Instream Flow Standard Assessment Report

Island of Maui
Hydrologic Unit 6056
Wailuanui

March 2008 *PUBLIC REVIEW DRAFT*

State of Hawaii
Department of Land and Natural Resources
Commission on Water Resource Management

COVER
The mouth of Wailuanui Stream empties into Wailua Nui Bay (right center) which is generally unsuitable for recreational swimming. The hydrologic unit of Wailuanui supports the largest complex of taro cultivation in the east Maui region (center) [Google Earth, 2008].

Note: This report is intended for both print and electronic dissemination and does not include diacritical marks in spelling of Hawaiian words, names, and place names due to problems associated with its use electronically. However, Commission staff has made attempts to include diacritical marks in direct quotations to preserve accuracy.

USFWS	United States Fish and Wildlife Service (Department of the Interior)
USGS	United States Geological Survey (Department of the Interior)
WQS	Water Quality Standards
WRPP	Water Resource Protection Plan (Commission on Water Resource Management)
WTF	water treatment facility

1.0 Introduction

General Overview

The hydrologic unit of Wailuanui is located on the northeast slope of East Maui Volcano (Haleakala), which forms the eastern part of the Hawaiian island of Maui (Figure 1-3). It covers an area of 6 square miles from the upper slopes of Haleakala at 8,891 feet elevation to the sea. The topography is gently sloping except for the steep sides of the Keanae Valley walls that are nearly 1,000 feet high (Gingerich, 2005), and the slopes near the summit of Haleakala. Wailuanui Stream is 6.4 miles in length with two main tributaries, West Wailuanui and East Wailuanui. The mountain slopes of the heavily vegetated Koolau Forest Reserve feed the tributaries as they flow in a northeasterly direction to Wailua Nui Bay. Most of the catchment is made up of forest reserves which cover slopes down to about 300 feet. Wailua village is located along the coast at the mouth of Keanae Valley. Land use around the village is mainly small-scale agriculture, including taro cultivation (Gingerich, 2005). There is one unnamed spring near the mouth of the hydrologic unit. The population in Wailuanui hydrologic unit is about 449 (Coral Reef Assessment and Monitoring Program, 2007).

Current Instream Flow Standard (IFS)

The current interim instream flow standard (IFS) for Wailuanui Stream was established by way of Hawaii Administrative Rules (HAR) §13-169-44, which, in pertinent part, reads as follows:

> <u>Interim instream flow standard for East Maui</u>. The Interim Instream Flow Standard for all streams on East Maui, as adopted by the commission on water resource management on June 15, 1988, shall be that amount of water flowing in each stream on the effective date of this standard, and as that flow may naturally vary throughout the year and from year to year without further amounts of water being diverted offstream through new or expanded diversions, and under the stream conditions existing on the effective date of the standard.

The current interim IFS became effective on October 8, 1988. Streamflow was not measured on that date; therefore, the current interim IFS is not a measurable value.

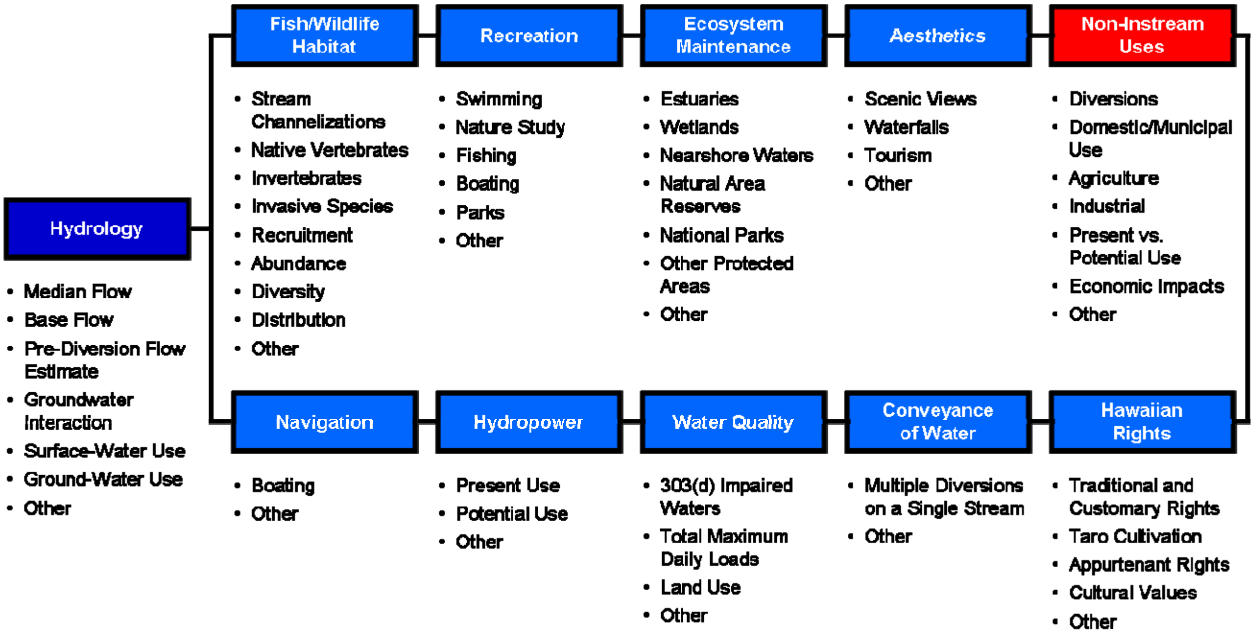
Instream Flow Standards

Under the State Water Code (Code), Chapter 174C, Hawaii Revised Statutes (HRS), the Commission on Water Resource Management (Commission) has the responsibility of establishing IFS on a stream-by-stream basis whenever necessary to protect the public interest in the waters of the State. Early in its history, the Commission recognized the complexity of establishing IFS for the State's estimated 376 perennial streams and instead set interim IFS at "status quo" levels. These interim IFS were defined as the amount of water flowing in each stream (with consideration for the natural variability in stream flow and conditions) at the time the administrative rules governing them were adopted in 1988 and 1989.

The Hawaii Supreme Court, upon reviewing the Waiahole Ditch Contested Case Decision and Order, held that such "status quo" interim IFS were not adequate to protect streams and required the Commission to take immediate steps to assess stream flow characteristics and develop quantitative interim IFS for affected Windward Oahu streams, as well as other streams statewide. The Hawaii Supreme Court also emphasized that "instream flow standards serve as the primary mechanism by which the Commission is to discharge its duty to protect and promote the entire range of public trust purposes dependent upon instream flows."

To the casual observer, IFS may appear relatively simple to establish upon a basic review of the Code provisions. However, the complex nature of IFS becomes apparent upon further review of the individual components that comprise surface water hydrology, instream uses, noninstream uses, and their interrelationships. The Commission has the distinct responsibility of weighing competing uses for a limited resource in a legal realm that is continuing to evolve. The following illustration (Figure 1-1) was developed to illustrate the wide range of information, in relation to hydrology, instream uses, and noninstream uses that should be addressed in conducting a comprehensive IFS assessment.

Figure 1-1. Information to consider in setting measurable instream flow standards.

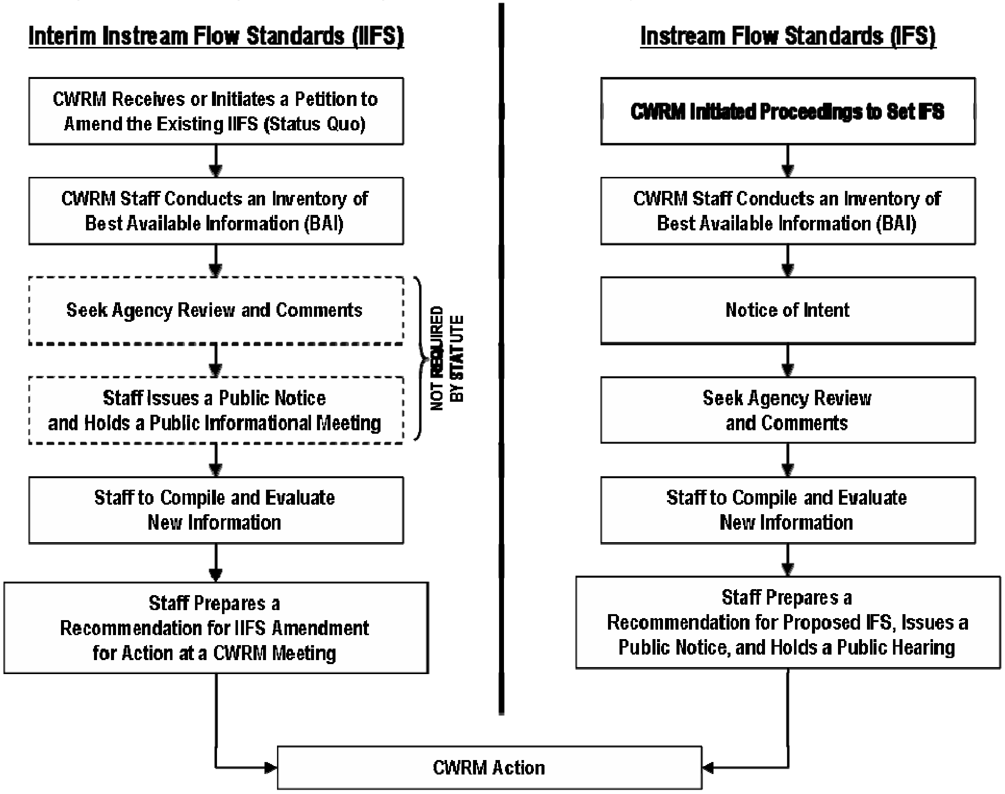


Interim Instream Flow Standard Process

The Code provides for a process to amend an interim IFS in order to protect the public interest pending the establishment of a permanent IFS. The Code, at §174C-71(2), describes this process including the role of the Commission to "weigh the importance of the present or potential instream values with the importance of the present or potential uses of water for noninstream purposes, including the economic impact of restricting such uses."

Recognizing the complexity of establishing measurable IFS, while cognizant of the Hawaii Supreme Court's mandate to designate interim IFS based on best available information under the Waiahole Combined Contested Case, the Commission at its December 13, 2006 meeting authorized staff to initiate and conduct public fact gathering. Under this adopted process (reflected in the left column of Figure 1-2), the Commission staff will conduct a preliminary inventory of best available information upon receipt of a petition to amend an existing interim IFS. The Commission staff shall then seek agency review and comments on the compiled information (compiled in an Instream Flow Standard Assessment Report) in conjunction with issuing a public notice for a public fact gathering meeting. Shortly thereafter (generally within 30 days), the Commission staff will conduct a public fact gathering meeting in, or near, the hydrologic unit of interest.

Figure 1-2. Simplified representation of the interim instream flow standard and permanent instream flow standard processes. Keys steps of the adopted interim IFS process are depicted in the left column by the boxes drawn with dotted lines.



Instream Flow Standard Assessment Report

The Instream Flow Standard Assessment Report (IFSAR) is a compilation of the hydrology, instream uses, and noninstream uses related to a specific stream and its respective surface water hydrologic unit. The report is organized in much the same way as the elements of IFS are depicted in Figure 1-1. The purpose of the IFSAR is to present the best available information for a given hydrologic unit, and to provide IFS recommendations. The IFSAR is intended to act as a living document that should be updated and revised as necessary, thus also serving as a stand-alone document in the event that the Commission receives a subsequent petition solely for the respective hydrologic unit.

Each report begins with an introduction of the subject hydrologic unit and the current IFS status. Section 2.0 is comprised of the various hydrologic unit characteristics that, both directly and indirectly, impact surface water resources. Section 3.0 contains a summary of available hydrologic information, while Sections 4.0 through 12.0 summarize the best available information for the nine instream uses as defined by the Code. Noninstream uses are summarized in Section 13.0. Maps are provided at the end of each section to help illustrate information presented within the section's text or tables. Finally, Section 14.0 provides a comprehensive listing of cited references and is intended to offer readers the opportunity to review IFSAR references in further detail.

Following the preparation of the IFSAR and initial agency and public review, information may be added to the IFSAR at any time. Dates of revision will be reflected as such. Future review of the IFSAR, by agencies and the public, will only be sought when a new petition to amend the interim (or permanent) instream flow standard is pending. Recommendations for IFS amendments shall be prepared separately as another stand-alone document. Thus, the IFSAR acts solely as a compendium of best available information and may be revised further without the need for subsequent public review following its initial preparation.

Surface Water Hydrologic Units

Early efforts to update the Commission’s Water Resource Protection Plan (WRPP) highlighted the need for surface water hydrologic units to delineate and codify Hawaii’s surface water resources. Surface water hydrologic units served as an important first-step towards improving the organization and management of surface water information that the Commission collects and maintains, including diversions, stream channel alterations, and water use.

In developing the surface water hydrologic units, the Commission staff reviewed various reports to arrive at a coding system that could meet the requirements for organizing and managing surface water information in a database environment, and could be easily understood by the general public and other agencies. For all intents and purposes, surface water hydrologic units are synonymous with watershed areas. Though Commission staff recognized that while instream uses may generally fall within a true surface drainage area, noninstream uses tend to be land-based and therefore may not always fall within the same drainage area.

In June 2005, the Commission adopted the report on surface water hydrologic units and authorized staff to implement its use in the development of information databases in support of establishing IFS (Commission on Water Resource Management, 2005a). The result is a surface water hydrologic unit code that is a unique combination of four digits. This code appears on the cover of each IFSAR above the hydrologic unit name.

Surface Water Definitions

Listed below are the most commonly referenced surface water terms as defined by the Code.

Agricultural use. The use of water for the growing, processing, and treating of crops, livestock, aquatic plants and animals, and ornamental flowers and similar foliage.

Channel alteration. (1) To obstruct, diminish, destroy, modify, or relocate a stream channel; (2) To change the direction of flow of water in a stream channel; (3) To place any material or structures in a stream channel; and (4) To remove any material or structures from a stream channel.

Continuous flowing water. A sufficient flow of water that could provide for migration and movement of fish, and includes those reaches of streams which, in their natural state, normally go dry seasonally at the location of the proposed alteration.

Domestic use. Any use of water for individual personal needs and for household purposes such as drinking, bathing, heating, cooking, noncommercial gardening, and sanitation.

Ground water. Any water found beneath the surface of the earth, whether in perched supply, dike-confined, flowing, or percolating in underground channels or streams, under artesian pressure or not, or otherwise.

Hydrologic unit. A surface drainage area or a ground water basin or a combination of the two.

Impoundment. Any lake, reservoir, pond, or other containment of surface water occupying a bed or depression in the earth's surface and having a discernible shoreline.

Instream Flow Standard. A quantity of flow of water or depth of water which is required to be present at a specific location in a stream system at certain specified times of the year to protect fishery, wildlife, recreational, aesthetic, scenic, and other beneficial instream uses.

Instream use. Beneficial uses of stream water for significant purposes which are located in the stream and which are achieved by leaving the water in the stream. Instream uses include, but are not limited to:

(1) Maintenance of fish and wildlife habitats;
(2) Outdoor recreational activities;
(3) Maintenance of ecosystems such as estuaries, wetlands, and stream vegetation;
(4) Aesthetic values such as waterfalls and scenic waterways;
(5) Navigation;
(6) Instream hydropower generation;
(7) Maintenance of water quality;
(8) The conveyance of irrigation and domestic water supplies to downstream points of diversion; and
(9) The protection of traditional and customary Hawaiian rights.

Interim instream flow standard. A temporary instream flow standard of immediate applicability, adopted by the Commission without the necessity of a public hearing, and terminating upon the establishment of an instream flow standard.

Municipal use. The domestic, industrial, and commercial use of water through public services available to persons of a county for the promotion and protection of their health, comfort, and safety, for the protection of property from fire, and for the purposes listed under the term "domestic use"

Noninstream use. The use of stream water that is diverted or removed from its stream channel and includes the use of stream water outside of the channel for domestic, agricultural, and industrial purposes.

Reasonable-beneficial use. The use of water in such a quantity as is necessary for economic and efficient utilization, for a purpose, and in a manner which is both reasonable and consistent with the state and county land use plans and the public interest.

Stream. Any river, creek, slough, or natural watercourse in which water usually flows in a defined bed or channel. It is not essential that the flowing be uniform or uninterrupted. The fact that some parts of the bed or channel have been dredged or improved does not prevent the watercourse from being a stream.

Stream channel. A natural or artificial watercourse with a definite bed and banks which periodically or continuously contains flowing water. The channel referred to is that which exists at the present time, regardless of where the channel may have been located at any time in the past.

Stream diversion. The act of removing water from a stream into a channel, pipeline, or other conduit.

Stream reach. A segment of a stream channel having a defined upstream and downstream point.

Stream system. The aggregate of water features comprising or associated with a stream, including the stream itself and its tributaries, headwaters, ponds, wetlands, and estuary.

Surface water. Both contained surface water--that is, water upon the surface of the earth in bounds created naturally or artificially including, but not limited to, streams, other watercourses, lakes, reservoirs, and coastal waters subject to state jurisdiction--and diffused surface water--that is, water occurring upon the surface of the ground other than in contained water bodies. Water from natural springs is surface water when it exits from the spring onto the earth's surface.

Sustainable yield. The maximum rate at which water may be withdrawn from a water source without impairing the utility or quality of the water source as determined by the Commission.

Time of withdrawal or diversion. In view of the nature, manner, and purposes of a reasonable and beneficial use of water, the most accurate method of describing the time when the water is withdrawn or diverted, including description in terms of hours, days, weeks, months, or physical, operational, or other conditions.

Watercourse. A stream and any canal, ditch, or other artificial watercourse in which water usually flows in a defined bed or channel. It is not essential that the flowing be uniform or uninterrupted.

