10.8 Annual Total Nationwide Costs and Fuel Savings .....	6

## CHAPTER 10: Gas Can Costs

This chapter presents a detailed analysis of the projected average gas can costs related to meeting new emissions standards, which would require the use of “best available controls.” These costs have been developed based on industry information, discussions with manufacturers (including confidential business information concerning technology costs), and engineering judgment. These costs include variable costs for improved materials used in manufacturing gas cans (including improved spouts), and fixed costs for research and development, tooling, and certification. Finally, this chapter presents estimated fuel savings and aggregate nationwide costs for gas cans.

### 10.1 Methodology

The following technology characterization and cost figures reflect our current best judgment based on engineering analysis, information from manufacturers, and the published literature. The analysis includes manufacturer markups to the retail level.

Costs of control typically include variable costs (for incremental hardware costs, assembly costs, and associated markups) and fixed costs (for tooling, R&D, and certification). Variable costs are marked up at a rate of 29 percent to account for gas can manufacturers' overhead and profit.<sup>1</sup> To account for additional warranty costs associated with a change in technology, we have added 5 percent of the incremental variable cost. We estimated a range of costs for different size gas cans and also an average per container cost based on the approximate sales weighting of the three gas can sizes.<sup>A</sup> All costs are in 2003 dollars.

We are not projecting any additional R&D costs associated with the new EPA gas can standards. Manufacturers have developed and are continuing to develop control technologies in response to the California (and other state) programs. EPA's program would be very similar to the California program and we believe the most likely approach for manufacturers will be to use the technologies developed for state programs nationwide. Manufacturers would incur the R&D costs even in the absence of EPA emissions standards. Further, the permeation barriers available are very well understood within the industry. Therefore, we believe manufacturers will use these same technologies for their nationwide product lines and would not incur significant new R&D costs due to an EPA program.

We estimate that tooling and certification costs would be incurred one year prior to production, on average. These fixed costs were increased by seven percent to reflect the time value of money over the one year period. The fixed costs then were recovered over the first five years of production at a rate of seven percent.

### 10.2 Costs for Permeation Control

#### *Multi-layered designs*

---

<sup>A</sup> Gas can sales for 1, 2, and 5 gallon containers are weighted at 33%, 33%, and 34% of total sales, respectively.

Manufacturers have indicated that most are likely to switch to multi-layer designs to meet permeation requirements. For this analysis, we considered a gas can design with a material composition of 3% EVOH at \$3.50/lb, 4% adhesive layer at \$1/lb and the remainder HDPE.<sup>2</sup> This resulted in materials costs ranging from \$0.29 to \$0.58 for 1 to 5 gallon containers, with an average materials cost of \$0.41.<sup>B</sup>

In some cases, blow molding machines can be retrofitted for multi-layer operation. The total cost of such a retrofit, including supporting equipment, would be about \$1,000,000 per machine. In other cases, a new blow-molding machine would be required. A machine that could blow-mold multi-layer tanks would approximately double the price of the blow-molding machine. For this analysis, we use a machine cost increase of \$2,000,000, including all molds and related set-up. For our analysis, we've projected that half the machines would be retrofit and half would be new, for an average cost of about 1,500,000 per machine. Our analysis uses an average total annual production of 350,000 blow-molded tanks per machine and an amortization of the capital costs over 5 years. This results in an average fixed cost per container of \$1.12. Adding the fixed costs to the variable costs described above gives an average per container cost for multi-layered cans of about \$1.53.

#### *Non-continuous Barrier Platelets*

Manufacturers may reduce permeation from blow-molded gas cans by blending in a low permeation material such as ethylene vinyl alcohol (EVOH) with the HDPE. This is typically known by its trade name, Sellar. The EVOH in the plastic forms non-continuous barrier platelets in the gas can during blow-molding that make it harder for fuel to permeate through the walls of the tank. Using this approach, no changes should be necessary in the blow-molding equipment, so the costs are based on increased material costs. We used 10 percent EVOH, which costs about \$3-4 per pound, and 90 percent HDPE, which costs about \$0.65-0.75 per pound. This equates to a price increase of about \$0.35 per pound. The increased cost for gas cans would range from \$0.69 to \$1.38, with an average cost increase of \$1.00 per container.

