SYMBYAX[®]

(olanzapine and fluoxetine HCl capsules)

WARNING

5 **Suicidality and Antidepressant Drugs** — Antidepressants increased the risk compared to
6 placebo of suicidal thinking and behavior (suicidality) in children, adolescents, and young
7 adults in short-term studies of major depressive disorder (MDD) and other psychiatric
8 disorders. Anyone considering the use of SYMBYAX or any other antidepressant in a
9 child, adolescent, or young adult must balance this risk with the clinical need. Short-term
10 studies did not show an increase in the risk of suicidality with antidepressants compared to
11 placebo in adults beyond age 24; there was a reduction in risk with antidepressants
12 compared to placebo in adults aged 65 and older. Depression and certain other psychiatric
13 disorders are themselves associated with increases in the risk of suicide. Patients of all ages
14 who are started on antidepressant therapy should be monitored appropriately and
15 observed closely for clinical worsening, suicidality, or unusual changes in behavior.
16 Families and caregivers should be advised of the need for close observation and
17 communication with the prescriber. SYMBYAX is not approved for use in pediatric
18 patients. (See WARNINGS, Clinical Worsening and Suicide Risk, PRECAUTIONS,
19 Information for Patients, and PRECAUTIONS, Pediatric Use.)

20 **Increased Mortality in Elderly Patients with Dementia-Related Psychosis** — Elderly
21 patients with dementia-related psychosis treated with atypical antipsychotic drugs are at
22 an increased risk of death compared to placebo. Analyses of seventeen placebo-controlled
23 trials (modal duration of 10 weeks) in these patients revealed a risk of death in the
24 drug-treated patients of between 1.6 to 1.7 times that seen in placebo-treated patients. Over
25 the course of a typical 10-week controlled trial, the rate of death in drug-treated patients
26 was about 4.5%, compared to a rate of about 2.6% in the placebo group. Although the
27 causes of death were varied, most of the deaths appeared to be either cardiovascular (e.g.,
28 heart failure, sudden death) or infections (e.g., pneumonia) in nature. SYMBYAX
29 (olanzapine and fluoxetine HCl) is not approved for the treatment of patients with
30 dementia-related psychosis (see WARNINGS).

DESCRIPTION

31
32 SYMBYAX[®] (olanzapine and fluoxetine HCl capsules) combines 2 psychotropic agents,
33 olanzapine (the active ingredient in Zyprexa[®], and Zyprexa Zydis[®]) and fluoxetine hydrochloride
34 (the active ingredient in Prozac[®], Prozac Weekly[™], and Sarafem[®]).

35 Olanzapine belongs to the thienobenzodiazepine class. The chemical designation is 2-methyl-
36 4-(4-methyl-1-piperazinyl)-10H-thieno[2,3-b] [1,5]benzodiazepine. The molecular formula is
37 C₁₇H₂₀N₄S, which corresponds to a molecular weight of 312.44.

38 Fluoxetine hydrochloride is a selective serotonin reuptake inhibitor (SSRI). The chemical
39 designation is (±)-N-methyl-3-phenyl-3-[(α,α,α-trifluoro-*p*-tolyl)oxy]propylamine
40 hydrochloride. The molecular formula is C₁₇H₁₈F₃NO•HCl, which corresponds to a molecular
41 weight of 345.79.

42 The chemical structures are:

olanzapine

fluoxetine hydrochloride

43
44
45
46
47
48
49

Olanzapine is a yellow crystalline solid, which is practically insoluble in water.

Fluoxetine hydrochloride is a white to off-white crystalline solid with a solubility of 14 mg/mL in water.

SYMBYAX capsules are available for oral administration in the following strength combinations:

	3 mg/25 mg	6 mg/25 mg	6 mg/50 mg	12 mg/25 mg	12 mg/50 mg
olanzapine equivalent	3	6	6	12	12
fluoxetine base equivalent	25	25	50	25	50

50
51
52
53
54

Each capsule also contains pregelatinized starch, gelatin, dimethicone, titanium dioxide, sodium lauryl sulfate, edible black ink, red iron oxide, yellow iron oxide, and/or black iron oxide.

CLINICAL PHARMACOLOGY

Pharmacodynamics

Although the exact mechanism of SYMBYAX is unknown, it has been proposed that the activation of 3 monoaminergic neural systems (serotonin, norepinephrine, and dopamine) is responsible for its enhanced antidepressant effect. This is supported by animal studies in which the olanzapine/fluoxetine combination has been shown to produce synergistic increases in norepinephrine and dopamine release in the prefrontal cortex compared with either component alone, as well as increases in serotonin.

Olanzapine is a psychotropic agent with high affinity binding to the following receptors: serotonin 5HT_{2A/2C}, 5HT₆, (K_i=4, 11, and 5 nM, respectively), dopamine D₁₋₄ (K_i=11 to 31 nM), histamine H₁ (K_i=7 nM), and adrenergic α₁ receptors (K_i=19 nM). Olanzapine is an antagonist with moderate affinity binding for serotonin 5HT₃ (K_i=57 nM) and muscarinic M₁₋₅ (K_i=73, 96, 132, 32, and 48 nM, respectively). Olanzapine binds weakly to GABA_A, BZD, and β-adrenergic receptors (K_i>10 μM). Fluoxetine is an inhibitor of the serotonin transporter and is a weak inhibitor of the norepinephrine and dopamine transporters.

Antagonism at receptors other than dopamine and 5HT₂ may explain some of the other therapeutic and side effects of olanzapine. Olanzapine's antagonism of muscarinic M₁₋₅ receptors

70

71 may explain its anticholinergic-like effects. The antagonism of histamine H₁ receptors by
72 olanzapine may explain the somnolence observed with this drug. The antagonism of
73 α_1 -adrenergic receptors by olanzapine may explain the orthostatic hypotension observed with
74 this drug. Fluoxetine has relatively low affinity for muscarinic, α_1 -adrenergic, and histamine H₁
75 receptors.

76 **Pharmacokinetics**

77 Fluoxetine (administered as a 60-mg single dose or 60 mg daily for 8 days) caused a small
78 increase in the mean maximum concentration of olanzapine (16%) following a 5-mg dose, an
79 increase in the mean area under the curve (17%) and a small decrease in mean apparent clearance
80 of olanzapine (16%). In another study, a similar decrease in apparent clearance of olanzapine of
81 14% was observed following olanzapine doses of 6 or 12 mg with concomitant fluoxetine doses
82 of 25 mg or more. The decrease in clearance reflects an increase in bioavailability. The terminal
83 half-life is not affected, and therefore the time to reach steady state should not be altered. The
84 overall steady-state plasma concentrations of olanzapine and fluoxetine when given as the
85 combination in the therapeutic dose ranges were comparable with those typically attained with
86 each of the monotherapies. The small change in olanzapine clearance, observed in both studies,
87 likely reflects the inhibition of a minor metabolic pathway for olanzapine via CYP2D6 by
88 fluoxetine, a potent CYP2D6 inhibitor, and was not deemed clinically significant. Therefore, the
89 pharmacokinetics of the individual components is expected to reasonably characterize the overall
90 pharmacokinetics of the combination.

91 **Absorption and Bioavailability**

92 **SYMBYAX** — Following a single oral 12-mg/50-mg dose of SYMBYAX, peak plasma
93 concentrations of olanzapine and fluoxetine occur at approximately 4 and 6 hours, respectively.
94 The effect of food on the absorption and bioavailability of SYMBYAX has not been evaluated.
95 The bioavailability of olanzapine given as Zyprexa, and the bioavailability of fluoxetine given as
96 Prozac were not affected by food. It is unlikely that there would be a significant food effect on
97 the bioavailability of SYMBYAX.

98 **Olanzapine** — Olanzapine is well absorbed and reaches peak concentration approximately 6
99 hours following an oral dose. Food does not affect the rate or extent of olanzapine absorption
100 when olanzapine is given as Zyprexa. It is eliminated extensively by first pass metabolism, with
101 approximately 40% of the dose metabolized before reaching the systemic circulation.

102 **Fluoxetine** — Following a single oral 40-mg dose, peak plasma concentrations of fluoxetine
103 from 15 to 55 ng/mL are observed after 6 to 8 hours. Food does not appear to affect the systemic
104 bioavailability of fluoxetine given as Prozac, although it may delay its absorption by 1 to 2
105 hours, which is probably not clinically significant.

106 **Distribution**

107 **SYMBYAX** — The in vitro binding to human plasma proteins of the olanzapine/fluoxetine
108 combination is similar to the binding of the individual components.

109 **Olanzapine** — Olanzapine is extensively distributed throughout the body, with a volume of
110 distribution of approximately 1000 L. It is 93% bound to plasma proteins over the concentration
111 range of 7 to 1100 ng/mL, binding primarily to albumin and α_1 -acid glycoprotein.

112 **Fluoxetine** — Over the concentration range from 200 to 1000 ng/mL, approximately 94.5% of
113 fluoxetine is bound in vitro to human serum proteins, including albumin and α_1 -glycoprotein.
114 The interaction between fluoxetine and other highly protein-bound drugs has not been fully
115 evaluated (*see* PRECAUTIONS, Drugs tightly bound to plasma proteins).

116 **Metabolism and Elimination**

117 **SYMBYAX** — SYMBYAX therapy yielded steady-state concentrations of norfluoxetine
118 similar to those seen with fluoxetine in the therapeutic dose range.

119 **Olanzapine** — Olanzapine displays linear pharmacokinetics over the clinical dosing range. Its
120 half-life ranges from 21 to 54 hours (5th to 95th percentile; mean of 30 hr), and apparent plasma
121 clearance ranges from 12 to 47 L/hr (5th to 95th percentile; mean of 25 L/hr). Administration of
122 olanzapine once daily leads to steady-state concentrations in about 1 week that are approximately
123 twice the concentrations after single doses. Plasma concentrations, half-life, and clearance of
124 olanzapine may vary between individuals on the basis of smoking status, gender, and age (*see*
125 *Special Populations*).

126 Following a single oral dose of ¹⁴C-labeled olanzapine, 7% of the dose of olanzapine was
127 recovered in the urine as unchanged drug, indicating that olanzapine is highly metabolized.
128 Approximately 57% and 30% of the dose was recovered in the urine and feces, respectively. In
129 the plasma, olanzapine accounted for only 12% of the AUC for total radioactivity, indicating
130 significant exposure to metabolites. After multiple dosing, the major circulating metabolites were
131 the 10-N-glucuronide, present at steady state at 44% of the concentration of olanzapine, and
132 4'-N-desmethyl olanzapine, present at steady state at 31% of the concentration of olanzapine.
133 Both metabolites lack pharmacological activity at the concentrations observed.

134 Direct glucuronidation and CYP450-mediated oxidation are the primary metabolic pathways
135 for olanzapine. In vitro studies suggest that CYP1A2, CYP2D6, and the flavin-containing
136 monooxygenase system are involved in olanzapine oxidation. CYP2D6-mediated oxidation
137 appears to be a minor metabolic pathway in vivo, because the clearance of olanzapine is not
138 reduced in subjects who are deficient in this enzyme.

139 **Fluoxetine** — Fluoxetine is a racemic mixture (50/50) of *R*-fluoxetine and *S*-fluoxetine
140 enantiomers. In animal models, both enantiomers are specific and potent serotonin uptake
141 inhibitors with essentially equivalent pharmacologic activity. The *S*-fluoxetine enantiomer is
142 eliminated more slowly and is the predominant enantiomer present in plasma at steady state.

143 Fluoxetine is extensively metabolized in the liver to its only identified active metabolite,
144 norfluoxetine, via the CYP2D6 pathway. A number of unidentified metabolites exist.

145 In animal models, *S*-norfluoxetine is a potent and selective inhibitor of serotonin uptake and
146 has activity essentially equivalent to *R*- or *S*-fluoxetine. *R*-norfluoxetine is significantly less
147 potent than the parent drug in the inhibition of serotonin uptake. The primary route of
148 elimination appears to be hepatic metabolism to inactive metabolites excreted by the kidney.

149 **Clinical Issues Related to Metabolism and Elimination** — The complexity of the
150 metabolism of fluoxetine has several consequences that may potentially affect the clinical use of
151 SYMBYAX.

152 Variability in metabolism — A subset (about 7%) of the population has reduced activity of the
153 drug metabolizing enzyme CYP2D6. Such individuals are referred to as “poor metabolizers” of
154 drugs such as debrisoquin, dextromethorphan, and the tricyclic antidepressants (TCAs). In a
155 study involving labeled and unlabeled enantiomers administered as a racemate, these individuals
156 metabolized *S*-fluoxetine at a slower rate and thus achieved higher concentrations of
157 *S*-fluoxetine. Consequently, concentrations of *S*-norfluoxetine at steady state were lower. The
158 metabolism of *R*-fluoxetine in these poor metabolizers appears normal. When compared with
159 normal metabolizers, the total sum at steady state of the plasma concentrations of the 4
160 enantiomers was not significantly greater among poor metabolizers. Thus, the net
161 pharmacodynamic activities were essentially the same. Alternative nonsaturable pathways

162 (non-CYP2D6) also contribute to the metabolism of fluoxetine. This explains how fluoxetine
163 achieves a steady-state concentration rather than increasing without limit.

164 Because the metabolism of fluoxetine, like that of a number of other compounds including
165 TCAs and other selective serotonin antidepressants, involves the CYP2D6 system, concomitant
166 therapy with drugs also metabolized by this enzyme system (such as the TCAs) may lead to drug
167 interactions (*see* PRECAUTIONS, Drug Interactions).

168 Accumulation and slow elimination — The relatively slow elimination of fluoxetine
169 (elimination half-life of 1 to 3 days after acute administration and 4 to 6 days after chronic
170 administration) and its active metabolite, norfluoxetine (elimination half-life of 4 to 16 days after
171 acute and chronic administration), leads to significant accumulation of these active species in
172 chronic use and delayed attainment of steady state, even when a fixed dose is used. After 30 days
173 of dosing at 40 mg/day, plasma concentrations of fluoxetine in the range of 91 to 302 ng/mL and
174 norfluoxetine in the range of 72 to 258 ng/mL have been observed. Plasma concentrations of
175 fluoxetine were higher than those predicted by single-dose studies, because the metabolism of
176 fluoxetine is not proportional to dose. However, norfluoxetine appears to have linear
177 pharmacokinetics. Its mean terminal half-life after a single dose was 8.6 days and after multiple
178 dosing was 9.3 days. Steady-state levels after prolonged dosing are similar to levels seen at 4 to 5
179 weeks.

180 The long elimination half-lives of fluoxetine and norfluoxetine assure that, even when dosing
181 is stopped, active drug substance will persist in the body for weeks (primarily depending on
182 individual patient characteristics, previous dosing regimen, and length of previous therapy at
183 discontinuation). This is of potential consequence when drug discontinuation is required or when
184 drugs are prescribed that might interact with fluoxetine and norfluoxetine following the
185 discontinuation of fluoxetine.

186 **Special Populations**

187 **Geriatric** — Based on the individual pharmacokinetic profiles of olanzapine and fluoxetine,
188 the pharmacokinetics of SYMBYAX may be altered in geriatric patients. Caution should be used
189 in dosing the elderly, especially if there are other factors that might additively influence drug
190 metabolism and/or pharmacodynamic sensitivity.

191 In a study involving 24 healthy subjects, the mean elimination half-life of olanzapine was
192 about 1.5 times greater in elderly subjects (>65 years of age) than in non-elderly subjects (≤65
193 years of age).