2.0 Unit Characteristics

Geology

The surface geology of the vast majority of the Wailuanui hydrologic unit is characterized by permeable[1] lavas; the Hana volcanics and older Kula volcanics. The Kula volcanics consist chiefly of aa flows (lava characterized by jagged, sharp surfaces with massive, relatively dense interior), poured out at progressively longer intervals so that numerous valleys were cut between the younger lava flows (Figure 2-3). They aggregate 2,000 feet thick on the summit and thin toward the isthmus where they are only about 50 feet thick. They are fairly permeable and carry perched water[2] in the eastern end of the mountain. The younger Hana volcanics consist of very permeable thin aa and pahoehoe (lava characterized by a smooth or ropy surface with variable interior, including lava tubes and other voids), flows poured out in rapid succession. Where the flows filled valleys they have an aggregate thickness of more than 1,000 feet; elsewhere they form a veneer 10 to 200 feet thick over older lavas. The lavas are so permeable that most rain sinks into them and percolates to the older rocks. Both types of lavas carry fresh water at sea level, but it is brackish on the leeward shore. There are some dikes[3] at the head of the hydrologic unit that may confine perched water. There are also cinder cones that are valuable as an area where water penetrates the ground easily. The coastal and near-coastal section of the hydrologic unit includes alluvium (deposits of sediment), some of which is poorly drained but has ribbons of gravel from which springs may issue. There is also an area of a relatively young basalt that is highly permeable and from which springs may issue. Within the Hana volcanics, there is a small area of the Honomanu volcanic series which predates the Kula volcanics. This area contains dikes. The Honomanu volcanic series is believed to form the basement of the entire Haleakala mountain to an unknown depth below sea level. Honomanu volcanics are predominantly pahoehoe flows ranging from 10 to 75 feet thick and are very vesicular. The Honomanu basalts are extremely permeable and yield water freely.

Table 2-1. Area and percentage of surface geologic features for Wailuanui hydrologic unit.

Symbol	Name	Rock Type	Lithology	Area (mi^2)	Percent of Unit
Qa	Alluvium	Sand and gravel		0.08	1.3
Qa	Alluvium	Sand and gravel	Cobble to sand, moderately sorted	0.15	2.4
Qhn1	Hana Volcanics	Lava flows	Aa	0.19	3.2
Qhn2	Hana Volcanics	Cinder and spatter	Coarse near-vent fallout deposits	0.01	0.2

Qhn4	Hana Volcanics	Lava flows	Aa	0.45	7.5
Qhn6	Hana Volcanics	Lava flows	Aa	0.55	9.1
Qhn6	Hana Volcanics	Lava flows	Aa, highly disrupted by monoclinal flexure	0.01	0.1
Qhn6	Hana Volcanics	Lava flows	Spiny pahoehoe	0.14	2.3

---

[1] Permeability is the ease with which water passes through material. It is a factor in determining whether precipitation runs off on the surface or descends into the ground.

[2] Perched water is water confined by an impermeable or slowly permeable layer, thus accumulating in a perched water table above the general regional water table. It is generally near-surface, and may supply springs.

[3] Dikes are younger columns of lava that force their way vertically into older rocks. As they are denser than the older rock, they impede the horizontal flow of water, effectively confining the water, sometimes hundreds of feet above sea level. The water trapped in these compartments is called dike-impounded water.

Table 2 1. Area and percentage of surface geologic features for Wailuanui hydrologic unit.

Symbol	Name	Rock Type	Lithology	Area (mi^2)	Percent of Unit
Qhni	Hana Volcanics	intrusion	Dike	0.00	0.0
Qhnt	Hana Volcanics	Ash, poorly to nonindurated	Well-sorted distal fallout	0.17	2.8

QTao	Older alluvium	Sand and gravel, partly lithified	Cobbles and sand in alluvial fans	0.04	0.6
Qtc	Talus and colluvium	Sand and gravel	Includes younger alluvial fans in Haleakala Crater	0.00	0

Soils

The soils of the Wailuanui hydrologic unit are mostly well-drained. The head of the hydrologic unit consists of cinders, rock outcrops, and very stony and rough mountainous land with little soil cover. Some of the land is very steeply sloping. The middle section of the hydrologic unit is characterized by soils that developed in volcanic ash and material weathered from cinders and basic igneous rock. The slope varies greatly so the soils range from well- to poorly-drained. Because of their ability to absorb water and to transmit it rapidly, these soils are important for maintenance of ground water for domestic use and irrigation. Approximately 2/3 of the way from the head of the hydrologic unit to the sea, the hydrologic unit consists of a well-drained silty clay developed in volcanic ash. Permeability is moderately rapid, runoff is slow, and the erosion hazard is slight.

Seaward of this are several soil types, including rough mountainous land and a well-drained silty clay whose permeability is moderately rapid, runoff is slow, and the erosion hazard is slight. The rough mountainous land consists of very steep land broken by numerous intermittent drainage channels. The soil cover is relatively thin and overlies saprolite (rock that has weathered in-place but not enough to be characterized as soil; it still retains some of the characteristics of rock).

The remainder of the makai third of the hydrologic unit consists of three soil types. One is stones, boulders, and soil deposited by streams along the bottoms of gulches and on alluvial fans. Another type is described as poorly drained soils that are periodically flooded by irrigations in order to grow crops that thrive in water (e.g. wetland taro and rice). The third soil type at the coast is a well-drained silty clay developed in material weathered from basic igneous rock. Permeability is moderately rapid, runoff is slow to medium, and the erosion hazard is slight to moderate.

The U.S. Department of Agriculture’s Natural Resources Conservation Service (formerly known as the Soil Conservation Service) divides soils into hydrologic soil groups (A, B, C, and D) according to the rate at which infiltration (intake of water) occurs when the soil is wet. The higher the infiltration rate, the faster the water is absorbed into the ground and the less there is to flow as surface runoff. Group A soils have the highest infiltration rates; group D soils have the lowest. In the Wailuanui hydrologic unit, 23.5 percent of soils are group A; 32.1 percent group B; 14.1 group C; and 30.3 percent group D. The soils with the low to very low infiltration rates are near the head of the hydrologic unit, so rainwater runs off rapidly into gulches and streams. Most of the soils in the lower part of the hydrologic unit have moderate to high infiltration rates (Figure 2-4).

During the field investigation for a study published by Gingrich (USGS) in 2005, Wailuanui Stream was found to be a "gaining stream", that is, the flow increases from seepage from ground water or springs in or alongside the channel. This includes West Wailuanui and East Wailuanui Streams, both above their confluence and further upstream, above the Koolau Ditch. The hydrology of these streams is discussed in more detail in Section 3.0, Hydrology.

Table 2-2. Area and percentage of soil types for the Wailuanui hydrologic unit.

Map Unit	Description	Area (mi^2)	Percent of Unit
HwC	Honolua silty clay, 7 to 15 percent slopes	0.17	2.9
KBID	Kailua silty clay, 3 to 25 percent slopes	0.36	6.0
TR	Tropaquepts	0.10	1.7
rCl	Cinder land	0.56	9.3
rHOD	Honomanu silty clay, 5 to 25 percent slopes	0.42	7.0
rHT	Hydrandepts-Tropaquods association	1.75	29.2
rRO	Rock outcrop	0.75	12.5
rRT	Rough mountainous land	0.95	15.8
rSM	Stony alluvial land	0.07	1.2
rVS	Very stony land	0.85	14.1

Rainfall

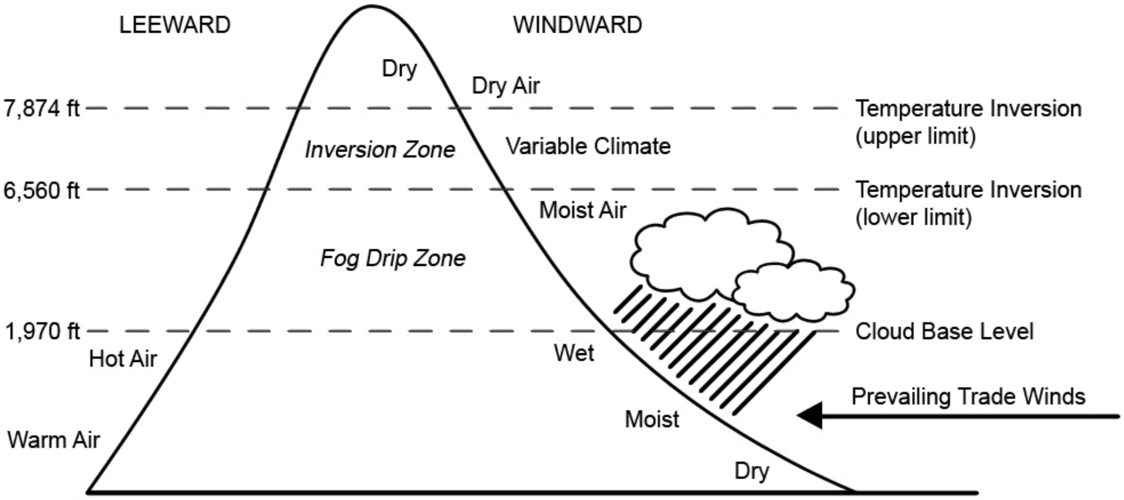
Rainfall distribution in Wailuanui is governed by the orographic[4] effect (Figure 2-1). Orographic precipitation occurs when the prevailing northeasterly trade winds lift warm air up the windward side of the mountains into higher elevations where cooler temperatures persist. As a result, frequent and heavy rainfall is observed at the windward mountain slopes. Once the moist air reaches the fog drip zone, cloud height is restricted by the temperature inversion, where temperature increases with elevation, thus favoring fog drip over rain-drop formation (Shade, 1999). Fog drip is a result of cloud-water droplets impacting vegetation (Scholl et al., 2002) and it can contribute significantly to ground water recharge. The fog drip zone on the windward side of East Maui Volcano (Haleakala) extends from the cloud base level at 1,970 feet to the lower limit of the most frequent temperature inversion base height at 6,560 feet (Giambelluca and Nullet, 1991).

A majority of the mountains in Hawaii peak in the fog drip zone. In such cases, air passes over the mountains, warming and drying while descending the leeward mountain slopes. When the mountains are at elevations higher than 6,000 feet (e.g. Haleakala), climate is affected by the presence and movement of the inversion. The temperature inversion zone typically extends from 6,560 feet to 7,874 feet. This region is influenced by a layer of moist air below and dry air above, making climate extremely variable (Giambelluca and Nullet, 1991). Above the inversion zone, the air is dry and sky is frequently clear (absence of clouds) with high solar radiation, creating an arid atmosphere with little rainfall.

---

[4] Orographic refers to influences of mountains and mountain ranges on airflow, but also used to describe effects on other meteorological quantities such as temperature, humidity, or precipitation distribution.

Figure 2-1. Orographic precipitation in the presence of mountains higher than 6,000 feet.



The hydrologic unit of Wailuanui is situated on the windward flank of the East Maui Volcano. Wailuanui receives near-daily orographic rainfall ranging from 150 inches per year at the coast to 280 inches per year near the center of the hydrologic unit. This rainfall drops down to 50-60 inches per year above the temperature inversion zone (Giambelluca et al., 1986). The high spatial variability in rainfall is evident where the mean annual rainfall decreases by about 27 inches with an average 500 feet drop in elevation in the lower half of the hydrologic unit. Rainfall is highest during the months of January to April, November and December where the mean monthly rainfall across the hydrologic unit is approximately 13-15 inches. In March, rainfall can reach as high as 36 inches in the mountains. For the rest of the year, the mean monthly rainfall ranges from 7 inches to 10 inches. The driest month is June in which less than 1 inch of rain falls at the coast.

Currently, fog drip data for east Maui are very limited. Shade (1999) used the monthly fog drip to rainfall ratios for the windward slopes of Mauna Loa on the island of Hawaii (Table 2-3) to calculate fog drip contribution to the water-budget in windward east Maui. The fog drip to rainfall ratios were estimated using 1) the fog drip zone boundaries for east Maui (Giambelluca and Nullet, 1991), and 2) an illustration that shows the relationship between fog drip and rainfall for the windward slopes of Mauna Loa, island of Hawaii (Juvik and Nullet, 1995). The contribution of fog drip in Wailuanui is calculated by multiplying the ratios with the monthly rainfall values (Giambelluca et al., 1986). Approximately 30 percent of Wailuanui lies in the fog drip zone (Figure 2-5) with an estimated average annual fog drip rate of 54 inches per year.

Table 2-3. Fog drip to rainfall ratios for the windward slopes of Mauna Loa on the island of Hawaii.

Month	Ratio (%)
January-March	13
April-June	27
July-September	67
October-November	40
December	27

Solar Radiation

Solar radiation is the sun's energy that arrives at the Earth's surface after considerable amounts have been absorbed by water vapor and gases in the Earth's atmosphere. The amount of solar radiation to reach the surface in a given area is dependent in part upon latitude and the sun's declination angle (angle from the sun to the equator), which is a function of the time of year. Hawaii's trade winds and the temperature inversion layer greatly affect solar radiation levels, the primary heat source for evaporation. High mountain ranges block moist trade-wind air flow and keep moisture beneath the inversion layer (Lau and Mink, 2006). As a result, windward slopes tend to be shaded by clouds and protected from solar radiation, while dry leeward areas receive a greater amount of solar radiation and thus have the higher levels of evaporation. In Wailuanui, estimated daily solar radiation ranges from 0 to 400 calories per square centimeter per day. Solar radiation decreases from the coast toward the mountains, where there is a zone with very low solar radiation and high rainfall. Upslope of that zone, solar radiation increases (and rainfall decreases) with elevation.

Evaporation

Evaporation is the loss of water to the atmosphere from soil surfaces and open water bodies (e.g. streams and lakes). Evaporation from plant surfaces (e.g. leaves, stems, flowers) is termed transpiration. Together, these two processes are commonly referred to as evapotranspiration, and it can significantly affect water yield because it determines the amount of rainfall that becomes streamflow. On a global scale, the amount of water that evaporates is about the same as the amount of water that falls on Earth as precipitation. However, more water evaporates from the ocean whereas on land, rainfall often exceeds evaporation. The rate of evaporation is dependent on many climatic factors including solar radiation, albedo[5], rainfall, humidity, wind speed, surface temperature, and sensible heat advection[6]. Higher evaporation rates are generally associated with greater net radiation, high wind speed and surface temperature, and lower humidity.

A common approach to estimating evaporation is to employ a relationship between potential evaporation and the available water in the hydrologic unit. Potential evaporation is the maximum rate of evaporation if water is not a limiting factor, and it is often measured with evaporation pans. In Hawaii, pan evaporation measurements were generally made in the lower elevations of the drier leeward slopes where sugarcane was grown. These data have been compiled and mapped by Ekern and Chang (1985). Unfortunately, pan evaporation data are available only for the lower slopes of west and central Maui. This makes estimating the evaporative demand on the hydrologic units in windward east Maui challenging.

Most of the drainage basins in Hawaii are characterized by a relatively large portion of the rainfall leaving the basin as evaporation and the rest as streamflow (Ekern and Chang, 1985). Based on the available pan evaporation data for Hawaii, evaporation generally decreases with increasing elevation below the temperature inversion[7] and the cloud layer (Figure 2-1). At low elevations near the coast, pan evaporation rates are influenced by sensible heat advection from the ocean (Nullet, 1987). Pan evaporation rates are enhanced in the winter by positive heat advection from the ocean, and the opposite occurs in the summer when pan evaporation rates are diminished by negative heat advection (Giambelluca and Nullet, 1992). With increasing distance from the windward coasts, positive heat advection from dry land surfaces becomes an important factor in determining the evaporative demand at the slopes (Nullet, 1987). Within

---

[5] Albedo is the proportion of solar radiation that is reflected from the Earth, clouds, and atmosphere without heating the receiving surface.

[6] Sensible heat advection refers to the transfer of heat energy that causes the rise and fall in the air temperature.

[7] Temperature inversion is when temperature increases with elevation.

the cloud layer, evaporation rates are particularly low due to the low radiation and high humidity caused by fog drip. Near the average height of the temperature inversion, evaporation rates are highly variable as they are mainly influenced by the movement of dry air from the above and moist air from below (Nullet and Giambelluca, 1990). Above the inversion, the clear sky and high solar radiation at the summits cause increased evaporation. Ekern and Chang (1985) reported evaporation increased to 50 percent more than surface oceanic rates near the Mauna Kea crest on the island of Hawaii.

Land Use

The Hawaii Land Use Commission (LUC) was established under the State Land Use Law (Chapter 205, Hawaii Revised Statutes) enacted in 1961. Prior to the LUC, the development of scattered subdivisions resulted in the loss of prime agricultural land that was being converted for residential use, while creating problems for public services trying to meet the demands of dispersed communities. The purpose of the law and the LUC is to preserve and protect Hawaii’s lands while ensuring that lands are used for the purposes they are best suited. Land use is classified into four broad categories: 1) agricultural; 2) conservation; 3) rural; and 4) urban.

Land use classification is an important component of examining the benefits of protecting instream uses and the appropriateness of surface water use for noninstream uses. While some may argue that land use, in general, should be based upon the availability of surface and ground water resources, land use classification continues to serve as a valuable tool for long-range planning purposes.

As of 2006, the LUC has classified 89.5 percent of the land in Wailuanui as conservation district and 10.5 percent as agricultural district (State of Hawaii, Office of Planning, 2006d). No lands were designated as rural or urban districts (Figure 2-6).

Land Cover

Land cover for the hydrologic unit of Wailuanui is represented by two separate 30-meter Landsat satellite images. One of the datasets is developed by the Coastal Change Analysis Program (C-CAP) and it provides a general overview of the land cover types in Wailuanui, e.g. forest, shrub land, grassland, developed areas, cultivated areas, and bare land (Table 2-4 and Figure 2-7). The second is developed by the Hawaii Gap Analysis Program (HI-GAP), which mapped the National Vegetation Classification System (NVCS) associations for each type of vegetation, creating a more comprehensive land cover dataset (Table 2-5 and Figure 2-8).

Based on the two land cover classification systems, the land cover of Wailuanui consists mainly of forested areas. Approximately half of the hydrologic unit is made up of native Ohia forests that spread throughout the intermediate slopes as part of the Koolau Forest Reserve and Waikamoi Preserve. The lower half of Wailuanui is dominated by alien forests with a mixture of alien grasslands. The upper slopes are part of the Haleakala National Park where a majority of the area is classified as bare land with little or no vegetation.

Table 2-4. C-CAP land cover classes and area distribution in Wailuanui hydrologic unit (Source: National Oceanographic and Atmospheric Agency, 2000).

Land Cover	Description	Area (mi^2)	Percent of Unit
Evergreen Forest	Areas where more than 67 percent of the trees remain green throughout the year	2.87	47.9
Bare Land	Bare soil, gravel, or other earthen material with little or no vegetation	1.35	22.5
Scrub/Shrub	Areas dominated by woody vegetation less than 6 meters in height	1.13	19
Grassland	Natural and managed herbaceous cover	0.63	10.6
Water	Open water	< 0.01	0.04
Low Intensity Developed	Constructed surface with substantial amounts of vegetated surface	< 0.01	0.02
Unconsolidated Shoreline	Material such as silt, sand, or gravel that is subject to inundation and redistribution by water	< 0.01	0.01

Table 2-5. HI-GAP land cover classes and area distribution in Wailuanui hydrologic unit (Source: HI-GAP, 2005).

