (Figure 4, bottom panel).

The final GAM relating VPA0 to the predictive environmental factors included the MAS_BT2 temperature anomaly and the NAO_WIN and NAO_FAL_1 climate indices (i.e., $p <= 0.20$). Note that the NAO_WIN index emerged as a significant predictive factor for VPA0 in the GAM model, even though the correlation of this factor with VPA0 was not initially identified as significant (r = 0.08, p = 0.72). Also, the NAO_FAL index failed to be retained in the GAM (i.e., $p > 0.20$), even though NAO_FAL was significantly correlated with VPA0 (r = 0.34, p = 0.09). The estimated combined effects of these predictive factors (x-axis) on the absolute magnitude of summer flounder recruitment (VPA0; y-axis) are presented in Table 3 and in the first panel of Figure 5 (GAM2). The combined predictive fit characterizes the strong 1983 year class and the weak 1988 and 2005 year classes relatively well. However, the subsequent panels of Figure 5 demonstrate that the relationship between VPA0 and the individual environmental factors is relatively weak as evidenced by the wide confidence intervals of the predicted VPA0.

The time series of the predictive factors from the GAM2 model (NAO_WIN, NAO_FAL_1 and MAS_BT2) were included as indices of age 0 recruitment (VPA0) in three derivative configurations of the summer flounder ADAPT VPA F07_ALL run to investigate their performance as potential calibration indices (i.e., as proxy indices of recruitment). Summary diagnostics for runs F07_ALL (all available survey indices included), F07_ALL_GAM2 (same as F07_ALL, but including environmental factors MAS_BT2, NAO_WIN, and NAO_FAL_1 as recruitment calibration indices), F07_GAM2_ONLY (including only the environmental factors MAS_BT2, NAO_WIN, and NAO_FAL_1 as recruitment calibration indices), and F07_MD0_MAS_BT2 (including only the MD DNR age 0 survey index [the best correlated trawl survey index with estimates from run F07_ALL] and the environmental factor MAS_BT2 [the best correlated environmental factor with estimates from run F07_ALL] as recruitment calibration indices) are presented in Table 4.

The inclusion of the environmental factors as recruitment calibration indices degraded the overall fit of the VPA, as diagnosed by increases in the magnitude of the MSR for the alternative runs (MSR = Mean Squared Residual = total sum of squared residuals divided by degrees of freedom). Estimates of the strong 1983 and weak 1988 year classes, estimated in the converged (stabilized) part of the VPA, were unchanged by the inclusion of the environmental factors. Estimates of the weak 2005 year class increased by up to 30% in the alternative runs; estimates of the average 2006 year class increased by up to 13% in the alternative runs.

In summary, the results of this work suggest there are relationships between commonly measured environmental factors such as regional water temperature anomalies and larger scale

climate indices and metrics of summer flounder recruitment success. However, these relationships are no stronger than those currently modeled using research survey indices of abundance. Inclusion of these environmental factors in alternative configurations of the current summer flounder assessment VPA does not significantly change the pattern of the recruitment time series or increase the precision of current recruitment estimates. The inclusion of the environmental factors in other summer flounder population dynamics models would not be expected to improve the reliability of forecasts or biological reference points.

Finally, it should be noted that a value of the NAO_WIN index for the 2006-2007 winter season (Dec. 2006-Mar 2007: NAO_WIN = 1.83) is available to use in the GAM1 model to predict the RSA for 2007 = 0.78; given the estimate of the SSB that will produce the 2007 year class (44.451 kmt), this predicted RSA equates to predicted recruitment in 2007 of 34.7 million fish – about 2% below the F07_ALL VPA time series average of 35.4 million fish. Since the fall NAO and temperature anomaly data are lagged forward, environmental factor data are also available to fit the GAM2 model to predict the 2007 VPA0 (NAO_FAL_1 = -0.43; MAS_BT2 = 1.205). The GAM2 model predicted 2007 value for VPA0 in 2007 is 50.4 million fish – about 42% above the F07_ALL VPA time series average of 35.4 million fish.

SAW 47 Working Paper 12 (TOR 6) – Wavelet Analysis

Wavelet Analysis of Trends in Summer Flounder YOY and Spawner-Recruit Relationships

by Eric Powell

Introduction

Two climatic signals are most significant in affecting oceanographic and estuarine processes in the Mid-Atlantic Bight, the North Atlantic Oscillation (NAO) and the Pacific North American (PNA). The NAO is closely related to the Arctic Oscillation (AO) and primarily affects temperature. The PNA has a well-described teleconnection with the El Niño-Southern Oscillation (ENSO) and is dominantly an effector of precipitation and, thus, freshwater inflow, in the northeast region. The NAO has a well-described 8-year cycle and indications of a 4-yr periodicity that are superimposed on longer-term trends. These periodicities are known to profoundly effect estuarine oyster populations, including recruitment and mortality.

