#### NUMBER 38

PENSION COVERAGE AMONG PRIVATE WAGE AND SALARY WORKERS: PRELIMINARY FINDINGS FROM THE 1988 SURVEY OF EMPLOYEE BENEFITS

John R. Woods

Program Analysis Staff Office of Research and Statistics Social Security Administration

August 1989

#### **EXECUTIVE SUMMARY**

Pension coverage is declining in the United States, and most of the decline can be attributed to decreasing coverage among younger workers. In addition, it appears that the types of pension coverage are shifting, with a decline in traditional pension plans and an increase in 401(k) plans.

These are perhaps the most important findings from a 1988 survey of American workers, similar to pension surveys in 1972, 1979 and 1983. The 1988 survey collected data from a sample representing 114 million workers who were currently employed. This paper examines patterns of pension coverage among all private wage and salary workers, but focuses on those working full time.

Using the commonly accepted definition of pension coverage, the study identified "covered" workers as those who were actually participating in a pension plan. Forty-six percent of full time private sector employees were participating in employer-financed pension plans in 1988--33 percent covered only by a basic plan, 7 percent covered only by a 401(k) type plan, and 6 percent dually covered. Among men, the total coverage rate was 49 percent, compared to 43 percent among women. Particularly low rates of pension coverage were found among several groups, including workers with less than five years on the job and those employed in small firms.

More important, however, were the changes over time. First, after an increase in pension coverage between 1972 and 1979, the coverage rates of full time workers decreased from 50 to 48 percent by 1983, and decreased again--to 46 percent--by 1988. Second, the losses in pension coverage have been concentrated among younger workers, and primarily among younger men. And third, limited evidence suggests a significant decline in coverage under defined benefit plans between 1983 and 1988, a decline that has been partly offset by increased coverage under 401(k) type plans.

The trend toward lower rates of pension coverage--and, particularly, the lower rates of coverage among younger men--has important implications for the future of private pension benefits in the United States. There are important implications, too, of the apparent shift in types of pension coverage. These are briefly discussed in the concluding section of the paper, along with recommendations for further research.

	,		

#### INTRODUCTION

Private pension benefits have long been recognized as an important component of retirement income in the United States. Because of this, the Social Security Administration (SSA) has actively promoted research on various aspects of employersponsored pensions.

One line of research, particularly important over the past two decades, has focused on changing patterns of pension coverage and vesting among American workers. 1/ Basic national statistics on pension coverage among private sector wage and salary workers were established in a series of SSA studies beginning in the 1950's.2/ This effort was considerably enhanced by findings from a survey co-sponsored by SSA in 1972—the first nationally representative survey designed to gather data from private sector workers on their pension coverage and vesting.3/ The 1972 survey was administered as a supplement to the Current Population Survey (CPS),4/ and this design was repeated in a second CPS pension supplement which was conducted in 1979.5/

Findings from these studies revealed a pattern of long-term growth in pension coverage, from about one-fourth of private wage and salary workers in the early 1950's to almost one-half by the

late 1970's.6/ Additional data indicated growth in other aspects of the private pension system. Income surveys, for example, documented increasing rates of pension receipt among the aged. In 1962, only 17 percent of men and 5 percent of women aged 65 and over were receiving income from private pensions or annuities; by 1986, receipt rates had increased to 33 percent for men and 13 percent for women.7/ Statistics on expenditures of private pension plans also pointed to significant growth. Total payments distributed by these plans (including monthly benefits and lump sum payments to aged and nonaged recipients) increased from about 17 billion dollars in 1976 to 104 billion dollars in 1986.8/

Based on coverage statistics, however, projections of future growth in the private pension system began to be called into question. During the 1970's, increases in the rate of pension coverage had leveled off, and studies from the mid-1980's suggested an actual downturn. One of the data sources revealing the decline in pension coverage was a third CPS pension survey, fielded in May 1983.9/

In order to update our knowledge about aspects of the pension system, including any further changes in pension coverage, a fourth CPS pension supplement was conducted in May 1988. This survey, similar to those in 1972, 1979, and 1983, was

designed and jointly sponsored by the Social Security

Administration, four other Federal agencies, 10/ and the Employee

Benefit Research Institute, a privately-funded research

organization. The 1988 interviews were conducted with persons in

one-half the CPS sample who were currently employed for pay.

Among those aged 16 and over, 27,496 interviews were completed,

representing an estimated 113.7 million workers. Of these, 76

percent were private wage and salary workers, 15 percent were

public sector employees, and 9 percent were self-employed.

With data from the 1988 survey having recently been made available for analysis, the purpose of this paper is to provide selected early findings on pension coverage among private wage and salary workers. In contrast to several studies in recent years which have used an expanded definition of pension coverage, 11/ this paper uses the more commonly accepted definition, counting workers as covered only if they are actually participating in a pension plan. In addition, much of the analysis—as in SSA's studies of the 1972 and 1979 data 12/--is restricted to a subset of private wage and salary workers, those working full time.13/

Specifically, the paper (a) describes 1988 coverage rates under two types of employer-sponsored pension plans, (b) examines some of the factors associated with differences in pension

coverage, and (c) compares the 1988 coverage rates to data from the 1983 survey and to rates reported in studies of the 1979 and 1972 data. Studies now underway will, in the future, provide a more in-depth analysis of pension coverage, examine other topics, including vesting and lump sum payments, and be extended to other groups of workers.