Land Cover	Area (mi^2)	Percent of Unit
Very Sparse Vegetation to Unvegetated	1.54	25.7
Closed Ohia Forest (native shrubs)	1.25	20.8
Open Ohia Forest (uluhe)	1.00	16.7
Alien Forest	0.89	14.8
Native Shrubland / Sparse Ohia (native shrubs)	0.60	10.0
Alien Grassland	0.18	3.0
Uncharacterized Open-Sparse Vegetation	0.17	2.9
Closed Ohia Forest (uluhe)	0.13	2.3
Uncharacterized Forest	0.09	1.5
Uluhe Shrubland	0.05	0.9
Native Wet Cliff Vegetation	0.03	0.4
Native Dry Cliff Vegetation	0.02	0.3
Kikuyu Grass Grassland / Pasture	0.02	0.3
Native Shrubland (alien grasses)	0.01	0.2
Alien Shrubland	0.01	0.1
Deschampsia Grassland	< 0.01	0.1
Closed Kiawe - Koa Haole Forest and Shrubland	< 0.01	< 0.1
Open Ohia Forest (native shrubs)	< 0.01	< 0.1

Flood Hazard

Floods usually occur following prolonged or heavy rainfall associated with tropical storms or hurricanes. The magnitude of the flood depends on topography, ground cover, and soil conditions. Rain falling on areas with steep slopes and soil saturated from previous rainfall events tends to produce severe floods in the low-lying areas. Four types of floods exist in Hawaii. Stream or river flooding occurs when the water level in a stream rises into the flood plain. A 100-year flood refers to the probability of the flood happening once in a hundred years, or 1 percent chance of happening in a given year. Flash floods occur within a few hours after a rainfall event, or they can be caused by breaching of flood safety structures such as a dam. Flash flooding is common in Hawaii because the small drainage basins often have a short response time, typically less than an hour, from peak rainfall to peak streamflow. They are powerful and dangerous in that they can develop quickly and carry rocks, mud, and all the debris in their path down to the coast, causing water quality problems in the near-shore waters. Some floods can even trigger massive landslides, blocking off an entire stream channel. One of the major historic flash flooding events occurred on December 5-6, 1988, when rainfall was at the average annual maximum, causing significant flash flooding in many parts of Maui (Fletcher III et al., 2002). Sheet flooding occurs when runoff builds up on previously saturated ground, flowing from the high mountain slopes to the sea in a shallow sheet (Pacific Disaster Center, 2007). Coastal flooding is the inundation of coastal land areas from excessive sea level rise associated with strong winds or a tsunami.

The Federal Emergency Management Agency (FEMA) developed maps that identify the flood-risk areas in an effort to mitigate life and property losses associated with flooding events. Based on these maps, FEMA did not identify any flood-risk zones in the hydrologic unit of Wailuanui.

Drought

Drought is generally defined as a shortage of water supply that usually results from lower than normal rainfall over an extended period of time, though it can also result from human activities that increase water demand (Giambelluca et al., 1991). The National Drought Mitigation Center (State of Hawaii, Commission on Water Resource Management, 2005b) uses two types of drought definitions — conceptual and operational. Conceptual definitions help people understand the general concept of drought. Operational definitions describe the onset and severity of a drought, and they are helpful in planning for drought mitigation efforts. The four operational definitions of drought are meteorological drought, agricultural drought, hydrological drought, and socioeconomic drought. Meteorological drought describes the departure of rainfall from normal based on meteorological measurements and understanding of the regional climatology. Agricultural drought occurs when not enough water is available to meet the water demands of a crop. Hydrological drought refers to declining surface and ground water levels. Lastly, socioeconomic drought occurs when water shortage affects the general public.

Impacts of drought are complex and can be categorized into three sectors: water supply; agriculture and commerce; and environment, public health, and safety sectors (State of Hawaii, Commission on Water Resource Management, 2005b). The water supply sector encompasses urban and rural drinking water systems that are affected when a drought depletes ground water supplies due to reduced recharge from rainfall. The agriculture and commerce sector includes the reduction of crop yield and livestock sizes due to insufficient water supply for crop irrigation and maintenance of ground cover for grazing. The environmental, public health, and safety sector focuses on wildfires that are both detrimental to the forest ecosystem as well as hazardous to the public. It also includes the impact of desiccating streams, such as the reduction of instream habitats for native species.

Droughts have affected the islands throughout Hawaii’s recorded history. The most severe events of the past 15 years are associated with the El Niño phenomenon. In January 1998, the National Weather Service’s network of 73 rain gauges throughout the State did not record a single above-normal rainfall, with 36 rain gauges recoding less than 25 percent of normal rainfall (State of Hawaii, Commission on Water Resource Management, 2005b). The most recent drought occurred in 2000-2002, affecting all islands, especially the southeastern end of the State. During that period, east Maui streams were at record low levels and cattle losses projected at 9 million dollars (State of Hawaii, Commission on Water Resource Management, 2005b).

With Hawaii’s limited water resources and growing water demands, droughts will continue to adversely affect the environment, economy, and the citizens of the State. Aggressive planning is necessary to make wise decisions regarding the allocation of water at the present time, and conserving water resources for generations to come. The Hawaii Drought Plan was established in 2000 in an effort to mitigate the long-term effects of drought. One of the projects that supplemented the plan was a drought risk and vulnerability assessment of the State, conducted by researchers at the University of Hawaii (2003). In this project, drought risk areas were determined based on rainfall variation in relation to water source, irrigated area, ground water yield, stream density, landform, drainage condition, and land use. Fifteen years of historical rainfall data were used. The Standardized Precipitation Index (SPI) was used as the drought index because of its ability to assess a range of rainfall conditions in Hawaii. It quantifies rainfall deficit for different time periods, i.e. 3 months and 12 months. Results of the study for Maui are summarized in Table 2-6. Based on the 12-month SPI, the Kula region has the greatest risk to drought impact of the Maui regions because of its dependence on surface water sources, which is limited by low rainfall. The growing population in the already densely populated area further stresses the water supply.

Table 2-6. Drought risk areas for Maui (University of Hawaii, 2003).

[Drought classifications of moderate, severe, and extreme have SPI values -1.00 to -1.49, -1.50 to -1.99, and -2.00 or less, respectively]

Sector	Drought Classification (based on 12-month SPI)		
	Moderate	Severe	Extreme
Water Supply	Kula, Kahului, Wailuku, Hana, Lahaina	Kula, Hana	Kula
Agriculture and Commerce	--	--	--
Environment, Public Health and Safety	Kula	Kula	Kula

Ground Water

Ground water is an important component of streamflow as it constitutes the base flow[8] of Hawaiian streams. When ground water is withdrawn from a well, the water level in the surrounding area is lowered. Nearby wetlands or ponds may shrink or even dry up if the pumping rate is sufficiently high (Gingerich and Oki, 2000). The long-term effects of ground water withdrawal include the reduction of streamflow, which may cause a decrease in stream habitats for native species and a reduction in the amount of water available for irrigation. The interaction between surface water and ground water warrants a close look at the ground water recharge and demand within the state as well as the individual hydrologic units.

In Hawaii, ground water is replenished by recharge from rainfall, fog drip, and irrigation water that percolate through the plant root zone to the subsurface rock. Recharge can be captured in three major fresh ground water systems: 1) fresh water-lens system; 2) dike-impounded system; and 3) perched system. The fresh water-lens system provides the most important sources of ground water. It includes a lens-shaped layer of fresh water, an intermediate transition zone of brackish water, and underlying salt water. In northeast Maui, a vertically extensive fresh water-lens system can extend several hundreds or even thousands of feet below mean sea level. A dike-impounded system is found in rift zones and caldera of a volcano where low-permeability dikes compartmentalize areas of permeable volcanic rocks, forming high-level water bodies. In Maui, dikes impound water to as high as 3,300 feet above mean sea level. A perched system is found in areas where low-permeability rocks impede the downward movement of percolated water sufficiently to allow a water body to form in the unsaturated zone above the lowest water table (Gingerich and Oki, 2000).

---

[8] Base flow is the water that enters a stream from persistent, slowly varying sources (such as the seepage of ground water), and maintains stream flow between water-input events (i.e., it is the flow that remains in a stream in times of little or no rainfall).

The hydrologic unit of Wailuanui lies within the Keanae aquifer system that has an area of 55.6 square miles. A general overview of the ground water occurrence and movement in this area is described in Gingerich (1999) and illustrated in Figure 2-9. The fresh water-lens system is vertically extensive, in which the saturated zone extends from the Honomanu Basalt at sea level through the Kula Volcanics and into the Hana Volcanics. Streams that intersect the water table continue to gain water as they descend to sea level. Wells open to any part of the aquifer will reduce streamflow and discharge to sea. One of the two production wells (well numbers 5108-01 and 5108-02) located at the boundary of Wailuanui and Waiokamilo taps into the aquifer for municipal use (Figure 2-9). Detailed information for each well is specified in Table 2-7. As of July 2005, the ground water demand of the Keanae aquifer system was only 0.162 million gallons per day, which is well below the aquifer's current sustainable yield of 96 million gallons per day (State of Hawaii, Commission on Water Resource Management, 2007). Estimated total ground water recharge without accounting for fog drip contribution is 171 million gallons per day, which represents 37 percent of total rainfall (Shade, 1999).

Ground water use information is only available by island. Among the major Hawaiian islands, Maui has the second highest number of production wells following Oahu. Of the 450 productions wells in Maui, 259 are low-capacity wells with a pumping rate of less than 25 gallons per minute. Assuming all the low-capacity production wells in Maui are pumping at 1,700 gallons per day, the island-wide withdrawal rate would be 0.44 million gallons per day. The cumulative impacts of small, domestic wells become particularly important when assessing areas where municipal water is unavailable (State of Hawaii, Commission on Water Resource Management, 2007). A majority of the reported ground water use in Maui is for agriculture (53 percent) and irrigation (34 percent) (Table 2-8).

3.0 Hydrology

The Commission, under the State Water Code, is tasked with establishing instream flow standards by weighing "the importance of the present or potential instream values with the importance of the present or potential uses of water for noninstream purposes, including the economic impact of restricting such uses." While the Code outlines the instream and offstream uses to be weighed, it assumes that hydrological conditions will also be weighed as part of this equation. The complexity lies in the variability of local surface water conditions that are dependent upon a wide range of factors, including rainfall, geology, and human impacts, as well as the availability of such information. The following is a summary of general hydrology and specific hydrologic characteristics for Wailuanui Stream.

Components of streamflow. Streamflow consists of: 1) direct surface runoff in the form of overland flow and subsurface flow that rapidly returns infiltrated water to the stream; 2) ground water discharge in the form of base flow; 3) water returned from streambank storage; 4) rain that falls directly on streams; and 5) additional water, including excess irrigation water discharged into streams by humans (Oki, 2003). The amount of runoff and ground water that contribute to total streamflow is dependent on the different components of the hydrologic cycle, as well as man-made structures such as diversions and other stream channel alterations (e.g. channelizations and dams).

Surface water and ground water interaction. Streams in Hawaii can either gain or lose water at different locations depending on the geohydrologic conditions. A stream gains water when the ground water table is above the streambed. When the water table is below the streambed, the stream can lose water. Where the streambed is lined with concrete or other low-permeability or impermeable material, interaction between surface water and ground water is unlikely. Figure 3-1 presents the stream reach characteristics of Wailuanui Stream and its tributaries, East and West Wailuanui Streams, taken from Gingerich (2005). From the lower reaches of the tributaries down to the coast, Wailuanui Stream is gaining flow from ground water. Base flow estimates at the USGS stream gaging stations on East and West Wailuanui indicate that the average annual gains upstream of the Koolau Ditch at 1,300 feet are 1.65 and 2.24 million gallons per day, respectively. Between the ditch and the station on Wailuanui Stream, the stream gains about 0.79 million gallons per day (Gingerich, 1999). The upper reaches were either uncertain or unclassified probably due to inaccessibility of the stream.

Streamflow Characteristics at USGS Continuous-Record Stream Gaging Stations. One of the most common statistics used to characterize streamflow is the median value of flow in a particular time period. This statistic is also referred to as the flow at 50 percent exceedence probability, or the flow that is equaled or exceeded 50 percent of the time (TFQ_{50}). The longer the time period that is used to determine the median flow value, the more representative the value is of the average flow conditions in the stream. Median flow is typically lower than the mean or average flow because of the bias in higher flows, especially during floods, present when calculating the mean flow. The flow at the 90 percent exceedence probability (TFQ_{90}) is commonly used to characterize low flows in a stream. In Hawaii, the base flow is usually exceeded less than 90 percent of the time, and in many cases less than 70 percent of the time (Oki, 2003).

Three USGS continuous-record stream gaging stations that are no longer taking active measurements are located along Wailuanui Stream and its tributaries: 1) station 16521000 is located at 620 feet elevation in Wailuanui Stream; 2) station 16519000 is at 1,268 feet elevation in the lower reach of West Wailuanui Stream; and 3) station 16520000 is at 1,287 feet elevation in the lower reach of East Wailuanui Stream (Figure 3-1). Tables 3.1-3.3 contain information on the location and flow-duration characteristics of each station. Based on the available streamflow data, the median flows (TFQ_{50}) at stations 16521000, 16519000, and 16520000 are 1.3, 5.1, and 3.7 cubic feet per second, respectively. Even though the stream sections between the stations are gaining reaches, the median flow at station 16521000 is lower than those at the tributaries because of water being diverted at the Koolau Ditch. Base flows (TFQ$_{90}$-TFQ$_{70}$) at the stations range from 0.45-0.84, 1.5-2.9, and 1.3-2.3 cubic feet per second, respectively.

Streamflow Characteristics at Ungaged Sites. In cooperation with the Commission on Water Resource Management, the USGS conducted a study (Gingerich, 2005) to assist in determining reasonable and beneficial offstream and instream uses of water in northeast Maui. The purpose of the study was to develop methods of estimating median streamflow, total flow statistics (TFQ), and base flow statistics (BFQ) at ungaged sites where observed data is unavailable. Basin characteristics and hydrologic data for northeast Maui were collected and analyzed. One of the products of the study is a set of regression equations that can be used to estimate natural (undiverted) TFQ_{50}, BFQ_{50}, TFQ_{95}, and BFQ_{95} at gaged and ungaged sites. The subscripts indicate the percentage of time the flow, either total or base flow, is equaled or exceeded.

Streamflow statistics at continuous-record gaging stations were estimated using the regression equations and then compared to the measured flow to assess the accuracy of the regression method. The statistics are presented in Table 3-4. Note that the measured flows are different from the TFQ_{50} values in Tables 3-1 to 3-3 for the corresponding stations. That is because the measured flows in the study were adjusted to a common base period for comparison so that the differences in flow among stations reflect spatial differences in climate and basin characteristics as well as temporal differences in rainfall (Gingerich, 2005). The regression equations were then applied to a selected ungaged site (WL) at the lower reach of Wailuanui Stream (Figure 3-1). Low-flow measurements were made at the ungaged site and compared to the estimated flows. The results are presented in Table 3-5.

Table 3-4. Stream flow statistics estimated using regression equations, lower and upper confidence intervals, standard errors, measured flows, and relative errors for continuous-record sites in Wailuanui (Gingerich, 2005).
[Flows are in cubic feet per second (cfs); 90% LCL and 90% UCL is 90-percent lower and upper confidence level; Standard error is in percent; Relative error is the percent difference between the measured statistic and the estimated statistic; Measured flows in ***bold italic*** fall within the lower and upper 90-percent confidence interval]

	Relative error	< -5	< -17	-27	< -28	

A summary of the natural (undiverted) streamflow statistics are presented in Table 3-6. The flow estimates at the ungaged site were a combination of low-flow measurements and regression estimates. The flow statistics are consistent with the nature of a gaining stream in which the site nearest to the outlet of the drainage basin (station WL) has the highest flow. Effects of diversions can be assessed by comparing the flow statistics under natural conditions (Table 3-6) and those under diverted conditions (Table 3-7). Diversion at the Koolau Ditch reduced flows at station 16521000 by 84 percent. Between station 16521000 and the ungaged site (WL), a number of diversions along the stream reduced flow by as much as 85 percent. In August 2002, USGS staff observed that the taro diversion at about 200 feet elevation on Wailuanui Stream diverted all the water from the stream and then subsequently returned a significant amount of the diverted water to the channel downstream. Therefore, the diverted flow statistics at the ungaged site were estimated by assuming 50 percent of the flow was diverted even though actual measurements were not made to confirm the assumption (Gingerich, 2005).

Table 3-6. Estimates of natural (undiverted) streamflow statistics for gaged and ungaged sites in Wailuanui (Source: Gingerich, 2005).

[Flows are in cubic feet per second (cfs)]

Stream location	TFQ_{50}	BFQ_{50}	TFQ_{95}	BFQ_{95}	Source of estimate
Wailuanui lower (WL)	11	6.7	2.7	2.3	Estimate at site WL plus equation adjustment; TFQ95: Estimate at site WL plus low-flow measurements
16521000	10	6.1	2.5	2.0	Continuous record gaging station plus upper site estimates
16520000	4.4	2.5	1.0	0.90	Continuous record gaging station
16519000	3.2	2.0	0.90	0.80	Continuous record gaging station

Table 3-7. Estimates of diverted stream flow statistics and percent flow reduction for gaged and ungaged sites in Wailuanui (Source: Gingerich, 2005).