194 The disposition of single doses of fluoxetine in healthy elderly subjects (>65 years of age) did
195 not differ significantly from that in younger normal subjects. However, given the long half-life
196 and nonlinear disposition of the drug, a single-dose study is not adequate to rule out the
197 possibility of altered pharmacokinetics in the elderly, particularly if they have systemic illness or
198 are receiving multiple drugs for concomitant diseases. The effects of age upon the metabolism of
199 fluoxetine have been investigated in 260 elderly but otherwise healthy depressed patients (≥60
200 years of age) who received 20 mg fluoxetine for 6 weeks. Combined fluoxetine plus
201 norfluoxetine plasma concentrations were 209.3 ± 85.7 ng/mL at the end of 6 weeks. No unusual
202 age-associated pattern of adverse events was observed in those elderly patients.

203 **Renal Impairment** — The pharmacokinetics of SYMBYAX has not been studied in patients
204 with renal impairment. However, olanzapine and fluoxetine individual pharmacokinetics do not
205 differ significantly in patients with renal impairment. SYMBYAX dosing adjustment based upon
206 renal impairment is not routinely required.

207 Because olanzapine is highly metabolized before excretion and only 7% of the drug is excreted
208 unchanged, renal dysfunction alone is unlikely to have a major impact on the pharmacokinetics
209 of olanzapine. The pharmacokinetic characteristics of olanzapine were similar in patients with
210 severe renal impairment and normal subjects, indicating that dosage adjustment based upon the
211 degree of renal impairment is not required. In addition, olanzapine is not removed by dialysis.
212 The effect of renal impairment on olanzapine metabolite elimination has not been studied.

213 In depressed patients on dialysis (N=12), fluoxetine administered as 20 mg once daily for 2
214 months produced steady-state fluoxetine and norfluoxetine plasma concentrations comparable
215 with those seen in patients with normal renal function. While the possibility exists that renally
216 excreted metabolites of fluoxetine may accumulate to higher levels in patients with severe renal
217 dysfunction, use of a lower or less frequent dose is not routinely necessary in renally impaired
218 patients.

219 **Hepatic Impairment** — Based on the individual pharmacokinetic profiles of olanzapine and
220 fluoxetine, the pharmacokinetics of SYMBYAX may be altered in patients with hepatic
221 impairment. The lowest starting dose should be considered for patients with hepatic impairment
222 (*see* PRECAUTIONS, Use in Patients with Concomitant Illness *and* DOSAGE AND
223 ADMINISTRATION, Special Populations).

224 Although the presence of hepatic impairment may be expected to reduce the clearance of
225 olanzapine, a study of the effect of impaired liver function in subjects (N=6) with clinically
226 significant cirrhosis (Childs-Pugh Classification A and B) revealed little effect on the
227 pharmacokinetics of olanzapine.

228 As might be predicted from its primary site of metabolism, liver impairment can affect the
229 elimination of fluoxetine. The elimination half-life of fluoxetine was prolonged in a study of
230 cirrhotic patients, with a mean of 7.6 days compared with the range of 2 to 3 days seen in
231 subjects without liver disease; norfluoxetine elimination was also delayed, with a mean duration
232 of 12 days for cirrhotic patients compared with the range of 7 to 9 days in normal subjects.

233 **Gender** — Clearance of olanzapine is approximately 30% lower in women than in men. There
234 were, however, no apparent differences between men and women in effectiveness or adverse
235 effects. Dosage modifications based on gender should not be needed.

236 **Smoking Status** — Olanzapine clearance is about 40% higher in smokers than in nonsmokers,
237 although dosage modifications are not routinely required.

238 **Race** — No SYMBYAX pharmacokinetic study was conducted to investigate the effects of
239 race. In vivo studies have shown that exposures to olanzapine are similar among Japanese,
240 Chinese and Caucasians, especially after normalization for body weight differences. Dosage
241 modifications for race, therefore, are not routinely required.

242 **Combined Effects** — The combined effects of age, smoking, and gender could lead to
243 substantial pharmacokinetic differences in populations. The clearance of olanzapine in young
244 smoking males, for example, may be 3 times higher than that in elderly nonsmoking females.
245 SYMBYAX dosing modification may be necessary in patients who exhibit a combination of
246 factors that may result in slower metabolism of the olanzapine component (*see* DOSAGE AND
247 ADMINISTRATION, Special Populations).

248 **CLINICAL STUDIES**

249 The efficacy of SYMBYAX for the treatment of depressive episodes associated with bipolar
250 disorder was established in 2 identically designed, 8-week, randomized, double-blind, controlled
251 studies of patients who met Diagnostic and Statistical Manual 4th edition (DSM-IV) criteria for
252 Bipolar I Disorder, Depressed utilizing flexible dosing of SYMBYAX (6/25, 6/50, or

253 12/50 mg/day), olanzapine (5 to 20 mg/day), and placebo. These studies included patients (≥ 18
 254 years of age) with or without psychotic symptoms and with or without a rapid cycling course.

255 The primary rating instrument used to assess depressive symptoms in these studies was the
 256 Montgomery-Asberg Depression Rating Scale (MADRS), a 10-item clinician-rated scale with
 257 total scores ranging from 0 to 60. The primary outcome measure of these studies was the change
 258 from baseline to endpoint in the MADRS total score. In both studies, SYMBYAX was
 259 statistically significantly superior to both olanzapine monotherapy and placebo in reduction of
 260 the MADRS total score. The results of the studies are summarized below (Table 1).

261
 262 **Table 1: MADRS Total Score**
 263 **Mean Change from Baseline to Endpoint**

	Treatment Group	Baseline Mean	Change to Endpoint Mean¹
Study 1	SYMBYAX (N=40)	30	-16 ^a
	Olanzapine (N=182)	32	-12
	Placebo (N=181)	31	-10
Study 2	SYMBYAX (N=42)	32	-18 ^a
	Olanzapine (N=169)	33	-14
	Placebo (N=174)	31	-9

264 ¹ Negative number denotes improvement from baseline.

265 ^a Statistically significant compared to both olanzapine and placebo.
 266

267 **INDICATIONS AND USAGE**

268 SYMBYAX is indicated for the treatment of depressive episodes associated with bipolar
 269 disorder. The efficacy of SYMBYAX was established in 2 identically designed, 8-week,
 270 randomized, double-blind clinical studies.

271 Unlike with unipolar depression, there are no established guidelines for the length of time
 272 patients with bipolar disorder experiencing a major depressive episode should be treated with
 273 agents containing antidepressant drugs.

274 The effectiveness of SYMBYAX for maintaining antidepressant response in this patient
 275 population beyond 8 weeks has not been established in controlled clinical studies. Physicians
 276 who elect to use SYMBYAX for extended periods should periodically reevaluate the benefits
 277 and long-term risks of the drug for the individual patient.

278 **CONTRAINDICATIONS**

279 **Hypersensitivity** — SYMBYAX is contraindicated in patients with a known hypersensitivity
 280 to the product or any component of the product.

281 **Monoamine Oxidase Inhibitors (MAOI)** — There have been reports of serious, sometimes
 282 fatal reactions (including hyperthermia, rigidity, myoclonus, autonomic instability with possible
 283 rapid fluctuations of vital signs, and mental status changes that include extreme agitation
 284 progressing to delirium and coma) in patients receiving fluoxetine in combination with an
 285 MAOI, and in patients who have recently discontinued fluoxetine and are then started on an

286 MAOI. Some cases presented with features resembling neuroleptic malignant syndrome.
 287 Therefore, SYMBYAX should not be used in combination with an MAOI, or within a minimum
 288 of 14 days of discontinuing therapy with an MAOI. Since fluoxetine and its major metabolite
 289 have very long elimination half-lives, at least 5 weeks [perhaps longer, especially if fluoxetine
 290 has been prescribed chronically and/or at higher doses (*see* CLINICAL PHARMACOLOGY,
 291 Accumulation and slow elimination)] should be allowed after stopping SYMBYAX before
 292 starting an MAOI.

293 **Pimozide** — Concomitant use in patients taking pimozide is contraindicated (*see*
 294 PRECAUTIONS).

295 **Thioridazine** — Thioridazine should not be administered with SYMBYAX or administered
 296 within a minimum of 5 weeks after discontinuation of SYMBYAX (*see* WARNINGS,
 297 Thioridazine).

298 WARNINGS

299 **Clinical Worsening and Suicide Risk** — Patients with major depressive disorder (MDD),
 300 both adult and pediatric, may experience worsening of their depression and/or the emergence of
 301 suicidal ideation and behavior (suicidality) or unusual changes in behavior, whether or not they
 302 are taking antidepressant medications, and this risk may persist until significant remission
 303 occurs. Suicide is a known risk of depression and certain other psychiatric disorders, and these
 304 disorders themselves are the strongest predictors of suicide. There has been a long-standing
 305 concern, however, that antidepressants may have a role in inducing worsening of depression and
 306 the emergence of suicidality in certain patients during the early phases of treatment. Pooled
 307 analyses of short-term placebo-controlled trials of antidepressant drugs (SSRIs and others)
 308 showed that these drugs increase the risk of suicidal thinking and behavior (suicidality) in
 309 children, adolescents, and young adults (ages 18-24) with major depressive disorder (MDD) and
 310 other psychiatric disorders. Short-term studies did not show an increase in the risk of suicidality
 311 with antidepressants compared to placebo in adults beyond age 24; there was a reduction with
 312 antidepressants compared to placebo in adults aged 65 and older.

313 The pooled analyses of placebo-controlled trials in children and adolescents with MDD,
 314 obsessive compulsive disorder (OCD), or other psychiatric disorders included a total of 24
 315 short-term trials of 9 antidepressant drugs in over 4400 patients. The pooled analyses of placebo-
 316 controlled trials in adults with MDD or other psychiatric disorders included a total of 295 short-
 317 term trials (median duration of 2 months) of 11 antidepressant drugs in over 77,000 patients.
 318 There was considerable variation in risk of suicidality among drugs, but a tendency toward an
 319 increase in the younger patients for almost all drugs studied. There were differences in absolute
 320 risk of suicidality across the different indications, with the highest incidence in MDD. The risk
 321 differences (drug versus placebo), however, were relatively stable within age strata and across
 322 indications. These risk differences (drug-placebo difference in the number of cases of suicidality
 323 per 1000 patients treated) are provided in Table 2.

324 **Table 2**

Age Range	Drug-Placebo Difference in Number of Cases of Suicidality per 1000 Patients Treated
	Increases Compared to Placebo
<18	14 additional cases
18-24	5 additional cases

	Decreases Compared to Placebo
25-64	1 fewer case
≥65	6 fewer cases

326

327 No suicides occurred in any of the pediatric trials. There were suicides in the adult trials, but
 328 the number was not sufficient to reach any conclusion about drug effect on suicide.

329 It is unknown whether the suicidality risk extends to longer-term use, i.e., beyond several
 330 months. However, there is substantial evidence from placebo-controlled maintenance trials in
 331 adults with depression that the use of antidepressants can delay the recurrence of depression.

332 **All patients being treated with antidepressants for any indication should be monitored**
 333 **appropriately and observed closely for clinical worsening, suicidality, and unusual changes**
 334 **in behavior, especially during the initial few months of a course of drug therapy, or at times**
 335 **of dose changes, either increases or decreases.**

336 The following symptoms, anxiety, agitation, panic attacks, insomnia, irritability, hostility,
 337 aggressiveness, impulsivity, akathisia (psychomotor restlessness), hypomania, and mania, have
 338 been reported in adult and pediatric patients being treated with antidepressants for major
 339 depressive disorder as well as for other indications, both psychiatric and nonpsychiatric.
 340 Although a causal link between the emergence of such symptoms and either the worsening of
 341 depression and/or the emergence of suicidal impulses has not been established, there is concern
 342 that such symptoms may represent precursors to emerging suicidality.

343 Consideration should be given to changing the therapeutic regimen, including possibly
 344 discontinuing the medication, in patients whose depression is persistently worse, or who are
 345 experiencing emergent suicidality or symptoms that might be precursors to worsening depression
 346 or suicidality, especially if these symptoms are severe, abrupt in onset, or were not part of the
 347 patient's presenting symptoms.

348 If the decision has been made to discontinue treatment, medication should be tapered, as
 349 rapidly as is feasible, but with recognition that abrupt discontinuation can be associated with
 350 certain symptoms (*see* PRECAUTIONS and DOSAGE AND ADMINISTRATION,
 351 Discontinuation of Treatment with SYMBYAX, for a description of the risks of discontinuation
 352 of SYMBYAX).

353 **Families and caregivers of patients being treated with antidepressants for major**
 354 **depressive disorder or other indications, both psychiatric and nonpsychiatric, should be**
 355 **alerted about the need to monitor patients for the emergence of agitation, irritability,**
 356 **unusual changes in behavior, and the other symptoms described above, as well as the**
 357 **emergence of suicidality, and to report such symptoms immediately to health care**
 358 **providers. Such monitoring should include daily observation by families and caregivers.**
 359 Prescriptions for SYMBYAX should be written for the smallest quantity of capsules consistent
 360 with good patient management, in order to reduce the risk of overdose.

361 It should be noted that SYMBYAX is not approved for use in treating any indications in the
 362 pediatric population.

363 **Screening Patients for Bipolar Disorder** — A major depressive episode may be the initial
 364 presentation of bipolar disorder. It is generally believed (though not established in controlled
 365 trials) that treating such an episode with an antidepressant alone may increase the likelihood of
 366 precipitation of a mixed/manic episode in patients at risk for bipolar disorder. Whether any of the
 367 symptoms described above represent such a conversion is unknown. However, prior to initiating
 368 treatment with an antidepressant, patients with depressive symptoms should be adequately

369 screened to determine if they are at risk for bipolar disorder; such screening should include a
370 detailed psychiatric history, including a family history of suicide, bipolar disorder, and
371 depression. It should be noted that SYMBYAX is approved for use in treating bipolar
372 depression.

373 **Increased Mortality in Elderly Patients with Dementia-Related Psychosis — Elderly**
374 **patients with dementia-related psychosis treated with atypical antipsychotic drugs are at**
375 **an increased risk of death compared to placebo. SYMBYAX (olanzapine and**
376 **fluoxetine HCl) is not approved for the treatment of patients with dementia-related**
377 **psychosis (see BOX WARNING).**

378 In olanzapine placebo-controlled clinical trials of elderly patients with dementia-related
379 psychosis, the incidence of death in olanzapine-treated patients was significantly greater than
380 placebo-treated patients (3.5% vs 1.5%, respectively).

381 **Cerebrovascular Adverse Events (CVAE), Including Stroke, in Elderly Patients with**
382 **Dementia-Related Psychosis** — Cerebrovascular adverse events (e.g., stroke, transient ischemic
383 attack), including fatalities, were reported in patients in trials of olanzapine in elderly patients
384 with dementia-related psychosis. In placebo-controlled trials, there was a significantly higher
385 incidence of cerebrovascular adverse events in patients treated with olanzapine compared to
386 patients treated with placebo. Olanzapine is not approved for the treatment of patients with
387 dementia-related psychosis.

