ABSTRACT

The Alaska Fisheries Science Center's 2001 West Coast triennial bottom trawl survey was conducted to assess stocks of groundfish inhabiting the continental shelf waters off the coasts of California, Oregon, Washington, and southern British Columbia. This was the ninth and final survey in a series spanning 25 years to monitor long-term trends in the distribution and abundance of these groundfish populations.

Although the objectives of the 2001 survey were similar to those of the previous surveys in the series, minor changes in the survey design have been made over the years. The five most recent surveys have shifted emphasis away from estimating rockfish abundance, as had been the case from 1977 through 1986, toward better assessing a broader range of groundfish species. The current design also focuses upon more precisely estimating the near-bottom component of the Pacific hake (*Merluccius productus*) and juvenile (age 1+) sablefish (*Anoplopoma fimbria*) resources. The 2001 survey encompassed the coastal waters from Pt. Conception, California, to central Vancouver Island, British Columbia ($34^{\circ}30' - 49^{\circ}06'N$). The depth range of the 2001 survey was 55 to 500 m, the same as it has been since 1995 when sampling was extended from the previous maximum depth of 366 m in order to cover the habitat of slope rockfish more completely. A total of 527 stations were occupied, of which 506 were successfully

sampled. Catches included over 166 fish species representing more than 57 families.

This report documents the survey design and methods used in 2001, summarizes biological and environmental data collected, and presents the results of standard analyses of distribution, abundance, and biological parameters for the commercially important groundfish species in the region. Data on water temperature, catch composition, relative abundance, and geographic distribution are reported. Estimates of biomass, population abundance, length composition and age composition are also presented. Data appendices are located in a separate volume.

INTRODUCTION

In 2001, the ninth and final in our series of groundfish assessment surveys of the continental shelf resources off the coasts of California, Oregon, Washington, and southern British Columbia was carried out by the National Marine Fisheries Service (NMFS) Resource Assessment and Conservation Engineering (RACE) Division of the Alaska Fisheries Science Center (AFSC). These bottom trawl surveys, initiated in 1977 and repeated triennially, have been designed to provide resource managers with fishery-independent data about the distribution, abundance, and biological characteristics of several commercially important species, particularly Pacific hake (also known as Pacific whiting; *Merluccius productus*), sablefish (*Anoplopoma fimbria*), and many of the shelf and slope rockfish (genus *Sebastodes*) species (Wilkins 1996). Hydroacoustic surveys of the off-bottom component of the Pacific hake population have been conducted concurrently with these bottom trawl surveys by the Midwater Assessment and Conservation Engineering (MACE) Task of the RACE Division.

The first of these bottom trawl surveys, conducted in 1977 (Gunderson and Sample 1980), sampled between Pt. Hueneme, California ($34^{\circ}00'N$), and the U.S.-Canada border in depths ranging from 91 to 457 m. The sampling effort was stratified by depth and latitude according to fishery catch information. The following two surveys, conducted in 1980 (Coleman 1986) and 1983 (Weinberg et al. 1984), emphasized obtaining better biomass

estimates of canary (*Sebastodes pinniger*) and yellowtail rockfish (*S. flavidus*), while maintaining the important general goals of a multispecies monitoring program. In 1980, strata were adjusted and sampling depths shifted to cover the 55-366 m depth interval, while the latitudinal boundaries extended from Monterey Bay, California ($36^{\circ}48'N$), to northern Vancouver Island, British Columbia ($50^{\circ}00'N$). The same area was surveyed using the same survey design in 1983 but only extended as far north as Vancouver Island's Estevan Point ($49^{\circ}15'N$). The results of the 1980 and 1983 surveys indicated that a better sampling design was needed to improve the precision of canary and yellowtail rockfish abundance estimates. Consequently, in 1986 the sampling effort was reallocated to concentrate on the 92-219 m depth interval north of $42^{\circ}35'N$ latitude, where canary and yellowtail rockfish were thought to be most abundant (Coleman 1988). Results of these first four surveys were used to examine trends in the distribution and abundance of 14 of the more commercially important groundfish species (Dark and Wilkins 1994).

Despite efforts to improve the precision of rockfish abundance estimates over the first four iterations of the triennial survey, the large variances of the estimates remained a problem. We concluded that precise estimates of rockfish abundance were not possible using current trawl survey methods and realistic sampling levels. It was clear that higher priority should be given to obtaining the information that our survey was better able to provide. Consequently, beginning in 1989 the

triennial bottom trawl survey was modified to monitor a broad range of demersal species and also focus on providing more precise estimates of the demersal component of the Pacific hake stock and sablefish pre-recruits (age 1+) (Weinberg et al. 1994, Zimmermann et al. 1994, Wilkins et al. 1998). The results of the 1977-92 surveys were used by Weinberg (1994) to describe rockfish community structure and species assemblages. His findings, as well as recent assessments of slope and shelf rockfish stocks (Rogers et al. 1996) indicated that more complete depth coverage of the habitats of these species during our surveys would improve our ability to assess them. In 1995, we redirected a portion of our samples from four small areas of high density sampling for Pacific hake and sablefish and placed them in a new, coastwide, deeper depth stratum ranging between 367 and 500 m. This survey design was repeated in 1998 (Shaw et al. 2000) and again in 2001.

The specific objectives of the 2001 survey were:

- 1) to describe and assess the demersal component of the Pacific hake resource;
- 2) to describe and assess the abundance of the shallow component of the sablefish resource, specifically those 1.5 years old, because the abundance of these pre-recruits estimated from trawl survey data has been shown to be consistent with that inferred from commercial catch levels;
- 3) to describe and assess shelf and slope rockfish stocks throughout their entire depth ranges;

- 4) to monitor the status of other important groundfish stocks;
- 5) to determine the biological characteristics (e.g., size and age compositions, size at maturity, length/weight relationships and feeding habits) of key groundfish species;
- 6) to collect oceanographic data describing the habitat, including surface temperatures, bottom temperatures, and water column temperature profiles at each sampling station; and
- 7) to collect samples from a variety of species for biological studies that will be conducted by scientists at various fishery agencies and academic institutions.

This report documents the 2001 survey design and field procedures used, summarizes the data collected, and presents the results of the standard RACE analyses. Included are summaries of catches, relative densities, distributions, and estimates of biomass, population abundance, and size composition for selected species. Age composition estimates are also included for three species for which ages have been determined from otolith collections and length-weight relationships are described for many groundfish species. For the sake of brevity, our discussion concentrates on the two primary target species of this survey, Pacific hake and sablefish, in the areas presently of most

concern to management. This report is also available on the AFSC web site,

<http://www.afsc.noaa.gov/Publications/techmemos.htm>

and can be viewed or printed using Adobe Acrobat Reader. Electronic data files and files containing results of analyses (e.g., size and age composition) can also be obtained from the authors upon request.

SURVEY METHODS

Survey Period and Sampling Area

The 2001 survey was conducted from 1 June to 27 August. While the start time coincided with the 1998 survey, it was earlier than most previous triennial surveys (mid-July through September). Trawl operations began off Pt. Conception, California ($34^{\circ}30'N$), and proceeded northward to central Vancouver Island off Esowista Peninsula ($49^{\circ}06'N$) sampling stations between the depths of 55 and 500 m. The survey area has extended southward to Point Conception since 1989 to allow for the detection of juvenile Pacific hake and sablefish concentrations which may be present between Point Conception and Monterey Bay. Stations off Vancouver Island were sampled to help estimate fish densities at the northern limit of the Pacific hake distribution and to collect more complete data sets on transboundary stocks such as yellowtail rockfish, Pacific ocean perch (*S. alutus*), and lingcod (*Ophiodon elongatus*).

Vessels and Sampling Gear

Two commercial trawlers, the U.S.-flagged F/V *Sea Storm* and the Canadian-flagged F/V *Frosti*, were chartered to conduct the bottom trawl survey. The *Sea Storm* fished continuously from 1 June to 5 August. The *Frosti* fished from 1 June to 27 August but was off charter between 23 June and 15 July. Each vessel was equipped with modern electronics including global positioning system (GPS) navigational aids. Vessel-specific details are presented in Table 1.

The standard RACE high-opening Nor'easter trawl, constructed of polyethylene mesh and equipped with rubber bobbin roller gear, was used aboard both vessels throughout the 2001 survey (Fig. 1). This trawl has a 27.2 m headrope and a 37.4 m footrope. All trawls were rigged consistently to RACE survey gear standards employing triple 55 m dandylines (1.59 cm steel cable) connected to each wing and fished with 2.1 × 1.5 m steel V-doors weighing approximately 567 kg each.

Measurements of the trawl opening were collected throughout the survey using a SCANMAR acoustical net mensuration system. Horizontal (wingtip to wingtip) openings were measured for 439 (87%) of the successfully completed tows. Vertical (center of headrope to bottom) openings were measured on all but three tows. Mean net widths and heights were calculated for each successfully measured trawl haul. In those instances when horizontal measurements were unavailable and good net height was available,

the best predictor of average net width (m) was width regressed on net height using the following relationships:

F/V *Sea Storm*

$$\text{Net width} = -1.24 \times H + 23.216$$

R/V *Frosti*

$$\text{Net width} = -0.9524 \times H + 21.268$$

where: H = net height (m).

For the tows for which no net height measurement was available the best predictor was a regression of net width on inverse depth using the following equation:

F/V *Sea Storm*

$$\text{Net width} = -58.271 / D + 14.131$$

These equations were derived by examining the relationship between mean net width and a set of variables known to be important in determining the horizontal opening of the net (Rose 1993). The overall mean path width of the net from successfully completed hauls was 13.71 m (range 11.28-15.24 m) by the *Sea Storm* and 14.05 m (range 12.24-15.89 m) by the *Frosti*.

Survey Area Stratification

The 2001 triennial survey sampled the entire survey area with a nearly uniform sampling density, which was similar to the low-density levels used in surveys prior to 1995. Ten latitudinal strata of similar size (Fig. 2) were used during the analyses to help ensure catch rates of various species were extrapolated to meaningful areas of their respective habitats.

The survey area was also stratified by depth since most groundfish species in the area exhibit a strong depth range preference. All West Coast triennial surveys prior to 1995 were divided into two major depth strata: 55-183 m representing a continental shelf habitat and 184-366 m representing the shelf break and the uppermost continental slope. Pacific hake and juvenile sablefish catch rates, in particular, are usually significantly higher in the shallower stratum. An additional deeper depth stratum (367-500 m) was added to the design of the survey beginning in 1995 so that the survey area would encompass the entire depth range of slope rockfish (*Sebastodes*) species.

Trawl Station Allocation

The 2001 survey replicated the 1995 and 1998 station pattern. A systematic-random design was used to allocate trawl stations to best achieve the primary survey objectives, which were to estimate the abundance and biological characteristics of Pacific hake and juvenile sablefish stocks and concurrently monitor the condition of a broader range of commercially

important groundfish species. Tracklines were placed across the survey area from the 55 m isobath due west extending to the 500 m isobath at intervals of 18.5 km along the coast. Stations were randomly placed along tracklines at the rate of one station per 7.4 km in the shallow stratum and one station per 9.3 km in the two deeper stratum. At least one station was assigned to each depth stratum along each trackline segment. A total of 610 stations were established. The number of stations allocated to each stratum, as well as the number successfully sampled, are shown in Table 2.

Trawling Procedures

Stations were located using GPS and then surveyed with an echo sounder prior to towing. Trawl site selection was determined by the lead scientist and the vessel captain based upon the following guidelines, listed in order of priority:

- 1) a 30 minute tow through the station at a constant depth or minimal change in depth (about 9-18 m);
- 2) a partial tow (15-29 minutes in duration) through the station at a constant or minimal change in depth;
- 3) choose an alternative site within 2.5 minutes of the original station's latitude and within about 18 m of the original station's depth; and
- 4) choose an alternative site which lies closer to the original intended station than any other adjacent

station and is within the depth boundaries of the stratum in which the original station is assigned.

If no favorable ground was located within about 2 hours, the station was declared untrawlable and abandoned.

Before starting the survey, the trawl warps on each vessel were measured with a wire meter and marked at 45.7 m (25 fm) increments. An exercise was then conducted to establish an appropriate amount of trawl warp to deploy at a given depth. We did this by deploying the trawl and towing it at the survey target speed of 1.5 m/sec (3 knots, speed over ground) over deep water, increasing the length of trawl warp by 183 m (100 fm) intervals and allowing the trawl to settle to an equilibrium depth at each warp length. A micro-bathythermograph (MBT) was attached to the trawl headrope during this exercise and the settling depth was recorded for different trawl warp lengths. We tabulated the minimum length of trawl warp needed to fish the trawl at any given bottom depth and paid out an additional 90-240 m of warp to enhance bottom contact.

Towing procedures were standardized following strict protocols so as to obtain standard samples. Skippers set the trawl and payed out the prescribed amount of trawl warp while traveling faster than the target towing speed. The vessel was slowed as the brakes were set on the trawl winches and the gear was allowed to sink toward bottom. Before the gear reached bottom, the speed of the vessel was increased to 1.5 m/sec (speed

over ground) so that the trawl was nearly in its fishing configuration when it contacted the bottom. The duration of the tow was measured from when the trawl reached bottom and settled into its equilibrium fishing configuration as determined from information provided by the Scanmar trawl mensuration system until retrieval was initiated. After achieving equilibrium, the trawl was towed at 1.5 m/sec for 30 minutes. The net was then retrieved by engaging the winches while maintaining the 1.5 m/sec tow speed. If the gear was damaged during the tow severely enough to affect catch composition, the haul was considered unsatisfactory and the station was either retowed or abandoned. Unsuccessful tows were not used to calculate biomass or population estimates. The two vessels usually fished alternate tracklines when operating together to distribute any potential vessel-specific sampling effect equally over the survey area.

Catch Sampling and Oceanographic Data Collection

Trawl catches weighing about 1.2 metric tons (t) or less were deposited directly onto a table and sorted to species. Species were then weighed to the nearest 0.1 kg using a mechanical platform scale and enumerated. Individual species or species groups weighing approximately 2 kg or less were typically weighed to the nearest gram on an electronic Marel digital read-out scale. Larger catches were weighed with a dynamometer or their weight estimated volumetrically. These large catches were then either processed in their entirety by bringing multiple loads to the sorting table or by emptying the codend into a deck

bin and lifting a representative subsample to the table with a cargo net in a manner described by Hughes (1976), or by single-species subsampling when the major component of the catch was one species (e.g., Pacific hake or spiny dogfish (*Squalus acanthias*)). For those few hauls when the cargo net was used to obtain a subsample of the catch, major groundfish species occurring in limited numbers and remaining in the deck bin were 100% sampled. For those hauls when a single species clearly comprised the majority of the catch a randomly selected subsample of that species was obtained and the remainder (non-subsample) discarded. The difference between the total catch weight measured by the dynamometer and the sum of the subsample weight for the dominant species and all other species was used to estimate the total non-subsample weight for the dominant species.

Fork length (FL) measurements (up to 200 per tow) were randomly obtained by sex for all flatfish, all rockfish, Pacific hake, sablefish, Pacific cod (*Gadus macrocephalus*), and walleye pollock (*Theragra chalcogramma*) whenever they were caught. Lengths were also obtained for other species as time allowed. Total length (TL) measurements were obtained for sharks and skates while anal length (tip of snout to origin of anal fin) measurements were taken for grenadiers. All Pacific halibut (*Hippoglossus stenolepis*) were measured and released, their weights estimated from the length data.

Otoliths (used for age determination), along with individual specimen weight and maturity data, were collected from

a variety of species. Collections for Pacific hake and sablefish were stratified by length interval (5 otoliths/sex/cm) for biological subareas. Random collections were made for bocaccio (*S. paucispinis*), chilipepper (*S. goodei*), Pacific ocean perch, and aurora (*S. aurora*), blackgill (*S. melanostomus*), canary, darkblotched (*S. crameri*), redstripe (*S. proriger*), silvergray (*S. brevispinis*), sharpchin (*S. zacentrus*), splitnose (*S. diploproa*), yelloweye (*S. ruberrimus*), yellowmouth (*S. reedi*), and yellowtail rockfish. Fin rays were collected from lingcod for determining age. Other requests for meristic data and for samples of stomach contents, tissues, and whole fish were also fulfilled as time allowed.

Surface temperatures were measured with bucket thermometers and MBTs. Water column temperature profiles and bottom temperatures were collected with MBTs. Additionally, several sediment samples were collected on an opportunistic basis with a Shipek sediment grab.

Data Analyses

Several analyses are performed routinely on RACE bottom trawl survey data. These include:

- 1) estimation of relative abundance,
- 2) estimation of population biomass,
- 3) estimation of population numbers, and
- 4) estimation of the population's size composition.

We use the area-swept method described by Gunderson and Sample (1980) to calculate catch rates, which are in turn used to estimate population biomass and numbers. Briefly, this method entails standardizing species catch rates from each station into catch per unit effort (CPUE) in terms of kilograms or numbers per hectare trawled (kg/ha, no./ha) and calculating the arithmetic mean CPUE for each sampling stratum. Effort, the product of distance fished during the tow (net on bottom) and path width, is determined from information provided by an electronic bottom contact sensor (BCS; Somerton and Weinberg 2001), MBT, the Scanmar trawl mensuration system, and GPS. Relative abundance (mean CPUE) of each species is then calculated for each International North Pacific Fisheries Commission (INPFC) area as the sum of the mean CPUEs of each appropriate sampling stratum weighted by their respective stratum areas. Population biomass and numbers in each stratum are estimated by multiplying the stratum mean CPUE by the stratum area. Stratum estimates are summed to provide biomass and population estimates for various portions of the survey area (e.g., INPFC areas, U.S. waters). In cases where our sampling strata overlap more than one INPFC area, we expand the overall sampling stratum mean CPUE to the area of that portion of the sampling stratum lying within the INPFC area.

The size composition of each species was estimated in a manner similar to the population estimate. Length-frequency data collected at each station were weighted by the CPUE (no./ha) of that species at that station, summed over all hauls in a stratum, and expanded to the stratum population estimate. As with

population estimates, stratum estimates were summed to derive the estimated size compositions for various portions of the survey area.

Ages were determined from otolith or fin ray samples collected from groundfish species. The age compositions of these stocks were estimated by multiplying their population size composition by age-length keys (matrices of length vs. age) constructed from the age data from corresponding or appropriately pooled strata.

RESULTS

Haul, Catch, and Biological Data

Successful samples were obtained from 506 of the 610 stations within the entire survey bounds. Twenty-one tows were unsuccessful due to damaged trawls or poor gear performance, 51 stations were abandoned due to untrawlable bottom, and 32 stations remained unsampled on the northernmost four tracklines due to lack of time. Figure 3 shows the location of successful tows by depth stratum. Sampling density in each INPFC area ranged from 3.94 to 11.97 hauls per 1,000 km² in the shallow strata, from 2.91 to 19.07 hauls per 1,000 km² in the middle strata, and from 4.52 to 30.08 hauls per 1,000 km² in the deep strata (Table 2). Over the entire survey area, the sampling density was slightly higher in the deep strata (13.06 hauls per 1,000 km²) than in the middle (10.28 hauls per 1,000 km²) or the shallow (7.35 hauls per 1,000 km²) strata. Overall, the average

sampling density was also higher in the U.S. portion of the survey area than in the Canadian portion.

To date, a total of 166 fish species representing 57 families have been identified to the species level from good performance tows over the course of the survey (Table 3). These numbers are likely to increase as specimens collected at sea and brought back to the AFSC for identification are processed. Table 3 also lists the frequencies of occurrence, depth ranges, and the range of distribution by latitude for all fish taxa identified in trawl samples. The rockfishes (family Scorpaenidae) were the most diverse with 40 species taken in successful trawl samples coastwide, followed by the flatfishes (families Bothidae and Pleuronectidae) with 18, and the sculpins (family Cottidae) with 14 species.

Length measurements were taken from 275,122 fish. A summary of the number of fish measured is presented in Table 4 by species, INPFC area, and depth stratum. The number of specimens collected surveywide for age analyses, length-weight relationships, and maturity are reported in Table 5. Appendix A (see separate Data Appendices volume) summarizes the catch data by haul for each vessel.

Temperature Data

Sea surface temperatures measured at 489 stations using MBT and bucket thermometer data ranged from 6.5° to 16.7°C. The overall mean surface temperature was 12.0°C. Temperature profiles of the water column (surface to bottom) were collected

at 463 stations. Bottom temperatures from these stations ranged from 5.2° to 10.8°C, averaging 7.2°C. Figure 4 illustrates the observed surface and bottom temperatures by latitude.

Relative Abundance

The 20 most abundant groundfish species are presented by depth stratum for the individual INPFC areas in Table 6. The complete listings of the relative abundance of all fish and invertebrates ranked by mean CPUE for each INPFC area and depth stratum are presented in Appendix B (see separate volume of Data Appendices). Average total fish densities were highest in the Monterey (212.8 kg/ha) INPFC area followed by the Vancouver (200.8 kg/ha), Columbia (159.1 kg/ha), Eureka (155.1 kg/ha), and Conception (144.3 kg/ha) INPFC areas.

Pacific hake was the most abundant species overall, accounting for about 36% (64.3 kg/ha) of the total survey CPUE and about 39% (67.5 kg/ha) in U.S. waters alone. Pacific hake abundance was greatest in the Eureka INPFC area (91.8 kg/ha), where it comprised about 59% of the area's total CPUE. Pacific hake were least abundant in the Vancouver INPFC area (21.7 kg/ha) where it accounted for about 11% of all fish. Besides the Eureka INPFC area, Pacific hake also dominated samples in the Monterey (82.1 kg/ha), Columbia (69.0 kg/ha) and Conception (31.4 kg/ha) INPFC areas.

Sablefish was the second most abundant fish species, both overall and in U.S. waters. Sablefish CPUE averaged 19.5 kg/ha for the entire survey, or about 11% of the total fish CPUE and

20.5 kg/ha, or about 12% of the CPUE in U.S. waters. Sablefish abundance was greatest in the Columbia INPFC area (23.9 kg/ha), followed by the Monterey (23.3 kg/ha), Vancouver (20.9 kg/ha), Conception (9.5 kg/ha), and Eureka (5.6 kg/ha) INPFC areas. Sablefish accounted for between 4% and 15% of INPFC area fish catches.

Dover sole (*Microstomus pacificus*) was the third most abundant fish species, both surveywide and in U.S. waters. The mean Dover sole catch rate was 14.9 kg/ha throughout the entire survey area, or about 8% of the CPUE and 15.1 kg/ha in the U.S. area or about 9% of the CPUE. Dover sole abundance was greatest in the Monterey (20.7 kg/ha) INPFC area, followed by the Conception (17.9 kg/ha), Vancouver (12.9 kg/ha), Columbia (12.2 kg/ha), and Eureka (11.7 kg/ha) INPFC areas. Dover sole accounted for between 6% and 12% of INPFC area fish catches.

Catch composition and relative densities varied widely among geographic areas. The five most prominent species in the Conception INPFC area were: Pacific hake, chilipepper (30.4 kg/ha), Dover sole, Pacific sanddab (*Citharichthys sordidus*; 13.9 kg/ha), and sablefish; in the Monterey INPFC area, Pacific hake, sablefish, Dover sole, shortbelly rockfish (*S. jordani*; 18.9 kg/ha), and chilipepper (11.5 kg/ha); in the Eureka INPFC area, Pacific hake, Dover sole, rex sole (*Glyptocephalus zachirus*; 8.6 kg/ha), Pacific sanddab (6.9 kg/ha), and spiny dogfish (5.7 kg/ha); in the Columbia INPFC area, Pacific hake,

sablefish, Dover sole, Pacific sanddab (10.9 kg/ha), and rex sole (7.5 kg/ha); in the U.S. Vancouver INPFC area, walleye pollock (34.8 kg/ha), sablefish, arrowtooth flounder (*Atheresthes stomias*; 25.7 kg/ha), spiny dogfish (16.9 kg/ha), and Pacific hake; and in the Canadian Vancouver INPFC area, walleye pollock (40.4 kg/ha), spiny dogfish (31.1 kg/ha), Pacific hake, arrowtooth flounder (21.4 kg/ha), and yellowtail rockfish (16.0 kg/ha).

The catch composition also varied among depth strata. In the shallow stratum (55-183 m) for the entire survey area, Pacific hake (85.8 kg/ha) dominated catches, followed by sablefish (23.9 kg/ha), Pacific sanddab (13.6 kg/ha), walleye pollock (9.7 kg/ha), and spiny dogfish (9.1 kg/ha). The five most abundant species in the middle depth stratum (184-366 m) were Pacific hake (44.1 kg/ha), shortbelly rockfish (22.9 kg/ha), Dover sole (22.6 kg/ha), splitnose rockfish (16.9 kg/ha), and sablefish (14.2 kg/ha). The five most abundant species in the deep stratum (367-500 m) were Dover sole (31.6 kg/ha), Pacific hake (14.2 kg/ha), sablefish (11.0 kg/ha), rex sole (7.6 kg/ha), and shortspine thornyhead (*Sebastolobus alascanus*; 5.3 kg/ha).

Maps of the geographical distribution of economically important species, based on catch rates at each station, are presented by species in Figures 5-35 in alphabetical order. Some commercially important species such as yelloweye and yellowmouth rockfish have not been mapped because they were caught so

infrequently. Distribution maps for the following species are provided:

| | | |
|-----------------------|---------------------|-----------------------|
| Arrowtooth flounder | Aurora rockfish | Blackgill rockfish |
| Bocaccio | Canary rockfish | Chilipepper |
| Darkblotched rockfish | Dover sole | English sole |
| Greenstriped rockfish | Lingcod | Longspine thornyhead |
| Pacific hake | Pacific halibut | Pacific ocean perch |
| Pacific sanddab | Petrale sole | Redstripe rockfish |
| Rex sole | Rougheye rockfish | Sablefish |
| Sharpchin rockfish | Shortbelly rockfish | Shortspine thornyhead |
| Silvergray rockfish | Spiny dogfish | Splitnose rockfish |
| Stripetail rockfish | Walleye pollock | Widow rockfish |
| Yellowtail rockfish | | |

The distribution of each species is presented by relative density classifications (high, moderate, and low) in the distribution maps. For each species, all non-zero station catch rates were sorted in increasing order and classified in either the lowest 60%, middle 30%, or top 10% of the catch rate values. Stations where the species was not caught are also shown. The distribution of sampling effort should be considered when viewing these charts since heavier sampling in an area may give the impression of high densities when, in fact, CPUE was only moderate or low.

Biomass and Population Estimates

Abundance estimates in metric tons (t) of biomass and associated 90% confidence intervals are presented for various taxa in the total survey and by INPFC area and depth stratum in Tables 7-10. Similarly, estimates of population numbers are presented for important species groups in Tables 11-14. Detailed

listings of biomass and population estimates are presented for the major species in Appendix C in the Data Appendices volume.

The on-bottom component of the Pacific hake population was estimated to be 383,560 t for the entire area (Table 7). Two of the five INPFC areas accounted for 69% of the total estimated Pacific hake biomass, 42% in the Columbia INPFC area and 27% in the Monterey area. Nearly 7% of the total estimated Pacific hake biomass (25,628 t) was found in Canadian waters. Pacific hake biomass was distributed mostly in the shallow stratum, 333,231 t (87%), with 41,352 t (11%) in the middle depth stratum, and 8,977 t (2%) in the deep stratum (Tables 8-10).

The total sablefish biomass estimate was 117,945 t (Table 7). The Columbia and Monterey INPFC areas contributed 45% and 25%, respectively, of the total sablefish biomass between the depths of 55 and 500 m. Sablefish in Canadian waters (8,869 t) amounted to 8% of the total. The distribution of sablefish biomass was greatest in the shallow stratum with 96,643 t (82%), 14,263 t (12%) in the middle depth stratum, and 7,040 t (6%) in the deep stratum (Tables 8-10).

The biomass and population estimates presented here are likely to be conservative since only a portion of the stock may be available to the bottom trawl and some escapement may occur. Because of the lack of data on species-by-species catchability, abundance calculations are based on the assumption that all fish in front of the trawl and between the wingtips are captured. The degree of this conservative bias will vary among species. For instance, a large portion of the total Pacific hake stock is

pelagic and would be missed by a bottom trawl. Also, because roller gear is used, escapement underneath the trawl is likely to occur, particularly for the flatfish species. Furthermore, the survey covers limited portions of the depth and geographic range of many of these species.

Length Composition

Estimated population length compositions for several groundfish species are presented in alphabetical order by sex and INPFC area (Figs. 36-69). The length compositions for Pacific hake and sablefish include separate presentations of their length compositions by depth stratum. The length compositions of the remaining species are presented for the combined depths only. Computer files of estimated length compositions, by sex and INPFC area, are available upon request for any species from which length data were collected.

Two length modes were evident in the Pacific hake length distributions. For the total survey area, a discrete peak was seen at 33 cm, and a smaller peak was seen at 47 cm (Fig. 47). The overall population mean length was 39.4 cm. Pacific hake ranged in length from 10 to 91 cm. The male and female components of the population were similar with the average length of females (40.6 cm) being slightly longer than that of the males (38.1 cm). The Conception INPFC area contained mostly small to medium-sized (<35 cm) Pacific hake, the Monterey INPFC area had mostly medium (>30 cm) and some large (>40 cm) Pacific hake, the

Eureka and Columbia INPFC areas contained mostly medium and large Pacific hake, and north of the Columbia INPFC area we found mostly large hake. Some small Pacific hake were evident in the Canadian portion of the Vancouver INPFC area. Pacific hake mean lengths increased steadily from south to north ranging from 32.2 cm in the Conception area to 52.2 cm in the Canadian portion of the Vancouver INPFC area. Mean lengths of Pacific hake increased with depth in the Conception and Monterey INPFC areas but decreased in the middle depth strata in the Eureka and Columbia INPFC areas. Both portions of the Vancouver INPFC contained larger fish, on average, than INPFC areas to the south but also demonstrated a general decrease in size between the shallow and deep depth strata (Figs. 48, 49, and 50).

Sablefish inhabit a wide range of depths, exceeding the bounds of this survey. Its size distribution can be described by data from this survey for only the shallow end of its range. At these depths, the estimated length distribution for sablefish for the entire area was generally bimodal with a sharp peak of smaller fish at 36 cm and a smaller peak at 42 cm (Fig. 58). The overall population mean length was 39.5 cm. Sablefish ranged in length from 18 to 91 cm. The male and female population components were similar with the mean length of females (39.8 cm) being slightly longer than that of the males (39.1 cm). Juvenile sablefish (<43 cm) accounted for 79% of the estimated population. Unimodal distributions were observed in the Conception, Monterey, and U.S. portion of the Vancouver INPFC area with peaks at 40 cm,

42 cm, and 38 cm, respectively. More bimodal size distributions were seen in Eureka, Columbia, and the Canadian portion of the Vancouver INPFC area with peaks at 38 and 47 cm, 36 and 46 cm, and 38 cm, respectively. A large population of sablefish under 40 cm were detected north of the Eureka INPFC area in the shallow depth stratum (Fig. 59). Sablefish in the deep stratum were larger than those found in the two shallower strata (Fig. 61).

Age Compositions

Otoliths or dorsal fin rays were collected for age determination from specimens of 17 groundfish species (Table 5). To date, ages have been assigned to the structures collected from Pacific hake, canary rockfish, and yellowtail rockfish. The age composition of these species has been estimated and is presented in Figures 70-72. For this report, each of these species has been treated as a single, homogenous stock and all age data collected during the 2001 survey has been used to estimate the species's length-age relationship. When it has been appropriate, the age compositions of several of these resources have been estimated and presented in more geographic detail in stock assessment documents published by the Pacific Fishery Management Council.

