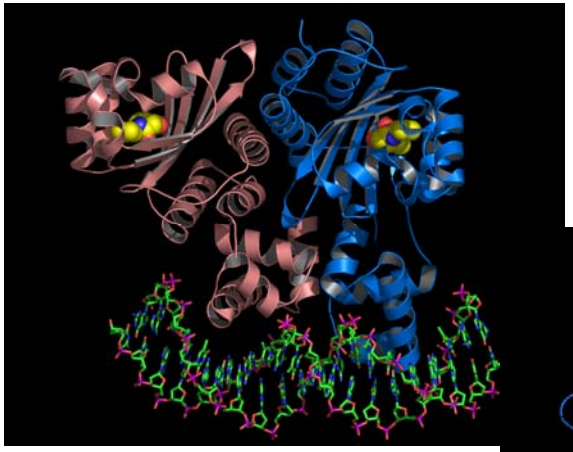
Structural Genomics
Exploring Protein Structure and Function

Andrzej Joachimiak

Structural Biology Center and
Midwest Center for Structural Genomics

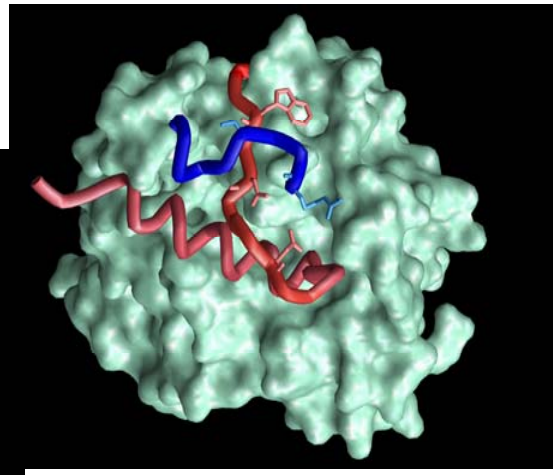
ORNL, July 12/13, 2005

The Protein World

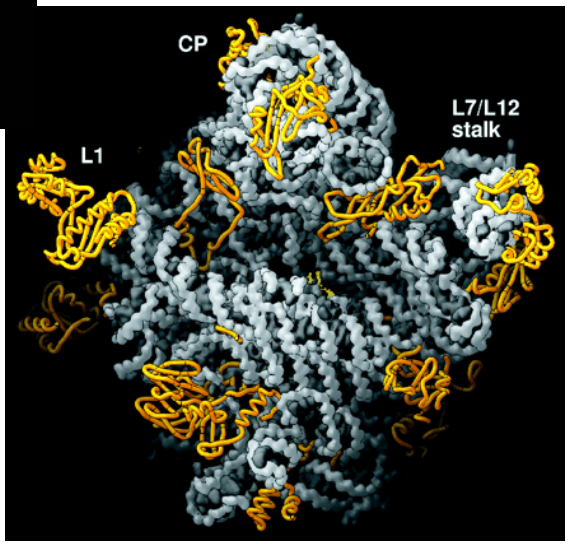


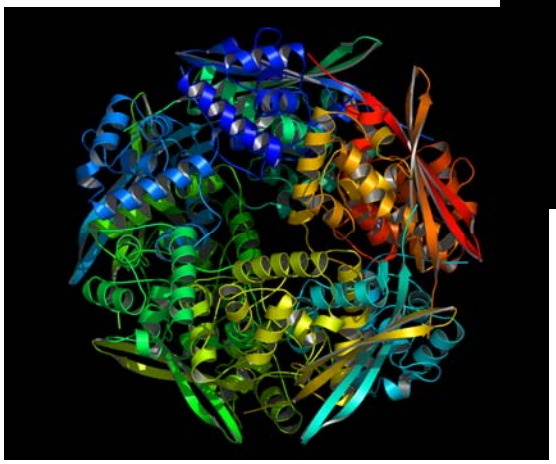
TraR, a pheromone-binding transcriptional factor

Protein with a knot

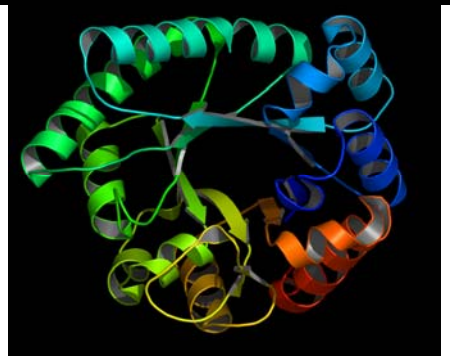


Ribosomal 50S subunit, multi-protein/RNA complex



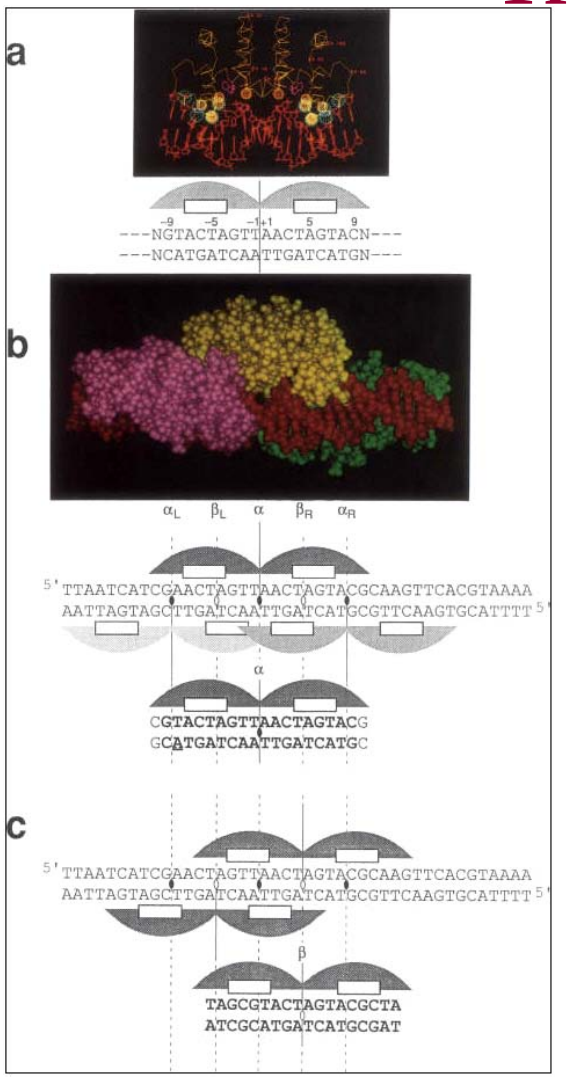


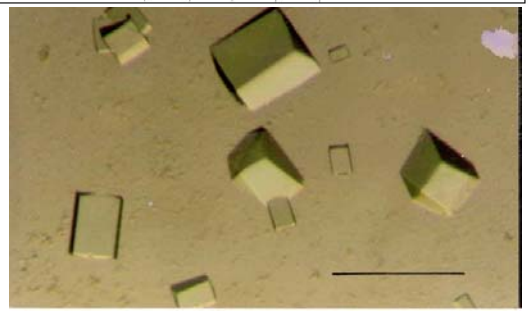
Cyanase, a homo-oligomeric enzyme

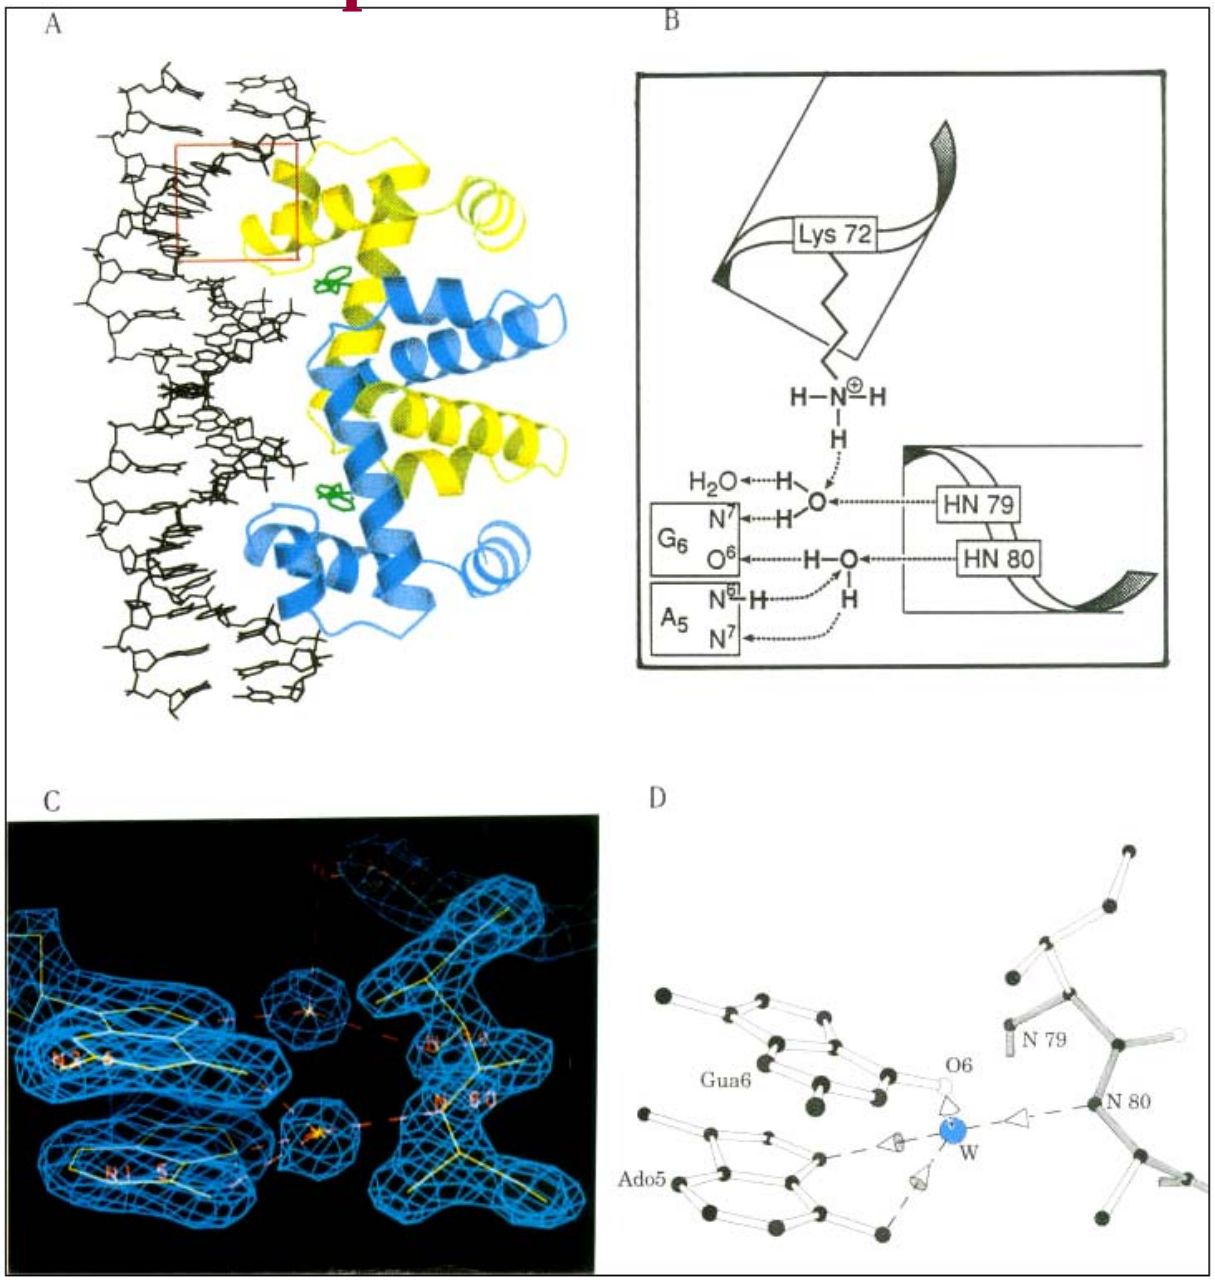


IolI, a monomeric enzyme

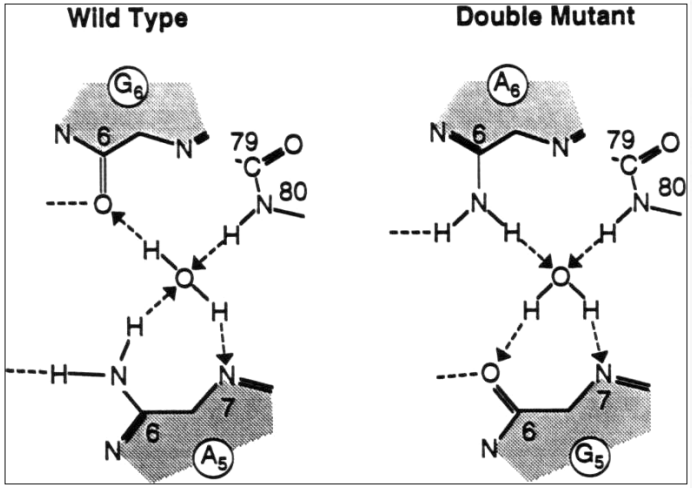
TrpR and its Complex with L-Trp and *trp* Operator DNA

