

D. Southern New England-Mid Atlantic Yellowtail Flounder by S.X. Cadrin and C.M. Legault

1.0 Background

The southern New England-Mid Atlantic yellowtail stock was at low biomass at relatively high F in 2001 (SSB was 1,900 mt and fully recruited F was 0.91; Cadrin 2003). This report updates catch and survey indices from the SAW36 analysis and estimates 2004 fishing mortality and 2005 stock abundance.

2.0 2005 Assessment

2.1 2002-2004 Landings

U.S. landings were prorated as described in NEFSC (1998; Table D1; Figure D1). Landings from southern New England-Mid Atlantic have steadily decreased since 2001 to 165mt in 2004. Port sampling was incomplete in 2002-2004 (Table D2), and does not allow for estimation of catch at age by geographic region, market category and half-year as done in the previous assessment (Cadrin 2003). Alternatively, 2002 and first-half 2003 landings at age were estimated by stock area, market category and half-year; second-half 2003 and 2003-2004 landings at age were derived from industry-based survey samples (Figure D2) for >33cm yellowtail, not separated by market category (Table D2).

2.2 2002-2004 Discards

Discarded catch from the trawl fishery was estimated from discard to kept ratios by half-year (NEFSC 1998). Discards from the scallop dredge fishery were estimated from discard to effort, because no yellowtail were landed by the scallop dredge fishery during 2002-2004. The number of observed trips, lengths and ages for 2002-2004 increased substantially (Table D3). Proportion of discarded catch increased from 14% of total catch in 2002 to 45% in 2004 (Table D1, Figure D1), primarily from trawl discards in the second half of 2004. Discards at age were estimated from observer lengths and combined observer and survey age-length keys. Total catch at age and mean weights at age are reported in Table D4 and Figure D3.

2.3 2002-2005 Survey Indices

Survey abundance and biomass indices are reported in Table D5. Estimates are from valid tows in the southern New England-Mid Atlantic area [offshore strata 1, 2, 5, 6, 9, 10, 69, 73, 74 (strata 69, 73, 74 excluded from the fall series); scallop strata 33, 34, 35, 46], standardized according to net, vessel, and door changes (NEFSC 1998). Survey data indicate a decrease in stock biomass since the 2002 stock assessment, weak recruitment and poor survival to older ages (Figures D4 and D5).

3.0 Assessment Results

3.1 Age-Based Analysis

Results of an updated VPA calibration of southern New England-Mid Atlantic yellowtail is summarized in Table D6. This analysis updates the assessment reported by Cadrin (2003) by including 2002-2004 landings and discards, 2002-2004 scallop and fall indices, and 2002-2005 winter and spring indices. Results indicate that fishing mortality remained high during 2002-2004, averaging 0.84 (Figure D6). Spawning biomass decreased to 695mt in 2004.

Retrospective analysis indicates a reversal in 2002 of the previous pattern of overestimating SSB and underestimating F (Figure D7). Bootstrap analysis indicates that abundance was estimated with moderate precision (CV=34-47%).

Reference points for status determination were estimated from yield and SSB per recruit analyses and the assumption of constant recruitment (Cadrin 2003). Assuming that F_{MSY} is approximately $F_{40\%}$ (0.26 on fully-recruited ages) and long-term average recruitment (61.57 million at age-1), $MSY=14,200$ mt and $SSB_{MSY}=69,500$ mt. Therefore, the stock is severely overfished (2004 $SSB=1\%SSB_{MSY}$) and overfishing is occurring (2004 $F=4 \cdot F_{MSY}$). The estimate of 2004 fishing mortality (0.99) is more than twice the F desired for the rebuilding program (0.37), and 2004 SSB is approximately 10% of the projected value (Figures D8 and 9).

3.2 Biomass-Based Analysis

Due to poor sampling in the late 1990s, a biomass dynamics model (ASPIC) was applied to the southern New England-Mid Atlantic yellowtail stock assessment to provide alternative perspectives on stock status. Biomass estimates from ASPIC are greater than those from the VPA in the last ten years, and estimates of F are lower, but the ASPIC estimate of 2004 biomass is only 6% of the ASPIC estimate of B_{MSY} (Figure D10). Therefore, ASPIC results also suggest that the stock is severely overfished.

4.0 Sources of Uncertainty

- Although historical perspective from production models are valuable, current biomass levels may not be reliable, because the model assumes high productivity at low stock size.
- Estimates of prorated landings and discard ratios are based on preliminary logbook data and are subject to change.

5.0 GARM Discussion

It was noted that there a number of trips with all discard and no kept in 2004 as well as a pattern of both large and small sizes discarded. This may be due in part to the inclusion of trips not using a groundfish day-at-sea, such as those targeting summer flounder that also catch and discard yellowtail. Industry representatives noted that even though catches have been low in recent years, there has still been a directed fishery for this stock with the possible exception of 2004. There will be additional disincentives to landing yellowtail in this region next year, since 1.5 DAS will be charged for every DAS fished. Therefore, continued discarding of legal sized fish as well as discards due to boats fishing on non-groundfish trips is likely.

Differences in the estimated fishing mortality rate for old fish between the SAW36 and updated versions of the ADAPT VPA software were discounted by the Panel because so few animals are present at the old ages. The Panel recommended use of the new software because it contains a number of improvements.

It was noted that the switching direction of retrospective bias coincides with the change to using observer samples in addition to port sampling. The Panel recommended that future assessments test using port sampling alone to see if the retrospective pattern is removed.

Patterns in residuals for the ASPIC fit were noted which led to discounting of the ASPIC model results. It was also noted that recent good sampling has increased confidence in the current VPA results. The Panel agreed that VPA is most appropriate method to measure stock status.

Projection Advice - The Panel recommended the average of 1994-2004 for both mean weights at age and partial recruitment for projections because there is no trend over time. The Panel agreed on using the most recent ten years of recruits-per-SSB to account for the low values of recruitment seen in the past decade while also accounting for the low SSB. The Panel notes that this choice of recruitment differs from that used in Amendment 13 projections and would not be expected to achieve rebuilding to B_{msy} in long-term projections. However, since only short term projections will be conducted, the Panel thought the current low recruitment should be reflected in these short term projections.

Research Recommendations

- Given the large decline in the stock abundance, the Panel noted that changes in maturity would be expected and recommended that this be explored in future assessments.
- Results appear to be sensitive to the ‘oldest age’ assumption, and alternative methods should be considered for the next benchmark assessment.
- The NEFSC winter survey is now showing a trend in recent years, and should be included in future ASPIC runs.