The age composition of the Pacific hake resource (Fig. 70) shows that the population is primarily supported by 2-year-olds followed by a decreasing continuum ranging from 3 to 8 years in

age. Older fish contribute relatively little to the size of this resource.

Both rockfish species also demonstrated unimodal age compositions where the majority of the population is supported by a continuous range of ages that taper off with time. The canary rockfish resource was comprised mostly of 5-to-11-year-old fish with the population most strongly supported by the 1993-1995 year classes (Fig. 71). The eldest canary rockfish in our sample was 56 years old. The yellowtail rockfish resource was comprised mostly of 11-to-16-year-old fish with the majority of the population coming from the 1987 to 1990 year classes (Fig. 72). These two rockfish species generally become fully available to the survey and commercial trawl gear when they are between 3 and 7 years old. Prior to that, they can be detected by the survey trawl when the younger age groups are notably abundant. Following their full recruitment to the gear, the age composition figures (Figs. 71 and 72) track the relatively constant decrease in their abundance as they age, a normal result of natural and fishing-induced mortality.

Length-Weight Relationships

From the individual fish weight samples, we determined length-weight relationships using a non-linear, least-squares regression model. Results of these analyses are summarized in Table 15 for males, females, and for all fish combined (including

unsexed fish, if data existed for them). The following equations describe the relationships for Pacific hake and sablefish:

Pacific hake: $W = 0.0060727 \times L^{3.010904}$ for males
 $W = 0.0044392 \times L^{3.103434}$ for females
 $W = 0.0051681 \times L^{3.060471}$ for all sexes

Sablefish: $W = 0.0030949 \times L^{3.292493}$ for males
 $W = 0.0031333 \times L^{3.287077}$ for females
 $W = 0.0031534 \times L^{3.286425}$ for all sexes

where:

W = estimated weight (g)

L = fork length (cm).

AFSC WEST COAST SURVEY DATA SOURCES

The 2001 West Coast triennial survey is the main source of fishery-independent information on the abundance, distribution, and length and age-composition for most of the commercially important species occupying the continental shelf. Other AFSC fishery-independent data sources used for stock assessments include the echo integration-trawl survey of the West Coast Pacific hake resource and the bottom trawl survey of upper continental slope groundfish resources (sablefish, Dover sole, and thornyheads). Future National Marine Fisheries Service stock

assessment surveys of West Coast shelf and slope resources have been assigned to the Northwest Fisheries Science Center (2725 Montlake Blvd. E., Seattle, WA 98112).

ACKNOWLEDGMENTS

Many individuals were involved with successfully conducting the 2001 West Coast triennial bottom trawl survey and summarizing the results. We are grateful to Captain S. Branstiter and his crew aboard the F/V *Sea Storm*, and Captains J. Roach and B. Dickens and their crew aboard the F/V *Frosti* for providing safe and efficient platforms from which to conduct our operations. We thank sea-going AFSC employees: B. Baker, D. Benjamin, J. Berger, L. Britt, S. Corey, R. Erickson, B. Floering, C. Gburski, C. Johnston, E. Jorgenson, B. Lauth, D. Limpinsel, S. McKillip, G. Mundell, R. Payne, J. Short, S. Syrjala, and H. Zenger; and scientists outside of the AFSC: D. Kamikawa, H. Lenihan, and P. Olson (Northwest Fisheries Science Center), J. Mason (Southwest Fisheries Science Center), A. Henry (California Department of Fish and Game), A. Byrne (Idaho Department of Fish and Game), T. Hart (Oregon State University), and D. Badger and J. Field (University of Washington). Sampling within the Monterey Bay, Gulf of the Farallones, and Cordell Bank National Marine Sanctuaries was conducted under Permit MBNMS/GFNMS/CBNMS Multi-2001-002. Sampling within the Olympic Coast National Marine Sanctuary was conducted under Permit OCNMS-07-99-A1.

ARROWTOOTH FLOUNDER

— male — female

Figure 36.-- Estimated population size composition and mean lengths of arrowtooth flounder by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

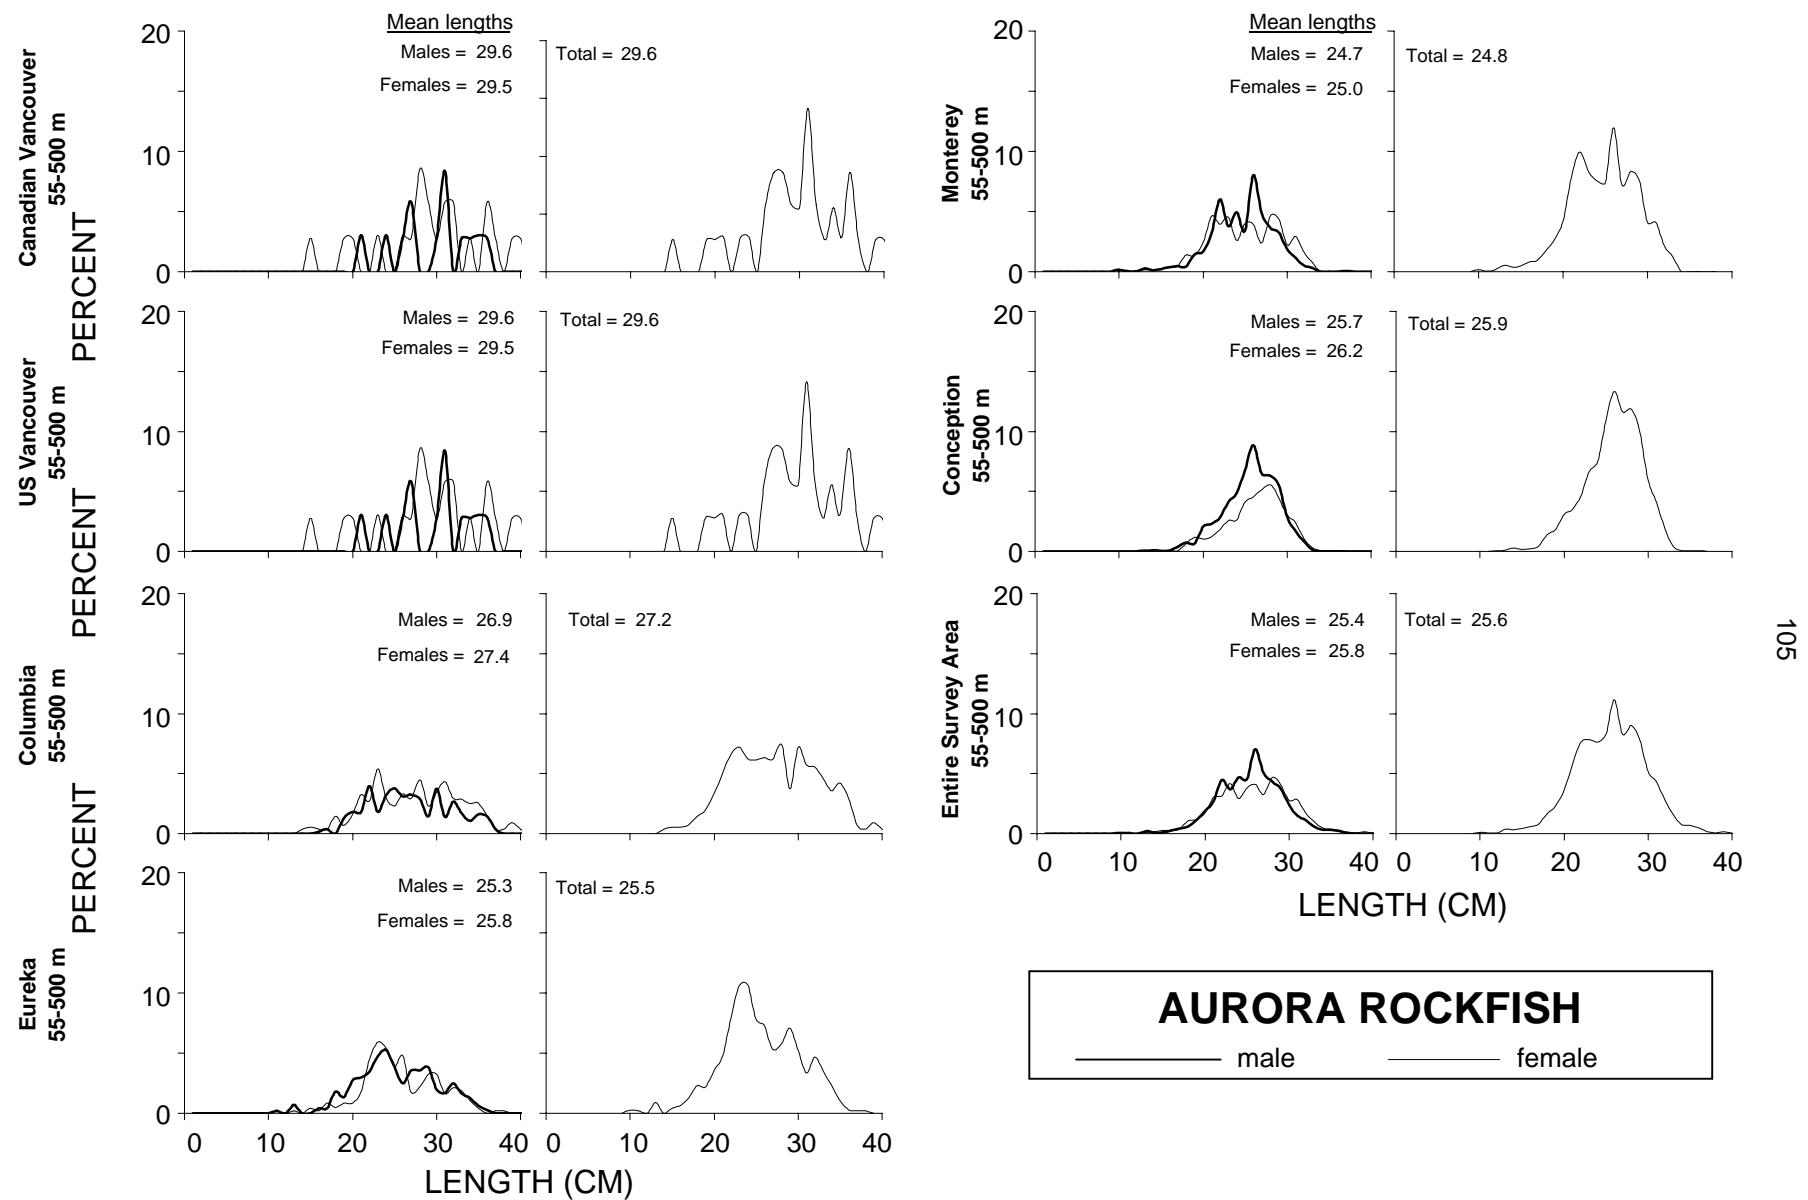

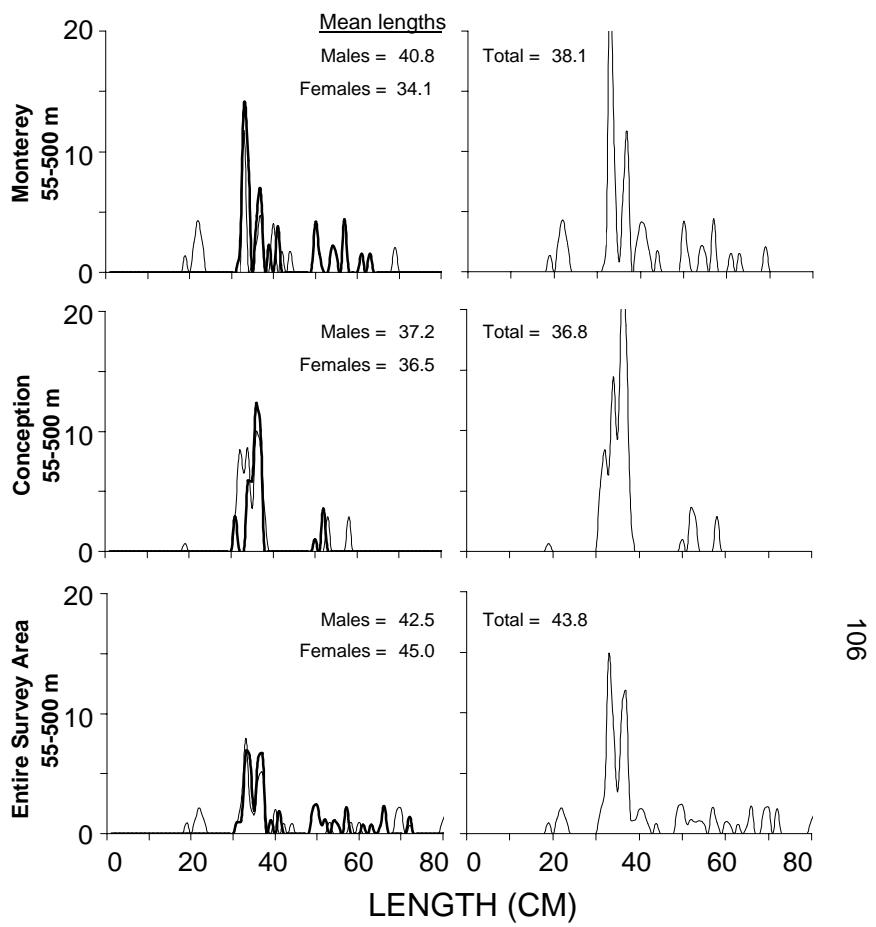

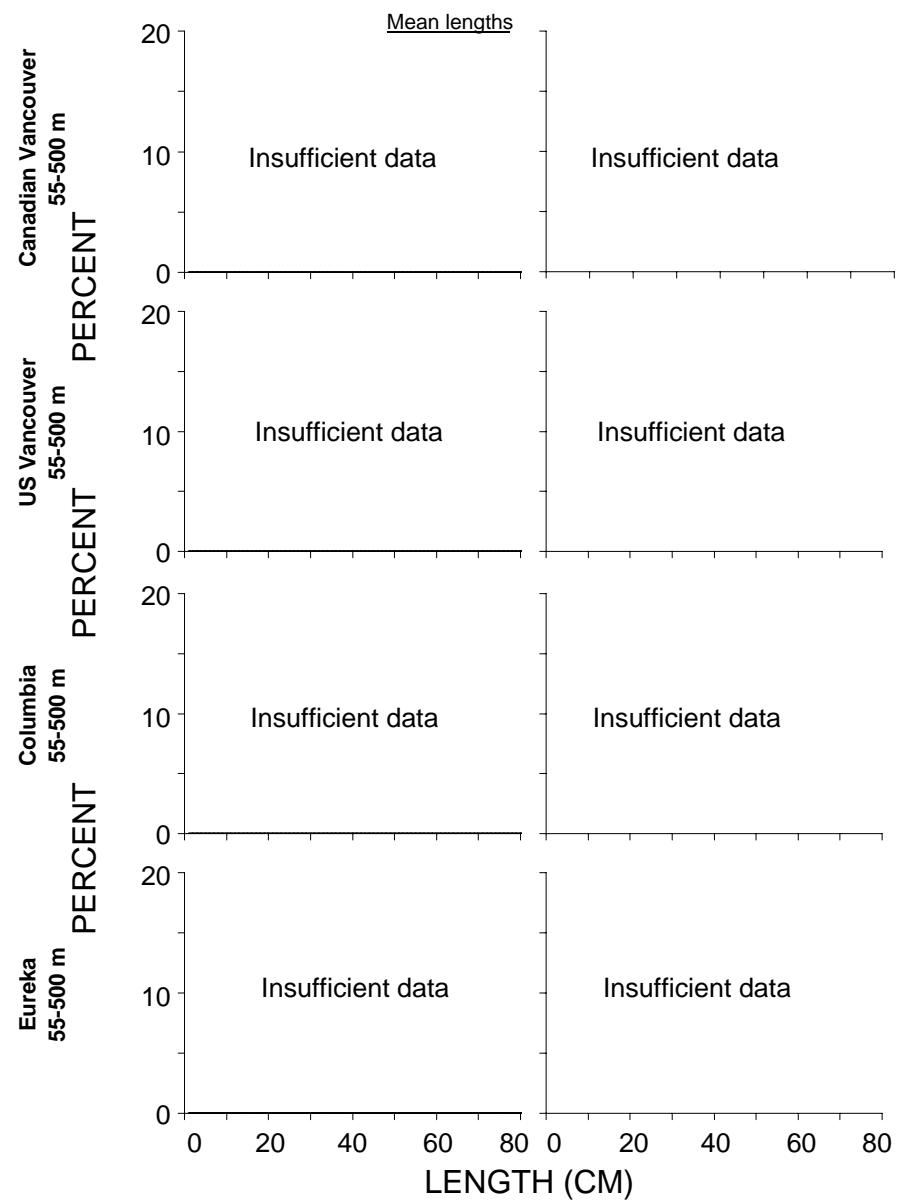

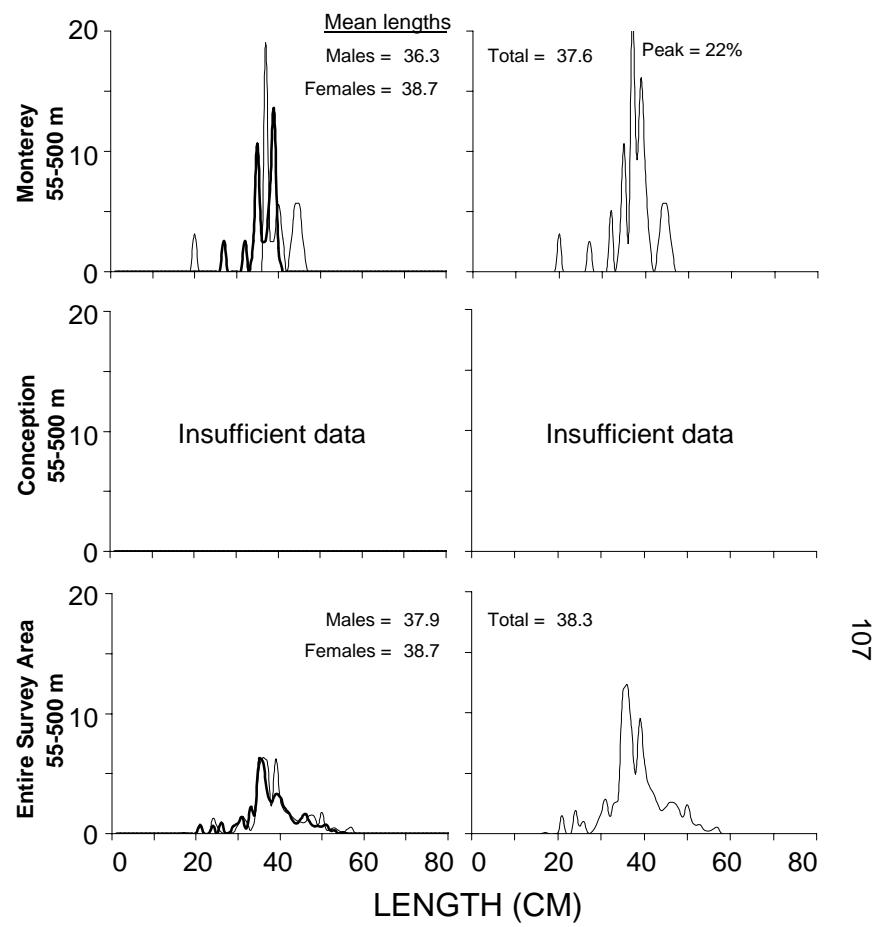

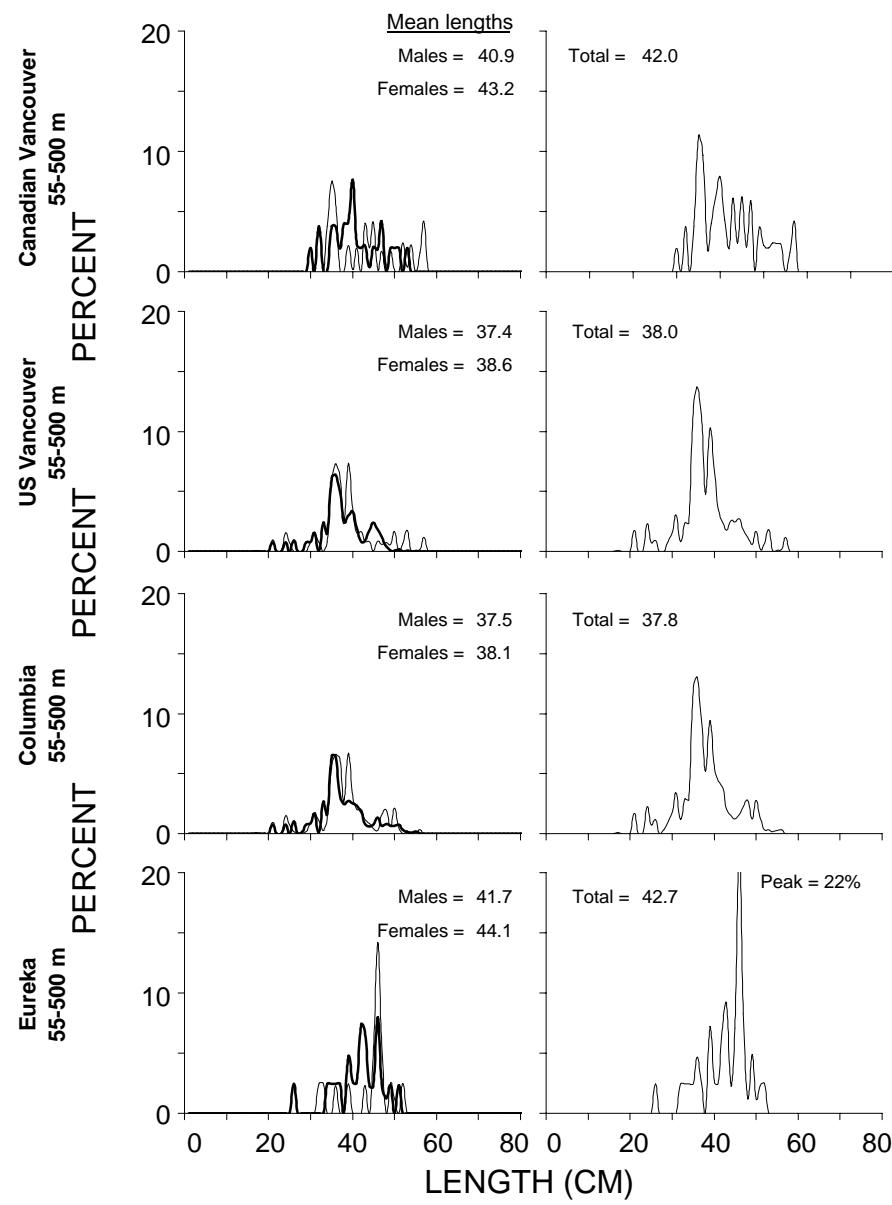

Figure 37.-- Estimated population size composition and mean lengths of aurora rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

BOCACCIO

male female

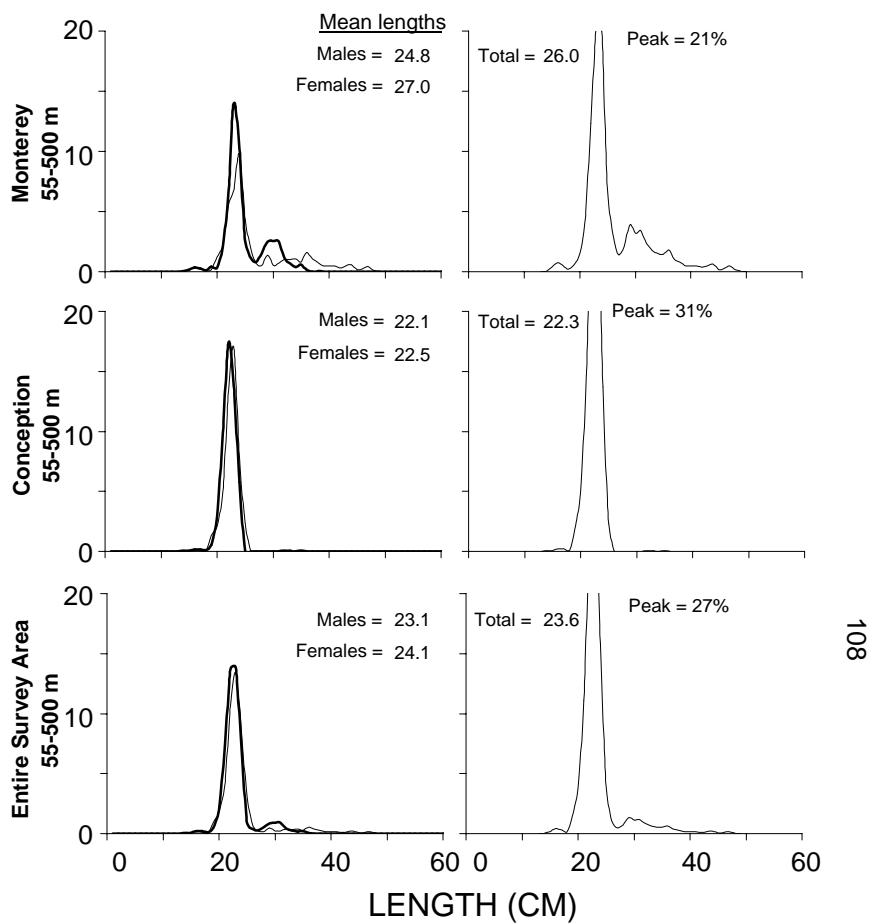

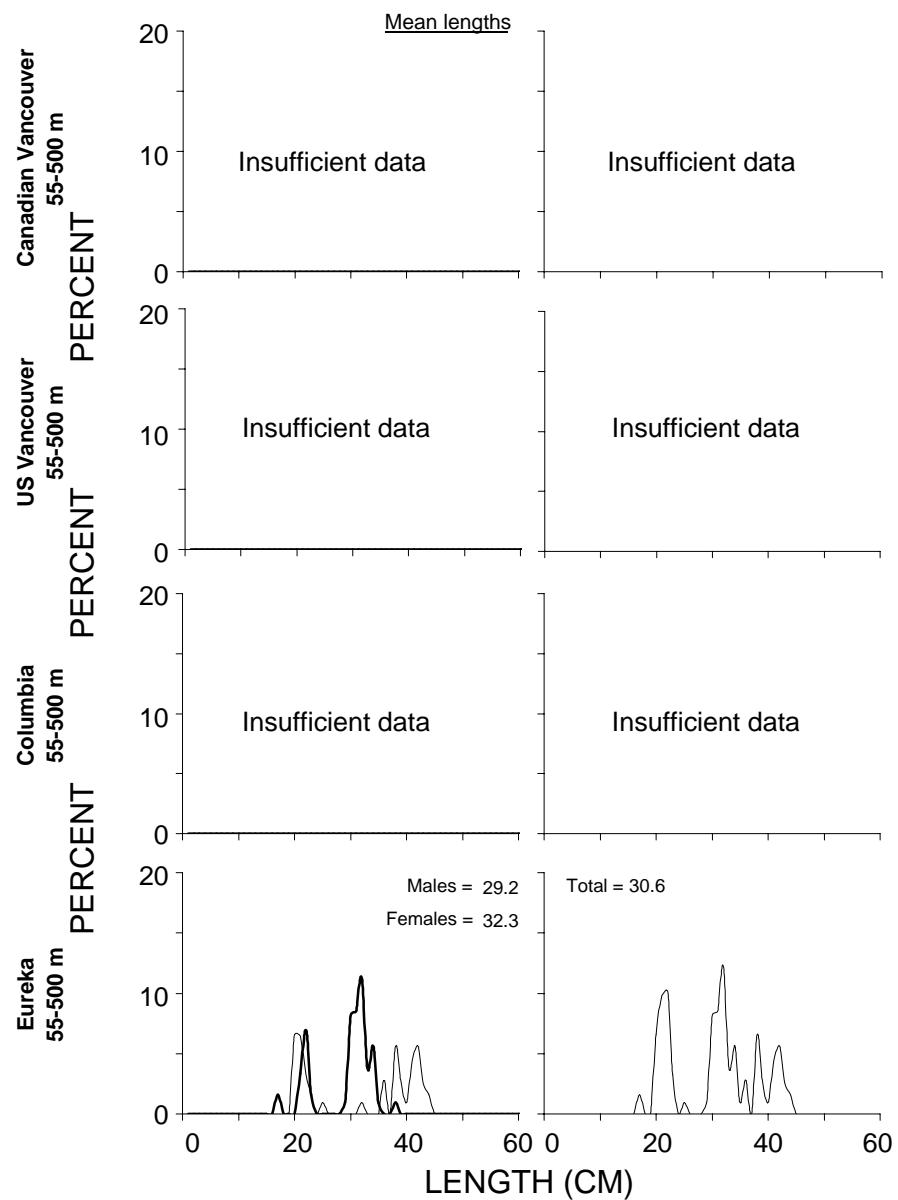

Figure 38.-- Estimated population size composition and mean lengths of bocaccio by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

CANARY ROCKFISH

male female

Figure 39.-- Estimated population size composition and mean lengths of canary rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

CHILIPEPPER

male female

Figure 40.-- Estimated population size composition and mean lengths of chilipepper by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

