NPDWR - National Primary Drinking Water Regulation  
SDWA - Safe Drinking Water Act

## Contaminant Candidate List 3 Microbes: Screening to the PCCL

### 1.0 Background and Scope

The document titled, *CCL 3 Microbes: Identifying the Universe* (USEPA, 2007) provides a summary of the statutory and regulatory background leading to development of a microbial Contaminant Candidate List (CCL) and the subsequent activities to develop a microbial CCL 3 universe as the initial step in a transparent and scientifically sound Contaminant Candidate List Classification Process (CCLCP).

This document summarizes criteria that the Environmental Protection Agency (EPA) uses for screening a universe of microbiological contaminants to identify those contaminants in the microbial CCL 3 universe to be placed on a Preliminary Contaminant Candidate List (PCCL). These criteria were developed in part following the recommendations of the National Research Council (NRC), the National Drinking Water Advisory Council (NDWAC) workgroup on the CCL process. The recommended screening process was reviewed by a panel of external experts, and the screening process described herein was derived from the subsequent deliberations of the EPA microbiology workgroup based upon the expert panel report.

### 2.0 Recommendations for Screening a Universe of Drinking Water Contaminants to Produce a PCCL

The NRC recommendations for a CCLCP are described in, *Classifying Drinking Water Contaminants for Regulatory Consideration* (NRC, 2001). The NRC workgroup identified a hierarchical framework for evaluating the potential occurrence of microbial contaminants in drinking water. This approach suggested that EPA could obtain data on microbial contaminant occurrence from existing occurrence databases and lists. Microbes with demonstrated or potential occurrence in drinking water, and microbes with demonstrated or potential ability to cause adverse health effects from drinking water exposure were recommended for inclusion in a PCCL.

The NRC workgroup report did not contain specific recommendations for selection and screening of microbial contaminants to a PCCL, and because occurrence data are not readily available to support the screening process envisioned by the NRC workgroup, the Agency requested further study of these issues by a workgroup convened by the NDWAC. NDWAC recommended selecting microbial contaminants for a PCCL based upon an assessment of occurrence attributes and health effects attributes relating to the plausibility of pathogen presence, survival, and transport through drinking water resulting in disease manifestations from drinking water exposure. These recommendations are described further in, *National Drinking Water Advisory Council Report on the CCL Classification Process* (NDWAC, 2004).

The microbial CCL 3 universe was defined by the NDWAC workgroup as microbes that are known to cause disease in humans. A literature review identified a list of 1,415 known human pathogens including bacterial, viral, protozoan, helminth, and fungal pathogens (Taylor et

al., 2001). The Taylor list was recommended as the basis of the microbial CCL 3 universe. EPA requested nominations from the scientific community for additions to the microbial CCL 3 universe, and four microbes were added to the list through the nomination process (USEPA, 2006). EPA also added 6 fungi that did not appear on the list of Taylor et al. (2001) but were identified in drinking water distribution systems. EPA also added one virus that was identified as an emerging pathogen of potential interest, thus bringing the total number of microbes in the CCL 3 universe to 1,425 pathogens.

Selection of microbes from the CCL 3 Universe for placement on the PCCL is based upon screening criteria that assess the potential of water-related transmission (occurrence) and the plausibility of causing waterborne disease by ingestion, inhalation, or dermal contact (health effects). NDWAC recommended ten screening criteria for initial screening of pathogens in the microbial CCL universe for placement on a PCCL. NDWAC also suggested that supplementing these screening criteria may be necessary to insure that microbes on a PCCL represent only those pathogens whose occurrence and health effects are attributable to drinking water. The principles supporting supplemental screening criteria include:

- biological characteristics related to occurrence and survival
- taxonomic consolidations of genera or species by designating a representative genus/species, i.e. allowing the designated type species of a pathogen to represent the genus for screening purposes
- reliance upon epidemiological data to determine potential of adverse health effects attributable to a drinking water source

The NDWAC workgroup evaluated the possibility of using virulence factor activity relationships (VFARs) as a means of identifying potential waterborne pathogens. The workgroup concluded that additional studies were necessary before VFARs could be used to screen microbes to a PCCL (NDWAC 2004).