#### CONCEPTUAL BACKGROUND AND MEASUREMENTS

Descriptions of the pension system typically distinguish between two types of pension plans: defined benefit plans and defined contribution plans. In common parlance, the defined benefit plan is the traditional "pension" plan, and it has long been the predominant form. Under such a plan, the worker is promised a specified benefit amount to be paid upon retirement, usually calculated according to earnings and years of service. In contrast, benefit levels under a defined contribution plan are based solely on the value of the individual worker's account at retirement, which is a function of the amount contributed to the account (by the employer or the employee) and any earnings on the account's investments. Defined contribution plans include deferred profit sharing plans, thrift or savings plans, and stock bonus plans. Often, these serve to provide secondary coverage for those already covered under a defined benefit plan. 14/

In recent years much attention has centered on a particular subtype of defined contribution plan--the kind that allows employees to make tax-deferred contributions to their retirement accounts. 15/ Authorized by sections 401(k) and 403(b) of the Internal Revenue Code, these plans have been known by various

names, including "salary reduction plans," "401(k) plans," and "pre-tax plans." While many of these plans offer an annuity to participants upon retirement, distribution options also include lump sum payments made at retirement or upon termination of employment. The extent to which these payments are used to promote retirement income security is not yet clear, and remains an issue of policy concern. 16/

When questions were developed for the 1988 survey, one goal was to maintain comparability with the earlier CPS pension supplements. With some modification in wording, the content of the basic question on pension coverage has remained the same in the 1979, 1983 and 1988 surveys. Respondents are first asked if a pension or retirement plan is provided for any of the employees where they work, and, if the answer is affirmative, are then asked if they are included in the plan. Since the type of plan is left unspecified in this question, positive responses may be referring to either defined benefit or defined contribution plans. However, based on independent estimates of the number of participants in different types of plans, 17/ it can be reasonably assumed that the majority of covered respondents are referring to defined benefit plans.

In the 1983 survey, a new coverage question was added, attempting to identify workers with coverage under a pre-tax type

of defined contribution plan--either as their only pension plan or in addition to the plan identified earlier. In 1988, the thrust of this question remained unchanged, but its wording was modified to reflect the diverse terminology commonly being used to refer to these plans. When asking respondents about their participation in such a "retirement savings plan," the interviewer added that "these plans are called by different names, including 401(k) plans, pre-tax plans, and tax-sheltered annuities."

These two sources of employer-sponsored pension coverage will be distinguished from each other, below, by referring to the first as coverage under a "basic pension plan" and the second as coverage under a "pre-tax retirement savings plan." Other measurement issues from the 1988 survey will be described in the course of presenting results.

#### PENSION COVERAGE IN 1988

# Coverage of Private Sector Employees Under Two Types of Plans

Among all private wage and salary workers in May 1988, 34 percent reported coverage under a basic pension plan (table 1), and 14 percent reported coverage under a pre-tax retirement savings plan (table 2). Again, the distinction should be made clear: the 34 percent coverage rate applies to a mixture of defined benefit and defined contribution plans (with defined benefit plans probably a clear majority), while the 14 percent figure represents coverage under a particular type of defined contribution plan.

Historically, men have displayed much higher rates of pension coverage than women, and throughout this analysis coverage rates will be reported by gender. In terms of basic pension coverage in 1988, the differences remain substantial, with men in the private sector reporting a 38 percent coverage rate compared to women's 29 percent (table 1). Men also reported a somewhat higher coverage rate than women under pre-tax retirement savings plans--16 percent compared to 12 percent (table 2).

In addition to these basic findings, there are several analytical issues reflected in the first two tables that need to be clarified, since they have implications for the interpretation of subsequent findings or for the replication of these findings by other researchers.

First, the data on basic pension coverage (table 1) reflect not only the questionnaire items previously described, but an additional item included in the interview. When the 1988 questionnaire was designed, it was expected that some respondents--who were in fact covered only by a pre-tax savings plan--might respond affirmatively to the first question on pension coverage and later respond affirmatively to the question on pre-tax savings coverage. To disentangle these respondents from those who were actually reporting dual coverage, a follow-up question asked respondents who reported both types of pension coverage if their retirement savings plan was the same one that they had described earlier, or was an additional plan. percent affirmed that they had been, in fact, referring only to their retirement savings plan. As a result, these workers are not included in the 34 percent covered by a "basic pension plan" in table 1.

A second issue concerns the contributory role of the employer in pre-tax retirement savings plans. While employers were

presumably contributing to all "basic" pension plans (table 1), only about four-fifths of the workers in pre-tax plans reported employer contributions (table 2). The remaining one-fifth might be described as covered by plans that were "employer-sponsored" but not "employer-financed," a distinction that will be used below.

Finally, 5 percent of all workers responded "don't know" to the question on pension coverage (table 1), and 4 percent gave the same response to the question on coverage under a retirement savings plan (table 2). Previous pension research has suggested that such respondents are probably not covered, since they are quite similar to noncovered workers on a range of coverage-related characteristics. 18/ Thus, if the "don't know" responses create any undercount in the number of covered workers, the effect is probably very slight.

# Total Coverage

All private sector employees. -- The coverage rates from tables 1 and 2 cannot simply be summed to produce a total rate of pension coverage under the two types of plans, since 7 percent of the workers were found to be dually covered. The findings on dual coverage are reported in table 3, along with a breakdown of those reporting only one type of coverage. 19/ Among all private wage and salary workers, 27 percent had basic pension coverage

only, 7 percent had pre-tax savings plan coverage only, and, as noted above, 7 percent were covered under both types of plans.