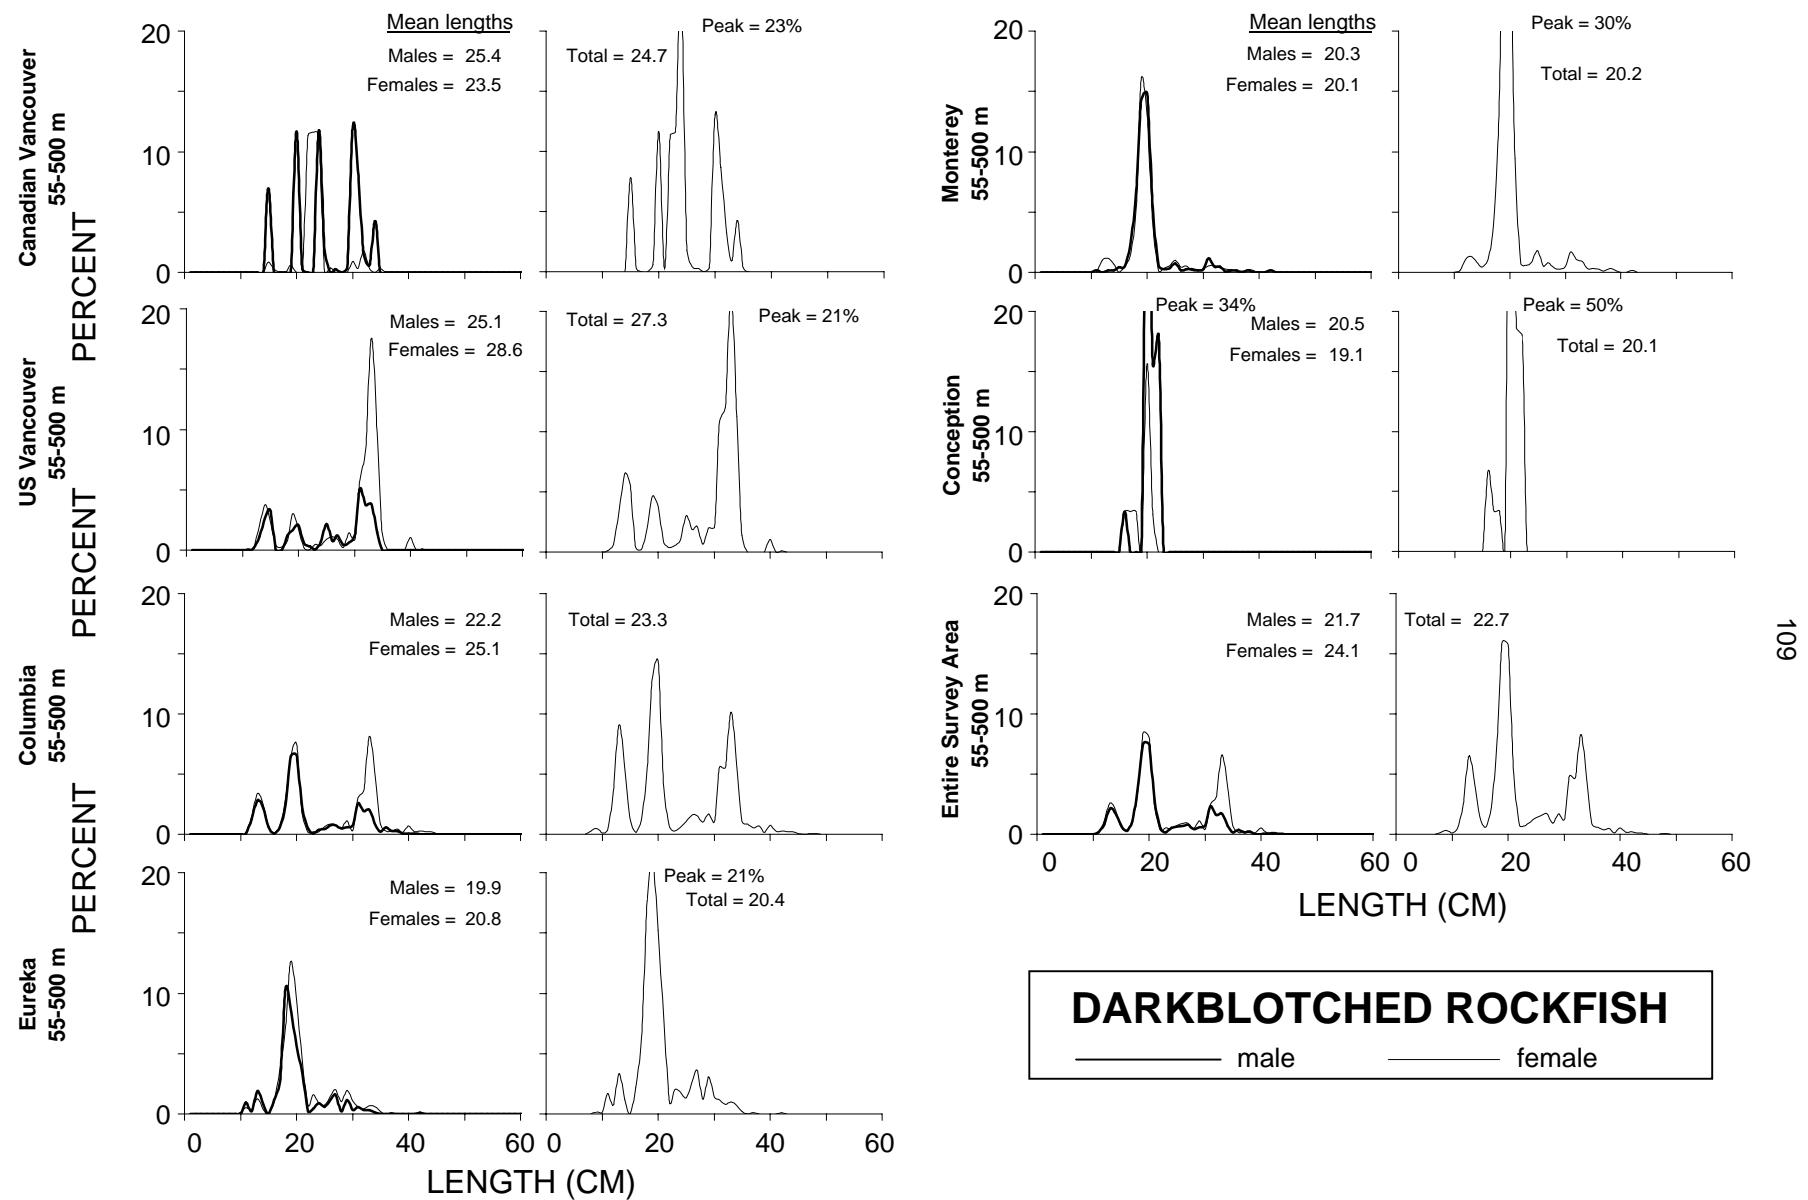

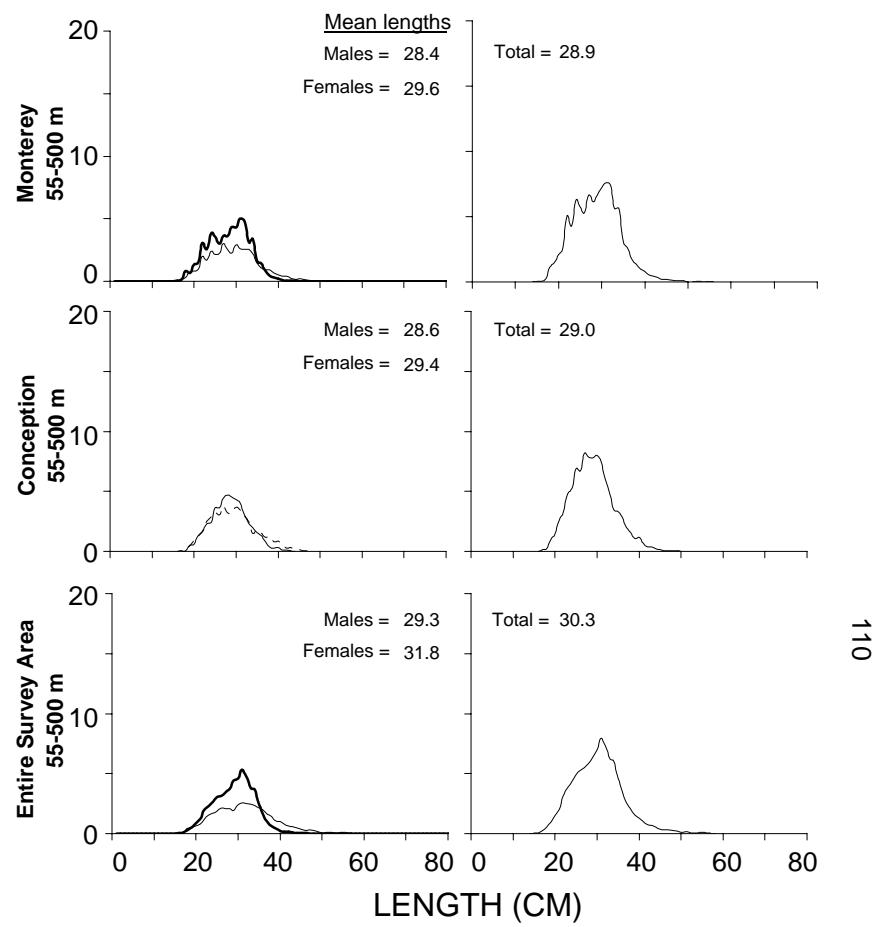

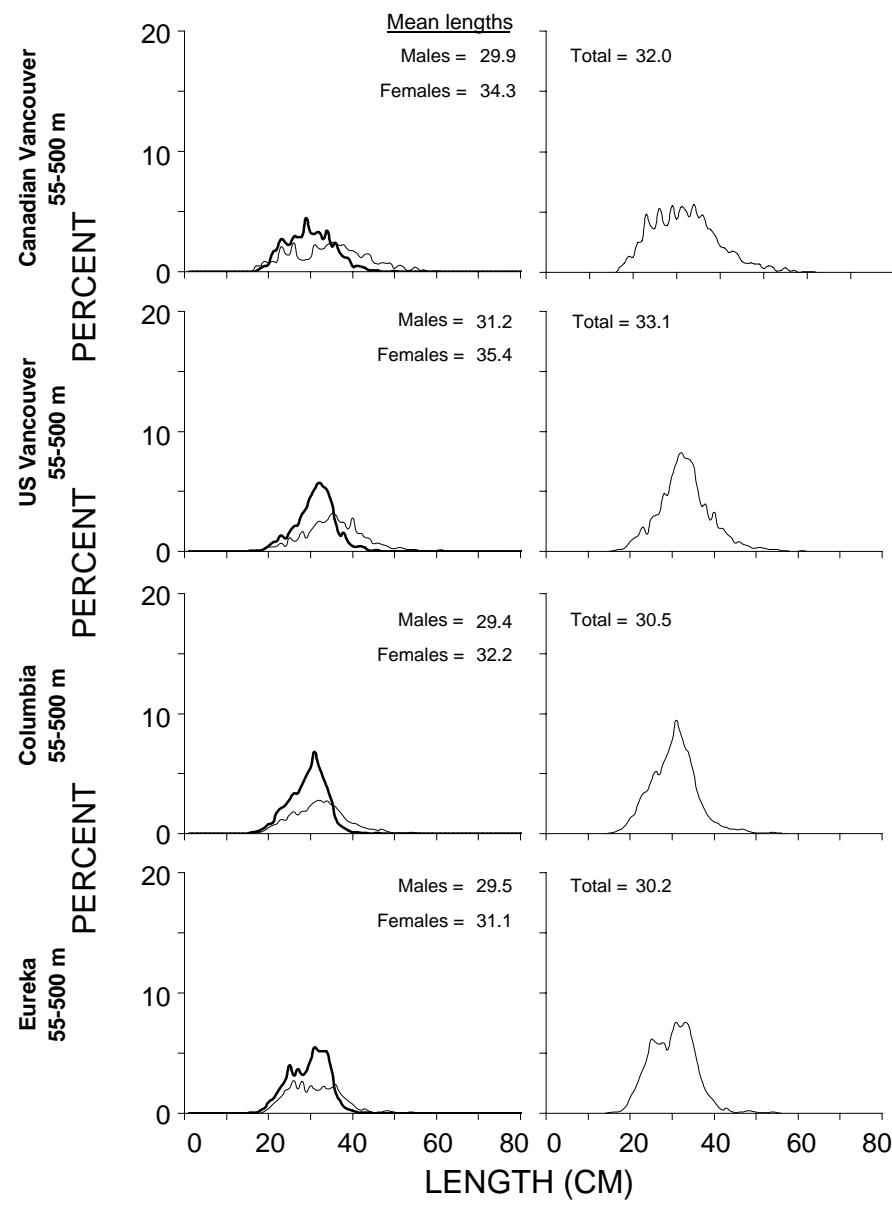

Figure 41.-- Estimated population size composition and mean lengths of darkblotched rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

DARKBLOTTCHED ROCKFISH

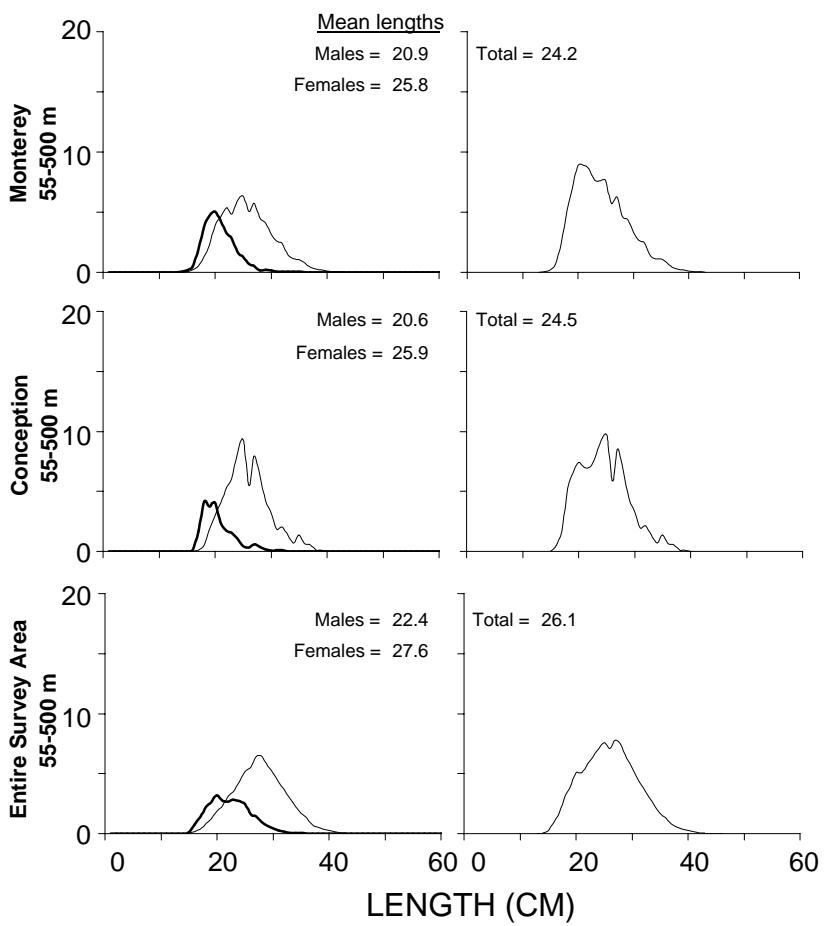

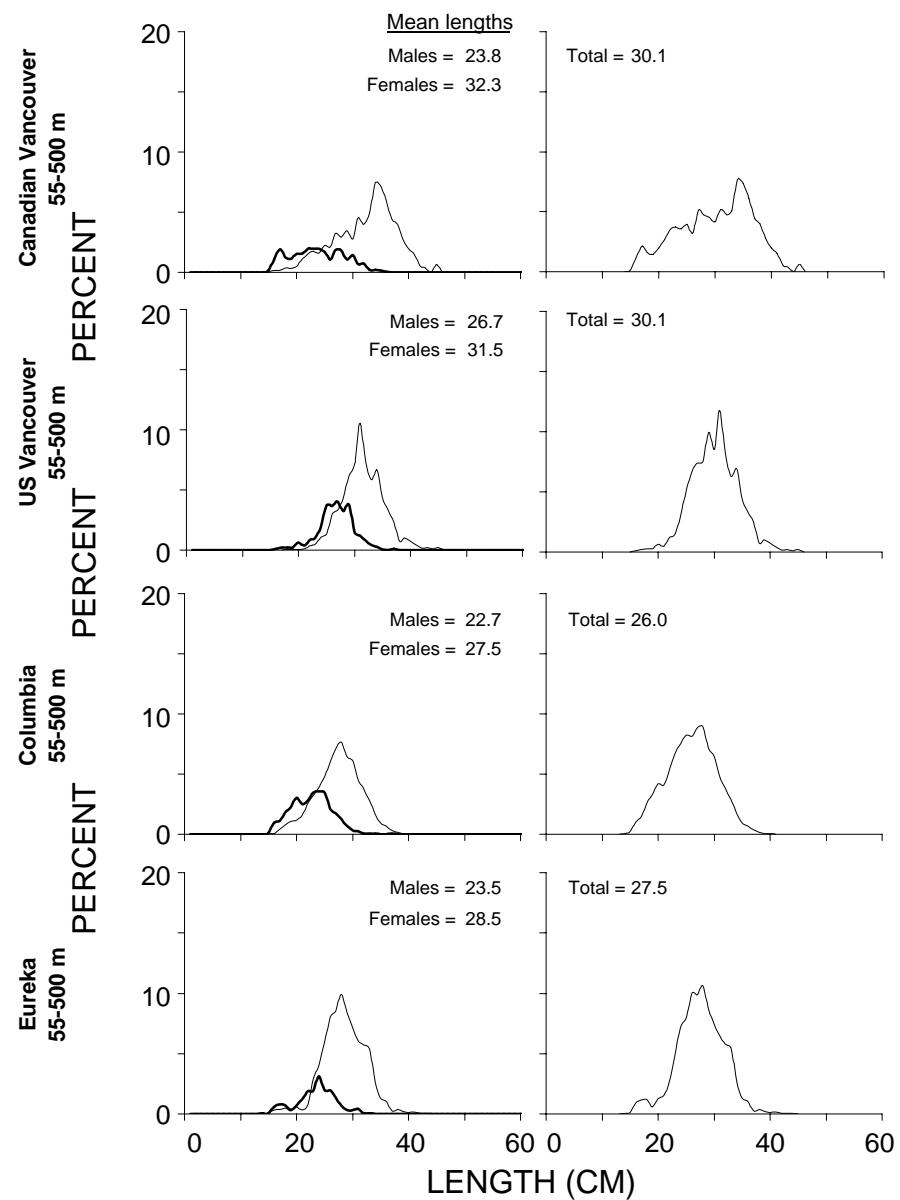

— male - - female

DOVER SOLE

— male — female

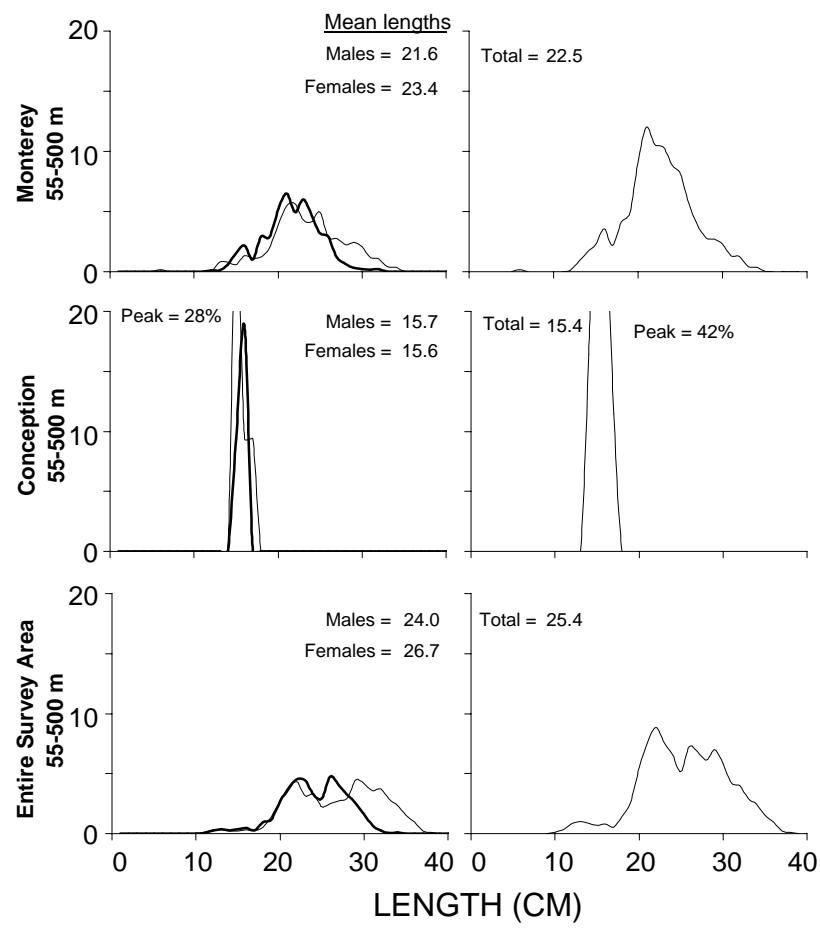

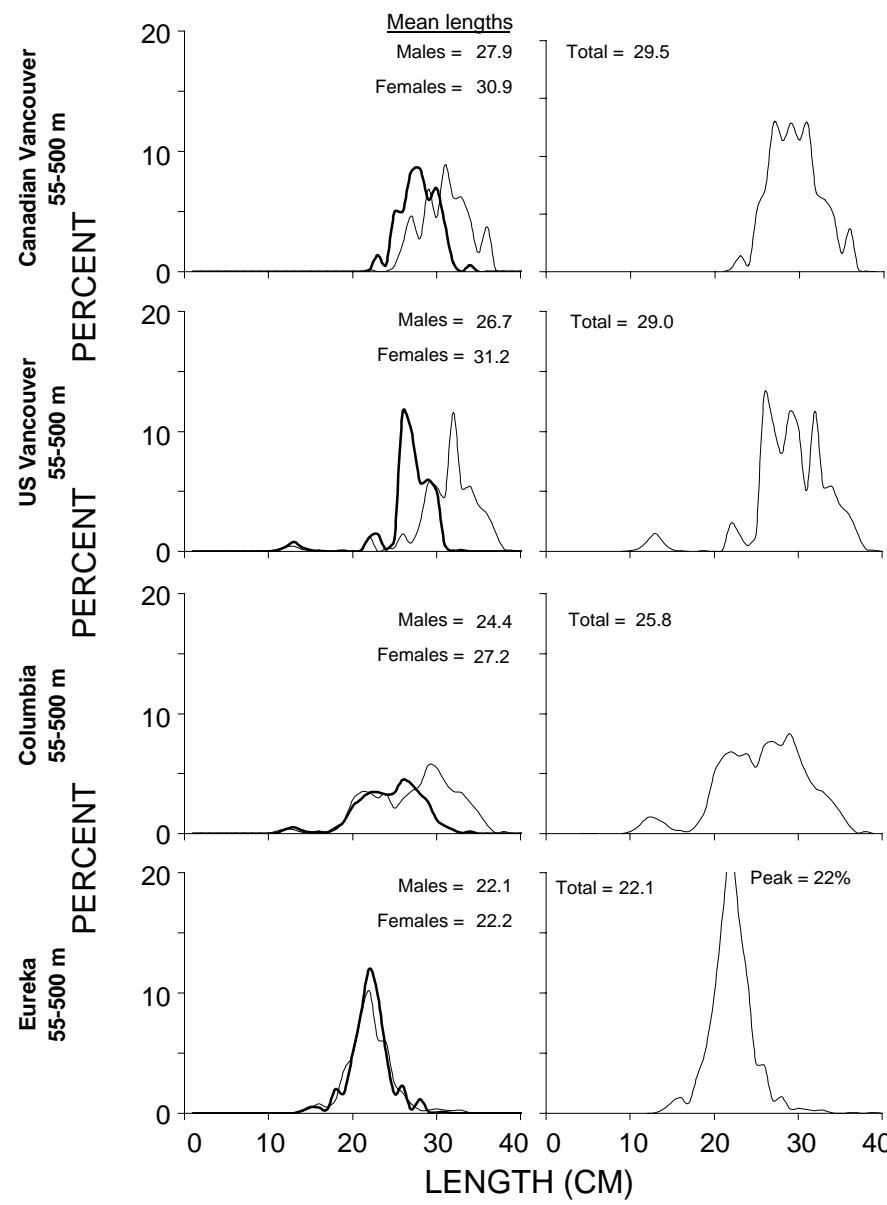

Figure 42.-- Estimated population size composition and mean lengths of Dover sole by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

ENGLISH SOLE

— male — female

Figure 43.-- Estimated population size composition and mean lengths of English sole by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

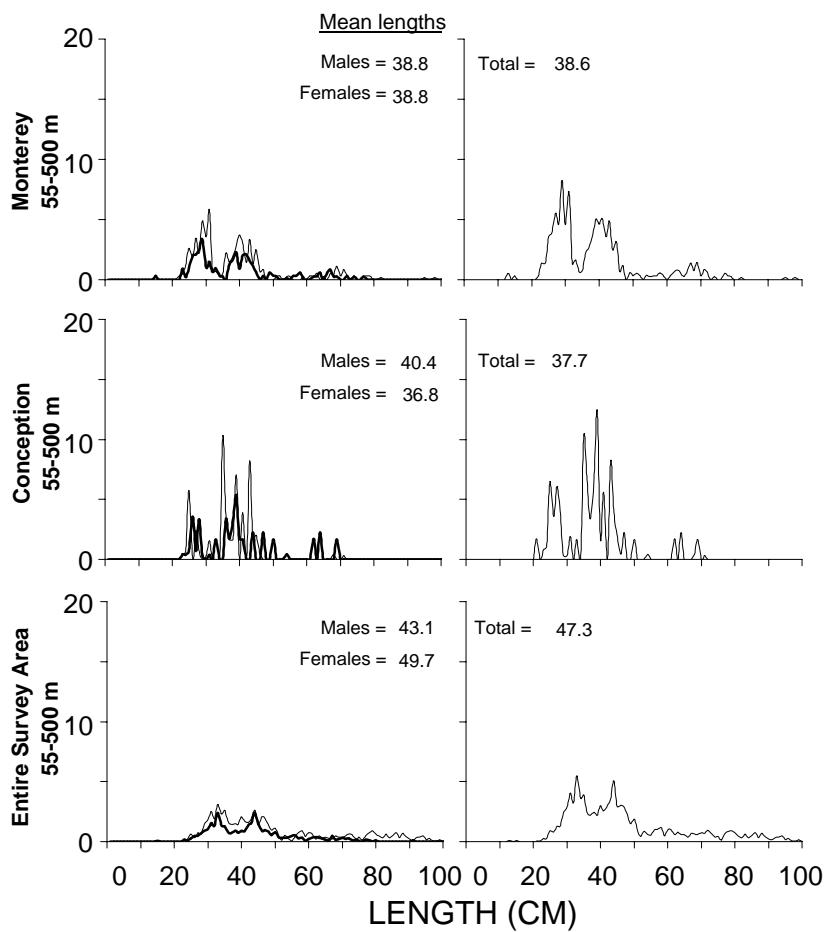

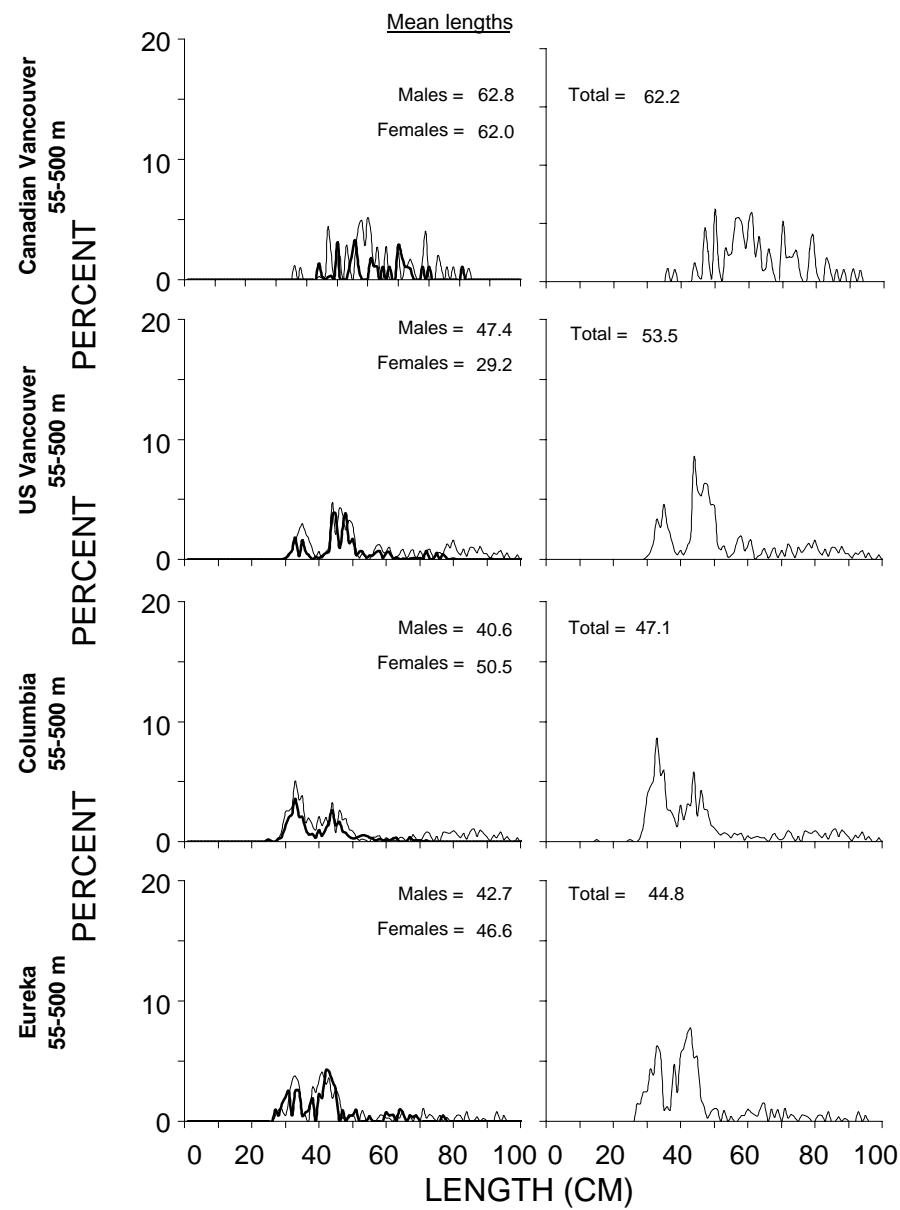

12

GREENSTRIPED ROCKFISH

male female

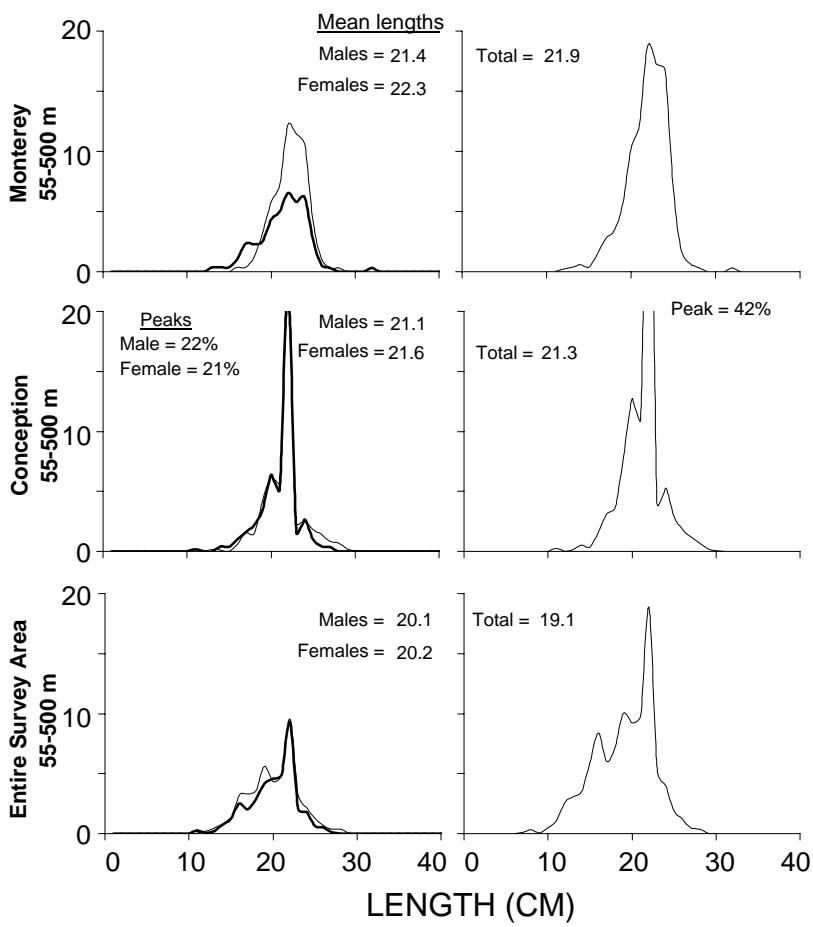

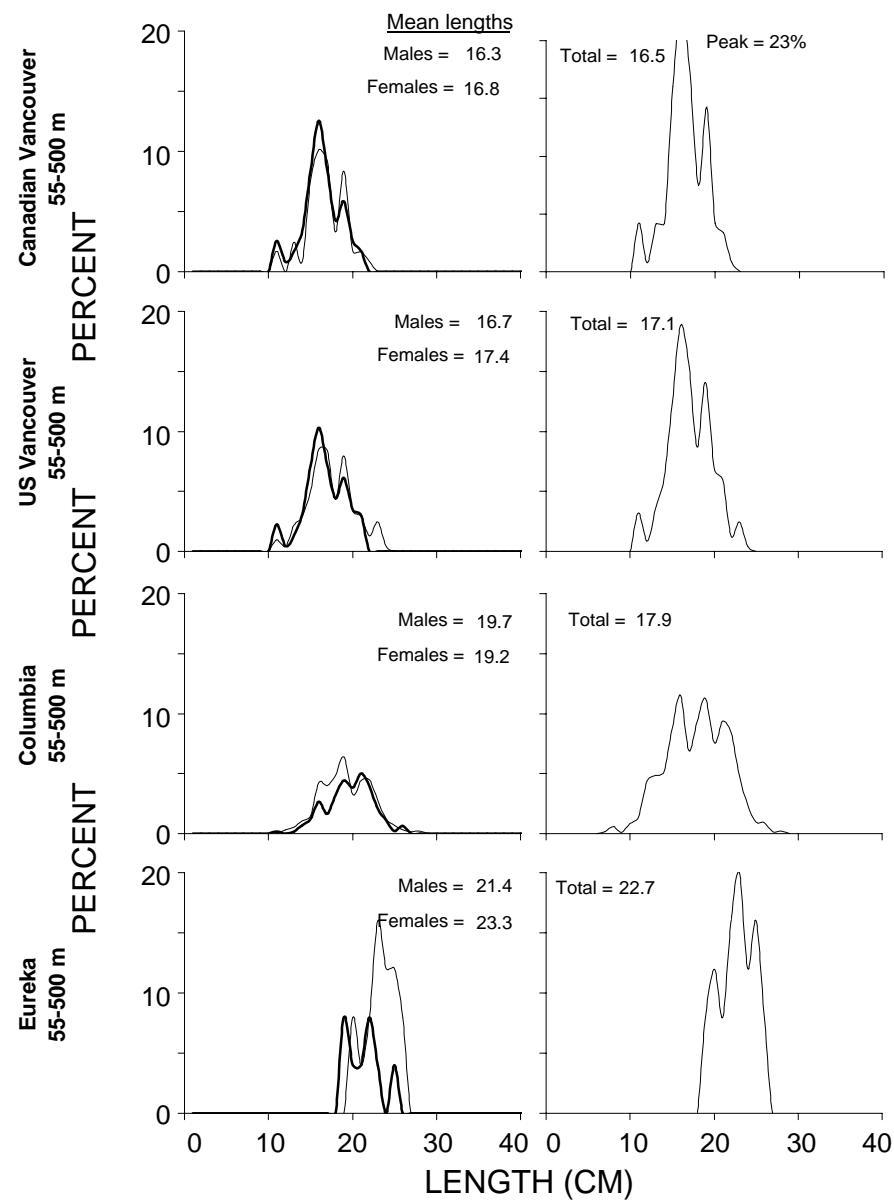

Figure 44.-- Estimated population size composition and mean lengths of greenstriped rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

