PROJECT APPROACH

Project Name and Location

LIDAR Data Acquisition within the Grand Canyon, AZ
Grand Canyon, AZ

Date of Data Acquisition**Pre-Flood:**

November 19, 2004

November 20, 2004

Post-Flood:

December 4, 2004

December 5, 2004

December 9, 2004

Dates of Data Processing

December 10, 2004 through February 18, 2005

General

Spectrum Mapping was tasked by the G&O/3Di joint venture to collect LIDAR data for 7 sites in the Grand Canyon. The sites were Paria, North Canyon, South Canyon, Eminence, Kwagunt, Palisades, and Palisades South. The total project area for the Grand Canyon was approximately 23 linear miles. This project area was flown pre-flood and post-flood. For the pre-flood acquisition the aircraft was equipped with the DATIS III system, including a 36 Khz Laser, an inertial measurement unit (IMU), and a dual frequency GPS receiver and antenna. The post-flood acquisition was conducted using Spectrum Mapping's RAMS system, including a 26 Khz Laser, an inertial measurement unit (IMU), and a dual frequency GPS receiver and antenna.

Project Area

Spectrum ensures that the geographic extent of the project area is collected using the correct mission profiles for the desired products. This is accomplished using TRACK'AIR, a digital mission-planning tool.

Mission planning consists of several steps that ensure proper flight preparation. First and foremost the project boundary for the site is acquired from our customer and imported into our flight planning software. Following this, available information such as elevation data, vegetation coverage and cultural feature extents are reviewed and general assessments are made by our Photogrammetrists to determine proper LIDAR system settings such as FOV (field of view). All LIDAR flight lines are flown with a minimum of 30% side overlap. The Grand Canyon project was flown to have 4x the coverage of typical flights. The contracted effective LIDAR spot data density is to be .56 square meters / sample. Each project area was flown a total of four (4) times, twice during pre-flood conditions and twice during post flood conditions.

Having set the previous parameters, the flight plan is prepared in digital form using our proprietary software. The existing elevation data is then imported and queried to calculate the flight altitudes for each flight line. Once flight planning is complete, waypoints in latitude/longitude and ellipsoid height are output to our flight management system.

GPS differential correction is required for our process. GPS planning software is used to predict PDOP (positional dilution of precision ... i.e. GPS quality) greater than 3.0. Should this

condition occur, laser data acquisition is suspended until the satellite geometry improves. Spectrum's base stations are full wave, dual frequency, GPS receivers that record data at a rate of 1 second. All base station data is recorded to 1GB flash memory cards for immediate use after the mission.

Acquisition Systems

Spectrum Mapping employs a DATIS III and a RAMS LIDAR system. Flight data was logged digitally to a 150Gb removable hard drive array on board the aircraft. GPS base station data was logged to flash memory cards. This allowed for rapid file transfer since tape systems have been eliminated from the process. Drives were downloaded daily, processed, and archived immediately following collection, yielding basic laser data within hours of data collection. Field checks of the data were performed each day to ensure complete coverage of the area flown that day for the laser data.

Data Acquisition

Our flight crew, comprised of a pilot and a system operator, mobilized to the project site ferrying all equipment and digital information required. Recovery of GPS base stations and coordination with the project ground control team were completed to identify correct base station and calibration site information.

A total of 7 base stations were used to collect GPS 1- second epoch data. Spectrum coordinated with the Grand Canyon Research and Monitoring Center for base station data collection

The flight crew was guided by a GPS controlled flight management system, which displays the flight plan; including altitude, heading, cross track deviation and PDOP. The system operator monitors flight management data in addition to laser information. During flight the crew monitors all functions in system operation and guidance ensuring a successful mission.

Ground Survey

Spectrum utilized airborne GPS methods for the production of this project. The GCMRC provided survey control support as required and vertical checkpoint surveys as needed for quality control.

GPS/IMU Processing

Position and orientation data must be processed first in order to resolve laser data, and verify flight coverage. All aircraft trajectory and exterior orientation parameters for imagery are generated during this process. Both horizontal and vertical project coordinate computations are accomplished at this stage. This processing takes approximately two times the actual flight time of the mission.

Raw Laser Data Processing

Laser data is then processed to resolve the range finder, scan angle, and position and orientation system data, using Spectrum's post-processor software. All returns are sorted to best reflect the vegetated and bare earth surfaces. Data are transformed from raw binary format to an LAS file format for filtering and custom projection. The most current NGS models are an integral part of the post-processing software, with custom projection options available.