As measured in this study, then, the best estimate of total coverage under employer-sponsored pension plans is 41 percent for all private sector employees--46 percent for the men and 35 percent for women.

Full time and part time employees. -- As expected, the coverage rates for full time workers were higher than for all private sector employees (table 3). Forty-eight percent were covered under an employer-sponsored plan--39 percent under a basic pension plan (including 8 percent dually covered) and 9 percent with only a pre-tax retirement savings plan. Among part time workers, coverage rates were quite low, with only 9 percent reporting coverage under either type of plan.

The coverage differences between men and women can be explained to some degree by their different rates of full time and part time employment. Twenty-six percent of the women were employed in low coverage part time work, compared to only 10 percent of the men (table 3). Holding the extent of employment constant for the two sexes results in a substantial narrowing of the gap in pension coverage. Among full time workers, 51 percent of the men reported coverage under an employer-sponsored plan, while 44 percent of the women did so. Among part time workers,

women were almost twice as likely as men to be covered, though coverage rates were very low for both sexes.

Coverage under employer-financed plans. -- Included in the group of workers covered only by a pre-tax retirement savings plan is a subset of workers whose plans were also being supported by employer contributions--among full time workers, 7 percent (table 3). Adding this group to the 39 percent of full time workers with "basic," employer-funded pension coverage yields an estimate that is more comparable to earlier studies, and one that will be used in later parts of the analysis: Among private full time wage and salary workers, 46 percent were covered under an employer-financed pension plan.

# Additional Retirement Savings Through IRAs

Since the emphasis in this section of the paper has been on determining total retirement plan coverage (whether the employer contributes to the plan or not), the analysis can be extended to a third type of retirement plan measured in the 1988 survey:

Individual Retirement Accounts (IRAs). While typically not "employer-sponsored," IRAs provide an alternative approach to retirement savings; thus, including them may give a more complete picture of the total number of workers who are actively accumulating assets for retirement.

The IRA question, coming later in the interview, asked respondents if they had made a contribution to an IRA in their own name during the 1987 tax year. This was the first year that changes instituted by the 1986 Tax Reform Act were in effect. According to these provisions, contributions to IRAs were fully tax deferred only for those persons who were not active participants in an employer-maintained retirement plan or whose adjusted gross incomes fell below certain phaseout levels (\$25,000 for an individual and \$40,000 for a married couple filing a joint return). Persons not eligible for tax-deferred treatment could still, however, make taxable contributions to an IRA, which would then accumulate untaxed.

Among all private wage and salary workers in May 1988, 12 percent reported making an IRA contribution during the previous tax year--13 percent of the men and 11 percent of the women (table 4). In general, full time workers reported a higher contribution rate than did those working part time (12 percent to 8 percent), though among women the contribution rates were virtually identical.

In addition to disaggregating IRA contribution rates by sex and extent of employment, table 4 also presents these rates for some of the categories of pension-covered and noncovered workers identified in the preceding analysis (table 3). Two findings are of particular interest: first, in all gender and employment

categories, workers covered by an employer-sponsored pension plan reported higher IRA contribution rates than did noncovered workers; and second, among all workers and full time workers, those with dual coverage reported slightly higher IRA contribution rates than did those who were covered under only one type of pension, plan.

Of greater interest to this analysis is the question of additional, non'-duplicative coverage. Specifically, how many of those not covered by an employer-sponsored plan made IRA contributions, and thus can be added to the total number of workers who have some form of retirement plan coverage? The data for the necessary calculations are in tables 3 and 4. Among all private wage and salary workers, 57 percent were not covered by an employer-sponsored plan, and 10 percent of these noncovered workers reported IRA contributions. The resulting 5.7 percent can be added to the total number of pension-covered workers (table 3) to yield an expanded estimate: As measured in this survey, 47 percent of all private wage and salary workers were participating in some kind of asset accumulation plan designed to yield resources at retirement. Among full time workers, this measure of retirement coverage reveals a total participation rate of 53 percent.20/

#### FACTORS ASSOCIATED WITH PENSION COVERAGE

In addition to gender and extent of employment, previous studies have identified numerous other factors associated with pension coverage. The purpose of this section is not to undertake a comprehensive analysis of these relationships, but to provide current data on some of them. The discussion here, as in the remainder of the paper, will be restricted to full time workers, and to coverage under employer-financed pension plans.

The factors under examination can be grouped into two categories: characteristics of the individual and characteristics of the job. In the first category are age, job tenure, and race; in the second category are industry, size of firm, and unionization. 21/ Each variable will be presented separately as it relates to pension coverage among private full time employees, with a further breakdown by sex. Future SSA studies of the 1988 data will make use of multivariate techniques and will be expanded to include other variables.

The Employee Retirement Income Security Act of 1974 (ERISA) established minimum standards for workers' participation in qualified pension plans.22/ Thereafter, any worker otherwise

eligible to participate in a pension plan could not be excluded after attaining the age of 25. With the passage of the Retirement Equity Act (REA) in 1984, this standard was lowered to 21.

Despite these regulations, workers aged 21-24 reported only a 25 percent coverage rate in the 1988 survey (table 5), suggesting that factors other than age itself are depressing their chances for coverage. In the age categories above 24, the coverage rates rise substantially—to 42 percent for those aged 25-29 and to 48 percent for those aged 30-34. Beyond age 34, the coverage rates remain fairly constant (varying between 54 and 58 percent), while among workers aged 60 and over, only 47 percent were covered. The latter decline undoubtedly reflects the departure of many pension—covered workers from the labor force as they become eligible for retirement.