[Flows are in cubic feet per second (cfs); Percent reduction is relative to undiverted flow at the same location]

Stream location	TFQ_{50}		BFQ_{50}		TFQ_{95}		BFQ_{95}		Comments
	Estimate	Percent reduction	Estimate	Percent reduction	Estimate	Percent reduction	Estimate	Percent reduction	
Wailuanui lower (WL)	1.7	85	1.1	85	0.81	70	0.56	76	Diverted at Koolau Ditch
16521000	1.6	84	1.0	84	0.39	84	0.32	84	Diverted at Koolau Ditch

4.0 Maintenance of Fish and Wildlife Habitat

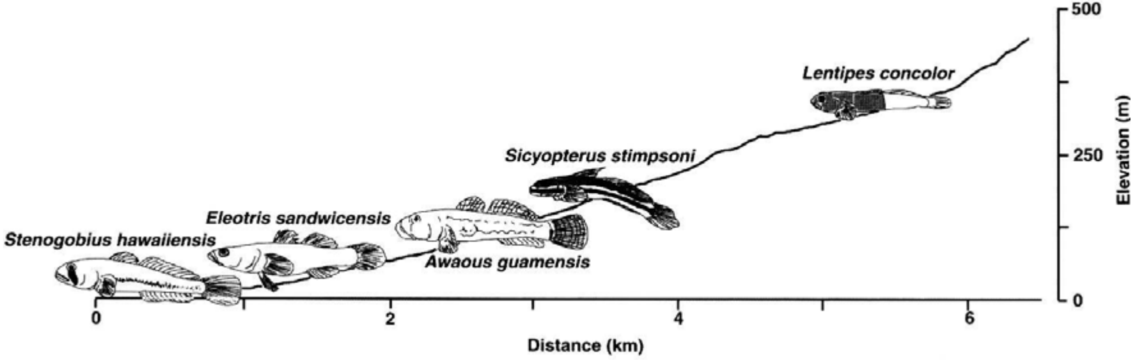
When people in Hawaii consider the protection of instream flows for the maintenance of fish habitat, their thoughts generally focus on just a handful of native species including five native fishes (four gobies and one eleotrid), two snails, one shrimp, and one prawn. Table 4-1 below identifies commonly mentioned native stream animals of Hawaii.

Table 4-1. List of commonly referred to native stream organisms. (Source: State of Hawaii, Division of Aquatic Resources, 1993).

Scientific Name	Hawaiian Name	Type
Awaous guamensis	‘O‘opu nakea	Goby
Lentipes concolor	‘O‘opu hi‘ukole (alamo‘o)	Goby
Sicyopterus stimpsoni	‘O‘opu nopili	Goby
Stenogobius hawaiiensis	‘O‘opu naniha	Goby
Eleotris sandwicensis	‘O‘opu akupa (okuhe)	Eleotrid
Atyoida bisulcata	‘Opae kala‘ole	Shrimp
Macrobrachium grandimanus	‘Opae ‘oeha‘a	Prawn
Neritina granosa	Hihiwai	Snail
Neritina vespertina	Hapawai	Snail

Hawaii’s native stream animals have amphidromous life cycles (Ego, 1956) meaning that they spend their larval stages in the ocean (salt water), then return to fresh water streams to spend their adult stage and reproduce. Newly hatched fish larvae are carried downstream to the ocean where they become part of the planktonic pool in the open ocean. The larvae remain at sea from a few weeks to a few months, eventually migrating back into a fresh water stream as juvenile *hinana*, or postlarvae (Radtke, R.L. et al., 1988). Once back in the stream the distribution of the five native fish species are largely dictated by their climbing ability (Nishimoto and Kuamoo, 1991) along the stream’s longitudinal gradient. This ability to climb is made possible by a fused pelvic fin which forms a suction disk. *Eleotris sandwicensis* lacks fused pelvic fins and is mostly found in lower stream reaches. *Stenogobius hawaiiensis* has fused pelvic fins, but lacks the musculature necessary for climbing (Nishimoto and Kuamoo, 1997). *Awaous guamensis* and *Sicyopterus stimpsoni* are able to ascend moderately high waterfalls (less than ~20 meters) (Fitzsimons and Nishimoto, 1990), while *Lentipes concolor* has the greatest climbing ability and has been observed at elevations higher than 3,000 feet (Fitzsimons and Nishimoto, 1990) and above waterfalls more than 900 feet in vertical height (Englund and Filbert, 1997). Figure 4-1 illustrates the elevational profile of these native fresh water fishes.

Figure 4-1. Elevational profile of a terminal-estuary stream on the Big Island of Hawaii (Hakalau Stream). (Source: McRae, 2007, and adapted with permission from Nishimoto and Kuamoo, 1991).



The maintenance, or restoration, of stream habitat requires an understanding of and the relationships between the various components that impact fish and wildlife habitat, and ultimately, the overall viability of a desired set of species. These components include, but are not limited to, species distribution and diversity, species abundance, predation and competition among native species, similar impacts by alien species, obstacles to migration, water quality, and streamflow. The Commission does not intend to delve into the biological complexities of Hawaiian streams, but rather to present basic evidence that conveys the general health of the subject stream. The biological aspects of Hawaii’s streams have an extensive history, and there is a wealth of knowledge which continues to grow and improve.

One of the earliest statewide stream assessments was undertaken by the Commission in cooperation with the National Park Service’s Hawaii Cooperative Park Service Unit. The 1990 Hawaii Stream Assessment (HSA) brought together a wide range of stakeholders to research and evaluate numerous stream-related attributes (e.g., hydrology, diversions, gaging, channelizations, hydroelectric uses, special areas, etc.). The HSA specifically focused on the inventory and assessment of four resource categories: 1) aquatic; 2) riparian; 3) cultural; and 4) recreational. Though no fieldwork was conducted in its preparation, the HSA involved considerable research and analysis of existing studies and reports. The data were evaluated according to predefined criteria and each stream received one of five ranks (outstanding, substantial, moderate, limited, and unknown). Based on the stream rankings, the HSA offered six different approaches to identifying candidate streams for protection.

Due to the broad scope of the HSA’s inventory and assessment, it continues to provide a valuable information base for the Commission’s Stream Protection and Management Program and will continue to be referred to in various sections of this report. For Wailuanui Stream, the aquatic resources were classified as “outstanding”. Wailuanui was noted for the presence of oopu alamoo (*L. concolor*) and oopu nopili (*S. stimpsoni*), along with one other species from its defined Native Species Group Two. No species from Introduced Species Group One were identified. The HSA classification was based on five surveys, with the last one conducted in 1980.

Table 4-2. Hawaii Stream Assessment categorization of aquatic resources in Wailuanui Stream.

Category	Value	Rank
Native Species Group 1 (NG1) Four native freshwater species were classified as “indicator species” and comprised the Native Species Group One (NG1). The committee considered these species, ‘o‘opu alamo‘o (*Lentipes concolor*), ‘o ‘opu nakea (*Awaous stamineus*), ‘o‘opu nopili (*Sicyopterus stimpsoni),* and hihiwai (Neritina granosa), as representatives of potentially high quality stream ecosystems.	2	Excellent
Native Species Group 1 (NG2) The other seven native species considered more common comprised Native Species Group Two (NG2). These included two ‘o‘opu akupa (*Eleotris sandwicensis*), ‘o‘opu naniha (*Stenogobius genivittatus*), aholehole (*Kuhlia sandvicensis*), ‘ama‘ama (*Mugil cephalus*), ‘o‘pae kala‘ole (*Atyoida bisulcata*), ‘o‘pae ‘oeha‘a (*Macrobrachium grandimanus*), and hapawai (*Theodoxus vespertinus*). Presence of these species was considered to be typical of a healthy native stream ecosystem.	1	Good
Introduced Species Group One (IG1) This group included noxious, non-native stream animals that may prey upon and/or out-compete with native species. *Macrobrachium lar.* (Tahitian prawn), was not included in this group even though it may pose a threat to native stream animals because it is believed to be present in almost all Hawaiian streams.	0	
Introduced Species Group Two (IG2) This consists of the non-native species considered to be innocuous to Hawaiian streams.	0	

Surface water diversion systems can have profound effects on the availability of instream habitats for native stream fauna (fish, shrimp, and snails). The major diversion systems in northeast Maui are operated by East Maui Irrigation Co, Ltd. With a few exceptions, the diversions capture all base flow and an unknown amount of total streamflow in each stream, decreasing flow downstream of the diversion and sometimes causing streams to go dry (Gingerich and Wolf, 2005). Changes in flow volume may influence the physical and chemical properties of stream water (e.g. temperature and pH) and flow characteristics (e.g. velocity), hence altering the stream ecosystem.

In cooperation with the Commission on Water Resource Management and others, the USGS conducted a study to assess the effects of surface water diversion systems on habitat availability for native stream species in northeast Maui, Hawaii. The goal was to determine a relationship between streamflow and habitat availability using a habitat selection model. By incorporating hydrology, stream morphology, and habitat characteristics, the model simulated habitat and streamflow relations for various species and life stages (Gingerich and Wolff, 2005). The end product of the study was a set of equations that estimates the area of usable streambed habitat over a range of streamflow under natural (undiverted) and diverted conditions.

The study focused on certain native fish, snail and shrimp species found in Hawaiian streams. Three fish species of the Gobiidae family, also known as gobies, were considered: 1) alamoo (*Lentipes concolor* (Gill)); 2) nopili (*Sicyopterus stimpsoni* (Gill)); and 3) nakea (*Awaous guamensis* (Valenciennes)). One of the fresh water snail species, *Neritina granosa* (Sowerby), commonly referred to as hihiwai, and the mountain shrimp, *Atyoida bisulcata* (Randall), also known as opae kalaole or mountain opae, were also considered in the study. All the species are amphidromous in which individuals migrate between a fresh water stream and the salt water ocean, and then return to the fresh water environment once in their lifetime. The gobies of interest have a fused pelvic fin, allowing them to climb upstream.

Wailuanui Stream was one of the studied streams used to develop the equations. Stream morphology data were collected directly upstream of the Koolau Ditch at about 1,400-1,700 feet elevation (upper site), midway to the coast at about 500-600 feet (middle site), and near the coast at 10-40 feet elevation (lower site). Estimated natural and diverted median total and base flows were compiled from Gingerich (2005). Habitat availability and species abundance were quantified using snorkel surveys made during daylight hours. The lower site was evaluated for adult and juvenile nopili, adult nakea, and hihiwai. Since the adult and juvenile alamoo, and opae do not typically live in the lower reaches, they were evaluated only in the middle and upper sites. Hydrologic data were entered into the habitat simulation model to estimate the area of usable streambed habitat over a range of streamflow values.

Outputs from the habitat simulation model are presented in a series of plots (Figures 4-2 and 4-3). In general, the plots show that as streamflow increases, the area of estimated usable streambed habitat for all interested species also increases. For all species except the opae, a flow of about 1 cubic foot per second in the middle and lower sites of Wailuanui Stream will maintain at least 50 percent of the expected natural habitat and a flow of 4.2 cubic feet per second will maintain 90 percent of the expected natural habitat (Table 4-3). When 50 percent of the natural base flow is present in the stream, at least 73 percent of the expected natural habitat is available. When 90 percent of the natural base flow is present, 95-97 percent of the expected natural habitat is available. At the middle site, more streambed habitat (64-70 percent) is available for the opae than the other species under diverted conditions. A flow of about 0.61 cubic feet per second will maintain at least 50 percent of the expected natural habitat and a flow of at least 2.4 cubic feet per second will maintain 90 percent of the expected natural habitat (Table 4-4). When 50 percent of the natural base flow is present in the stream, 82-92 percent of the expected natural habitat is available.

Figure 4-2. Total estimated habitat and percent of estimated habitat relative to natural habitat at selected streamflow values in Wailuanui Stream. (Source: Gingerich and Wolff, 2005).

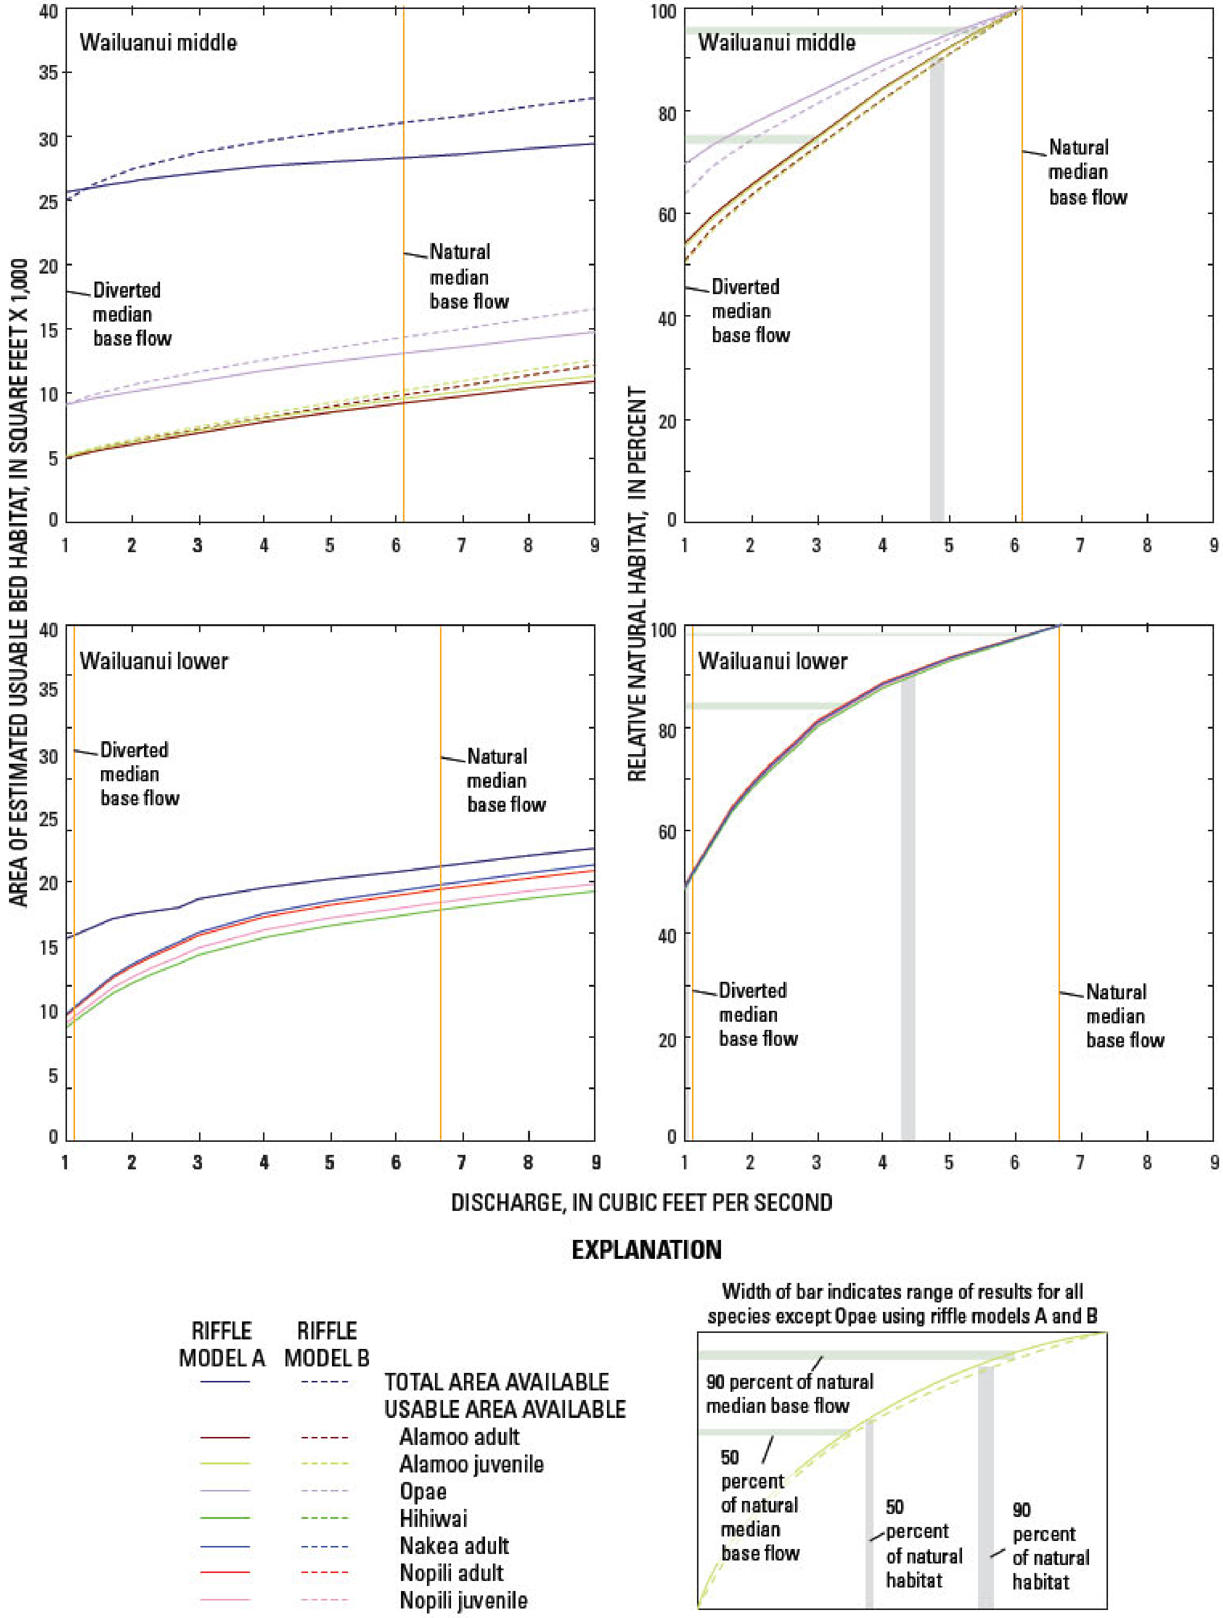


Table 4-3. Summary of modeled habitat for Wailuanui Stream (Source: Gingerich and Wolff, 2005).
[ft^3/s is cubic foot per second]

Stream site	Median base flow remaining in stream (ft^3/s)		Habitat available at diverted median base flow conditions relative to habitat available at natural median base flow condition (% of natural habitat)	Flow needed to produce habitat relative to habitat available at natural median base-flow conditions (ft^3/s)		Amount of habitat relative to habitat available at natural median base-flow conditions with flow at percentage of natural base flow	
	Diverted	Natural		50% of natural habitat	90% of natural habitat	50% of natural base flow	90% of natural base flow
lower	1.1	6.7	51 – 52	1 – 1.1	4.2 – 4.4	83 – 84	97
middle	1.0	6.1	50 – 54	.66 – 1	4.7 – 4.9	73 – 75	95 – 96

Table 4-4. Summary of modeled opae habitat for Wailuanui Stream (Source: Gingerich and Wolff, 2005).
[ft^3/s is cubic foot per second; NA, not applicable]

Stream site	Median base flow remaining in stream (ft^3/s)		Habitat available at diverted median base flow conditions relative to habitat available at natural median base flow condition (% of natural habitat)	Flow needed to produce habitat relative to habitat available at natural median base-flow conditions (ft^3/s)		Amount of habitat relative to habitat available at natural median base-flow conditions with flow at percentage of natural base flow	
	Diverted	Natural		50% of natural habitat	90% of natural habitat	50% of natural base flow	90% of natural base flow
middle	1.0	6.1	64 – 70	NA	4.1 – 4.4	82 – 84	97
middle - lower	0.2	6.7	40 – 64	.61	2.4 – 4.4	84 – 92	97 – 98

NOTE: The Commission is currently awaiting updated stream survey data for Wailuanui Stream from the State of Hawaii Division of Aquatic Resources. Figure 4-4 provides an indication of the range of survey information available as of 2006.