Laser data are thinned for quick projection of swath coverage. Spectrum's LIDIMAGE™ software is also used at this stage for a rudimentary test of the data validity. LIDIMAGE™ is a fast-generating bitmap utility for rapid viewing of the DEM data. Any seams, holes, or other unwanted artifacts could be quickly identified for potential re-flight areas.

Anomaly Data Filtering

The LIDAR system collects elevation and position information from all reflective surfaces. The task is to identify and remove those features that would be defined as an anomaly (high or low points).

Spectrum houses all laser points in a database LAS (format) that retains information about flight day and time, return number, laser scan angle, and other proprietary information. This data is displayed and manipulated using our proprietary tools and software. The database is reviewed and areas of like characteristics are delineated and flagged. A laser processing group, will determine which type of filtering technique(s) need to be applied to each type of area. Factors that affect this decision are slope, vegetation and cultural features. Each project has unique characteristics that can only be assessed after the data is collected. The data is flagged in the LAS format and as part of the QC process, reviewed to ensure correct depiction.

Data voids may occur from several different causes, including the following:

Natural

- LIDAR pulses may be naturally absorbed by water bodies or areas recently covered with asphalt. Such voids are normally considered to be unavoidable.

Operational

- The LIDAR system may have malfunctioned for some reason.
- Heavy winds, flight navigation system (FNS) error or pilot error may have caused "holidays" between flight lines.

Procedural

- Data points may be un-intentionally removed as part of the bare-earth post-processing to delete points that impinged on the tops of manmade structures or failed to penetrate dense vegetation. This process was not used in the filtering of the LIDAR anomalies for the Grand Canyon project.

Data voids caused by removal of LIDAR data points on manmade structures are acceptable.

As part of the field QC process, data voids caused operational constraints are re-collected if required. No data voids were identified in this project.

Quality Assurance

A rigorous quality assurance program insures that the final data products meet all requirements prior to delivery to the customer. Quality Assurance / Quality Control is embedded into the overall data acquisition and processing steps we use. Quality assurance is inherent in developing the project plan, acquisition, verifying data and processing, and assuring that the final products meet all requirements in accordance with the contract. Spectrum Mapping's quality assurance procedures follow the "FEMA Guidelines and Specifications for Flood Hazard Mapping Partners, Appendix A: Guidance for Aerial Mapping and Surveying" for use of LIDAR mapping technology.

4/25/2005

DATA PROCESSING PROCEDURES

Data Processing Procedures

Data was delivered to Spectrum Mapping's Albuquerque office from the field on external hard drives. The data is cataloged and copied onto the processing computer disk drives. The data is then re-verified for coverage and quality. The data is then ready for calibration. Once the data is calibrated it is sent to the processing department for post processing. The first step in the LIDAR data processing is to produce the x, y, and z laser returns using Spectrum's proprietary LIDAR data processing software. The next step in the laser data processing is to combine the flight lines in a merge process that eliminates any redundant points. For the Grand Canyon project the LIDAR flight lines were not merged. The individual flight lines were cropped to correspond to the project area boundaries. Noise or anomalous returns are filtered from all data during this processing step.

The next step in the post-processing of the DEM data is to perform the ellipsoid to orthometric height conversion using the National Geodetic Survey (NGS) Geoid Model, GEOID03. All elevation data was processed in this way on a point-by-point basis. Datum and coordinate system conversion from WGS84 to NAD83, was undertaken by using the NADCOM standard algorithm. The data is then brought into ArcGIS 8.2 and converted into a hillshade. This allows for better quality control.

The final step was to assemble the DEMs into the correct specified delivery format. Data was delivered in ellipsoid and orthometric heights. The coordinate system is State Plane, Arizona Zone 202. Horizontal reference is NAD83. Vertical control reference datum is NAVD88. Units of measurement are in meters. All the variably-spaced x, y, z DEM points data were converted to ASCII comma delimited point files.

Deliverable DEM Data

Data Deliverables:

First Return
First Return Intensity
Last Return
Multi Return
Metadata

Data Format:

First Return, Variably spaced DEM data, comma delimited ASCII point files
Last Return, Variably spaced DEM data, comma delimited ASCII point files
First Return Intensity, Variably spaced DEM data, comma delimited ASCII point files
Multi Return, Variably spaced DEM data, comma delimited ASCII point files
Metadata – FGDC compliant xml files and project report in MSWord .doc

Map Coordinate System and Datum:

Arizona State Plane, Zone 202, NAD83, NAVD88
Ellipsoid (WGS-84) and Orthometric heights were delivered.