388 **Hyperglycemia and Diabetes Mellitus** — Hyperglycemia, in some cases extreme and
389 associated with ketoacidosis or hyperosmolar coma or death, has been reported in patients treated
390 with atypical antipsychotics, including olanzapine alone, as well as olanzapine taken
391 concomitantly with fluoxetine. Assessment of the relationship between atypical antipsychotic use
392 and glucose abnormalities is complicated by the possibility of an increased background risk of
393 diabetes mellitus in patients with schizophrenia and the increasing incidence of diabetes mellitus
394 in the general population. Given these confounders, the relationship between atypical
395 antipsychotic use and hyperglycemia-related adverse events is not completely understood.
396 However, epidemiological studies suggest an increased risk of treatment-emergent
397 hyperglycemia-related adverse events in patients treated with the atypical antipsychotics. Precise
398 risk estimates for hyperglycemia-related adverse events in patients treated with atypical
399 antipsychotics are not available.

400 Patients with an established diagnosis of diabetes mellitus who are started on atypical
401 antipsychotics should be monitored regularly for worsening of glucose control. Patients with risk
402 factors for diabetes mellitus (e.g., obesity, family history of diabetes) who are starting treatment
403 with atypical antipsychotics should undergo fasting blood glucose testing at the beginning of
404 treatment and periodically during treatment. Any patient treated with atypical antipsychotics
405 should be monitored for symptoms of hyperglycemia including polydipsia, polyuria, polyphagia,
406 and weakness. Patients who develop symptoms of hyperglycemia during treatment with atypical
407 antipsychotics should undergo fasting blood glucose testing. In some cases, hyperglycemia has
408 resolved when the atypical antipsychotic was discontinued; however, some patients required
409 continuation of anti-diabetic treatment despite discontinuation of the suspect drug.

410 **Orthostatic Hypotension** — SYMBYAX may induce orthostatic hypotension associated with
411 dizziness, tachycardia, bradycardia, and in some patients, syncope, especially during the initial
412 dose-titration period.

413 In the bipolar depression studies, statistically significantly more orthostatic changes occurred
414 with the SYMBYAX group compared to placebo and olanzapine groups. Orthostatic systolic

415 blood pressure decrease of at least 30 mm Hg occurred in 7.3% (6/82), 1.4% (5/346), and 1.4%
416 (5/352) of the SYMBYAX, olanzapine and placebo groups, respectively. Among the group of
417 controlled clinical studies with SYMBYAX, an orthostatic systolic blood pressure decrease of \geq
418 30 mm Hg occurred in 4% (21/512) of SYMBYAX-treated patients, 5% (10/204) of
419 fluoxetine-treated patients, 2% (16/644) of olanzapine-treated patients, and 2% (8/445) of
420 placebo-treated patients. In this group of studies, the incidence of syncope in SYMBYAX-treated
421 patients was 0.4% (2/571) compared to placebo 0.2% (1/477).

422 In a clinical pharmacology study of SYMBYAX, three healthy subjects were discontinued
423 from the trial after experiencing severe, but self-limited, hypotension and bradycardia that
424 occurred 2 to 9 hours following a single 12-mg/50-mg dose of SYMBYAX. Reactions consisting
425 of this combination of hypotension and bradycardia (and also accompanied by sinus pause) have
426 been observed in at least three other healthy subjects treated with various formulations of
427 olanzapine (one oral, two intramuscular). In controlled clinical studies, the incidence of patients
428 with a ≥ 20 bpm decrease in orthostatic pulse concomitantly with a ≥ 20 mm Hg decrease in
429 orthostatic systolic blood pressure was 0.4% (2/549) in the SYMBYAX group, 0.2% (1/455) in
430 the placebo group, 0.8% (5/659) in the olanzapine group, and 0% (0/241) in the fluoxetine group.

431 SYMBYAX should be used with particular caution in patients with known cardiovascular
432 disease (history of myocardial infarction or ischemia, heart failure, or conduction abnormalities),
433 cerebrovascular disease, or conditions that would predispose patients to hypotension
434 (dehydration, hypovolemia, and treatment with antihypertensive medications).

435 **Allergic Events and Rash** — In SYMBYAX premarketing controlled clinical studies, the
436 overall incidence of rash or allergic events in SYMBYAX-treated patients [4.6% (26/571)] was
437 similar to that of placebo [5.2% (25/477)]. The majority of the cases of rash and/or urticaria were
438 mild; however, three patients discontinued (one due to rash, which was moderate in severity, and
439 two due to allergic events, one of which included face edema).

440 In fluoxetine US clinical studies, 7% of 10,782 fluoxetine-treated patients developed various
441 types of rashes and/or urticaria. Among the cases of rash and/or urticaria reported in
442 premarketing clinical studies, almost a third were withdrawn from treatment because of the rash
443 and/or systemic signs or symptoms associated with the rash. Clinical findings reported in
444 association with rash include fever, leukocytosis, arthralgias, edema, carpal tunnel syndrome,
445 respiratory distress, lymphadenopathy, proteinuria, and mild transaminase elevation. Most
446 patients improved promptly with discontinuation of fluoxetine and/or adjunctive treatment with
447 antihistamines or steroids, and all patients experiencing these events were reported to recover
448 completely.

449 In fluoxetine premarketing clinical studies, 2 patients are known to have developed a serious
450 cutaneous systemic illness. In neither patient was there an unequivocal diagnosis, but 1 was
451 considered to have a leukocytoclastic vasculitis, and the other, a severe desquamating syndrome
452 that was considered variously to be a vasculitis or erythema multiforme. Other patients have had
453 systemic syndromes suggestive of serum sickness.

454 Since the introduction of fluoxetine, systemic events, possibly related to vasculitis, have
455 developed in patients with rash. Although these events are rare, they may be serious, involving
456 the lung, kidney, or liver. Death has been reported to occur in association with these systemic
457 events.

458 Anaphylactoid events, including bronchospasm, angioedema, and urticaria alone and in
459 combination, have been reported.

460 Pulmonary events, including inflammatory processes of varying histopathology and/or fibrosis,
461 have been reported rarely. These events have occurred with dyspnea as the only preceding
462 symptom.

463 Whether these systemic events and rash have a common underlying cause or are due to
464 different etiologies or pathogenic processes is not known. Furthermore, a specific underlying
465 immunologic basis for these events has not been identified. Upon the appearance of rash or of
466 other possible allergic phenomena for which an alternative etiology cannot be identified,
467 SYMBYAX should be discontinued.

468 **Serotonin Syndrome** — The development of a potentially life-threatening serotonin syndrome
469 may occur with SNRIs and SSRIs, including SYMBYAX treatment, particularly with
470 concomitant use of serotonergic drugs (including triptans) and with drugs which impair
471 metabolism of serotonin (including MAOIs). Serotonin syndrome symptoms may include mental
472 status changes (e.g., agitation, hallucinations, coma), autonomic instability (e.g., tachycardia,
473 labile blood pressure, hyperthermia), neuromuscular aberrations (e.g., hyperreflexia,
474 incoordination) and/or gastrointestinal symptoms (e.g., nausea, vomiting, diarrhea).

475 The concomitant use of SYMBYAX with MAOIs intended to treat depression is
476 contraindicated (*see* CONTRAINDICATIONS, Monoamine Oxidase Inhibitors (MAOI) *and*
477 PRECAUTIONS, Drug Interactions).

478 If concomitant treatment of SYMBYAX with a 5-hydroxytryptamine receptor agonist (triptan)
479 is clinically warranted, careful observation of the patient is advised, particularly during treatment
480 initiation and dose increases (*see* PRECAUTIONS, Drug Interactions).

481 The concomitant use of SYMBYAX with serotonin precursors (such as tryptophan) is not
482 recommended (*see* PRECAUTIONS, Drug Interactions).

483 **Neuroleptic Malignant Syndrome (NMS)** — A potentially fatal symptom complex
484 sometimes referred to as NMS has been reported in association with administration of
485 antipsychotic drugs, including olanzapine. Clinical manifestations of NMS are hyperpyrexia,
486 muscle rigidity, altered mental status, and evidence of autonomic instability (irregular pulse or
487 blood pressure, tachycardia, diaphoresis, and cardiac dysrhythmia). Additional signs may include
488 elevated creatinine phosphokinase, myoglobinuria (rhabdomyolysis), and acute renal failure.

489 The diagnostic evaluation of patients with this syndrome is complicated. In arriving at a
490 diagnosis, it is important to exclude cases where the clinical presentation includes both serious
491 medical illness (e.g., pneumonia, systemic infection, etc.) and untreated or inadequately treated
492 extrapyramidal signs and symptoms (EPS). Other important considerations in the differential
493 diagnosis include central anticholinergic toxicity, heat stroke, drug fever, and primary central
494 nervous system pathology.

495 The management of NMS should include: 1) immediate discontinuation of antipsychotic drugs
496 and other drugs not essential to concurrent therapy, 2) intensive symptomatic treatment and
497 medical monitoring, and 3) treatment of any concomitant serious medical problems for which
498 specific treatments are available. There is no general agreement about specific pharmacological
499 treatment regimens for NMS.

500 If after recovering from NMS, a patient requires treatment with an antipsychotic, the patient
501 should be carefully monitored, since recurrences of NMS have been reported.

502 **Tardive Dyskinesia** — A syndrome of potentially irreversible, involuntary, dyskinetic
503 movements may develop in patients treated with antipsychotic drugs. Although the prevalence of
504 the syndrome appears to be highest among the elderly, especially elderly women, it is impossible
505 to rely upon prevalence estimates to predict, at the inception of antipsychotic treatment, which

506 patients are likely to develop the syndrome. Whether antipsychotic drug products differ in their
507 potential to cause tardive dyskinesia is unknown.

508 The risk of developing tardive dyskinesia and the likelihood that it will become irreversible are
509 believed to increase as the duration of treatment and the total cumulative dose of antipsychotic
510 drugs administered to the patient increase. However, the syndrome can develop, although much
511 less commonly, after relatively brief treatment periods at low doses or may even arise after
512 discontinuation of treatment.

513 There is no known treatment for established cases of tardive dyskinesia, although the syndrome
514 may remit, partially or completely, if antipsychotic treatment is withdrawn. Antipsychotic
515 treatment itself, however, may suppress (or partially suppress) the signs and symptoms of the
516 syndrome and thereby may possibly mask the underlying process. The effect that symptomatic
517 suppression has upon the long-term course of the syndrome is unknown.

518 The incidence of dyskinetic movement in SYMBYAX-treated patients was infrequent. The
519 mean score on the Abnormal Involuntary Movement Scale (AIMS) across clinical studies
520 involving SYMBYAX-treated patients decreased from baseline. Nonetheless, SYMBYAX
521 should be prescribed in a manner that is most likely to minimize the risk of tardive dyskinesia. If
522 signs and symptoms of tardive dyskinesia appear in a patient on SYMBYAX, drug
523 discontinuation should be considered. However, some patients may require treatment with
524 SYMBYAX despite the presence of the syndrome. The need for continued treatment should be
525 reassessed periodically.

526 **Thioridazine** — In a study of 19 healthy male subjects, which included 6 slow and 13 rapid
527 hydroxylators of debrisoquin, a single 25-mg oral dose of thioridazine produced a 2.4-fold higher
528 C_{max} and a 4.5-fold higher AUC for thioridazine in the slow hydroxylators compared with the
529 rapid hydroxylators. The rate of debrisoquin hydroxylation is felt to depend on the level of
530 CYP2D6 isozyme activity. Thus, this study suggests that drugs that inhibit CYP2D6, such as
531 certain SSRIs, including fluoxetine, will produce elevated plasma levels of thioridazine (*see*
532 PRECAUTIONS).

533 Thioridazine administration produces a dose-related prolongation of the QT_c interval, which is
534 associated with serious ventricular arrhythmias, such as torsades de pointes-type arrhythmias and
535 sudden death. This risk is expected to increase with fluoxetine-induced inhibition of thioridazine
536 metabolism (*see* CONTRAINDICATIONS, Thioridazine).

537

PRECAUTIONS

538 General

539 **Concomitant Use of Olanzapine and Fluoxetine Products** — SYMBYAX contains the same
540 active ingredients that are in Zyprexa and Zyprexa Zydis (olanzapine) and in Prozac, Prozac
541 Weekly, and Sarafem (fluoxetine HCl). Caution should be exercised when prescribing these
542 medications concomitantly with SYMBYAX.

543 **Abnormal Bleeding** — Published case reports have documented the occurrence of bleeding
544 episodes in patients treated with psychotropic drugs that interfere with serotonin reuptake.
545 Subsequent epidemiological studies, both of the case-control and cohort design, have
546 demonstrated an association between use of psychotropic drugs that interfere with serotonin
547 reuptake and the occurrence of upper gastrointestinal bleeding. In two studies, concurrent use of
548 a nonsteroidal anti-inflammatory drug (NSAID) or aspirin potentiated the risk of bleeding (*see*
549 DRUG INTERACTIONS). Although these studies focused on upper gastrointestinal bleeding,
550 there is reason to believe that bleeding at other sites may be similarly potentiated. Patients should

551 be cautioned regarding the risk of bleeding associated with the concomitant use of SYMBYAX
552 with NSAIDs, aspirin, or other drugs that affect coagulation.

553 **Mania/Hypomania** — In the two controlled bipolar depression studies there was no
554 statistically significant difference in the incidence of manic events (manic reaction or manic
555 depressive reaction) between SYMBYAX- and placebo-treated patients. In one of the studies, the
556 incidence of manic events was (7% [3/43]) in SYMBYAX-treated patients compared to (3%
557 [5/184]) in placebo-treated patients. In the other study, the incidence of manic events was (2%
558 [1/43]) in SYMBYAX-treated patients compared to (8% [15/193]) in placebo-treated patients.
559 This limited controlled trial experience of SYMBYAX in the treatment of bipolar depression
560 makes it difficult to interpret these findings until additional data is obtained. Because of this and
561 the cyclical nature of bipolar disorder, patients should be monitored closely for the development
562 of symptoms of mania/hypomania during treatment with SYMBYAX.

563 **Body Temperature Regulation** — Disruption of the body's ability to reduce core body
564 temperature has been attributed to antipsychotic drugs. Appropriate care is advised when
565 prescribing SYMBYAX for patients who will be experiencing conditions which may contribute
566 to an elevation in core body temperature (e.g., exercising strenuously, exposure to extreme heat,
567 receiving concomitant medication with anticholinergic activity, or being subject to dehydration).

568 **Cognitive and Motor Impairment** — Somnolence was a commonly reported adverse event
569 associated with SYMBYAX treatment, occurring at an incidence of 22% in SYMBYAX patients
570 compared with 11% in placebo patients. Somnolence led to discontinuation in 2% (10/571) of
571 patients in the premarketing controlled clinical studies.

572 As with any CNS-active drug, SYMBYAX has the potential to impair judgment, thinking, or
573 motor skills. Patients should be cautioned about operating hazardous machinery, including
574 automobiles, until they are reasonably certain that SYMBYAX therapy does not affect them
575 adversely.

576 **Discontinuation of Treatment with SYMBYAX**

577 During marketing of fluoxetine, a component of SYMBYAX, and other SSRIs and SNRIs
578 (serotonin and norepinephrine reuptake inhibitors), there have been spontaneous reports of
579 adverse events occurring upon discontinuation of these drugs, particularly when abrupt,
580 including the following: dysphoric mood, irritability, agitation, dizziness, sensory disturbances
581 (e.g., paresthesias such as electric shock sensations), anxiety, confusion, headache, lethargy,
582 emotional lability, insomnia, and hypomania. While these events are generally self-limiting,
583 there have been reports of serious discontinuation symptoms. Patients should be monitored for
584 these symptoms when discontinuing treatment with fluoxetine. A gradual reduction in the dose
585 rather than abrupt cessation is recommended whenever possible. If intolerable symptoms occur
586 following a decrease in the dose or upon discontinuation of treatment, then resuming the
587 previously prescribed dose may be considered. Subsequently, the physician may continue
588 decreasing the dose but at a more gradual rate. Plasma fluoxetine and norfluoxetine
589 concentration decrease gradually at the conclusion of therapy, which may minimize the risk of
590 discontinuation symptoms with this drug (*see* DOSAGE AND ADMINISTRATION).