Another important consideration of fish and wildlife habitat is the presence of critical habitat. Under the Endangered Species Act, the U.S. Fish and Wildlife Service is responsible for designating critical habitat for threatened and endangered species. Though there are very few threatened or endangered Hawaiian species that are directly impacted by streamflow (e.g., Newcomb's snail), the availability of surface water may still have indirect consequences for other species. Based upon current designations, there are no known critical habitat areas for fish and wildlife associated with Wailuanui Stream.

In addition to critical habitat, the presence of native bird habitat should not be overlooked. Bird habitat ranges from urban environments and grasslands, to wetlands and native rainforests. Within these habitat ranges, streams provide an important source of food and water for native birds. Springs flow into loi and fishponds where native waterbirds, such as the *aukuu* (black-crowned night-heron) and the *koloa* (Hawaiian duck), search for food and locations to build a nest for their young. Streams are also valuable indicators of forest health. Since the headwaters of streams typically originate from forested areas, a forest with dense vegetation, especially along the stream bank would help prevent erosion, thus yielding cleaner fresh water for fish and wildlife as well as water demands in the lowland areas.

A diversity of native birds can be found in east Maui. Some of the notable species found in Haleakala National Park include the Hawaii (Dark-rumped) Petrel, *Nene* (Hawaiian Goose), and Common *Amakihi* (Pratt, 1993). Within Waikamoi Preserve and the northeast slope of Haleakala above 4,000 feet, the species found are the Maui Parrotbill, Maui Creeper, and *Akohekohe* (Crested Honeycreeper). The *Iiwi*, Red-billed Leiothrix, and *Apapane* are more common in Waikamoi Preserve. The U.S. Fish and Wildlife Service (n.d.) estimated the habitat ranges for native Hawaiian forest birds based on vegetation boundaries. In Wailuanui, the native forest bird habitat spans 1.3 square miles across the intermediate slopes of the hydrologic unit where Waikamoi Preserve resides (Figure 4-5).

5.0 Outdoor Recreational Activities

Water-related recreation is an integral part of life in Hawaii. Though beaches may attract more users, the value of maintaining streamflow is important to sustaining recreational opportunities for residents and tourists alike. Streams are often utilized for water-based activities, such as boating, fishing, and swimming, while offering added value to land-based activities such as camping, hiking, and hunting. Growing attention to environmental issues worldwide has increased awareness of stream and watershed protection and expanded opportunities for the study of nature; however, this must be weighed in conjunction with the growth of the eco-tourism industry and the burdens that are placed on Hawaii's natural resources.

The recreational resources of Wailuanui Stream were classified as "outstanding" by the HSA's regional recreation committee; however Wailuanui was not ranked as one of the outstanding streams statewide. The HSA identified opportunities for fishing, hunting, swimming, and scenic views related to Wailuanui. Of a total of seven experiences (opportunities categorized by a recreational opportunity spectrum), five were defined as high quality experiences (Table 5-1).

Table 5-1. Hawaii Stream Assessment survey of recreational opportunities at Wailuanui Stream by type of experience.

	Urban		Country		Semi-Natural		Natural	
	Norm	High	Norm	High	Norm	High	Norm	High
Camping

Fishing				■		■		
Hunting					■			
Swimming			■					
Boating								
Parks								
	Trail		Road		Ocean		Air	
Scenic Views				■		■		■
	Educational		Botanical					
Nature Study								

The Commission looked at available GIS data to identify recreational resources similar to the HSA's recreational assessment. Figure 5-1 illustrates the recreational opportunities related to Wailuanui. The Ke Alaloa O Maui, or Piilani, Trail is a rugged coastal 8-mile trail that stretches between Wailuanui and Heleleikeoha, or Ulaino, to the east. The trail is part of a historic King's trail that encompassed the island. Other portions of the trail are open for hiking, but the current status of this one is unknown.

According to public hunting data, Hunting Unit B on the island of Maui consists of portions of the Koolau Forest Reserve. The portion of the hunting area unit within Wailuanui is approximately 1.99 square miles or 33.3 percent of the hydrologic unit (Figure 5-2). A permit is required for the hunting of wild pigs and goats, using rifle, shotgun, bows and arrows, and dogs. Bags limits are two pigs and two goats of either sex per day, while the hunting season is open year-round on Saturdays, Sundays, and State holidays. Handguns are allowed for the hunting of pigs with or without dogs.

Since changes to streamflow and stream configurations have raised concerns regarding their impact to on-shore and near-shore activities, the Commission attempted to identify these various activities in relation to

Wailuanui Stream. A 1981 Maui Resource Atlas, prepared by the Department of Transportation's Harbors Division, inventoried coral reefs and coastal recreational activities. Looking at available GIS data, the Commission identified the following activities that were known to occur or observed at or near Wailuanui (Wailua Nui Bay): gill netting, throw netting; torch fishing, pole and line fishing, and board surfing (Figure 5-1).

In addition, John Clark, in his book *The Beaches of Maui County*, describes Wailuanui as follows:

> Wailua means 'two waters' and is the name of one of the most famous taro-producing areas on Maui. The large patches under cultivation can best be seen from the Hāna Highway where it passes inland and above the village of Wailua. This area is part of the Koʻolau district and is actually made up of two land divisions, Wailuanui and Wailuaiki. This Wailua in Koʻolau is sometimes confused with the Wailua of the Kīpahulu district, an entirely different place.
>
> Wailua Beach is composed of boulders and is unprotected from the open ocean. The alongshore currents are very strong throughout the year, no matter what the ocean conditions are. Swimming is very dangerous. Occasionally the waves are good enough for surfing, but heavy surf makes the currents worse, increasing the dangers in the ocean. The area is frequented primarily by fishermen. Keep Out signs have been posted by the County of Maui near the bottom of the access road to keep visitors from driving all the way to the shoreline, as their cars invariably get stuck at the bottom of the steep hill and there is no help available for miles. Anyone not familiar with the area should park above the signs and walk the remaining distance.

Another facet of recreation is the unique educational opportunities that streams provide for nature study. One way to approach this is to identify established study sites or nature centers that offer structured stream education programs. In lieu of these sites, the Commission considered available GIS data to identify schools in proximity to Wailuanui Stream that may utilize the stream as part of its curriculum. Keanae Elementary School, established in 1915, is the only public education facility in the area and is less than a half-mile from Wailuanui Stream, and is in fact in closer proximity to Waiokamilo Stream. However, Keanae Elementary was closed in 2005, for the time being, due to a lack of students. Local area students must now attend Hana High and Elementary (San Nicholas, 2005).

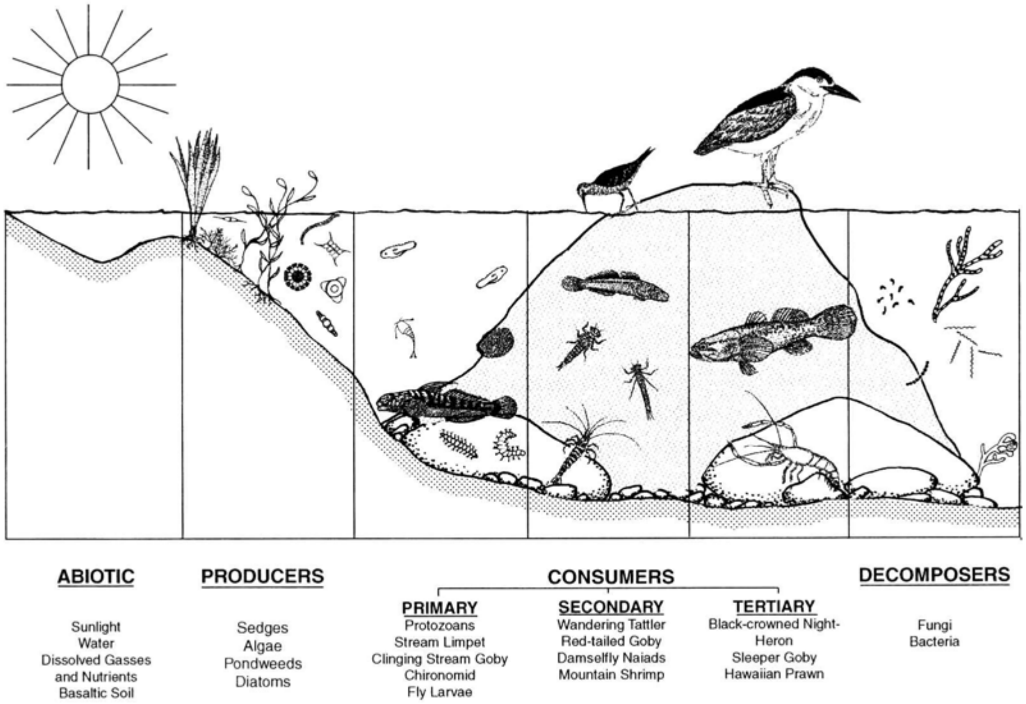
6.0 Maintenance of Ecosystems

An ecosystem can be generally defined as the complex interrelationships of living (biotic) organisms and nonliving (abiotic) environmental components functioning as a particular ecological unit. Depending upon consideration of scale, there may be a number of ecosystem types that occur along a given stream such as estuaries, wetlands, and stream vegetation, according to the State Water Code. Figure 6-1 provides a simplified ecosystem represented in a Hawaiian stream. The entire hydrologic unit, as it relates to hydrologic functions of the stream, could also be considered an ecosystem in a very broad context.

Figure 6-1. Simplified ecosystem illustrated in a Hawaiian stream. (Source: Ziegler, 2002, illustration by Keith Kruger)



The Hawaiian resource-use concept of *ahupuaa* is closely related to the Western concepts of ecosystem maintenance. Native Hawaiians were only allowed to grow crops, hunt, fish, and gather materials within the limits of their *ahupuaa*, so there was substantial incentive for them to manage and conserve the resources within their living unit. Likewise, watershed resources must be properly managed and conserved to sustain the health of the stream and the instream uses that are dependent upon it.

The riparian resources of Wailuanui Stream were classified as “substantial” by the HSA. The HSA ranked the streams according to a scoring system using six of the seven variables presented in Table 6-1. Detrimental organisms were not considered in the final ranking; however, their presence and abundance are considerable ecosystem variables.

Table 6-1. Hawaii Stream Assessment indicators of riparian resources for Wailuanui Stream.

Category	Value
Listed threatened and endangered species:: These species are generally dependent upon undisturbed habitat. Their presence is, therefore an indication of the integrity of the native vegetation. The presence of these species along a stream course was considered to be a positive attribute; with the more types of threatened and endangered species associated with a stream the higher the value of the resource. Only federally listed threatened or endangered forest or water birds that have been extensively documented within the last 15 years were included.	None
Recovery habitat: Recovery habitat consists of those areas identified by the USFWS and DLNR as essential habitat for the recovery of threatened and endangered species. Streams that have recovery habitat anywhere along their length were included.	None
Other rare organisms and communities: Many species that are candidates for endangered or threatened status have not been processed through all of the requirements of the Endangered Species Act. Also a number of plant communities associated with streams have become extremely rare. These rare organisms and communities were considered to be as indicative of natural Hawaiian biological processes as are listed threatened and endangered species.	None.
Protected areas: The riparian resources of streams that pass through natural area reserves, refuges and other protected areas are accorded special protection from degradation. Protected areas were so designated because of features other than their riparian resources. The presence of these areas along a stream, however, indicates that native processes are promoted and alien influences controlled.	Protected Headwaters to the sea
Wetlands: Wetlands are important riparian resources. They provide habitat for many species and are often important nursery areas. Because they are often extensive areas of flat land generally with deep soil, many have been drained and converted to agricultural or urban uses. Those that remain are, therefore, invaluable as well as being indicators of lack of disturbance.	None
Native forest: The proportion of a stream course flowing through native forest provides an indication of the potential “naturalness” of the quality of a stream’s watershed; the greater the percentage of a stream flowing through native forest most of which is protected in forest reserves the more significant the resource. Only the length of the main course of a stream (to the nearest 10 percent) that passes through native forest was recorded.	70%
Detrimental organisms: Some animals and plants have a negative influence on streams. Wild animals (e.g., pigs, goats, deer) destroy vegetation, open forests, accelerate soil erosion, and contaminate the water with fecal material. Weedy plants can dramatically alter the nature of a stream generally by impeding water flow. Three species, California grass, hau, and red mangrove, are considered to have the greatest influence. The presence of any of these animals or plants along a stream course was considered a potentially negative factor, while the degree of detriment is dependent on the number of species present.	2 (Hau, Pigs)

For the purpose of this section, management areas are those locales that have been identified by federal, state, county, or private entities as having natural or cultural resources of particular value. The result of various government programs and privately-funded initiatives has been a wide assortment of management areas with often common goals. Such designated areas include forest reserves, private preserves, natural area reserves, wildlife sanctuaries, national parks, historic landmarks, and so on. In Wailuanui, there are three large management areas (Haleakala National Park, Koolau Forest Reserve, and Waikamoi Preserve) which comprise over 80 percent of the hydrologic unit (Table 6-2).

Table 6-2. Management areas located within the Wailuanui hydrologic unit.

Area Name	Managed by	Area (mi^2)	Percent of Unit
Haleakala National Park	U.S. National Park Service	1.73	28.9
The Haleakala National Park was established in 1916 and currently encompasses 30,183 acres (47.09 sq. mi.) of land, of which 24,719 acres have been designated as Wilderness Area. General management policies of the National Park System focuses on the preservation of natural, cultural, and archaeological resources, while providing for public use and recreation.			
Koolau Forest Reserve	State Division of Forestry and Wildlife	2.12	35.3
The Koolau Forest Reserve, consisting of over 31,000 acres (48.45 sq. mi.) is one of eight reserves on the Island of Maui that are managed by DLNR's Division of Forestry and Wildlife. These reserves are established as multi-use land areas that incorporate various, and often competing, public uses and benefits. The management goals of the Forest Reserve System include: 1) Protect and manage forested watersheds for production of fresh water supply for public uses now and into the future; 2) Maintain biological integrity of native ecosystems; 3) Provide public recreational opportunities; and 4) Strengthen the economy by assisting in the production of high quality forest products in support of a sustainable forest industry.			
Waikamoi Preserve	The Nature Conservancy	0.96	16.1
The Waikamoi Preserve is managed by The Nature Conservancy of Hawaii (TNCH) and encompasses a total area of 5,230 acres (8.16 sq. mi.). The preserve was established in 1983 to protect the unique native biodiversity of east Maui including 63 species of rare plants and 13 species of birds (seven are endangered). The management rights of the land, owned by the Haleakala Ranch Company, were conveyed to TNCH through a permanent conservation easement. Public access is available through the National Park Service and the East Maui Watershed Partnership, and scientific research opportunities are offered through TNCH.			
Wailua Valley State Wayside	State Division of State Parks	< 0.01	< 0.1
The Wailua Valley State Wayside is managed by DLNR's Division of State Parks and provides a mauka viewpoint of Keanae Valley and Koolau Gap in Haleakala's rim, and of Wailua Village with its surrounding taro fields makai. There are no restroom facilities located at this wayside, nor are there any opportunities for recreational activities other than sightseeing.			

In addition to the individual management areas outlined above, watershed partnerships are another valuable component of ecosystem maintenance. Watershed partnerships are voluntary alliances between public and private landowners who are committed to responsible management, protection, and enhancement of their forested watershed lands. There are currently nine partnerships established statewide, three of which are on Maui. Table 6-3 provides a summary of the partnership areas, partners, and management goals of the East Maui Watershed Partnership.

Table 6-3. Watershed partnerships associated with Wailuanui hydrologic unit.

Management Area	Year Established	Total Area (mi^2)	Area (mi^2)	Percent of Unit
East Maui Watershed Partnership	1991	186.73	5.18	86.5
The East Maui Watershed Partnership (EMWP) is comprised of The Nature Conservancy, East Maui Irrigation Co. Ltd., Haleakala National Park, Haleakala Ranch Company, County of Maui Department of Water Supply, State Department of Land and Natural, Kipahulu Ohana, Natural Resources Conservation Service, and Tri-Isle Resource Conservation and Development Council of Hawaii. The management priorities of the EMWP include: 1) Watershed resource monitoring; 2) Animal control; 3) Weed control; 4) Management infrastructure; and 5) Public education and awareness programs. The EMWP has made considerable progress towards achieving their management objectives through various projects including over seven miles of fence construction and on-going maintenance, the survey and removal of invasive plant species, eradication of animal species through an expanded hunting program, implementation of runoff and stream protection measures, water quality monitoring, and successful public education and outreach campaigns.				

In 1974, the U.S. Fish and Wildlife Service (USFWS) initiated a new National Wetlands Inventory that was considerably broader in scope than an earlier 1954 inventory that had focused solely on valuable waterfowl habitat. The inventory for Hawaii was completed in 1978 and utilized a hierarchical structure in the classification of various lands. The USFWS defines wetlands as "lands transitional between terrestrial and aquatic systems where the water table is usually at or near the surface or the land is covered by shallow water" (Cowardin, L.M. et al., 1979). Approximately 27 percent of Wailuanui is classified as seasonal, non-tidal palustrine wetlands occurring in the central portion of the hydrologic unit (Table 6-4 and Figure 6-2). Palustrine wetlands are nontidal wetlands dominated by trees, shrubs, persistent emergents, emergent mosses or lichens, or wetlands that occur in tidal areas where salinity due to ocean-derived salts is below 0.5 percent.

Table 6-4. Wetland classifications for Wailuanui hydrologic unit (Source: U.S. Fish and Wildlife Service, 1978).