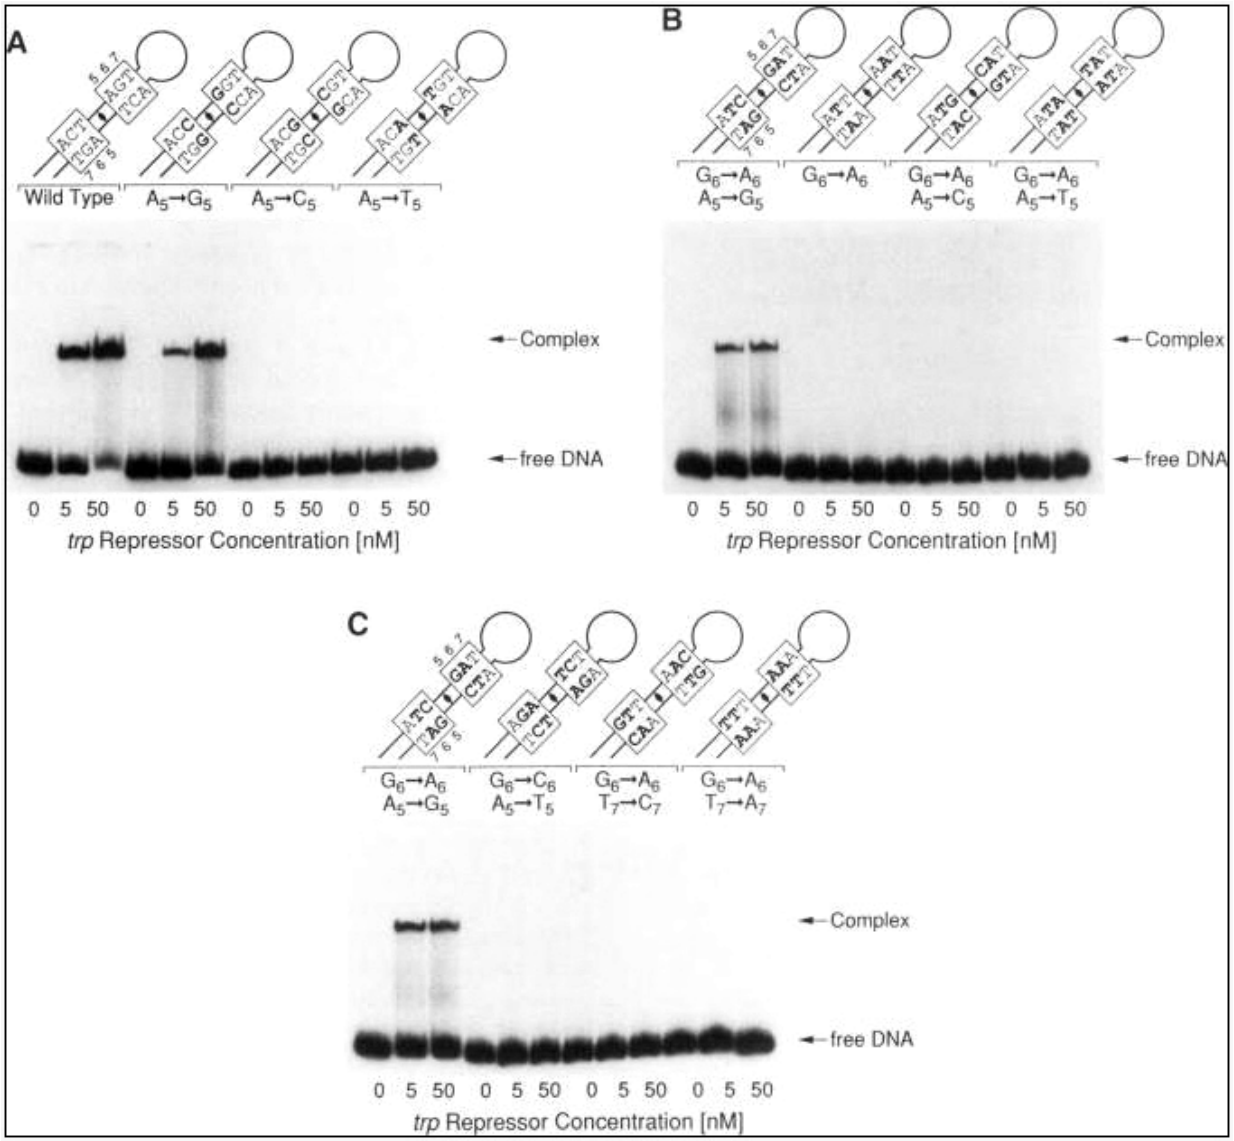




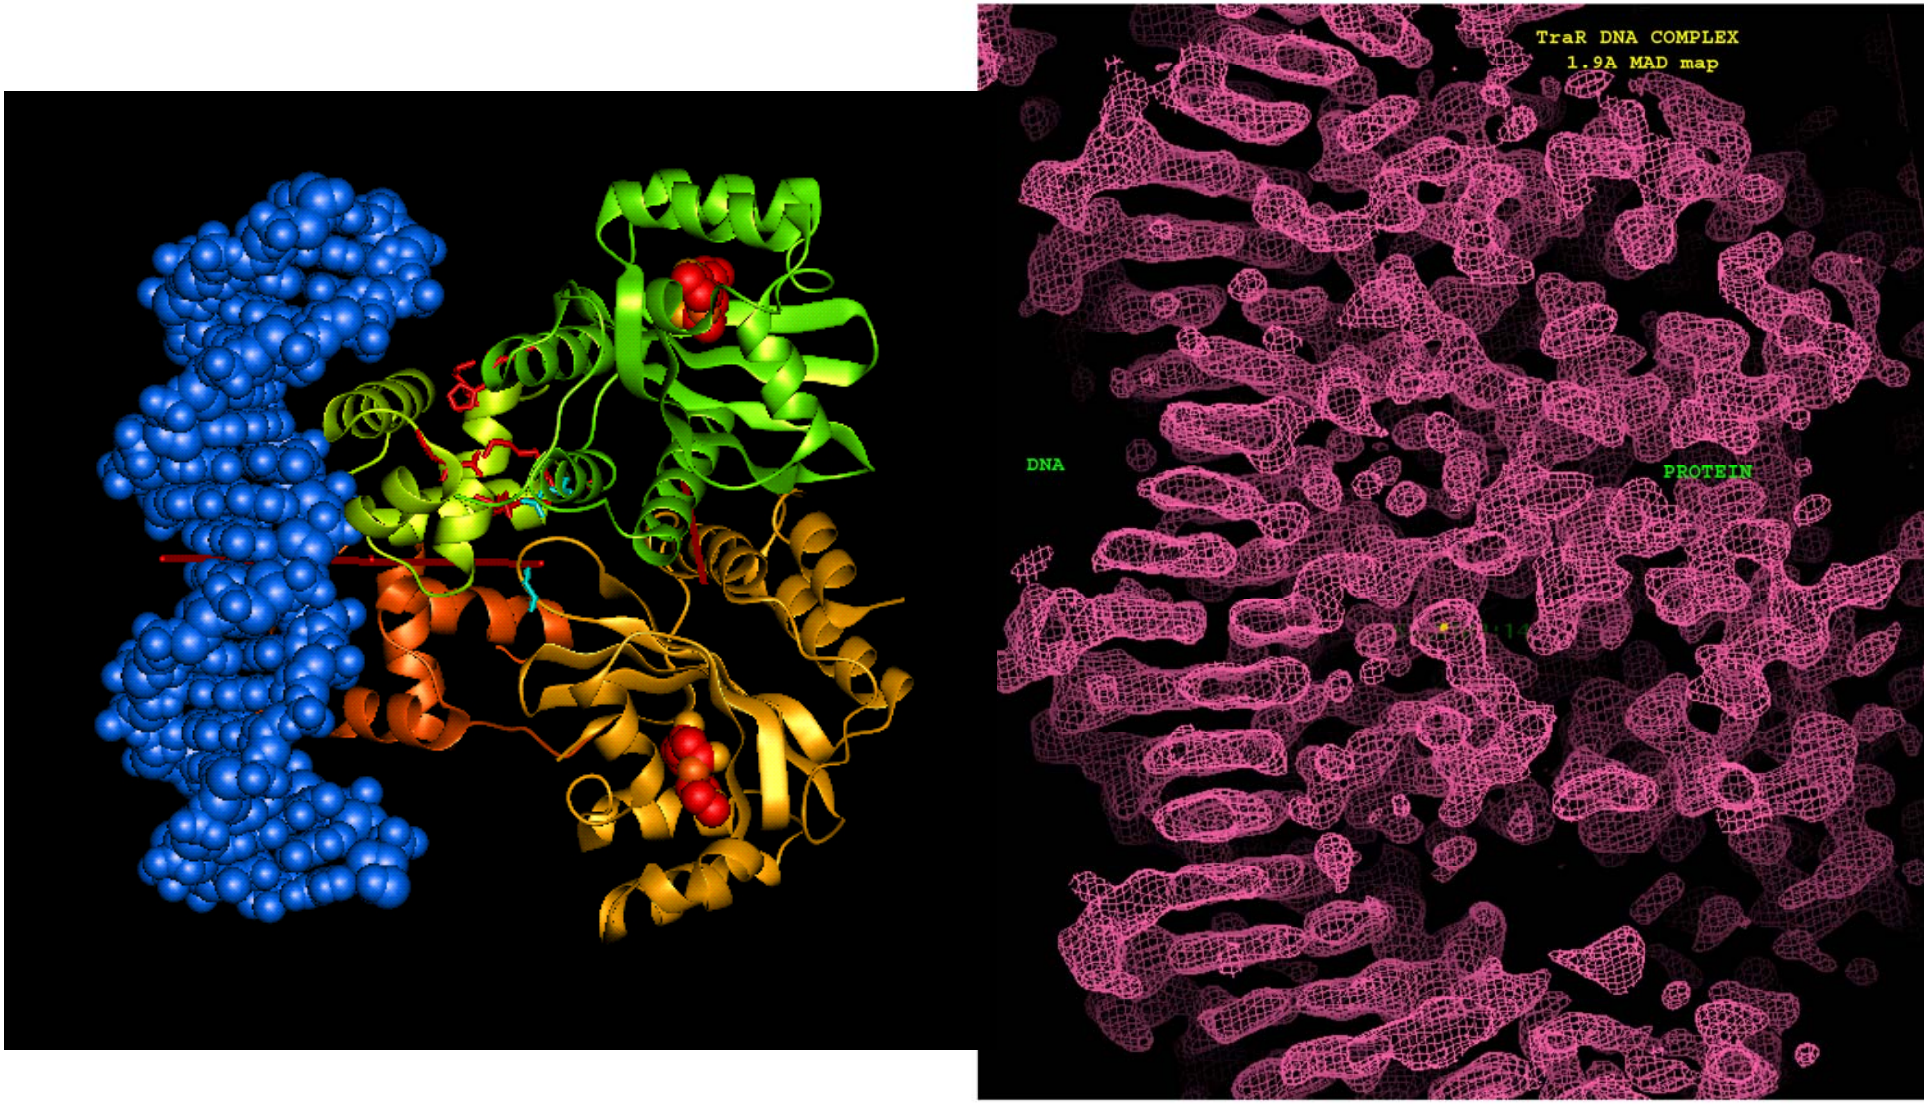


trp Operator Double Mutant Binds TrpR Specifically

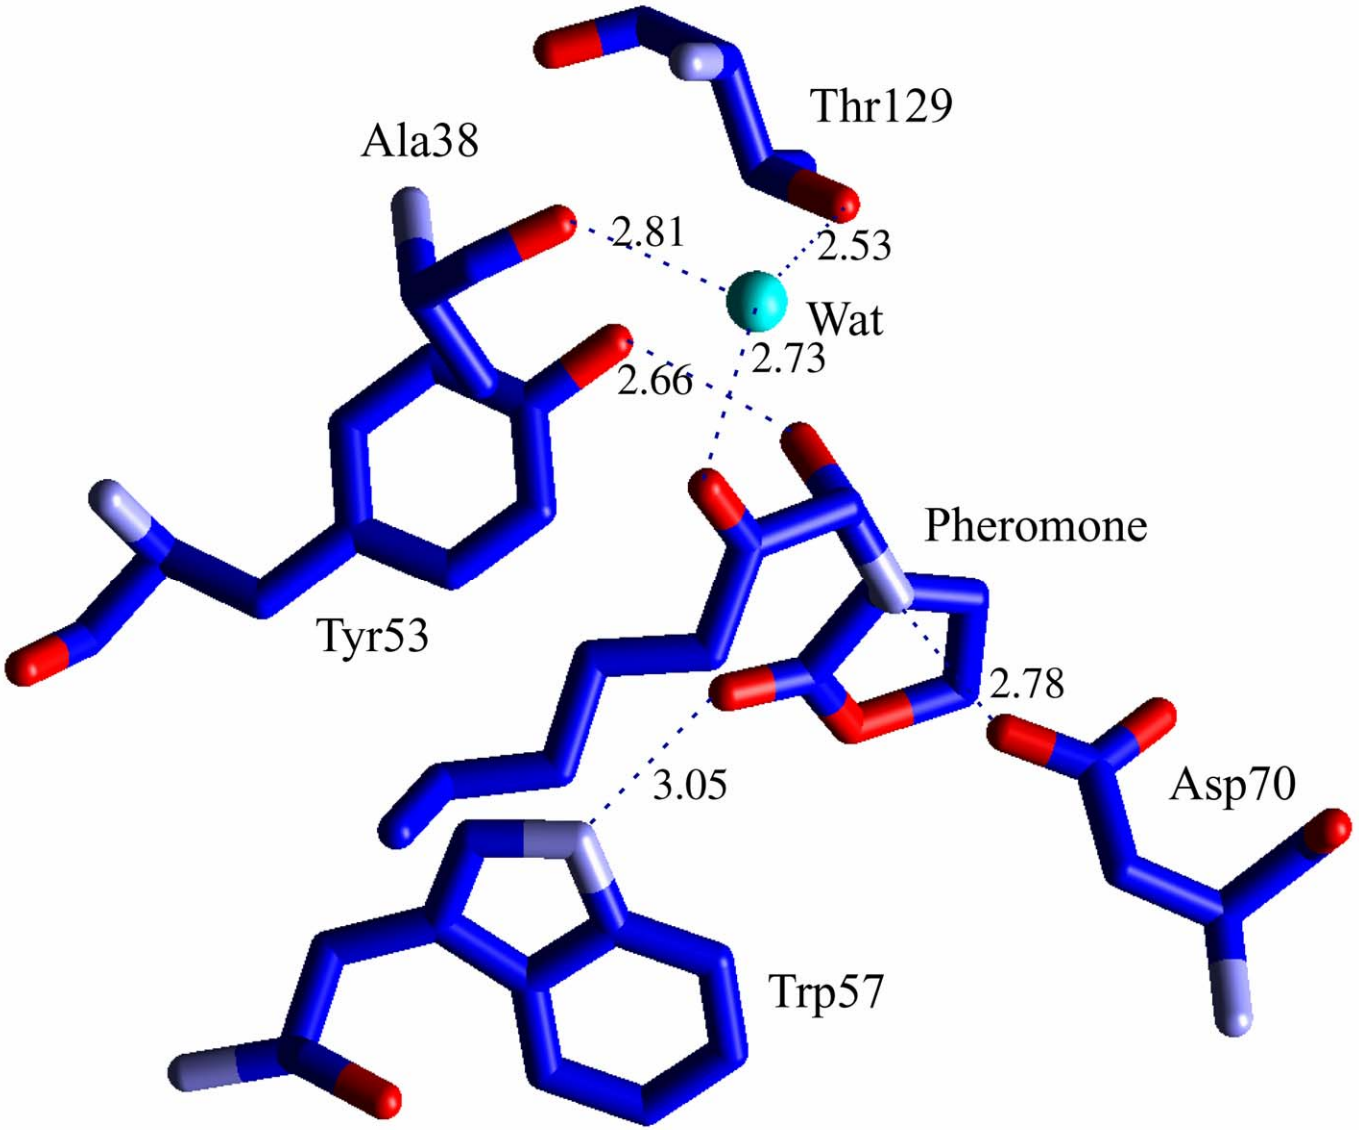




TraR/Pheromone/DNA Complex at 1.9 Å



Pheromone Binding Pocket – HSL is Fully Embedded within the Protein



Genomic Information is Being Accumulated Rapidly

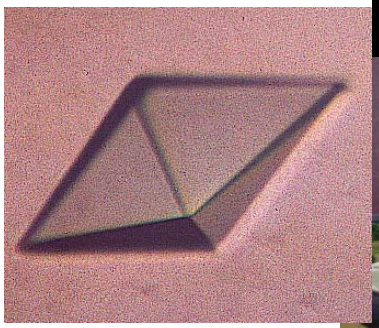
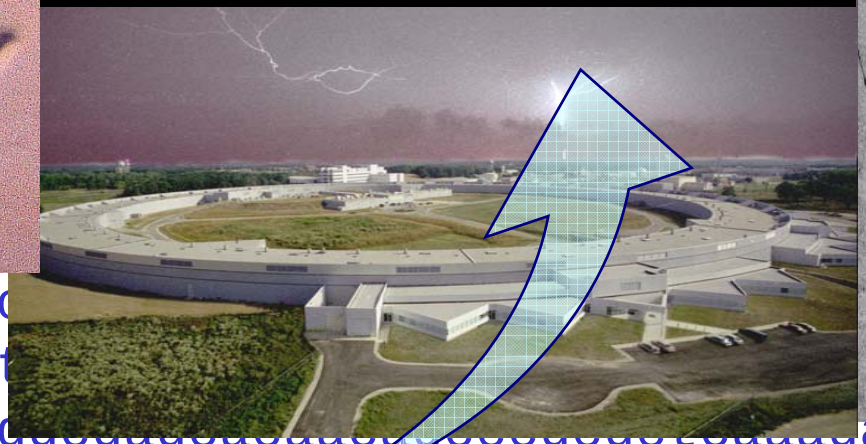
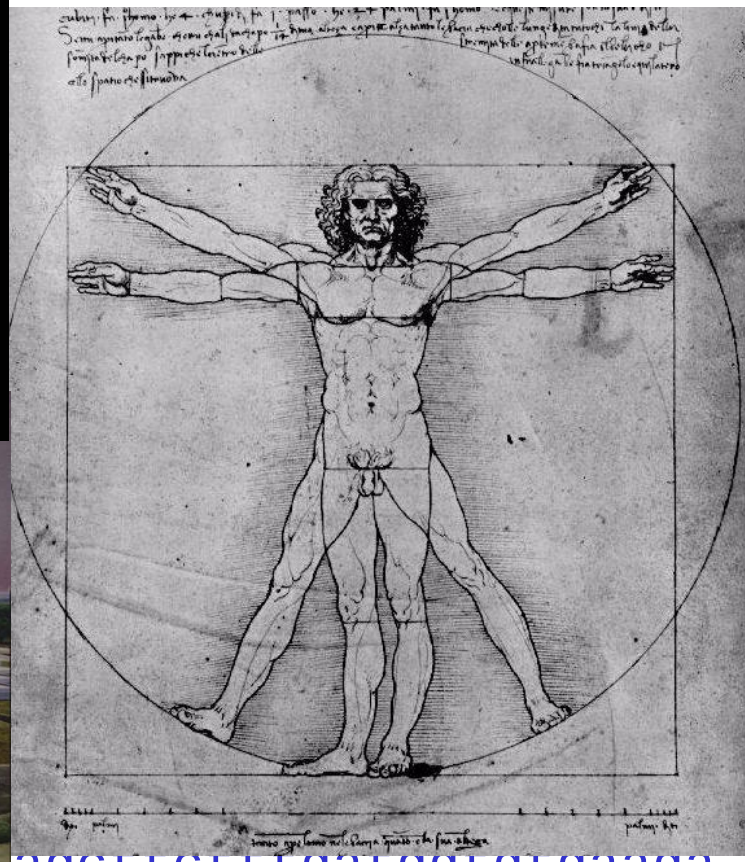
From Gene to Structure and Function







Structural Genomics and Protein Structure Initiative

- **Exploring Protein Folding Space**
  - **Experimental determination of novel proteins using X-ray crystallography or NMR**
  - **Computer homology modeling of protein structures using protein folds database**
- **Approach**
  - **Cluster protein sequences (ORFs) in all known genomes into homologous groups (superfamilies and families)**
  - **Determine structure of few members of each family**
  - **Computer model all other members of family**
- **Using this approach it is believed that we need to determine structures of 15,000 – 20,000 members of protein families to cover 90% of protein fold space**

Midwest Center for Structural Genomics

PSI Protein Structure Initiative

www.mcsg.anl.gov

W. Anderson, A. Edwards, D. Fremont, A. Joachimiak,
W. Minor, Z. Otwinowski, C. Orengo, J. Thornton,

How Many Targets Are There?