GEOID Used:

Geoid 03

4/25/2005

PROJECT SUMMARY

Project Summary

Spectrum Mapping collected approximately 23 linear miles of data for the Grand Canyon project area. This data was collected in two separate acquisitions. Pre-flood acquisition took place on November 19, 2004 and November 20, 2004. Post-flood acquisition took place on December 4, 5 and December 9, 2004.

There were no problems encountered during the pre-flood acquisition. The seven sites were collected with 4X coverage. During the post-flood acquisition, the DATIS III sensor had an issue with the scanning mirror motor and was not able to finish collection. Spectrum sent out a different sensor RAMS (Leica ALS40) to finish the post collection. This sensor did not have the intensity module the DATIS III sensor included, due to this inconsistency Spectrum agreed to provide Multi-return data. This data was collected on December 4th, 5th. When the data was removed from the hard drive there was an error reading the data off of the device. This caused a few areas to have very small gaps. This data was recollected on December 9th. Spectrum communicated with the Grand Canyon staff to make sure the site acquisitions were acquired at the lowest flow possible. The post flood acquisition was collected to have 4X the coverage using the RAMS system.

There were no problems encountered during the processing of the data.

The data meets contract specifications for vertical accuracy of 15 cm. The DEM accuracy for the pre flood collections was 13 cm RMSE and the post flood collections was 10.3 cm RMSE.

4/25/2005

LIDAR SYSTEM DATA REPORT

General System Acquisition Parameters

DATIS III System Specifications for Grand Canyon Project

Operational Parameter	Quantity	Units
Minimum height difference for distinguishing multiple returns	0.75	Meters
Spot Size	0.46	Meters
Swath Width	844	Meters
Flight Line Spacing	200	Meters
Altitude (Above Ground Level)	1828	Meters
Ground Speed	110	Knots
Scan Half Angle	13	Degrees
Scan Interval	0.035	Seconds
Active Scan	0.023	Seconds
Duty Cycle	66	%
Firing Rate	36500	Hertz
LIDAR Samples Per Scan	840	
Cross-Track LIDAR Spot Spacing	1.01	Meters
In-Track LIDAR Spot Spacing	2.16	Meters
LIDAR Spot Density in a Single Pass	1.99	Square meters / sample
Flight Line Coverage	4X	
Effective LIDAR Spot Data Density	0.56	Square meters / sample

RAMS™ System Specifications

Laser	
Laser Altitude	10,000 feet AGL Max
Laser Swath Width	7,250 feet Max
Laser Scan FOV	45 Degrees Max
Scan Rate	0-35 Hz (FOV dependent)
Laser Pulse Rate	100Hz-15kHz Max
Laser Returns	5 at 15kHz
Cross Track Spacing	0-25 feet
Along Track Spacing	3 feet minimum (Airspeed dependent)
Nominal X/Y Ground Sample Distance	10 feet
X, Y, Z Positional Accuracy	less than 1 foot RMSE absolute

Accuracy of the Topographic Surface Products

The control points below were supplied by GCMRS.

Pre Flood RMSE

FLIGHT REPORT

Mission Logs

The Mission logs document the individual mission's date, time, flight altitude, airspeed, laser settings, and any pertinent notes taken while the flight was occurring.

SYSTEM CALIBRATION REPORT

System Calibration

The Spectrum RAMS LIDAR system uses multiple layers of system calibration. The initial instrument calibration is accomplished during the system fabrication. All critical components (IMU, LIDAR, Camera, and Scanner) are optically aligned to a common optical bench using NIST traceable optical collimators and optical flats. This alignment is initially carried out to 2 arc seconds. In addition to the optical bench calibration, the LIDAR system is operated against a series of known targets to determine both scale factor and bias accuracy. All system timing is derived from GPS.

On any aircraft installation the critical factor is location of the GPS antenna and IMU positioning with respect to the RAMS optical reference. This is accomplished through a differential GPS survey. After installation in the aircraft, the system is then flown against a ground test range that was developed using high accuracy GPS points from a licensed surveyor. This range provides several hundred points that are used to statistically verify the in flight calibration.