System Type	Class	Regime	Area (mi^2)	Percent of Unit
Palustrine	Forested, broad-leaved evergreen	Seasonal non-tidal	1.03	17.1
Palustrine	Scrub/shrub, broad-leaved evergreen	Seasonal non-tidal	0.59	9.9

A series of vegetation maps describing upland plant communities was prepared as part of a USFWS survey in 1976 to 1981 to determine the current status of native forest birds and their associated habitats. Table 6-5 and Figure 6-3 present the portion of the hydrologic unit (~1000 feet above mean sea level) that was surveyed and the degree of disturbance of native forest. Nearly one-third of the unit is predominantly native species, while another one-third of the unit is non-vegetated due to its high elevation above the tree line atop Haleakala.

Table 6-5. Distribution of native and alien plant species for Wailuanui hydrologic unit (Jacobi, 1989).

Canopy Type	Area (mi^2)	Percent of Unit
Communities totally dominated by native species of plants	1.97	32.9
Communities that have the dominant vegetation layer occupied by native species and the subdominant layer primarily occupied by exotic species	0.05	0.8
Communities dominated by introduced species but contain remnant populations of native species; no native community structure remaining	0.18	3.0
Communities that are totally dominated by introduced plants; virtually no native species remaining	0.16	2.7
Non-vegetated areas or disturbance not determined	1.89	31.6
Unknown	0.30	5.0

Based upon current designations, the hydrologic unit of Wailuanui contains critical habitat areas for three plant species (Table 6-6).

Table 6-6. Percentage of critical habitat areas for Wailuanui hydrologic unit.

Scientific Name	Common/Hawaiian Name	Description	Area (mi^2)	Percent of Unit
Argyroxiphium sandwicense ssp. Macrocephalum	ʻahinahina	Plant	1.72	28.7
Asplenium fragile var. insulare	No common name	Plant	0.26	4.3
Geranium multiflorum.1	nohoanu	Plant	1.99	33.3

The density of threatened and endangered plant species is low at elevations below 1,700 feet, while the majority of the hydrologic unit, roughly 73 percent, has a high concentration of threatened and endangered plant species at higher elevations (Table 6-7 and Figure 6-4).

Table 6-7. Density of threatened and endangered plants for Wailuanui hydrologic unit.

Density	Area (mi^2)	Percent of Unit
High concentration of threatened and endangered species	4.37	73.0
Low concentration of threatened and endangered species	1.61	27.0

A current working paper is being developed by the University of Hawaii's Economic Research Organization (UHERO), entitled *Environmental Valuation and the Hawaiian Economy*, which discusses the use of existing measures of economic performance and alternative statistical devices to provide an economic valuation of threatened environmental resources. The paper focuses on the Koolau, Oahu watershed and illustrates three categories of positive natural capital (forest resources, shoreline resources, and water resources) against a fourth category (alien species) that degrades natural capital. In the case of the Koolau forests, a benchmark level of degradation is first defined for comparison against the current value of the Koolau system. The Koolau case study considers a hypothetical major disturbance caused by a substantial increased population of pigs with a major forest conversion from native trees to the non-indigenous Miconia (*Miconia calvescens*), along with the continued "creep" of urban areas into the upper watershed (Kaiser, B. et al., n.d.).

Recognizing that in the United States, the incorporation of environmental and natural resource considerations into economic measures is still very limited, the paper provides the estimated Net Present Value (NPV) for "Koolau Forest Amenities". These values are presented in Table 6-8 below.

Table 6-8. Estimated Net Present Value (NPV) for Koolau Forest Amenities (Source: Kaiser, B. et al., n.d.).

Amenity	Estimated Net Present Value (NPV)	Important limitations
Ground water quantity	$4.57 to $8.52 billion NPV	Optimal extraction assumed.
Water quality	$83.7 to $394 million NPV	Using averted dredging cost estimates.
In-stream uses	$82.4 to $242.4 million NPV	Contingent valuation estimate for a single small fish species.
Species habitat	$487 to $1,434 million NPV	Contingent valuation estimate for a single small bird species.
Biodiversity	$660,000 to $5.5 million NPV	Average cost of listing 11 species in Koolaus.
Subsistence	$34.7 to $131 million NPV	Based on replacement value of pigs hunted.
Hunting	$62.8 to $237 million NPV	Based on fraction of hunting expenditures in state. Does not include damages from pigs to the other amenities.
Aesthetic values	$1.04 to $3.07 million NPV	Contingent valuation; Households value open space for aesthetic reasons.
Commercial harvests	$600,000 to $2.4 million NPV	Based on small sustainable extraction of koa.
Ecotourism	$1.0 to $2.98 billion NPV	Based on fraction of direct revenues to ecotourism activities.
Climate control	$82.2 million	Based on replacement costs of contribution of all tropical forests to carbon sequestration.
Estimated value of joint services:	**$7.444 to $14.032 billion**	

Following upon the results of the Koolau case study, the paper provides a brief comparison with the east Maui forests, noting the particular importance of the east Maui watershed as the single largest source of surface water in the state, home to some of the most intact and extensive native forests left in Hawaii, along with having the State's largest concentration of endangered forest birds. In both cases, the Koolaus and east Maui, the most valuable aspects of the forested areas are believed to be ecotourism, aesthetic pleasure, species habitat, water quality, and water quantity. Both regions are roughly the same size; however, the east Maui forests may have greater value due to greater species diversity and native habitat, and the County of Maui's dependence upon surface water as a drinking water source (water quality) (Kaiser, B. et al., n.d.).

7.0 Aesthetic Values

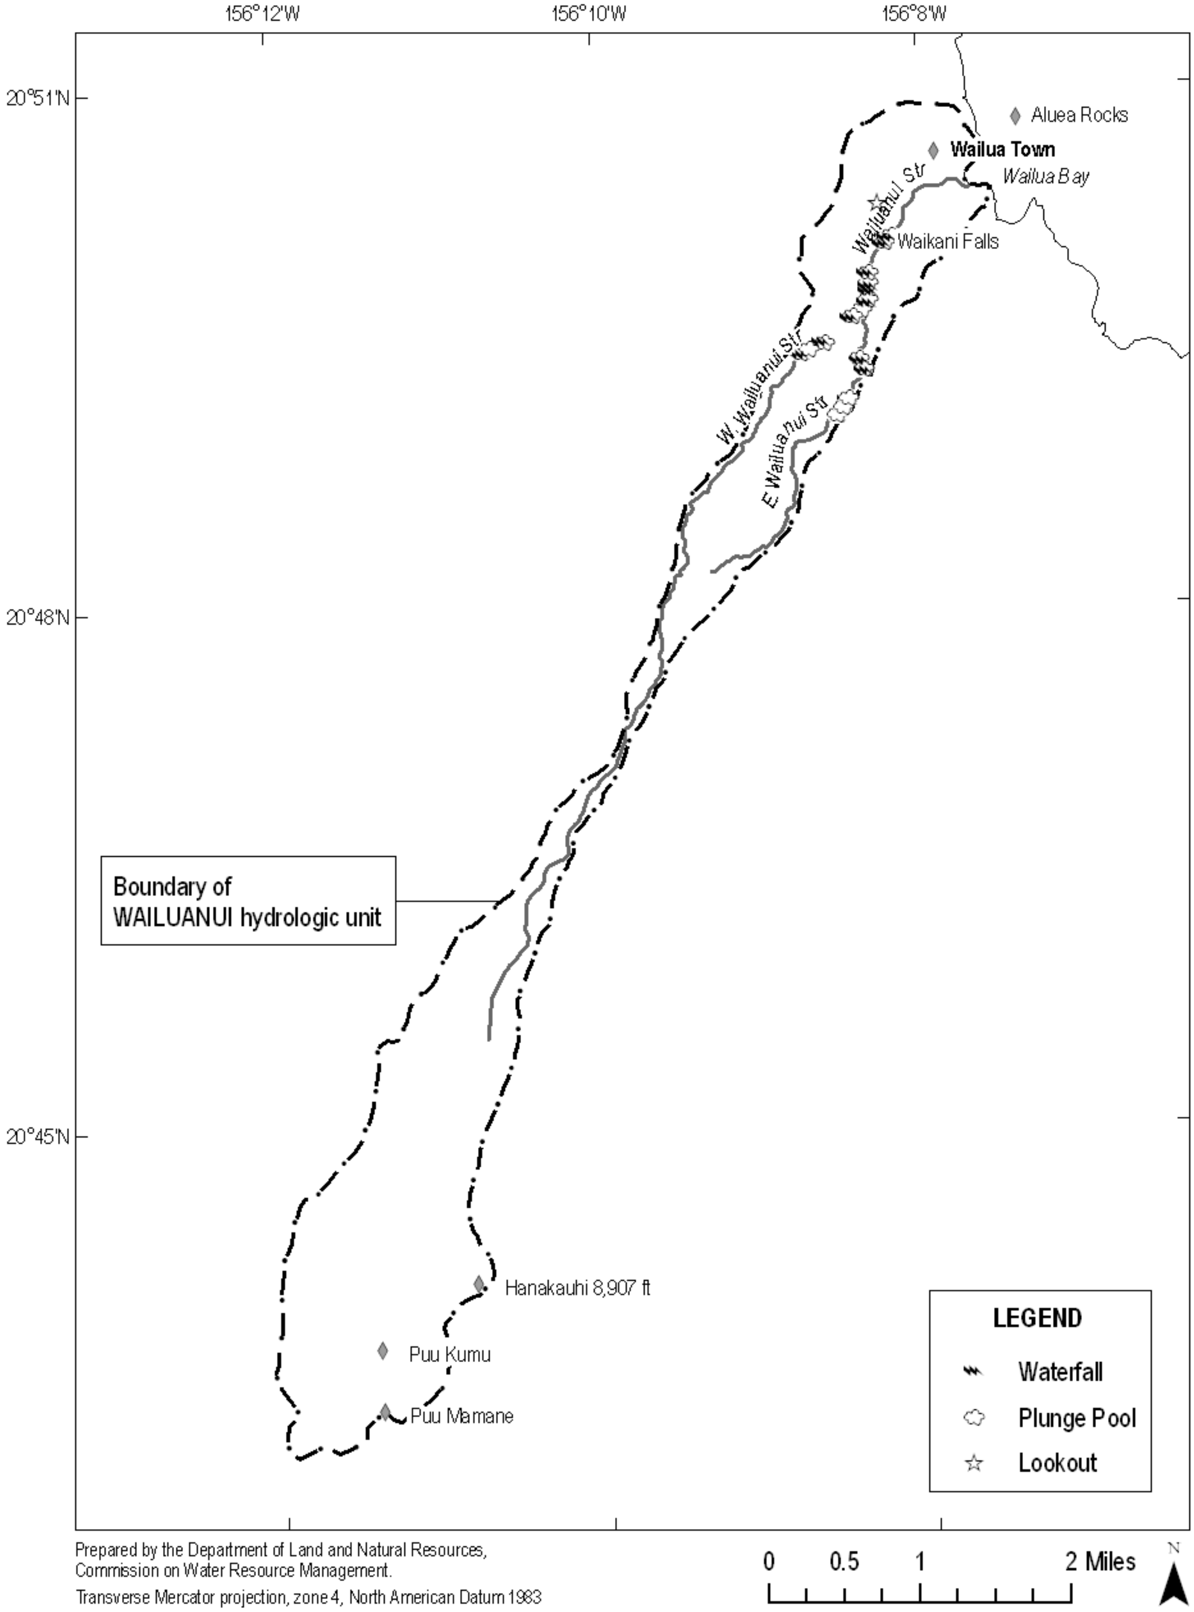
Aesthetics is a multi-sensory experience related to an individual's perception of beauty. Since aesthetics by definition is a subjective observation, a stream's aesthetic value cannot be determined quantitatively (Wilson Okamoto & Associates, Inc., 1983). However, there are certain elements, either within or surrounding a stream, which appeal to an observer's visual and audio senses, such as waterfalls and cascading plunge pools. Several assumptions were made in identifying the elements that give Wailuanui Stream a particular aesthetic quality.

The headwaters of Wailuanui Stream originate in the lush tropical forests of the Koolau Forest Reserve. Along with its tributaries West and East Wailuanui Streams, they flow northeasterly through the evergreen forests that cover a majority of the drainage basin. A number of waterfalls are located along the streams, three on each of the tributaries and six on the main channel, most of which are immediately followed by a plunge pool. Waikani Falls is among the waterfalls located in the more accessible lower reaches of Wailuanui Stream. A lookout point is located about 250 feet elevation that provides a picturesque view of the upper basin and the lower basin where Wailuanui Stream empties into Wailua Nui Bay (Figure 7-1).

In a 2007 Hawaii State Parks Survey, released by the Hawaii Tourism Authority, scenic views accounted for 21 percent of the park visits statewide, though that was a decrease from 25 percent in a 2003 survey. Other aesthetic-related motivations include viewing famous land marks (9 percent), hiking trails and walks (7 percent), guided tour stops (6 percent), and viewing of flora and fauna (2 percent). On the island of Maui, visitors preference to visit state parks for scenic views (26 percent) was second only to uses for outings with family and friends (29 percent). In comparison, residents primarily used state parks for ocean/water activities (30 percent), followed by outings with friends and family (28 percent), and then scenic views (9 percent). Overall, Maui residents were very satisfied with scenic views giving a score of 9.7 (on a scale of 1 to 10, with 10 being outstanding), with out-of-state visitors giving a score of 9.3.

Specifically for the Wailua Valley State Wayside, which is managed by DLNR's Division of State Parks, the HSA survey identified a reduction from 95,400 visitors in 2003 to 30,900 visitors in 2007. Of those utilizing the wayside in 2007, 25,000 were visitors (78,800 in 2003) and 5,900 were residents (16,600 in 2003). The large gap between use of the wayside by visitors and residents is generally attributed to preference of activities by the two groups. With the exception of hiking, residents tend to engage in more active or social activities at parks, while visitors prefer to enjoy the scenery.

Figure 7-1. Aesthetic points of interest for the Wailuanui hydrologic unit (Source: Gingerich and Wolff, 2005, Plate 1; U.S. Geological Survey, 1996).



8.0 Navigation

The State Water Code, Chapter 174C, HRS, includes navigation as one of nine identified instream uses; however, it fails to further define navigation. Navigational water use is largely defined as water utilized for commercial, and sometimes recreational, transportation. In the continental United States, this includes water used to lift a vessel in a lock or to maintain a navigable channel level. Under the provisions of the Clean Water Act, navigable waters also include wetlands (Nevada Division of Water Resources, n.d.).

Hawaii streams are generally too short and steep to support navigable uses. If recreational boating (primarily kayaks and small boats) is included under the definition of navigation, then there are only a handful of streams statewide that actually support recreational boating and even fewer that support commercial boating operations. Kauai’s Wailua River is the only fresh water waterway where large boat commercial operations exist, and no streams are believed to serve as a means for the commercial transportation of goods.

The hydrologic unit of Wailuanui is not known to support any instream uses of navigation.

9.0 Instream Hydropower Generation

The generation of hydropower is typically accomplished through instream dams and power generators; however, the relatively short lengths and flashy nature of Hawaii's streams often require water to be diverted to offstream power generators. In these "run-of-river" (i.e., utilizes water flow without dams or reservoirs) designs, water is diverted through a series of ditches, pipes, and penstocks to the powerplant, and then returned to the stream. Some designs call for the powerplant to be situated such that the drop of water level (head) exiting the plant can be sent to fields for crop irrigation instead.

Considering the definition of instream hydropower generation, there are no known true instream hydropower systems located on Wailuanui Stream, nor has the potential for hydropower generation been identified in previous reports (W.A. Hirai & Associates, Inc., 1981).

While the following information should perhaps be a part of Section 13.0, Noninstream uses, it has been included here for further consideration. Carol Wilcox, in her book *Sugar Water: Hawaii's Plantation Ditches*, described the use of surface water for generating hydroelectricity by Hawaiian Commercial and Sugar Company as follows:

> On Maui, Hawaiian Commercial and Sugar Company (HC&S) had three hydroelectric plants, all utilizing water collected by the East Maui Irrigation Company (EMI) irrigation system. The earliest, Paia Hydro, was built by Maui Agricultural Company in 1912 with a 800-kilowatt capacity. In 1923, the penstock was extended to a higher elevation, thus increasing the capacity to 1000 kilowatts. HC&S built a 4000-kilowatt hydroplant at Kaheka in 1924. In 1982, a 500-kilowatt hydroelectric powerplant was installed at the Hamakua Ditch above Paia. Located only 50 feet below the Wailoa Forebay, this "low-head" hydroplant takes water through a 36-inch pipe and discharges it into the Hamakua Ditch.
>
> Besides these three hydros, HC&S has a bagasse-powered steam powerplant at the Paia factory, and the Central Powerplant, built in 1918, located at Kahului. In 1921, electric lighting was brought to the camp houses. By the 1930s this was the largest plantation power system in Hawaii, with a 12,000-kilowatt capacity. The largest consumer was the water pumps (6000 kilowatts), then the factory (1500 kilowatts), and general uses such as lighting, feed mill, dairy, carpentry shop, refrigerator plants, machine shops, and "talkie movie houses" (400 kilowatts). Surplus power (900 kilowatts) was sold to Kahului Railroad Company and to Maui Electric Company. The Central Powerplant supplied power for all of central Maui until after World War II. In 1984, the combined total capacity of all HC&S power-generating systems was rated at 37,300 kilowatts.

The hydrologic unit of Wailuanui is not known to support any instream or noninstream generation of hydroelectricity.

10.0 Maintenance of Water Quality

The maintenance of water quality is important due to its direct impact upon the maintenance of other instream uses such as fish and wildlife habitat, outdoor recreation, ecosystems, aesthetics, and taro cultivation (traditional and customary Hawaiian rights). Water quantity may directly impact water quality, as reduction of stream flows often results in increased water temperatures, and higher flows can aid in quickly diluting stream contamination events. Surface water temperatures may fluctuate widely in response to seasonal and diurnal variations, water column depth, channel substrate, presence of riparian vegetation, and ground water influx. Surface water also differs considerably from ground water, generally exhibiting lower concentrations of total dissolved solids, chlorides, and other major ions, along with higher concentrations of suspended solids, turbidity, microorganisms, and organic forms of nutrients (Lau and Mink, 2006). Findings of a 2004 USGS National Water Quality Assessment (NAWQA) Program report identified land use, storm-related runoff, and ground water inflow as major contributors of surface water contaminants (Anthony, S.S. et al., 2004).