- **A novel protein family landscape protocol was developed at UCL by C. Orengo and allowed clustering of ORFs:**
  - **>1,000,000 sequences from 150 completed genomes.**
  - **These genes were clustered into >50,000 protein families.**
  - **There were >150,000 singleton sequences unique to specific organisms (10-15%/genome).**
  - **>14,500 genes in these genomes were labelled as 'priority 1' targets and share no detectable sequence similarity to a sequence of structure in the PDB.**
  - **6,190 Pfam families, 2,108 with homologue in PDB.**
  - **1,200 very large Pfam families with no structural homologue cover 70% of sequence space.**
- **Currently there are ~2,500,000 ORFs in public databases and ~27,000 protein structures (~4,300 nonredundant)**

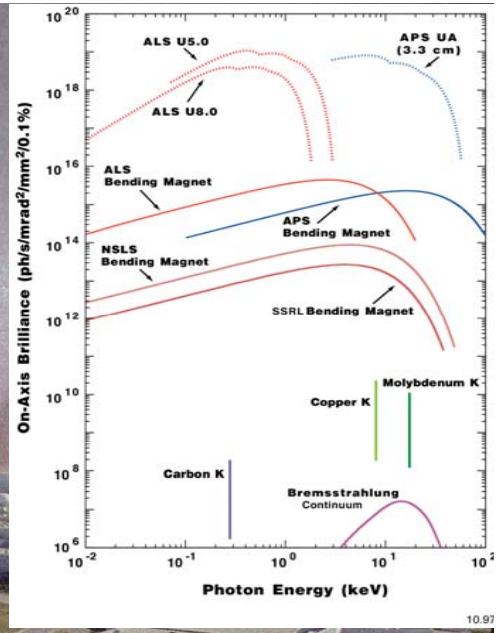
Third Generation Synchrotron Beamlines for Macromolecular Crystallography

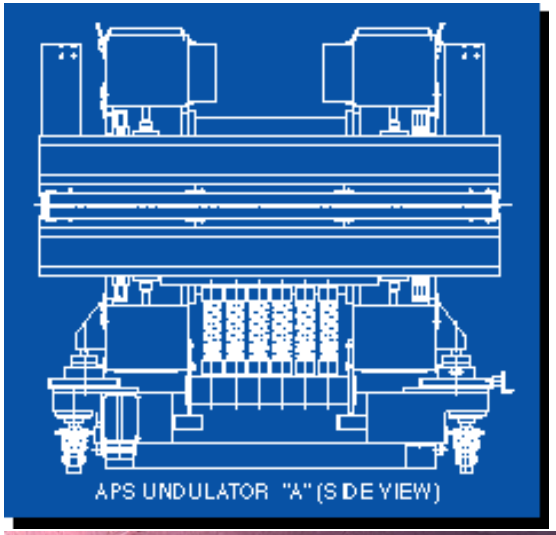
Advanced Photon Source:

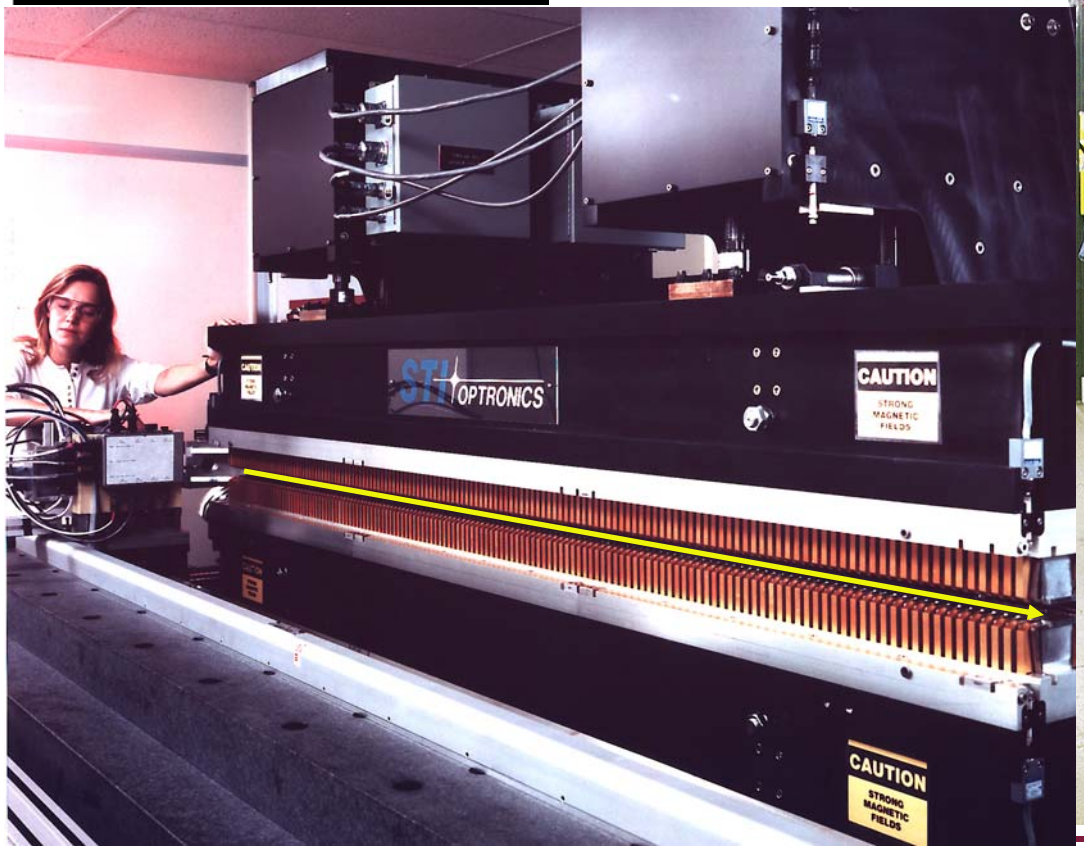
- Dedicated storage ring with enhanced spectral properties
- Intense, brilliant beams tailored to wide range of biological experiments
- Undulator source
- Anomalous diffraction
- Atomic resolution
- CCD area detectors
- Cryo-crystallography
- Advanced computing
- Optimized for speed and efficiency

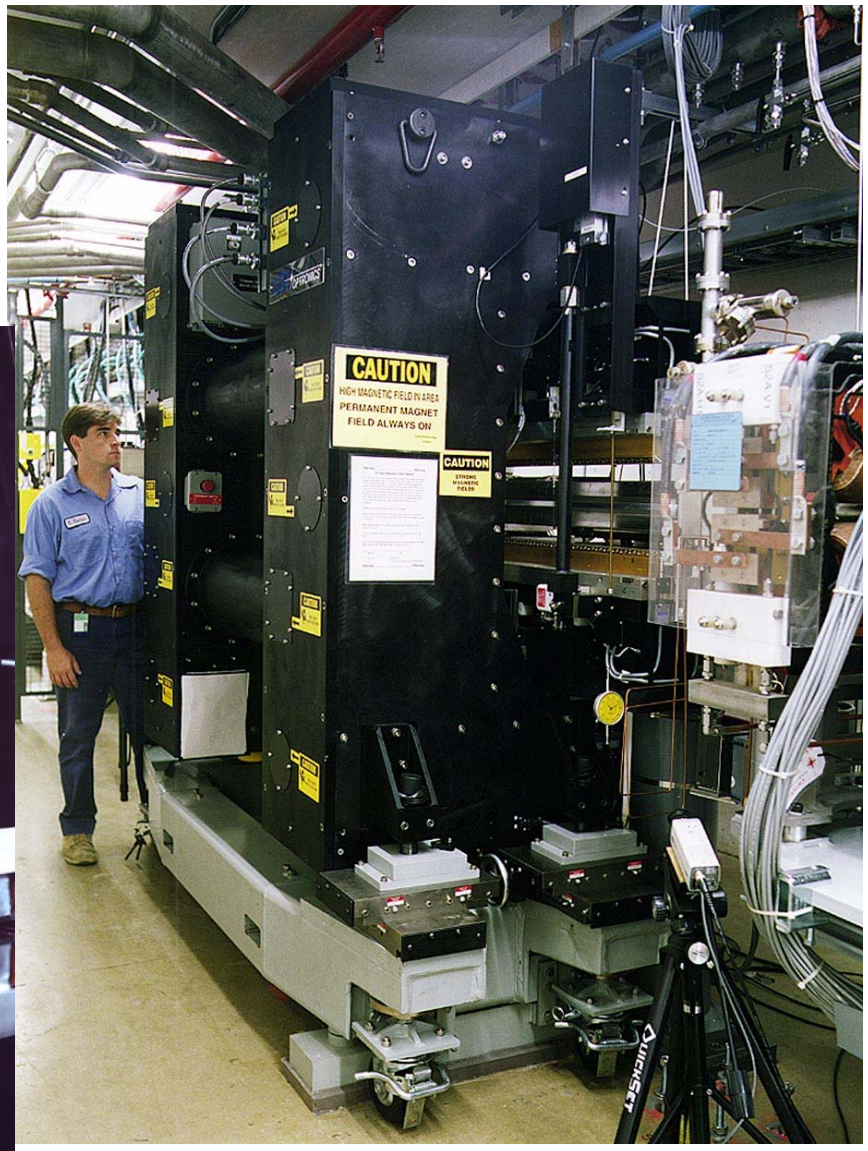


SBC

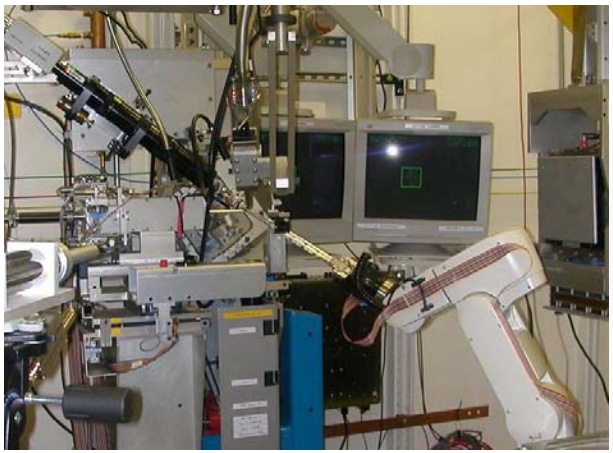
APS Undulator A



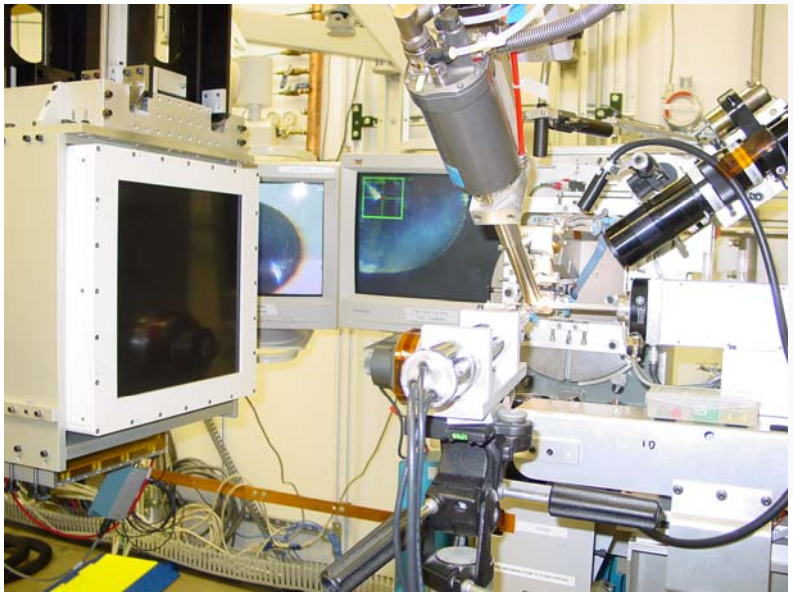


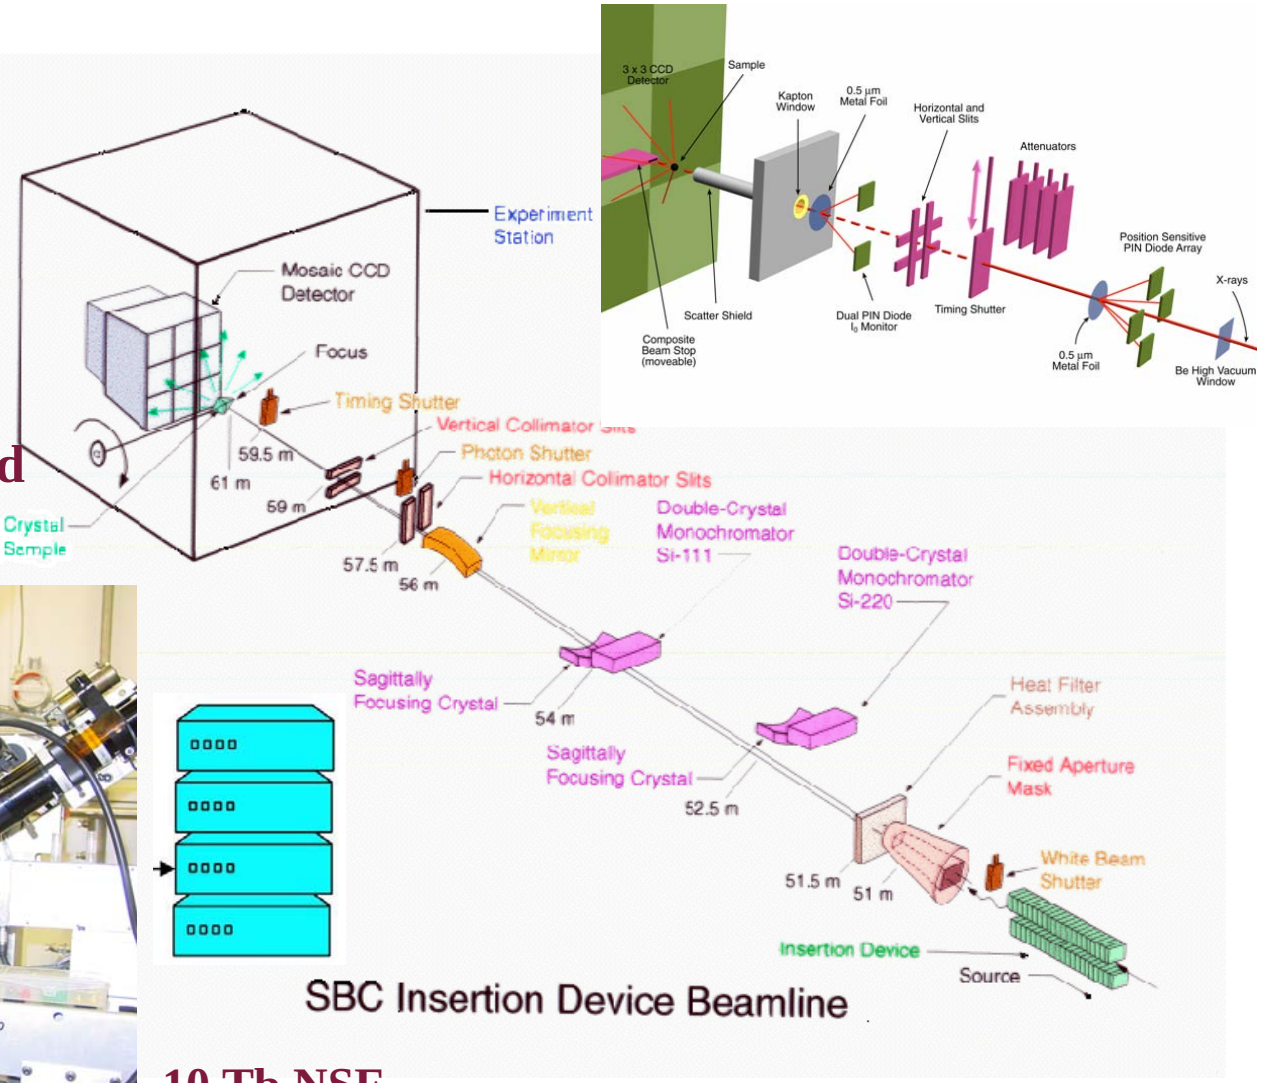


Dedicated X-ray Beamlines for Macromolecular Crystallography - SBC 19ID and 19BM Beamlines at the Advanced Photon Source – 851 PDB Deposits