Methods

Meteorological Data Sets

Monthly values for the NAO and PNA indices were obtained from the National Weather Service Climate Prediction Center [1]. Both are obtained from a rotated principal component analysis using the monthly standardized 500-mb height anomalies obtained from the CDAS in the analysis region 20^o N-90^o N. Details are provided at the NOAA web site.

Analytical Approach

The time series technique of wavelet analysis was used. Application of this technique to oyster populations is described in Soniat et al. (2006), who reference a wide range of other applications of this technique. Wavelet analysis resolves localized variations in the strength of a signal (i.e., the wave) within a time series. With this approach, the original time series is decomposed into a time-frequency space, which allows the dominant components (i.e., the wavelets) that make up the wave to be identified. Soniat et al (2006) provide references to source the mathematical details of the technique. Earlier analyses by our group have evaluated the use of a number of mother wavelets (e.g., Paul, Morlet). The Morlet wavelets have good frequency resolution, but smear the dominant signals in the time domain. The Paul wavelets provide good time resolution, but smear the signals in the frequency domain. Comparison of the two show that, for applications of the type that follow, the Morlet wavelet provides adequate time resolution and superior frequency resolution over the results obtained from the Paul wavelet. As a consequence, the Morlet wavelet is used here.

[1] www.cpc.ncep.noaa.gov/products/precip/CWlink

Fisheries data

The fisheries data used are the spawning stock biomass (SSB) and recruitment estimates (VPA0) for summer flounder obtained as described by Terceiro[2].

Results

Four wavelet analyses are reported as representative of a number of different analyses. Each is a cross-wavelet analysis, equivalent to a cross-correlational analysis, comparing either the NAO or PNA to either the VPA0 or VPA0/SSB (labeled `SR' on the plots that follow) index.

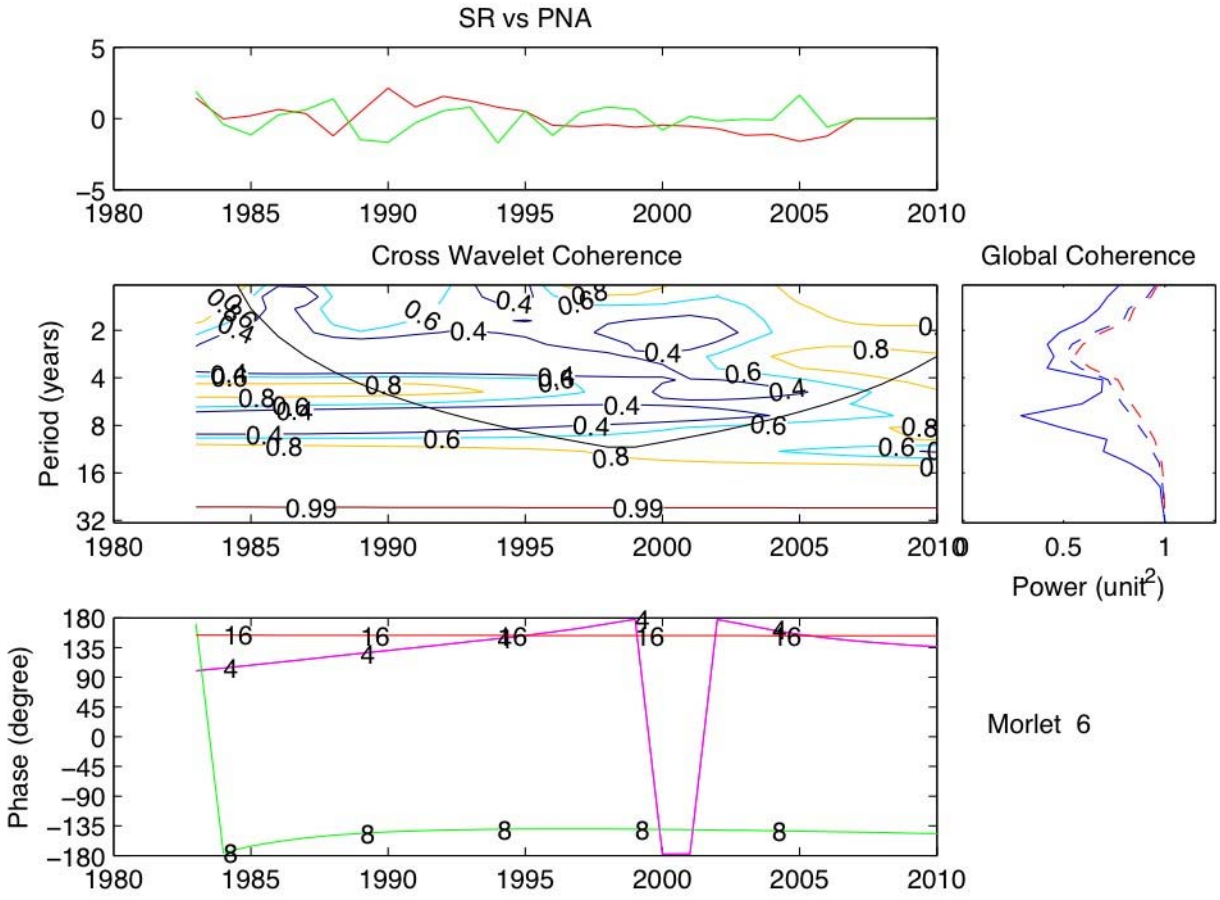

Figure 1. Cross-wavelet analysis between the VPA0/SSB (spawner-recruit) index and the PNA (Pacific North American) index.