The State of Hawaii Department of Health (DOH), Environmental Planning Office maintains State Water Quality Standards (WQS), a requirement under the Federal Clean Water Act (CWA) of the Environmental Protection Agency (EPA). The CWA aims to keep waters safe for plants and animals to live and people to wade, swim, and fish. Water Quality Standards are the measures that states use to evaluate the physical, chemical, and biological health of their waters.

State WQS define: 1) the classification system for State surface waters, which assigns different protected uses to different water classes; 2) the specific numeric or narrative water quality criteria needed to achieve that use; and 3) a general antidegradation policy, which maintains and protects water quality for the uses defined for a class. Quantitative and qualitative data are utilized. Numeric water quality criteria have specific numeric concentrations (levels of pollutants) that must be met. Narrative water quality criteria are statements that must be met, such as "all waters shall be free of substances attributable to domestic, industrial, or other controllable sources of pollutants (State of Hawaii, Department of Health, 2004)." Conventional pollutants include nutrients and sediments. Toxic pollutants include pesticides and heavy metals. Indicator bacteria are utilized to assess bacterial levels. Biological assessments of aquatic communities are also included in the data collected.

A 2006 DOH report to the EPA integrates CWA section (§) 305(b) and §303(d). CWA §305(b) requires states to describe the overall water quality statewide and the extent to which water quality provides for the protection and propagation of a balanced population of shellfish, fish, and wildlife and allows recreational activities in and on the water.…The CWA §303(d) requires states to submit a list of Water-Quality Limited Segments, waters that do not meet state water quality standards, plus a priority ranking of listed waters, based on the severity of pollution and the uses of the waters.…The §303(d) list leads to action (State of Hawaii, Department of Health, 2006, Executive Summary)."

The sources for the 2006 integrated report are Hawaii's 2004 §303(d) list, plus readily-available data collected from any State water bodies over the preceding 6 years (State of Hawaii, Department of Health, 2006). Per §303(d), impaired waters are listed after review of "'all existing and readily available water quality-related data and information' from a broad set of data sources" (State of Hawaii, Department of Health, 2004, p.57). However, available data are not comprehensive of all the streams in the State. According to the Hawaii Administrative Rules Title 11 Chapter 54 (HAR 11-54) all State waters are subject to monitoring; however, in the most recent list published (2006), only 74 streams statewide had sufficient data for evaluation of whether exceedence of WQS occurred. Wailuanui Stream does not appear on the 2006 List of Impaired Waters in Hawaii, Clean Water Act §303(d); this includes East

Wailuanui Stream nor West Wailuanui Stream; i.e. neither tributary appears in the list. It appears that no data were available for Wailuanui Stream.

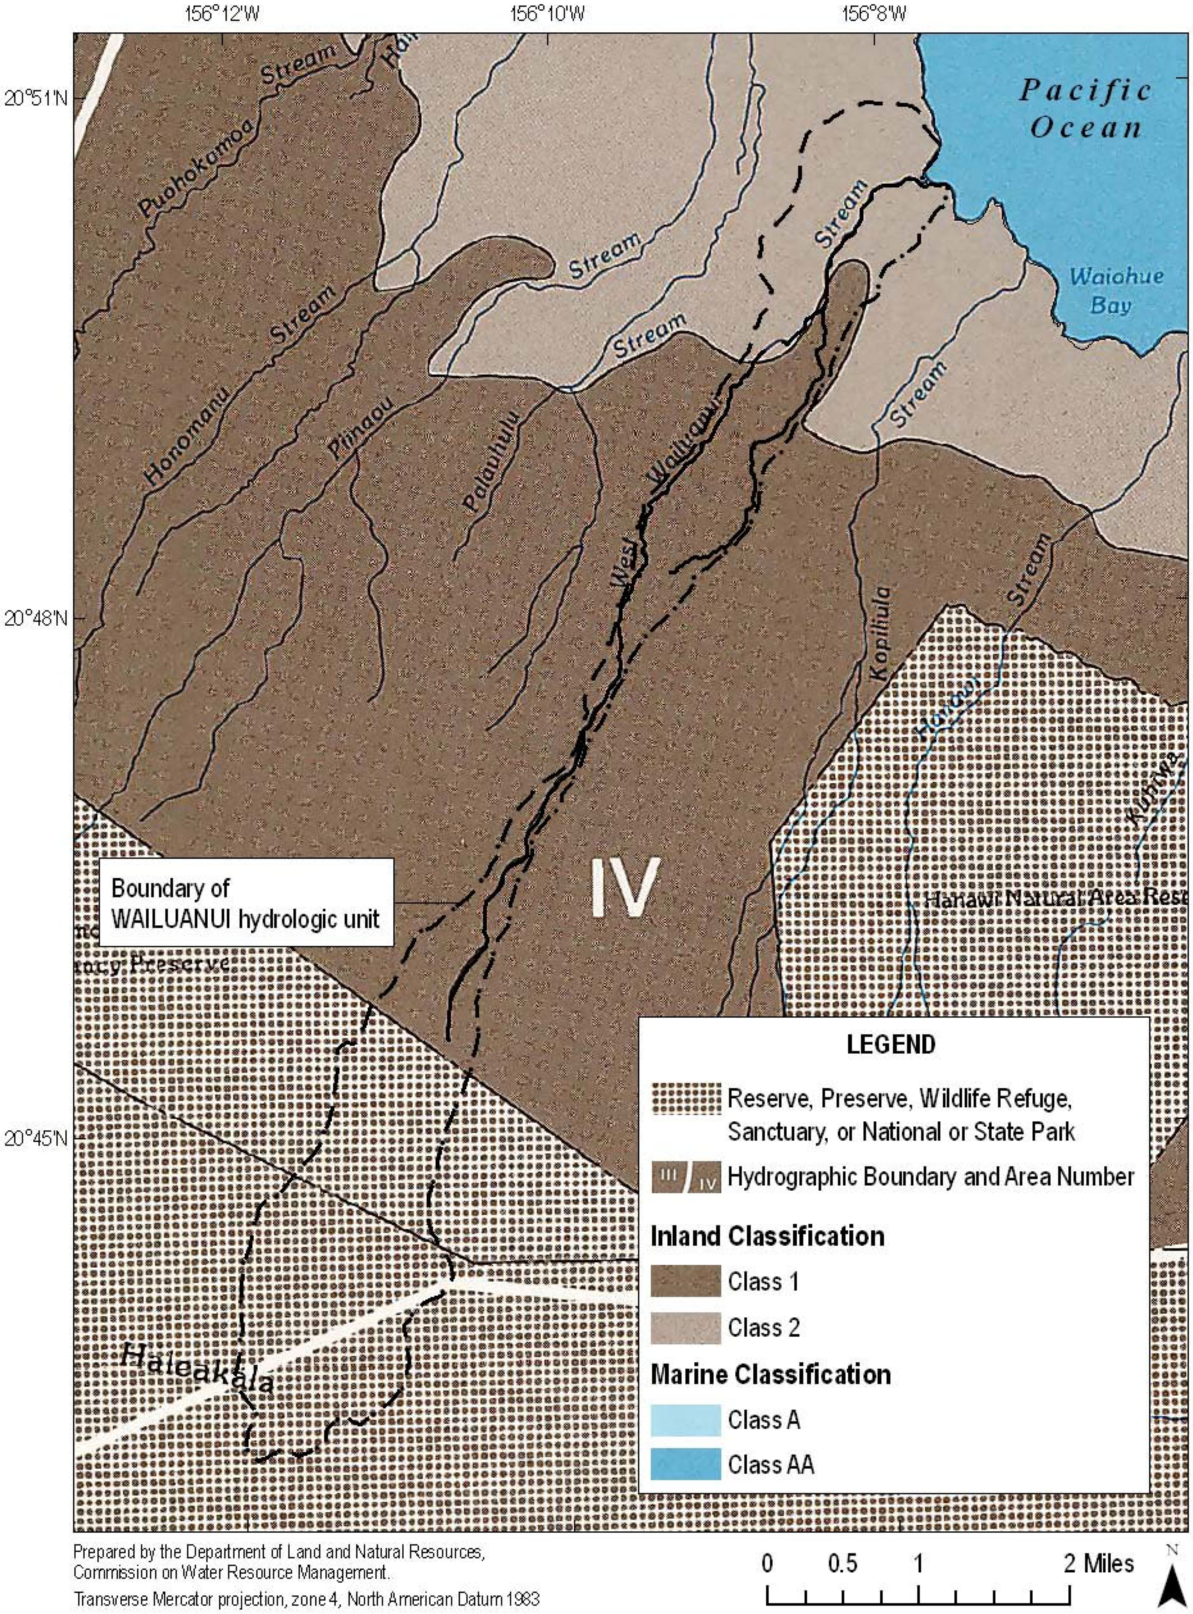
The 2006 integrated report indicates that the “current WQS require the use of enterococci as the indicator bacteria for evaluating public health risks in inland waters; however, no new data was [*sic*] available for this parameter in inland waters. [DOH Clean Water Branch] efforts have been focused on coastal areas (State of Hawaii, Department of Health, 2006, Chapter II, p.20).” The report also states: “Public health concerns may be underreported. Leptospirosis is not included as a specific water quality standard parameter. However, all fresh waters within the state are considered potential sources of Leptospirosis infection by the epidemiology section of the Hawaii State Department of Health. No direct tests have been approved or utilized to ascertain the extent of the public health threat through water sampling. Epidemiologic evidence has linked several illness outbreaks to contact with fresh water, leading authorities to issue blanket advisories for all fresh waters of the state (State of Hawaii, Department of Health, 2006, Chapter II, p.3).”

HAR 11-54 addresses WQS. It classifies inland and marine waters for purposes of applying standards and water quality parameters. Class 1 inland waters are protected to “remain in their natural state as nearly as possible with an absolute minimum of pollution from any human-caused source.” These waters are used for a number of purposes including domestic water supply, protection of native breeding stock, and baseline references from which human-caused changes can be measured. Class 2 inland waters are protected for uses such as recreational purposes, support of aquatic life, and agricultural water supplies. Waters in natural reserves, preserves, sanctuaries, refuges, national and state parks, and state or federal fish and wildlife refuges are considered Class 1 waters.

West Wailuanui Stream is Class 2 from the coast to approximately 1,380 feet elevation, excepting for a small area near the confluence with East Wailuanui Stream, where it is Class 1. Above 1,380 feet elevation, West Wailuanui Stream is Class 1. East Wailuanui Stream is Class 2 from the coast to approximately 1,000 feet elevation. Above that elevation, it is Class 1. It should be noted that there is no direct relationship between elevation and water quality.

HAR 11-54 classifies marine waters. The objective of Class AA waters is that they “remain in their natural pristine state as nearly as possible with an absolute minimum of pollution or alteration of water quality from any human-caused source or actions.” Class A waters are protected for recreational purposes and aesthetic enjoyment; and protection of fish, shellfish, and wildlife. Discharge into these waters is permitted under regulation. The marine waters at the mouth of the entire Wailuanui hydrologic unit are Class AA waters. Figure 10-1 shows the Wailuanui hydrologic unit, including inland and marine (coastal) water classifications.

Figure 10-1. Water quality standards for the Wailuanui hydrologic unit. (Source: State of Hawaii, Department of Health, 1987). The classifications are general in nature and should be used in conjunction with Hawaii Administrative Rules, Chapter 11-54, Water Quality Standards.



Prepared by the Department of Land and Natural Resources, Commission on Water Resource Management.

11.0 Conveyance of Irrigation and Domestic Water Supplies

Under the State Water Code, the conveyance of irrigation and domestic water supplies to downstream points of diversion is included as one of nine listed instream uses. The thought of the stream as a conveyance mechanism for noninstream purposes almost seems contrary to the concept of instream flow standards. However, the inclusion of this instream use is intended to ensure the availability of water to all those who may have a legally protected right to the water flowing in a stream. Of particular importance in this section is the diversion of surface water for domestic purposes. In its August 2000 decision on the Waiahole Ditch Combined Contested Case Hearing, the Hawaii Supreme Court identified domestic water use of the general public, particularly drinking water, as one of, ultimately, four trust purposes.

The Commission's records for the hydrologic unit of Wailuanui indicate that there are a total of seven registered diversions, of which three are non-East Maui Irrigation Company (EMI) diversions. Since EMI diversions transport water to locations outside of this hydrologic unit, the information is not discussed in this section; rather, it is included in Section 13.0, Noninstream uses. Of the remaining three diversions, none was declared for domestic purposes. Two diversions are utilized for irrigation of various crops and livestock, including the cultivation of taro. One diversion, declared by the Maui Department of Water Supply, diverts water for municipal use. One other registrant (File reference: VILLALON C) declared water use for 1.25 acres of taro; however, the application was considered incomplete and is not included in totals above.

This information is derived from original registration documents, much of which has not been field verified and may have changed. In 2007, the Commission contracted R.M. Towill Corporation to conduct a statewide diversion verification inventory starting with priority areas across the island of Maui. The Commission is currently awaiting the results of the field verifications and plans to include this data upon further assessment of best available information. More detailed information on each registered diversion may be found in Table 13-1 in Section 13.0, Noninstream uses.

NOTE: The Commission is currently awaiting stream diversion verification data for Wailuanui Stream from its consultants.

12.0 Protection of Traditional and Customary Hawaiian Rights

The maintenance of instream flows is important to the protection of traditional and customary Hawaiian rights, as they relate to the maintenance of stream resources (e.g., hihiwai, opae, oopu) for gathering, recreation, and the cultivation of taro. In ancient Hawaii, the islands (*moku*) were subdivided into political subdivisions, or ahupuaa, for the purposes of taxation. The term ahupuaa in fact comes from the altar (*ahu*) that marked the seaward boundary of each subdivision upon which a wooden head of a pig (*puaa*) was placed at the time of the *Makahiki* festival when harvest offerings were collected for the rain god and his earthly representative (Handy et al., 1972).

Each ahupuaa had fixed boundaries that were usually delineated by natural features of the land, such as mountain ridges, and typically ran like a wedge from the mountains to the ocean thus providing its inhabitants with access to all the natural resources necessary for sustenance. The beach, with its fishing rights, were referred to as *ipu kai* (meat bowl), while the upland areas for cultivation were called *umeke ai* (*poi* container hung in a net) (Handy et al., 1972). As noted earlier in Section 6.0, Western concepts of ecosystem maintenance and watersheds are similar to the Hawaiian concept of ahupuaa, and so the Commission's surface water hydrologic units often coincide with or overlap ahupuaa boundaries. The hydrologic unit of Wailuanui encompasses the ahupuaa of Wailua Nui, Keanae, Haiku Uka, Kalialinui, Papaanui, Kahikinui, and Nuu as shown in Figure 12-2.

Appurtenant rights are rights to the use of water utilized by (non-riparian) parcels of land at the time of their original conversion into fee simple lands: When land allotted during the 1848 Mahele was confirmed to the awardee by the Land Commission and/or when the Royal Patent was issued based on such award, the conveyance of the parcel of land carried with it the appurtenant right to water (State of Hawaii, Commission on Water Resource Management, 2007). These rights are provided for under the State Water Code, HRS §174C-101, as follows:

- Provisions of this chapter shall not be construed to amend or modify rights or entitlements to water as provided for by the Hawaiian Homes Commission Act, 1920, as amended, and by chapters 167 and 168, relating to the Molokai irrigation system. Decisions of the commission on water resource management relating to the planning for regulation, management, and conservation of water resources in the State shall, to the extent applicable and consistent with other legal requirements and authority, incorporate and protect adequate reserves of water for current and foreseeable development and use of Hawaiian home lands as set forth in section 221 of the Hawaiian Homes Commission Act.

- No provision of this chapter shall diminish or extinguish trust revenues derived from existing water licenses unless compensation is made.

- Traditional and customary rights of ahupuaa tenants who are descendants of native Hawaiians who inhabited the Hawaiian Islands prior to 1778 shall not be abridged or denied by this chapter. Such traditional and customary rights shall include, but not be limited to, the cultivation or propagation of taro on one's own kuleana and the gathering of hihiwai, opae, oopu, limu, thatch, ti leaf, aho cord, and medicinal plants for subsistence, cultural, and religious purposes.

- The appurtenant water rights of kuleana and taro lands, along with those traditional and customary rights assured by this section, shall not be diminished or extinguished by a failure to apply for or to receive a permit under this chapter. (The exercise of an appurtenant water right is still subject to the water use permit requirements of the Water Code, but there is no deadline to

> exercise that right without losing it, as is the case for correlative and riparian rights, which must have been exercised before designation of a water management area.)

In August 2000, the Hawaii Supreme Court issued its decision in the Waiahole Ditch Combined Contested Case Hearing, upholding the exercise of Native Hawaiian and traditional and customary rights as a public trust purpose. These rights are described in the Commission's 2007 *Water Resource Protection Plan – Public Review Draft*, as follows:

> Appurtenant water rights are rights to the use of water utilized by (non-riparian) parcels of land at the time of their original conversion into fee simple lands i.e., when land allotted by the 1848 Mahele was confirmed to the awardee by the Land Commission and/or when the Royal Patent was issued based on such award, the conveyance of the parcel of land carried with it the appurtenant right to water.[9] The amount of water under an appurtenant right is the amount that was being used at the time of the Land Commission award and is established by cultivation methods that approximate the methods utilized at the time of the Mahele, for example, growing wetland taro.[10] Once established, future uses are not limited to the cultivation of traditional products approximating those utilized at the time of the Mahele[11], as long as those uses are reasonable, and if in a water management area, meets the State Water Code's test of reasonable and beneficial use ("the use of water in such a quantity as is necessary for economic and efficient utilization, for a purpose, and in a manner which is both reasonable and consistent with the State and county land use plans and the public interest"). As mentioned earlier, appurtenant rights are preserved under the State Water Code, so even in designated water management areas, an unexercised appurtenant right is not extinguished and must be issued a water use permit when applied for, as long as the water use permit requirements are met [Figure 12-1].

The Hawaii Legislative Session of 2002 clarified that the Commission is empowered to "determine appurtenant rights, including quantification of the amount of water entitled to by that right," (HRS §174C-5(15)). In those cases where a Commission decision may affect an appurtenant right, it is the claimant's duty to assert the appurtenant right and to gather the information required by the Commission to rule on the claim. The Commission is currently in the process of developing a procedural manual to aid in the understanding and assembling of information to substantiate an appurtenant rights claim.

