

Resource Survey Report

Bottom Trawl Survey

Cape Hatteras - Gulf of Maine
September 5 - October 26, 2006
R/V ALBATROSS IV

NOAA Fisheries
Northeast Fisheries Science Center
Woods Hole, MA 02543

Scientists working up a catch made up primarily of Wreckfish (*Polyprion americanus*) and Deepbody boarfish (*Antigonia capros*)

Large catch of Haddock (*Melanogrammus aeglefinus*) on northern Georges Bank

Large Atlantic cod (*Gadus morhua*) caught on Jeffreys Ledge

Deck crew changing trawl-nets between stations

Northeast Fisheries Science Center

Fall Bottom Trawl Survey

Cape Hatteras - Gulf of Maine
September 5 - October 26, 2006

This report consists of field notes, station and catch summaries and a series of geographical plots of commercially and recreationally important species caught during the Northeast Fisheries Science Center's 2006 fall bottom trawl survey conducted by the *R/V ALBATROSS IV*. Tows were made with a #36 Yankee otter trawl rigged with rollers, 5 fathom legs and 1000 pound polyvalent doors. The cod end and upper belly were lined with 1/2-inch mesh to retain young-of-the-year fish.

Because of the 30-minute tow duration, and random selection of station locations, catches can be light compared with commercial tows. Also, vessel operations are on a 24-hour basis and catches have not been adjusted for day/night differences. Nevertheless, these data can provide fishermen with useful information about the distribution and relative abundance of species inhabiting the survey area (Cape Hatteras to the Gulf of Maine).

The data are now summarized from audited catch files generated from the Fisheries Scientific Computer System (FSCS).

For further information contact Russell Brown (508-495-2380) or Linda Despres (508-495-2346), NOAA Fisheries, Northeast Fisheries Science Center, 166 Water Street, Woods Hole, MA 02543.

Field Notes

In an effort to share some of the natural history observations made during the bottom trawl survey, we have requested that the Chief Scientist on each part of the cruise comment on some of the more interesting catches that were brought aboard the *R/V ALBATROSS IV*.

No hurricanes

The first leg of the fall groundfish survey for 2006 was a welcome change in weather from the last few years. Although hurricanes threatened from the distance, there was no need to actually “play tag” in order to avoid uncomfortable seas. Mild swells in the Hatteras region were the only indication of the kind of conditions that every mariner wants to avoid.

Large shortfin squid

2006 proved to be an interesting year biologically. With each Autumn Survey there are changes, some subtle, some quite obvious, and this year was no exception. The first thing that stood out this season was the abundance of large Illex (or northern shortfin) squid, up to 11.4 inches mantle length. We have certainly captured large Illex in past years, but the average size was larger than normal. Illex larger than 11.8 inches have not been observed on the survey since 1990. We encountered more Illex squid in excess of 10.8 inches (27 cm) in the 2006 Autumn survey than during all autumn surveys conducted from 1991-2005 combined. Northern shortfin squid have a lifespan of less than one year. It would be interesting to investigate factors contributed to a more productive growth rate in 2006.

Southern shrimp in northern areas

The next major noticeable change was the abundance of penaeid shrimp. Mixed penaeid shrimp species, red, white and brown shrimp, were observed all the way up to Long Island. Many of them were quite large – perhaps not by southern standards, but certainly larger than the average northern pandalid shrimp.

Missing round herring

The other major change that caught our scientist’s attention was the lack of round herring, *Etrumeus teres*, in the offshore Mid-Atlantic Bight stations. In most years, the survey will capture large amounts of round herring in the outer three deeper water strata, but this year they were almost totally absent. They eventually started to appear inshore off the Long Island coast, but in small numbers.