Goniostat, Q315 detector and robot for crystal mounting



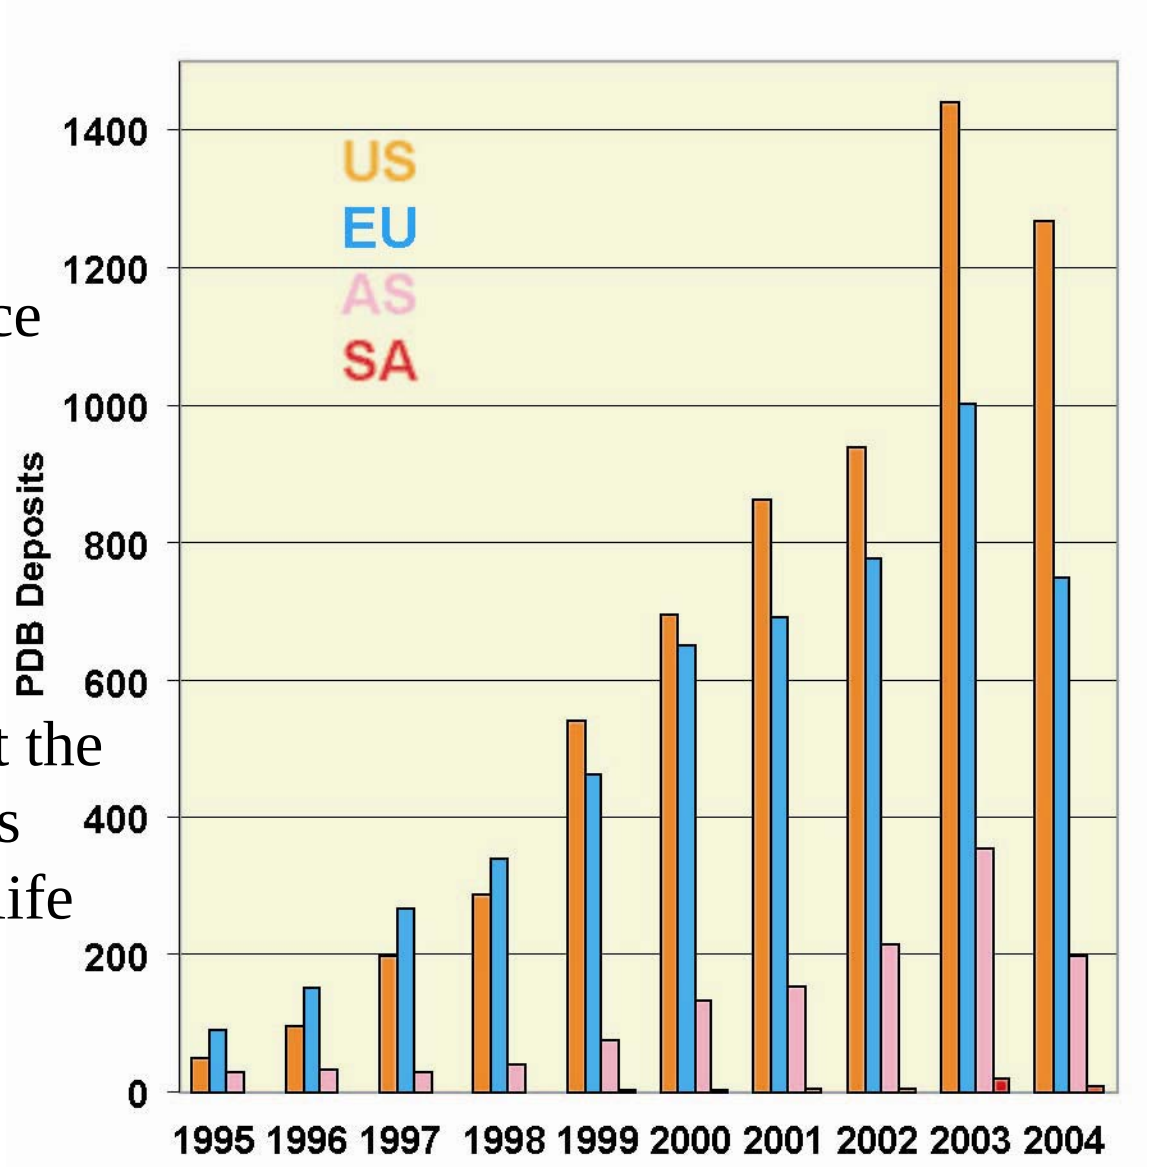


10 Tb NSF Storage

Structures of Proteins in PDB

- Single crystal x-ray crystallography ~23,000
- Nuclear magnetic resonance ~4,000
- Single crystals neutron crystallography ~few

- For x-ray data collection at the synchrotron cryofreezing is essential - extends crystal life facilitating better data



Aldose Reductase at 0.66 Å – Protonation of His110 – a Key Catalytic Residue

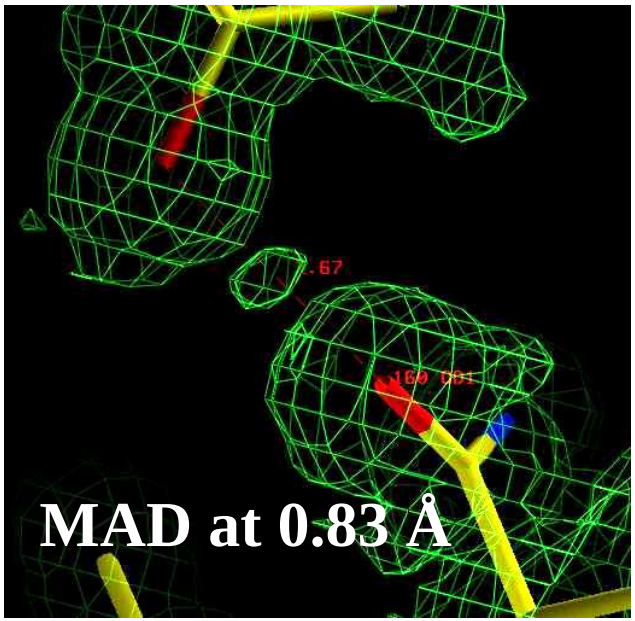
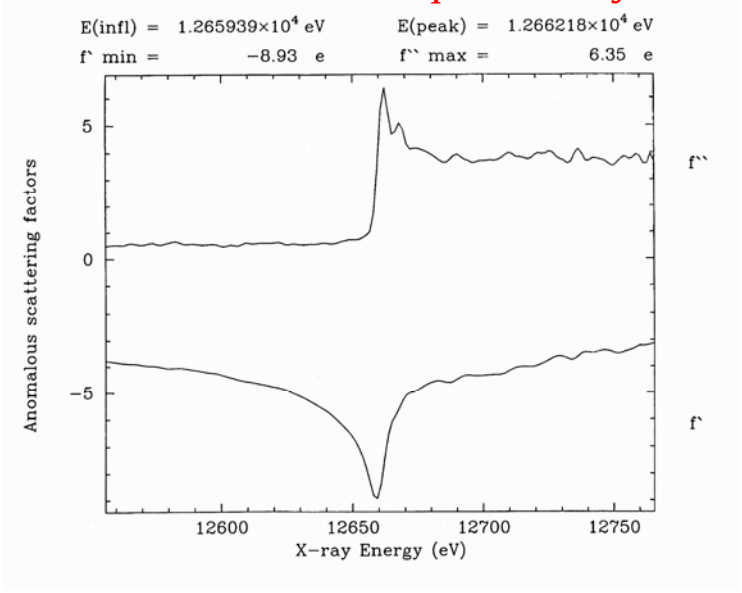
Multi- and Single-wavelength Anomalous Diffraction Using Synchrotron Sources Creates an Opportunity for Automation of Structure Determination

- All “heavy – N>50” and “light – 20<N<50” atoms show good anomalous signal associated with K, L and M edges
- “Heavy” atoms can be readily introduced into proteins (SeMet, Br, I, Xe, Ar, As, metal ions (Rb etc)) and DNA/RNA (Br)
- MAD/SAD does not require a native crystal
- Anomalous signal does not decay with resolution
- Use of anomalous signal simplifies approach to structure determination and improves isomorphism
- The anomalous signal is weak (1-6%)
- Optimal data collection requires a synchrotron facility

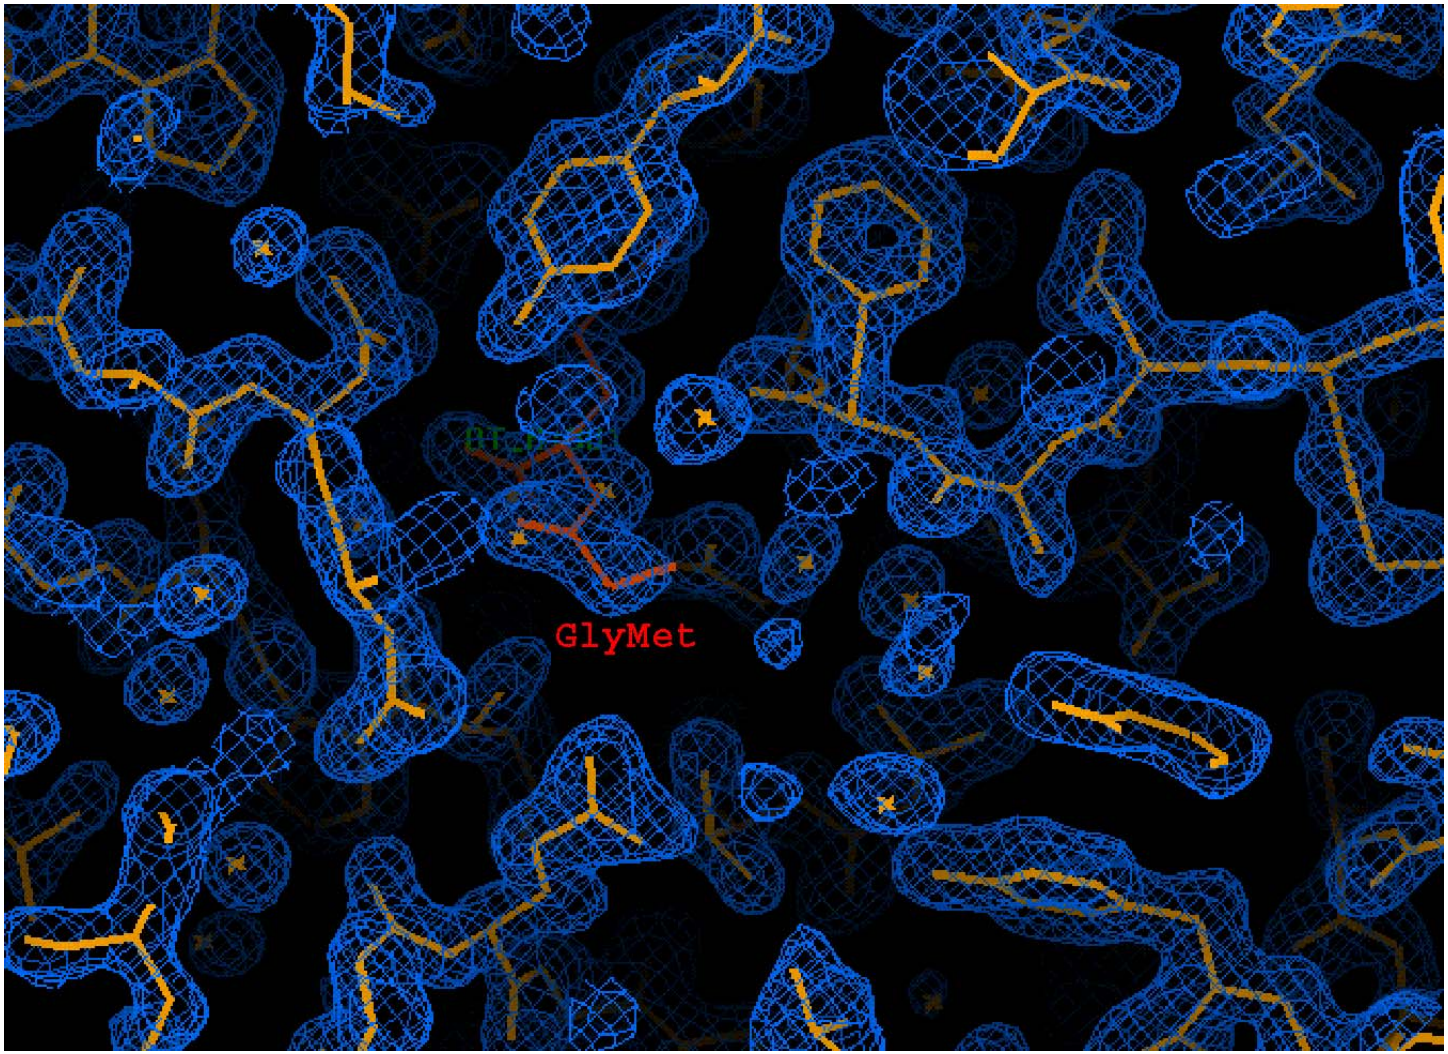




MAD/SAD for PROTEINS

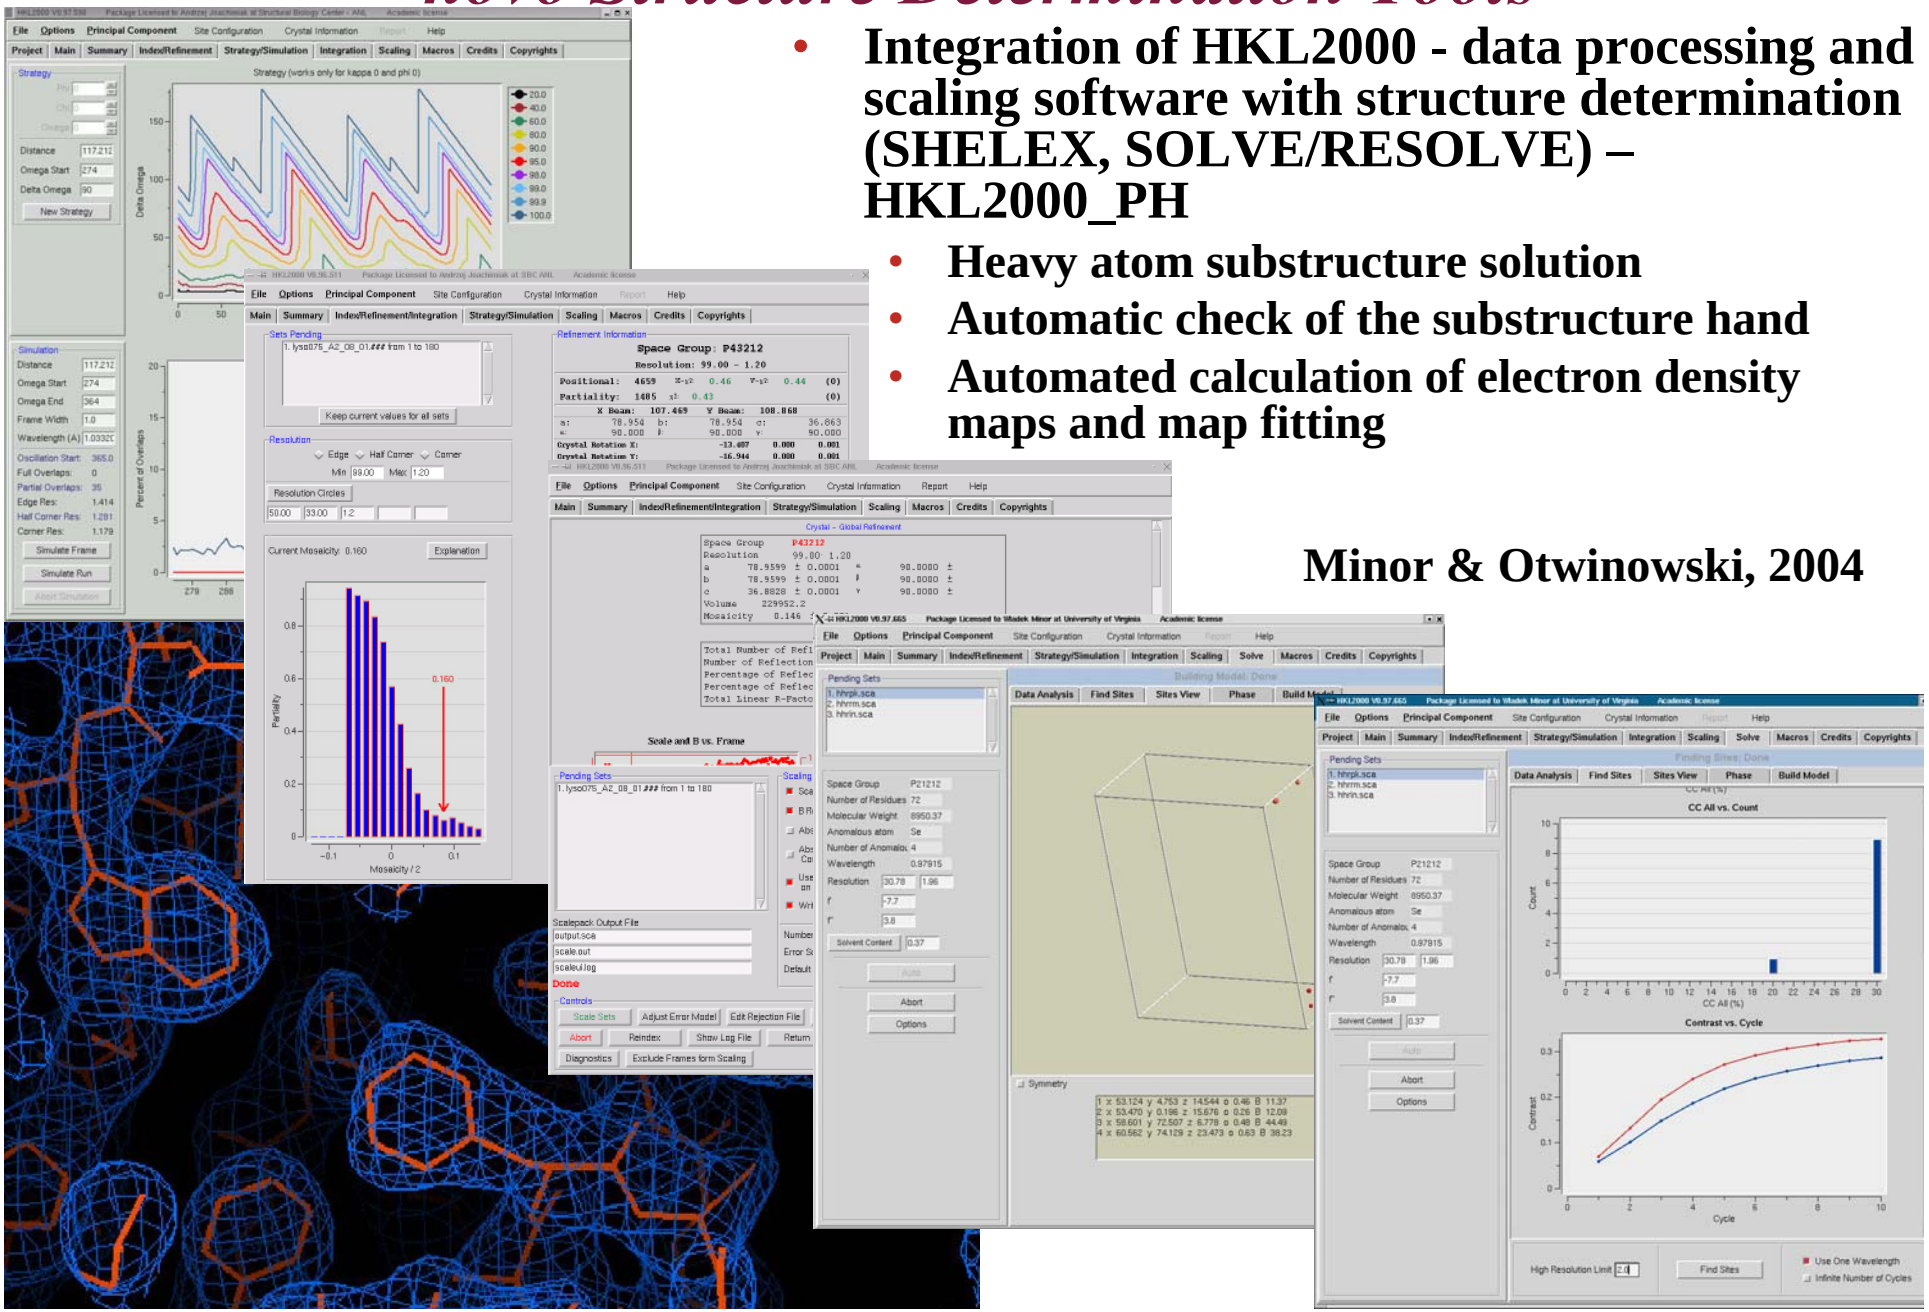
- *In vivo* protein labeling with SeMet
- Standard protocol for data collection and structure determination
- High-resolution and high quality allows auto-tracing