One of the benefits of a LIDAR system is that the calibration of the system is verified each time two or more flight lines are combined. This is a result of taking measurements on a common point from multiple locations (i.e. the ground point is fixed and each flight line that sees this is a different instrument location). When multiple flight lines can be combined with no artifacts then the calibration of the system is validated in terms of range and angular accuracies. Our standard practice requires that at least one flight line within the project be flown in both directions for calibration verification of range and angular accuracy.

Another important area of quality control is edge matching. All edge matching discrepancies in LIDAR DEM data occur between two flight lines. Identification of edge matching discrepancies is performed by overlaying either the contour or the shaded relief model representation of the original DEM. If edge artifacts are found in the overlap area between two flight lines then this represents an edge discrepancy. The GPS / IMU data is then reevaluated to check for any possible errors in the post processing or a spike in the PDOP at the time of data acquisition. Usually this type of problem is resolved by reprocessing the GPS / IMU.

For accuracy verification, static survey points are collected, using static benchmarks where available. These survey points within the project boundary are selected to allow a statistical absolute elevation verification of the data. This data set is then statistically compared to the project LIDAR DEM data after the combination of flight lines to verify accuracy both horizontal and vertical. The RMSE (Root Mean Square Error) of the LIDAR DEM will be calculated using the ground GPS data to ensure that the vertical error is less than 0.15 m and the horizontal is less than 0.5 m.

GPS / Calibration Processing Summary

All GPS phase data was post-processed with continuous kinematic survey techniques using “On the Fly” (OTF) integer ambiguity resolution. The GPS data was processed with forward and reverse processing algorithms. The results from each process were combined to yield a single fixed integer phase differential solution of the aircraft trajectory. Plots of altitude and the forward and reverse GPS solution residuals (RMS and DOP) are attached for each day of flight. Spikes in the vertical component of these plots occur in turns and ferrying to and from collection sites, and do not affect the integrity of the solution. The RMS separation values (25%-75% weighting) for all flights are summarized below.

The Processing Summary provides statistics about the final solution. The processing summary includes details such as solution type, baseline distances, number of epochs in total, epochs not processed, and epochs with bad C/A code and L1 phase measurements.

Statistics such as RMS values of the C/A code, L1 phase, L1 Doppler measurements, quality number percentages, estimated position standard deviations calculated from the Kalman filtering, and percentages of epochs having double difference DOPs over 10, provide a quick, convenient method of assessing processed solutions. The forward/reverse separation RMS values for Easting (E), Northing(N), and Heighting (H) are listed, and the forward/reverse separation RMS values of E,N, and H for 25%-75% weighting.

The latter RMS values take into account the weighting of the forward/reverse combined solution only in the region of 25%-75% where the float solution has had time to converge to a lower value of error since the larger error values occur at the beginning of the processing direction. The same can be said for a Kinematic Ambiguity Resolution (KAR) fixed solution as well. The RMS values for the 25%-75% weighting of the combined solution are generally lower than the RMS values from the forward/reverse separation because if one solution has high error values, most of the weighting will go to the other processing direction.

The following is checked in the Processing Summary:

The forward/reverse separation RMS values of E,N, and H are generally low if a fixed integer solution has been obtained. The values should be less than 0.05 meters, but no greater than 0.10 meters.

The Quality Number Percentages should almost all be Quality 1. This number is typically close to 100%, with 1% in Quality 2 for a fixed integer solution.

PDOP

The DOP values are measures of satellite geometry, which changes with time due to satellite motion. PDOP values of less than 3 are considered excellent, which combines the HDOP and VDOP. The user should watch for spikes in this plot, as it could signify sudden changes in the satellite constellation (for example, if several satellites are obstructed temporarily the DOP values should suddenly increase).