LINGCOD

male female

Figure 45.-- Estimated population size composition and mean lengths of lingcod by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

LONGSPINE THORNYHEAD

male

female

Figure 46.-- Estimated population size composition and mean lengths of longspine thornyhead by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

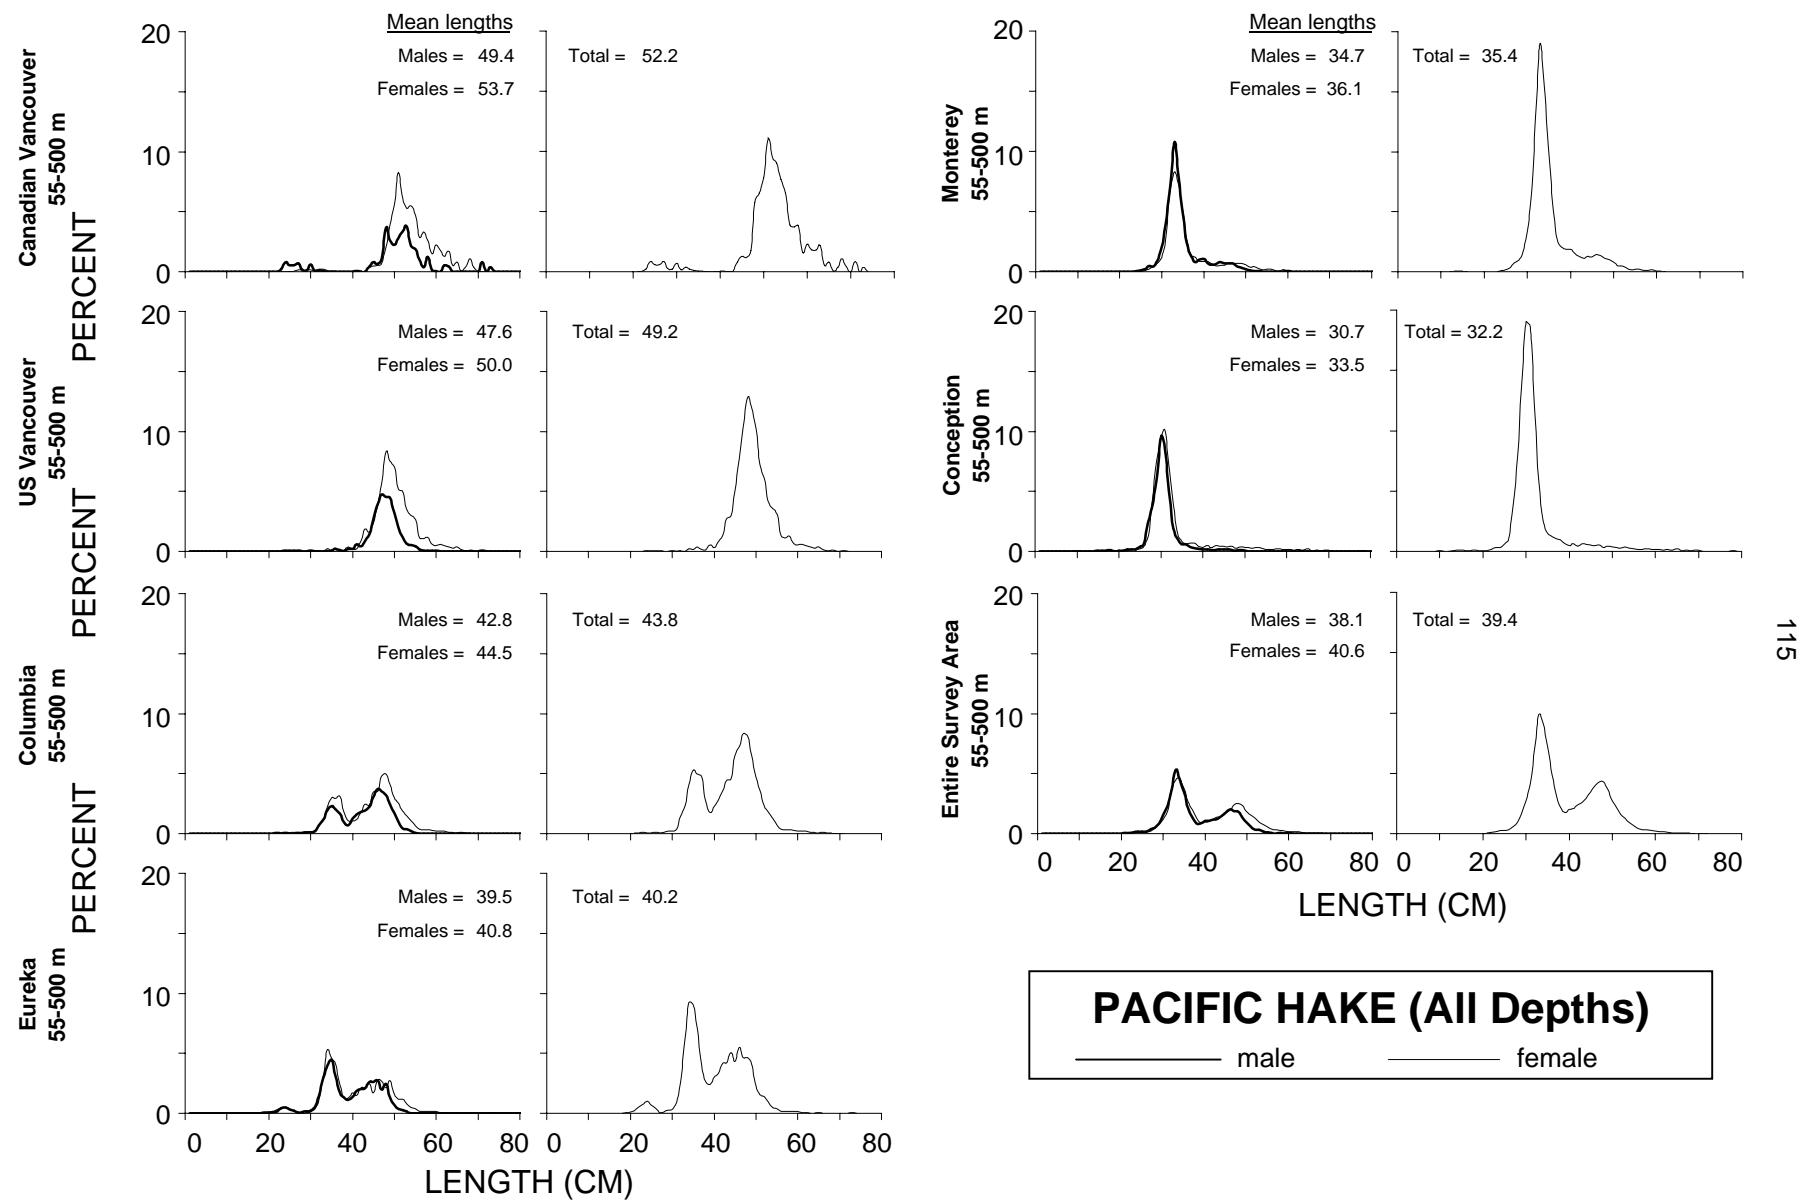

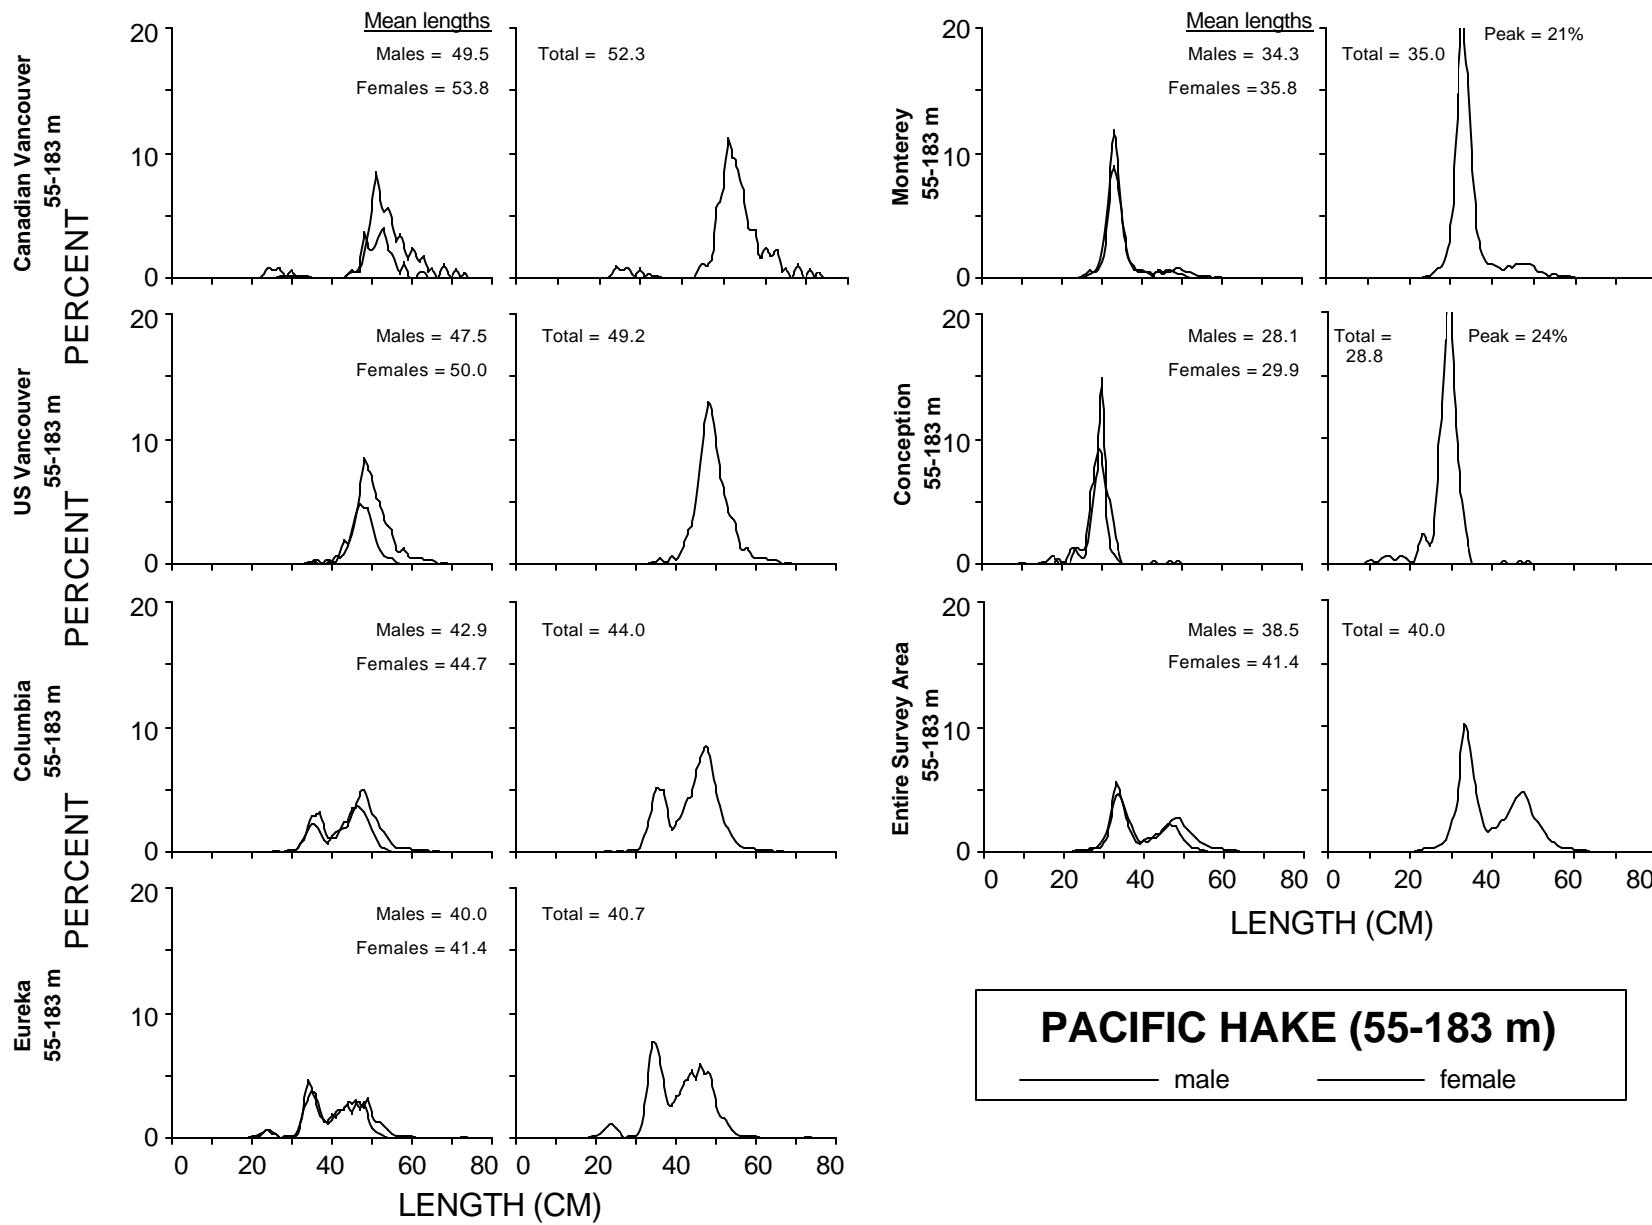

Figure 47.-- Estimated population size composition and mean lengths of Pacific hake by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

91

Figure 48.-- Estimated population size composition and mean lengths of Pacific hake by sex and International North Pacific Fisheries Commission area for the shallow depth stratum (55-183 m) from the 2001 triennial bottom trawl survey.

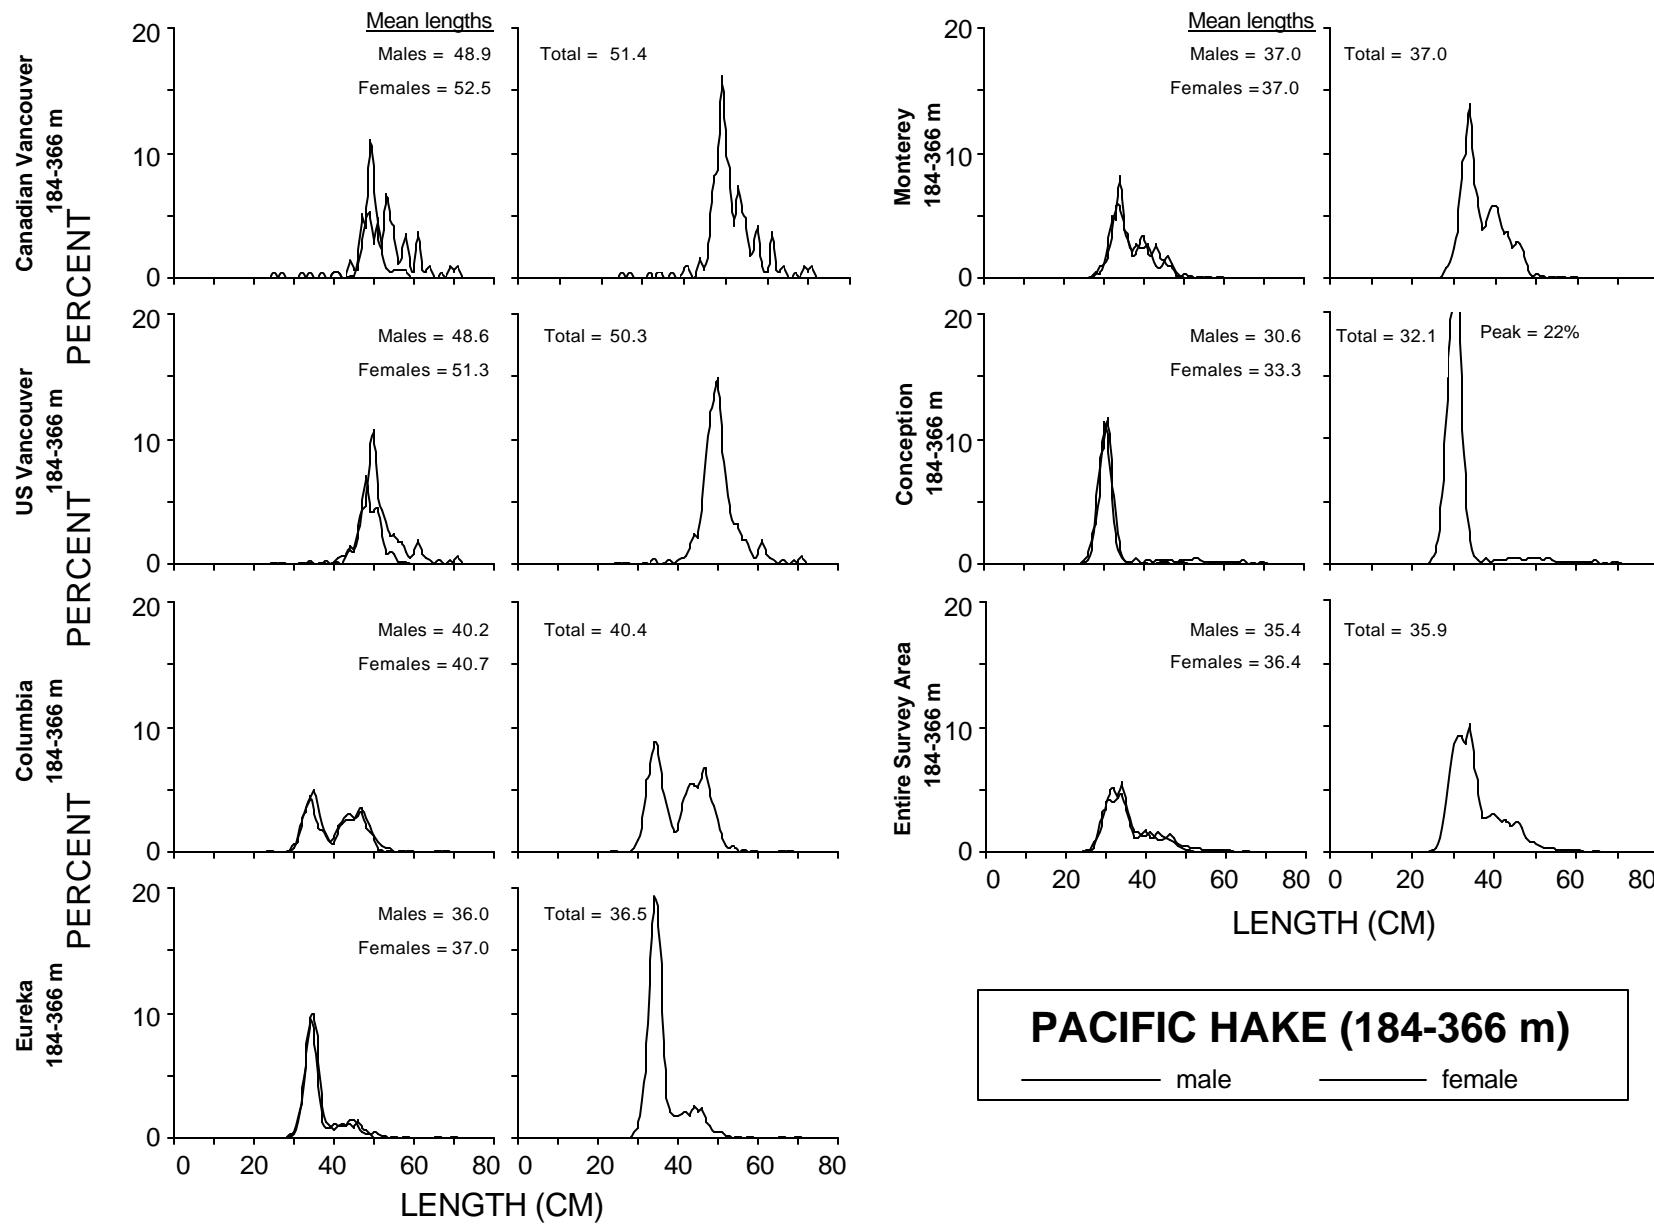

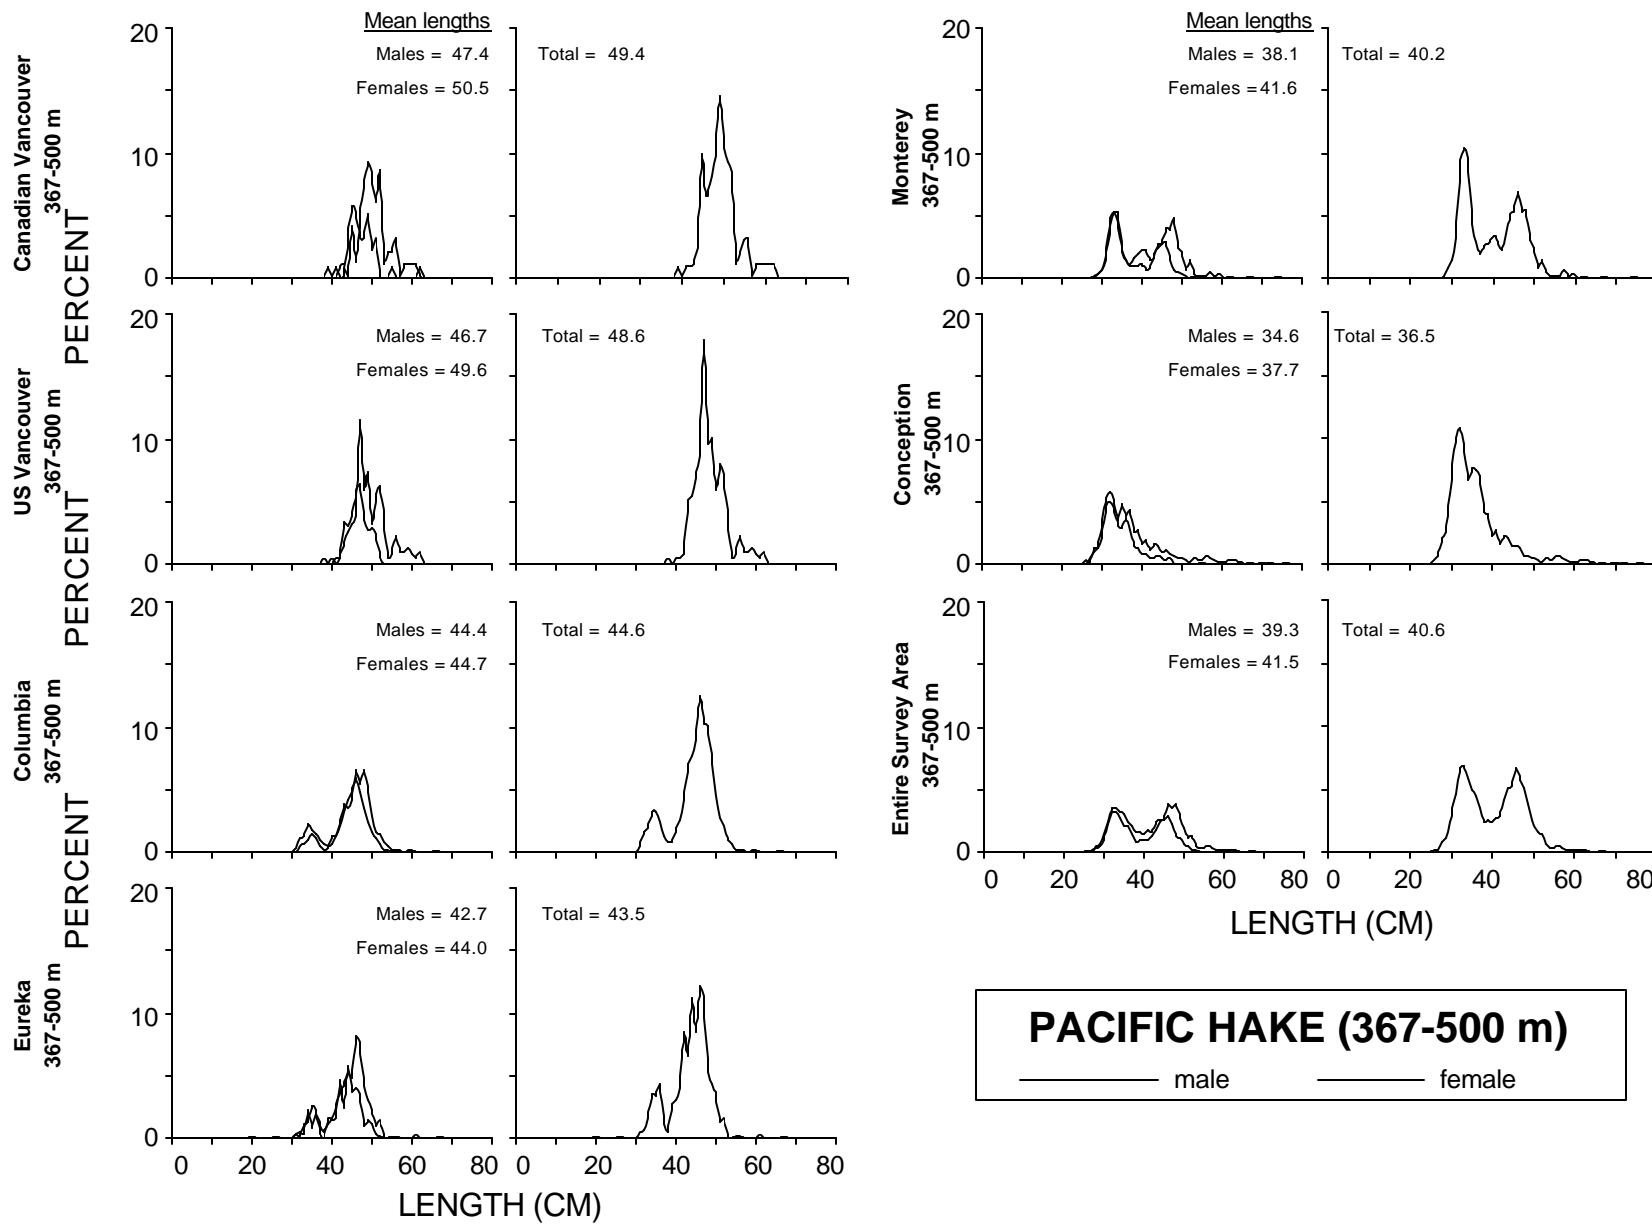

Figure 49.-- Estimated population size composition and mean lengths of Pacific hake by sex and International North Pacific Fisheries Commission area for the middle depth stratum (184-366 m) from the 2001 triennial bottom trawl survey.

81

Figure 50.-- Estimated population size composition and mean lengths of Pacific hake by sex and International North Pacific Fisheries Commission area for the deep depth stratum (367-500 m) from the 2001 triennial bottom trawl survey.