#### *Fluorination*

We have also estimated costs for fluorination since some gas can manufacturers have used this approach to meet current California standards. Our surface treatment cost estimates are based on price quotes from a company that specializes in this fluorination.<sup>3</sup> We estimate that gas can costs would range from \$0.86 to \$3.30, with an average cost of \$1.84. These prices do not include the cost of transporting the gas cans; we estimated that shipping, handling and overhead costs would be an additional \$0.30 per gas can.<sup>4</sup>

### **10.3 Spout Costs**

Manufacturers would need to move from a simple pouring spout to an automatic closing spout in order to meet evaporative emissions standards. The automatic closing spouts would include a spring closing mechanism. For this analysis, we estimated an average variable cost

---

<sup>B</sup> This analysis was done using container weights of 1.5, 2.0, and 3.0 pounds for 1, 2, and 5 gallon containers, respectively.

increase for spouts of about \$0.85 including assembly costs, based on discussions with gas can manufacturers. We have also estimated \$200,000 for tooling per 1 million spouts. This results in a fixed cost for tooling of about \$0.05 per spout, for a total spout cost of \$0.90. The spout costs would not likely vary by gas can size.

## **10.4 Certification Costs**

Manufacturers will need to integrate the emission control technology into their designs and there will be some engineering and clerical effort needed to submit the required information for certification. We expect that in the early years, gas can manufacturers will perform durability and permeation testing for certification. They will be able to carry over this data in future years and to gas cans that are made of similar materials and have the same permeation control strategy regardless of gas can size.

Manufacturers would need to run certification testing for their gas cans and then submit the data and supporting information to EPA for certification. Based on the current approach used by manufacturers, we've estimated that each manufacturer would contract out testing at a cost of about \$7,500 per manufacturer. We've included an additional cost of \$5,000 for staff time for the certification process, for a total certification cost of \$12,500 per manufacturer.

To calculate a per gas can certification cost, we calculated a total industry cost for certification of \$62,500 and spread this cost over industry-wide sales of 22,000,000 units. As with other fixed costs, we amortized the cost over 5 years of sales to calculate per unit certification costs. Due to the large sales volumes, the analysis results in an average per can cost for certification of less than one cent.

## **10.5 Per Container Total Costs**

We based our cost analysis on costs associated with multi-layer gas cans. We believe most manufacturers will continue down the path of using this technology since it is robust, has well understood emissions performance, and appears to have the lowest cost once the capital costs are recovered. Other options for permeation barriers have similar overall costs, especially in the near-term. If manufacturers select a different permeation barrier approach such as non-continuous barrier platelets or fluorination, tooling costs would be lower, but would be offset by higher variable costs. Our estimated per container costs are shown in Table 10.5-1. The weighted average costs would be \$2.69. These costs are similar to cost data shared with us by manufacturers on a confidential basis.

**Table 10.5-1. Costs per Gas Can**

	1 gallon	2 gallon	5 gallon
Variable costs			
- Permeation Barrier	\$0.22	\$0.28	\$0.44
- Spout	\$0.85	\$0.85	\$0.85
Total Variable Costs	\$1.07	\$1.13	\$1.29
Total Variable costs w/ OEM Mark-up and warranty	\$1.40	\$1.48	\$1.69
Tooling	\$1.17	\$1.17	\$1.17
Certification	Less than \$0.01	Less than \$0.01	Less than \$0.01
Total	\$2.57	\$2.65	\$2.86

Costs are well understood due to the experience manufacturers have had previously with permeation emissions control technologies and with the California gas can program. We are estimating costs based on the likely technology path manufacturers will take to meet the standards. Costs could be somewhat higher or lower if manufacturers use a different mix of control technologies or use multiple technologies across their product lines. Other sources of potential uncertainty include whether costs might be lower on a nationwide basis due to economies of scale or due to additional learning by the manufacturers.