EPA restricted the PCCL to pathogens that are known to be associated with source water, and recreational water only if the water is also drinking water (e.g., swimming pools) are considered as candidates for the PCCL. Screening criteria are used to exclude those pathogens whose biological properties are incompatible with water transmission by ingestion, inhalation or dermal contact, and those pathogens that are typically introduced from sources other than drinking water.

### **3.0      Definition of Screening Criteria and Rationale for Their Application**

Screening criteria were developed based upon epidemiology, geographical distribution, and biological properties in the host and in the environment. Screening criteria recommended by NDWAC, as amended by the EPA microbiology workgroup following external peer review, are listed below. Only one criterion is needed to screen out a pathogen. All pathogens that are not excluded under any screening criteria are moved to the PCCL. However, any pathogen documented to cause disease transmitted through drinking water, regardless of the following screening criteria, is considered for the PCCL.

**Criterion 1:**

Anaerobes (microorganisms that cannot survive in oxygenated environments)

Anaerobes are microorganisms that cannot survive in the presence of oxygen (Murray et al., 2007). Because of oxygen toxicity, they are unable to survive in the ambient water environment, and they pose negligible threat to human health from drinking water exposure. Examples of anaerobes that are screened out based on this screening criterion include members of the bacterial genera *Actinomyces*, *Bacteroides*, *Clostridium*, *Eubacterium*, *Fusobacterium*, and *Prevotella*, among others (Murray et al., 2007).

**Criterion 2:**

Fastidious or obligate intracellular pathogens (environmental survival in water implausible)

Fastidious or obligate intracellular pathogens rely upon their host to provide essential nutrients and growth factors that are not present in the environment, hence these pathogens cannot survive outside their hosts. Many fastidious or obligate intracellular pathogens have a narrow temperature and pH range as a result of host adaptation, and they cannot survive the wide range of temperatures and pH common in the ambient environment. Examples of fastidious or obligate intracellular pathogens that are screened out include members of the genera *Chlamydophila*, *Mycoplasma*, and *Orientia* (Murray et al., 2007). This criterion is applied only to bacteria, since all viruses are obligate intracellular pathogens (Knipe and Howley, 2007).

**Criterion 3:**

Pathogens exclusively transmitted by direct or indirect contact with blood or body fluids (including sexually transmitted diseases)

Some pathogens are transmitted by direct or indirect contact with blood or body fluids, where fecal-oral transmission or transmission by aerosolized water is not observed (Mandel et al. 2005). Pathogens causing bloodborne diseases and sexually transmitted diseases are highly host adapted, fastidious, and are usually not present in feces. They do not survive under environmental conditions, and they are not transmitted by the fecal-oral route, either by direct contact with feces or indirect contact with contaminated drinking water. Examples of pathogens transmitted by blood or body fluids include the etiologic agents of gonorrhea and syphilis, *Chlamydia*, herpes virus, human immunodeficiency virus, and hepatitis virus B, C, D and G (Murray et al., 2007).

**Criterion 4:**

Pathogens transmitted by vectors

Vectors include arthropods and rodents (Acha and Szyfres, 2001). Pathogens transmitted by vectors depend upon either insect or other bites, or close contact with rodents, and these pathogens are not transmitted by contact with drinking water. Mosquitoes, ticks, and fleas are the most common vectors of arthropod-borne diseases (Krauss, et al., 2003). Examples of vector-borne pathogens include bacteria, viruses, protozoa, and helminths. The genera *Babesia*,

*Borrelia, Brugia, Dirofilaria, Ehrlichia, Leishmania, Plasmodium, Trypanosoma, Rickettsia,* and all arthropod-borne viruses were not moved to the PCCL (Murray et al., 2007).