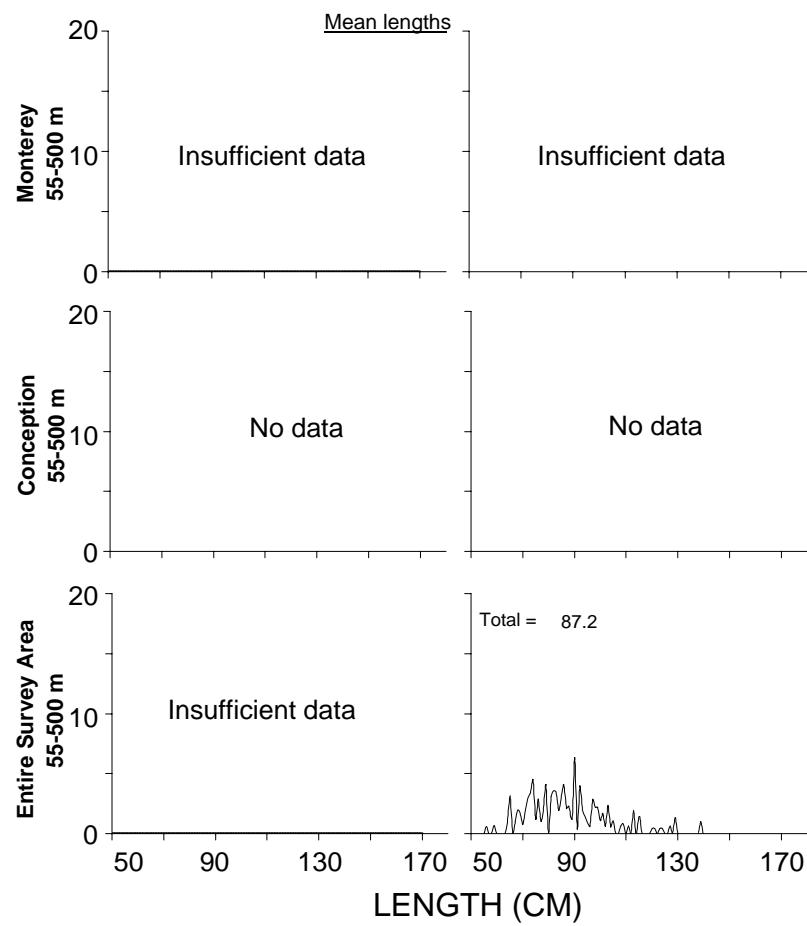

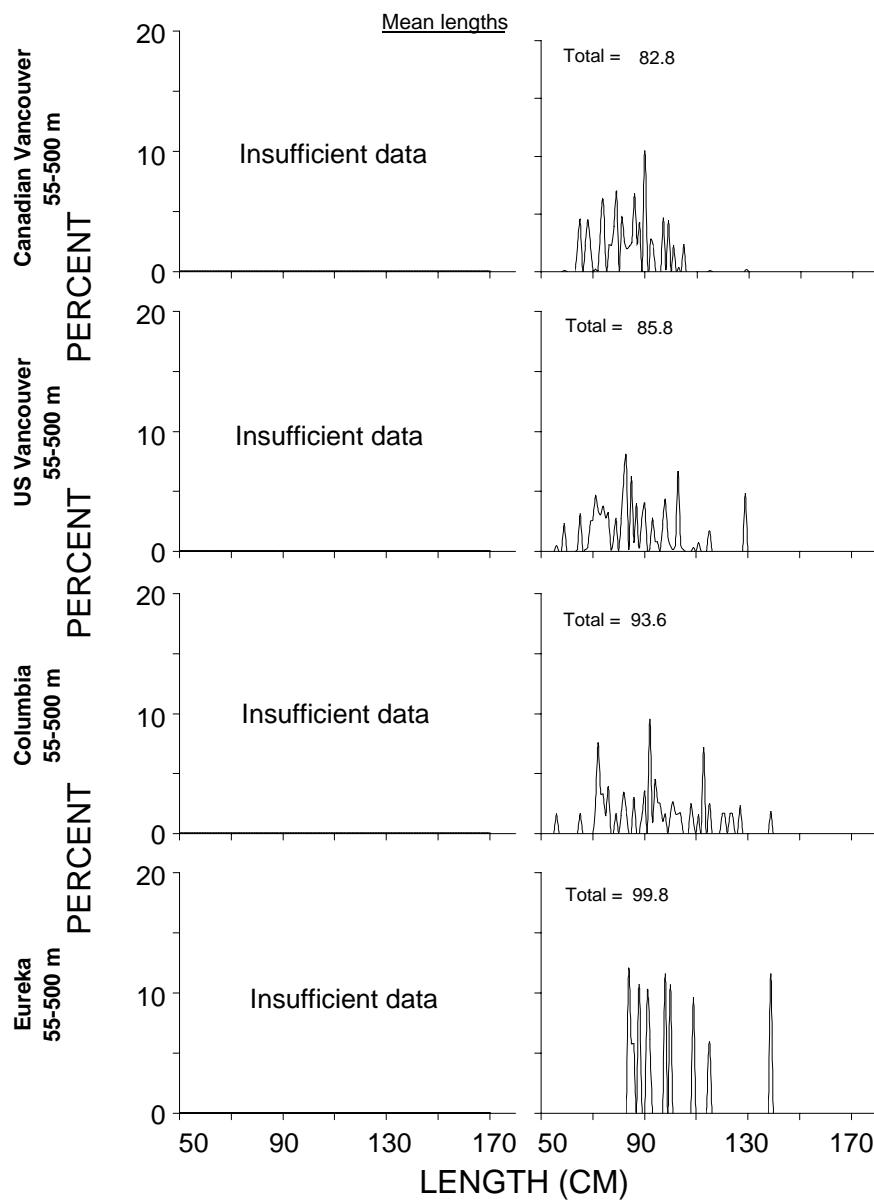

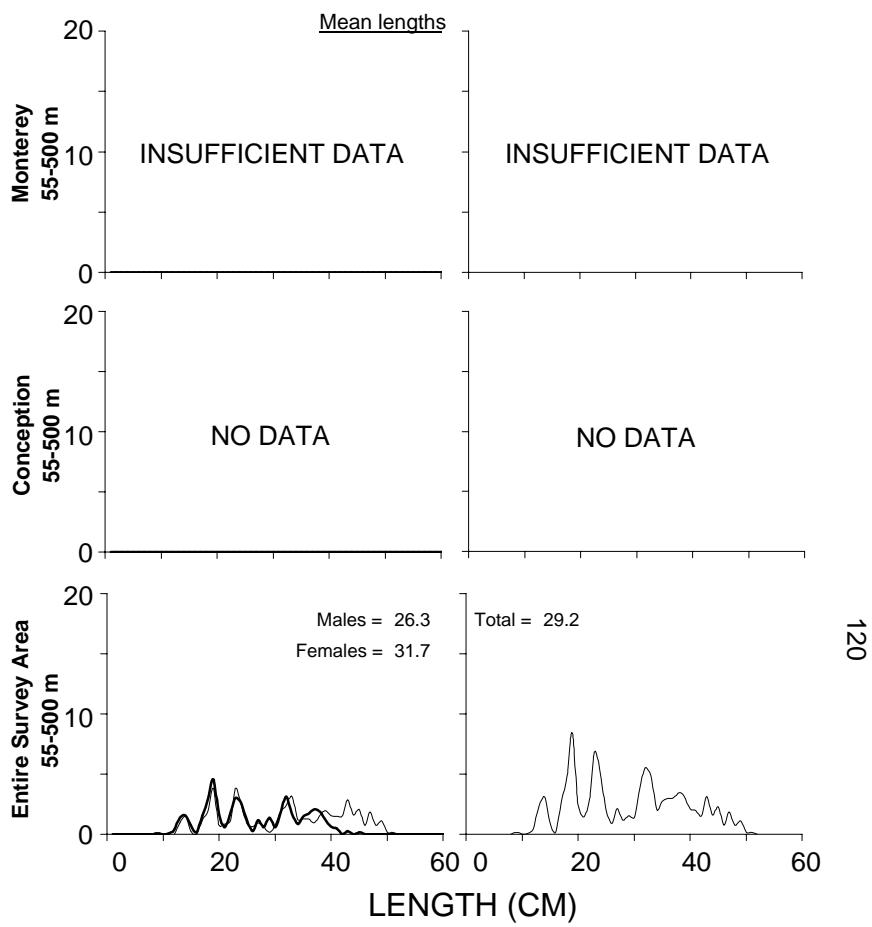

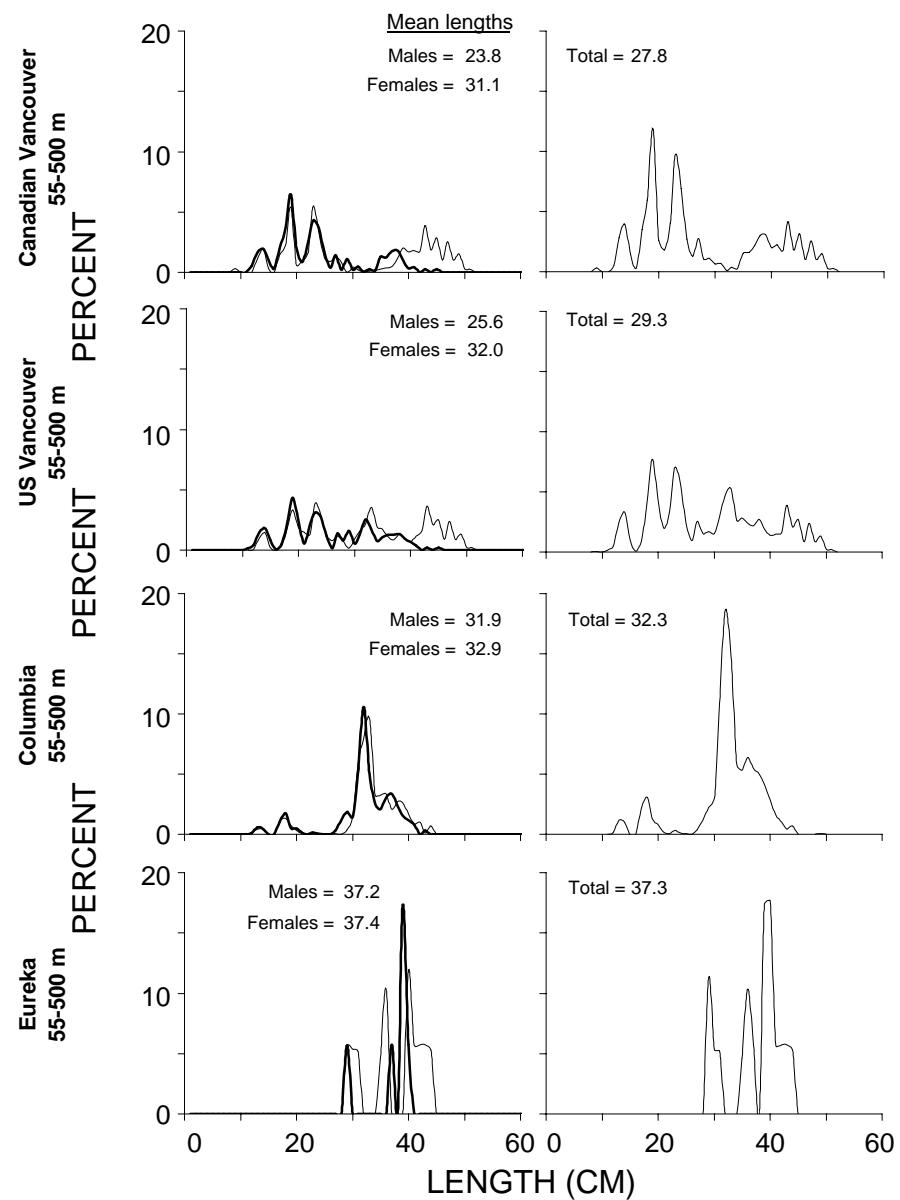

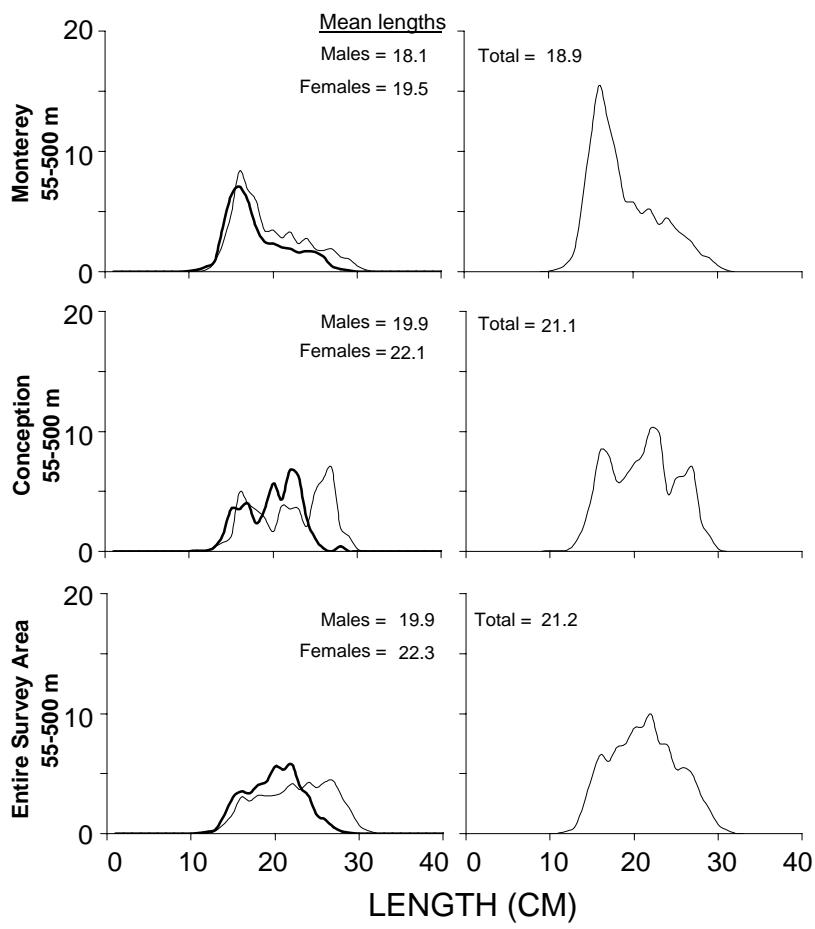

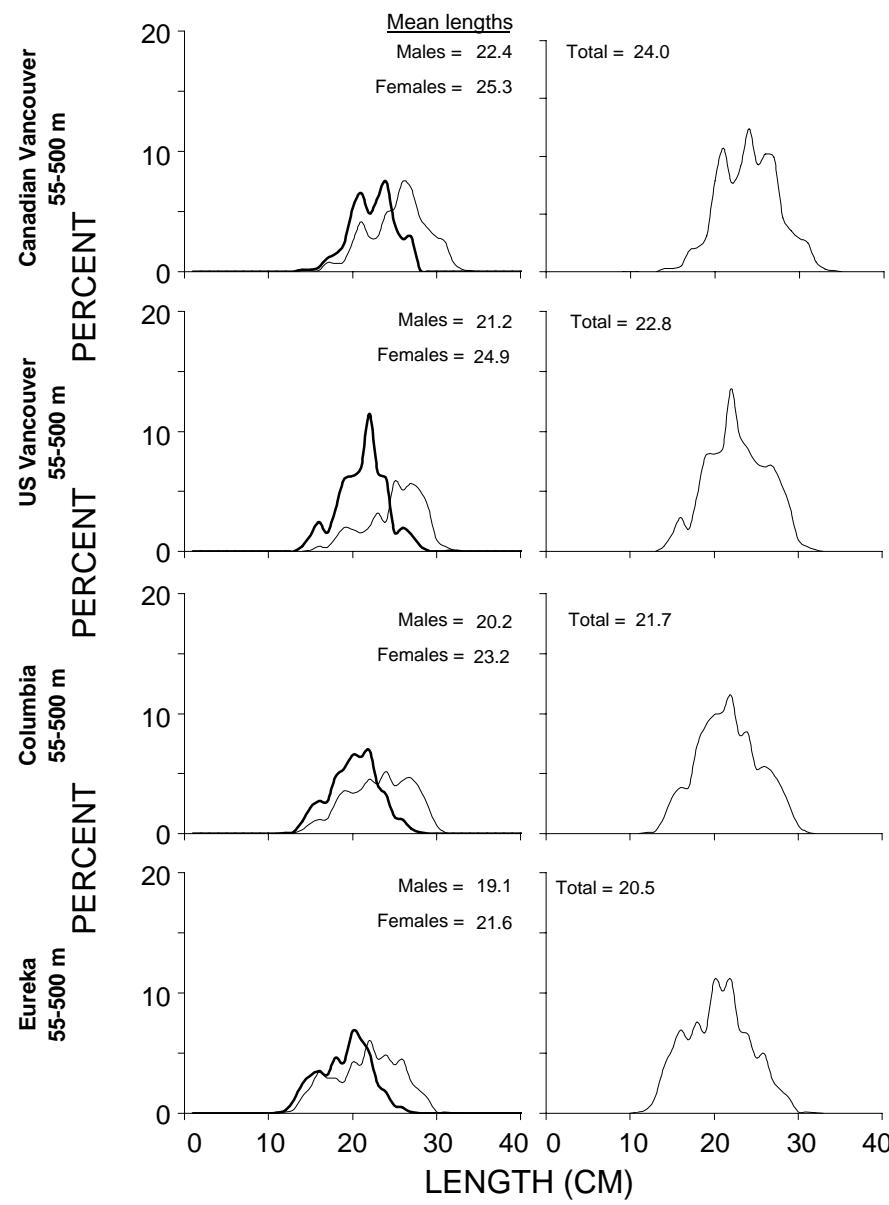

Figure 51.-- Estimated population size composition and mean length of Pacific halibut by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

PACIFIC OCEAN PERCH

— male — female

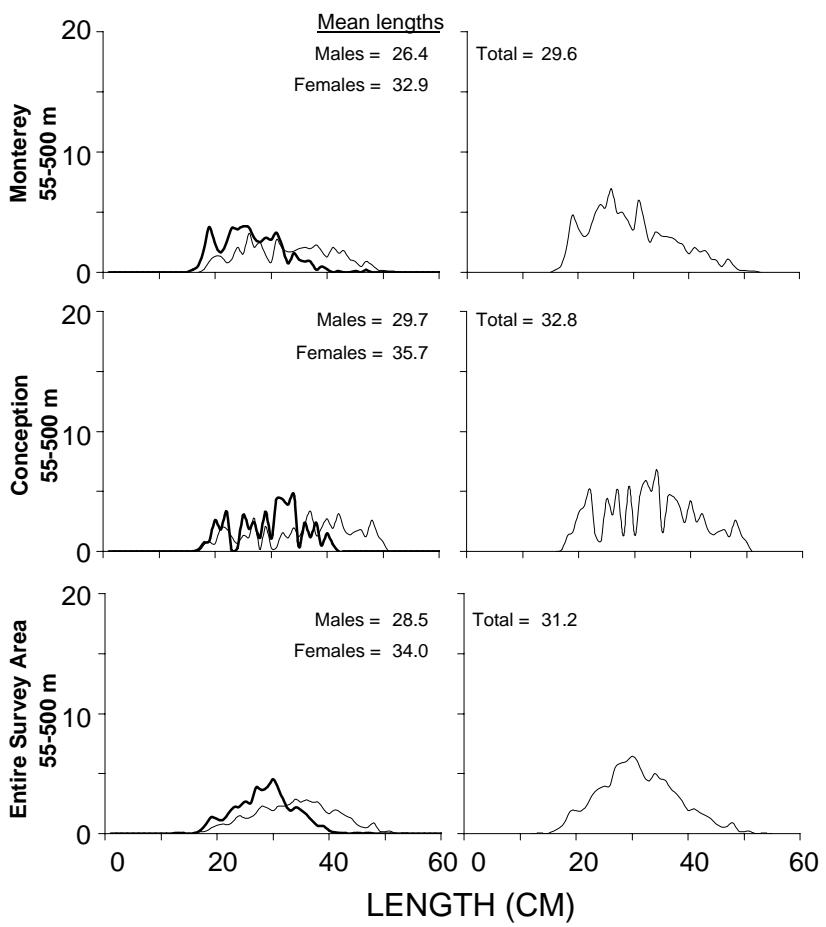

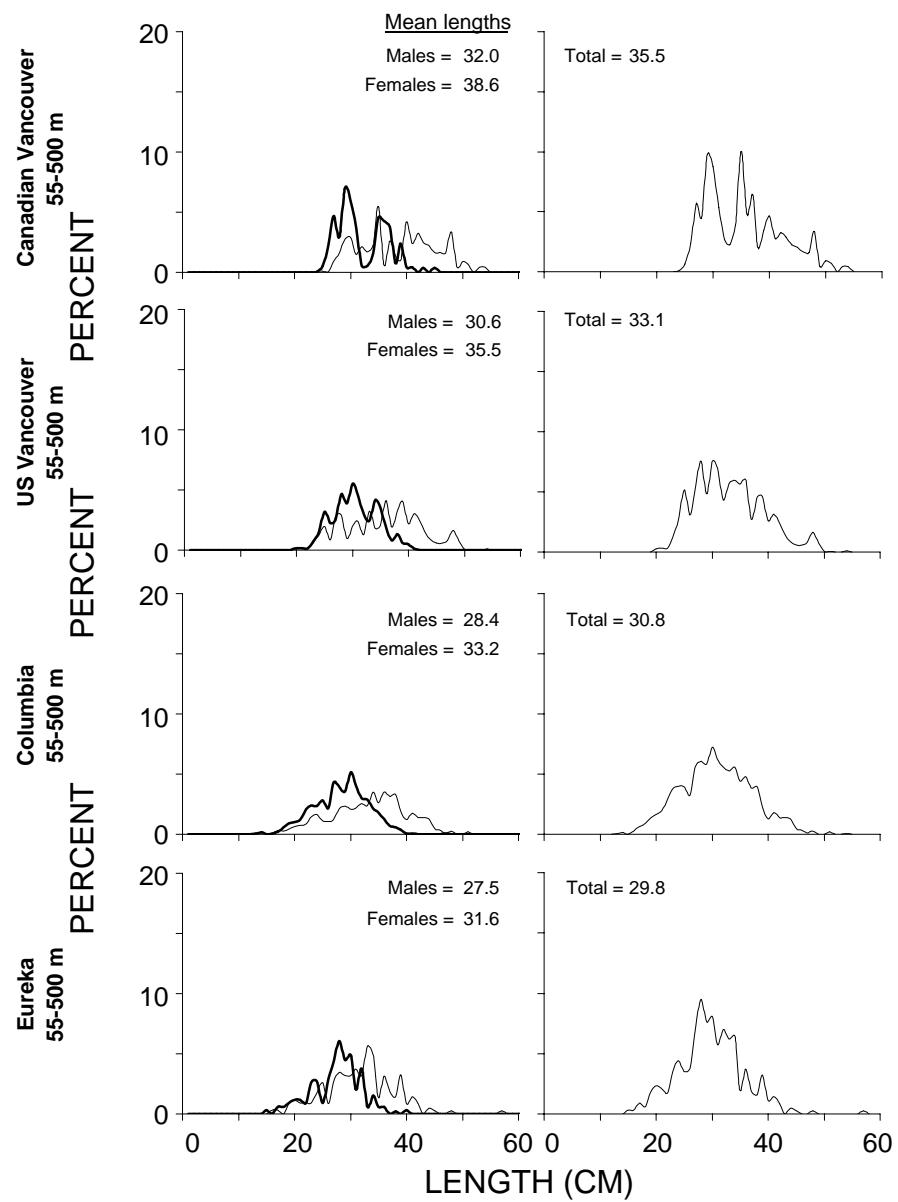

Figure 52.-- Estimated population size composition and mean lengths of Pacific ocean perch by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

PACIFIC SANDDAB

— male — female

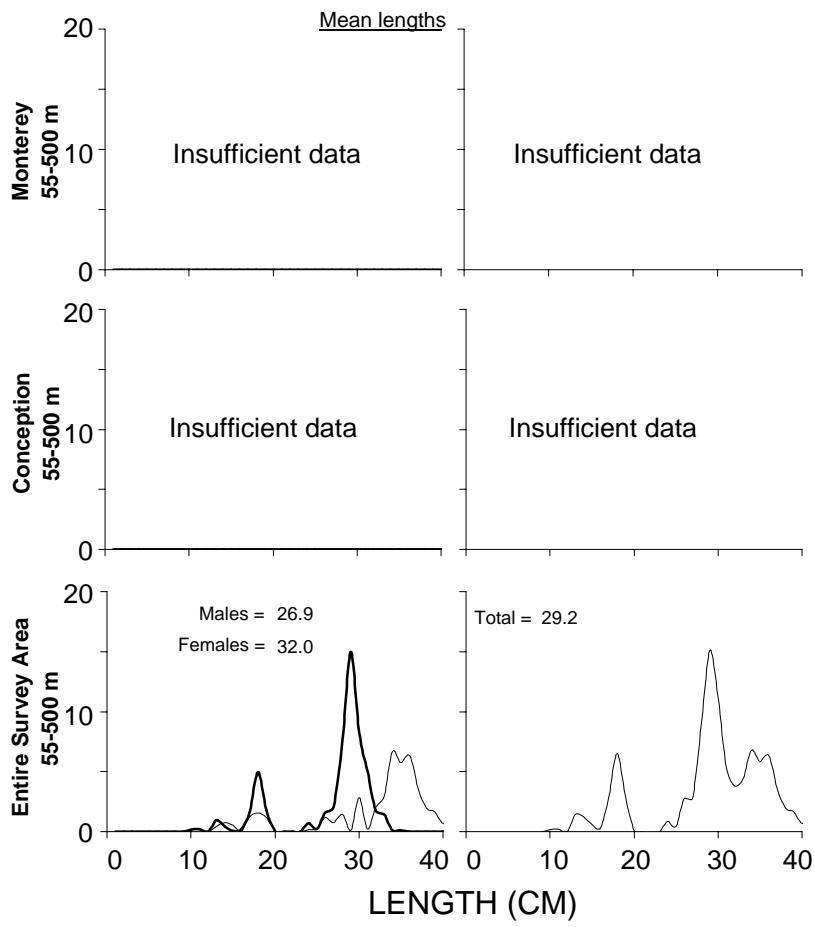

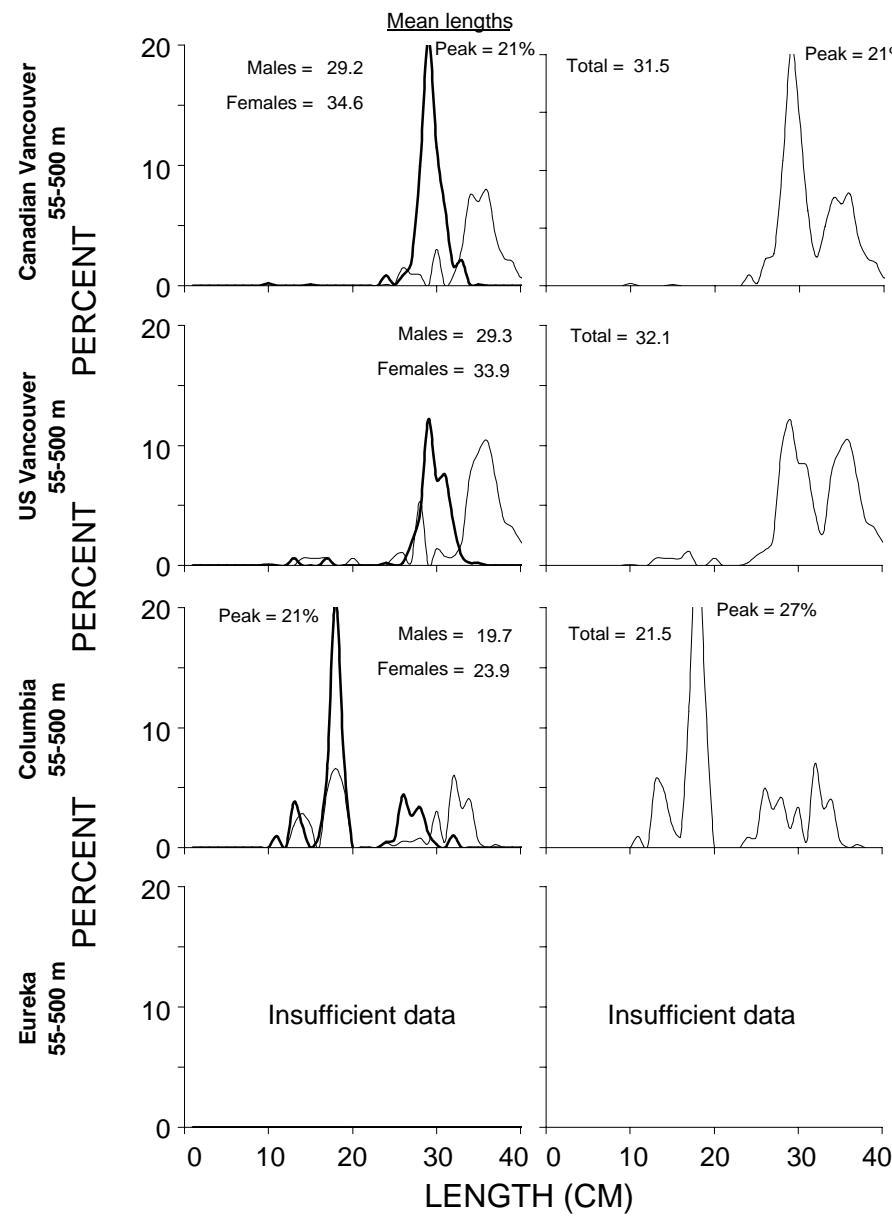

Figure 53.-- Estimated population size composition and mean lengths of Pacific sanddab by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

PETRALE SOLE

— male — female

Figure 54.-- Estimated population size composition and mean lengths of petrale sole by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

