Rapid Assessment Reference Condition Model

The Rapid Assessment is a component of the LANDFIRE project. Reference condition models for the Rapid Assessment were created through a series of expert workshops and a peer-review process in 2004 and 2005. For more information, please visit www.landfire.gov. Please direct questions to helpdesk@landfire.gov.

Geographic Range

Montane chaparral is primarily located in the southern and central Sierra Nevada on steep south and west aspects. It also occurs elsewhere throughout the state within montane forests, especially within the Transverse Ranges.

Biophysical Site Description

Primarily on steep south and west aspects in canyons, on glaciated landscapes, recent volcanics and areas with low site productivity/ shallow soils, and on decomposed granitic soils on the east side of the Sierra Nevada.

Vegetation Description

Montane chaparral includes a number of floristically distinct types of shrublands. Greenleaf manzanita, mountain whitethorn, pinemat manzanita, deerbrush, snowbrush, huckleberry oak, bush chinquapin and many other shrub species are common and dominant in the early and open seral stages. Ponderosa pine, Jeffrey pine, sugar pine, Douglas-fir, bigcone Douglas-fir, Coulter Pine, white fir, incense cedar, red fir, and lodgepole pine are present in the mid seral stages and dominant in late seral closed stands. In the Peninsular and Transverse Ranges, Palmer ceanothus and Mexican or pink-bract manzanitas may also be characteristic. Sites influenced by Great Basin or Mojave desert climates may have mixtures of montane chaparral and species such as antelope bitterbrush and mountain big sagebrush.

Disturbance Description

Stand replacing fires occur mostly in the shrub dominated stages. In the conifer dominated late seral closed stage surface fire is also important. FRI is generally greater than that of the surrounding forested landscape - perhaps double (Nagel and Taylor, in press) - due to the lack of flammability of many young shrub fields without a long history of fuel accumulation.

Adjacency or Identification Concerns

This includes several types of montane shrublands on sites that are typically seral to conifers. Montane chaparral is usually embedded within mixed conifer, red fir, white fir, Jeffrey pine, and other conifer forests on sites that are prone to stand replacing fire, or on otherwise disturbed or more open sites.

This PNVG is identical to the PNVG R2CHAPmn from the Great Basin model zone

Scale Description	Sources of Scale Data	✓ Literature	Local Data	✓ Expert Estimate

Montane chaparral typically originates following large stand replacing fires in conifer forests. A variety of montane shrubs occupy the site and limit establishment and growth of conifers. If these shrublands burn again before succession to late seral close forest, they can stay shrub dominated for long periods of time (centuries). Patch size can be quite large, especially in the northern part of the state.

Issues/Problems

Not sure about historic composition of seral stages. System described over broad area on east and west side of Sierras. It also occurs elsewhere, however, most literature summarized is characteristic of the Sierra Nevada range. Sugihara and Sherlock created a 4-box model. Based on anonymous feedback, Shlisky edited the model to 3-boxes, removing the tree-dominated state. This determination was based on a hypothesis that the 4-box model overlapped too-much with mixed conifer PNVGs. Overlap will be reviewed during the mapping phase, and determination of which model works best (Sugihara and Sherlock vs. Sugihara et al.) will be made at that time.

Model Evolution and Comments

This model may be redundant with the mixed conifer models (i.e., dominant species in classes B and C are all trees, not shrubs), and could be captured within Vegetation Class A of the mixed conifer, red fir/ white fir, and the red fir/w white pine models, by including shrub species in the descriptions. This issue needs to be rectified when the first draft Rapid Assessment map is constructed, and relationships between forest and montane chaparral PNVGs can be assessed. As modeled, it's possible that montane chaparral could be mapped as a PNVG only in areas where it does not turn into forest with lack of fire and succession. Would this be hard to map? What Shlisky tried with the model: 1) class D (forest) from original model deleted, and reference % of old class D combined with new class C, and 2) surface fire removed and replaced by mixed fire (no surface fire expected in this type). Lots of fire may not necessarily lead to a persistent shrub field except on steep, especially s-facing slopes(?). On thinner soils at higher elevation, fire is not necessary to perpetuate shrubs - trees don't grow there for other reasons.

Succession Classes** Succession classes are the equivalent of "Vegetation Fuel Classes" as defined in the Interagency FRCC Guidebook (www.frcc.gov).