Figure 1 shows the cross-wavelet analysis between the spawner-recruit index and the PNA. The top graph reports the data time series standardized to a mean of zero. The middle righthand graph labeled `global coherence' reports the significance of periodicities from <1 to >16 years. The dashed lines on this graph identify the significance at the $\alpha = 0.10$ (left dashed line) and $\alpha = 0.05$ (right dashed line) levels. The time series is 24 years long. A rule-of-thumb is

[2] Working Paper: Modeling environmental factors and summer flounder recruitment success.

that no periodicity can be safely identified with a period that exceeds half the time series length, so that results exceeding 12 years should be ignored. In the case of the PNA and the spawner-recruit relationship, no significant periodic interaction is found. Other analyses, not figured here, also failed to find any relationship with the PNA and recruitment (VPA0).

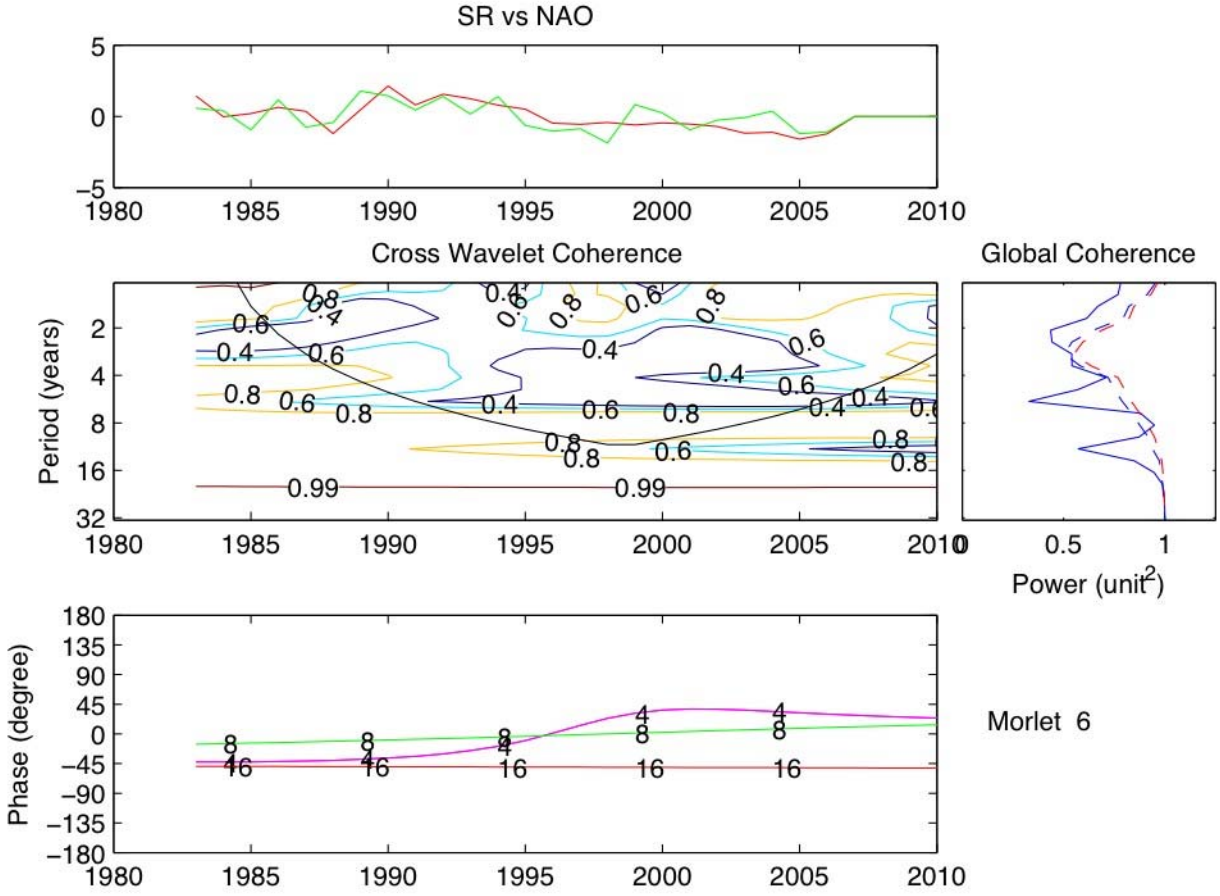

Figure 2. Cross-wavelet analysis between the VPA0/SSB (spawner-recruit) index and the NAO (North American Oscillation) Index.