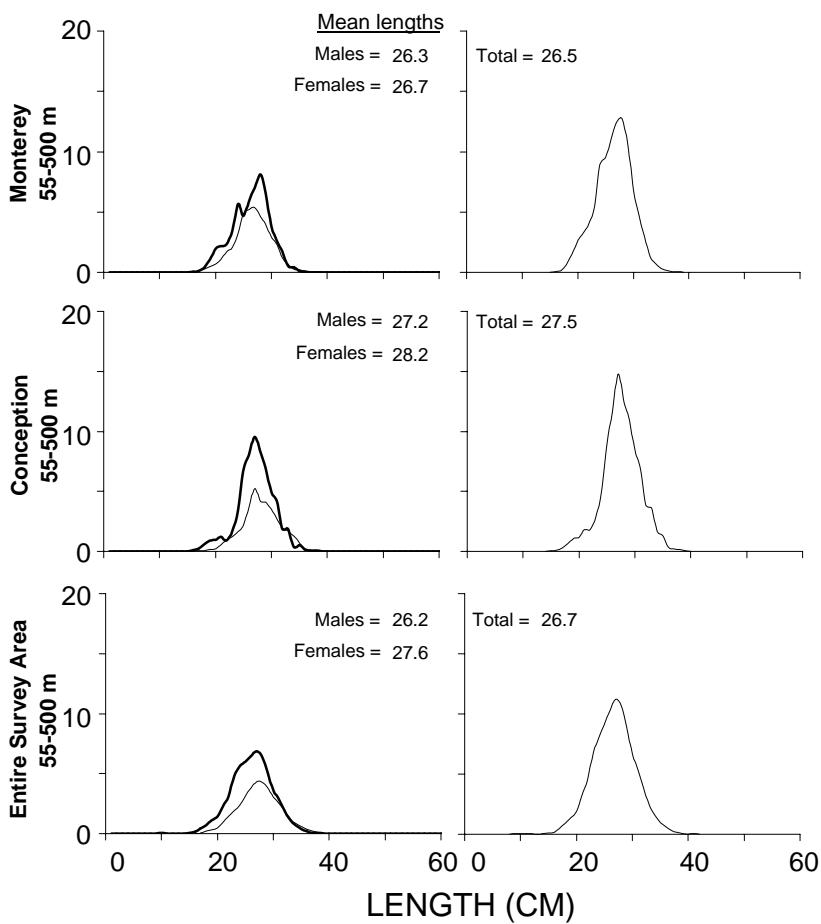

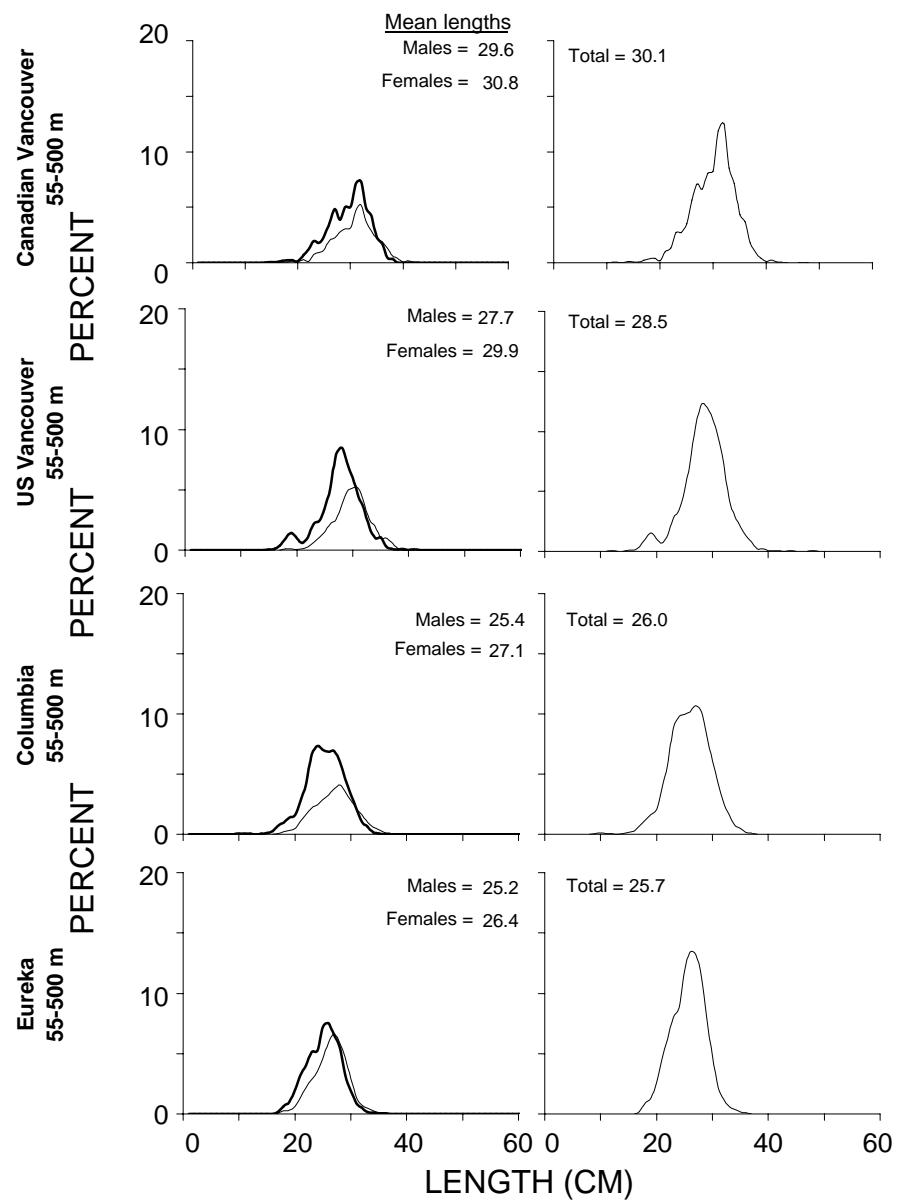

123

REDSTRIPE ROCKFISH

male

female

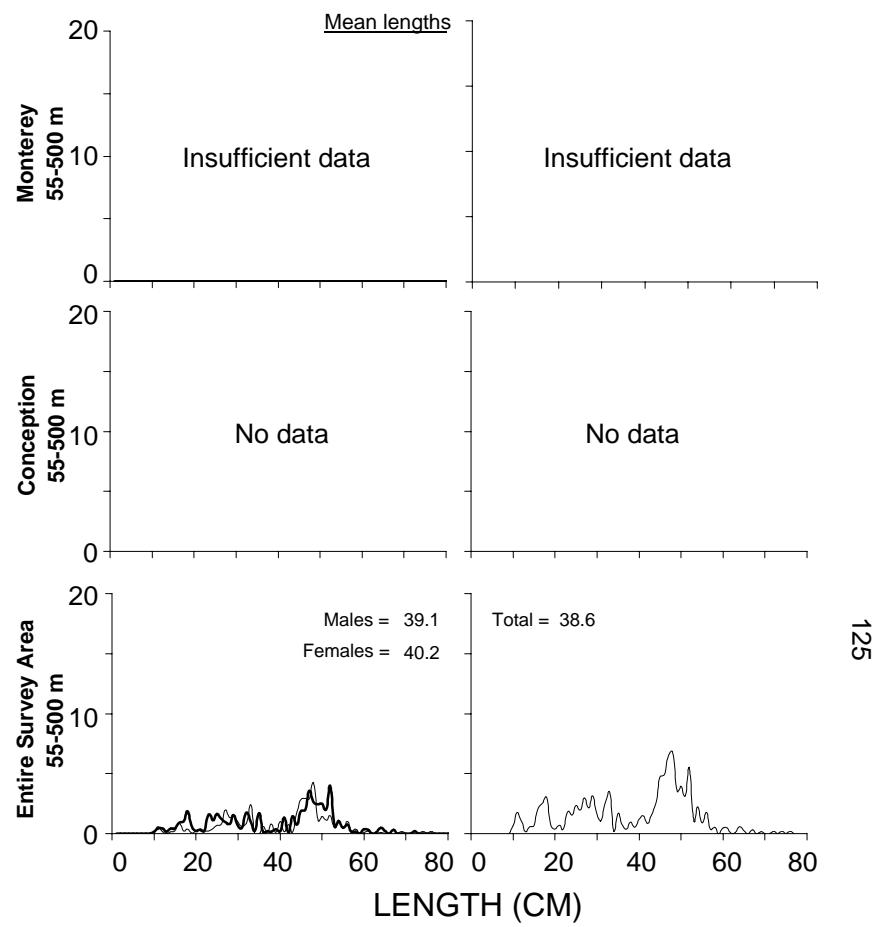

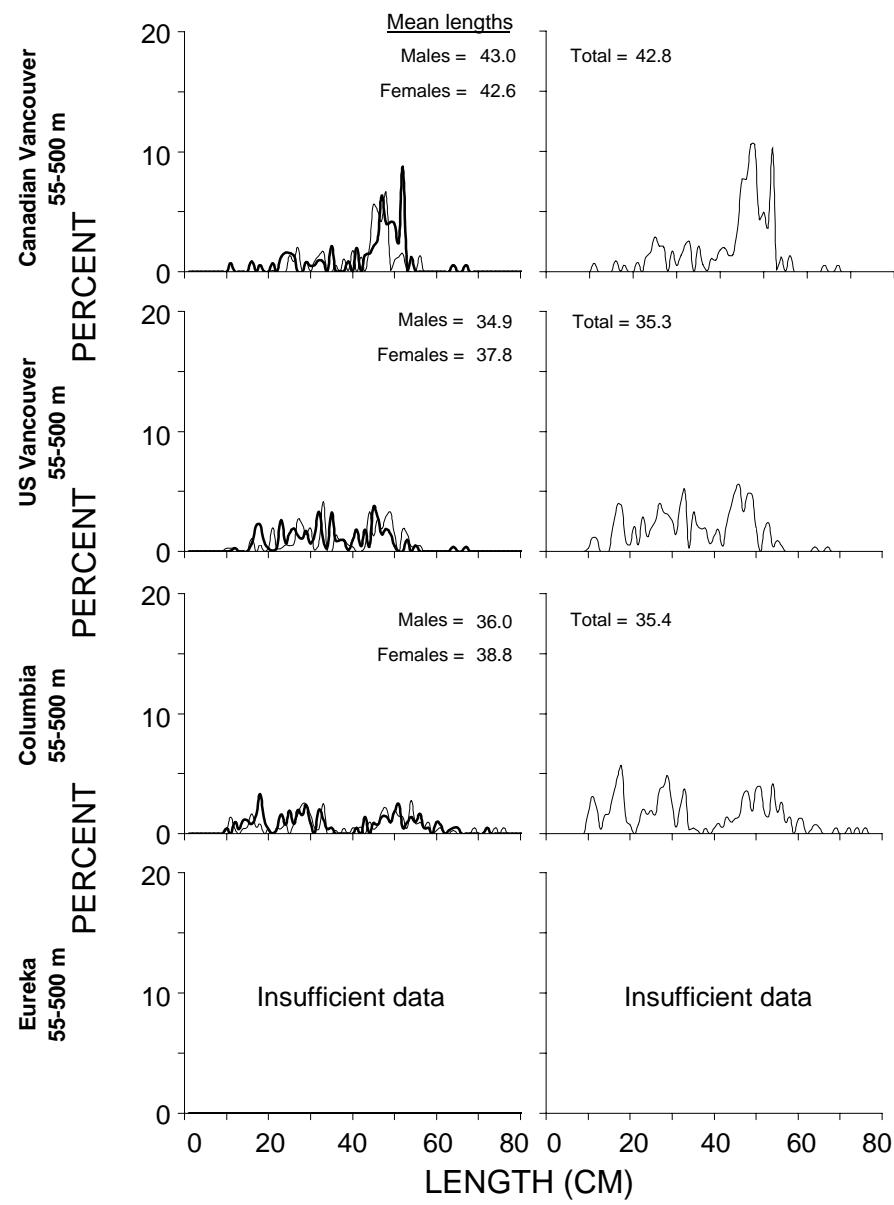

Figure 55.-- Estimated population size composition and mean lengths of redstripe rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

REX SOLE

male female

Figure 56.-- Estimated population size composition and mean lengths of rex sole by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

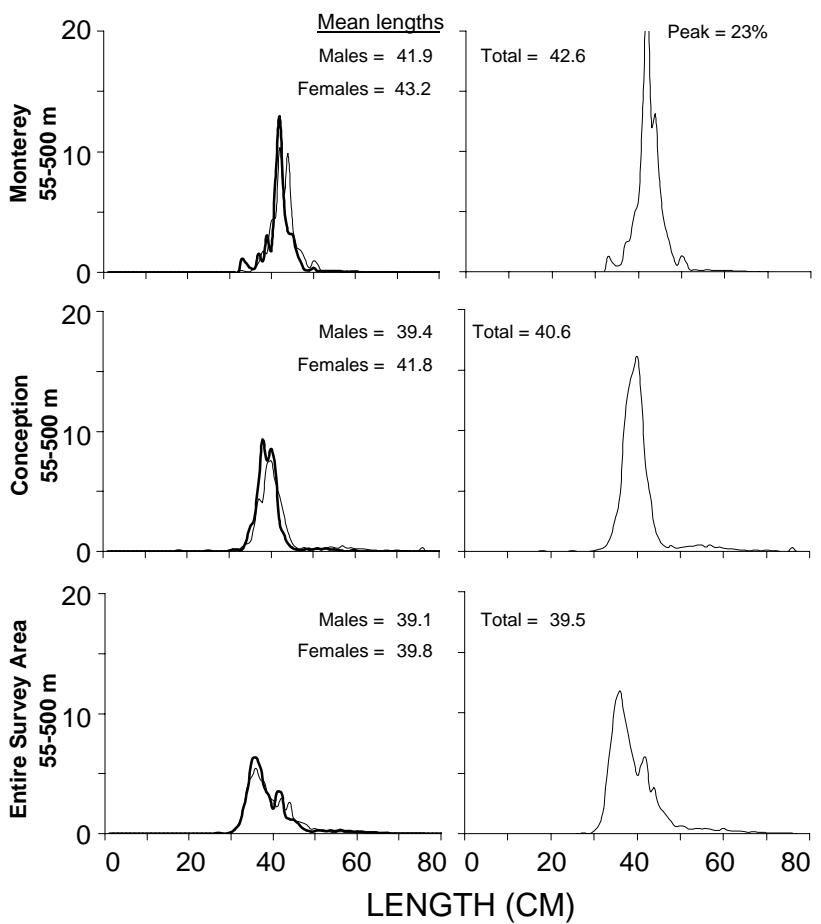

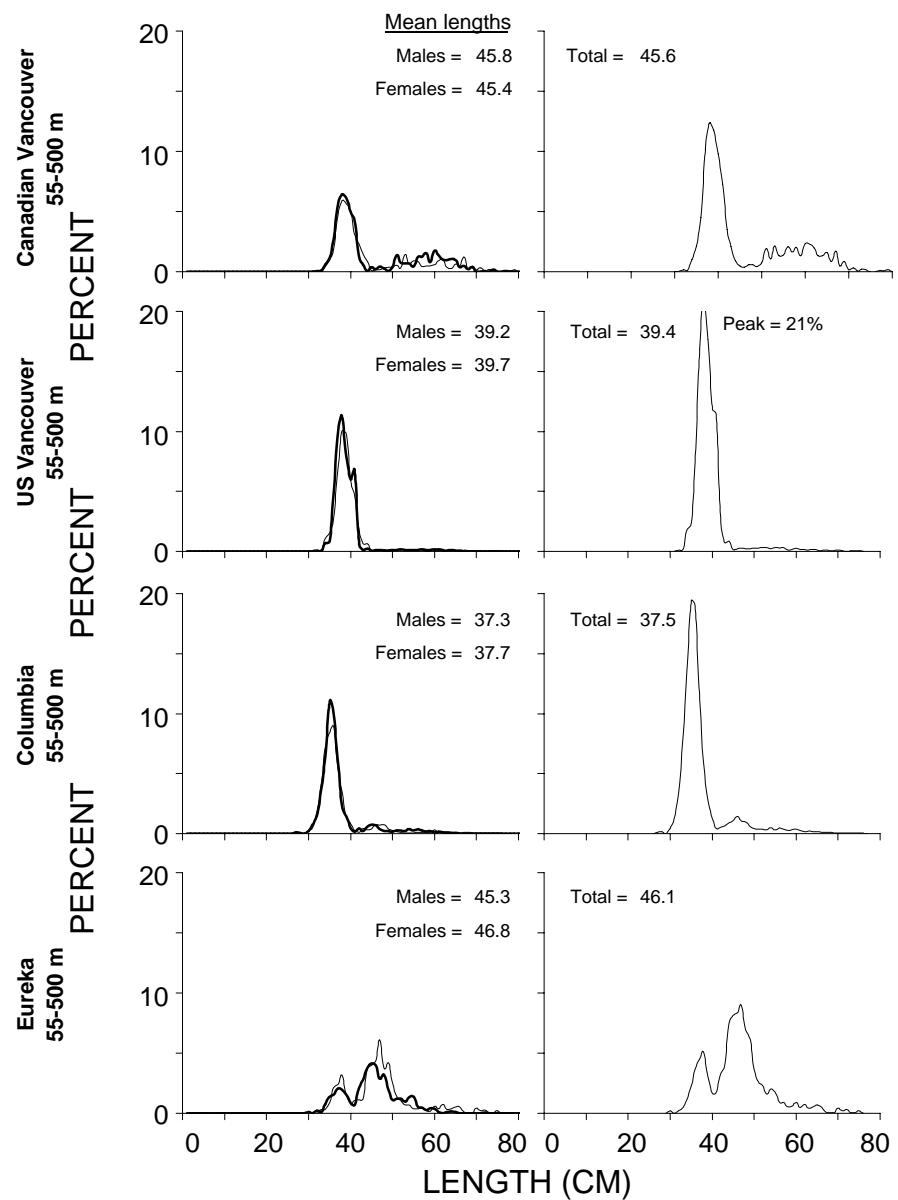

ROUGHEYE ROCKFISH

male

female

Figure 57.-- Estimated population size composition and mean lengths of rougheye rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

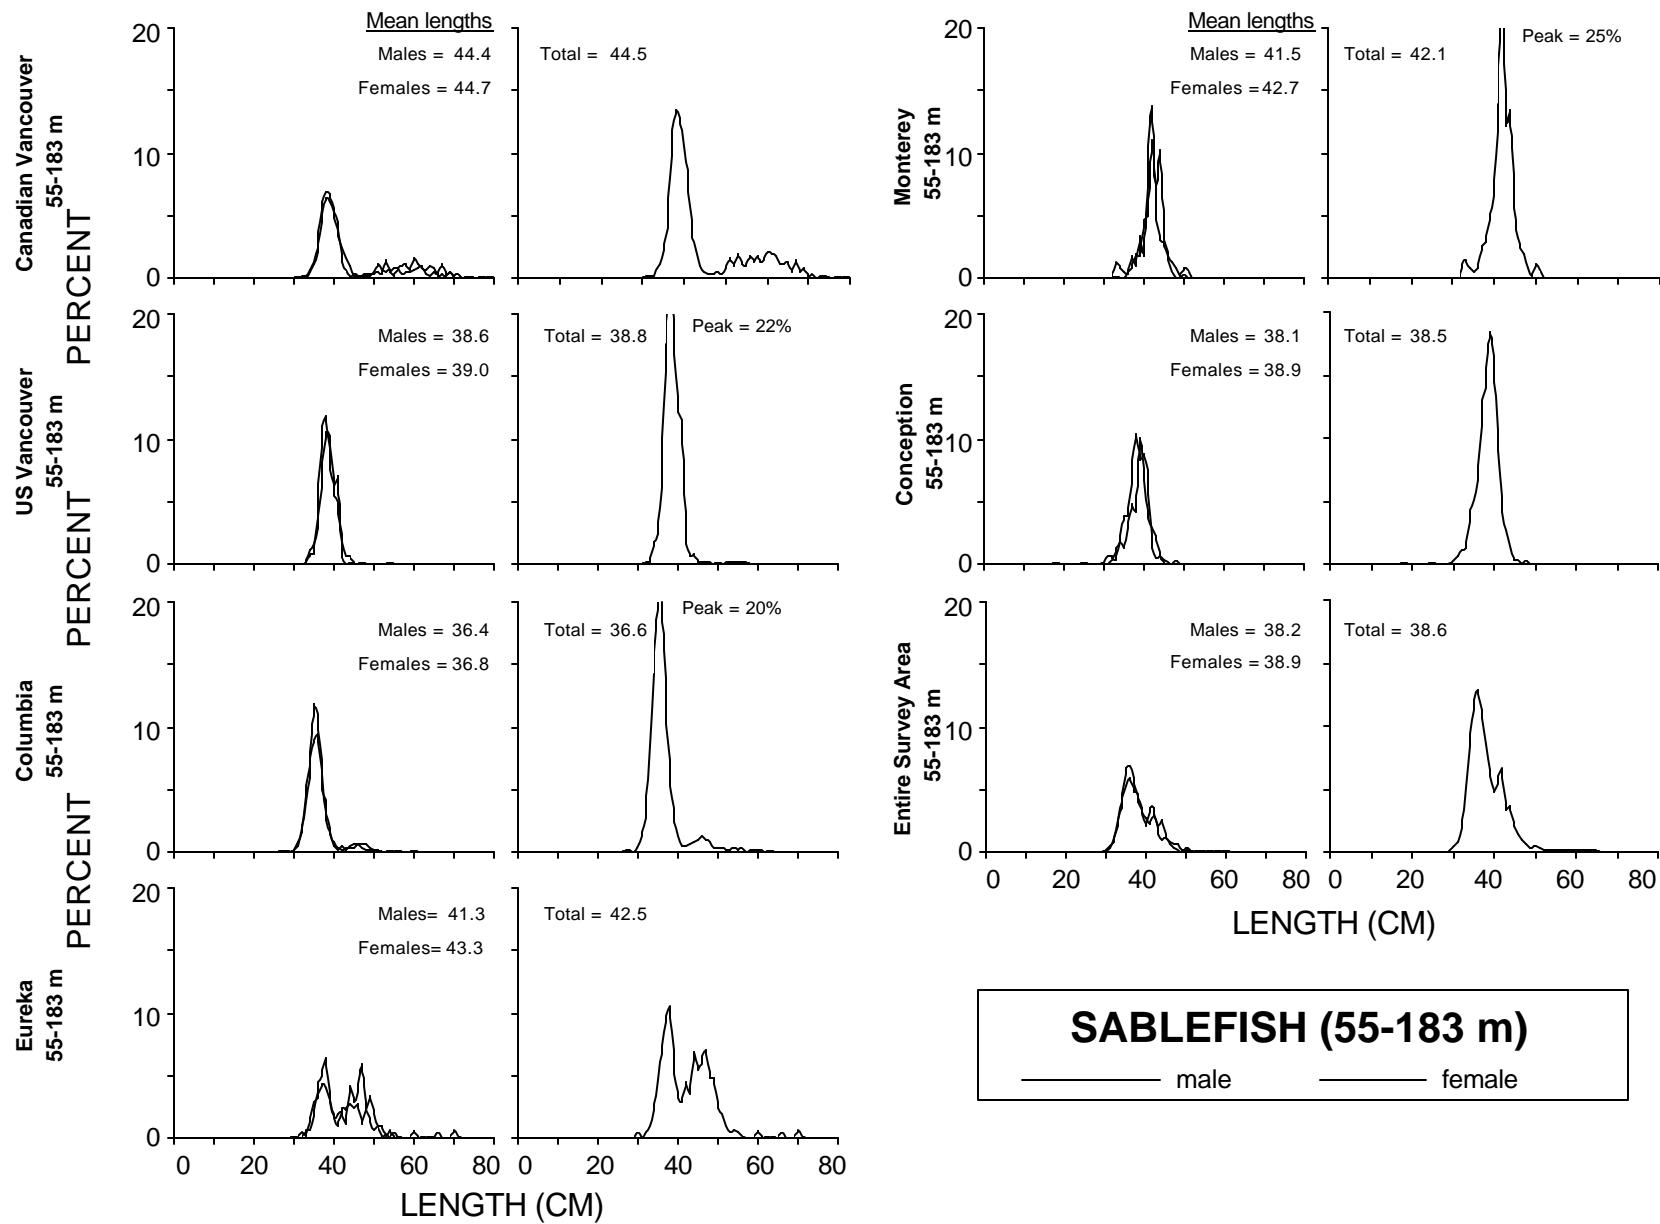

SABLEFISH (All Depths)

male

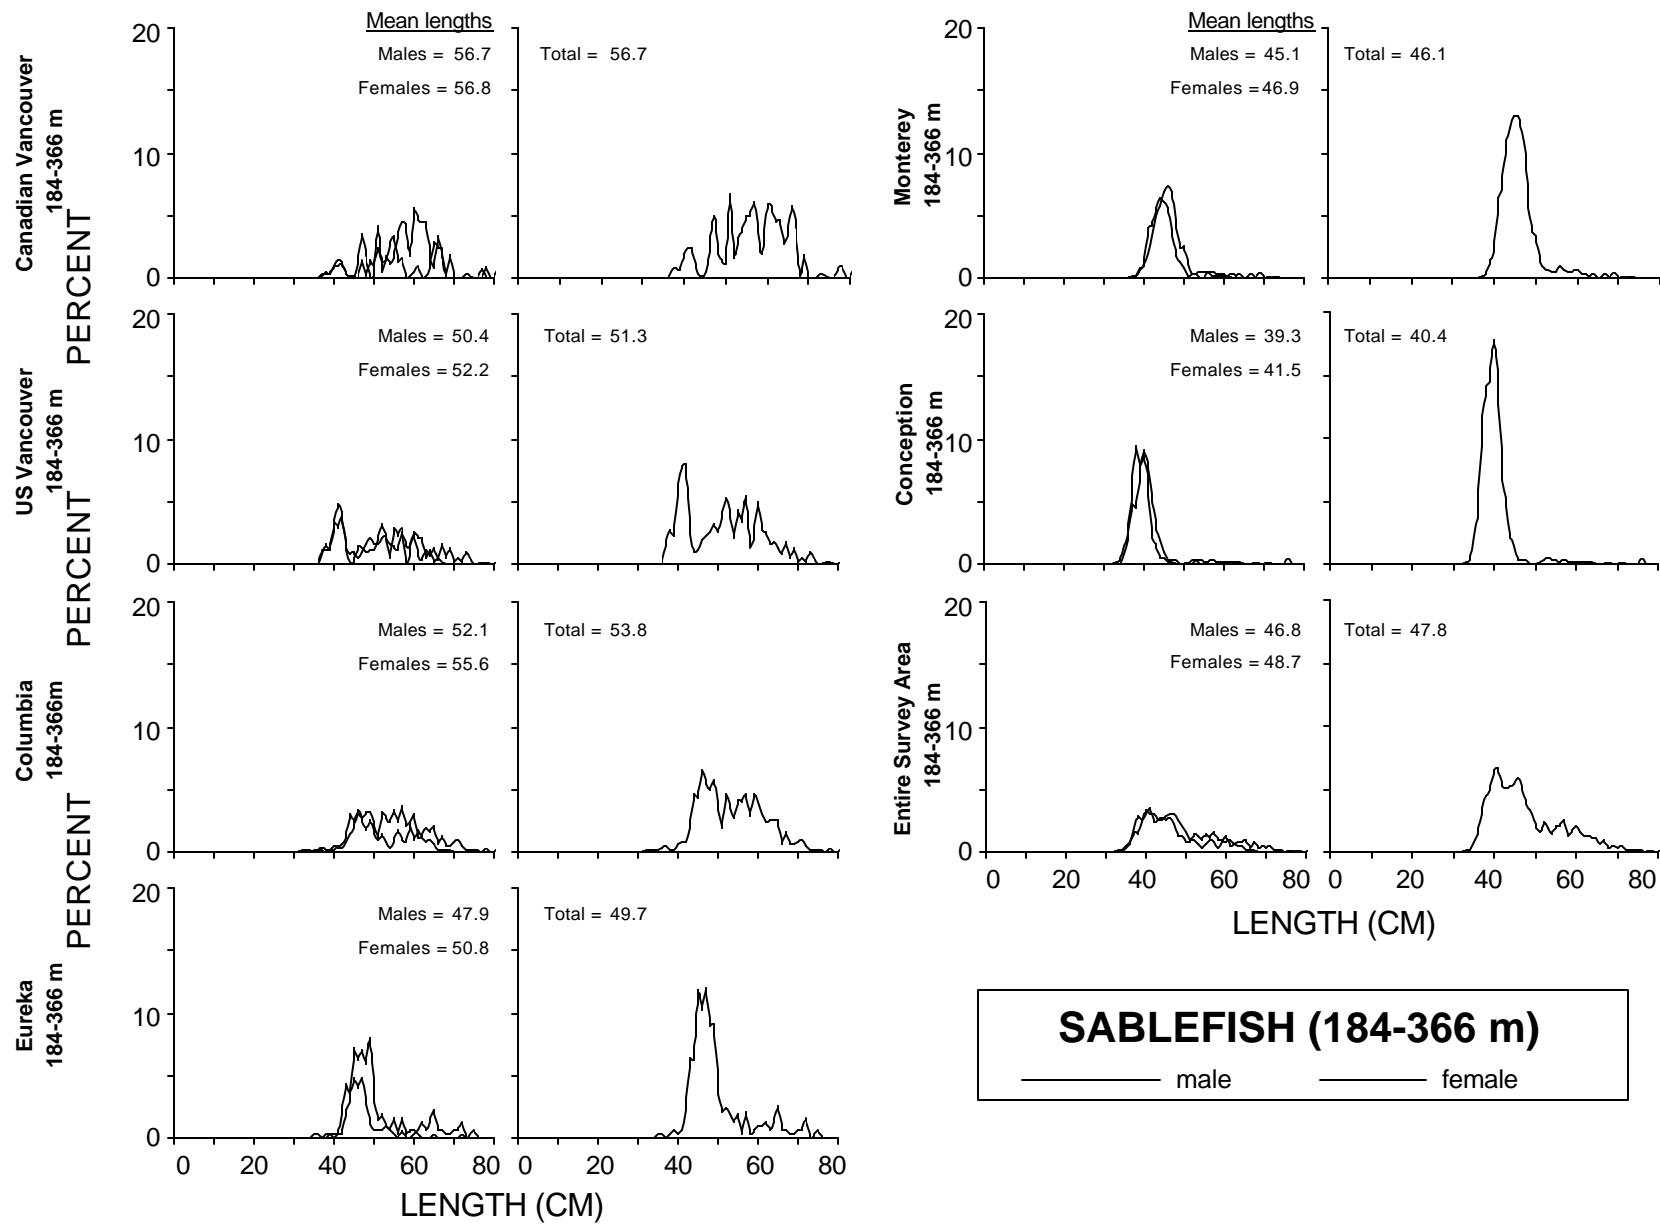

female

Figure 58.-- Estimated population size composition and mean lengths of sablefish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

127

Figure 59.-- Estimated population size composition and mean lengths of sablefish by sex and International North Pacific Fisheries Commission area for the shallow depth stratum (55-183 m) from the 2001 triennial bottom trawl survey.

128

Figure 60.-- Estimated population size composition and mean lengths of sablefish by sex and International North Pacific Fisheries Commission area for the middle depth stratum (184-366 m) from the 2001 triennial bottom trawl survey.