**Criterion 5:**

Microflora indigenous to the gastrointestinal tract, skin and mucous membranes

The human body is colonized with a rich and commensal microflora (Finegold et al., 1983; Drasar and Barrow, 1985; Isenberg and D'Amato, 1995). Some microbes that colonize the human body are transitory, while others are part of the continuing normal flora of the body. Microbes comprising normal flora have a characteristic ecological niche, but sometimes conditions permit their access to areas of the body where they may exhibit pathogenic potential resulting in infection and disease. Infections with normally innocuous microbes are called opportunistic infections, because of their ability to exploit host conditions that may periodically predispose them to disease. Because exposure to normal flora microbes is continuous throughout life, and because the populations of normal flora microbes exceed the number of these microbes present in drinking water by many orders of magnitude, drinking water represents an improbable source of infection and disease. Examples of normal flora include members of the genera *Capnocytophaga, Corynebacterium, Staphylococcus, Streptococcus*, and several yeasts (Murray et al., 2007).

**Criterion 6:**

Pathogens transmitted solely by respiratory secretions

Pathogens causing respiratory disease are typically transmitted by direct contact with respiratory secretions, either by inhalation of aerosols, by direct person-to-person contact, or by contact with fomites. Drinking water is an unlikely mode of transmission because the number of pathogens in respiratory secretions and the continuity of exposure to respiratory secretions far exceed exposure through drinking water (Bennet and Brachman, 1998). Examples of pathogens transmitted by respiratory secretions include the etiologic agents of tuberculosis, diphtheria, whooping cough, measles, rubella, and influenza (Knipe and Howley, 2007; Murray et al., 2007; Mandel et al., 2005).

**Criterion 7:**

Pathogens whose life cycle is incompatible with drinking water transmission

Some pathogens such as helminths, require intermediate hosts to complete their life cycles, and incidental infection of humans results in an interruption of their life cycle with subsequent death of the pathogen (Acha and Szyfres, 2001). Some pathogens are adapted to a single route of transmission such as rabies virus, which is transmitted by animal bites. Some pathogens are specifically adapted to survive in a unique ecological niche, and they cannot withstand any alteration of conditions to which they are adapted. For example, rabies virus, *Dientamoeba fragilis, Enterobius vermicularis*, and many helminths remain in the microbial CCL 3 universe and are not considered for the PCCL based on this criterion (Murray et al., 2007; Ashford and Crewe, 2003).

**Criterion 8:**

Pathogens where drinking water-related transmission is not implicated

Some pathogens cause such rare occurrences of disease that only a few cases have been reported in medical literature, and these rare occurrences of disease present limited opportunity to protect public health from drinking water exposure (Acha and Szyfres, 2001; Knipe and Howley, 2007; Murray et al., 2007; Mandel et al., 2005). Some pathogens are associated with direct transmission from animals to humans, or other transmission routes that do not involve drinking water (Acha and Szyfres, 2001; Krauss et al, 2003; Howard, 2003). Examples of pathogens that remain in the microbial CCL 3 universe after application of this criterion are *Leptospira*, *Listeria*, *Nosema*, and the etiologic agents of several zoonotic virus infections (Knipe and Howley, 2007; Murray et al., 2007).

**Criterion 9**

Natural habitat is in the environment without epidemiological evidence of drinking water-related disease

The environment is teeming with microorganisms, at varying concentrations, and humans are in constant contact with these microorganisms throughout their lives (Bennett and Brachman, 1998; Isenberg and D'Amato, 1995). Microorganisms naturally present in the environment are not considered a threat to public health as a result of drinking water exposure unless epidemiological evidence demonstrates a potential for water-related disease. Thus, outbreaks occurring in nosocomial settings or attributable to recreational water resulting from post-delivery contamination of drinking water are not sufficient to place a microorganism on the PCCL unless the drinking water system was shown to be contaminated (Wenzel, 2003). *Acinetobacter*, *Gordonia*, *Nocardia*, *Pseudomonas*, and most fungi are excluded from the PCCL based on this criterion (Murray et al., 2007; Howard, 2003).