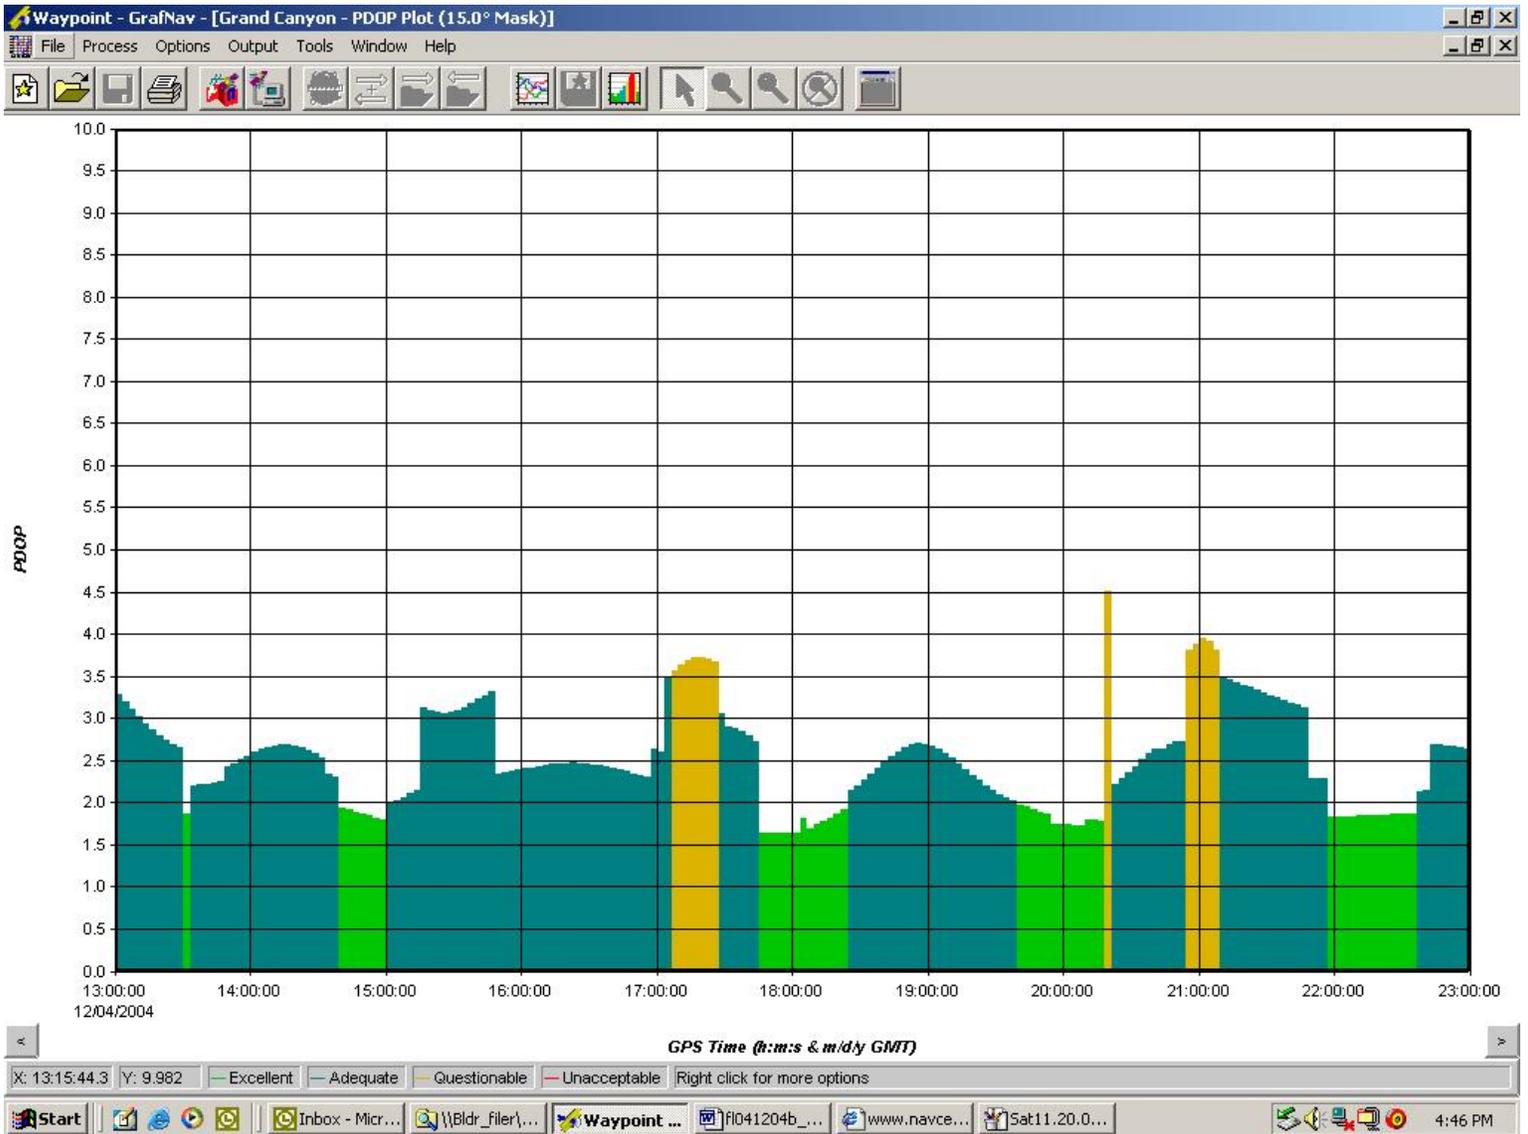

November 19, 2004 Mission a and b

December 4, 2004 Mission a and b

December 5, 2004

December 9, 2004 missions a and b

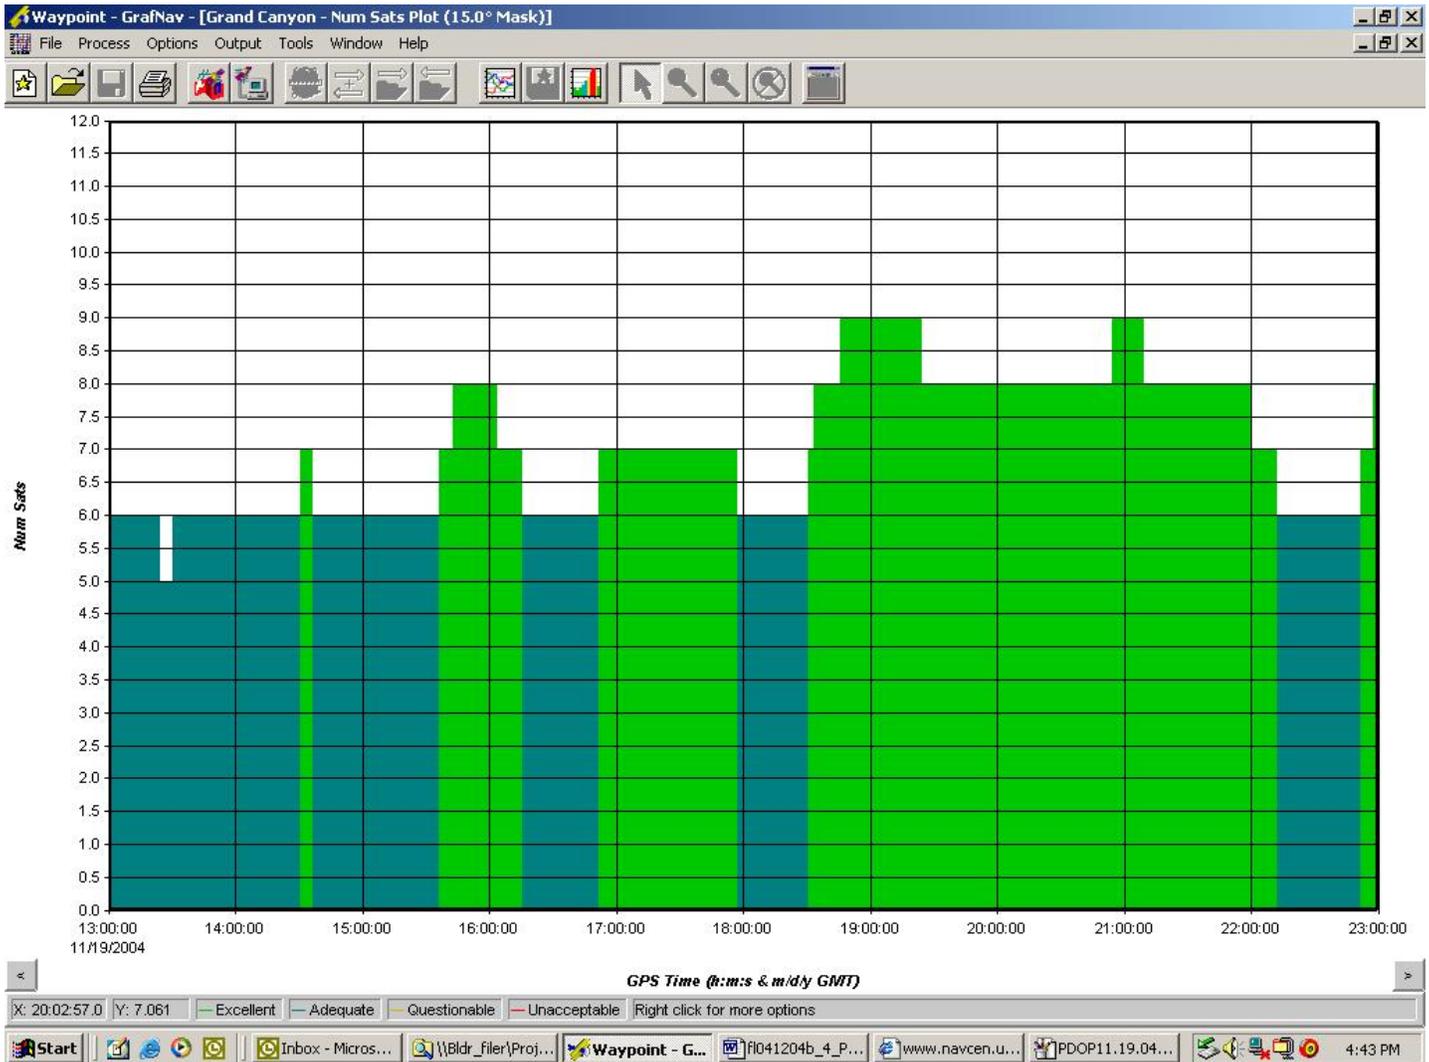

Satellite Lock

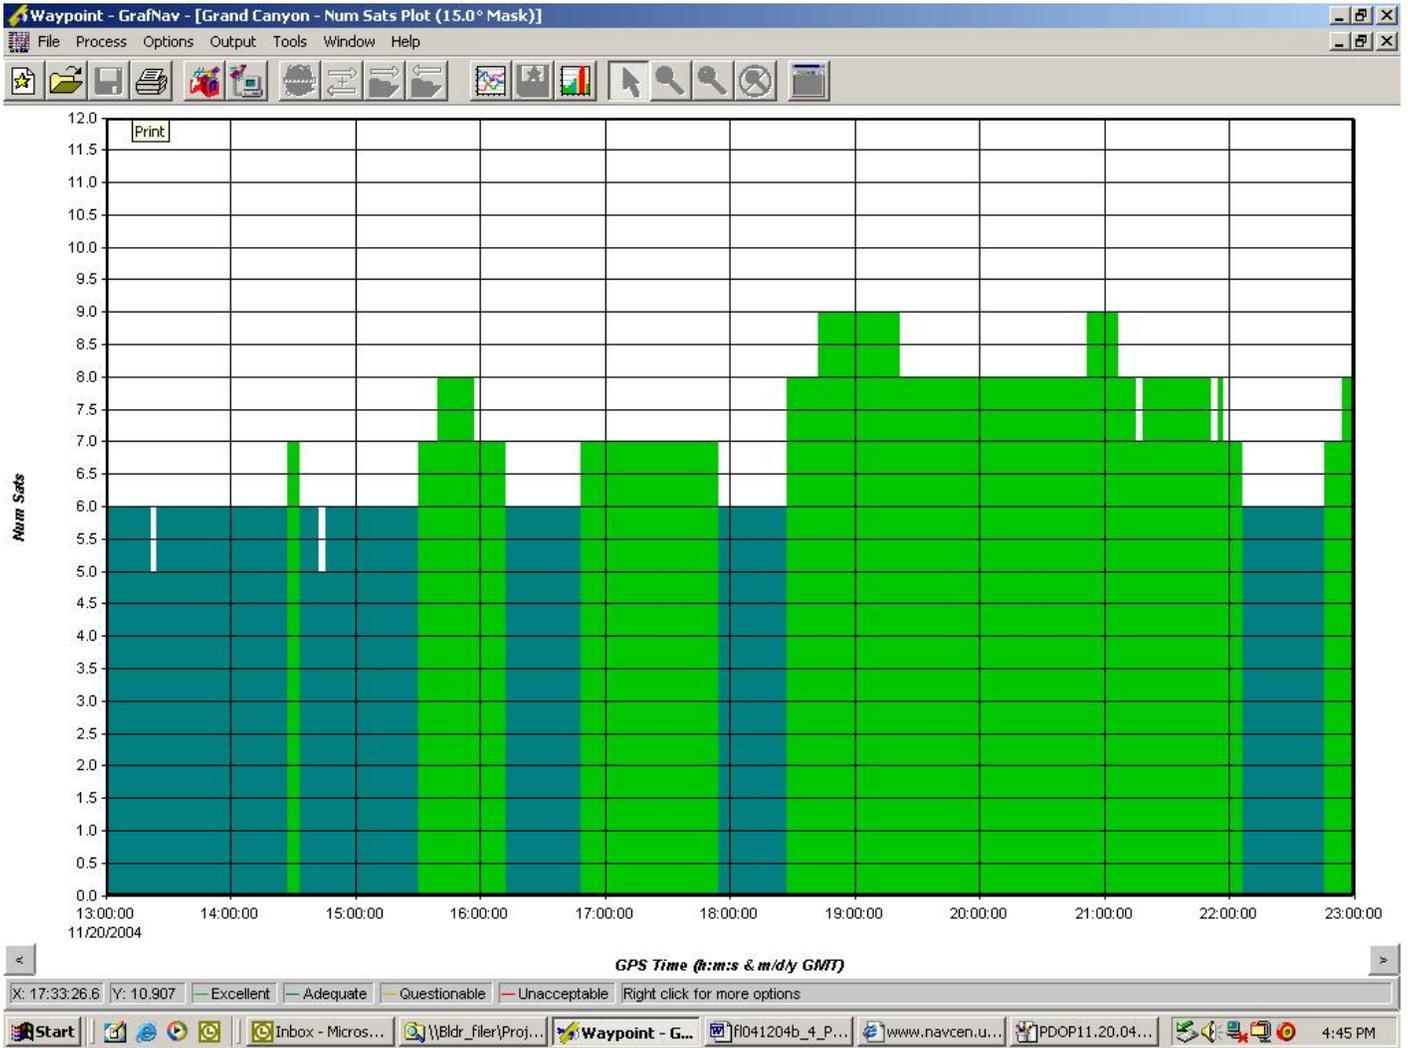

Plotting the number of satellites tracked during the survey is a good way to determine where data gaps occur due to total loss of lock. It also serves to identify areas of the survey that may

not be as accurately or reliably determined as others. For example, KAR requires a minimum of five satellites to engage; therefore you know those periods of less than five satellites may not have an integer fixed solution.

APPENDIX B – PREVIOUS PROJECT REPORTS

Previous Project Reports

Airborne LiDAR Data Acquisition – Grand Canyon, Arizona

Contract number: DACW43-03-D-0509

Task Order Number: 0005