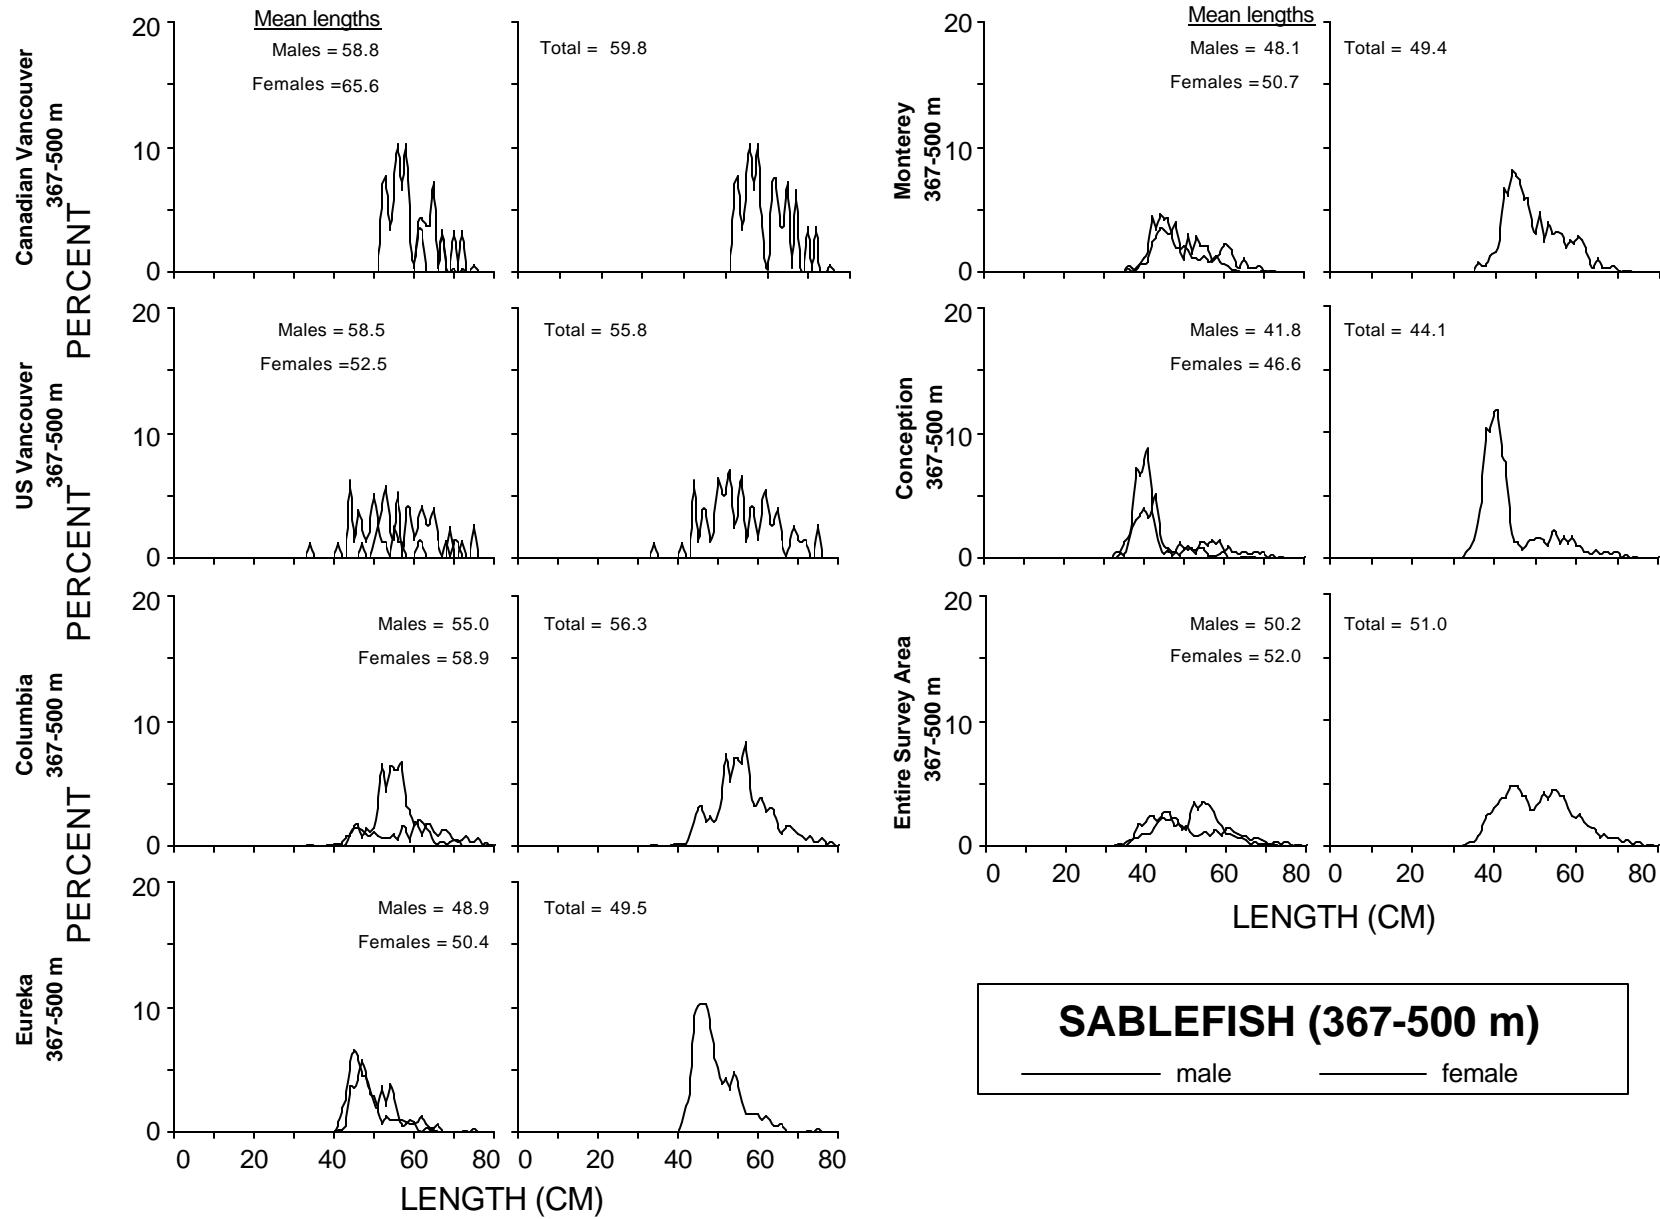

Figure 61.-- Estimated population size composition and mean lengths of sablefish by sex and International North Pacific Fisheries Commission area for the deep depth stratum (367-500 m) from the 2001 triennial bottom trawl survey.

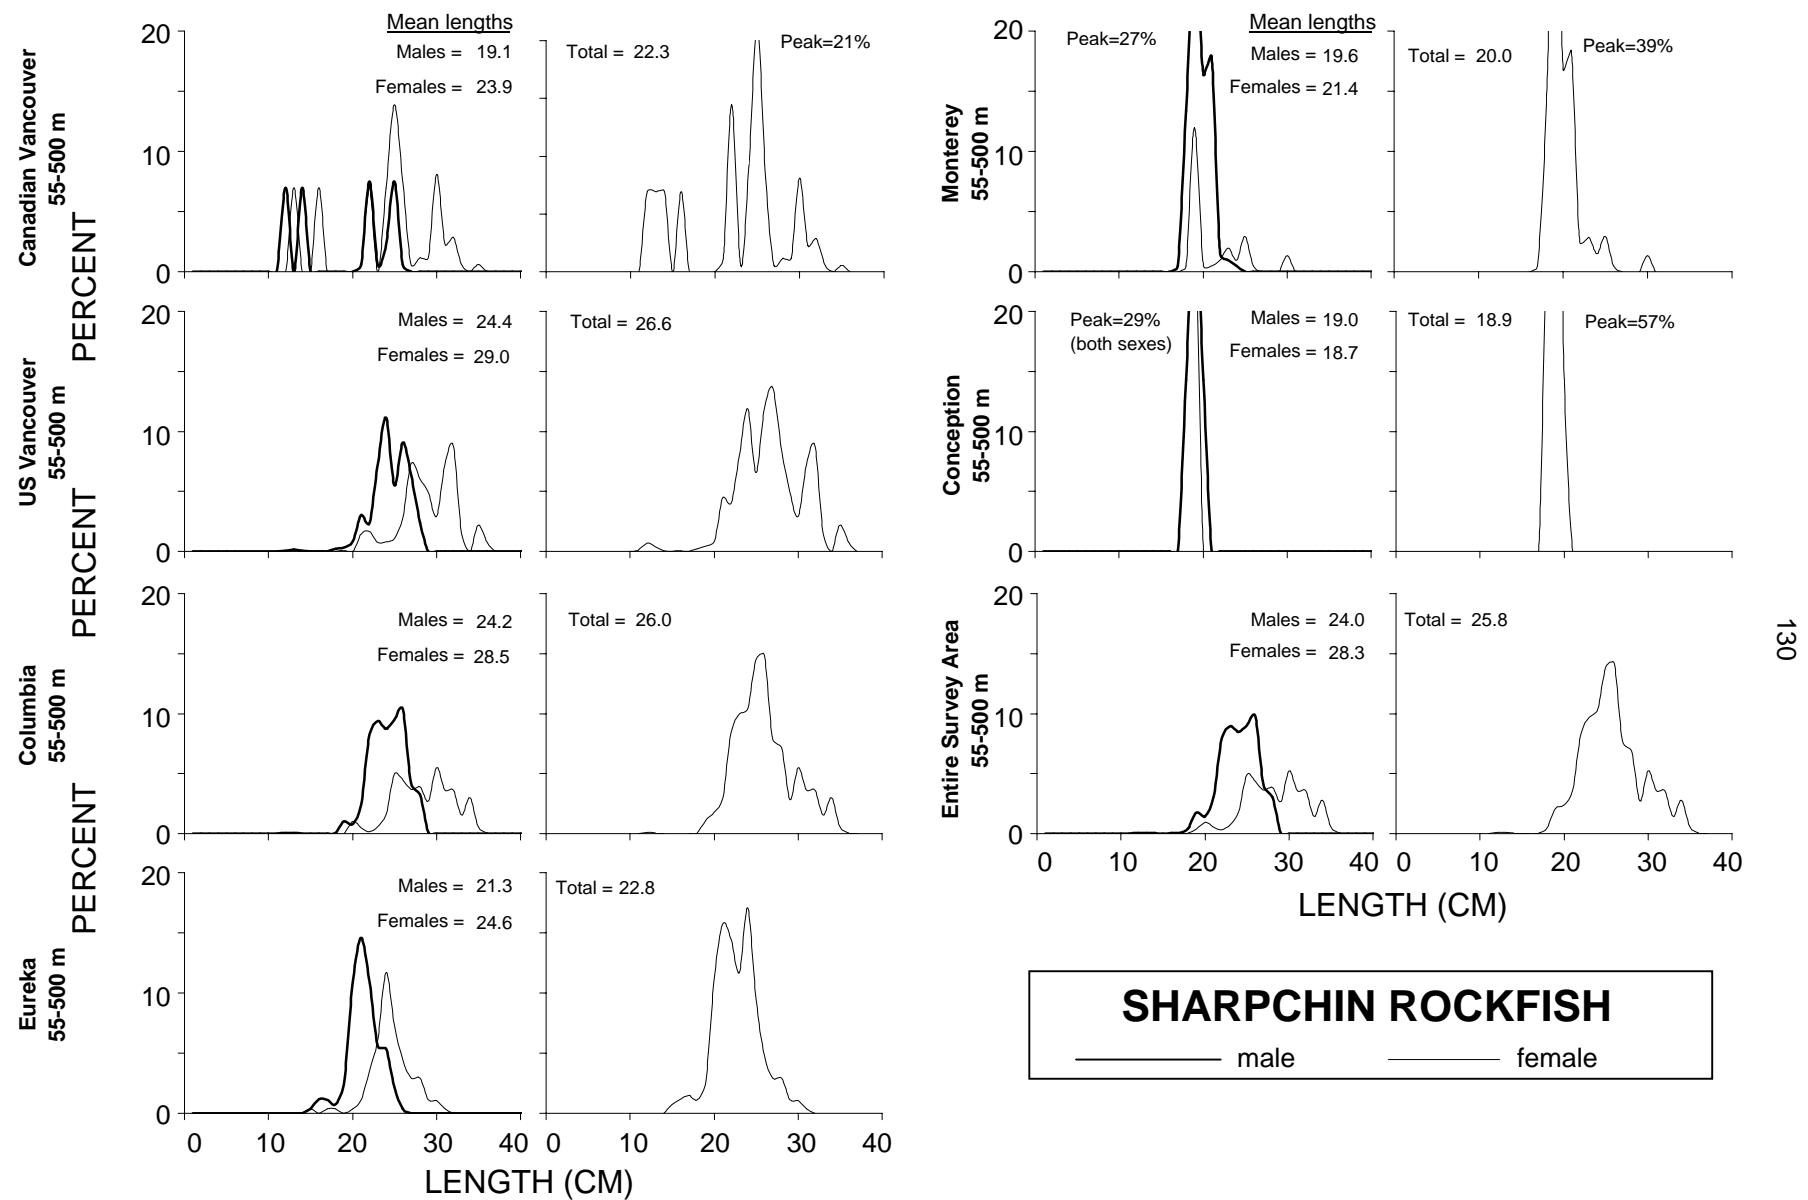

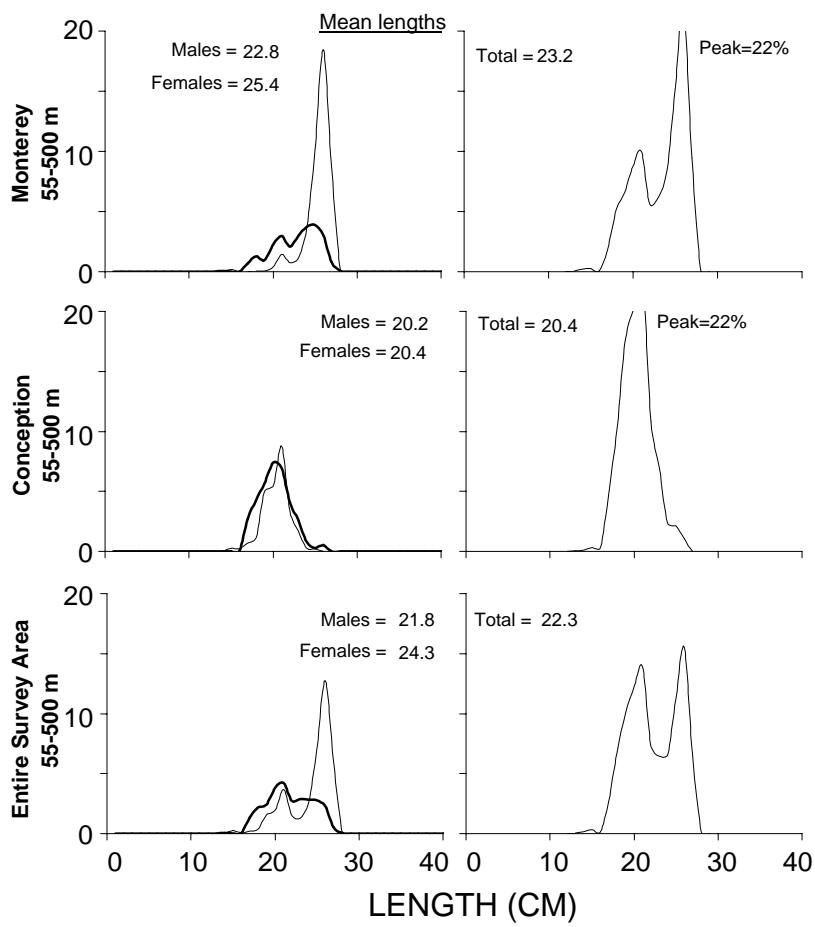

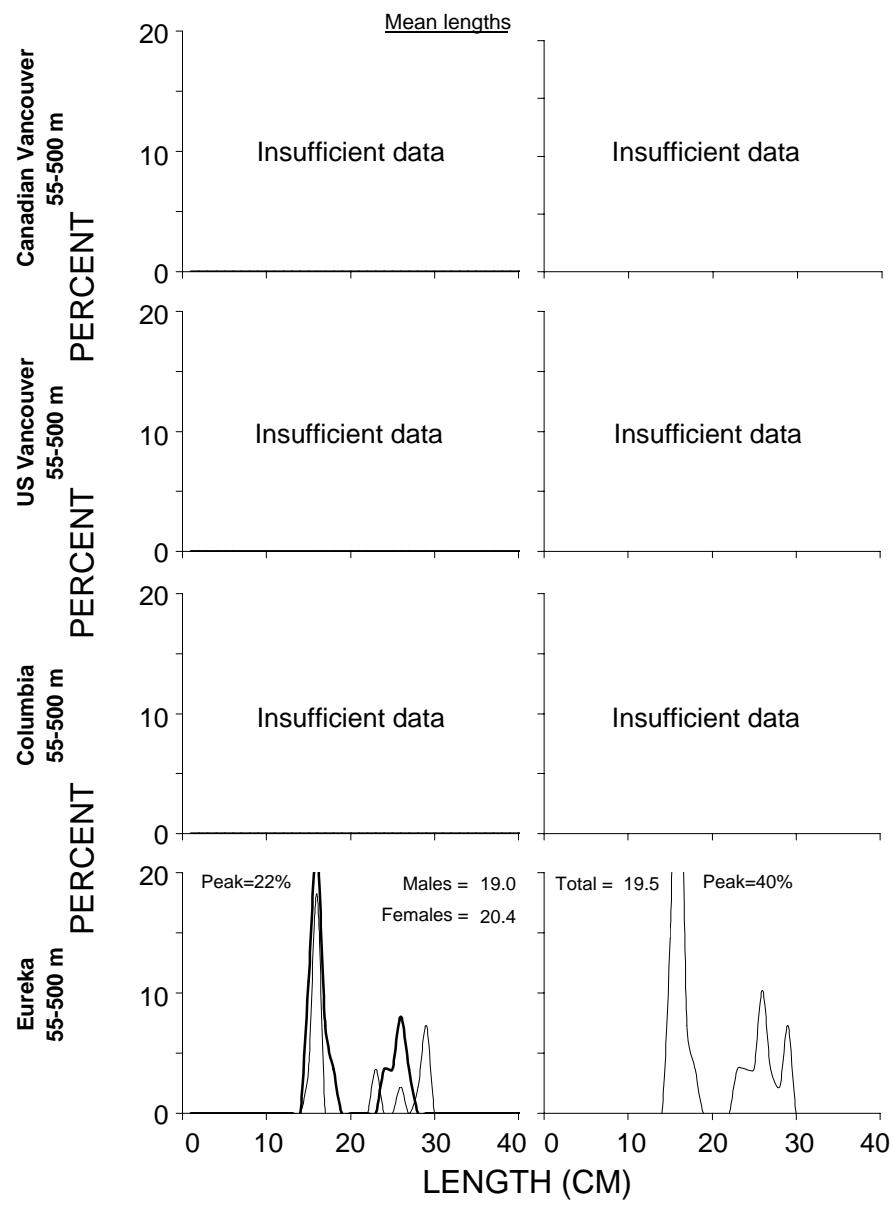

Figure 62.-- Estimated population size composition and mean lengths of sharpchin rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

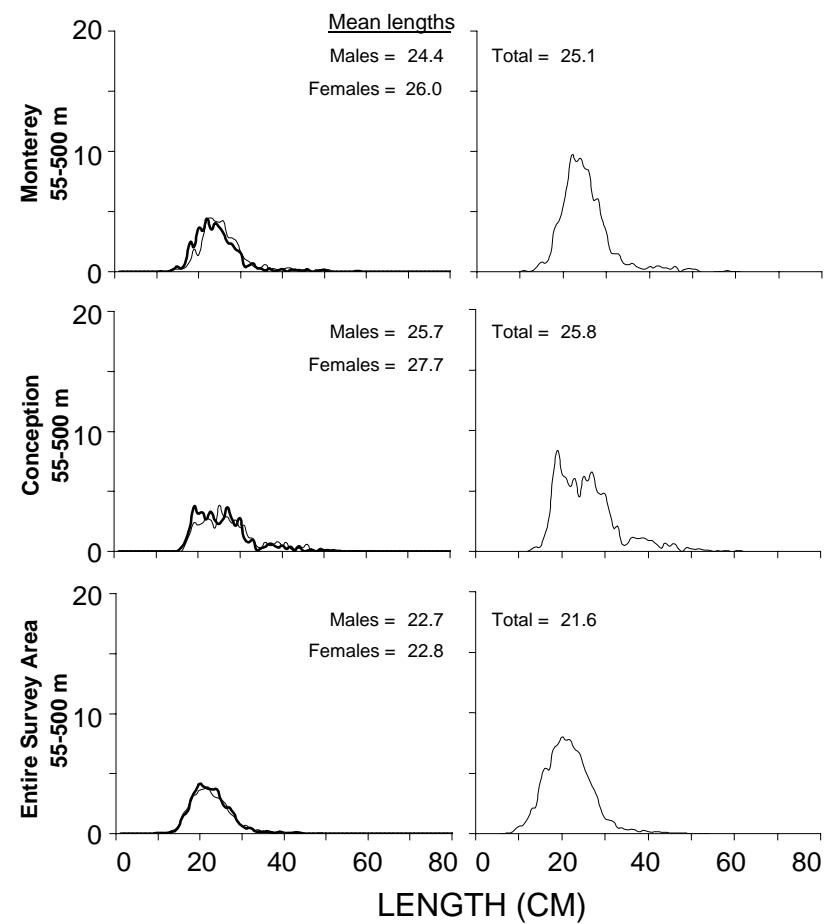

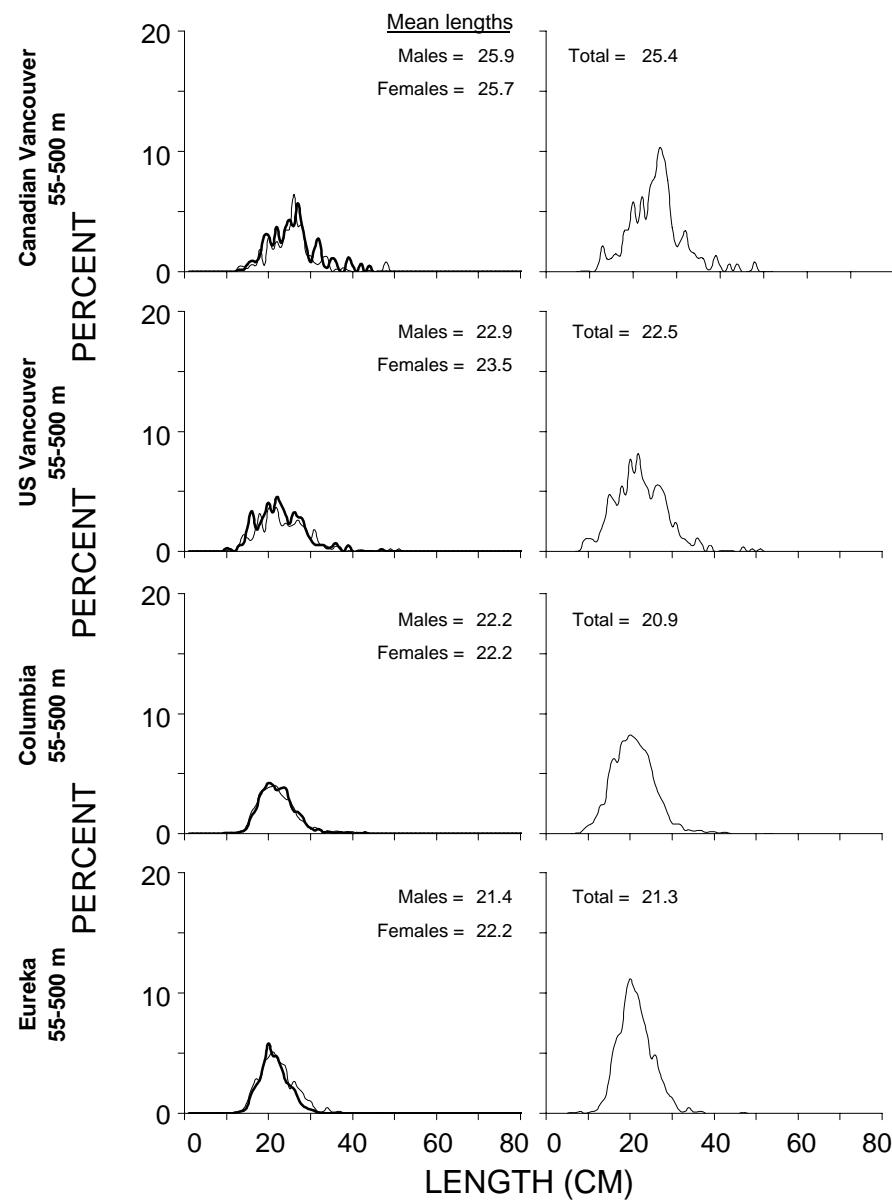

SHORTBELLY ROCKFISH

male

female

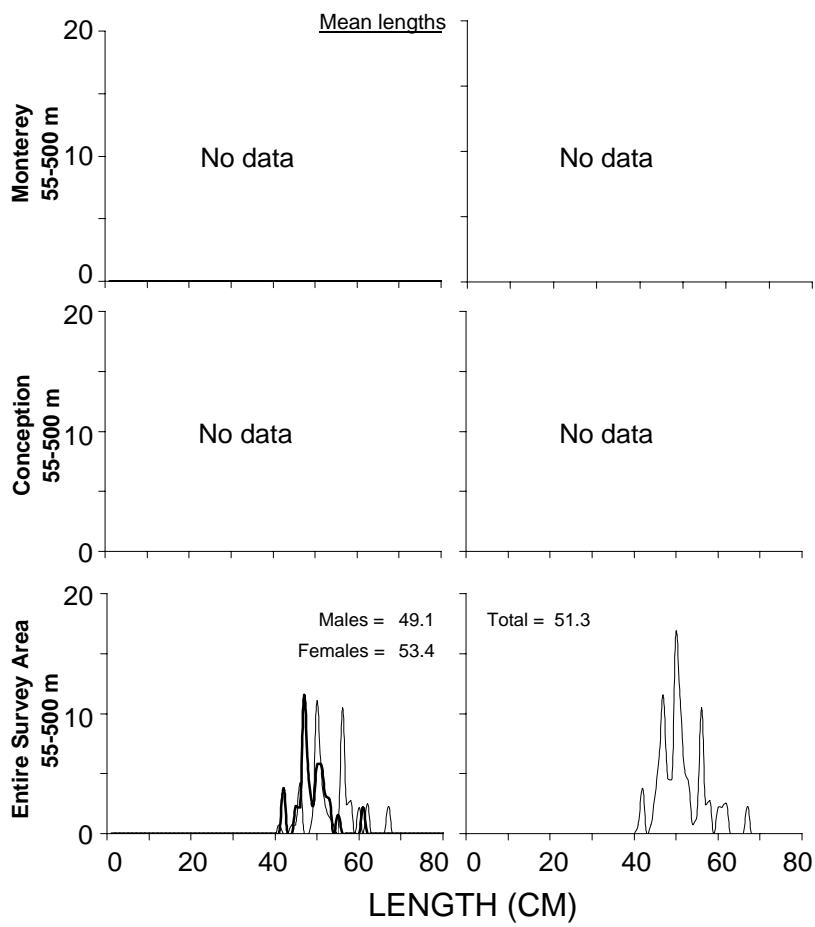

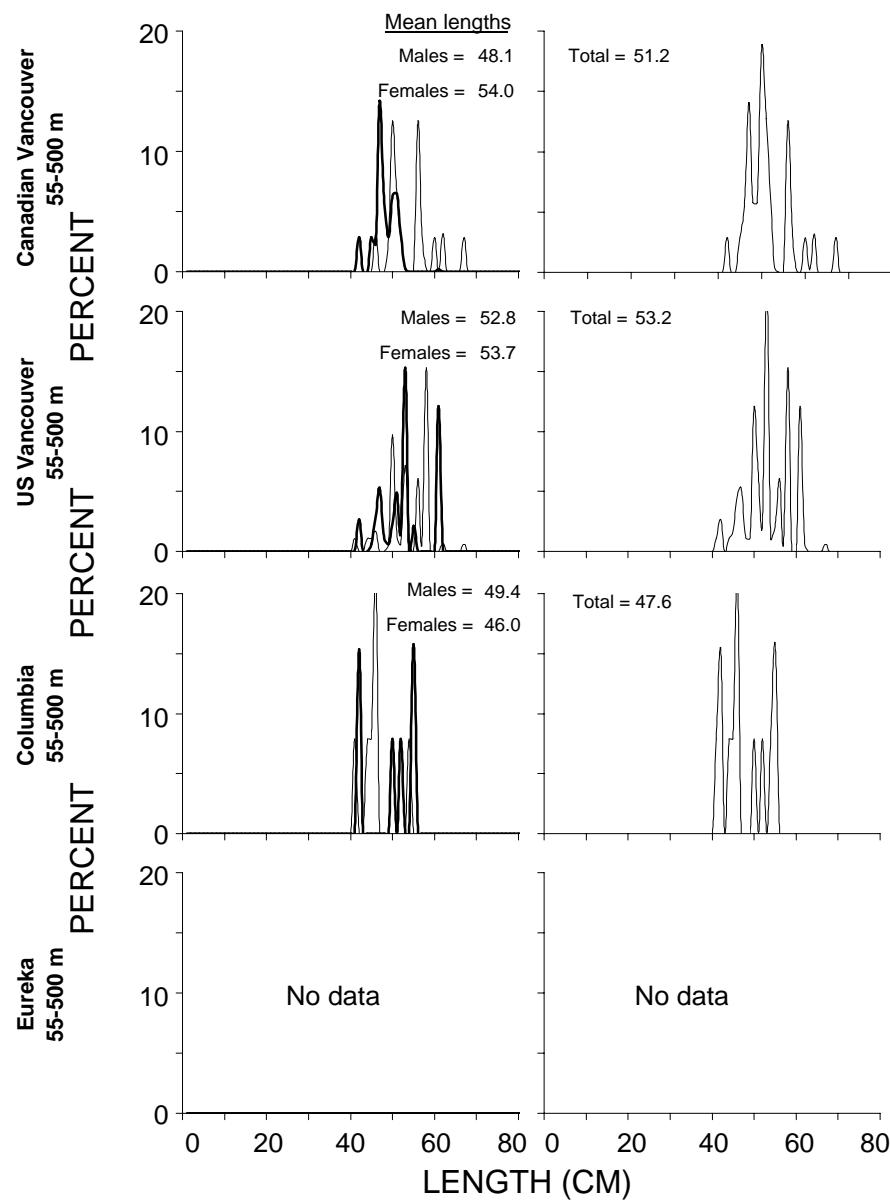

Figure 63.-- Estimated population size composition and mean lengths of shortbelly rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

SHORTSPINE THORNYHEAD

— male — female

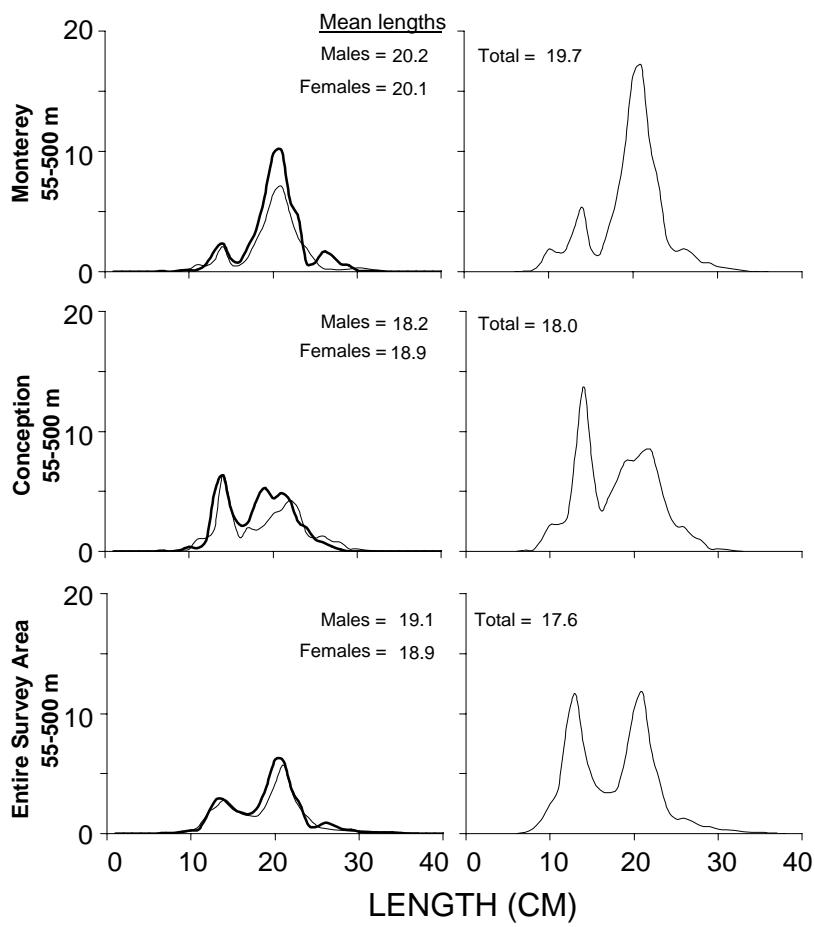

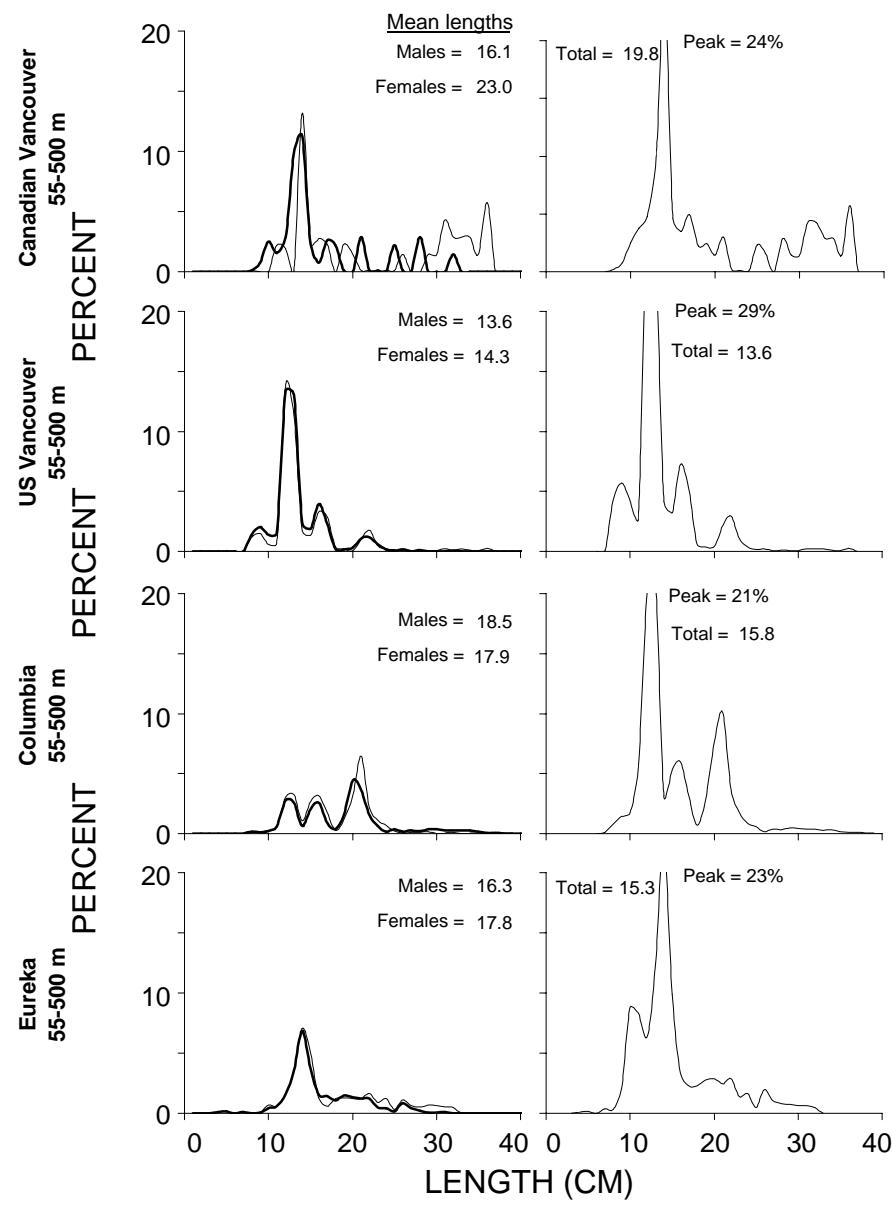

Figure 64.-- Estimated population size composition and mean lengths of shortspine thornyhead by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

