COMMISSION ON WATER RESOURCE MANAGEMENT  
Department of Land and Natural Resources

May 24 P 3:00

12-53-12 PETITION TO AMEND INTERIM INSTREAM FLOW STANDARDS

HONOMANU STREAM, EAST MAUI

Instructions: Please print in ink or type and send completed petition with attachments to the Commission on Water Resource Management, P.O. Box 621, Honolulu, Hawaii 96809. Petition must be accompanied by a non-refundable filing fee of \$25.00 payable to the Dept. of Land and Natural Resources. The Commission may not accept incomplete applications. For assistance, call the Regulation Branch at 587-0225.

1. PETITIONER

## Honomanu Stream

Honomanu Stream is one of the longest streams in the study area (8.7 mi) and headed at one of the highest altitudes (7,800 ft) (plate 1). The stream also has the most deeply incised valley in the study area (excluding Keanae Valley), nearly 1,000 ft below the upland surface at 600 ft altitude. Accordingly, the stream gradient near the coast is low compared with adjacent streams, about 470 ft/mi. Honomanu Basalt is well exposed along the valley walls and floor for 2.5 mi from the coast but upstream of this point (1,600 ft altitude) only Kula Volcanics are present (Stearns and Macdonald, 1942). Unconsolidated alluvial deposits are found as far as 3,000 to 4,000 ft upstream from the coast. Streamflow is captured by three of the surface-water diversion systems (table 4).

Honomanu Stream has never been dry at gaging station 5270 immediately upstream of the Spreckels Ditch at 1,733 ft altitude nor at gaging stations 5240, 5260, and 5250 at 2,900 ft altitude on three stream branches (table 2, plate 1). Base-flow estimates from the two long-term streamflow records on the main branch indicate that the average annual gains from ground water are about 0.6 Mgal/d between gaging station 5240 at 2,900 ft altitude and gaging station 5270 at 1,733 ft altitude (table 2, fig. 15K). Independent sets of streamflow measurements were made three times (table 14). Measurements were made some time in the 1920's between 3,030 ft and 1,733 ft altitude that show a gain of about 1.6 Mgal/d (written commun. from J.H. Hofmann to J.H. Foss, November 17, 1932 in USGS Hawaii District files). Streamflow data from August 19, 1920 confirm this pattern (table 14). A set of measurements along a 3,000-ft section between 2,900 ft and 2,500 ft altitude on October 7, 1932 shows gains of about 0.10 Mgal/d (Hofmann, 1934). As part of this study, streamflow measurements were made on June 20, 1995 between 3,050 ft altitude and the coast. These measurements show a total gain of about 1 Mgal/d upstream of 1,733 ft altitude and a minor gain downstream to about 360 ft altitude. EMI records indicate that the stream was dry in March 1928 at about 500 ft altitude (table 10). Because several waterfalls make access to the stream at 500 ft altitude difficult, this measurement was likely made at the base of the falls near 360 ft altitude. Downstream of 360 ft altitude (Honomanu 10a, plate 1, at the

base of a large waterfall), base flow decreased and the stream was dry between 90 ft and 2 ft altitude. During low-flow conditions no total gain downstream of about 1,733 ft altitude probably exists until close to sea level. Near sea level, about 1.4 Mgal/d of flow issues from several springs in the Honomanu Basalt. These springs are likely issuing from the top of the freshwater lens. The stream valley downstream of the waterfall is floored by alluvial deposits all the way to the coast so the springs could also represent streamflow which had been lost to interbedded flow reemerging near sea level.

A water budget was calculated for the 2.55-mi<sup>2</sup> area upstream of gaging station 5240 (Shade, 1999). In the water budget, 19.63 Mgal/d of rainfall and 6.05 Mgal/d of fog drip is apportioned into 7.05 Mgal/d of runoff, 3.65 Mgal/d of evapotranspiration, and 14.98 Mgal/d of recharge (table 1, fig. 6). The amount of base flow in this subbasin is only about 5 percent of the estimated recharge to the subbasin. Therefore, it appears likely that most of the recharge follows deeper ground-water flow paths and eventually discharges further downgradient offshore or at the shoreline.

## **Streamflow**

Estimates of streamflow and base flow are based on streamflow records of varying length and from different times. The error associated with comparing these records is not considered significant because the average annual values used in the comparisons are expected to be within about 10 percent of the true value in most cases. A statistical analysis of five streamflow records, each with more than 60 years of record, shows that the average annual discharge for any 10-year period within that record has a standard error of 12 percent when compared with the whole record (Fontaine, 1996). When the length of the subset is increased to a 50-year period, the standard error only improves to 5 percent. Thirty nine of the streamflow records for the study area are equal to or greater than 10 years long.

For this study, the length of the period of record at each gaging station was determined to be unimportant by comparing each record to three reference records from the study area. The three longest streamflow records, 5080 (73 years), 5180 (76 years), and 5870 (85 years) were chosen as reference records. For each other individual record, a time period equal to the length of that record was chosen. A subset of a reference record was then selected from this same time period and the average flow during that time period was compared with the total reference record to estimate the ratio of flow during the subset period to the reference period. This analysis was made for all three reference records and the result was averaged to obtain a period-of-record scale factor for each of the other records. The scale factor ranged from 0.88 to 1.13 (table 2). This variability is consistent with the statistical analysis reported by Fontaine (1996). This range of accuracy is considered sufficient for the type of comparisons made in this study, and therefore, no corrections were made to any of the records to account for differences in length or period of record.

**Table 14.** Streamflow, temperature, and specific conductance in Honomanu Stream, northeast Maui, Hawaii  
 [ft, feet; Mgal/d, million gallons per day; °C, degrees Celsius;  $\mu\text{S}/\text{cm}$ , microsiemens per centimeter; --, not determined; altitudes estimated from U.S. Geological Survey topographic maps, Keanae, Kiholoa, and Nahiku quadrangles; 1920 flow data from Hofmann; written communication from Foss, 11/17/32, in U.S. Geological Survey Hawaii District files and daily discharge data from Grover and Stewart (1924); 1932 flow data from Hofmann (1934) and daily discharge data from Grover and Carson (1935); all other data is unpublished in files of U.S. Geological Survey, Hawaii District office unless otherwise noted; Gaging station number is preceded by 16 and ends in 00]