591 **Dysphagia** — Esophageal dysmotility and aspiration have been associated with antipsychotic
592 drug use. Aspiration pneumonia is a common cause of morbidity and mortality in patients with
593 advanced Alzheimer's disease. Olanzapine and other antipsychotic drugs should be used
594 cautiously in patients at risk for aspiration pneumonia.

595 **Half-Life** — Because of the long elimination half-lives of fluoxetine and its major active
596 metabolite, changes in dose will not be fully reflected in plasma for several weeks, affecting both

597 strategies for titration to final dose and withdrawal from treatment (*see* CLINICAL
598 PHARMACOLOGY, Accumulation and slow elimination).

599 **Hyperprolactinemia** — As with other drugs that antagonize dopamine D₂ receptors,
600 SYMBYAX elevates prolactin levels, and a modest elevation persists during administration;
601 however, possibly associated clinical manifestations (e.g., galactorrhea and breast enlargement)
602 were infrequently observed.

603 Tissue culture experiments indicate that approximately one-third of human breast cancers are
604 prolactin dependent *in vitro*, a factor of potential importance if the prescription of these drugs is
605 contemplated in a patient with previously detected breast cancer of this type. Although
606 disturbances such as galactorrhea, amenorrhea, gynecomastia, and impotence have been reported
607 with prolactin-elevating compounds, the clinical significance of elevated serum prolactin levels
608 is unknown for most patients. As is common with compounds that increase prolactin release, an
609 increase in mammary gland neoplasia was observed in the olanzapine carcinogenicity studies
610 conducted in mice and rats (*see* Carcinogenesis). However, neither clinical studies nor
611 epidemiologic studies have shown an association between chronic administration of this class of
612 drugs and tumorigenesis in humans; the available evidence is considered too limited to be
613 conclusive.

614 **Hyponatremia** — Hyponatremia has been observed in SYMBYAX premarketing clinical
615 studies. In controlled trials, no SYMBYAX-treated patients had a treatment-emergent serum
616 sodium below 130 mmol/L; however, a lowering of serum sodium below the reference range
617 occurred at an incidence of 2% (10/500) of SYMBYAX patients compared with 0.5% (2/380) of
618 placebo patients. In open label studies, 0.3% (5/1889) of these SYMBYAX-treated patients had a
619 treatment-emergent serum sodium below 130 mmol/L.

620 Cases of hyponatremia (some with serum sodium lower than 110 mmol/L) have been reported
621 with fluoxetine. The hyponatremia appeared to be reversible when fluoxetine was discontinued.
622 Although these cases were complex with varying possible etiologies, some were possibly due to
623 the syndrome of inappropriate antidiuretic hormone secretion (SIADH). The majority of these
624 occurrences have been in older patients and in patients taking diuretics or who were otherwise
625 volume depleted. In two 6-week controlled studies in patients ≥ 60 years of age, 10 of 323
626 fluoxetine patients and 6 of 327 placebo recipients had a lowering of serum sodium below the
627 reference range; this difference was not statistically significant. The lowest observed
628 concentration was 129 mmol/L. The observed decreases were not clinically significant.

629 **Seizures** — Seizures occurred in 0.2% (4/2066) of SYMBYAX-treated patients during
630 open-label premarketing clinical studies. No seizures occurred in the premarketing controlled
631 SYMBYAX studies. Seizures have also been reported with both olanzapine and fluoxetine
632 monotherapy. Therefore, SYMBYAX should be used cautiously in patients with a history of
633 seizures or with conditions that potentially lower the seizure threshold. Conditions that lower the
634 seizure threshold may be more prevalent in a population of ≥ 65 years of age.

635 **Transaminase Elevations** — As with olanzapine, asymptomatic elevations of hepatic
636 transaminases [ALT (SGPT), AST (SGOT), and GGT] and alkaline phosphatase have been
637 observed with SYMBYAX. In the SYMBYAX-controlled database, ALT (SGPT) elevations (≥ 3
638 times the upper limit of the normal range) were observed in 6.3% (31/495) of patients exposed to
639 SYMBYAX compared with 0.5% (2/384) of the placebo patients and 4.5% (25/560) of
640 olanzapine-treated patients. The difference between SYMBYAX and placebo was statistically
641 significant. None of these 31 SYMBYAX-treated patients experienced jaundice and three had
642 transient elevations > 200 IU/L.

643 In olanzapine placebo-controlled studies, clinically significant ALT (SGPT) elevations (≥ 3
644 times the upper limit of the normal range) were observed in 2% (6/243) of patients exposed to
645 olanzapine compared with 0% (0/115) of the placebo patients. None of these patients
646 experienced jaundice. In 2 of these patients, liver enzymes decreased toward normal despite
647 continued treatment, and in 2 others, enzymes decreased upon discontinuation of olanzapine. In
648 the remaining 2 patients, 1, seropositive for hepatitis C, had persistent enzyme elevations for 4
649 months after discontinuation, and the other had insufficient follow-up to determine if enzymes
650 normalized.

651 Within the larger olanzapine premarketing database of about 2400 patients with baseline SGPT
652 ≤ 90 IU/L, the incidence of SGPT elevation to >200 IU/L was 2% (50/2381). Again, none of
653 these patients experienced jaundice or other symptoms attributable to liver impairment and most
654 had transient changes that tended to normalize while olanzapine treatment was continued.
655 Among all 2500 patients in olanzapine clinical studies, approximately 1% (23/2500)
656 discontinued treatment due to transaminase increases.

657 Rare postmarketing reports of hepatitis have been received. Very rare cases of cholestatic or
658 mixed liver injury have also been reported in the postmarketing period.

659 Caution should be exercised in patients with signs and symptoms of hepatic impairment, in
660 patients with pre-existing conditions associated with limited hepatic functional reserve, and in
661 patients who are being treated with potentially hepatotoxic drugs. Periodic assessment of
662 transaminases is recommended in patients with significant hepatic disease (*see* Laboratory
663 Tests).

664 **Weight Gain** — In clinical studies, the mean weight increase for SYMBYAX-treated patients
665 was statistically significantly greater than placebo-treated (3.6 kg vs -0.3 kg) and
666 fluoxetine-treated (3.6 kg vs -0.7 kg) patients, but was not statistically significantly different
667 from olanzapine-treated patients (3.6 kg vs 3.0 kg). Fourteen percent of SYMBYAX-treated
668 patients met criterion for having gained $>10\%$ of their baseline weight. This was statistically
669 significantly greater than placebo-treated ($<1\%$) and fluoxetine-treated patients ($<1\%$) but was
670 not statistically significantly different than olanzapine-treated patients (11%).

671 **Use in Patients with Concomitant Illness**

672 Clinical experience with SYMBYAX in patients with concomitant systemic illnesses is limited
673 (*see* CLINICAL PHARMACOLOGY, Renal Impairment *and* Hepatic Impairment). The
674 following precautions for the individual components may be applicable to SYMBYAX.

675 Olanzapine exhibits in vitro muscarinic receptor affinity. In premarketing clinical studies,
676 SYMBYAX was associated with constipation, dry mouth, and tachycardia, all adverse events
677 possibly related to cholinergic antagonism. Such adverse events were not often the basis for
678 study discontinuations; SYMBYAX should be used with caution in patients with clinically
679 significant prostatic hypertrophy, narrow angle glaucoma, a history of paralytic ileus, or related
680 conditions.

681 In five placebo-controlled studies of olanzapine in elderly patients with dementia-related
682 psychosis (n=1184), the following treatment-emergent adverse events were reported in
683 olanzapine-treated patients at an incidence of at least 2% and significantly greater than
684 placebo-treated patients: falls, somnolence, peripheral edema, abnormal gait, urinary
685 incontinence, lethargy, increased weight, asthenia, pyrexia, pneumonia, dry mouth and visual
686 hallucinations. The rate of discontinuation due to adverse events was significantly greater with
687 olanzapine than placebo (13% vs 7%). Elderly patients with dementia-related psychosis treated
688 with olanzapine are at an increased risk of death compared to placebo. Olanzapine is not

689 approved for the treatment of patients with dementia-related psychosis. If the prescriber elects to
690 treat elderly patients with dementia-related psychosis, vigilance should be exercised (*see* BOX
691 WARNING *and* WARNINGS).

692 As with other CNS-active drugs, SYMBYAX should be used with caution in elderly patients
693 with dementia. Olanzapine is not approved for the treatment of patients with dementia-related
694 psychosis. If the prescriber elects to treat elderly patients with dementia-related psychosis,
695 vigilance should be exercised (*see* BOX WARNING *and* WARNINGS).

696 SYMBYAX has not been evaluated or used to any appreciable extent in patients with a recent
697 history of myocardial infarction or unstable heart disease. Patients with these diagnoses were
698 excluded from clinical studies during the premarket testing.

699 Caution is advised when using SYMBYAX in cardiac patients and in patients with diseases or
700 conditions that could affect hemodynamic responses (*see* WARNINGS, Orthostatic
701 Hypotension).

702 In subjects with cirrhosis of the liver, the clearances of fluoxetine and its active metabolite,
703 norfluoxetine, were decreased, thus increasing the elimination half-lives of these substances. A
704 lower dose of the fluoxetine-component of SYMBYAX should be used in patients with cirrhosis.
705 Caution is advised when using SYMBYAX in patients with diseases or conditions that could
706 affect its metabolism (*see* CLINICAL PHARMACOLOGY, Hepatic Impairment *and* DOSING
707 AND ADMINISTRATION, Special Populations).

708 Olanzapine and fluoxetine individual pharmacokinetics do not differ significantly in patients
709 with renal impairment. SYMBYAX dosing adjustment based upon renal impairment is not
710 routinely required (*see* CLINICAL PHARMACOLOGY, Renal Impairment).

711 Information for Patients

712 Prescribers or other health professionals should inform patients, their families, and their
713 caregivers about the benefits and risks associated with treatment with SYMBYAX and should
714 counsel them in its appropriate use. A patient Medication Guide about “Antidepressant
715 Medicines, Depression and other Serious Mental Illness, and Suicidal Thoughts or Actions” is
716 available for SYMBYAX. The prescriber or health professional should instruct patients, their
717 families, and their caregivers to read the Medication Guide and should assist them in
718 understanding its contents. Patients should be given the opportunity to discuss the contents of the
719 Medication Guide and to obtain answers to any questions they may have. The complete text of
720 the Medication Guide is reprinted at the end of this document.

721 Patients should be advised of the following issues and asked to alert their prescriber if these
722 occur while taking SYMBYAX.

723 **Clinical Worsening and Suicide Risk** — Patients, their families, and their caregivers should
724 be encouraged to be alert to the emergence of anxiety, agitation, panic attacks, insomnia,
725 irritability, hostility, aggressiveness, impulsivity, akathisia (psychomotor restlessness),
726 hypomania, mania, other unusual changes in behavior, worsening of depression, and suicidal
727 ideation, especially early during antidepressant treatment and when the dose is adjusted up or
728 down. Families and caregivers of patients should be advised to look for the emergence of such
729 symptoms on a day-to-day basis, since changes may be abrupt. Such symptoms should be
730 reported to the patient’s prescriber or health professional, especially if they are severe, abrupt in
731 onset, or were not part of the patient’s presenting symptoms. Symptoms such as these may be
732 associated with an increased risk for suicidal thinking and behavior and indicate a need for very
733 close monitoring and possibly changes in the medication.

734 **Serotonin Syndrome** — Patients should be cautioned about the risk of serotonin syndrome
735 with the concomitant use of SYMBYAX and triptans, tramadol or other serotonergic agents.

736 **Abnormal Bleeding** — Patients should be cautioned about the concomitant use of
737 SYMBYAX and NSAIDs, aspirin, or other drugs that affect coagulation since the combined use
738 of psychotropic drugs that interfere with serotonin reuptake and these agents has been associated
739 with an increased risk of bleeding (*see* PRECAUTIONS, Abnormal Bleeding).

740 **Alcohol** — Patients should be advised to avoid alcohol while taking SYMBYAX.

741 **Cognitive and Motor Impairment** — As with any CNS-active drug, SYMBYAX has the
742 potential to impair judgment, thinking, or motor skills. Patients should be cautioned about
743 operating hazardous machinery, including automobiles, until they are reasonably certain that
744 SYMBYAX therapy does not affect them adversely.

745 **Concomitant Medication** — Patients should be advised to inform their physician if they are
746 taking Prozac[®], Prozac Weekly[™], Sarafem[®], fluoxetine, Zyprexa[®], or Zyprexa Zydis[®]. Patients
747 should also be advised to inform their physicians if they are taking or plan to take any
748 prescription or over-the-counter drugs, including herbal supplements, since there is a potential
749 for interactions.

750 **Heat Exposure and Dehydration** — Patients should be advised regarding appropriate care in
751 avoiding overheating and dehydration.

752 **Nursing** — Patients, if taking SYMBYAX, should be advised not to breast-feed.

753 **Orthostatic Hypotension** — Patients should be advised of the risk of orthostatic hypotension,
754 especially during the period of initial dose titration and in association with the use of
755 concomitant drugs that may potentiate the orthostatic effect of olanzapine, e.g., diazepam or
756 alcohol (*see* WARNINGS *and* Drug Interactions).

757 **Pregnancy** — Patients should be advised to notify their physician if they become pregnant or
758 intend to become pregnant during SYMBYAX therapy.

759 **Rash** — Patients should be advised to notify their physician if they develop a rash or hives
760 while taking SYMBYAX.

761 **Treatment Adherence** — Patients should be advised to take SYMBYAX exactly as
762 prescribed, and to continue taking SYMBYAX as prescribed even after their mood symptoms
763 improve. Patients should be advised that they should not alter their dosing regimen, or stop
764 taking SYMBYAX, without consulting their physician.

765 Patient information is printed at the end of this insert. Physicians should discuss this
766 information with their patients and instruct them to read the Medication Guide before starting
767 therapy with SYMBYAX and each time their prescription is refilled.

768 **Laboratory Tests**

769 Periodic assessment of transaminases is recommended in patients with significant hepatic
770 disease (*see* Transaminase Elevations).

771 **Drug Interactions**

772 The risks of using SYMBYAX in combination with other drugs have not been extensively
773 evaluated in systematic studies. The drug-drug interactions of the individual components are
774 applicable to SYMBYAX. As with all drugs, the potential for interaction by a variety of
775 mechanisms (e.g., pharmacodynamic, pharmacokinetic drug inhibition or enhancement, etc.) is a
776 possibility. Caution is advised if the concomitant administration of SYMBYAX and other
777 CNS-active drugs is required. In evaluating individual cases, consideration should be given to
778 using lower initial doses of the concomitantly administered drugs, using conservative titration

779 schedules, and monitoring of clinical status (*see* CLINICAL PHARMACOLOGY, Accumulation
780 and slow elimination).