**Criterion 10**

Pathogens not endemic to North America

Some pathogens have an exclusive geographical distribution, and they are not naturally present in North America (Ashford and Crewe, 2003; Murray et al., 2007; Palmer et al., 1998). Only pathogens endemic to North America have the potential to contaminate drinking water in the U.S. Several helminths such as most *Diphyllobothrium*, and *Paragonimus* species and several viruses such as the hemorrhagic fever viruses and poxviruses would remain in the microbial CCL universe after application of this criterion.

**Criterion 11**

A genus and species or serotype may be chosen to represent a group of closely related organisms

EPA has chosen a few pathogens to represent a group based on all serotypes within a group sharing essential biological properties in common with the group. Designation of a representative group provides adequate protection of public health under the CCLCP (Murray et

al., 2007). Pathogens that represent other pathogens in their group are the following: *Arcobacter butzleri*, *Campylobacter jejuni*, *Helicobacter pylori*, *Legionella pneumophila*, *Salmonella enterica*, *Shigella sonnei*, Adenovirus, Astrovirus, Enterovirus, Microsporidia, and *Entamoeba histolytica*.

### **Criterion 12**

Current taxonomy does not support the classification listed by Taylor et al. (2001).

Microbial taxonomy and nomenclature is a dynamic science, and taxonomic classifications are constantly changing. Original taxonomic classifications were based upon the phenotypic characteristics of microorganisms, but these classifications are being revised as genotypic information becomes available. New genera are formed, sometimes prematurely, based upon partial genomic data, and taxonomists do not always agree with proposed changes. Under this criterion, the genera *Fluoribacter* and *Tatlockia* are combined with the genus *Legionella* for screening purposes (Murray et al., 2007).

### **3.1 Application of Screening Criteria to the Microbial CCL Universe**

Bacteria, viruses, protozoa, helminths, and fungi in the CCL 3 Universe are shown respectively in the tables of Attachment A, and *CCL 3 Microbes: Identifying the Universe*. Each table identifies the pathogens in each category and indicates which screening criteria were applied to remove pathogens from further consideration in the CCL Process. Those pathogens not excluded by at least 1 of the 10 screening criteria or consolidated under criteria 11 or 12 pass on to the PCCL. The summary data from the screening is shown in Exhibit 1.

#### **Exhibit 1. Summary of Screening Microbial CCL 3 Universe**

Pathogen Class	Total	Screening Criteria												On PCCL
		1	2	3	4	5	6	7	8	9	10	11	12	
Bacteria	540	125	14	10	37	117	7	0	29	154	2	28	5	12
Viruses	219	0	0	26	99	0	17	1	16	0	45	8	0	7
Protozoa <sup>1</sup>	66	0	0	1	29	3	0	4	7	7	0	6	0	7
Helminths	287	0	0	0	25	0	0	107	0	0	155	0	0	0
Fungi	313	0	0	0	0	13	1	0	0	309	0	0	0	3
<b>Total</b>	<b>1,425</b>	<b>125</b>	<b>14</b>	<b>37</b>	<b>190</b>	<b>133</b>	<b>25</b>	<b>112</b>	<b>52</b>	<b>470</b>	<b>202</b>	<b>42</b>	<b>5</b>	<b>29</b>

<sup>1</sup>Cryptosporidium and Giardia are considered to be regulated by LT2. They were not screened and were not considered for CCL3.

Based upon this screening exercise conducted on 1,425 pathogens in the microbial CCL universe 1,394 pathogens were excluded from consideration while 29 pathogens passed to the PCCL. The specific screening decisions and references are presented in Attachment A.

## 4.0 Additional Screening Criteria Considered

As the CCL3 process developed, EPA considered screening criteria in addition to the twelve described above. While each of these additional criteria had merit, they were not consistent with the ultimate goal of the CCL3. The goal of the CCL is to identify potential contaminants that may require regulation. The basis for regulating specific contaminants is:

- Occurrence at a level and frequency that presents a potential public health risk, and
- The feasibility and opportunity for achieving meaningful reduction of exposure from such contaminants.