MAD/SAD Phasing Provides Higher Quality Electron Density Maps, Allows Automated Interpretation and Improves Structure Quality



APC009, 1.7 Å SAD Map 1σ, 1 Se/297 AA (32 kDa)

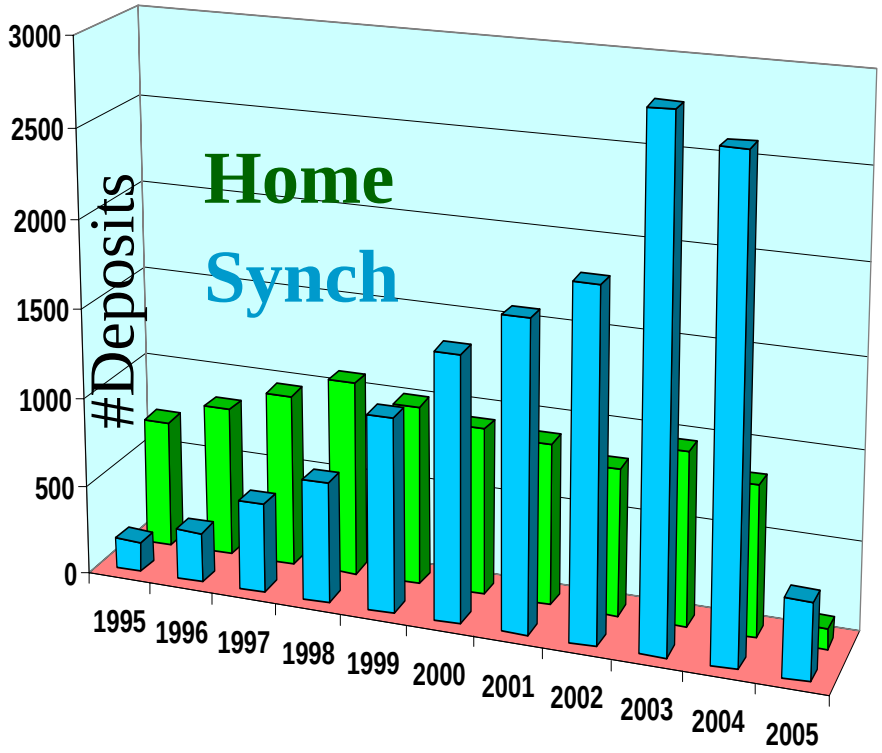
Integration of Data Collection Experiment with HTP de novo Structure Determination Tools

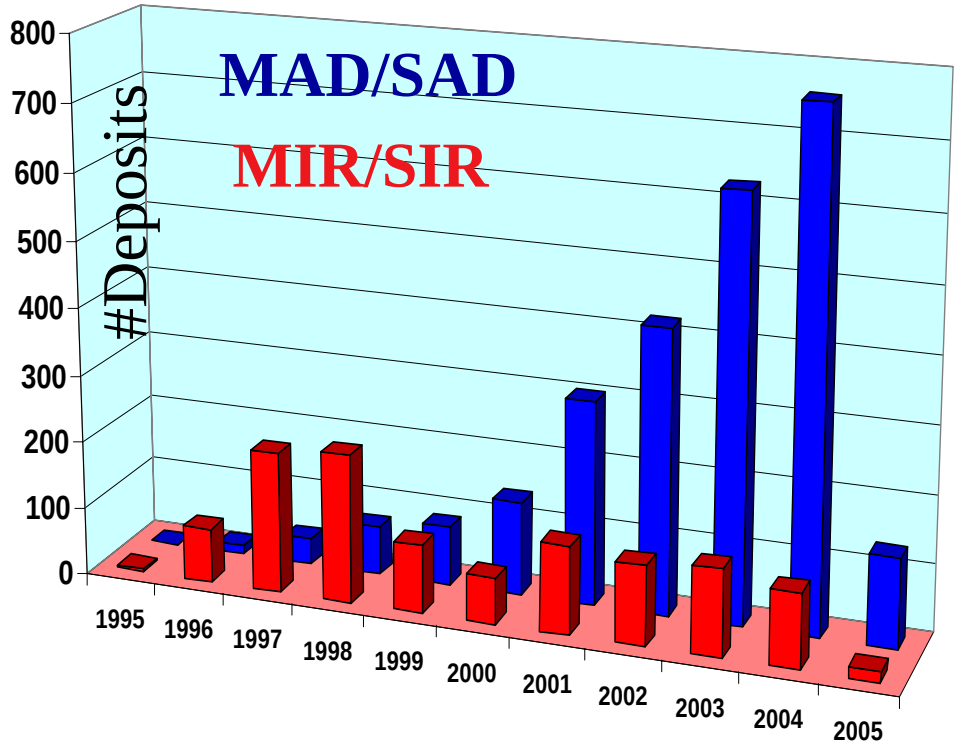


- **Integration of HKL2000 - data processing and scaling software with structure determination (SHELEX, SOLVE/RESOLVE) – HKL2000_PH**
  - **Heavy atom substructure solution**
  - **Automatic check of the substructure hand**
  - **Automated calculation of electron density maps and map fitting**

Minor & Otwinowski, 2004

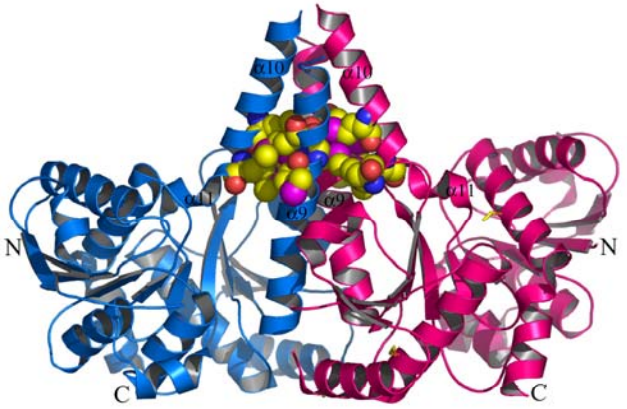
Effect of Synchrotron Sources on Protein Structure Determination