SILVERGRAY ROCKFISH

male female

Figure 65.-- Estimated population size composition and mean lengths of silvergray rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

SPLITNOSE ROCKFISH

male

female

Figure 66.-- Estimated population size composition and mean lengths of splitnose rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

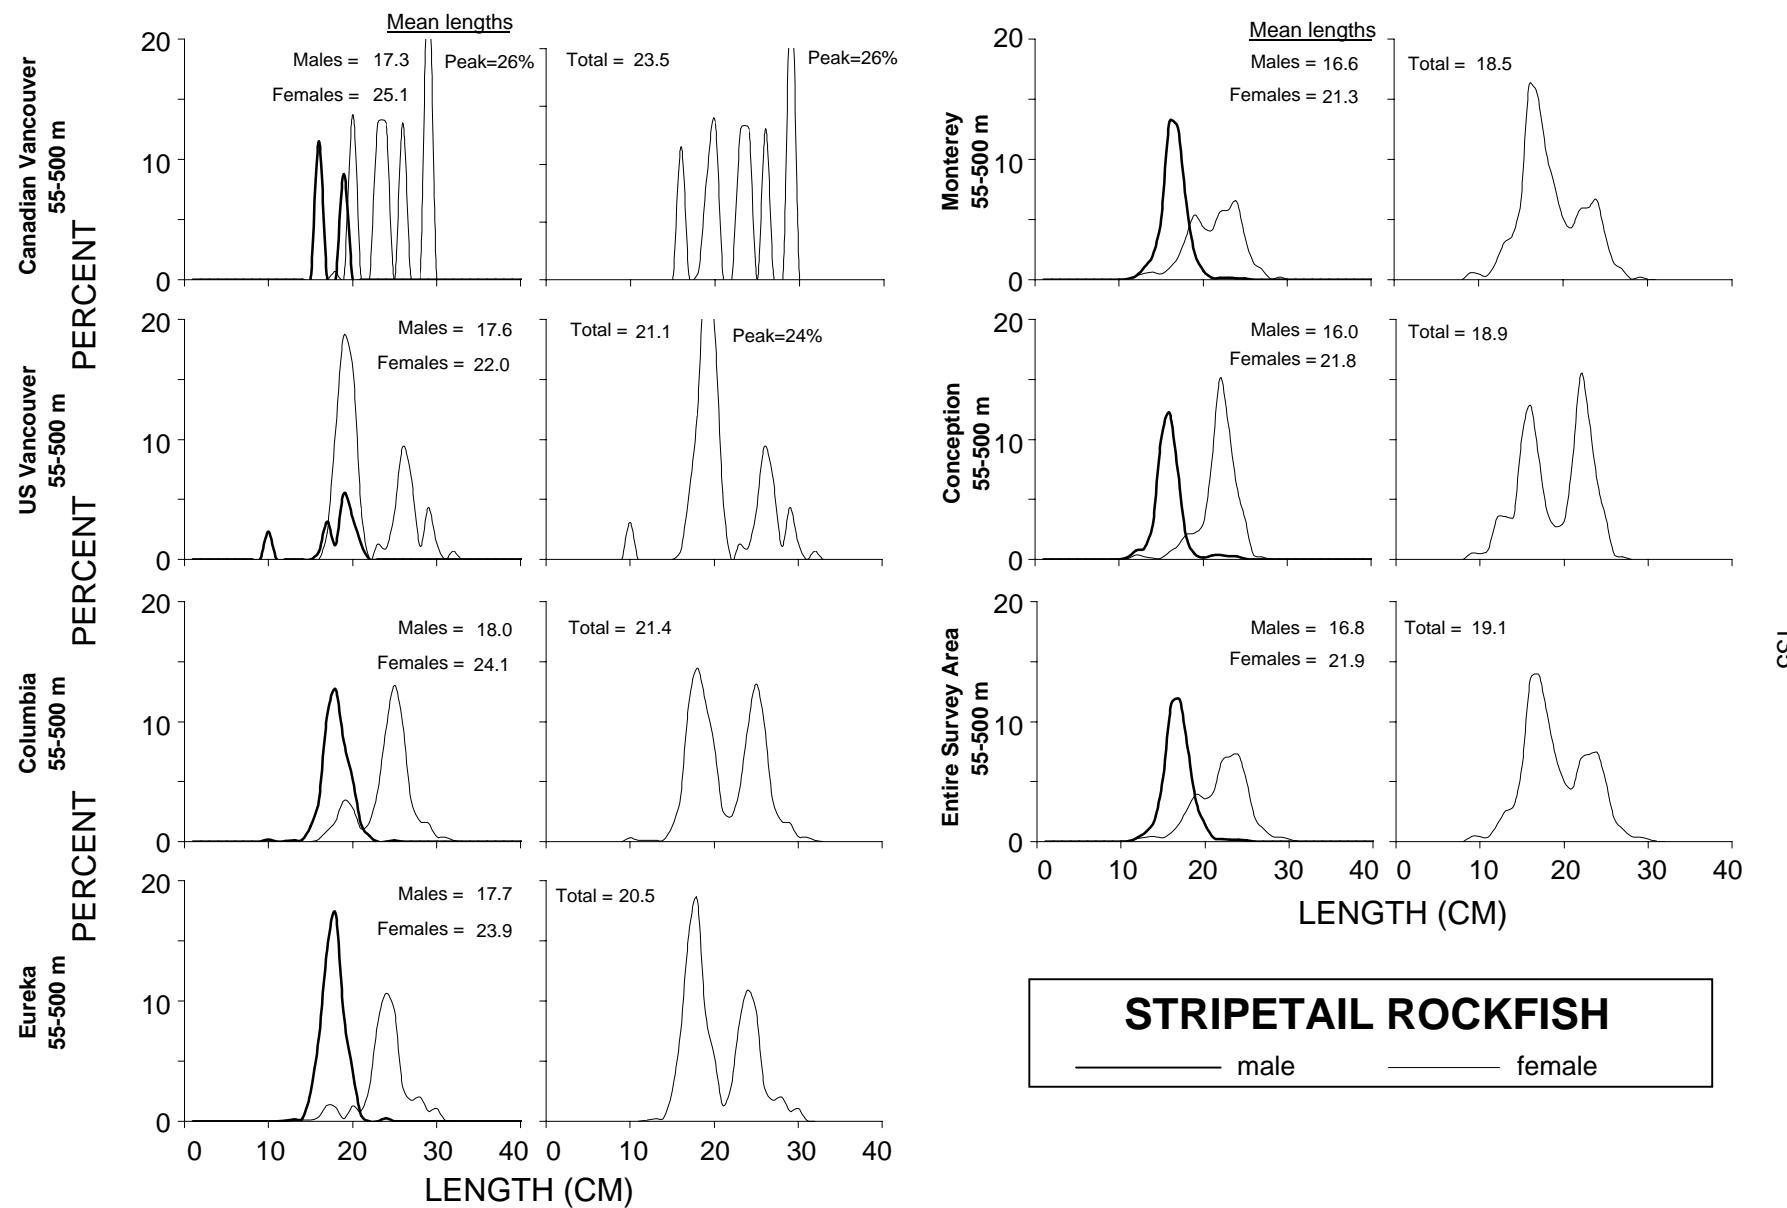

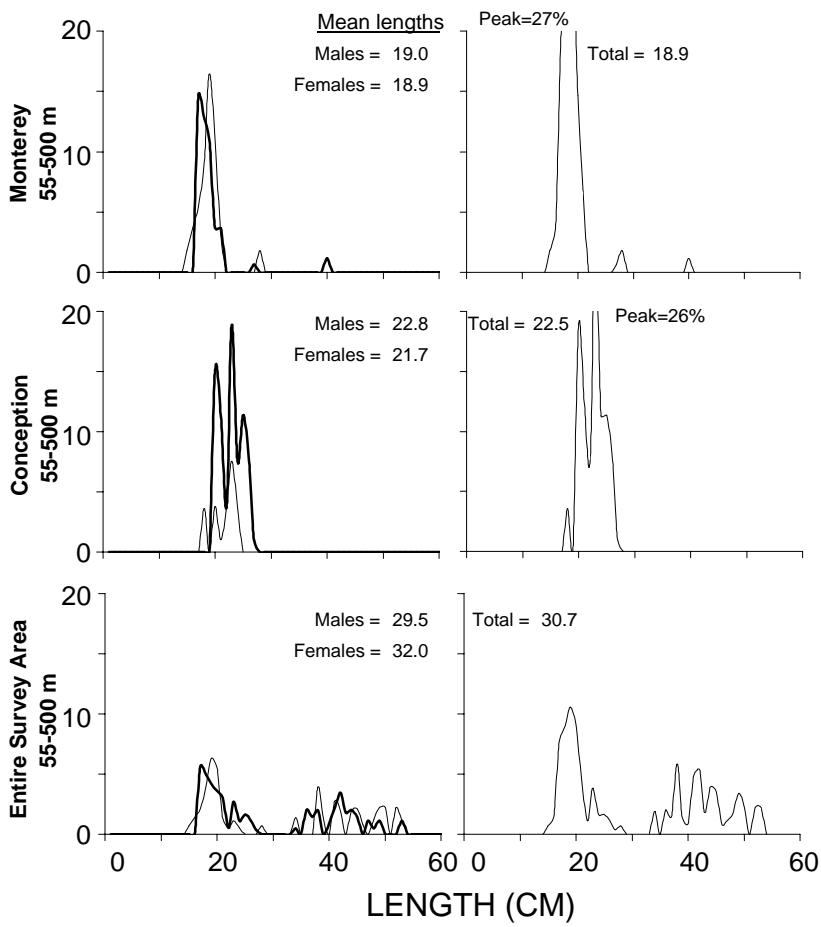

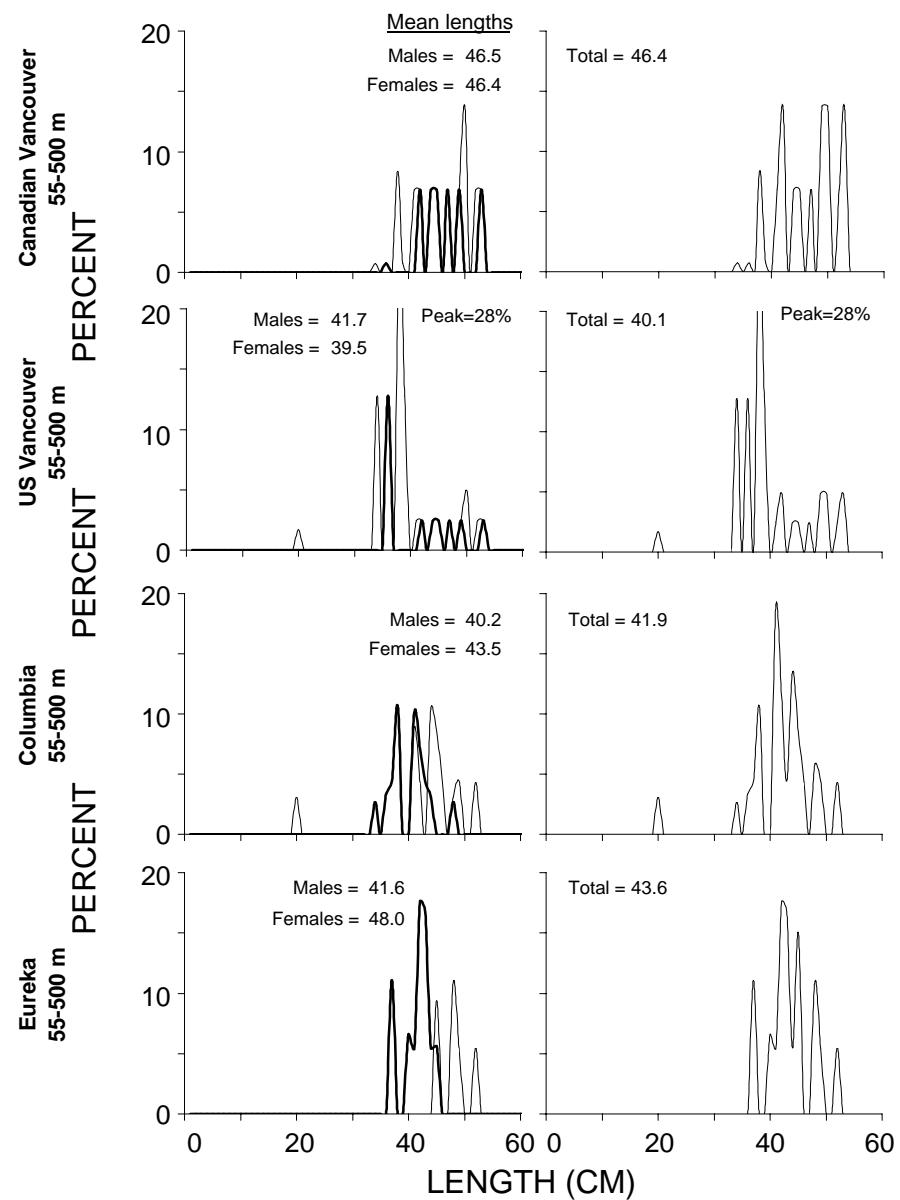

Figure 67.-- Estimated population size composition and mean lengths of stripetail rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

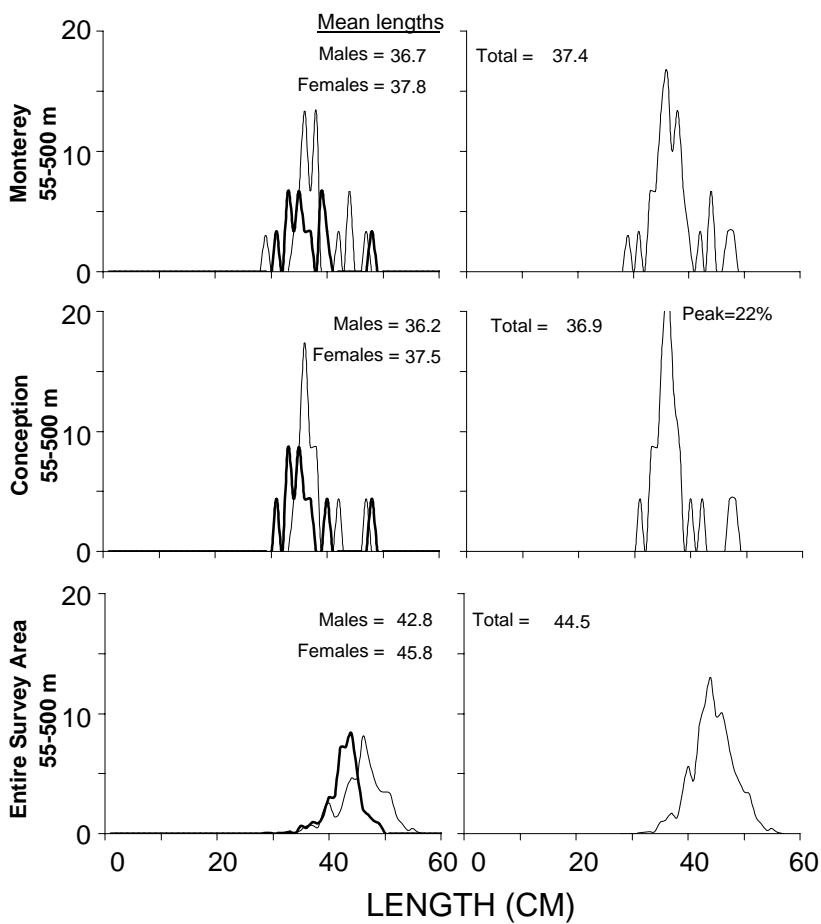

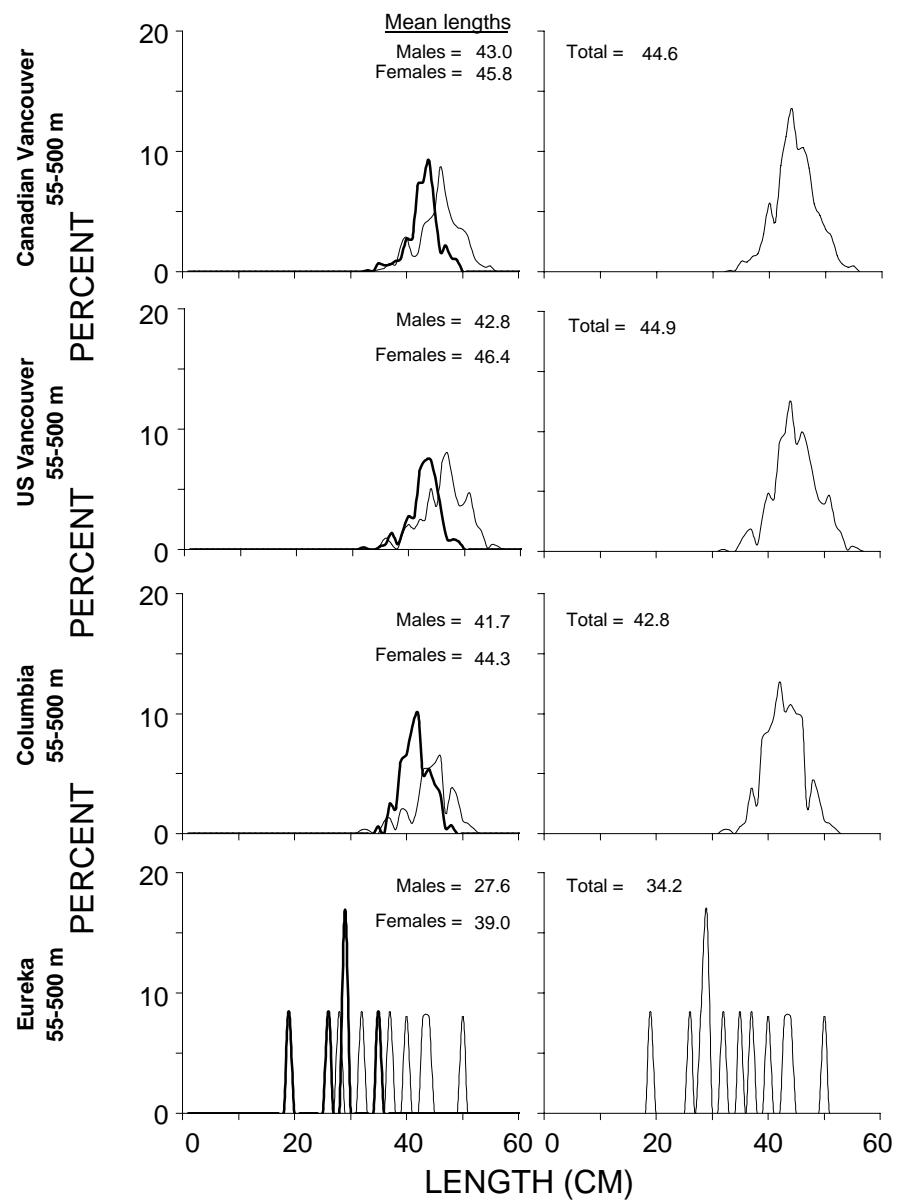

WIDOW ROCKFISH

male

female

Figure 68.-- Estimated population size composition and mean lengths of widow rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

137

YELLOWTAIL ROCKFISH

male female

Figure 69.-- Estimated population size composition and mean lengths of yellowtail rockfish by sex and International North Pacific Fisheries Commission area for all depths (55-500 m) from the 2001 triennial bottom trawl survey.

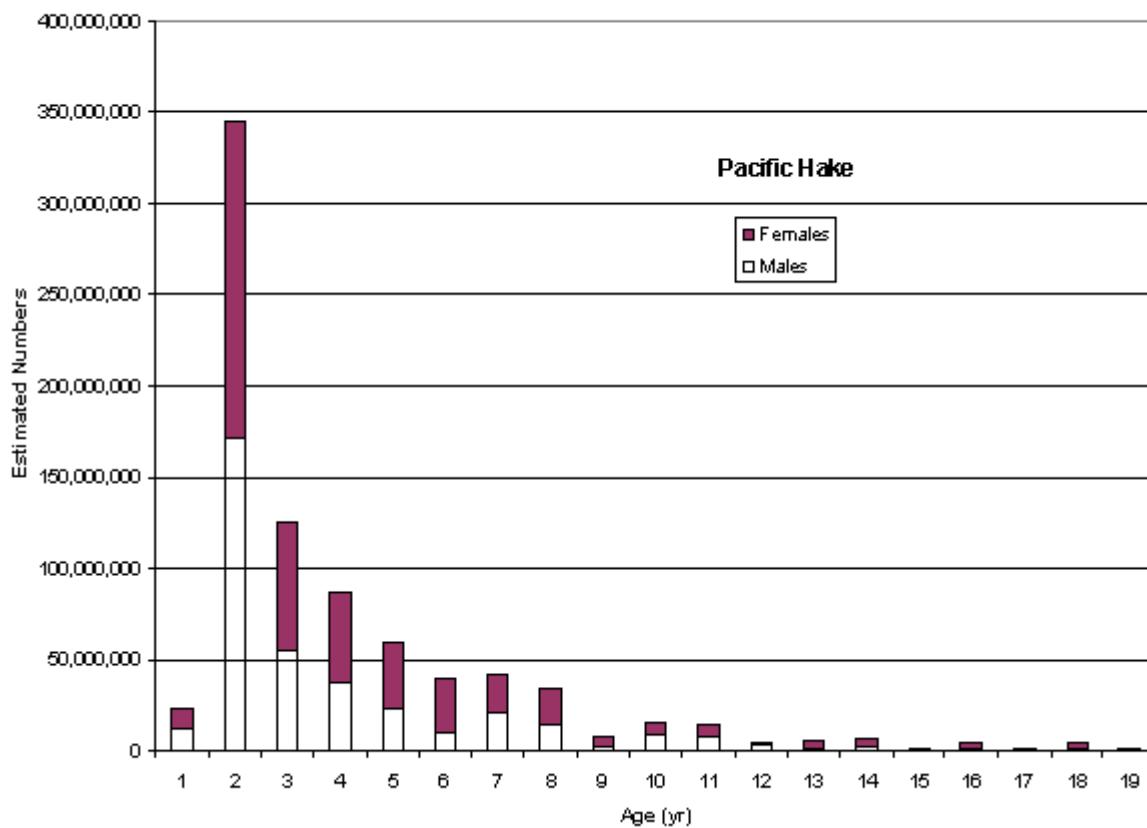

Figure 70.--The age composition of the Pacific hake resource off California, Oregon, Washington, and British Columbia in 2001, based upon results of the West Coast triennial bottom trawl survey, all areas and depths combined.

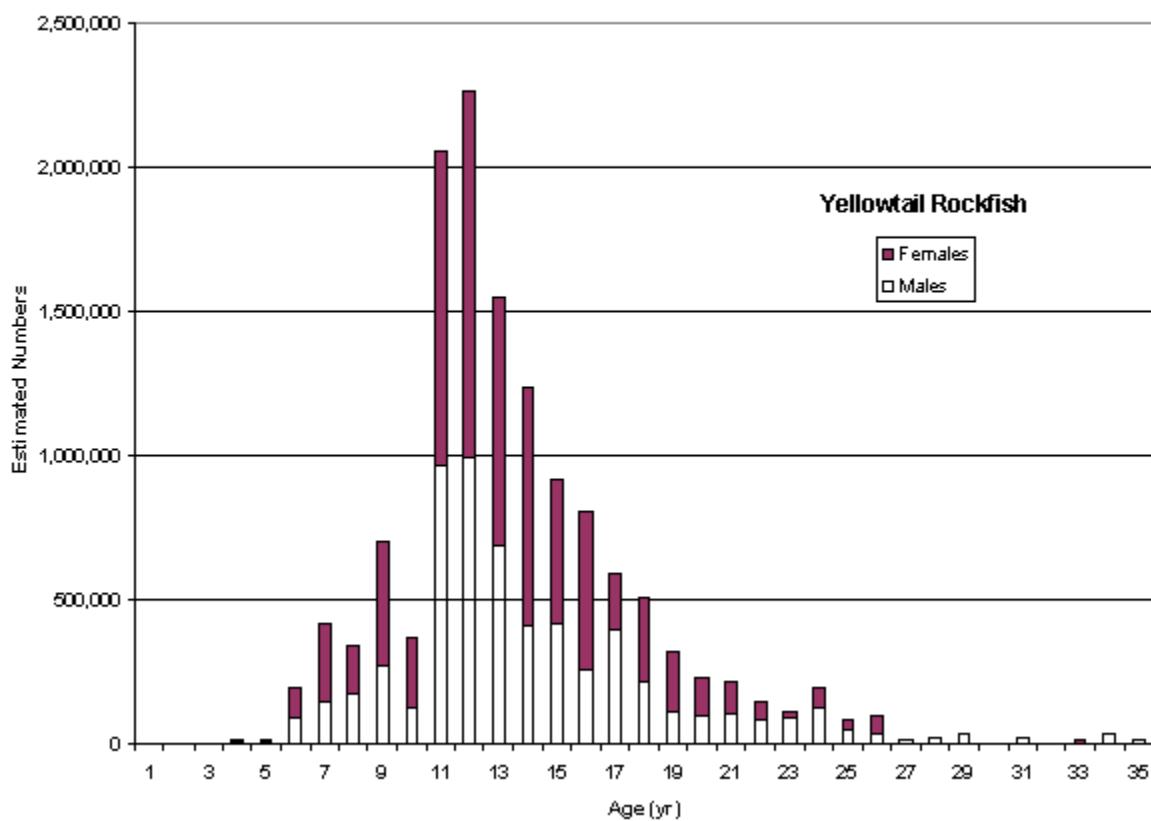

Figure 72.--The age composition of the yellowtail rockfish resource off California, Oregon, Washington, and British Columbia in 2001, based upon results of the West Coast triennial bottom trawl survey, all areas and depths combined.

RECENT TECHNICAL MEMORANDUMS

Copies of this and other NOAA Technical Memorandums are available from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22167 (web site: www.ntis.gov). Paper and microfiche copies vary in price.

AFSC-

- 127 MARQUETTE, W. M. 2002. Annotated bibliography of the bowhead whale, *Balaena mysticetus*, 1767-1983, 325 p. NTIS number pending.
- 126 HONKALEHTO, T., W. PATTON, S. DE BLOIS, and N. WILLIAMSON. 2002. Echo integration-trawl survey results for walleye pollock (*Theragra chalcogramma*) on the Bering Sea shelf and slope during summer 2000, 66 p. NTIS number pending.
- 125 HONKALEHTO, T., N. WILLIAMSON, and S. DE BLOIS. 2002. Echo integration-trawl survey results for walleye pollock (*Theragra chalcogramma*) on the Bering Sea shelf and slope during summer 1999, 77 p. NTIS number pending.
- 124 ANGLISS, R. P., D. P. DEMASTER, and A. L. LOPEZ. 2001. Alaska marine mammal stock assessments, 2001, 203 p. NTIS number pending.
- 123 ROBSON , B. W. (editor). 2001. Fur seal investigations, 1999, 52 p. NTIS No. PB2002-100418.
- 122 SEASE, J. L., W. P. TAYLOR, T. R. LOUGHIN, and K. W. PITCHER. 2001. Aerial and land-based surveys of Steller sea lions (*Eumetopias jubatus*) in Alaska, June and July 1999 and 2000, 52 p. NTIS No. PB2001-107277.
- 121 BRITT, L. L., and M. H. MARTIN. 2001. Data report: 1999 Gulf of Alaska bottom trawl survey, 249 p. NTIS No. PB2001-105324
- 120 LAUTH, R. R. 2001. The 2000 Pacific west coast upper continental slope trawl survey of groundfish resources off Washington, Oregon, and California: Estimates of distribution, abundance, and length composition, 284 p. NTIS No. PB2001-105327.
- 119 FERRERO, R. C., HILL, D. P. DEMASTER, P. S. HILL, M. M. MUTO, and A. L. LOPEZ. 2000. Alaska marine mammal stock assessments, 2000, 191p. NTIS No. PB2001-102015.
- 118 WILSON, C. D., M. A. GUTTORMSEN, K. COOKE, M. W. SAUNDERS, and R. KIESER. 2000. Echo integration-trawl survey of Pacific hake, *Merluccius productus*, off the Pacific coast of the United States and Canada during July-August, 1998, 103 p. NTIS No. PB2000-108482.
- 117 ORR, J. W., M. A. BROWN, and D. C. BAKER. 2000. Guide to rockfishes (Scorpaenidae) of the genera *Sebastodes*, *Sebastolobus*, and *Adelosebastodes* of the northeast Pacific Ocean, second edition, 47 p. NTIS No. PB2001-100757.
- 116 WION, D. A., and R. A. MCCONNAUGHEY (editors). 2000. Mobile fishing gear effects on benthic habitats: A bibliography, 163 p. NTIS No. PB2000-108106.
- 115 LAUTH, R. R. 2000. The 1999 Pacific west coast upper continental slope trawl survey of groundfish resources off Washington, Oregon, and California: Estimates of distribution, abundance, and length composition, 287 p. NTIS No. PB2000-106004.
- 114 SHAW, F. R., M. E. WILKINS, K. L. WEINBERG, M. ZIMMERMANN, and R. R. LAUTH. 2000. The 1998 Pacific west coast bottom trawl survey of groundfish resources: Estimates of distribution, abundance, and length and age composition, 138 p. + Appendices. NTIS No. PB2000-105410.