A particularly interesting finding emerges from the comparison of men and women's coverage rates, controlling for age. Among the younger age groups, there is virtual equality between the sexes, with women even reporting slightly higher rates of pension coverage than men. At the same time, this parity between the sexes is achieved at relatively low levels of pension coverage, with only 11-12 percent covered in the 16-20 age group, 24-26 percent covered in the 21-24 age group, 41-42 percent covered at ages 25-29, and 48 percent covered at ages

30-34. Among older workers, men's traditionally higher rates of pension coverage are still manifested rather strongly, rising to a 14 percentage point advantage over women in the 50-54 age group (63 percent to 49 percent). Further analysis of these data will be presented later in the paper, with comparisons made to findings from earlier surveys.

#### Job Tenure

A second participation standard established by ERISA concerns the worker's length of employment on a job. Workers otherwise eligible to participate in a qualified pension plan can not be excluded from the plan once they have completed one year of service.

Clearly, as shown in table 6, job stability increases the likelihood of pension coverage. Despite ERISA standards, workers with only one to four years of job tenure had a coverage rate of 36 percent in 1988--again, suggesting that factors other than job tenure are involved. Among workers with less than one year of job tenure, the coverage rate was even lower (16 percent). These two groups of workers, it may be noted, comprised more than one-half of all full time private sector workers at the time of the survey. For the remaining workers, those with five or more years on a job, coverage rates were relatively high, showing a steady

increase with increasing tenure, and reaching a peak of 80 percent among those with twenty to twenty-four years of service.

These patterns hold for both men and women. Moreover, controlling for length of employment also reduces pension coverage disparities between the sexes. Among workers with one to fourteen years of job tenure, there was virtually no relationship between sex and pension coverage.

## Race

Like sex, race is not very strongly related to variations in pension coverage among full time workers (table 7). In 1988, whites reported a coverage rate of 47 percent, compared to 42 percent for blacks and 45 percent for other races. This relationship was stronger among men, with whites displaying a 7 percentage point advantage over blacks and a 4 percentage point advantage over blacks and a 4 percentage point advantage over men of other races, but the relationship was very weak among women.

Within racial groups, differences between the sexes were not uniform. The overall disparity between men and women is essentially a disparity among whites (who represented 87 percent of all full time workers in this study), 49 percent for white men and 43 percent for women. In contrast, among blacks and other races, men and women had nearly identical coverage rates.

# Industry

Industries in the private sector can be grouped into three rough categories according to their workers' 1988 rates of pension coverage (table 8). Included in the group with relatively high coverage rates are four industries: manufacturing; mining; transportation and public utilities; and finance, insurance and real estate. Workers' coverage rates in these industries ranged from a high of 64 percent (durable goods manufacturing) to a low of 57 percent (finance, insurance and real estate). In the group with "medium" rates of coverage (close to the 46 percent rate for all workers) are two industries: wholesale trade and professional and related services. Composing the group with low coverage rates (ranging from a high of 30 percent covered to a low of 12 percent) are construction, retail trade, other services, and agriculture.

The same rough groupings obtain among both men and women. Within subdivisions in manufacturing, however, women's coverage rates varied considerably. Those in nondurable goods manufacturing reported a pension coverage rate of only 50 percent, compared with 62 percent among women in durable goods manufacturing.

Finally, the relationship of gender to pension coverage does not hold across all industries. In the finance, insurance and

real estate industry, for example, coverage rates for men and women were virtually identical; and women in transportation and public utilities actually had a higher rate of coverage than their male co-workers (63 to 58 percent). In contrast, men's advantage in overall rates of pension coverage was even more marked in two other industries—15 percentage points higher than women in nondurable goods manufacturing and 14 percentage points higher in wholesale trade.

## Firm Size

As measured in the CPS pension supplement surveys, "size of firm" refers to the number of workers employed at all locations operated by a particular organization or business. The 1988 survey used a more finely differentiated set of response categories than the surveys in 1983 and 1979. For example, while the lowest response category in previous surveys was "fewer than 25," the 1988 survey divided this into "fewer than 10" and "10 to 24."

In general, these distinctions proved worth making, revealing quite clearly the strong positive relationship between the size of firms and the pension coverage rates of their workers (table 9). Workers in very small firms (with fewer than ten employees) reported a pension coverage rate of only 11 percent. Coverage remained quite low in firms with 10 to 24 workers (22 percent) and in firms with 25 to 49 workers (29 percent). Only in the highest category available in the CPS data (250 or more

workers) 23/ did the coverage rate exceed the 46 percent coverage rate for all workers. In firms of this size, 67 percent of the workers reported that they were covered by a pension. Previous research suggests that coverage rates are even higher in firms of 500 or more workers. 24/

The relationship between firm size and pension coverage appears both for men and for women. On the other hand, the relationship between sex and pension coverage varies somewhat according to firm size. In medium and large firms, men's coverage rates were 8 to 10 percentage points higher than women's, while in firms with fewer than 25 workers—firms characterized by low rates of pension coverage—men and women were almost equally disadvantaged.

## Union Representation

The influence of labor unions in promoting workers' pension coverage was strongly reflected in the 1988 survey (table 10). Of full time private sector employees who responded to the CPS questions on union representation, only 17 percent were members of a union or in jobs covered by a union or employee association contract. For this minority of workers, however, the pension coverage rate was 75 percent, compared to 43 percent among those without union representation. Controlling for gender, the relationship between union representation and pension coverage was slightly stronger for men than for women.