## 10.6 Costs for Gas Cans Complying with State Programs

The above costs are for currently uncontrolled gas cans. Some states have adopted gas can programs, based on the original California program which took effect in 2001.<sup>C</sup> The original California program contained permeation requirements that would be significantly less stringent than the standards considered in this cost analysis (about a 50 percent emission reduction compared to an 80 to 90 percent emission reduction). Because the standards considered in this cost analysis are more stringent than those currently in place in states with programs, we have estimated costs associated with the difference. For purposes of the cost analysis, we have estimated that the costs associated with meeting the state programs would be half those for the permeation requirements considered here, resulting in a cost difference of \$0.77 per container.

Although there technically is a difference in stringency between current state programs and the potential EPA requirements and we are including costs associated with the difference, it is unlikely that these costs would be realized. California has adopted revised program requirements that are essentially equivalent to those being considered by EPA. Manufacturers are in the process of incorporating more robust permeation controls in response to the new California program. Manufacturers would want to avoid carrying two different products and would likely use the more robust permeation controls in all states with programs. Also, in the absence of an EPA program, states would likely adopt the new California requirements eventually.

## 10.7 Fuel Savings

The emissions reductions due to reduced evaporative losses and reduced spills from gas cans translate into gasoline savings. As described in Chapter 2, we have estimated the annual HC reductions due to new standards. By dividing the tons reduced by the number of gas cans in use we can estimate the annual tons reduction per gas can. In 2015, after the program is fully implemented, we estimated that there would be 88,023,896 gas cans in use nationwide and that those cans would be responsible for about 182,933 tons of HC reduction. We can then translate the tons reduction per can per year (0.002 tons, or 4.1 pounds) to gallons using a fuel density of 6 lbs/gallon (for lighter hydrocarbons which evaporate first). We used an average life of 5 years for gas cans and used a discount rate of seven percent to estimate total average undiscounted and discounted fuel savings per gas can, provided below. We calculated the savings using \$1.52 per gallon of gasoline.<sup>5</sup> These savings would offset the cost of the gas can controls.

**Table 10.7-1. Average Fuel Savings Over Life of Gas Can**

HC reduced (pounds)	20.5
Fuel Savings (gallons)	3.4
Undiscounted Savings	\$5.17
Discounted Savings	\$4.24

## 10.8 Annual Total Nationwide Costs and Fuel Savings

The above analyses provide incremental per unit gas can cost estimates. Using these per unit costs and projections of future annual sales, we have estimated total aggregate annual costs. The aggregate costs are presented on a cash flow basis, with hardware and fixed costs incurred in the year the gas cans are sold and fuel savings occurring over the life of the gas can. To project annual sales into the future, we started with an estimated 22 million gas cans sold nationwide in 2002 and then grew sales by 2 percent per year.<sup>6</sup> The resulting sales estimates for select years are shown in Table 10.8-1 below. To estimate sales in states with and without existing gas can programs, we projected that 39 percent of overall sales would be in states with existing gas can programs. This estimate is based on current estimated gas can populations by state provided in Chapter 2 of the RIA.

**Table 10.8-1. Projected Annual Gas Can Sales**

	2009	2015	2020	2030
Projected sales	25,271,085	28,459,346	31,421,417	38,302,533

For total fuel savings, we used the nationwide HC reductions estimated in Chapter 2 of the RIA and the methodology described above to convert to gallons of fuel saved nationwide, and then to savings in dollars. We estimate that fuel savings ramp up as new gas cans replace old ones and would more than offset the aggregate costs in the long term, for an overall savings. Table 10.8-2 presents the results of this analysis. As shown in the table, aggregate costs start out at about \$50 million and then drop to \$28 million in 2014 when the fixed costs have been

recovered. Fuel savings start out at about \$14 million per year and reach \$91 million in 2014. After 2014, increases in costs and savings are due to gas can sales and population growth.

As noted above, fixed costs due to certification and tooling are expected to actually be incurred on average one year prior to the start of the program. We estimate that the total fixed costs in that year would be about \$90 million.

**Table 10.8-2. Annual Nationwide Gas Can Costs and Fuel Savings**

Calendar Year	Variable Costs	Fixed Costs	Total Costs	Fuel Savings	Net Cost
2008	0	0	0	0	0
2009	\$ 25,548,976	\$ 23,573,284	\$49,122,261	\$14,381,149	\$34,741,111