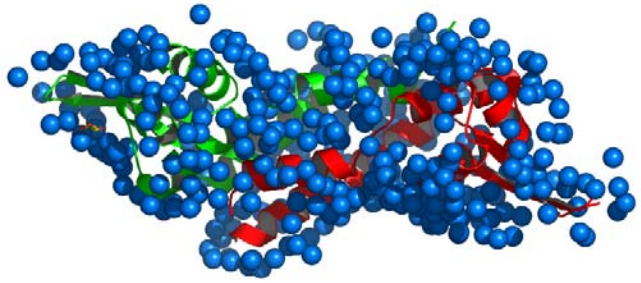


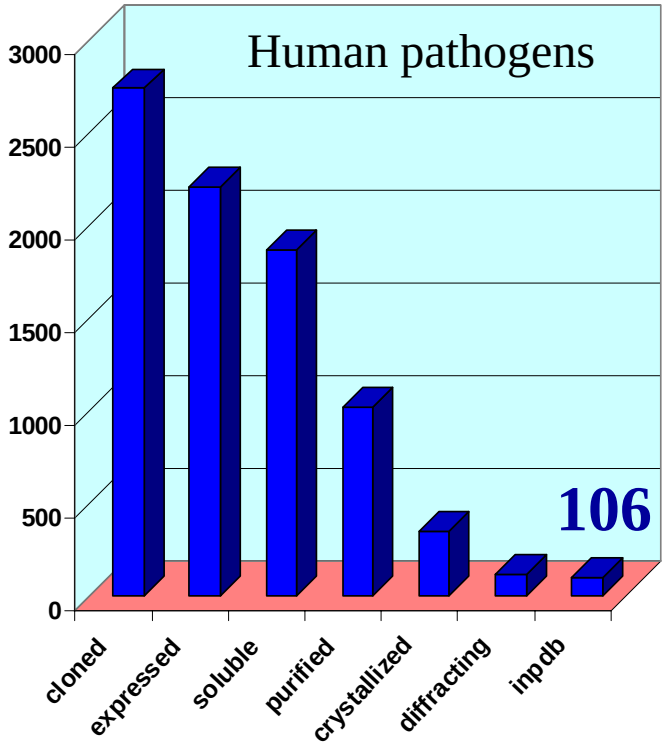


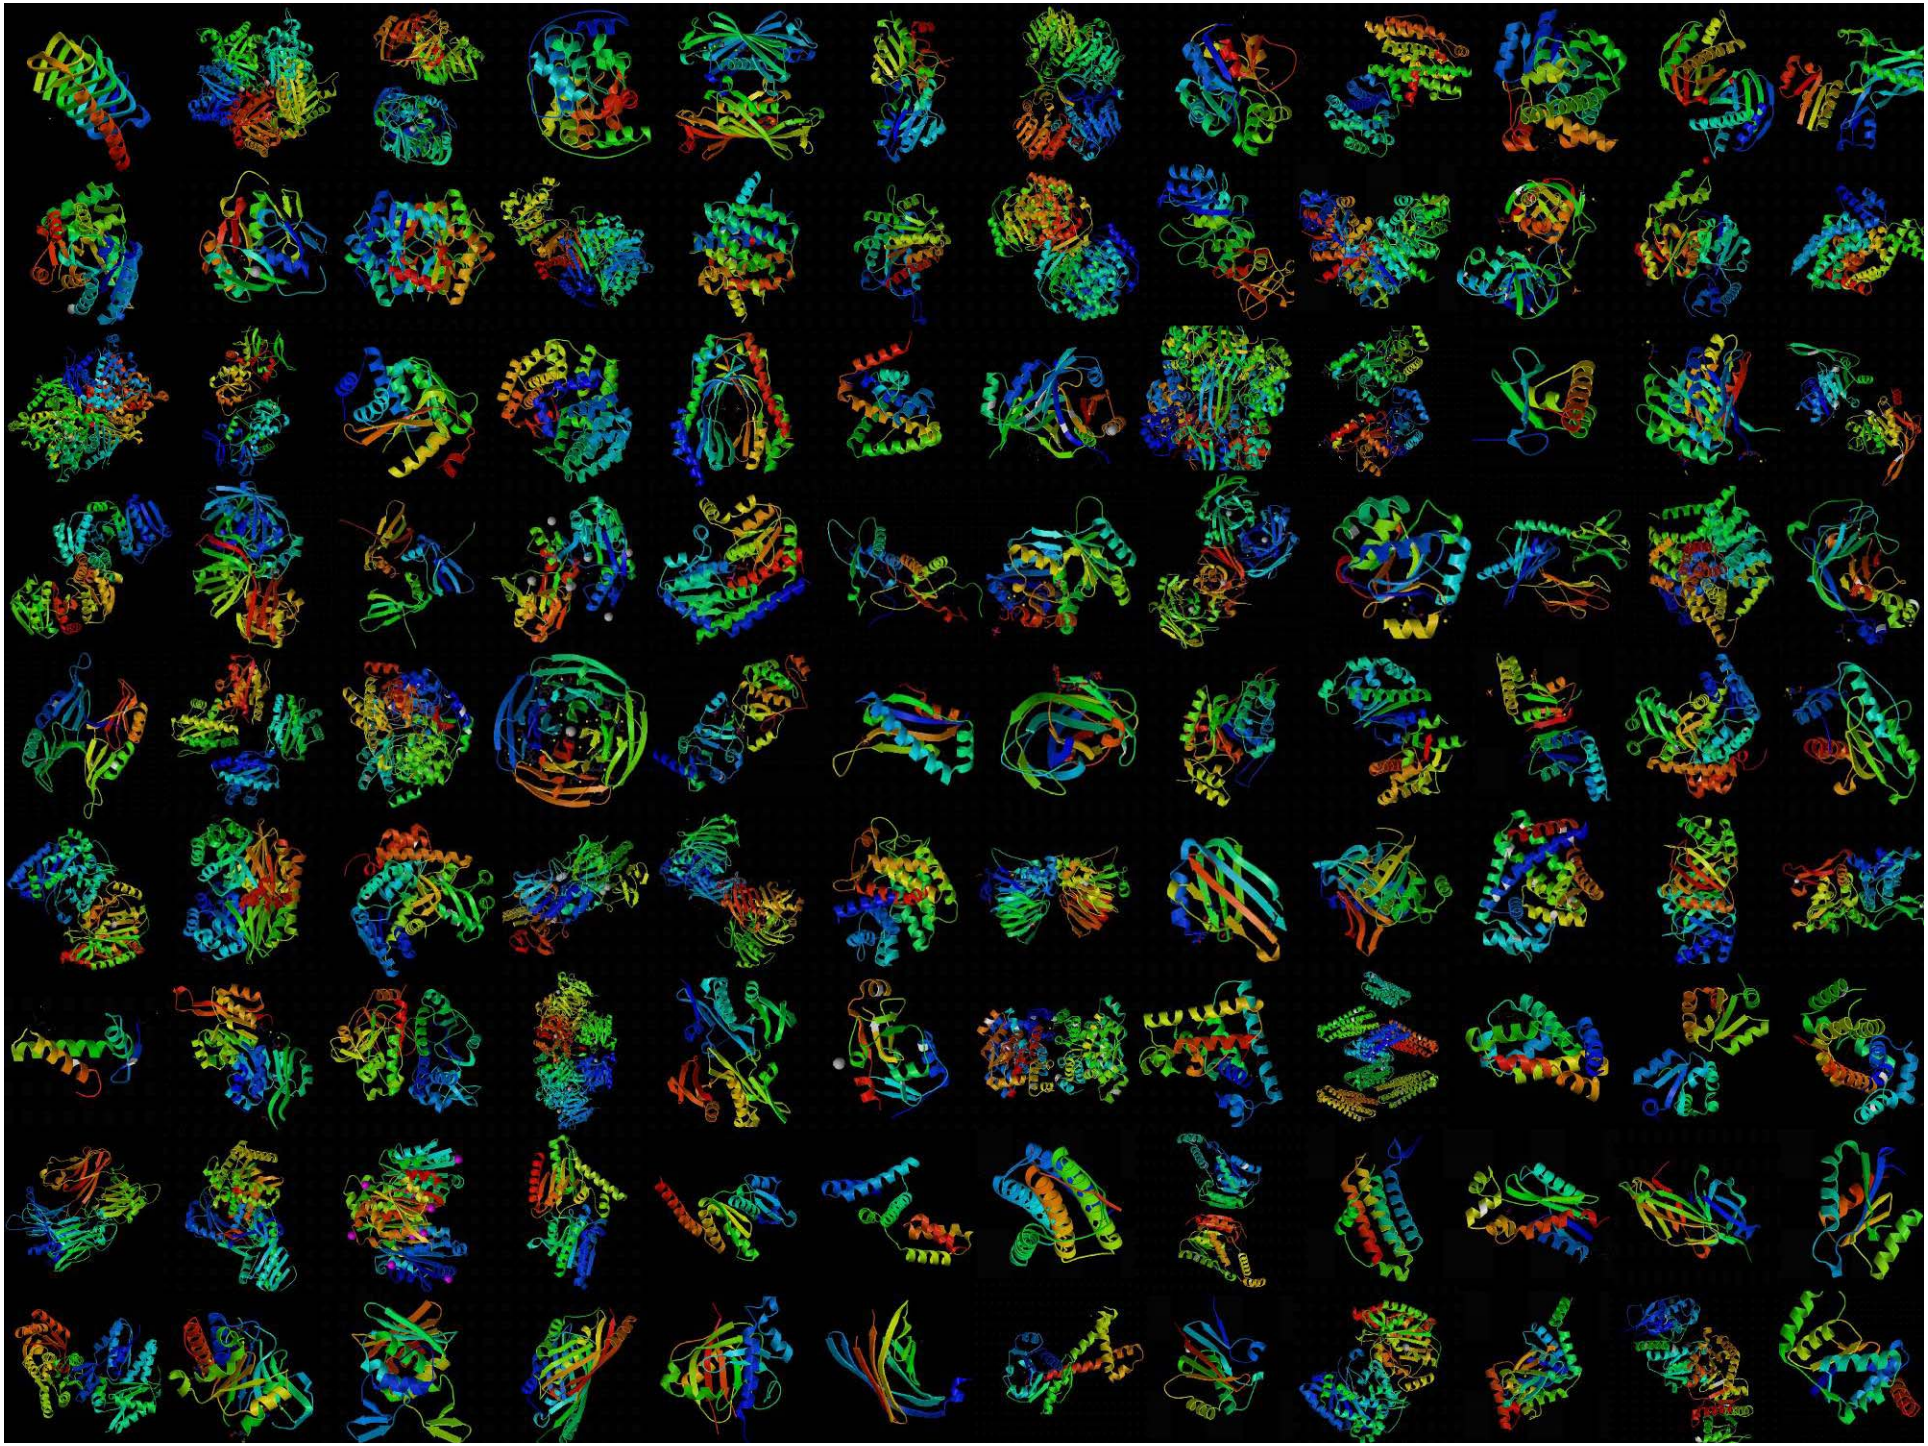
MCSG Progress, July 8, 2005

- **Targets (genes) 14,266**
- **Stopped projects 1,258**
- **Cloned genes 5,475**
- **Expressed proteins 4,052**
- **Soluble proteins 3,211**
- **Purified proteins 2,120**
- **Crystals 824**
- **Diffracting crystals 324**
- **New structures in PDB 273**
- **Total structures in PDB 281**
- **New folds 24**









July 8, 2005 – 273 MCSG Structures in PDB

- **In 2004 MCSG has deposited 112 structures to PDB (103 in the past 10 months).**
- **Full lengths proteins:**
  - **Average gene size 319 AA (range 97 - 783AA).**
  - **MW~33 kDa (range 11 kDa – 90 kDa, 11kDa/AU - 330 kDa/AU).**
  - **On average proteins are dimers (range 1-16 subunits).**
  - **Average resolution 1.94 Å (range 1.1- 3.2 Å).**
  - **Average R=20.0%, Rfree=23.9%.**
  - **79% structures are unique**
- **All structures determined using anomalous signal and synchrotron radiation:**
  - **250 (91%) MAD/SAD with SeMet substituted proteins (range 1Se/297 – 108 Se/2720),**
    - **Six proteins were crystallized using mutagenesis (Derewenda)**
    - **Fifteen proteins were crystallized after reductive methylation**
  - **22 SAD/MIR with other HA (Hg, Pt, Zn, Cd, I).**
  - **1 molecular replacement.**

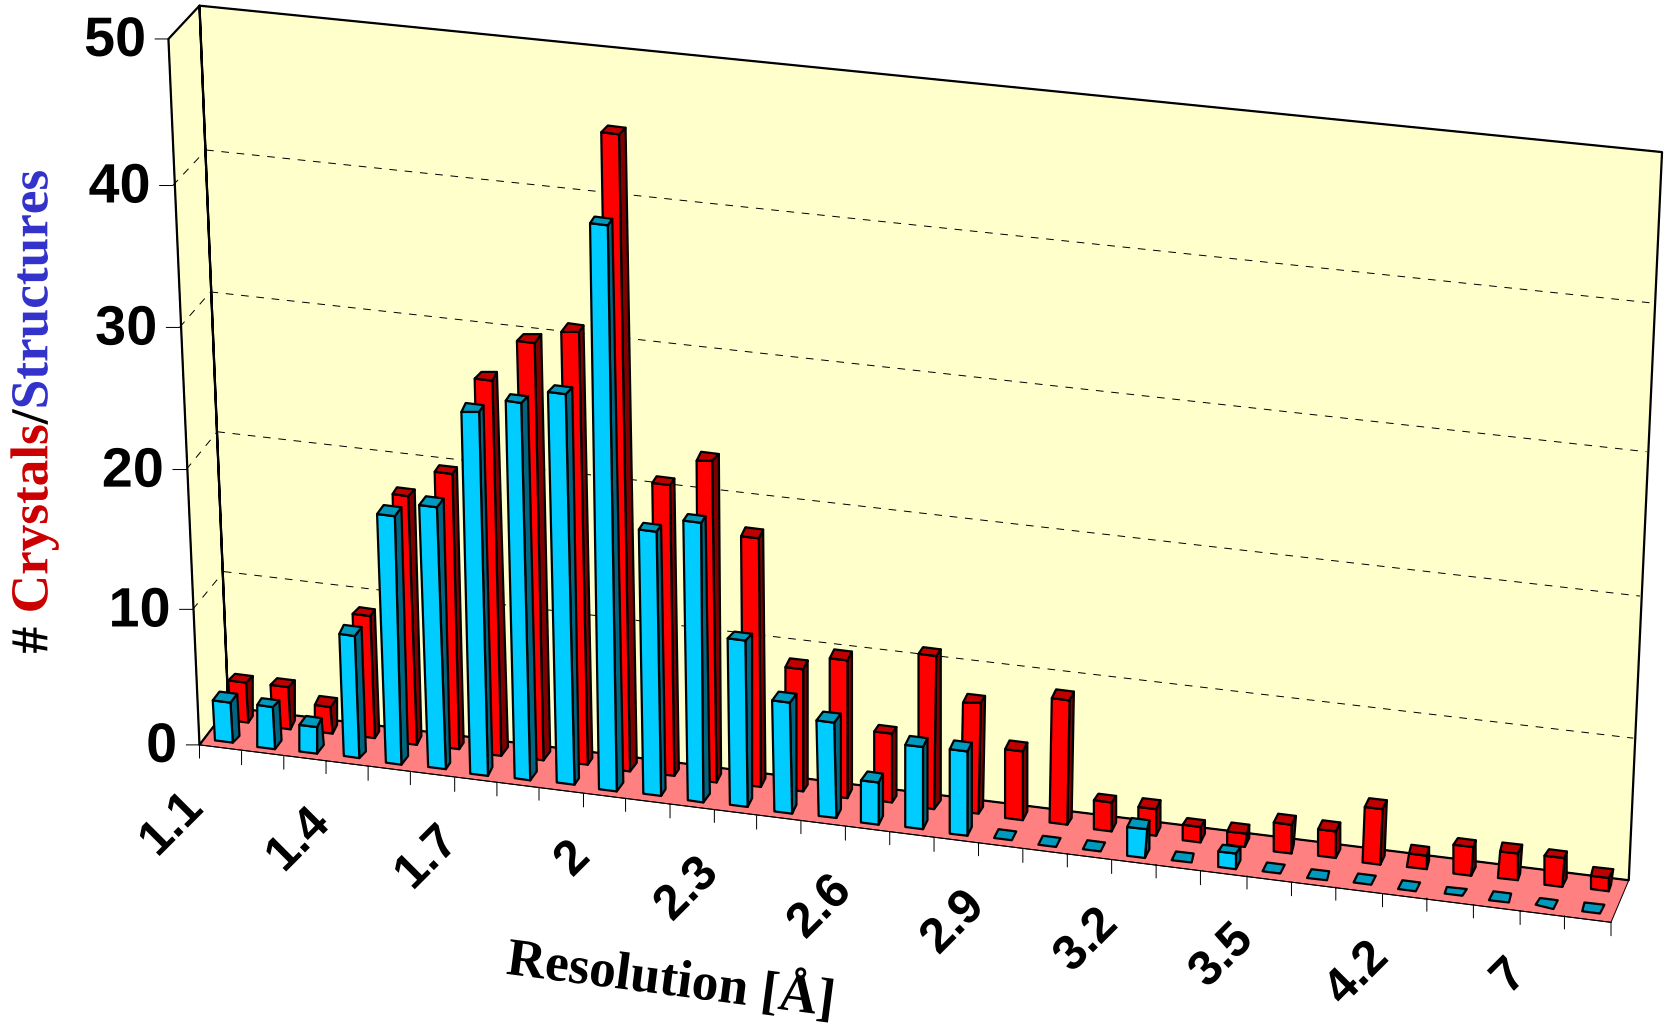
~13% of MCSG Structures Have Been Determined at 1.5 Å or Higher Resolution



Structural Genomics can Contribute at Least Three Tools

- **A comprehensive dictionary of high-resolution protein structures determined experimentally by x-ray crystallography and NMR**
- **A comprehensive library of recombinant protein expression clones representing protein structures and functions**
- **Methods for automated, HTP implementation of the currently powerful but tedious and labor-intensive protocols of molecular biology**
- **Some functional information derived from structure**

Cyanase – an Enzyme Created by Oligomerization of DNA-Binding Protein

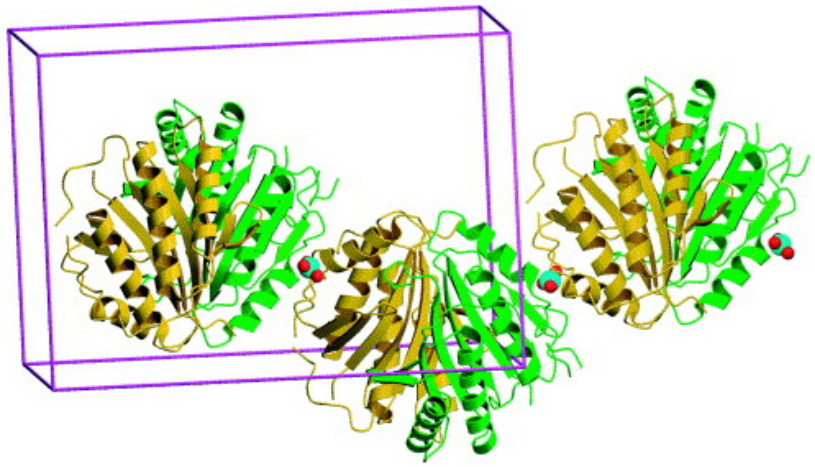
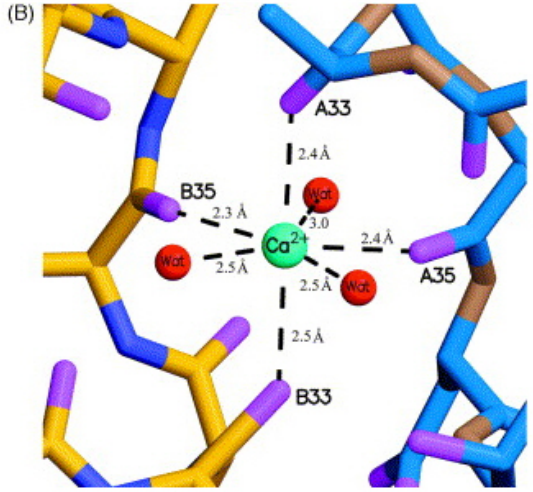
Surface Conformational Entropy Reduction

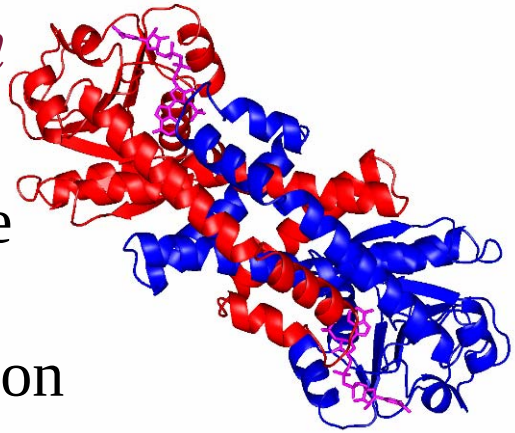
- A surface conformational entropy reduction was applied to a set of 20 *B. subtilis* proteins that failed in the initial crystallization screens.
- Two double mutants of YkoF - a thiamin-binding protein - (K112A/E114A and K33A/K34A) were designed. The K33A/K34A mutant crystallized readily and showed a strong requirement for divalent ions.
- The crystal structure was determined to 1.65 Å.
- The mutagenesis created an intermolecular Ca^{2+} binding site, essential for the formation of the crystal lattice.
- From a set of 20 *B. subtilis* targets we were able to crystallize 11 proteins, 7 as native and 6 mutated (2 proteins crystallize both as native and mutated).





Derewenda et al.

Orthologue Scanning Approach



- 48 presumed essential genes in *B. anthracis* were used to identify orthologues in 18 genomes.
- 233 genes were cloned and screened for expression and solubility.

Organism	Strain	GC Con
Enterococcus faecalis	V583	37.53%
Streptococcus pyogenes	SF370	38.51%

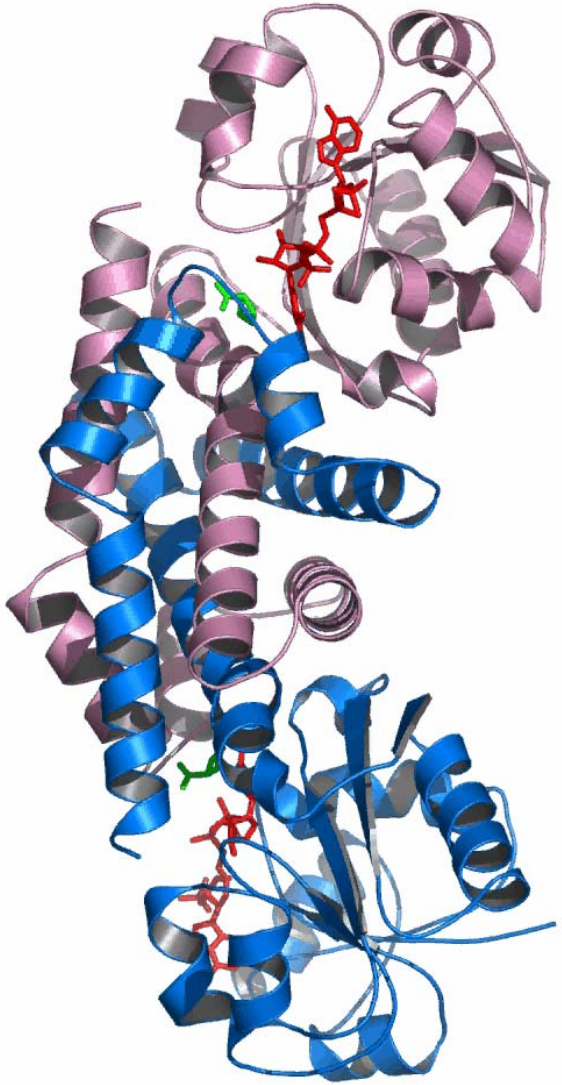
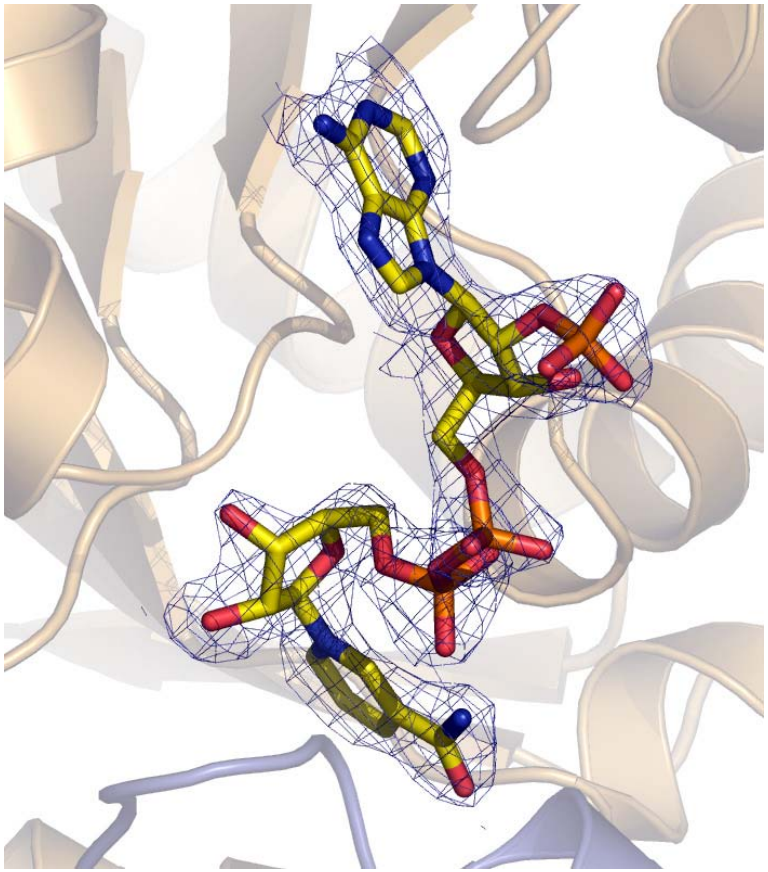
Crystal Structures of Δ1-Pyrroline-5-Carboxylate Reductase from Neisseria meningitides and Streptococcus pyogenes