Listing contaminants on the CCL identifies the need for collecting additional information to inform the basis for potential regulations, and if that threshold of information is met, to support new regulation or revisions to existing regulations to control or improve control for such contaminants. If contaminants are not listed on a CCL (e.g., CCL 3), EPA may include those contaminants as occurrence and health effects information becomes available in a future listing. The following subsections present additional screening criteria that EPA considered but elected not to use at this time.

### 4.1 Organism Covered by Existing Regulations

#### 4.1.1 Organisms Covered by Fecal Indicator Monitoring

EPA considered a screening criterion based upon contaminants that might be controlled through drinking water monitoring requirements under current drinking water regulations. Many of the bacteria in the CCL Universe, including the *Enterobacteriaceae* and members of the genera *Campylobacter* and *Vibrio*, are associated with fecal contamination and as such their presence could be signaled by the monitoring requirements under the Total Coliform Rule (TCR). Under the TCR, EPA chose to require monitoring for *Escherichia coli* (and total coliforms) in finished drinking water because it provides a broad indication of the potential presence of fecal pathogens in drinking water, though more so for bacteria than for viruses and protozoa.

EPA chose not to exclude common enteric bacterial pathogens from the PCCL even though they may be indicated by the TCR. Numerous waterborne disease outbreaks have occurred in systems that were in compliance with maximum contaminant limit (MCL) drinking water monitoring requirements under the TCR. EPA recognizes that monitoring under the TCR (i.e., monitoring for total coliforms and *E. coli* or fecal coliforms when total coliforms are present, (Oldstadt, et al., 2007)) may not always be protective against bacterial fecal contamination. The frequency of total coliform monitoring under the TCR is limited, especially for smaller systems, thus transitory fecal contamination could go undetected. EPA believes that enteric pathogens should be included for further regulatory consideration in the CCL because monitoring under the TCR may be too limited to protect against specific types of bacterial fecal contamination.

#### **4.1.2 Organisms Covered by Treatment Technique**

According to the Safe Drinking Water Act (SDWA), EPA must select contaminants that “at the time of publication, are not subject to any proposed or promulgated national primary drinking water regulation...” In promulgating regulations for drinking water contaminants, EPA can set either a legal limit (MCL) and require monitoring for the contaminant in drinking water or EPA can establish a treatment technique requirement.

The Surface Water Treatment Rule (SWTR) included maximum contaminant level goals (MCLGs), for *Legionella*, *Giardia*, and viruses of zero because any amount of exposure to these contaminants represents some public health risk. Since measuring disease-causing microbes in drinking water is not considered to be feasible, EPA established a treatment technique requirement for these contaminants. The purpose of subsequent treatment technique requirements (Interim Enhanced Surface Water Treatment Rule, Long Term Surface Water Treatment Rule 1 and Long Term Surface Water Treatment Rule 2), which included an MCLG of zero for *Cryptosporidium*, is to reduce disease incidence associated with *Cryptosporidium* and other pathogenic microorganisms in drinking water. Therefore, they are excluded from the PCCL. *Cryptosporidium* and *Giardia* have a substantial amount of associated research regarding health effects and sensitivity to various treatment control measures.

The Ground Water Rule (GWR) sets treatment technique requirements to control for viruses (and pathogenic bacteria), because it was not feasible to directly monitor for viruses (or pathogenic bacteria) in drinking water. Under the GWR, if systems detect total coliforms in the distribution system, they are required to monitor for a fecal indicator (*E. coli*, coliphage, or enterococci) in the source water. If fecal contamination is found in the source water, the system must take remedial action to address contamination.