Figure 2 shows results of the cross-wavelet analysis for the spawner-recruit index and the NAO. The analysis shows two significant coherences, at 4 years and 8 years (middle, right plot labeled `global coherence'). These same two periodicities are significant in other species we have examined such as oysters. The lower plot shows the phase relationships, with the first variable leading the second. Thus, the 8-year periodicity has a phase of near 0. Highs in NAO and the spawner-recruit index more or less coincide. The 4-yr periodicity shows a strong shift in phase between 1995 and 2000. Prior to 1995, the phase was -45^{o}. That is, NAO led the spawner-recruit relationship by

$4 \times (45^{o} / 360^{o}) = 0.5$ yr. After 2000, the two periods were nearly synchronous.

Figure 3 shows the results of cross-wavelet analysis between the VPA0 index and NAO. The 8-year signal is significant and the 4-yr signal barely so. The phase shift in the 4-year signal is dramatic.

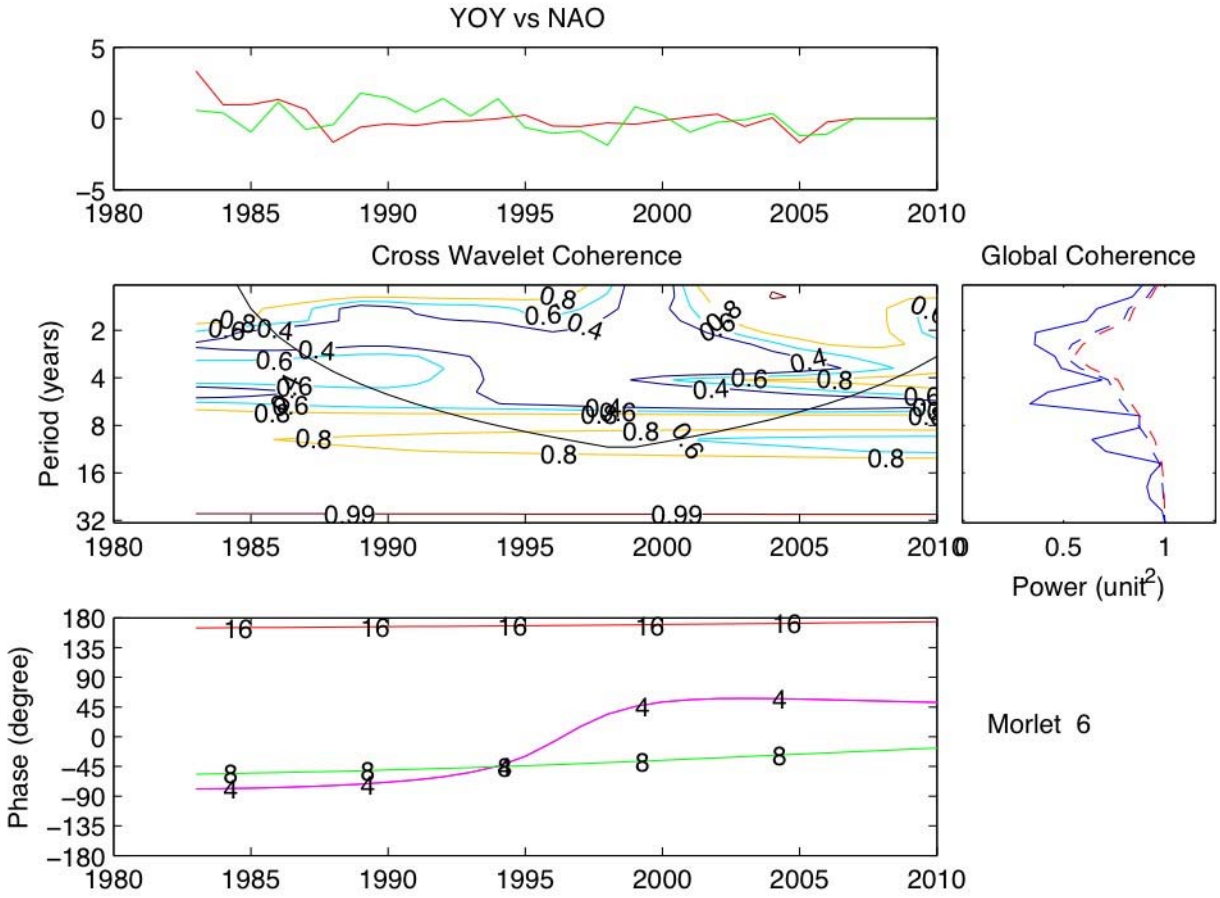

Figure 3. Cross-wavelet analysis between the VPA0 index and the NAO (North American Oscillation) Index.