Finally, there was one especially interesting capture off the Mid-Atlantic Bight, which was a first for our 40 + year time series. A perfect condition crimson rover, *Erythrocles monodi*, was captured in one of our offshore tows. It had managed to wedge itself into the mantle of a large Illex, and thus the Illex prevented the scale and fin damage that many fish encounter in a trawl. Oddly enough, fish entrapped in squid mantles are commonly observed. How they get there is a matter of speculation, but it happens quite often. The crimson rover is a member of the sea rover family, a little known family of fishes, or *Emmelichthyidae*, and it resembles a cross between a vermillion snapper and a wenchman, with the body shape of a round herring.

More supersized specimens

The largest specimens of two fish species ever taken during the history of the survey came across the deck during leg 2 of the survey. A 33.5 inch weakfish weighing a little over 14 pounds was caught on inshore station 165 (south of Pt Judith); the previous record for the largest weakfish was a 33.1 inch fish captured in the spring of 1987. This fish had a large volume of scup in its stomach. According to Bigelow and Schroeder, off southern Massachusetts, the largest fish run 6 - 10 pounds whereas most usually weigh 1 - 7 pounds and are between 14 - 28 inches long.

A 24.4 inch black sea bass weighed in at over 6 pounds and was taken on station 167 (south of Montauk). We have to go back to 1979 in order to find the next largest black sea bass caught during our surveys at 24 inches. This trophy fish had eaten crab and northern sea robin for its last meal. The all-tackle game fish record is a 10 pound fish caught at Virginia Beach, VA in January 2000 (IGFA 2001) which still stands to this day.

Species variety

The 4th leg of the fall survey was only four days long due to the progress made by the previous legs. The trip began in Cape Cod Bay and it is always interesting to see the high diversity in the bay at this time of year. We caught more than twenty different species at every station in the bay, including a few tropical strays. It is very common for spiny dogfish to school by sex, so that one gender or the other dominates the catch in an area. We also noticed that female dogfish were greatly outnumbering the males at most stations. We ended our leg with an unsuccessful attempt to grapple for the trawl door that was lost on the last station of leg 2 (our first such loss in almost a decade).