Report #1: November 2004 – January 2005

Submitted to:

Mr. Kurt Allen

PhotoScience

9001 Edmonston road, Suite G100

Greenbelt, MD 20770

301.345.4488

Project tasks completed in November 2004

Grand Canyon Data Acquisition – Pre Flood

- Pre flood acquisition of all 6 LTMS. Data was collected to have 4x point density.
- Flights occurred on November 19th and 20th with the DATIS III sensor.
- Data has gone through initial GPS/IMU post processing to ensure coverage.
- Currently confirming data collect with project control.

Project tasks completed in December 2004

Grand Canyon Data Acquisition - Post Flood

- Post flood acquisition of all 6 LTMS. Data was collected to have 4x the point density.
- Full coverage for all sites with ALS40 (RAMS) sensor.
- Data collected on December 4th and 9th.
- Data has gone through initial GPS/IMU post processing to ensure coverage

Project tasks completed in January 2005

Grand Canyon Data Processing

- Post flood acquisition has been processed with all base station data, QC'd, and calibrated.
- Post flood data has been processed to remove anomalies.
- Pre flood acquisition has been processed with all base station data, QC'd and calibrated.

Problems encountered to date

Acquisition

- The project had a very tight collection window. Pre flood data needed to be collected November 17th through the 20th and post flood collections were to take place November 27th through the 30th.
- Pre flood data was acquired using the DATIS III sensor.
- Spectrum was onsite with the DATIS III sensor for post collect when there was a problem with the DATIS III sensor. Spectrum proposed to collect the project areas using the ALS40 sensor (RAMS). This was approved and system was mobilized to finish collection.
- Spectrum finished collection of the 7 reaches on December 4th.
- Spectrum had a hard drive issue when pulling data off of hard drive that was stored in aircraft. We had to recollect small areas where data was deleted from the hard drive.
- Data was recollected on December 9th. Sites 2, 5 and 7 were collected to coincide with the low flow (8,000 cfs) previously collected over Dec 4-5.

Project tasks remaining

- Confirmation of Pre-flood acquisition data. Currently validating with control.
- Processing of Pre-flood data.
- Metadata and report compilation.
- Tiling and naming of data.

Schedule

- Delivery of first and last return LIDAR data is anticipated to be complete by February 21, 2005
- Delivery of metadata and flight index maps is anticipated to be complete by February 28, 2005

Data to be delivered in Arizona State Plane, zone 202, NAD83, meters (ellipsoid and orthometric heights), Geoid03
