## Haipuaena Stream

Haipuaena Stream is headed near 5,200 ft altitude between Waikamoi and Honomanu Streams, 6.5 mi from the coast (plate 1). The Haipuaena Stream valley is similar in gradient and incision to adjacent Puohokamoa Stream valley at 600 ft altitude but is steeper at the coast. The contact between the Honomanu Basalt and the overlying Kula Volcanics is within 1,000 ft of the shore, which accounts for the steep gradient of Haipuaena Stream near the coast (Stearns and Macdonald, 1942). Streamflow is captured by five of the surface-water diversion systems (table 4). In addition, water was diverted at 1,880 ft altitude into Kolea Stream to the east from 1938 to 1960 to generate electricity.

Seven gaging stations were operated on Haipuaena Stream and two of the diversion ditches (Fontaine, 1996) (table 2, plate 1). At the Upper Kula Pipeline near 4,300 ft altitude, gaging station 5310 recorded the diverted flow and gaging station 5311 recorded streamflow past the diversion. These two records were added together to obtain the total flow at this altitude (0.97 Mgal/d) and the estimated average annual base flow (0.14 Mgal/d) for 1947–67 (fig. 15J). Three gaging stations measured flow for less than a year on three stream branches at about 2,900 ft altitude. Streamflow diverted into Kolea Stream was measured at gaging station 5350. This record was added to the streamflow record from gaging station 5360 (1,512 ft altitude) upstream of Spreckels Ditch to obtain a record of the total streamflow (table 2) and a base-flow estimate at this altitude (fig. 15J). The base-flow estimates indicate that the average annual gains from ground water are 2.5 Mgal/d between 4,300 ft and 1,500 ft altitude.

Streamflow measurements were also made on two occasions along several stream sections (table 13, plate 1). Measurements were made some time in the 1920's between 2,860 and 1,510 ft altitude that show continuous gains totaling about 0.9 Mgal/d (written commun. from J.H. Hofmann to J.H. Foss, November 17, 1932 in USGS Hawaii District files). Streamflow data from gaging stations 5360 and 5320 on two dates in 1962 and 1965 confirm this pattern (table 13). Measurements were also made on October 13, 1932 between 2,860 ft and 2,500 ft altitude during low base-flow conditions (table 13). These measurements, along with concurrent records from gaging stations, show a gain of about 0.1

Mgal/d in this short reach of the main branch of Haipuaena Stream (Hofmann, 1934). Overall, Haipuaena Stream appears to gain water continuously upstream of 1,500 ft altitude from at least as high as 4,300 altitude. EMI records from March 1928 show that the stream was dry at about 500 ft altitude indicating no gain in flow downstream of the lowest diversion system at about 900 ft altitude (table 10). A water budget was not estimated for this subbasin.

## **Streamflow**

Estimates of streamflow and base flow are based on streamflow records of varying length and from different times. The error associated with comparing these records is not considered significant because the average annual values used in the comparisons are expected to be within about 10 percent of the true value in most cases. A statistical analysis of five streamflow records, each with more than 60 years of record, shows that the average annual discharge for any 10-year period within that record has a standard error of 12 percent when compared with the whole record (Fontaine, 1996). When the length of the subset is increased to a 50-year period, the standard error only improves to 5 percent. Thirty nine of the streamflow records for the study area are equal to or greater than 10 years long.

For this study, the length of the period of record at each gaging station was determined to be unimportant by comparing each record to three reference records from the study area. The three longest streamflow records, 5080 (73 years), 5180 (76 years), and 5870 (85 years) were chosen as reference records. For each other individual record, a time period equal to the length of that record was chosen. A subset of a reference record was then selected from this same time period and the average flow during that time period was compared with the total reference record to estimate the ratio of flow during the subset period to the reference period. This analysis was made for all three reference records and the result was averaged to obtain a period-of-record scale factor for each of the other records. The scale factor ranged from 0.88 to 1.13 (table 2). This variability is consistent with the statistical analysis reported by Fontaine (1996). This range of accuracy is considered sufficient for the type of comparisons made in this study, and therefore, no corrections were made to any of the records to account for differences in length or period of record.

DURATION DATA VALUES ARE INTERPOLATED FROM DURATION TABLE:

DATA ARE NOT ANALYTICALLY FITTED TO A PARTICULAR STATISTICAL DISTRIBUTION,  
AND THE USER IS RESPONSIBLE FOR ASSESSMENT AND INTERPRETATION.

ADDITIONAL CONDITIONS FOR THIS RUN ARE:

STATISTICS ARE BASED ON LOGARITHMS (BASE 10).  
NUMBER OF VALUES IS REDUCED FOR EACH NEAR-ZERO OR ZERO VALUE.

NUMBER OF VALUES = 19 (NUMBER OF NEAR-ZERO VALUES = 0)

DURATION DATA VALUES ARE INTERPOLATED FROM DURATION TABLE:

DATA ARE NOT ANALYTICALLY FITTED TO A PARTICULAR STATISTICAL DISTRIBUTION,  
AND THE USER IS RESPONSIBLE FOR ASSESSMENT AND INTERPRETATION.

ADDITIONAL CONDITIONS FOR THIS RUN ARE:  
STATISTICS ARE BASED ON LOGARITHMS (BASE 10).

NUMBER OF VALUES IS REDUCED FOR EACH NEAR-ZERO OR ZERO VALUE.

NUMBER OF VALUES = 19 (NUMBER OF NEAR-ZERO VALUES = 0)

DURATION DATA VALUES ARE INTERPOLATED FROM DURATION TABLE:

DATA ARE NOT ANALYTICALLY FITTED TO A PARTICULAR STATISTICAL DISTRIBUTION,  
AND THE USER IS RESPONSIBLE FOR ASSESSMENT AND INTERPRETATION.

ADDITIONAL CONDITIONS FOR THIS RUN ARE:  
STATISTICS ARE BASED ON LOGARITHMS (BASE 10). NUMBER OF VALUES IS REDUCED FOR EACH NEAR-ZERO OR ZERO VALUE.

NUMBER OF VALUES = 19 (NUMBER OF NEAR-ZERO VALUES = 0)