781 Antihypertensive agents — Because of the potential for olanzapine to induce hypotension,
782 SYMBYAX may enhance the effects of certain antihypertensive agents (*see* WARNINGS,
783 Orthostatic Hypotension).

784 Anti-Parkinsonian — The olanzapine component of SYMBYAX may antagonize the effects of
785 levodopa and dopamine agonists.

786 Benzodiazepines — Multiple doses of olanzapine did not influence the pharmacokinetics of
787 diazepam and its active metabolite N-desmethyldiazepam. However, the coadministration of
788 diazepam with olanzapine potentiated the orthostatic hypotension observed with olanzapine.

789 When concurrently administered with fluoxetine, the half-life of diazepam may be prolonged
790 in some patients (*see* CLINICAL PHARMACOLOGY, Accumulation and slow elimination).
791 Coadministration of alprazolam and fluoxetine has resulted in increased alprazolam plasma
792 concentrations and in further psychomotor performance decrement due to increased alprazolam
793 levels.

794 Biperiden — Multiple doses of olanzapine did not influence the pharmacokinetics of biperiden.

795 Carbamazepine — Carbamazepine therapy (200 mg BID) causes an approximate 50% increase
796 in the clearance of olanzapine. This increase is likely due to the fact that carbamazepine is a
797 potent inducer of CYP1A2 activity. Higher daily doses of carbamazepine may cause an even
798 greater increase in olanzapine clearance.

799 Patients on stable doses of carbamazepine have developed elevated plasma anticonvulsant
800 concentrations and clinical anticonvulsant toxicity following initiation of concomitant fluoxetine
801 treatment.

802 Clozapine — Elevation of blood levels of clozapine has been observed in patients receiving
803 concomitant fluoxetine.

804 Electroconvulsive therapy (ECT) — There are no clinical studies establishing the benefit of the
805 combined use of ECT and fluoxetine. There have been rare reports of prolonged seizures in
806 patients on fluoxetine receiving ECT treatment (*see* Seizures).

807 Ethanol — Ethanol (45 mg/70 kg single dose) did not have an effect on olanzapine
808 pharmacokinetics. The coadministration of ethanol with SYMBYAX may potentiate sedation
809 and orthostatic hypotension.

810 Fluvoxamine — Fluvoxamine, a CYP1A2 inhibitor, decreases the clearance of olanzapine.
811 This results in a mean increase in olanzapine C_{max} following fluvoxamine administration of 54%
812 in female nonsmokers and 77% in male smokers. The mean increase in olanzapine AUC is 52%
813 and 108%, respectively. Lower doses of the olanzapine component of SYMBYAX should be
814 considered in patients receiving concomitant treatment with fluvoxamine.

815 Haloperidol — Elevation of blood levels of haloperidol has been observed in patients receiving
816 concomitant fluoxetine.

817 Lithium — Multiple doses of olanzapine did not influence the pharmacokinetics of lithium.

818 There have been reports of both increased and decreased lithium levels when lithium was used
819 concomitantly with fluoxetine. Cases of lithium toxicity and increased serotonergic effects have
820 been reported. Lithium levels should be monitored in patients taking SYMBYAX concomitantly
821 with lithium.

822 Monoamine oxidase inhibitors — *See* CONTRAINDICATIONS.

823 Phenytoin — Patients on stable doses of phenytoin have developed elevated plasma levels of
824 phenytoin with clinical phenytoin toxicity following initiation of concomitant fluoxetine.

825 Pimozide — Clinical studies of pimozide with other antidepressants demonstrate an increase in
826 drug interaction or QT_c prolongation. While a specific study with pimozide and fluoxetine has
827 not been conducted, the potential for drug interactions or QT_c prolongation warrants restricting
828 the concurrent use of pimozide and fluoxetine. Concomitant use of fluoxetine and pimozide is
829 contraindicated (*see* CONTRAINDICATIONS).

830 Serotonergic drugs — Based on the mechanism of action of SNRIs and SSRIs, including
831 SYMBYAX, and the potential for serotonin syndrome, caution is advised when SYMBYAX is
832 coadministered with other drugs that may affect the serotonergic neurotransmitter systems, such
833 as triptans, linezolid (an antibiotic which is a reversible non-selective MAOI), lithium, tramadol,
834 or St. John's Wort (*see* WARNINGS, Serotonin Syndrome). The concomitant use of
835 SYMBYAX with other SSRIs, SNRIs or tryptophan is not recommended (*see* Tryptophan).

836 Theophylline — Multiple doses of olanzapine did not affect the pharmacokinetics of
837 theophylline or its metabolites.

838 Thioridazine — *See* CONTRAINDICATIONS and WARNINGS, Thioridazine.

839 Tricyclic antidepressants (TCAs) — Single doses of olanzapine did not affect the
840 pharmacokinetics of imipramine or its active metabolite desipramine.

841 In two fluoxetine studies, previously stable plasma levels of imipramine and desipramine have
842 increased >2- to 10-fold when fluoxetine has been administered in combination. This influence
843 may persist for three weeks or longer after fluoxetine is discontinued. Thus, the dose of TCA
844 may need to be reduced and plasma TCA concentrations may need to be monitored temporarily
845 when SYMBYAX is coadministered or has been recently discontinued (*see* Drugs metabolized
846 by CYP2D6 and CLINICAL PHARMACOLOGY, Accumulation and slow elimination).

847 Triptans — There have been rare postmarketing reports of serotonin syndrome with use of an
848 SSRI and a triptan. If concomitant treatment of SYMBYAX with a triptan is clinically
849 warranted, careful observation of the patient is advised, particularly during treatment initiation
850 and dose increases (*see* WARNINGS, Serotonin Syndrome).

851 Tryptophan — Five patients receiving fluoxetine in combination with tryptophan experienced
852 adverse reactions, including agitation, restlessness, and gastrointestinal distress.

853 Valproate — In vitro studies using human liver microsomes determined that olanzapine has
854 little potential to inhibit the major metabolic pathway, glucuronidation, of valproate. Further,
855 valproate has little effect on the metabolism of olanzapine in vitro. Thus, a clinically significant
856 pharmacokinetic interaction between olanzapine and valproate is unlikely.

857 Warfarin — Warfarin (20-mg single dose) did not affect olanzapine pharmacokinetics. Single
858 doses of olanzapine did not affect the pharmacokinetics of warfarin.

859 Altered anticoagulant effects, including increased bleeding, have been reported when
860 fluoxetine is coadministered with warfarin (*see* PRECAUTIONS, Abnormal Bleeding). Patients
861 receiving warfarin therapy should receive careful coagulation monitoring when SYMBYAX is
862 initiated or stopped.

863 Drugs that interfere with hemostasis (NSAIDs, aspirin, warfarin, etc.) — Serotonin release by
864 platelets plays an important role in hemostasis. Epidemiological studies of the case-control and
865 cohort design that have demonstrated an association between use of psychotropic drugs that
866 interfere with serotonin reuptake and the occurrence of upper gastrointestinal bleeding have also
867 shown that concurrent use of an NSAID or aspirin potentiated the risk of bleeding (*see*
868 PRECAUTIONS, Abnormal Bleeding). Thus, patients should be cautioned about the use of such
869 drugs concurrently with SYMBYAX.

870 Drugs metabolized by CYP2D6 — In vitro studies utilizing human liver microsomes suggest
871 that olanzapine has little potential to inhibit CYP2D6. Thus, olanzapine is unlikely to cause
872 clinically important drug interactions mediated by this enzyme.

873 Fluoxetine inhibits the activity of CYP2D6, and may make individuals with normal CYP2D6
874 metabolic activity resemble a poor metabolizer. Coadministration of fluoxetine with other drugs
875 that are metabolized by CYP2D6, including certain antidepressants (e.g., TCAs), antipsychotics
876 (e.g., phenothiazines and most atypicals), and antiarrhythmics (e.g., propafenone, flecainide, and
877 others) should be approached with caution. Therapy with medications that are predominantly
878 metabolized by the CYP2D6 system and that have a relatively narrow therapeutic index should
879 be initiated at the low end of the dose range if a patient is receiving fluoxetine concurrently or
880 has taken it in the previous five weeks. If fluoxetine is added to the treatment regimen of a
881 patient already receiving a drug metabolized by CYP2D6, the need for a decreased dose of the
882 original medication should be considered. Drugs with a narrow therapeutic index represent the
883 greatest concern (including but not limited to, flecainide, propafenone, vinblastine, and TCAs).
884 Due to the risk of serious ventricular arrhythmias and sudden death potentially associated with
885 elevated thioridazine plasma levels, thioridazine should not be administered with fluoxetine or
886 within a minimum of five weeks after fluoxetine has been discontinued (*see*
887 CONTRAINDICATIONS, Monoamine Oxidase Inhibitors (MAOI) *and* WARNINGS,
888 Thioridazine).

889 Drugs metabolized by CYP3A — In vitro studies utilizing human liver microsomes suggest
890 that olanzapine has little potential to inhibit CYP3A. Thus, olanzapine is unlikely to cause
891 clinically important drug interactions mediated by these enzymes.

892 In an in vivo interaction study involving the coadministration of fluoxetine with single doses of
893 terfenadine (a CYP3A substrate), no increase in plasma terfenadine concentrations occurred with
894 concomitant fluoxetine. In addition, in vitro studies have shown ketoconazole, a potent inhibitor
895 of CYP3A activity, to be at least 100 times more potent than fluoxetine or norfluoxetine as an
896 inhibitor of the metabolism of several substrates for this enzyme, including astemizole, cisapride,
897 and midazolam. These data indicate that fluoxetine's extent of inhibition of CYP3A activity is
898 not likely to be of clinical significance.

899 Effect of olanzapine on drugs metabolized by other CYP enzymes — In vitro studies utilizing
900 human liver microsomes suggest that olanzapine has little potential to inhibit CYP1A2,
901 CYP2C9, and CYP2C19. Thus, olanzapine is unlikely to cause clinically important drug
902 interactions mediated by these enzymes.

903 The effect of other drugs on olanzapine — Fluoxetine, an inhibitor of CYP2D6, decreases
904 olanzapine clearance a small amount (*see* CLINICAL PHARMACOLOGY, Pharmacokinetics).
905 Agents that induce CYP1A2 or glucuronyl transferase enzymes, such as omeprazole and
906 rifampin, may cause an increase in olanzapine clearance. Fluvoxamine, an inhibitor of CYP1A2,
907 decreases olanzapine clearance (*see* Drug Interactions, Fluvoxamine). The effect of CYP1A2
908 inhibitors, such as fluvoxamine and some fluoroquinolone antibiotics, on SYMBYAX has not
909 been evaluated. Although olanzapine is metabolized by multiple enzyme systems, induction or
910 inhibition of a single enzyme may appreciably alter olanzapine clearance. Therefore, a dosage
911 increase (for induction) or a dosage decrease (for inhibition) may need to be considered with
912 specific drugs.

913 Drugs tightly bound to plasma proteins — The in vitro binding of SYMBYAX to human
914 plasma proteins is similar to the individual components. The interaction between SYMBYAX
915 and other highly protein-bound drugs has not been fully evaluated. Because fluoxetine is tightly

916 bound to plasma protein, the administration of fluoxetine to a patient taking another drug that is
917 tightly bound to protein (e.g., Coumadin, digitoxin) may cause a shift in plasma concentrations
918 potentially resulting in an adverse effect. Conversely, adverse effects may result from
919 displacement of protein-bound fluoxetine by other tightly bound drugs (*see* CLINICAL
920 PHARMACOLOGY, Distribution *and* PRECAUTIONS, Drug Interactions).

921 **Carcinogenesis, Mutagenesis, Impairment of Fertility**

922 No carcinogenicity, mutagenicity, or fertility studies were conducted with SYMBYAX. The
923 following data are based on findings in studies performed with the individual components.

924 **Carcinogenesis**

925 Olanzapine — Oral carcinogenicity studies were conducted in mice and rats. Olanzapine was
926 administered to mice in two 78-week studies at doses of 3, 10, and 30/20 mg/kg/day [equivalent
927 to 0.8 to 5 times the maximum recommended human daily dose (MRHD) on a mg/m² basis] and
928 0.25, 2, and 8 mg/kg/day (equivalent to 0.06 to 2 times the MRHD on a mg/m² basis). Rats were
929 dosed for 2 years at doses of 0.25, 1, 2.5, and 4 mg/kg/day (males) and 0.25, 1, 4, and
930 8 mg/kg/day (females) (equivalent to 0.1 to 2 and 0.1 to 4 times the MRHD on a mg/m² basis,
931 respectively). The incidence of liver hemangiomas and hemangiosarcomas was significantly
932 increased in one mouse study in females dosed at 8 mg/kg/day (2 times the MRHD on a mg/m²
933 basis). These tumors were not increased in another mouse study in females dosed at 10 or
934 30/20 mg/kg/day (2 to 5 times the MRHD on a mg/m² basis); in this study, there was a high
935 incidence of early mortalities in males of the 30/20 mg/kg/day group. The incidence of
936 mammary gland adenomas and adenocarcinomas was significantly increased in female mice
937 dosed at ≥2 mg/kg/day and in female rats dosed at ≥4 mg/kg/day (0.5 and 2 times the MRHD on
938 a mg/m² basis, respectively). Antipsychotic drugs have been shown to chronically elevate
939 prolactin levels in rodents. Serum prolactin levels were not measured during the olanzapine
940 carcinogenicity studies; however, measurements during subchronic toxicity studies showed that
941 olanzapine elevated serum prolactin levels up to 4-fold in rats at the same doses used in the
942 carcinogenicity study. An increase in mammary gland neoplasms has been found in rodents after
943 chronic administration of other antipsychotic drugs and is considered to be prolactin-mediated.
944 The relevance for human risk of the finding of prolactin-mediated endocrine tumors in rodents is
945 unknown (*see* PRECAUTIONS, Hyperprolactinemia).

946 Fluoxetine — The dietary administration of fluoxetine to rats and mice for two years at doses
947 of up to 10 and 12 mg/kg/day, respectively (approximately 1.2 and 0.7 times, respectively, the
948 MRHD on a mg/m² basis), produced no evidence of carcinogenicity.

949 **Mutagenesis**

950 Olanzapine — No evidence of mutagenic potential for olanzapine was found in the Ames
951 reverse mutation test, in vivo micronucleus test in mice, the chromosomal aberration test in
952 Chinese hamster ovary cells, unscheduled DNA synthesis test in rat hepatocytes, induction of
953 forward mutation test in mouse lymphoma cells, or in vivo sister chromatid exchange test in
954 bone marrow of Chinese hamsters.

955 Fluoxetine — Fluoxetine and norfluoxetine have been shown to have no genotoxic effects
956 based on the following assays: bacterial mutation assay, DNA repair assay in cultured rat
957 hepatocytes, mouse lymphoma assay, and in vivo sister chromatid exchange assay in Chinese
958 hamster bone marrow cells.

959 Impairment of Fertility

960 SYMBYAX — Fertility studies were not conducted with SYMBYAX. However, in a
961 repeat-dose rat toxicology study of three months duration, ovary weight was decreased in
962 females treated with the low-dose [2 and 4 mg/kg/day (1 and 0.5 times the MRHD on a mg/m²
963 basis), respectively] and high-dose [4 and 8 mg/kg/day (2 and 1 times the MRHD on a mg/m²
964 basis), respectively] combinations of olanzapine and fluoxetine. Decreased ovary weight, and
965 corpora luteal depletion and uterine atrophy were observed to a greater extent in the females
966 receiving the high-dose combination than in females receiving either olanzapine or fluoxetine
967 alone. In a 3-month repeat-dose dog toxicology study, reduced epididymal sperm and reduced
968 testicular and prostate weights were observed with the high-dose combination of olanzapine and
969 fluoxetine [5 and 5 mg/kg/day (9 and 2 times the MRHD on a mg/m² basis), respectively] and
970 with olanzapine alone (5 mg/kg/day or 9 times the MRHD on a mg/m² basis).