The spawner-recruit index has a long-term downward trend that might affect the wavelet analysis. A final analysis was conducted with this trend in the spawner-recruit relationship removed prior to analysis. Figure 4 shows that the 8-year periodicity remains strongly significant. The 4-year periodicity is no longer significant, although the phase shift remains apparent.

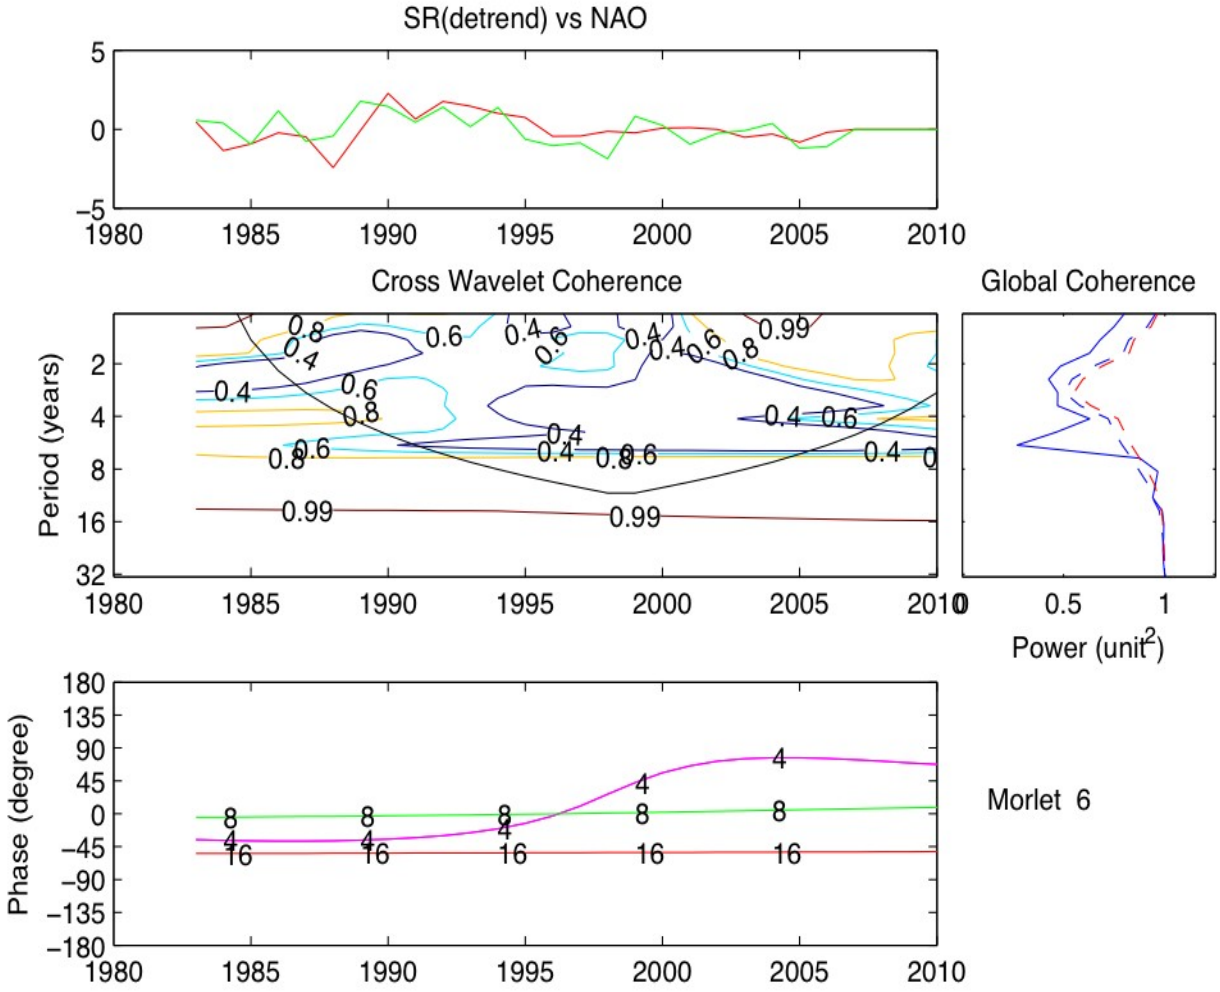

Figure 4. Cross-wavelet analysis between the VPA0/SSB index and the NAO (North American Oscillation) Index, with the spawner-recruit relationship de-trended prior to analysis.

Conclusions

No evidence exists for a relationship between the PNA and summer flounder recruitment. On the other hand, a relationship between the NAO and summer flounder recruitment is strongly supported. The 8-year periodicity, the dominant periodicity in the NAO, is identified as significantly correlated with an 8-year periodicity in the recruitment indices in all analyses. The significance level consistently exceeds $\alpha = 0.05$. No substantive phase shift occurs. The two periodicities are in near-synchrony so that high NAO and high recruitment indices occur more or less simultaneously.