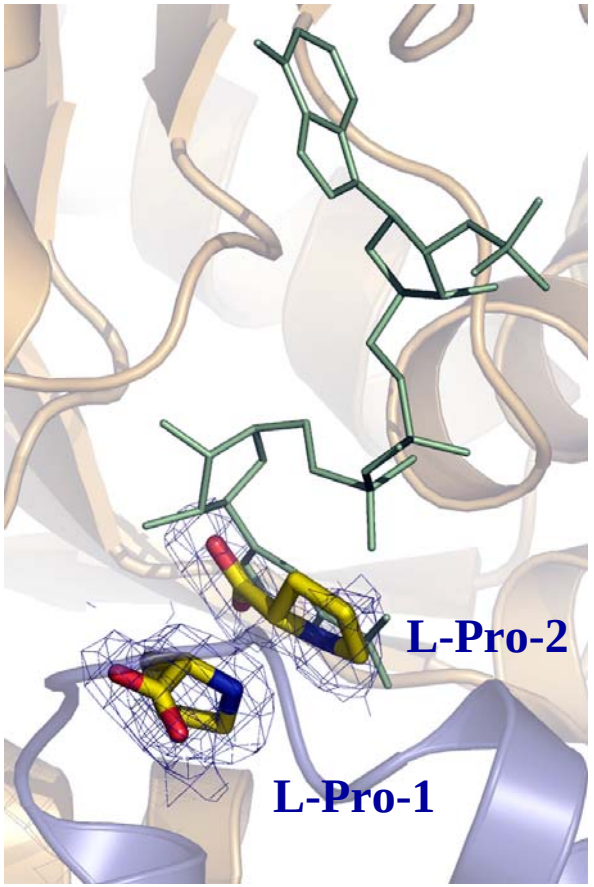
- **L-proline plays an important role in proteins**
- **The last step of proline biosynthesis, the conversion of Δ1-pyrroline-5-carboxylate (P5C) to L-proline is catalyzed by Δ1-pyrroline-5-carboxylate reductase (P5CR) using NADPH as cofactor**
- **P5CR is a member of a very large family (>400 family members)**
- **To increase the chance of obtaining a crystal structure from a member of this large and important family of enzymes, orthologues from 14 organisms have been cloned.**
- **9 P5CR enzymes expressed, 3 crystallized and 2 produced x-ray quality crystals**
- **The catalytic unit of P5CR is a dimer composed of "three" functional domains**
- **The N-terminal domain of P5CR shows an alpha-beta-alpha sandwich – a Rossman fold**
- **The C-terminal dimerization domain is rich in α-helical structure and shows domain swapping**



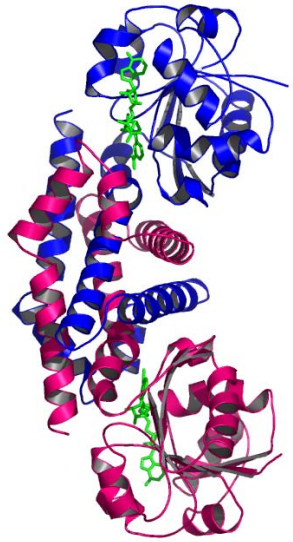
Binding $NADP^+$ and L-Proline

- Comparison of the P5CR native structure with structures P5CR complexed with L-proline and $NADP^+$ provides unique information about key functional features, the active site and the catalytic mechanism
  - Each ligand is bound to a distinct domain
  - Hydrite is transferred from pro-S face of nicotinamide ring and is unidirectional
  - Crystal structure shows how product L-Pro inhibits reaction

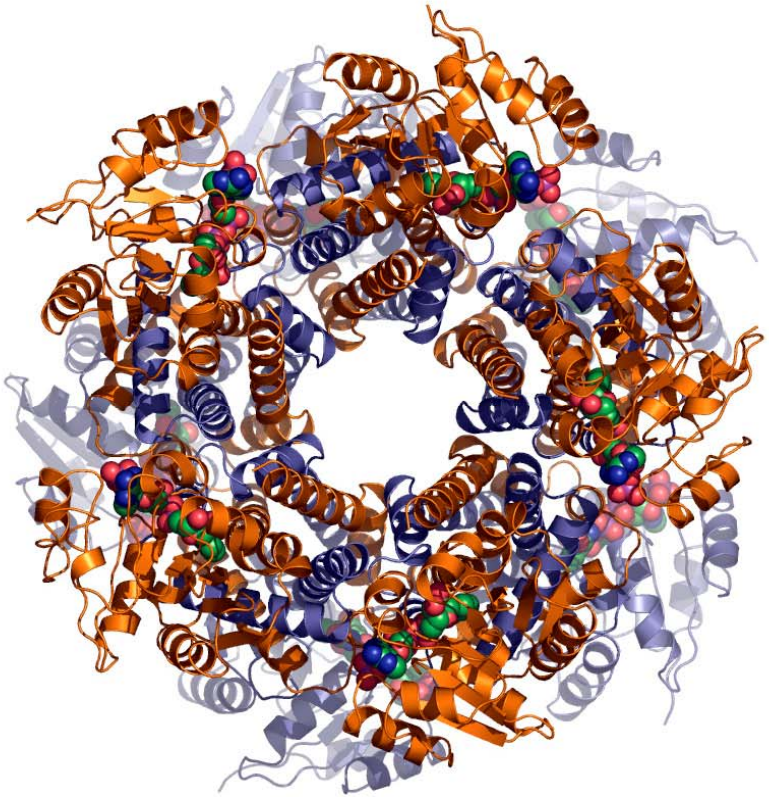


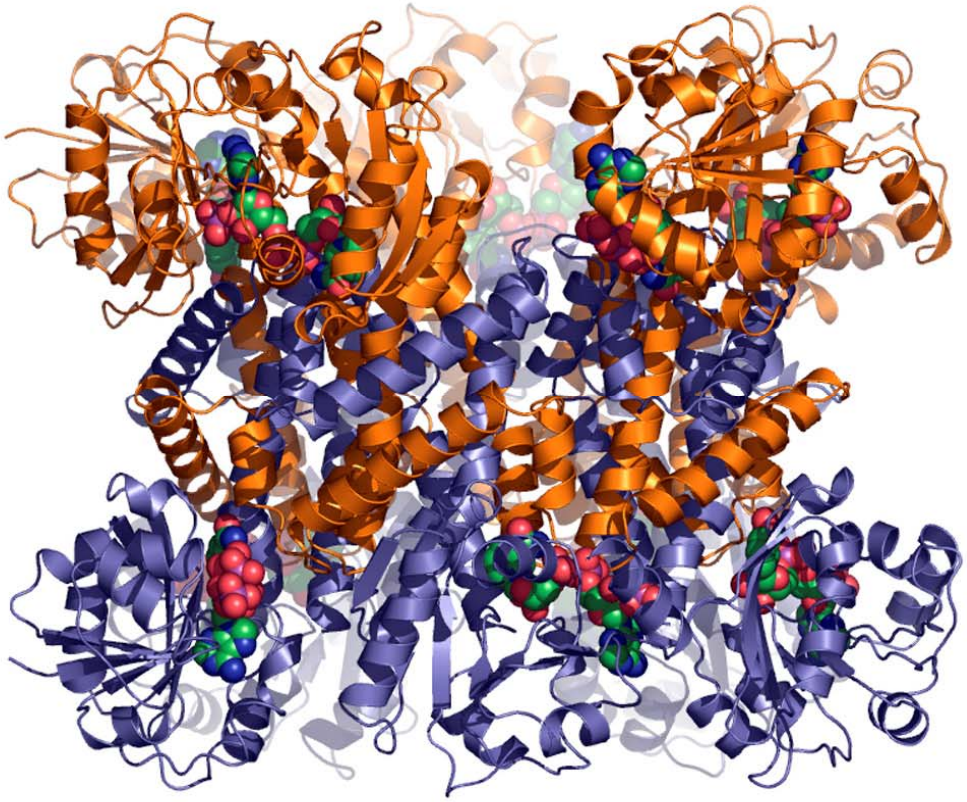


P5CR Basic Catalytic Unit is a Dimer, but it can Assemble into Larger Structures that Seems Species Specific



- P5CR from *N. meningitides* is a dimer
- P5CR from *S. pyogenes* is a decamer (pentamer of dimers)





Structural Genomics Results

- **New structures confirmed the hypothesis that the structure-based classification of proteins contains far fewer protein families than sequence-based classifications:**
  - **Protein structure is better conserved than amino acid sequence, and**
  - **Can reveal distant evolutionary relationships that are undetectable by sequence comparisons**
- **Structures of singletons and proteins from very small families showed familiar folds, contradicting the hypothesis that these families may represent a rich reservoir of new folds**
  - **Sequence-based methods have major limitations for identifying proteins with potentially new folds**

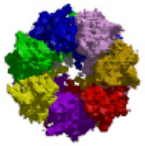
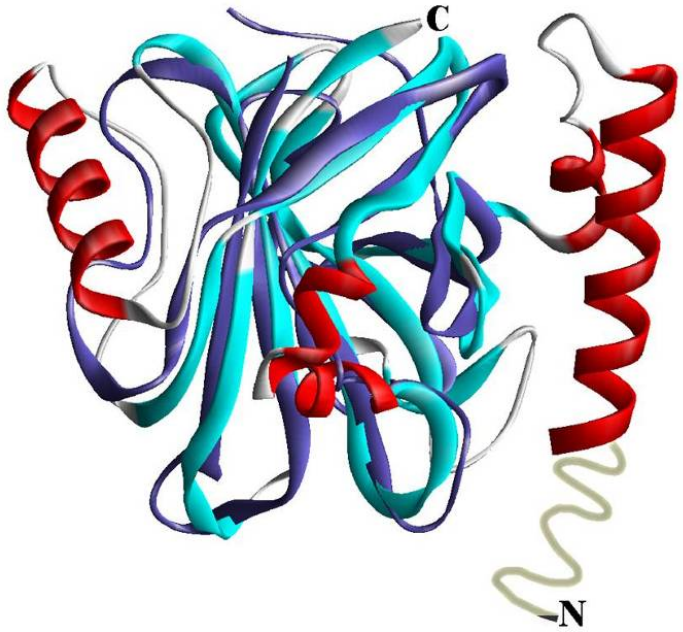
Functional Analysis



ProFunc *Analysis of a protein's 3D structure to help identify its likely biochemical function*



The aim of the ProFunc server is to help identify the likely biochemical function of a protein from its three-dimensional structure. It uses a series of methods, including fold matching, residue conservation, surface cleft analysis, and functional 3D templates, to identify both the protein's likely active site and possible homologues in the PDB.

Some of the methods take minutes to run; others take hours. You will be notified by e-mail when the entire process is complete, but can check on preliminary results as they become available.

From this page you can submit your own structure, analyse an existing PDB entry, or retrieve the results of a previously submitted run.

Choose option A, B or C:

A

Upload PDB-format file: Browse... UPLOAD

or

B

Get existing PDB file PDB code:

or

C

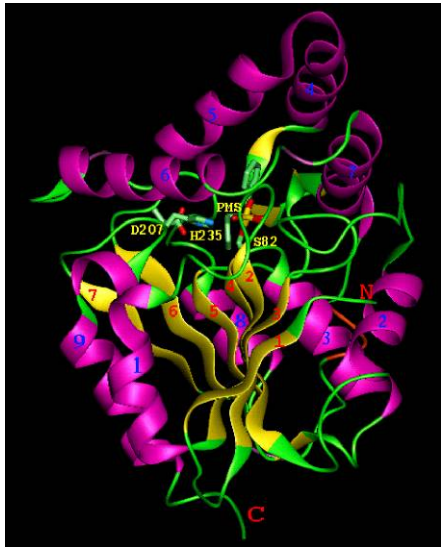
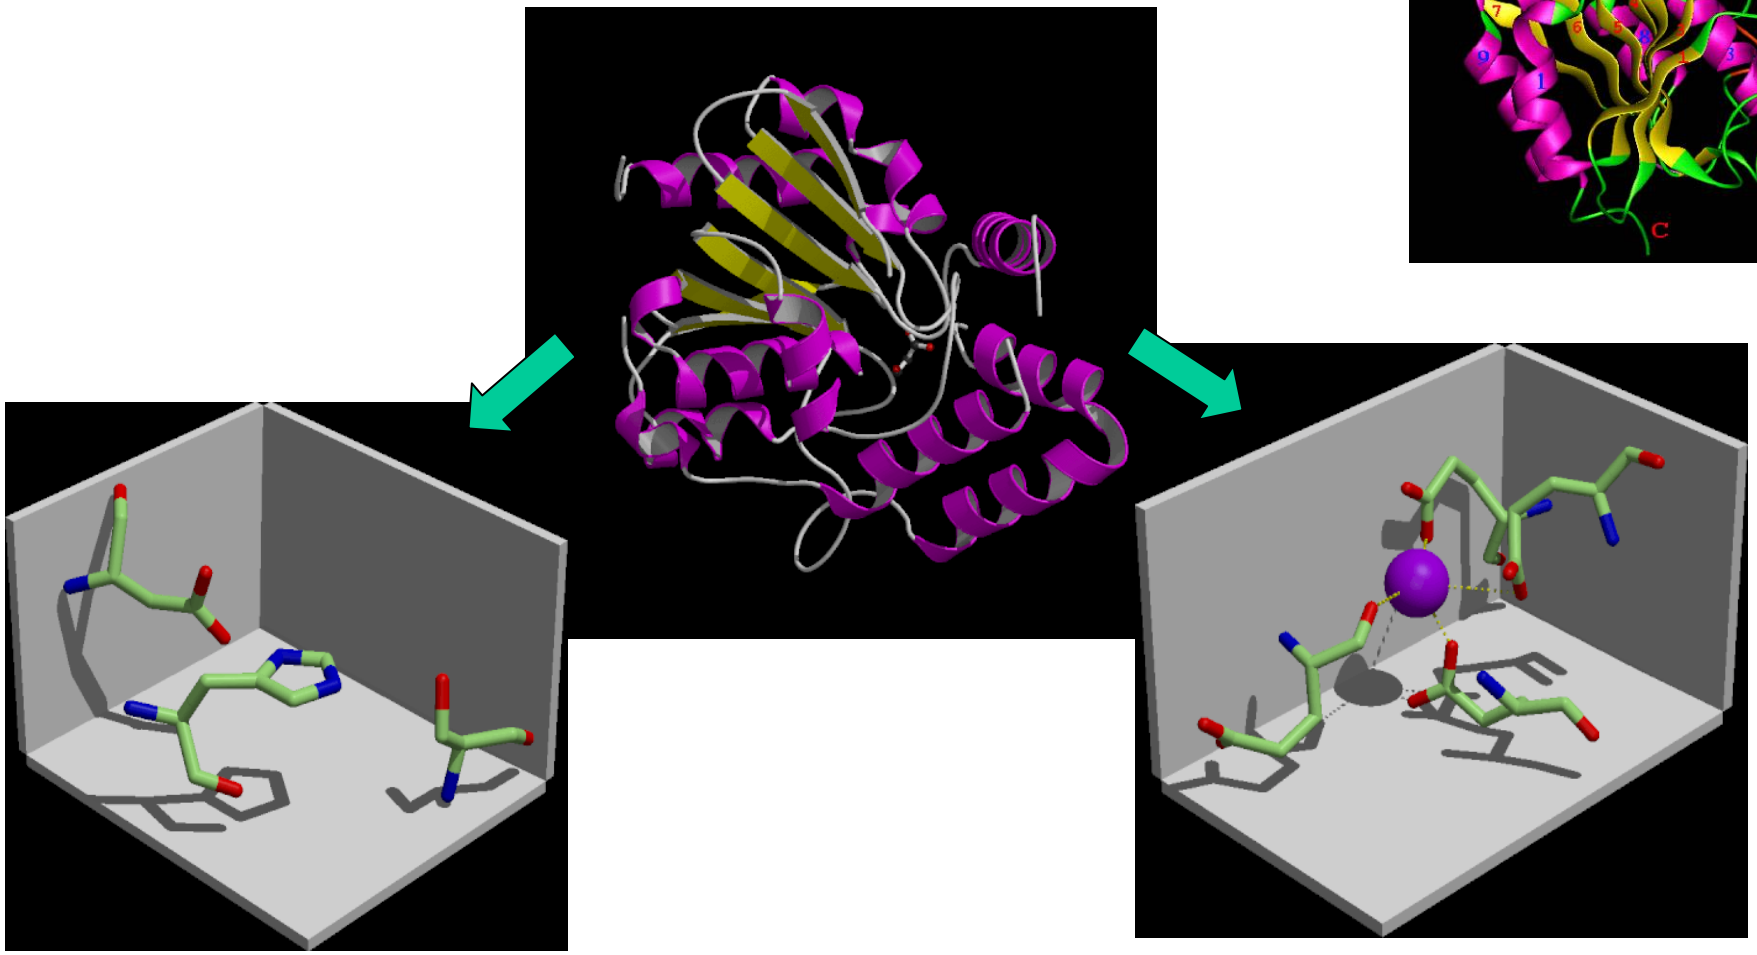
Predicting Function from Structure