971 Olanzapine — In a fertility and reproductive performance study in rats, male mating
972 performance, but not fertility, was impaired at a dose of 22.4 mg/kg/day and female fertility was
973 decreased at a dose of 3 mg/kg/day (11 and 1.5 times the MRHD on a mg/m² basis, respectively).
974 Discontinuance of olanzapine treatment reversed the effects on male-mating performance. In
975 female rats, the precoital period was increased and the mating index reduced at 5 mg/kg/day (2.5
976 times the MRHD on a mg/m² basis). Diestrus was prolonged and estrus was delayed at
977 1.1 mg/kg/day (0.6 times the MRHD on a mg/m² basis); therefore, olanzapine may produce a
978 delay in ovulation.

979 Fluoxetine — Two fertility studies conducted in adult rats at doses of up to 7.5 and
980 12.5 mg/kg/day (approximately 0.9 and 1.5 times the MRHD on a mg/m² basis) indicated that
981 fluoxetine had no adverse effects on fertility (*see* Pediatric Use).

982 **Pregnancy — Pregnancy Category C**

983 SYMBYAX

984 Embryo fetal development studies were conducted in rats and rabbits with olanzapine and
985 fluoxetine in low-dose and high-dose combinations. In rats, the doses were: 2 and 4 mg/kg/day
986 (low-dose) [1 and 0.5 times the MRHD on a mg/m² basis, respectively], and 4 and 8 mg/kg/day
987 (high-dose) [2 and 1 times the MRHD on a mg/m² basis, respectively]. In rabbits, the doses were
988 4 and 4 mg/kg/day (low-dose) [4 and 1 times the MRHD on a mg/m² basis, respectively], and 8
989 and 8 mg/kg/day (high-dose) [9 and 2 times the MRHD on a mg/m² basis, respectively]. In these
990 studies, olanzapine and fluoxetine were also administered alone at the high-doses (4 and
991 8 mg/kg/day, respectively, in the rat; 8 and 8 mg/kg/day, respectively, in the rabbit). In the
992 rabbit, there was no evidence of teratogenicity; however, the high-dose combination produced
993 decreases in fetal weight and retarded skeletal ossification in conjunction with maternal toxicity.
994 Similarly, in the rat there was no evidence of teratogenicity; however, a decrease in fetal weight
995 was observed with the high-dose combination.

996 In a pre- and postnatal study conducted in rats, olanzapine and fluoxetine were administered
997 during pregnancy and throughout lactation in combination (low-dose: 2 and 4 mg/kg/day [1 and
998 0.5 times the MRHD on a mg/m² basis], respectively, high-dose: 4 and 8 mg/kg/day [2 and 1
999 times the MRHD on a mg/m² basis], respectively, and alone: 4 and 8 mg/kg/day [2 and 1 times
1000 the MRHD on a mg/m² basis], respectively). Administration of the high-dose combination
1001 resulted in a marked elevation in offspring mortality and growth retardation in comparison to the
1002 same doses of olanzapine and fluoxetine administered alone. These effects were not observed
1003 with the low-dose combination; however, there were a few cases of testicular degeneration and
1004 atrophy, depletion of epididymal sperm and infertility in the male progeny. The effects of the

1005 high-dose combination on postnatal endpoints could not be assessed due to high progeny
1006 mortality.

1007 There are no adequate and well-controlled studies with SYMBYAX in pregnant women.
1008 SYMBYAX should be used during pregnancy only if the potential benefit justifies the
1009 potential risk to the fetus.

1010 Olanzapine

1011 In reproduction studies in rats at doses up to 18 mg/kg/day and in rabbits at doses up to
1012 30 mg/kg/day (9 and 30 times the MRHD on a mg/m² basis, respectively), no evidence of
1013 teratogenicity was observed. In a rat teratology study, early resorptions and increased numbers of
1014 nonviable fetuses were observed at a dose of 18 mg/kg/day (9 times the MRHD on a mg/m²
1015 basis). Gestation was prolonged at 10 mg/kg/day (5 times the MRHD on a mg/m² basis). In a
1016 rabbit teratology study, fetal toxicity (manifested as increased resorptions and decreased fetal
1017 weight) occurred at a maternally toxic dose of 30 mg/kg/day (30 times the MRHD on a mg/m²
1018 basis).

1019 Placental transfer of olanzapine occurs in rat pups.

1020 There are no adequate and well-controlled clinical studies with olanzapine in pregnant women.
1021 Seven pregnancies were observed during premarketing clinical studies with olanzapine,
1022 including two resulting in normal births, one resulting in neonatal death due to a cardiovascular
1023 defect, three therapeutic abortions, and one spontaneous abortion.

1024 Fluoxetine

1025 In embryo fetal development studies in rats and rabbits, there was no evidence of teratogenicity
1026 following administration of up to 12.5 and 15 mg/kg/day, respectively (1.5 and 3.6 times the
1027 MRHD on a mg/m² basis, respectively) throughout organogenesis. However, in rat reproduction
1028 studies, an increase in stillborn pups, a decrease in pup weight, and an increase in pup deaths
1029 during the first 7 days postpartum occurred following maternal exposure to 12 mg/kg/day (1.5
1030 times the MRHD on a mg/m² basis) during gestation or 7.5 mg/kg/day (0.9 times the MRHD on
1031 a mg/m² basis) during gestation and lactation. There was no evidence of developmental
1032 neurotoxicity in the surviving offspring of rats treated with 12 mg/kg/day during gestation. The
1033 no-effect dose for rat pup mortality was 5 mg/kg/day (0.6 times the MRHD on a mg/m² basis).

1034 **Nonteratogenic Effects** — Neonates exposed to fluoxetine and other SSRIs or serotonin and
1035 norepinephrine reuptake inhibitors (SNRIs), late in the third trimester have developed
1036 complications requiring prolonged hospitalization, respiratory support, and tube feeding. Such
1037 complications can arise immediately upon delivery. Reported clinical findings have included
1038 respiratory distress, cyanosis, apnea, seizures, temperature instability, feeding difficulty,
1039 vomiting, hypoglycemia, hypotonia, hypertonia, hyperreflexia, tremor, jitteriness, irritability, and
1040 constant crying. These features are consistent with either a direct toxic effect of SSRIs and
1041 SNRIs or, possibly, a drug discontinuation syndrome. It should be noted that, in some cases, the
1042 clinical picture is consistent with serotonin syndrome (*see* CONTRAINDICATIONS,
1043 Monoamine Oxidase Inhibitors).

1044 Infants exposed to SSRIs in late pregnancy may have an increased risk for persistent
1045 pulmonary hypertension of the newborn (PPHN). PPHN occurs in 1-2 per 1000 live births in the
1046 general population and is associated with substantial neonatal morbidity and mortality. In a
1047 retrospective case-control study of 377 women whose infants were born with PPHN and 836
1048 women whose infants were born healthy, the risk for developing PPHN was approximately
1049 six-fold higher for infants exposed to SSRIs after the 20th week of gestation compared to infants
1050 who had not been exposed to antidepressants during pregnancy. There is currently no

1051 corroborative evidence regarding the risk for PPHN following exposure to SSRIs in pregnancy;
1052 this is the first study that has investigated the potential risk. The study did not include enough
1053 cases with exposure to individual SSRIs to determine if all SSRIs posed similar levels of PPHN
1054 risk.

1055 When treating a pregnant woman with fluoxetine during the third trimester, the physician
1056 should carefully consider both the potential risks and benefits of treatment (*see* DOSAGE AND
1057 ADMINISTRATION). Physicians should note that in a prospective longitudinal study of 201
1058 women with a history of major depression who were euthymic at the beginning of pregnancy,
1059 women who discontinued antidepressant medication during pregnancy were more likely to
1060 experience a relapse of major depression than women who continued antidepressant medication.

1061 **Labor and Delivery**

1062 SYMBYAX

1063 The effect of SYMBYAX on labor and delivery in humans is unknown. Parturition in rats was
1064 not affected by SYMBYAX. SYMBYAX should be used during labor and delivery only if the
1065 potential benefit justifies the potential risk.

1066 Olanzapine

1067 Parturition in rats was not affected by olanzapine. The effect of olanzapine on labor and
1068 delivery in humans is unknown.

1069 Fluoxetine

1070 The effect of fluoxetine on labor and delivery in humans is unknown. Fluoxetine crosses the
1071 placenta; therefore, there is a possibility that fluoxetine may have adverse effects on the
1072 newborn.

1073 **Nursing Mothers**

1074 SYMBYAX

1075 There are no adequate and well-controlled studies with SYMBYAX in nursing mothers or
1076 infants. No studies have been conducted to examine the excretion of olanzapine or fluoxetine in
1077 breast milk following SYMBYAX treatment. It is recommended that women not breast-feed
1078 when receiving SYMBYAX.

1079 Olanzapine

1080 In a study in lactating, healthy women, olanzapine was excreted in breast milk. Mean infant
1081 dose at steady state was estimated to be 1.8% of the maternal olanzapine dose.

1082 Fluoxetine

1083 Fluoxetine is excreted in human breast milk. In one breast milk sample, the concentration of
1084 fluoxetine plus norfluoxetine was 70.4 ng/mL. The concentration in the mother's plasma was
1085 295.0 ng/mL. No adverse effects on the infant were reported. In another case, an infant nursed by
1086 a mother on fluoxetine developed crying, sleep disturbance, vomiting, and watery stools. The
1087 infant's plasma drug levels were 340 ng/mL of fluoxetine and 208 ng/mL of norfluoxetine on the
1088 2nd day of feeding.

1089 **Pediatric Use**

1090 Safety and effectiveness in the pediatric population have not been established (*see* BOX
1091 WARNING *and* WARNINGS, Clinical Worsening and Suicide Risk). Anyone considering the
1092 use of SYMBYAX in a child or adolescent must balance the potential risks with the clinical
1093 need.

1094 Fluoxetine

1095 Significant toxicity, including myotoxicity, long-term neurobehavioral and reproductive
1096 toxicity, and impaired bone development, has been observed following exposure of juvenile
1097 animals to fluoxetine. Some of these effects occurred at clinically relevant exposures.

1098 In a study in which fluoxetine (3, 10, or 30 mg/kg) was orally administered to young rats from
1099 weaning (Postnatal Day 21) through adulthood (Day 90), male and female sexual development
1100 was delayed at all doses, and growth (body weight gain, femur length) was decreased during the
1101 dosing period in animals receiving the highest dose. At the end of the treatment period, serum
1102 levels of creatine kinase (marker of muscle damage) were increased at the intermediate and high
1103 doses, and abnormal muscle and reproductive organ histopathology (skeletal muscle
1104 degeneration and necrosis, testicular degeneration and necrosis, epididymal vacuolation and
1105 hypospermia) was observed at the high dose. When animals were evaluated after a recovery
1106 period (up to 11 weeks after cessation of dosing), neurobehavioral abnormalities (decreased
1107 reactivity at all doses and learning deficit at the high dose) and reproductive functional
1108 impairment (decreased mating at all doses and impaired fertility at the high dose) were seen; in
1109 addition, testicular and epididymal microscopic lesions and decreased sperm concentrations were
1110 found in the high dose group, indicating that the reproductive organ effects seen at the end of
1111 treatment were irreversible. The reversibility of fluoxetine-induced muscle damage was not
1112 assessed. Adverse effects similar to those observed in rats treated with fluoxetine during the
1113 juvenile period have not been reported after administration of fluoxetine to adult animals. Plasma
1114 exposures (AUC) to fluoxetine in juvenile rats receiving the low, intermediate, and high dose in
1115 this study were approximately 0.1-0.2, 1-2, and 5-10 times, respectively, the average exposure in
1116 pediatric patients receiving the maximum recommended dose (MRD) of 20 mg/day. Rat
1117 exposures to the major metabolite, norfluoxetine, were approximately 0.3-0.8, 1-8, and 3-20
1118 times, respectively, pediatric exposure at the MRD.

1119 A specific effect of fluoxetine on bone development has been reported in mice treated with
1120 fluoxetine during the juvenile period. When mice were treated with fluoxetine (5 or 20 mg/kg,
1121 intraperitoneal) for 4 weeks starting at 4 weeks of age, bone formation was reduced resulting in
1122 decreased bone mineral content and density. These doses did not affect overall growth (body
1123 weight gain or femoral length). The doses administered to juvenile mice in this study are
1124 approximately 0.5 and 2 times the MRD for pediatric patients on a body surface area (mg/m²)
1125 basis.

1126 In another mouse study, administration of fluoxetine (10 mg/kg intraperitoneal) during early
1127 postnatal development (Postnatal Days 4 to 21) produced abnormal emotional behaviors
1128 (decreased exploratory behavior in elevated plus-maze, increased shock avoidance latency) in
1129 adulthood (12 weeks of age). The dose used in this study is approximately equal to the pediatric
1130 MRD on a mg/m² basis. Because of the early dosing period in this study, the significance of
1131 these findings to the approved pediatric use in humans is uncertain.

1132 Geriatric Use

1133 SYMBYAX

1134 Clinical studies of SYMBYAX did not include sufficient numbers of patients ≥ 65 years of age
1135 to determine whether they respond differently from younger patients. Other reported clinical
1136 experience has not identified differences in responses between the elderly and younger patients.
1137 In general, dose selection for an elderly patient should be cautious, usually starting at the low end
1138 of the dosing range, reflecting the greater frequency of decreased hepatic, renal, or cardiac

1139 function, and of concomitant disease or other drug therapy (*see* DOSAGE AND
1140 ADMINISTRATION).

1141 Olanzapine

1142 Of the 2500 patients in premarketing clinical studies with olanzapine, 11% (263 patients) were
1143 ≥ 65 years of age. In patients with schizophrenia, there was no indication of any different
1144 tolerability of olanzapine in the elderly compared with younger patients. Studies in patients with
1145 dementia-related psychosis have suggested that there may be a different tolerability profile in
1146 this population compared with younger patients with schizophrenia. In placebo-controlled
1147 studies of olanzapine in elderly patients with dementia-related psychosis, there was a
1148 significantly higher incidence of cerebrovascular adverse events (e.g., stroke, transient ischemic
1149 attack) in patients treated with olanzapine compared to patients treated with placebo. Olanzapine
1150 is not approved for the treatment of patients with dementia-related psychosis. If the prescriber
1151 elects to treat elderly patients with dementia-related psychosis, vigilance should be exercised
1152 (*see* BOX WARNING, WARNINGS, PRECAUTIONS, Use in Patients with Concomitant
1153 Illness and DOSAGE AND ADMINISTRATION, Special Populations).

1154 As with other CNS-active drugs, olanzapine should be used with caution in elderly patients
1155 with dementia. Also, the presence of factors that might decrease pharmacokinetic clearance or
1156 increase the pharmacodynamic response to olanzapine should lead to consideration of a lower
1157 starting dose for any geriatric patient.