In most analyses, a 4-year periodicity also occurs, although sometimes at a weaker level of significance. This interaction is consistently associated with a phase shift between 1995 and 2000. Such phase shifts are frequently associated with substantive long-term changes in population dynamics. However, this periodicity was no longer significant after the long-term trend in the spawner-recruit data was eliminated. This suggests that the interaction of the two time series was primarily associated with subsets of the time series record. A detailed

examination of the coherence over the time series suggests that the 4-year periodicity was stronger pre-1995 and post-2000 and that the phase shift was coincident with a decline in the significance of this periodicity during the intervening years.

The NAO is consistently associated with temperature shifts in the North Atlantic. The present analysis suggest that some portion of the variability in summer flounder recruitment since 1982 can be explained by this climate forcer and its expression in changes in the temperature regime experienced by the fish.

I have not included a long list of references. Those interested in further information on wavelet analysis are directed towards the references contained in Soniat et al. (2006) [Soniat, T.M., J.M. Klinck, E.N. Powell and E.E. Hofmann. 2006. Understanding the success and failure of oyster populations: Climatic cycles and *Perkinsus marinus. J. Shellfish Res.* 25:83-93]. A recent review of the NAO/AO that provides access to this literature is Cohen and Barlow (2005) [Cohen, J. and M. Barlow. 2005. The NAO, the AO, and global warming: how closely related? *J. Climate* 18:2298-4513].

GARM 2008 Reference Points Meeting
Woods Hole, MA
28 April – 2 May

Summary

There is currently no generally agreed methodological approach to adjusting projections to account for retrospective patterns in the stock assessment. This paper presents three alternative approaches and compares the resulting time series of spawning stock biomass, landings, and fishing mortality rate based on a summer flounder-like stock assessment. The three adjustments for retrospective patterns all reduce landings in the quota setting year, but the magnitude of the reduction is quite variable and the implications for future years in the projections are quite different. Adjusting the fishing mortality rate in the quota setting year is not recommended in the context of rebuilding programs because the future catches are greater than the unadjusted projections. Adjusting all ages in the starting population creates the largest decrease in projected catch, but typically cannot be justified based on the patterns observed at age. Making adjustments to the starting population based on the age specific retrospective patterns produces the most consistent approach, although the overall impact is relatively minor. A number of technical questions remain regarding exactly how to compute the retrospective adjustments at age. Management strategy evaluation work is required in the future to determine if any adjustment method performs better than the others.

Introduction

Term of Reference 1 for the GARM 2008 Biological Reference Points meeting is for relevant stocks, determine the influence of retrospective patterns in parameter estimates (e.g., fishing mortality, biomass, and/or recruitment) from assessment models on the computation of BRPs and on specification of initial conditions for forecasting.

This paper addresses only the latter aspect of this TOR, methods for adjusting initial conditions for forecasting when the stock assessment exhibits a retrospective pattern.

There is currently no generally agreed methodological approach to adjusting projections to account for retrospective patterns in the stock assessment. Two types of approaches that have been tried are: 1) adjust the TAC by the amount of retrospective seen in the SSB and 2) adjust the initial population to account for the retrospective pattern. The first approach can also be constructed by adjusting the fishing mortality rate in the quota year to account for the retrospective pattern observed in F. These two approaches will produce similar changes in the quota for next year, but have widely different implications for rebuilding strategies. This is because the first approach does not adjust the population, so the reduction in quota will actually allow the population to grow more and allow more fishing during the rest of the rebuilding period. In contrast, the second approach has a compounding effect, forcing a reduction in F during the rebuilding because the initial population abundance is further away from the target than the unadjusted population. The second approach is consistent in how the retrospective adjustment impacts the projections and is favored over the first approach.

There remain a number of technical issues for how to make the adjustment to the initial population abundance. All ages in the initial population could be scaled according to some average retrospective change, or else age-specific retrospective adjustments could be applied. The calculation of the average retrospective change can also be done numerous ways, as an average of the one-year update from the last five years or as the average change from the original to the most recent assessment result from the last five years, for example. Even more complex derivations can be made to fill in how much change is expected to occur based on regression of previous changes. There was insufficient time to address these issues through management strategy evaluations (MSE), the tool needed. Instead, a number of examples are provided to demonstrate the magnitude of effect that can occur when retrospective adjustments are made.

Methods

A stock assessment similar to the summer flounder 2007 assessment was used as the basis for all comparisons. This assessment demonstrated a strong retrospective pattern with F adjusted higher and SSB adjusted lower with additional years of data (Figure 1). The SSB target for rebuilding was determined to be 89,411 metric tons. A catch of 7,762 metric tons was assumed to be caught in 2007, the quota for that year. An iterative search found the constant F needed to rebuild the stock to the SSB target in year 2012 with 50% probability when no adjustments were made to the initial population to account for the retrospective pattern (Frebuild).