EPA did not exclude specific viruses and *Legionella* from the PCCL even though they have broad category MCLGs and treatment technique requirements. Viruses and *Legionella* include a wide range of taxa for which EPA has much less information concerning health effects and treatment information. The available information for different viral taxa (e.g., dose response and treatment data) was very limited when setting the treatment technique requirements for surface water and ground water systems. Also, different viral taxa have been implicated in various waterborne disease outbreaks in distribution systems. EPA did not have viral dose response or treatment data at the time of promulgating the treatment technique requirements. *Legionella* has been recognized as occurring in public water systems and has been recently implicated in numerous waterborne disease outbreaks (WBDOs) in distribution.

## 5.0 Data Sources Used for Screening the Microbial CCL 3 Universe

Various data sources were used to gather the information for this screening process. The data sources used were evaluated by EPA to ensure they were authoritative and appropriate. For microbes, the universe list was defined as all known human pathogens using the compilation of Taylor et al. (2001) as a practical starting point. This list was supplemented by adding fungi isolated from drinking water distribution systems that did not appear on the Taylor list, and by nominations from the scientific community, as described earlier in this report (see also *CCL 3 Microbes: Identifying the Universe*, EPA, 2007). For microbes, the data sources were sought to develop the information needed for screening (and later scoring) for the pathogens in the defined CCL 3 Microbial Universe.

The hierarchy of text-based resource materials begins with recently compiled authoritative reference books such as *The Manual of Clinical Microbiology*, 9<sup>th</sup> Edition, and *Field's Virology*, 5<sup>th</sup> Edition, both published in 2007. Both of these two-volume reference books have become established as the leading authoritative reference sources in their respective fields, both references have evolved through multiple editions, and both publications are considered reference standards to the scientific community for their scope and depth of coverage. They are edited by world-recognized authorities, and chapters are written by an international team of subject experts. *The parasites of Homo sapiens*, second edition, is a comprehensive source for information on the helminthes. These and other compiled sources listed in the reference list below were used to provide the information for screening the pathogens in the microbial CCL 3 Universe.

Primary publications were used to supplement compiled sources as necessary to support screening decisions for the fungi that were added to the CCL 3 Microbial Universe. However, some pathogens in the CCL 3 Microbial Universe were unusual or obscure, and were not covered in the compiled or primary sources. They required alternative sources, and these pathogens were searched for individually, using Web searches of authoritative on-line sources.

Web references were used to find information for screening rarely encountered viruses, protozoa, and fungi, primarily for information related to Criterion 9, “natural habitat in the environment,” or Criterion 10, “pathogen not endemic to North America”. Selected Web references were evaluated to ensure that the site sponsors possessed the expertise to authoritatively address the issues of habitat and geographical distribution of the pathogen in question, and that the information was presented objectively and reviewed by members of the scientific community. Emphasis was placed upon Web sites sponsored and supported by government agencies or academic institutions, with evidence of peer review, such as an editorial board and/or expert contributors and reviewers.

Attachment A, The CCL 3 Microbial Universe List, tabulates the screening decisions for the CCL 3 Microbial Universe, and shows the screening reference used to support the decision. Page ranges cited and Web addresses/links provided are as narrow and specific as they can be, to identify the information related to the screening criterion used. Many pathogens could be screened by several criteria, however only one criterion is noted in the tabulation. Understanding

the complete context and rationale for a screening decision often requires a review of the complete chapter from which the specified page range was taken.

## **6.0      Summary**

Properly designed screening criteria will restrict the microbial PCCL to human pathogens that may cause drinking water-related diseases from ingestion, inhalation, or dermal contact. Pathogens failing to meet these criteria will remain in the microbial universe until epidemiological surveillance data or nomination processes support their reevaluation.

Ten screening criteria and two consolidation criteria have been proposed for selection of pathogens in the microbial CCL3 universe to a PCCL. Application of these twelve criteria to the microbial CCL3 universe results in a PCCL containing 29 pathogens

<sup>1</sup>Cryptosporidium and Giardia are considered to be regulated by LT2. They were not subjected to the screening process, though they were used as examples of contaminants that need to be regulated to validate screening criteria and scoring protocols. These organisms will not be listed on CCL3.