1158 Fluoxetine

1159 US fluoxetine clinical studies (10,782 patients) included 687 patients ≥ 65 years of age and 93
1160 patients ≥ 75 years of age. No overall differences in safety or effectiveness were observed
1161 between these subjects and younger subjects, and other reported clinical experience has not
1162 identified differences in responses between the elderly and younger patients, but greater
1163 sensitivity of some older individuals cannot be ruled out. As with other SSRIs, fluoxetine has
1164 been associated with cases of clinically significant hyponatremia in elderly patients.

1165 ADVERSE REACTIONS

1166 The information below is derived from a premarketing clinical study database for SYMBYAX
1167 consisting of 2066 patients with various diagnoses with approximately 1061 patient-years of
1168 exposure. The conditions and duration of treatment with SYMBYAX varied greatly and included
1169 (in overlapping categories) open-label and double-blind phases of studies, inpatients and
1170 outpatients, fixed-dose and dose-titration studies, and short-term or long-term exposure.

1171 Adverse events were recorded by clinical investigators using descriptive terminology of their
1172 own choosing. Consequently, it is not possible to provide a meaningful estimate of the
1173 proportion of individuals experiencing adverse events without first grouping similar types of
1174 events into a limited (i.e., reduced) number of standardized event categories.

1175 In the tables and tabulations that follow, COSTART Dictionary terminology has been used to
1176 classify reported adverse events. The data in the tables represent the proportion of individuals
1177 who experienced, at least once, a treatment-emergent adverse event of the type listed. An event
1178 was considered treatment-emergent if it occurred for the first time or worsened while receiving
1179 therapy following baseline evaluation. It is possible that events reported during therapy were not
1180 necessarily related to drug exposure.

1181 The prescriber should be aware that the figures in the tables and tabulations cannot be used to
1182 predict the incidence of side effects in the course of usual medical practice where patient
1183 characteristics and other factors differ from those that prevailed in the clinical studies. Similarly,

1184 the cited frequencies cannot be compared with figures obtained from other clinical investigations
 1185 involving different treatments, uses, and investigators. The cited figures, however, do provide the
 1186 prescribing clinician with some basis for estimating the relative contribution of drug and
 1187 non-drug factors to the side effect incidence rate in the population studied.

1188 **Incidence in Controlled Clinical Studies**

1189 The following findings are based on the short-term, controlled premarketing studies in various
 1190 diagnoses including bipolar depression.

1191 Adverse events associated with discontinuation of treatment — Overall, 10% of the patients in
 1192 the SYMBYAX group discontinued due to adverse events compared with 4.6% for placebo.
 1193 Table 3 enumerates the adverse events leading to discontinuation associated with the use of
 1194 SYMBYAX (incidence of at least 1% for SYMBYAX and greater than that for placebo). The
 1195 bipolar depression column shows the incidence of adverse events with SYMBYAX in the bipolar
 1196 depression studies and the “SYMBYAX-Controlled” column shows the incidence in the
 1197 controlled SYMBYAX studies; the placebo column shows the incidence in the pooled controlled
 1198 studies that included a placebo arm.

1199

1200

Table 3: Adverse Events Associated with Discontinuation*

Adverse Event	Percentage of Patients Reporting Event		
	SYMBYAX		Placebo
	Bipolar Depression (N=86)	SYMBYAX-Controlled (N=571)	(N=477)
Asthenia	0	1	0
Somnolence	0	2	0
Weight gain	0	2	0
Chest pain	1	0	0

1201

* Table includes events associated with discontinuation of at least 1% and greater than placebo

1202

1203 Commonly observed adverse events in controlled clinical studies — The most commonly
 1204 observed adverse events associated with the use of SYMBYAX (incidence of $\geq 5\%$ and at least
 1205 twice that for placebo in the SYMBYAX-controlled database) were: asthenia, edema, increased
 1206 appetite, peripheral edema, pharyngitis, somnolence, thinking abnormal, tremor, and weight
 1207 gain.

1208 Adverse events occurring at an incidence of 2% or more in controlled clinical studies —

1209 Table 4 enumerates the treatment-emergent adverse events associated with the use of
 1210 SYMBYAX (incidence of at least 2% for SYMBYAX and twice or more that for placebo).

1211

1212

1213

**Table 4: Treatment-Emergent Adverse Events:
Incidence in Controlled Clinical Studies**

Body System/Adverse Event ¹	Percentage of Patients Reporting Event		
	SYMBYAX		Placebo
	Bipolar Depression (N=86)	SYMBYAX-Controlled (N=571)	(N=477)
Body as a Whole			
Asthenia	13	15	3
Accidental injury	5	3	2
Fever	4	3	1

Cardiovascular System			
Hypertension	2	2	1
Tachycardia	2	2	0
Digestive System			
Diarrhea	19	8	7
Dry mouth	16	11	6
Increased appetite	13	16	4
Tooth disorder	1	2	1
Metabolic and Nutritional Disorders			
Weight gain	17	21	3
Peripheral edema	4	8	1
Edema	0	5	0
Musculoskeletal System			
Joint disorder	1	2	1
Twitching	6	2	1
Arthralgia	5	3	1
Nervous System			
Somnolence	21	22	11
Tremor	9	8	3
Thinking abnormal	6	6	3
Libido decreased	4	2	1
Hyperkinesia	2	1	1
Personality disorder	2	1	1
Sleep disorder	2	1	1
Amnesia	1	3	0
Respiratory System			
Pharyngitis	4	6	3
Dyspnea	1	2	1
Special Senses			
Amblyopia	5	4	2
Ear pain	2	1	1
Otitis media	2	0	0
Speech disorder	0	2	0
Urogenital System			
Abnormal ejaculation ²	7	2	1
Impotence ²	4	2	1
Anorgasmia	3	1	0

1214 ¹ Included are events reported by at least 2% of patients taking SYMBYAX except the following events, which had
1215 an incidence on placebo \geq SYMBYAX: abdominal pain, abnormal dreams, agitation, akathisia, anorexia, anxiety,
1216 apathy, back pain, chest pain, constipation, cough increased, depression, dizziness, dysmenorrhea (adjusted for
1217 gender), dyspepsia, flatulence, flu syndrome, headache, hypertonia, insomnia, manic reaction, myalgia, nausea,
1218 nervousness, pain, palpitation, paresthesia, rash, rhinitis, sinusitis, sweating, vomiting.

1219 ² Adjusted for gender.

1220 Additional Findings Observed in Clinical Studies

1221 The following findings are based on clinical studies.

1222 Effect on cardiac repolarization — The mean increase in QT_c interval for SYMBYAX-treated
1223 patients (4.9 msec) in clinical studies was significantly greater than that for placebo-treated
1224 (-0.9 msec) and olanzapine-treated (0.6 msec) patients, but was not significantly different from
1225 fluoxetine-treated (3.7 msec) patients. There were no differences between patients treated with
1226 SYMBYAX, placebo, olanzapine, or fluoxetine in the incidence of QT_c outliers (>500 msec).

1227 Laboratory changes — In SYMBYAX clinical studies, SYMBYAX was associated with
1228 asymptomatic mean increases in alkaline phosphatase, cholesterol, GGT, and uric acid compared
1229 with placebo (*see* PRECAUTIONS, Transaminase Elevations).

1230 SYMBYAX was associated with a slight decrease in hemoglobin that was statistically
1231 significantly greater than that seen with placebo, olanzapine, and fluoxetine.

1232 An elevation in serum prolactin was observed with SYMBYAX. This elevation was not
1233 statistically different than that seen with olanzapine (*see* PRECAUTIONS, Hyperprolactinemia).

1234 In olanzapine clinical studies among olanzapine-treated patients with random triglyceride
1235 levels of <150 mg/dL at baseline (N=659), 0.5% of patients experienced triglyceride levels of
1236 ≥500 mg/dL anytime during the trials. In these same trials, olanzapine-treated patients (N=1185)
1237 had a mean increase of 20 mg/dL in triglycerides from a mean baseline value of 175 mg/dL.

1238 In olanzapine placebo-controlled trials, olanzapine-treated patients with random cholesterol
1239 levels of <200 mg/dL at baseline (N=1034) experienced cholesterol levels of ≥240 mg/dL
1240 anytime during the trials more often than placebo-treated patients (N=602) (3.6% vs 2.2%,
1241 respectively). In these same trials, olanzapine-treated patients (N=2528) had a mean increase of
1242 0.4 mg/dL in cholesterol from a mean baseline value of 203 mg/dL, which was significantly
1243 different compared to placebo-treated patients (N=1415) with a mean decrease of 4.6 mg/dL
1244 from a mean baseline value of 203 mg/dL.

1245 Sexual dysfunction — In the pool of controlled SYMBYAX studies, there were higher rates of
1246 the treatment-emergent adverse events decreased libido, anorgasmia, impotence and abnormal
1247 ejaculation in the SYMBYAX group than in the placebo group. One case of decreased libido led
1248 to discontinuation in the SYMBYAX group. In the controlled studies that contained a fluoxetine
1249 arm, the rates of decreased libido and abnormal ejaculation in the SYMBYAX group were less
1250 than the rates in the fluoxetine group. None of the differences were statistically significant.

1251 Sexual dysfunction, including priapism, has been reported with all SSRIs. While it is difficult
1252 to know the precise risk of sexual dysfunction associated with the use of SSRIs, physicians
1253 should routinely inquire about such possible side effects.

1254 Vital signs — Tachycardia, bradycardia, and orthostatic hypotension have occurred in
1255 SYMBYAX-treated patients (*see* WARNINGS, Orthostatic Hypotension). The mean pulse of
1256 SYMBYAX-treated patients was reduced by 1.6 beats/min.

1257 Additional findings — In a single 8-week randomized, double-blind, fixed-dose, study
1258 comparing 10 (N=199), 20 (N=200) and 40 (N=200) mg/day of olanzapine in patients with
1259 schizophrenia or schizoaffective disorder, statistically significant differences among 3 dose
1260 groups were observed for the following safety outcomes: weight gain, prolactin elevation, fatigue
1261 and dizziness. Mean baseline to endpoint increase in weight (10 mg/day: 1.9 kg; 20 mg/day:
1262 2.3 kg; 40 mg/day: 3 kg) was observed with significant differences between 10 vs 40 mg/day.
1263 Incidence of treatment-emergent prolactin elevation >24.2 ng/mL (female) or >18.77 ng/mL
1264 (male) at any time during the trial (10 mg/day: 31.2%; 20 mg/day: 42.7%; 40 mg/day: 61.1%)
1265 with significant differences between 10 vs 40 mg/day and 20 vs 40 mg/day; fatigue (10 mg/day:
1266 1.5%; 20 mg/day: 2.1%; 40 mg/day: 6.6%) with significant differences between 10 vs 40 and

1267 20 vs 40 mg/day; and dizziness (10 mg/day: 2.6%; 20 mg/day: 1.6%; 40 mg/day: 6.6%) with
1268 significant differences between 20 vs 40 mg, was observed.

1269 **Other Events Observed in Clinical Studies**

1270 Following is a list of all treatment-emergent adverse events reported at anytime by individuals
1271 taking SYMBYAX in clinical studies except (1) those listed in the body or footnotes of Tables 3
1272 and 4 above or elsewhere in labeling, (2) those for which the COSTART terms were
1273 uninformative or misleading, (3) those events for which a causal relationship to SYMBYAX use
1274 was considered remote, and (4) events occurring in only 1 patient treated with SYMBYAX and
1275 which did not have a substantial probability of being acutely life-threatening.

1276 Events are classified within body system categories using the following definitions: frequent
1277 adverse events are defined as those occurring on 1 or more occasions in at least 1/100 patients,
1278 infrequent adverse events are those occurring in 1/100 to 1/1000 patients, and rare events are
1279 those occurring in <1/1000 patients.

1280 **Body as a Whole** — *Frequent*: chills, infection, neck pain, neck rigidity, photosensitivity
1281 reaction; *Infrequent*: cellulitis, cyst, hernia, intentional injury, intentional overdose, malaise,
1282 moniliasis, overdose, pelvic pain, suicide attempt; *Rare*: death, tolerance decreased.

1283 **Cardiovascular System** — *Frequent*: migraine, vasodilatation; *Infrequent*: arrhythmia,
1284 bradycardia, cerebral ischemia, electrocardiogram abnormal, hypotension, QT-interval
1285 prolonged; *Rare*: angina pectoris, atrial arrhythmia, atrial fibrillation, bundle branch block,
1286 congestive heart failure, myocardial infarct, peripheral vascular disorder, T-wave inverted.

1287 **Digestive System** — *Frequent*: increased salivation, thirst; *Infrequent*: cholelithiasis, colitis,
1288 eructation, esophagitis, gastritis, gastroenteritis, gingivitis, hepatomegaly, nausea and vomiting,
1289 peptic ulcer, periodontal abscess, stomatitis, tooth caries; *Rare*: aphthous stomatitis, fecal
1290 incontinence, gastrointestinal hemorrhage, gum hemorrhage, intestinal obstruction, liver fatty
1291 deposit, pancreatitis.

1292 **Endocrine System** — *Infrequent*: hypothyroidism.

1293 **Hemic and Lymphatic System** — *Frequent*: ecchymosis; *Infrequent*: anemia, leukocytosis,
1294 lymphadenopathy; *Rare*: coagulation disorder, leukopenia, purpura, thrombocythemia.

1295 **Metabolic and Nutritional** — *Frequent*: generalized edema, weight loss; *Infrequent*: alcohol
1296 intolerance, dehydration, glycosuria, hyperlipemia, hypoglycemia, hypokalemia, obesity; *Rare*:
1297 acidosis, bilirubinemia, creatinine increased, gout, hyperkalemia, hypoglycemic reaction.

1298 **Musculoskeletal System** — *Infrequent*: arthritis, bone disorder, generalized spasm, leg
1299 cramps, tendinous contracture, tenosynovitis; *Rare*: arthrosis, bursitis, myasthenia, myopathy,
1300 osteoporosis, rheumatoid arthritis.

1301 **Nervous System** — *Infrequent*: abnormal gait, ataxia, buccoglossal syndrome, cogwheel
1302 rigidity, coma, confusion, depersonalization, dysarthria, emotional lability, euphoria,
1303 extrapyramidal syndrome, hostility, hypesthesia, hypokinesia, incoordination, movement
1304 disorder, myoclonus, neuralgia, neurosis, vertigo; *Rare*: acute brain syndrome, aphasia, dystonia,
1305 libido increased, subarachnoid hemorrhage, withdrawal syndrome.

1306 **Respiratory System** — *Frequent*: bronchitis, lung disorder; *Infrequent*: apnea, asthma,
1307 epistaxis, hiccup, hyperventilation, laryngitis, pneumonia, voice alteration, yawn; *Rare*:
1308 emphysema, hemoptysis, laryngismus.

1309 **Skin and Appendages** — *Infrequent*: acne, alopecia, contact dermatitis, dry skin, eczema,
1310 pruritis, psoriasis, skin discoloration, vesiculobullous rash; *Rare*: exfoliative dermatitis,
1311 maculopapular rash, seborrhea, skin ulcer.

1312 **Special Senses** — *Frequent*: abnormal vision, taste perversion, tinnitus; *Infrequent*:
 1313 abnormality of accommodation, conjunctivitis, deafness, diplopia, dry eyes, eye pain, miosis;
 1314 *Rare*: eye hemorrhage.