Retrospective adjustments were made in three different ways:

1. The F in 2008 was adjusted from Frebuild
2. The initial population abundance at age in 2007 was reduced over all ages at the same rate

3. The initial population abundance at age in 2007 was reduced by age-specific rates

The F adjustment was made based on the average of the last 5 years single year update retrospective, meaning a 28% reduction in F2008. When the initial population abundance at age in 2007 was reduced over all ages at the same rate, the same reduction as case 1 was applied, meaning the numbers at age at the start of 2007 were all reduced by 28%. This was selected as a compromise between the lower one year adjustments to SSB and the higher full year adjustments to SSB, and to allow more direct comparison between cases 1 and 2. The third case adjusted all ages based on the age specific one year adjustments averaged over the last five years, which resulted in both increases and decreases to the initial population abundance in 2007 (Table 1).

Results

Time series of spawning stock biomass (thousand metric tons), landings (thousand metric tons), and fully selected fishing mortality rate are presented in both Table 2 and Figure 2. The landings in 2007 are assumed constant for all four runs. The median spawning stock biomass in 2012 was the target and the fishing mortality rates were solved to an extreme number of digits to ensure complete consistency with the SSBmsy target in 2012. The Base and adj F cases have the same starting population and thus the same F in 2007, while the two adj N cases have lower starting populations which require higher F in 2007 to achieve the landings. The three retrospective adjustment approaches all reduce landings in 2008 relative to the Base case. However, the adj F case then allows landings to increase above the Base case for the remaining years because the stock has been fished lighter in 2008. This increase in landings for years 2009-2012, causing the adj F case to have the highest total landings over all years. The two adj N cases both have lower catches for years 2008-2012 relative to the Base case due to starting at a lower initial stock abundance. However, the adj N by age case has nearly the same level of landings in years 2009-2012 as the Base case (less than 5% difference). This similarity is due to the large changes in retrospective adjustment occurring for the oldest ages, which wash out of the projections relatively quickly. In contrast, the adj N all ages case reduces all cohorts significantly, requiring a greater number of years to remove their impact in the projections.

Discussion

In most of the groundfish assessments examined to date, the retrospective patterns are most pronounced for the oldest ages and least pronounced for the youngest ages. This means that adjusting all ages with the same factor is not warranted. Making the age-specific adjustments will cause the short-term catch to decrease, but the effect will not last long in most cases.

There are many other ways that the retrospective adjustments could be formed. For example, the full adjustment relating the shorter time series to the full time series could be used. Other approaches could be used to estimate the corrections for incomplete cohorts and then create the average retrospective adjustment on similar time periods. However, none of the approaches have been tested using management strategy evaluations.

One question that inevitably arises when dealing with retrospective patterns is “What happens if the retrospective pattern goes away or changes direction?” In these cases, adjusting for the retrospective pattern will be worse than not adjusting. However, while changes in direction of retrospective patterns have been observed in some stocks, they are the exception.

Table 1. Average of the most recent 5 years of single year adjustments in retrospective pattern observed by age.

Age	Retro Change
0	4.8%
1	4.8%
2	4.2%
3	-0.4%
4	-6.0%
5	3.2%
6	-65.5%
7	-26.8%

Table 2. Comparison of median spawning stock biomass, landings, and fishing mortality rate time series for the unadjusted (Base) and three alternative approaches to adjusting for retrospective patterns: F, N all ages, and N by age.

Spawning Stock Biomass (thousand metric tons)

Year	Base	adj F	adj N all ages	adj N by age
2007	51.719	51.719	35.068	47.005
2008	61.535	63.644	44.193	58.433
2009	70.123	72.113	56.044	68.188
2010	78.314	79.666	68.438	77.169
2011	83.796	84.457	78.846	83.219
2012	89.411	89.411	89.411	89.411

Landings (thousand metric tons)

Year	Base	adj F	adj N all ages	adj N by age
2007	7.762	7.762	7.762	7.762
2008	7.936	5.851	3.831	7.108
2009	9.583	10.312	4.976	9.048
2010	10.882	11.643	6.303	10.644
2011	12.366	12.957	7.849	12.145

Procedures for Issuing Manuscripts in the *Northeast Fisheries Science Center Reference Document* (CRD) Series

Clearance

All manuscripts submitted for issuance as CRDs must have cleared the NEFSC's manuscript/abstract/webpage review process. If any author is not a federal employee, he/she will be required to sign an "NEFSC Release-of-Copyright Form." If your manuscript includes material from another work which has been copyrighted, then you will need to work with the NEFSC's Editorial Office to arrange for permission to use that material by securing release signatures on the "NEFSC Use-of-Copyrighted-Work Permission Form."