#### CHANGES IN PENSION COVERAGE

As noted earlier, one of the goals of the 1988 survey was to obtain data to compare with results from earlier CPS pension supplements, thereby permitting the analysis of changes in workers' pension coverage and vesting. Some of the similarities in sampling and in interview questions designed to measure pension coverage have already been described. A remaining comparability issue, however, needs to be addressed.

In the 1972 interview, respondents were asked if they were covered by "a pension or profit sharing plan providing retirement benefits." In 1979, the coverage question was made less specific, inquiring about "a pension or other type of retirement plan," and this more general referent was retained in the 1983 and 1988 questionnaires. In 1988, however, a follow-up question was added. Persons who did not respond affirmatively to the general question on coverage were then asked if they were included in "a deferred profit sharing plan or a stock plan" designed for retirement benefits. Two percent of the full time workers—apparently not having thought of these particular plans as "retirement plans"—responded affirmatively to the follow-up question. These respondents are included in coverage statistics

reported throughout this study, and they become problematic only when 1988 coverage rates are being compared to those from earlier surveys. The assumption used in the following analysis is that, based on these variations in questionnaire design, the coverage rates for 1979 and 1983 may be slightly underestimated compared to those for 1972 and 1988.

Having acknowledged this issue, the analysis in this section focuses, first, on changes in rates and types of pension coverage, and second, on changes among different age groups.

Again, the discussion is restricted to full time private wage and salary workers, and to coverage under employer-financed plans.

## Declining Coverage

The modest decline in pension coverage, first documented in the 1983 survey, continued through 1988 (table 11). Over the course of the four CPS pension supplements, the coverage rate increased from 48 to 50 percent between 1972 and 1979, dropped to 48 percent in 1983, and dropped again—to 46 percent—in 1988.25/Further, without the additional 1988 data on deferred profit sharing and stock plans, described above, the decline from 1983 to 1988 would have been even more pronounced, 4 rather than 2 percentage points.

The coverage rates of men and women have also changed over the course of the four CPS supplements (table 11). Women have

gained steadily since 1972, though in small increments, while the coverage rates of men have shown a decline in both surveys since 1979. There is a striking symmetry in these changes. While women gained 5 percentage points in pension coverage rates over the period 1972-1988, men lost an equal 5 percentage points in coverage. Thus, men's 16 percentage point advantage over women in 1972 (54 to 38 percent covered) had been reduced to 6 percentage points by 1988 (49 to 43 percent).

# Indications of Changing Types of Coverage

In addition to showing the changes in pension coverage from 1972 to 1988, table 11 also presents the breakdown on types of coverage under employer-financed plans in 1988--39 percent of full time workers covered under a basic pension plan (including 6 percent dually covered) and 7 percent with only a pre-tax retirement savings plan. Strictly comparable figures are not available from the earlier surveys. However, based on data that are available, one may speculate about changes in types of coverage during this period.

The pension coverage reported in 1972 and 1979 undoubtedly included some tax-sheltered annuities (403b plans) and at least a small number of pre-tax defined contribution plans. The latter type of plan was permitted as early as the 1950's, but was apparently not widespread. Further, the formation of new plans

of this type was prohibited in June 1974, and the freeze was not lifted until the implementation of section 401(k) of the Internal Revenue Code, effective January 1, 1980.

Partly in response to this policy change, a question on pretax coverage was added to the 1983 questionnaire. Tabulations of the 1983 data (not shown separately) indicate that 48 percent of all full time private employees were covered under a "basic" pension plan (including 3 percent with both basic and pre-tax coverage), and 0.3 percent had a pre-tax savings plan only. Unfortunately, these figures cannot be fully trusted. Due to a design flaw in the 1983 questionnaire, the number of workers with pre-tax plans was probably underestimated by several percentage points, and the number with basic coverage was correspondingly overestimated.26/

Nonetheless, other data sources suggest that there has been a substantial increase in pre-tax coverage in recent years, and a substantial decline in coverage under defined benefit plans. 27/ Although our tabulations probably overestimate coverage under a basic pension plan in 1983, the resulting estimates of change in basic coverage between 1983 and 1988 (from 48 to 39 percent) closely correspond to the rate of decline in defined benefit plan coverage in the Bureau of Labor Statistics' surveys of medium and large firms. 28/ The BLS data, representing about one-third of

full time private sector employees, show that coverage under defined benefit plans decreased by 14.6 percent between 1983 and 1988.29/ The CPS data, reported above for all full time private sector employees, suggest that coverage under a "basic" pension plan decreased by 18.8 percent during the same period. Using a more conservative estimate of basic coverage in 1983 would, of course, produce a lower rate of decline.

# The Changing Experience of Younger Workers

A rather important finding emerges when changes in the rate of pension coverage are examined for different age groups: The overall decline in pension coverage between 1972 and 1988 can largely be accounted for by declining rates of coverage among younger workers--primarily among younger men (table 12).

The pattern is clear. Compared to their counterparts in 1972, the coverage rate among workers aged 16 to 25 in 1988 was 10 percentage points lower (31 percent in 1972, 21 percent in 1988); those aged 25 to 30 had a coverage rate 6 percentage points lower than their 1972 counterparts; and workers aged 30 to 35 had a coverage rate 4 percentage points lower (table 12). In contrast, the 1988 coverage rates of groups in the age range 35 to 55 were virtually unchanged compared to similar age groups in 1972; and workers aged 55 and older actually displayed an increase in pension coverage compared to their 1972 counterparts.