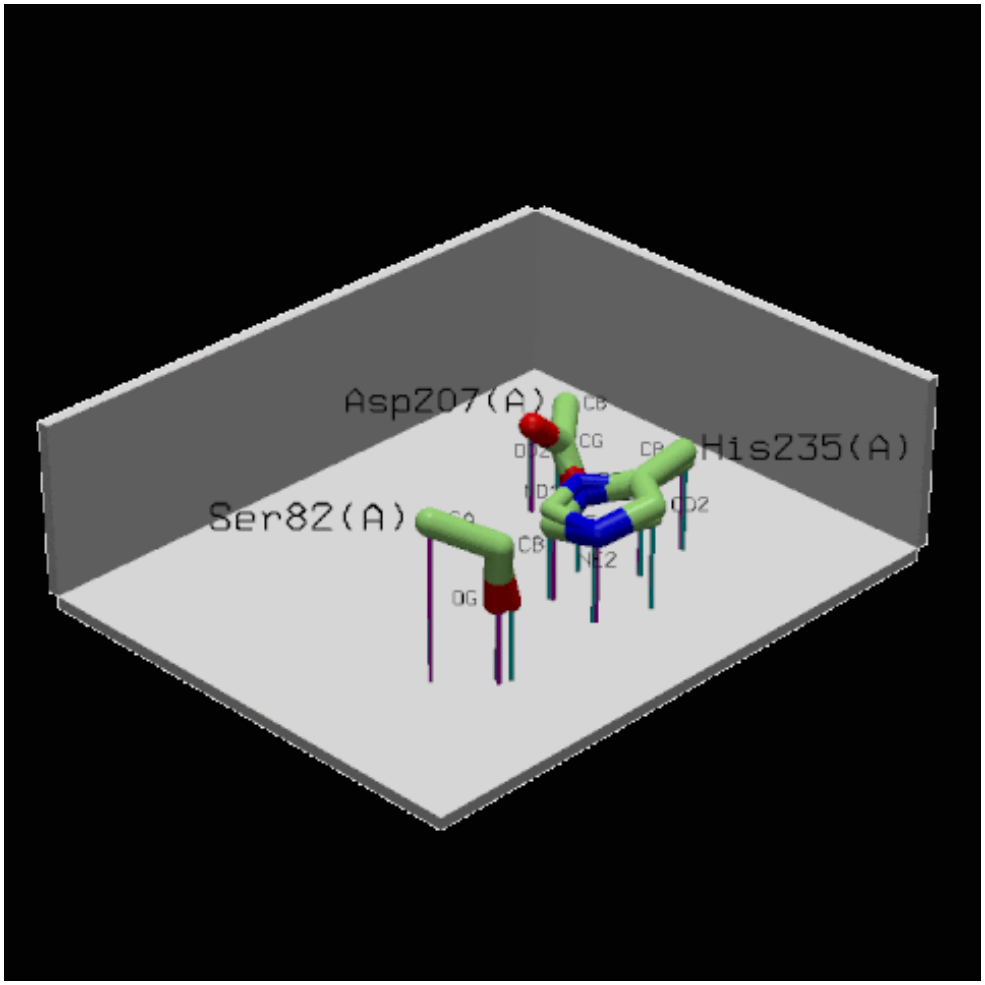
Catalytic residues

(189 active site templates)

Metal-binding sites

(~600 templates)

Proof of 3D Template Concept: BioH

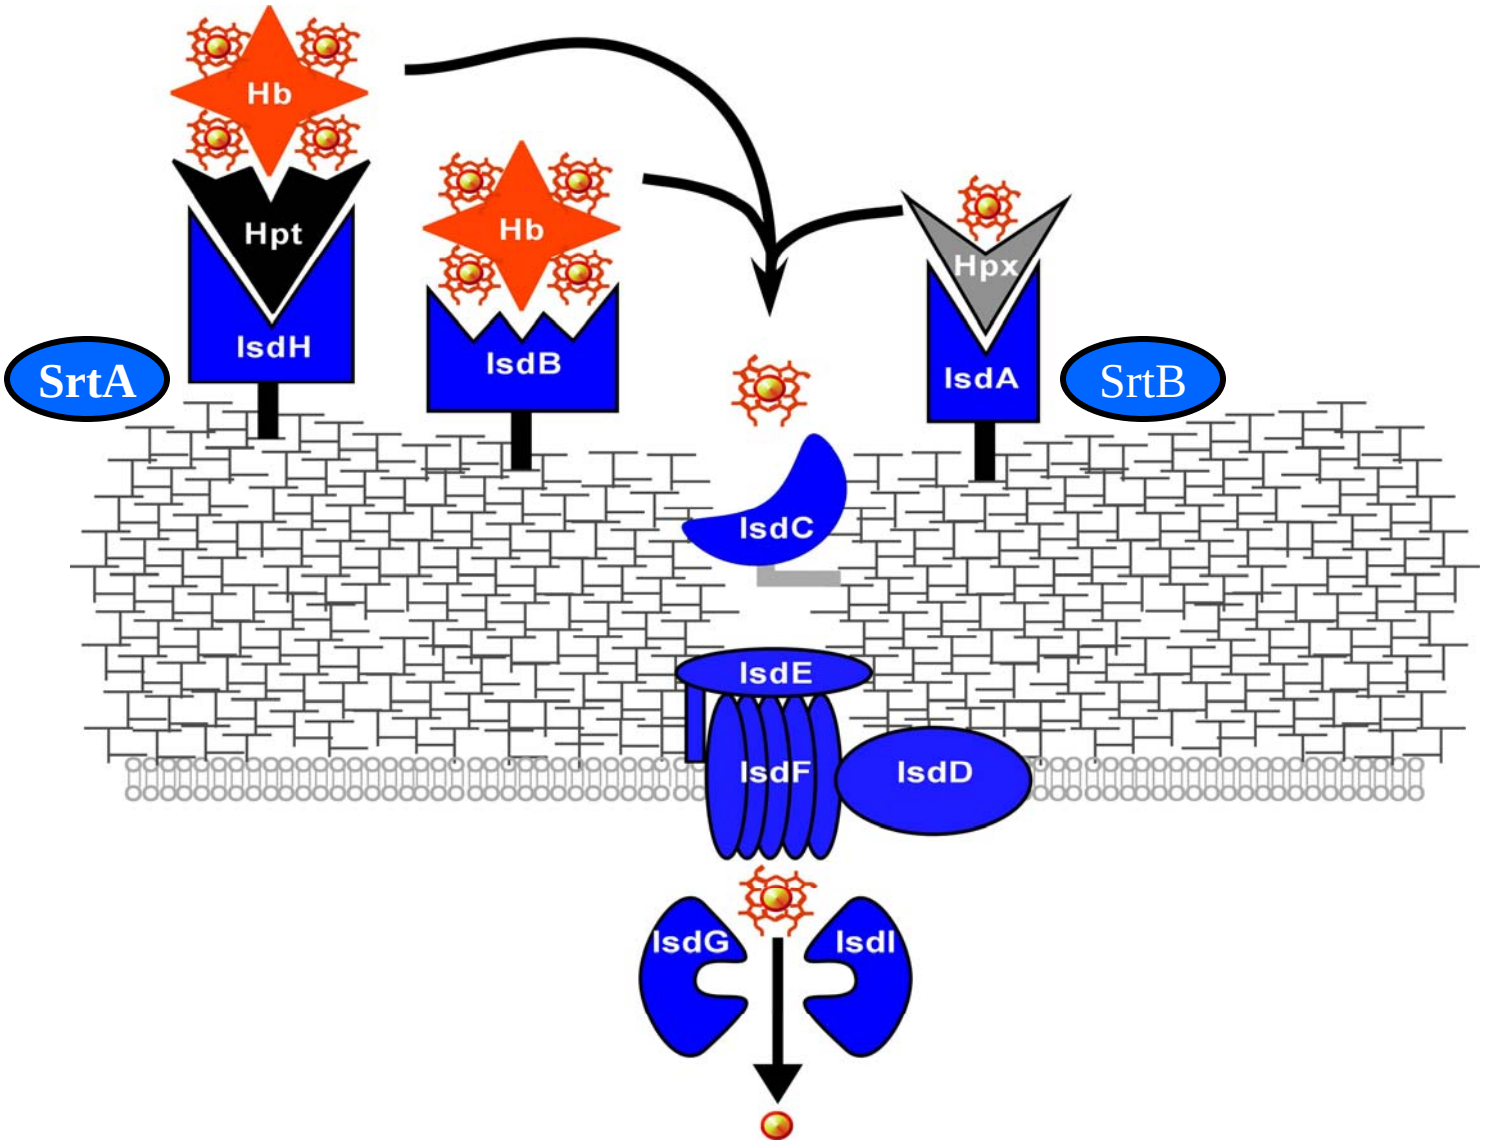


- **BioH – protein in *E. coli* involved in biotin metabolism – function unknown**
- **Crystal structure determined**
- **Catalytic triad identified**
- **Now proven experimentally to be correct**
- **BioH is carboxyesterase**

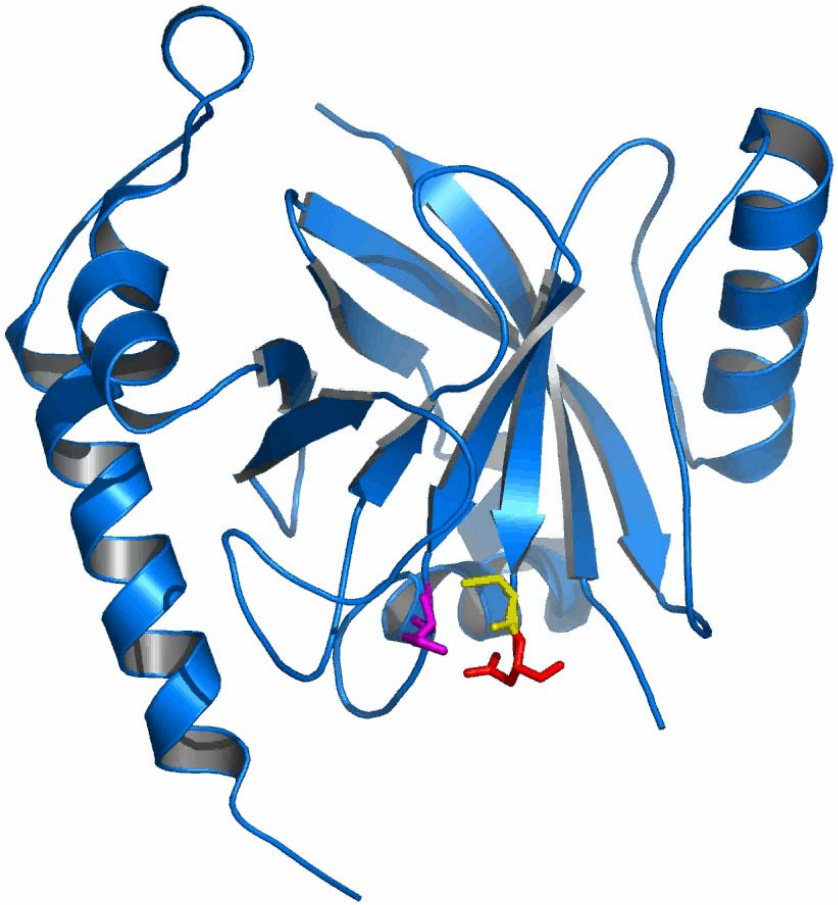
Template shown in thin bonds,
actual side chains in thick

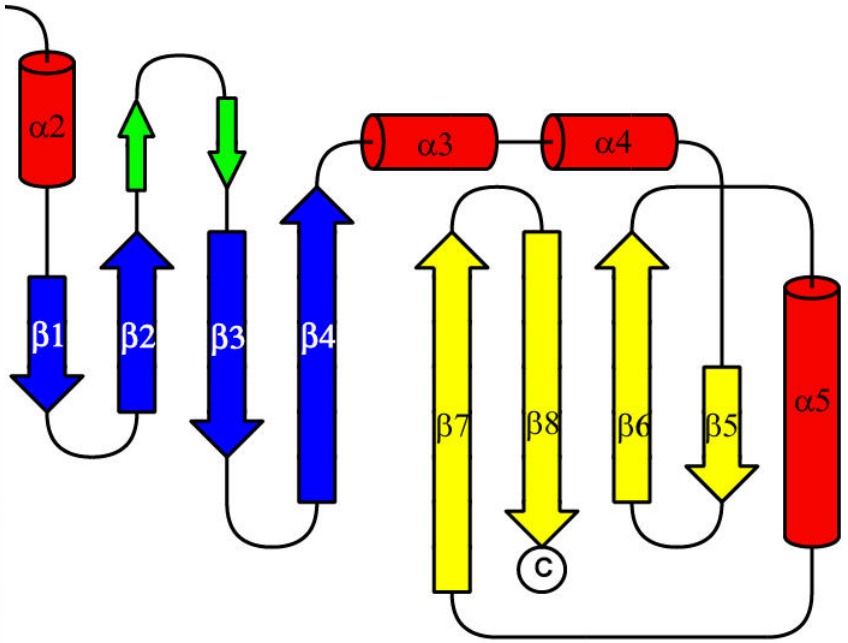
- **Ser-His-Asp catalytic triad (rmsd = 0.26Å)**
- **All 3 residues highly conserved**
- **At site of ligand binding**

A Model for Isd-mediated Heme-iron Transport in Gram Positive Pathogens



Structure of B. anthracis *Sortase B is Similar to Sortase B from* S. aureus





Active site contains
Catalytic triad Cys-His-Asp

Active Site of Sortases B from S. aureus *and* B. anthracis *Shows Catalytic Trial (with a Caveat)*

Impact of Structural Genomics

- **Structural genomics will map protein folding space and provide insight into relationship between amino acid sequence and 3D structure**
  - **New technology for cost-effective molecular biology and protein purification will evolve from the project**
  - **SG will enhance crystallographic capabilities by significantly reducing the time and cost required to determine protein 3D structures**
  - **Bottlenecks will be identified and practical solutions will be establish**
  - **All "easy" structures will be solved rapidly**
  - **The HTP technologies will be developed to handle challenging biological systems and will benefit biology and biotechnology**
- **Structural information will provide new insight into protein function**
- **We will gain complete structural understanding of many processes and pathways in the cell**
- **New hypothesis will be formulated**
- **New functional proteins will be created through rational design**
- **Libraries of genes, expression clones and proteins will be produced and will be available to public**

Why Neutron Crystallography?

- **The protein neutron structures can reveal number of important (and often unexpected) details:**
  - **Hydrogen atoms (~1% of the protein mass but critical for understanding protein packing, enzyme catalysis and interactions),**
  - **Protonation states and H-bonds,**
  - **Solvent structure – can distinguish water from other solvent components (Cl, Na, Mg, etc),**
- **Can define accurately atomic positions (unexpected stereochemistry, distortion of bond lengths)**
- **No radiation damage – native structure can be observed at wide range of temperatures,**
- **Hydrogen exchange with deuterium – solvent accessibility and dynamics,**
- **All these issues are critical to understand catalytic mechanism, interactions, solvent structure and potentially may have impact on structure-based drug design,**
- **Thus far low flux did not allow for large scale effort,**
- **With construction of the SNS there is an unique opportunity to build neutron crystallography beam line that can make an important contribution to biology, highly complementary to x-ray data**