For more information, NEFSC authors should see the NEFSC's online publication policy manual, "Manuscript/abstract/webpage preparation, review, and dissemination: NEFSC author's guide to policy, process, and procedure," located in the Publications/Manuscript Review section of the NEFSC intranet page.

Organization

Manuscripts must have an abstract and table of contents, and (if applicable) lists of figures and tables. As much as possible, use traditional scientific manuscript organization for sections: "Introduction," "Study Area" and/or "Experimental Apparatus," "Methods," "Results," "Discussion," "Conclusions," "Acknowledgments," and "Literature/References Cited."

Style

The CRD series is obligated to conform with the style contained in the current edition of the United States Government Printing Office Style Manual. That style manual is silent on many aspects of scientific manuscripts. The CRD series relies more on the CSE Style Manual. Manuscripts should be prepared to conform with these style manuals.

The CRD series uses the American Fisheries Society's guides to names of fishes, mollusks, and decapod crustaceans, the Society for Marine Mammalogy's guide to names of marine mammals, the Biosciences Information Service's guide to serial title abbreviations, and the ISO's (International Standardization Organization) guide to statistical terms.

For in-text citation, use the name-date system. A special effort should be made to ensure that all necessary bibliographic information is included in the list of cited works. Personal communications must include date, full name, and full mailing address of the contact.

Preparation

Once your document has cleared the review process, the Editorial Office will contact you with publication needs – for example, revised text (if necessary) and separate digital figures and tables if they are embedded in the document. Materials may be submitted to the Editorial Office as files on zip disks or CDs, email attachments, or intranet downloads. Text files should be in Microsoft Word, tables may be in Word or Excel, and graphics files may be in a variety of formats (JPG, GIF, Excel, PowerPoint, etc.).

Production and Distribution

The Editorial Office will perform a copy-edit of the document and may request further revisions. The Editorial Office will develop the inside and outside front covers, the inside and outside back covers, and the title and bibliographic control pages of the document.

Once both the PDF (print) and Web versions of the CRD are ready, the Editorial Office will contact you to review both versions and submit corrections or changes before the document is posted online.

A number of organizations and individuals in the Northeast Region will be notified by e-mail of the availability of the document online.

MEDIA MAIL

Publications and Reports of the Northeast Fisheries Science Center

The mission of NOAA's National Marine Fisheries Service (NMFS) is "stewardship of living marine resources for the benefit of the nation through their science-based conservation and management and promotion of the health of their environment." As the research arm of the NMFS's Northeast Region, the Northeast Fisheries Science Center (NEFSC) supports the NMFS mission by "conducting ecosystem-based research and assessments of living marine resources, with a focus on the Northeast Shelf, to promote the recovery and long-term sustainability of these resources and to generate social and economic opportunities and benefits from their use." Results of NEFSC research are largely reported in primary scientific media (*e.g.*, anonymously-peer-reviewed scientific journals). However, to assist itself in providing data, information, and advice to its constituents, the NEFSC occasionally releases its results in its own media. Currently, there are three such media:

NOAA Technical Memorandum NMFS-NE -- This series is issued irregularly. The series typically includes: data reports of long-term field or lab studies of important species or habitats; synthesis reports for important species or habitats; annual reports of overall assessment or monitoring programs; manuals describing program-wide surveying or experimental techniques; literature surveys of important species or habitat topics; proceedings and collected papers of scientific meetings; and indexed and/or annotated bibliographies. All issues receive internal scientific review and most issues receive technical and copy editing.

Northeast Fisheries Science Center Reference Document -- This series is issued irregularly. The series typically includes: data reports on field and lab studies; progress reports on experiments, monitoring, and assessments; background papers for, collected abstracts of, and/or summary reports of scientific meetings; and simple bibliographies. Issues receive internal scientific review and most issues receive copy editing.

Resource Survey Report (formerly *Fishermen's Report*) -- This information report is a regularly-issued, quick-turnaround report on the distribution and relative abundance of selected living marine resources as derived from each of the NEFSC's periodic research vessel surveys of the Northeast's continental shelf. This report undergoes internal review, but receives no technical or copy editing.

TO OBTAIN A COPY of a *NOAA Technical Memorandum NMFS-NE* or a *Northeast Fisheries Science Center Reference Document*, either contact the NEFSC Editorial Office (166 Water St., Woods Hole, MA 02543-1026; 508-495-2350) or consult the NEFSC webpage on "Reports and Publications" (http://www.nefsc.noaa.gov/nefsc/publications/). To access *Resource Survey Report*, consult the Ecosystem Surveys Branch webpage (http://www.nefsc.noaa.gov/femad/ecosurvey/mainpage/).

ANY USE OF TRADE OR BRAND NAMES IN ANY NEFSC PUBLICATION OR REPORT DOES NOT IMPLY ENDORSEMENT.