These changes in coverage rates were compounded by changes in the age distribution of full time private sector employees—an increase in the proportion of those under the age of 35 (from 43 percent in 1972 to 50 percent in 1988), and a decrease in the proportion of workers aged 55 and over (from 15 to 11 percent).

The comparison between 1972 and 1988 masks some important variations in pension coverage revealed in the 1979 and 1983 data (table 12). The only appreciable gains over the 16 year period occurred between 1972 and 1979. Losses were experienced in almost all age categories between 1979 and 1983, and between 1983 and 1988 the changes were uniformly negative. Indeed, the 1983-1988 losses in pension coverage among younger age categories were not substantially different from those experienced among most of the older age groups.

As noted, the overall decline in pension coverage between 1972 and 1988 can largely be attributed to changes in the coverage of younger men. Except in the youngest age category, women of all ages have shown net increases in pension coverage over the sixteen year period; men in the age groups between 35 and 60 have basically held their own or experienced only slight losses in pension coverage; and men in the age category 60 and over have experienced modest gains. The substantial losses in pension coverage have been concentrated in the cohorts of younger

men: among those aged 16 to 25 in 1988, a 14 percentage point loss compared to their 1972 counterparts; among those aged 25 to 30, an 11 percentage point loss; and among those aged 30 to 35, a loss of 8 percentage points.

These patterns also help to clarify a finding reported earlier in the paper—the parity in 1988 coverage rates between younger men and women. It is now clear that, in the two youngest groups (aged 29 or under), this parity has been achieved not by substantial gains among new cohorts of young women workers, but by substantial losses among new cohorts of young men—thus, at a relatively low level of pension coverage. In contrast, the parity at ages 30—34 may be attributed to important gains by women and equally important losses by men. Finally, while pension coverage has increased significantly among women aged 35 or older, men between the ages of 35 and 60 experienced only slight net changes between 1972 and 1988. Thus, despite the narrowing gender gap over the course of the four surveys, men in these older groups continue to have considerably higher rates of pension coverage than women.

#### SUMMARY

Based on data for private wage and salary workers in May 1988, this paper examined pension coverage under two types of employer-sponsored pension plans. Some of the factors associated with employer-financed pension coverage were also examined, and comparisons were made to findings on pension coverage of full time workers in 1972, 1979 and 1983. "Covered" workers were defined as those who were actually participating in a pension plan.

Among all private sector employees in this study, 34 percent were covered by a "basic" pension plan (most of which, presumably, were defined benefit plans), and 14 percent were covered by a pre-tax retirement savings plan, a subtype of defined contribution plan. Since 7 percent of the respondents were covered by both types of plans, the total coverage rate under employer-sponsored plans was 41 percent.

Twelve percent of the respondents reported that they had contributed to an IRA in 1987. IRA usage was somewhat higher among those already covered by a pension plan than among noncovered workers. Six percent of the respondents were not covered by an employer-sponsored plan but were contributing to an

IRA, yielding a total of 47 percent who were participating in either an employer-sponsored or an individual retirement plan.

While it was assumed—as in previous studies—that all
"basic" coverage was being funded by employers, only four—fifths
of those in pre—tax retirement savings plans reported that
employers were also contributing to these plans. The remainder
of the analysis was restricted to coverage under employer—
financed plans, and it was further restricted to full time
workers. A total of 46 percent of these workers were found to be
covered under employer—financed pension plans—33 percent covered
only by a basic plan, 7 percent covered only by a pre—tax plan,
and 6 percent dually covered. Among men, the coverage rate was
49 percent, compared to 43 percent among women.

Several individual and job-related characteristics were found to be associated with employer-financed pension coverage among full time employees.

- Coverage rates were quite low among workers under the age of 25, but substantially higher among those aged 35 to 60.
- Pension coverage was also low among those with less than five years of employment on the job, but relatively high among those with five or more years of job tenure.
- Racial differences were not substantial. Whites reported a coverage rate of 47 percent, compared to 42 percent among blacks and 45 percent among other races.
- Industries with relatively high rates of pension coverage included manufacturing, mining, transportation, and finance,

insurance and real estate; industries with low rates of coverage included construction, retail trade, non-professional services, and agriculture.

- The size of the employing firm was strongly related to pension coverage. Coverage rates ranged from 11 percent in firms with fewer than 10 workers to 67 percent in firms with 250 or more workers.
- Among the minority of workers represented by a labor union, 75 percent reported pension coverage, compared to a 43 percent coverage rate among workers without union representation.

Perhaps most important, the analysis revealed significant changes in pension coverage among full time workers over the past sixteen years: a continuing decline in the rate of coverage since 1979, the fact that most of this decrease can be attributed to falling coverage rates among younger men, and some evidence that the most recent decline in pension coverage has been concentrated in defined benefit plans.

- While previous studies had shown that overall pension coverage increased from 48 to 50 percent between 1972 and 1979, this study confirmed a decline to 48 percent through 1983, and a further decline to 46 percent in 1988. In addition, since coverage rates in 1979 and 1983 were probably underestimated by 1 to 2 percentage points, the recent decrease in pension coverage may have been even more pronounced.
- Over the course of the four CPS supplements, women's coverage rates have increased steadily, while coverage among men has decreased in both surveys since 1979. Thus, men's 16 percentage point advantage in pension coverage rates in 1972 had been reduced to a 6 percentage point advantage by 1988.
- Losses in pension coverage have been concentrated among younger workers, and primarily among younger men. Indeed, given changes in the age distribution of workers, the overall decline in coverage between 1972 and 1988 can be largely attributed to

decreased pension coverage in succeeding cohorts of men under the age of 35.