1315 **Urogenital System** — *Frequent*: breast pain, menorrhagia¹, urinary frequency, urinary
 1316 incontinence, urinary tract infection; *Infrequent*: amenorrhea¹, breast enlargement, breast
 1317 neoplasm, cystitis, dysuria, female lactation¹, fibrocystic breast¹, hematuria, hypomenorrhea¹,
 1318 leukorrhea¹, menopause¹, metrorrhagia¹, oliguria, ovarian disorder¹, polyuria, urinary retention,
 1319 urinary urgency, urination impaired, vaginal hemorrhage¹, vaginal moniliasis¹, vaginitis¹; *Rare*:
 1320 breast carcinoma, breast engorgement, endometrial disorder¹, gynecomastia¹, kidney calculus,
 1321 uterine fibroids enlarged¹.

1322 ¹ Adjusted for gender.

1323

1324 **Other Events Observed with Olanzapine or Fluoxetine Monotherapy**

1325 The following adverse events were not observed in SYMBYAX-treated patients during
 1326 premarketing clinical studies but have been reported with olanzapine or fluoxetine monotherapy:
 1327 aplastic anemia, cholestatic jaundice, diabetic coma, dyskinesia, eosinophilic pneumonia,
 1328 erythema multiforme, hepatitis, idiosyncratic hepatitis, jaundice, neutropenia, priapism,
 1329 pulmonary embolism, rhabdomyolysis, serotonin syndrome, serum sickness-like reaction, sudden
 1330 unexpected death, suicidal ideation, vasculitis, venous thromboembolic events (including
 1331 pulmonary embolism and deep venous thrombosis), violent behaviors. Random cholesterol levels
 1332 of ≥ 240 mg/dL and random triglyceride levels of ≥ 1000 mg/dL have been reported.

1333

1334 **DRUG ABUSE AND DEPENDENCE**

1334 **Controlled Substance Class** — SYMBYAX is not a controlled substance.

1335 **Physical and Psychological Dependence** — SYMBYAX, as with fluoxetine and olanzapine,
 1336 has not been systematically studied in humans for its potential for abuse, tolerance, or physical
 1337 dependence. While the clinical studies did not reveal any tendency for any drug-seeking
 1338 behavior, these observations were not systematic, and it is not possible to predict on the basis of
 1339 this limited experience the extent to which a CNS-active drug will be misused, diverted, and/or
 1340 abused once marketed. Consequently, physicians should carefully evaluate patients for history of
 1341 drug abuse and follow such patients closely, observing them for signs of misuse or abuse of
 1342 SYMBYAX (e.g., development of tolerance, incrementation of dose, drug-seeking behavior).

1343 In studies in rats and rhesus monkeys designed to assess abuse and dependence potential,
 1344 olanzapine alone was shown to have acute depressive CNS effects but little or no potential of
 1345 abuse or physical dependence at oral doses up to 15 (rat) and 8 (monkey) times the MRHD
 1346 (20 mg) on a mg/m^2 basis.

1347

1348 **OVERDOSAGE**

1348 **SYMBYAX**

1349 During premarketing clinical studies of the olanzapine/fluoxetine combination, overdose of
 1350 both fluoxetine and olanzapine were reported in five study subjects. Four of the five subjects
 1351 experienced loss of consciousness (3) or coma (1). No fatalities occurred.

1352 Since the market introduction of olanzapine in October 1996, adverse event cases involving
 1353 combination use of fluoxetine and olanzapine have been reported to Eli Lilly and Company. An
 1354 overdose of combination therapy is defined as confirmed or suspected ingestion of a dose of
 1355 olanzapine 20 mg or greater in combination with a dose of fluoxetine 80 mg or greater. As of
 1356 1 February 2002, 12 cases of combination therapy overdose were reported, most of which

1357 involved additional substances. Adverse events associated with these reports included
1358 somnolence; impaired consciousness (coma, lethargy); impaired neurologic function (ataxia,
1359 confusion, convulsions, dysarthria); arrhythmias; and fatality. Fatalities have been confounded
1360 by exposure to additional substances including alcohol, thioridazine, oxycodone, and
1361 propoxyphene.

1362 **Olanzapine**

1363 In postmarketing reports of overdose with olanzapine alone, symptoms have been reported in
1364 the majority of cases. In symptomatic patients, symptoms with $\geq 10\%$ incidence included
1365 agitation/aggressiveness, dysarthria, tachycardia, various extrapyramidal symptoms, and reduced
1366 level of consciousness ranging from sedation to coma. Among less commonly reported
1367 symptoms were the following potentially medically serious events: aspiration, cardiopulmonary
1368 arrest, cardiac arrhythmias (such as supraventricular tachycardia as well as a patient that
1369 experienced sinus pause with spontaneous resumption of normal rhythm), delirium, possible
1370 neuroleptic malignant syndrome, respiratory depression/arrest, convulsion, hypertension, and
1371 hypotension. Eli Lilly and Company has received reports of fatality in association with overdose
1372 of olanzapine alone. In 1 case of death, the amount of acutely ingested olanzapine was reported
1373 to be possibly as low as 450 mg; however, in another case, a patient was reported to survive an
1374 acute olanzapine ingestion of 1500 mg.

1375 **Fluoxetine**

1376 Worldwide exposure to fluoxetine is estimated to be over 38 million patients (circa 1999). Of
1377 the 1578 cases of overdose involving fluoxetine, alone or with other drugs, reported from this
1378 population, there were 195 deaths.

1379 Among 633 adult patients who overdosed on fluoxetine alone, 34 resulted in a fatal outcome,
1380 378 completely recovered, and 15 patients experienced sequelae after overdose, including
1381 abnormal accommodation, abnormal gait, confusion, unresponsiveness, nervousness, pulmonary
1382 dysfunction, vertigo, tremor, elevated blood pressure, impotence, movement disorder, and
1383 hypomania. The remaining 206 patients had an unknown outcome. The most common signs and
1384 symptoms associated with non-fatal overdose were seizures, somnolence, nausea, tachycardia,
1385 and vomiting. The largest known ingestion of fluoxetine in adult patients was 8 grams in a
1386 patient who took fluoxetine alone and who subsequently recovered. However, in an adult patient
1387 who took fluoxetine alone, an ingestion as low as 520 mg has been associated with lethal
1388 outcome, but causality has not been established.

1389 Among pediatric patients (ages 3 months to 17 years), there were 156 cases of overdose
1390 involving fluoxetine alone or in combination with other drugs. Six patients died, 127 patients
1391 completely recovered, 1 patient experienced renal failure, and 22 patients had an unknown
1392 outcome. One of the 6 fatalities was a 9-year-old boy who had a history of OCD, Tourette's
1393 Syndrome with tics, attention deficit disorder, and fetal alcohol syndrome. He had been receiving
1394 100 mg of fluoxetine daily for 6 months in addition to clonidine, methylphenidate, and
1395 promethazine. Mixed-drug ingestion or other methods of suicide complicated all 6 overdoses in
1396 children that resulted in fatalities. The largest ingestion in pediatric patients was 3 grams, which
1397 was non-lethal.

1398 Other important adverse events reported with fluoxetine overdose (single or multiple drugs)
1399 included coma, delirium, ECG abnormalities (such as QT-interval prolongation and ventricular
1400 tachycardia, including torsades de pointes-type arrhythmias), hypotension, mania, neuroleptic
1401 malignant syndrome-like events, pyrexia, stupor, and syncope.

1402 **Management of Overdose** — In managing overdose, the possibility of multiple drug
1403 involvement should be considered. In case of acute overdose, establish and maintain an airway
1404 and ensure adequate ventilation, which may include intubation. Induction of emesis is not
1405 recommended as the possibility of obtundation, seizures, or dystonic reactions of the head and
1406 neck following overdose may create a risk for aspiration. Gastric lavage (after intubation, if
1407 patient is unconscious) and administration of activated charcoal together with a laxative should
1408 be considered. Cardiovascular monitoring should commence immediately and should include
1409 continuous electrocardiographic monitoring to detect possible arrhythmias.

1410 A specific precaution involves patients who are taking or have recently taken SYMBYAX and
1411 may have ingested excessive quantities of a TCA (tricyclic antidepressant). In such cases,
1412 accumulation of the parent TCA and/or an active metabolite may increase the possibility of
1413 serious sequelae and extend the time needed for close medical observation.

1414 Due to the large volume of distribution of olanzapine and fluoxetine, forced diuresis, dialysis,
1415 hemoperfusion, and exchange transfusion are unlikely to be of benefit. No specific antidote for
1416 either fluoxetine or olanzapine overdose is known. Hypotension and circulatory collapse should
1417 be treated with appropriate measures such as intravenous fluids and/or sympathomimetic agents.
1418 Do not use epinephrine, dopamine, or other sympathomimetics with β -agonist activity, since beta
1419 stimulation may worsen hypotension in the setting of olanzapine-induced alpha blockade.

1420 The physician should consider contacting a poison control center for additional information on
1421 the treatment of any overdose. Telephone numbers for certified poison control centers are listed
1422 in the *Physicians' Desk Reference (PDR)*.

1423 **DOSAGE AND ADMINISTRATION**

1424 SYMBYAX should be administered once daily in the evening, generally beginning with the
1425 6-mg/25-mg capsule. While food has no appreciable effect on the absorption of olanzapine and
1426 fluoxetine given individually, the effect of food on the absorption of SYMBYAX has not been
1427 studied. Dosage adjustments, if indicated, can be made according to efficacy and tolerability.
1428 Antidepressant efficacy was demonstrated with SYMBYAX in a dose range of olanzapine 6 to
1429 12 mg and fluoxetine 25 to 50 mg (*see CLINICAL STUDIES*).

1430 The safety of doses above 18 mg/75 mg has not been evaluated in clinical studies.

1431 **Special Populations**

1432 The starting dose of SYMBYAX 3 mg/25 mg - 6 mg/25 mg should be used for patients with a
1433 predisposition to hypotensive reactions, patients with hepatic impairment, or patients who exhibit
1434 a combination of factors that may slow the metabolism of SYMBYAX (female gender, geriatric
1435 age, nonsmoking status) or those patients who may be pharmacodynamically sensitive to
1436 olanzapine. When indicated, dose escalation should be performed with caution in these patients.
1437 SYMBYAX has not been systematically studied in patients over 65 years of age or in patients
1438 <18 years of age (*see WARNINGS, Orthostatic Hypotension, PRECAUTIONS, Pediatric Use,*
1439 *and Geriatric Use, and CLINICAL PHARMACOLOGY, Pharmacokinetics*).

1440 **Treatment of Pregnant Women During the Third Trimester**

1441 Neonates exposed to fluoxetine, a component of SYMBYAX, and other SSRIs or SNRIs, late
1442 in the third trimester have developed complications requiring prolonged hospitalization,
1443 respiratory support, and tube feeding (*see PRECAUTIONS*). When treating pregnant women
1444 with fluoxetine during the third trimester, the physician should carefully consider the potential
1445 risks and benefits of treatment. The physician may consider tapering fluoxetine in the third
1446 trimester.

1447 **Discontinuation of Treatment with SYMBYAX**

1448 Symptoms associated with discontinuation of fluoxetine, a component of SYMBYAX, and
 1449 other SSRIs and SNRIs, have been reported (*see* PRECAUTIONS). Patients should be monitored
 1450 for these symptoms when discontinuing treatment. A gradual reduction in the dose rather than
 1451 abrupt cessation is recommended whenever possible. If intolerable symptoms occur following a
 1452 decrease in the dose or upon discontinuation of treatment, then resuming the previously
 1453 prescribed dose may be considered. Subsequently, the physician may continue decreasing the
 1454 dose but at a more gradual rate. Plasma fluoxetine and norfluoxetine concentration decrease
 1455 gradually at the conclusion of therapy which may minimize the risk of discontinuation symptoms
 1456 with this drug.

1457 **HOW SUPPLIED**

1458 SYMBYAX capsules are supplied in 3/25-, 6/25-, 6/50-, 12/25-, and 12/50-mg (mg equivalent
 1459 olanzapine/mg equivalent fluoxetine^a) strengths.

Medication Guide

1475 **Antidepressant Medicines, Depression and other Serious Mental**
 1476 **Illnesses, and Suicidal Thoughts or Actions**

1477 Read the Medication Guide that comes with your or your family member's antidepressant
 1478 medicine. This Medication Guide is only about the risk of suicidal thoughts and actions with
 1479 antidepressant medicines. **Talk to your, or your family member's, healthcare provider**
 1480 **about:**

- 1481 • all risks and benefits of treatment with antidepressant medicines
- 1482 • all treatment choices for depression or other serious mental illness

1483 **What is the most important information I should know about antidepressant**
 1484 **medicines, depression and other serious mental illnesses, and suicidal thoughts**
 1485 **or actions?**

1486 **1. Antidepressant medicines may increase suicidal thoughts or actions in some children,**
 1487 **teenagers, and young adults within the first few months of treatment.**

1488 **2. Depression and other serious mental illnesses are the most important causes of**
 1489 **suicidal thoughts and actions. Some people may have a particularly high risk of**
 1490 **having suicidal thoughts or actions.** These include people who have (or have a family
 1491 history of) bipolar illness (also called manic-depressive illness) or suicidal thoughts or
 1492 actions.

1493 **3. How can I watch for and try to prevent suicidal thoughts and actions in myself or a**
 1494 **family member?**

- 1495 • Pay close attention to any changes, especially sudden changes, in mood, behaviors,
 1496 thoughts, or feelings. This is very important when an antidepressant medicine is
 1497 started or when the dose is changed.
- 1498 • Call the healthcare provider right away to report new or sudden changes in mood,
 1499 behavior, thoughts, or feelings.
- 1500 • Keep all follow-up visits with the healthcare provider as scheduled. Call the
 1501 healthcare provider between visits as needed, especially if you have concerns about
 1502 symptoms.

1503 **Call a healthcare provider right away if you or your family member has any of the**
 1504 **following symptoms, especially if they are new, worse, or worry you:**

- 1505 • thoughts about suicide or dying
- 1506 • attempts to commit suicide
- 1507 • new or worse depression
- 1508 • new or worse anxiety
- 1509 • feeling very agitated or restless
- 1510 • panic attacks
- 1511 • trouble sleeping (insomnia)
- 1512 • new or worse irritability

- 1513 • acting aggressive, being angry, or violent
- 1514 • acting on dangerous impulses
- 1515 • an extreme increase in activity and talking (mania)
- 1516 • other unusual changes in behavior or mood

What else do I need to know about antidepressant medicines?

- 1518 • **Never stop an antidepressant medicine without first talking to a healthcare provider.**
1519 Stopping an antidepressant medicine suddenly can cause other symptoms.
- 1520 • **Antidepressants are medicines used to treat depression and other illnesses.** It is
1521 important to discuss all the risks of treating depression and also the risks of not treating it.
1522 Patients and their families or other caregivers should discuss all treatment choices with the
1523 healthcare provider, not just the use of antidepressants.
- 1524 • **Antidepressant medicines have other side effects.** Talk to the healthcare provider about
1525 the side effects of the medicine prescribed for you or your family member.
- 1526 • **Antidepressant medicines can interact with other medicines.** Know all of the medicines
1527 that you or your family member takes. Keep a list of all medicines to show the healthcare
1528 provider. Do not start new medicines without first checking with your healthcare provider.
- 1529 • **Not all antidepressant medicines prescribed for children are FDA approved for use in**
1530 **children.** Talk to your child's healthcare provider for more information.

1531 *This Medication Guide has been approved by the US Food and Drug Administration for*
1532 *all antidepressants.*