Extra Stations

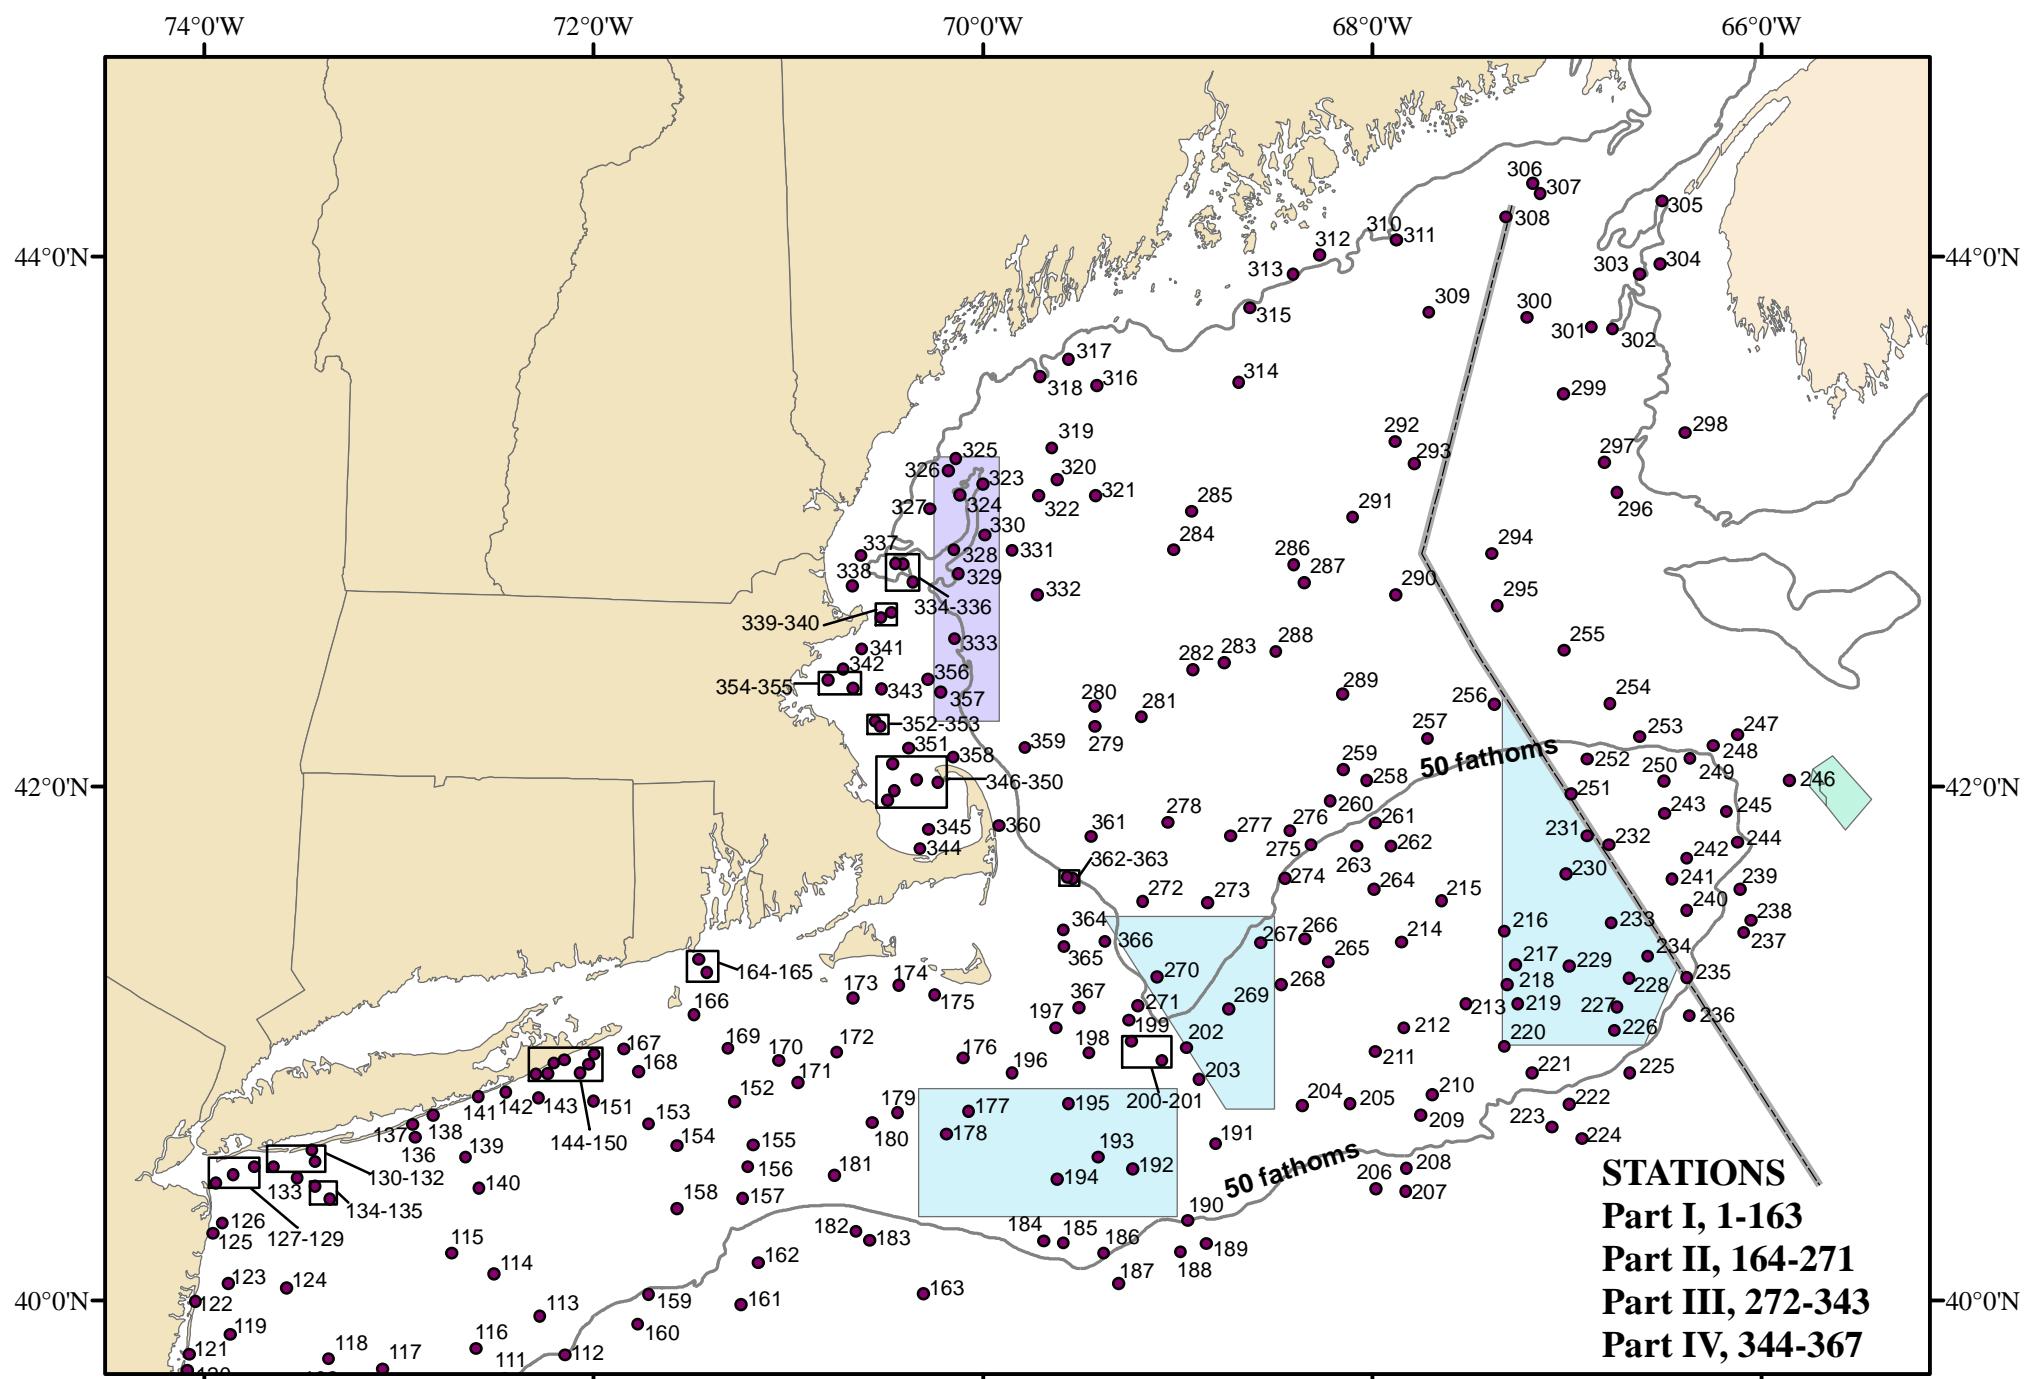

Due to a scheduling opportunity and efficient operations, we were able to complete an additional 30 random stations (approximately a 9% increase in total survey effort) during the Autumn survey. These additional survey stations were allocated to specific areas to detect yellowtail flounder recruitment in Southern New England, yellowtail flounder distributions in general on the Northeast Peak of Georges Bank, and Atlantic cod distributions in the Gulf of Maine. Completion of these stations should improve the precision of survey indices for these three stocks, and provide a clearer picture of resource distribution. Since the additional tows were randomly selected within our sampling design, data can be readily incorporated into stock assessments for these stocks. We believe that reserving a portion of the total sampling effort to be adaptively allocated to answer short term assessment and management questions should be a key consideration in the design of future surveys.