- While women under the age of 35 have achieved parity with men, the parity for those under 30 is at relatively low levels of pension coverage. More meaningful gains have been made by middle-aged and older women, but men in these age groups continue to have coverage rates that are 8 to 14 percentage points higher.
- The evidence regarding changing types of pension coverage is limited. However, it is suggested that coverage under defined benefit plans may have declined by as much as 15 percent between 1983 and 1988, a decline that has been partly offset by increased coverage under defined contribution plans which allow pre-tax employee contributions.

## CONCLUSIONS

The trend toward lower rates of pension coverage among current workers—and, particularly, the lower rates of coverage among younger workers—may have important implications for the future of private pension benefits in the United States. The eventual outcome, of course, will depend on a complex array of factors: the extent to which younger workers continue to have lower rates of coverage relative to previous cohorts as they move into their prime working years; the proportion of covered workers who will become vested and eventually receive benefits; and the size of benefit amounts relative to other sources of income.

Based on coverage statistics alone, however, the findings in this paper suggest decreasing rates of private pension receipt in the future, and a corresponding increased reliance on other sources of retirement income, including Social Security.

The apparent, partial shift from defined benefit to defined contribution plan coverage has additional implications for the future of private pension benefits. Compared to traditional pension plans, defined contribution plans are generally thought to provide less retirement security to employees. Further, the extent to which employees' contributions to pre-tax plans are

actually used to produce retirement income remains an important issue of concern.

These and other implications of the changing patterns of pension coverage need to be more fully explored. In addition, further research is needed to clarify the nature and causes of these changes. Future data gathering efforts should continue to be focused on changes in rates of pension coverage, but particular attention must be devoted to coverage rates among new cohorts of workers and to possible changes in types of coverage.

In the meantime, currently available data should be used to analyze the causes of the decline in pension coverage among younger workers, to document any changes in patterns of vesting, and to explore the extent and disposition of lump sum payments. Clearly, the research agenda is full. However, just as clearly, the knowledge to be gained will be critical to future policy debates on retirement income security.

<sup>2/</sup> Source: Daniel J. Beller, "Coverage Patterns of Full-Time Employees Under Private Retirement Plans," Social Security Bulletin, July 1981, table 2.

<sup>3/</sup> Includes workers whose basic pension coverage was identified only through a follow-up question used in the 1988 survey--2 percent of men, women, and all workers.

<sup>4/</sup> Among those aged 21-24 in 1983, the coverage rate was 28 percent; in 1988 the corresponding rate was 25 percent.

## NOTES

- 1. Typically, workers are defined as "covered" by a pension plan on a particular job when they have met the plan's eligibility requirements and are participating in the plan. "Vesting" is achieved by such workers when they acquire a nonforfeitable right to future benefits.
- 2. Findings from the early years of this research are summarized in Alfred M. Skolnik, "Ten Years of Employee-Benefit Plans,"

  <u>Social Security Bulletin</u>, April 1966, pages 3-19. The final article in the series was Martha Remy Yohalem, "Employee-Benefit Plans, 1975," <u>Social Security Bulletin</u>, November 1977, pages 19-28.
- 3. A description of the 1972 survey and analysis of its data are presented in Walter W. Kolodrubetz and Donald M. Landay, "Coverage and Vesting of Full-Time Employees Under Private Retirement Plans," <u>Social Security Bulletin</u>, November 1973, pages 20-36. The fact that the 1972 questionnaire was administered only to full time private wage and salary workers aged 16 and over requires that any comparisons to 1972 be made in terms of this particular population. Further, the article by Kolodrubetz and Landay is the only known publication which reports the 1972 data. Since the 1972 data file no longer exists, any comparisons that include 1972 must therefore use the data as presented in their study.
- 4. The Current Population Survey (CPS) is a monthly survey conducted by the Bureau of the Census with a nationally representative sample of households. For a detailed description of the basic CPS design, see the Bureau of the Census, The Current Population Survey: Design and Methodology, Technical Paper no. 40, 1978.
- 5. The 1979 survey was also co-sponsored by the Social Security Administration. A description of this survey and analysis of its data on pension coverage are presented in Daniel J. Beller, "Coverage Patterns of Full-Time Employees Under Private Retirement Plans," Social Security Bulletin, July 1981, pages 3-11. See also Gayle Thompson Rogers, "Vesting of Private Pension Benefits in 1979 and Change From 1972," Social Security Bulletin, July 1981, pages 12-29.

Murray, The Aged Population of the United States: The 1963 Social Security Survey of the Aged, Research Report No. 19, Social Security Administration, 1967, table 3.21; and Susan Grad, Income of the Population 55 and Over, 1986, Office of Research and Statistics, Office of Policy, Social Security Administration, June 1988, table 5.
- 8. Wilmer L. Kerns and Milton P. Glanz, "Private Social Welfare Expenditures, 1972-1985," <u>Social Security Bulletin</u>, August 1988, table 7.
- 9. The 1983 survey was sponsored by the Department of Health and Human Services and by the Employee Benefit Research Institute. A description of this survey and a comprehensive analysis of its data are presented in Emily S. Andrews, The Changing Profile of Pensions in America, Washington, DC, Employee Benefit Research Institute, 1985.
- 10. The Congressional Budget Office, the Department of Labor, the Pension Benefit Guaranty Corporation, and the Small Business Administration.
- 11. See, for example, Emily S. Andrews, The Changing Profile of Pensions in America, Washington, DC, Employee Benefit Research Institute, 1985, page 12. This study defined workers as "covered" if any of the employing firm's workers were being provided an employer-financed pension plan. (Following some introductory instructions by the interviewer, the specific questionnaire item was: "Does your employer or union contribute to a pension or retirement plan for any of its employees or members?") In contrast, workers who subsequently responded that they were included in the plan were designated "participants."
- 12. Kolodrubetz and Landay, November 1973, op.cit.; Beller, July 1981, op.cit.; and Rogers, July 1981, op.cit.
- 13. Full time workers are defined as those who usually work 35 or more hours per week on their principal job, while part time workers are defined as those usually working between 1 and 34 hours per week.

- 14. For a comprehensive discussion of defined benefit and defined contribution plans, see Dan M. McGill, <u>Fundamentals of Private Pensions</u>, 5th ed., Homewood, Ill., Richard D. Irwin, 1984.
- 15. Employee Benefit Research Institute, "401(k) Cash or Deferred Arrangements," <u>EBRI Issue Brief</u>, No. 46, September 1985.
- 16. Several studies have indicated that preretirement distributions are typically spent rather than saved. See, for example, Andrews, op.cit., 1985, pages 162-164. Because of concern over this issue, the Tax Reform Act of 1986 applied a 10 percent additional income tax to non-retirement distributions from qualified retirement plans.
- 17. See, for example, Kotlikoff and Smith, op.cit., table 4.1.3.
- 18. See Gayle Thompson Rogers, Pension Coverage and Vesting Among Private Wage and Salary Workers, 1979: Preliminary Estimates from the 1979 Survey of Pension Plan Coverage (Working Paper no. 16), Office of Research and Statistics, Office of Policy, Social Security Administration, 1980.
- 19. The classifications "only" basic pension coverage and "only" pre-tax savings coverage are based, of course, on the measures obtained in this particular survey. Some additional sources of dual coverage might have been identified with additional questions—for example, defined contribution plans that are not primary plans and that do not allow pre-tax employee contributions.
- 20. Including in these calculations the small number of workers who "didn't know" about their pension coverage has no effect on the findings, adding only 0.1 percent to the total participation rate for all workers and 0.3 percent for full time workers.
- 21. Age, job tenure, race, and industry were reported in SSA's studies of the 1972 and 1979 data; firm size and unionization were also reported for the 1979 data. In the present study, these variables have generally been categorized in ways similar to the two previous studies, enabling readers to make comparisons as they choose. As noted previously, the 1972 data were reported for full time private sector employees in Kolodrubetz and Landay, November 1973, op.cit., and the 1979 data were reported for the same population in Beller, July 1981, op.cit.
- 22. "Qualified" plans are those that meet standards required for favorable tax treatment under ERISA and the Internal Revenue Code.

- 23. Although the 1988 survey included response categories of 250-499, 500-999, and 1000 or more, these responses were topcoded at 250 by the Bureau of the Census in the data file recently released.
- 24. In his analysis of the 1979 CPS pension supplement data, Beller, July 1981, op.cit., reported a coverage rate of 81 percent in firms with 500 or more employees.
- 25. Following the precedent set in studies of the 1979 data, workers not responding on pension coverage were included in the base in each of the four years and allocated proportionally among the other response categories.
- The problem centers on those who would have had only pre-tax coverage in 1983. In responding to the first question on coverage (asking about their inclusion in "a pension or retirement plan"), most of these persons would probably have responded in the affirmative. (In 1988, about 80 percent of the comparable respondents answered "yes.") When faced with the later question on pre-tax coverage, however, either a "yes" or a "no" response from these persons would have resulted in erroneous (In effect, the question read "In addition to your basic plan, do you participate in a salary reduction plan, sometimes called either a 401k or 403b plan...?") Those who responded "yes" to this question would have been erroneously counted as dually covered, while those responding "no" (the more likely response) would have been counted as having only a basic pension plan. As described earlier, this flaw in questionnaire design was corrected in the 1988 survey.
- 27. Data on 401(k) participation are included in reports from the Bureau of Labor Statistics (BLS) for 1985, 1986 and 1988. See U.S. Department of Labor, Bureau of Labor Statistics, Employee Benefits in Medium and Large Firms, 1985 (Bulletin No. 2262), July 1986; Employee Benefits in Medium and Large Firms, 1986 (Bulletin No. 2281), June 1987; and "BLS Reports on Employee Benefits in Medium and Large Firms in 1988," News Release, April 4, 1989. Data on defined benefit plan coverage have been provided in each issue in the BLS series, beginning with the 1979 edition. For data on coverage under 403(b) plans, see American Council of Life Insurance, Pension Facts 1987, Washington, DC, American Council of Life Insurance, 1987, pages 8-9.

- 28. First conducted in 1979, the BLS survey periodically samples firms with at least 100 or 250 employees, depending on the industry, and gathers data on the actual incidence of employee benefits being provided by these firms.
- 29. The actual BLS coverage rates were 82 percent in 1983 and, based on a comparable sample, 70 percent in 1988. See U.S. Department of Labor, Bureau of Labor Statistics, <a href="Employee">Employee</a>
  Benefits in Medium and Large Firms, 1983 (Bulletin No. 2213), August 1984; and "BLS Reports on Employee Benefits in Medium and Large Firms in 1988," <a href="News Release">News Release</a>, April 4, 1989.