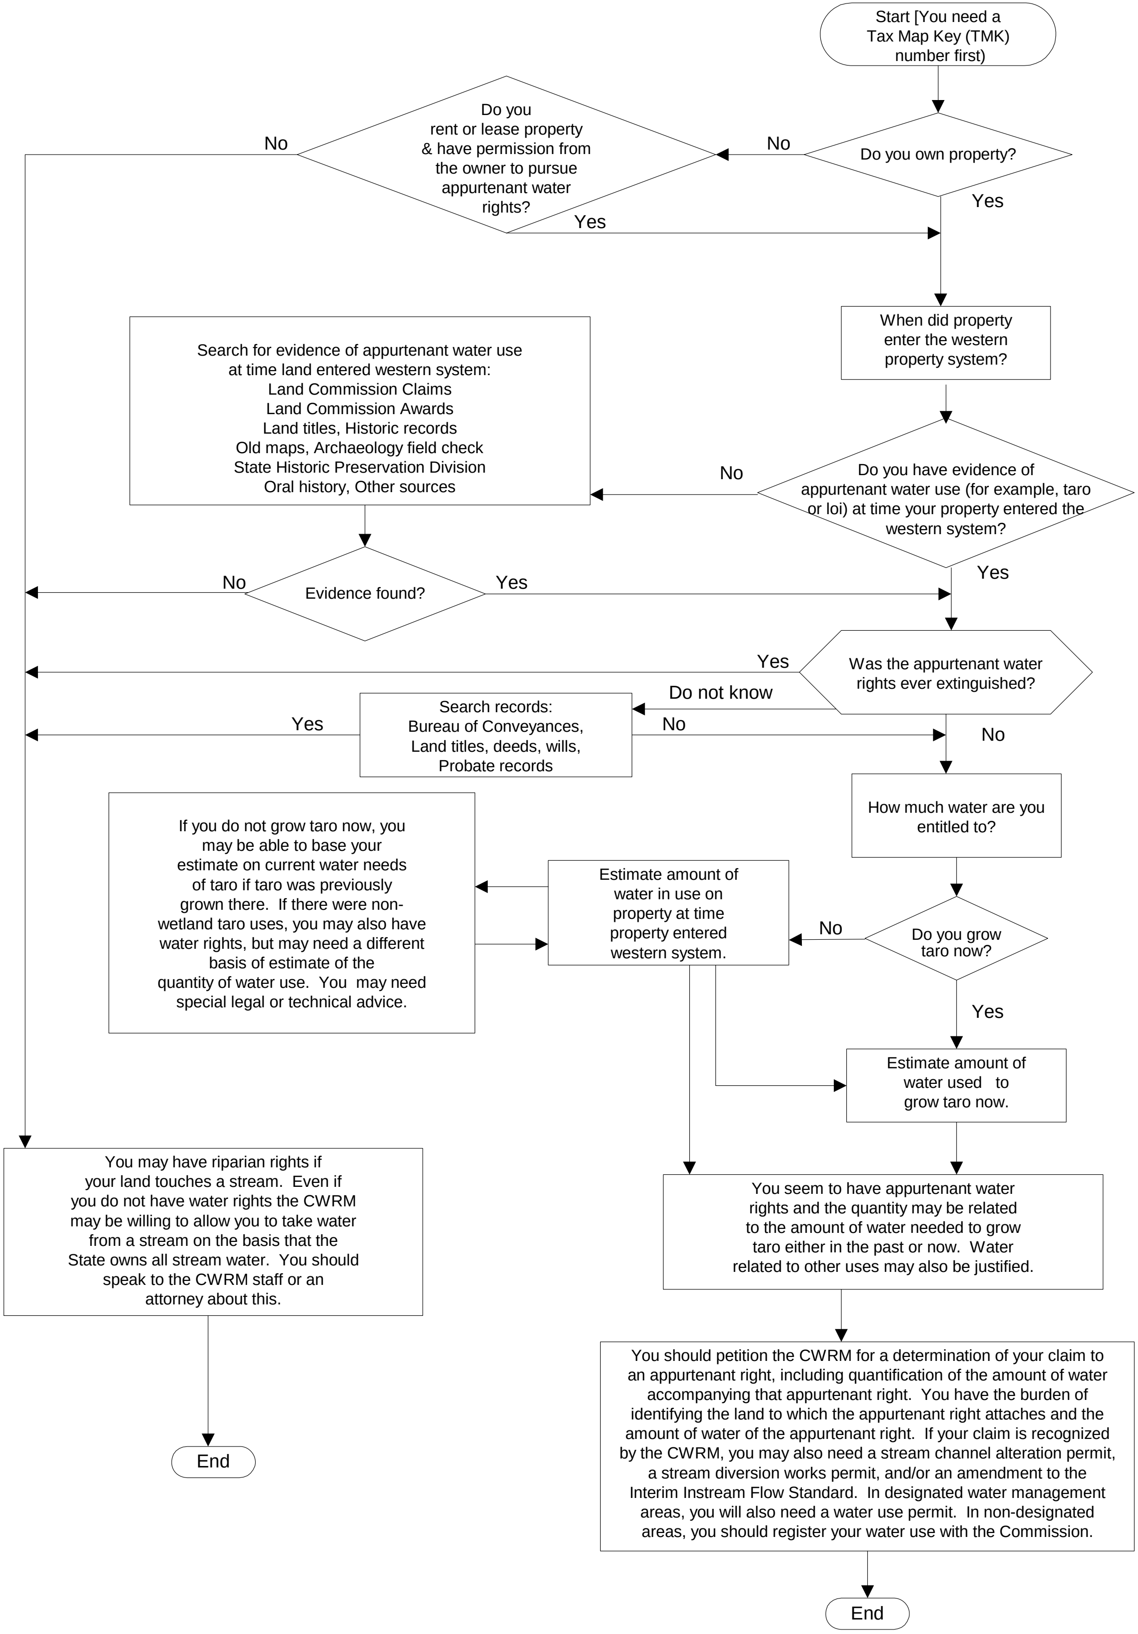
Figure 12-1. Generalized process for determining appurtenant water rights. This process is generalized and may not fully explain all possible situations. It does not apply to Hawaiian Homes Lands. If you are Native Hawaiian you may have other water rights.



The Commission conducted a cursory assessment of tax map key parcels to identify their associated Land Commission Awards, in an attempt to identify the potential for future appurtenant rights claims within the hydrologic unit of Wailuanui. In addition to original reference documents, a 2001 inventory conducted by Kumu Pono Associates, under contract by East Maui Irrigation Company, serves as a valuable reference of historical accounts of the lands of Hamakua Poko, Hamakua Loa and Koolau, Maui Hikina (east Maui). Table 12-1 presents the results of the Commission's assessment.

In accordance with the State Water Code and the Supreme Court's decision in the Waiahole Ditch Combined Contested Case Hearing, the Commission is focused on the assertion and exercise of appurtenant rights as it largely relates to the cultivation of taro. Wetland kalo or taro (*Colocasia esculenta* (L.) Schott) is an integral part of Hawaiian culture and agricultural tradition. The preferred method of wetland taro cultivation, where terrain and access to water permitted, was the construction of loi (flooded terraces) and loi complexes. These terraces traditionally received stream water via carefully engineered open channels called auwai. The auwai carried water, sometimes great distances, from the stream to the loi via gravity flow. In a system of multiple loi, water may either be fed to individual loi through separate little ditches if possible, or in the case of steeper slopes, water would overflow and drain from one loi to the next. Outflow from the loi may eventually be returned to the stream.

The loi also served other needs including the farming of subsidiary crops such as banana, sugar cane, and ti plants that were planted on its banks, and the raising of fish such as oopu, awa, and aholehole within the waters of the loi itself. At least 85 varieties of taro were collected in 1931, each of which varied in color, locale, and growing conditions. The water needs of taro under wet conditions depend upon: 1) climate; 2) location and season (weather); 3) evaporation rate; 4) soil type; 5) ground water hydrology; 5) water temperature; and 6) agronomic conditions (crop stage; planting density and arrangement; taro variety; soil amendment and fertilization regime; loi drainage scheme; irrigation system management; and weed, pest, and disease prevalence and management).

In 2002, the State Office of Hawaiian Affairs cosponsored a "No Ka Lo'i Conference", in the hopes bringing together taro farmers from around the state to share knowledge on the cultivation of taro. An outcome of the conference was an acknowledgement that farmers needed to better understand the water requirements of their taro crops to ensure and protect their water resource interests. The result of this effort was a 2007 USGS wetland kalo water use study, prepared in cooperation with the State Office of Hawaiian Affairs, which specifically examined flow and water temperature data in a total of 10 cultivation areas on four islands in Hawaii. Two of the loi (flooded terrace) complexes are located in east Maui (Wailua and Keanae).

The study reiterated the importance of water temperature in preventing root rot – according to a University of Hawaii study (1997) temperature should not exceed 78ºF (25.6ºC) yet not get so cold that it slows the growth of taro. The 2007 study, however, noted that, "although irrigation flows for kalo cultivation have been measured with varying degrees of scientific accuracy, there is disagreement regarding the amount of water used and needed for successful kalo cultivation, with water temperature recognized as a critical factor. Most studies have focused on the amount of water consumed rather than the amount needed to flow through the irrigation system for successful kalo cultivation." As a result, the study was designed to measure the throughflow of water in commercially viable loi complexes, rather than measuring the consumption of water during taro growth.

Because water requirements for taro vary with the stage of maturity of the plants, all the cultivation areas selected for the study were at approximately the same stage (i.e. near harvesting, when continuous flooding is required). Temperature measurements were made every 15 minutes for approximately 2 months. Flow measurements were collected at the beginning and the end of that period. Data were collected during the dry season (June – October), when water requirements for cooling kalo are higher. Surface water temperatures generally begin to rise in April and remain elevated through September, due to increased solar heating. Water inflow temperature was measured in 17 loi complexes, and only three had inflow temperatures rising above 27ºC (the threshold temperature above which wetland kalo is more susceptible to fungi and associated rotting diseases).

The average and median inflows from all 10 cultivation areas studied are listed in Table 12-2 below. The study indicated that the "values are consistent with previously reported inflow and are significantly higher than values generally estimated for consumption during kalo cultivation." It should also be noted that farmers were interviewed during field visits; most "believed that their supply of irrigation water was insufficient for proper kalo cultivation."

Table 12-2. Summary of water use calculated from loi and loi complexes by island, State of Hawaii (Source: Gingerich et al., 2007, Table 10).

[gad = gallons per acre per day; na = not available]

Island	Complex				Loi			
	Number	Average water use (gad)	Average windward water use (gad)	Average leeward water use (gad)	Number	Average water use (gad)	Average windward water use (gad)	Average leeward water use (gad)
Kauai	6	120,000	97,000	260,000	2	220,000	220,000	na
Oahu	5	310,000	380,000	44,000	4	400,000	460,000	210,000
Maui	6	230,000	230,000	na	na	na	na	na
Hawaii	2	710,000	710,000	na	na	na	na	na
Average of all measurements		260,000	270,000	150,000	350,000	370,000	210,000	350,000
Median of all measurements		150,000	150,000	150,000	270,000	320,000	210,000	270,000

The windward Maui areas chosen for the study were Waihee, Wailua, and Keanae. Wailua and Keanae each have numerous individual loi and loi complexes. Three of the Wailua area complexes were available for study: 1) Lakini complex, supplied through an auwai with water diverted from Hamau Stream, which in turn receives diverted water from Waiokamilo Stream; 2) Wailua complex, supplied through an auwai with water diverted from Waiokamilo Stream; and 3) Waikani complex, supplied through an auwai with water diverted from Wailuanui Stream. The loi in Keanae were treated as a single complex supplied by the Keanae Flume, which diverts water from Palauhulu Stream.

The study results are presented in Table 12-3 (discharge measurements) and Table 12-4 (water-temperature statistics).

Table 12-3. Summary of discharge measurements and areas for selected loi complexes, island of Maui (Source: Gingerich et al., 2007, Table 6).

[Mgd = million gallons per day; gad = gallons per acre per day; na = not applicable; average water use is determined by summing the averages of each complex or loi and dividing by the number of complexes or loi.]

According to a 1995 cultural landscape study prepared by Group 70 International, Inc. et al., for the County of Maui Planning Department, the Wailuanui loi complex is considerable larger than the Keanae loi complex. The Wailuanui complex also relies on three different sources of water, two of which are associated with Waiokamilo Stream and feed specific portions of the complex. Gingerich et al. (2007) refer to the two Waiokamilo-associated complexes as Wailua complex and Wailua (Lakini) complex. The third, Wailua (Waikani) complex, is approximately 2.80 acres in size and consists of 19 individual loi. Wailua (Waikani) is situated on the southeastern end of Wailuanui and is fed by a mauka diversion located at the base of Waikani Falls. According to residents, the intake was frequently prone to damage by flood conditions; however, the problem had been partially remedied by the installation of a 300-foot long buried pipeline consisting of an underwater intake located in the pool at the foot of the waterfall. The pipe empties into a partially concrete-lined auwai running adjacent to Hana Highway towards the Wailuanui complex.

Group 70 International, Inc. et al. (1995) noted the complexity of the entire Wailuanui complex, having identified 339 individual loi from a 1982 aerial photograph and also indicated that portions of the complex had been converted to rice cultivation by the early 1900s. However, several portions of the auwai that feed the Wailuanui complex are not functional and many loi have been abandoned and overtaken by vegetation.

The Commission’s records for the hydrologic unit of Wailuanui indicate that there are a total of seven registered diversions, of which three are non-EMI diversions. Of these non-EMI diversions, two registrants declared water use for taro cultivation with an estimated cultivable area of 351.0 acres (0.55 square miles). This estimation of taro acreage includes a collective registration by the Keanae/Wailuanui

Native Hawaiian Land Association (File reference: EAST MAUI TARO) which declared water use for approximately 350 acres of taro from both Waiokamilo and Wailuanui Streams. In addition, EAST MAUI TARO claimed water use for other irrigation purposes including the watering of livestock and the cultivation of fruits, flowers, and other plants. One other registrant (File reference: VILLALON C) declared water use for 1.25 acres of taro; however, the application was considered incomplete and is not included in totals above. This information is derived from original registration documents, much of which has not been field verified and may have changed. As noted earlier, the Commission is currently awaiting the results of the field verifications and plans to include this data upon further assessment of best available information. More detailed information on each registered diversion may be found in Table 13-1 in Section 13.0, Noninstream uses.

Historical uses of Wailuanui Stream can also provide some insight into the protection of traditional and customary Hawaiian rights. Without delving into the extensive archive of literature (refer to East Maui Irrigation Company, 2001), Handy and Handy, in *Native Planters of Old Hawaii*, provides a limited regional description as follows:

> Beyond Keʻanae is a sizable bay formed by erosion where three streams flow into the ocean. Facing the bay on its west side is a pocket of land which slopes gently seaward from the base of a cliff which corresponds to that separating Keʻanae Valley from the peninsula. This cliff probably represents an old shore line during a period of subsidence. About half the gently sloping land seaward of the cliff was terraced with loʻi which were watered by Wailuanui (Big Wailua) Stream, the larger of the three that flow into the bay. The land beyond the terraced area, on the Keʻanae side toward the sea, is too high for irrigation; here sweet potatoes were planted. And on high ground, there was a war temple. A road runs down to the bay between the terraced area and the higher ground, and along this road are the houses of the people, and the Roman Catholic Church.
>
> Wailua has been notable for its continued occupancy and cultivation by Hawaiian families. This has been due, we were told, to the influence of the Catholic mission. Land titles here are very complicated, too much so to be defined correctly by an outsider.
>
> There are several small stream between Keʻanae and Wailuanui. They flow in deep small gorges, and the terrain is very rough, but there were a few small *loʻi* developments. There are said to have been two springs of fresh water, which were opened by Kane and Kanaloa in their travels on Maui. From these springs, in a valley named ʻOhiʻa, comes the water that irrigates the *loʻi* in Wailua, so says the legend (*Ka Nupepa Kuʻokoʻa*, October 4, 1923). The Wailuanui Stream gushes down in a beautiful cascade in its gorge just before flowing into the *loʻi* area. This cascade is called Wai-o-Kane (Water of Kane).

The HSA classified the cultural resources of Wailuanui Stream as “substantial”. Data were collected in three general areas of: 1) archaeological; 2) historical; and 3) modern practices. Archaeological data were originally compiled by the State Historic Preservation Division and are only current to the date of the HSA (Table 12-5).

Table 12-5. Cultural resource elements evaluated as part of the Hawaii Stream Assessment for Wailuanui Stream.

Category	Value
Survey coverage: The extent of archaeological survey coverage was analyzed and recorded as complete, partial, very limited and none. Few valleys are completely surveyed. Many have little or no survey coverage.	Very limited
Predictability: The ability to predict what historic sites might be in unsurveyed areas was scored as high, medium or low predictability or unable to predict. A high score was assigned if archaeologists were able to predict likely site patterns in a valley given historic documents, extensive archaeological surveys in nearby or similar valleys, and/or partial survey coverage. A low score was assigned if archaeologists were unable to predict site patterns in a valley because of a lack of historical or archaeological information. A medium score was assigned to all other cases.	Medium
Number of Sites: The actual number of historic sites known in each valley is straightforward yet very time consuming to count. Instead, archaeologists used survey information to estimate the number of sites in each valley. These figures, adequate for this broad-based assessment, are only rough estimates.	1
Valley significance as a Whole District: The overall evaluation of each valley's significance was made considering each valley a district. The significance criteria of the National and Hawaii Registers of Historic Places was used. Criterion A applies if the district is significant in addressing broad patterns of prehistory or early history. Criterion B applies if the district is associated with important people (rulers) or deities. Criterion C applies if the district contains excellent examples of site types. Criterion D applies if the district is significant for information contained in its sites. Finally, Criterion E applies if the district is culturally significant for traditionally known places or events or for sites such as burials, religious structures, trails, and other culturally noteworthy sites.	A, D, E
Site Density: The density patterns of historic sites make up a variable extremely important to planners. Three ranks were assigned: low for very few sites due either to normal site patterning or extensive land alteration, moderate for scattered clusters of sites, and high for continuous sites. Valleys with moderate or high density patterns are generally considered moderate or high sensitivity areas.	Moderate
Site Specific Significance: The site specific significance variable was developed for valleys that had low densities of sites (very few sites) due either to normal site patterning or to extensive land alteration. An example of the first type might be a valley with housing sites on the side but too narrow for taro or housing sites on the valley floor. The second type might be a valley in which there had been sugar cane cultivation but a large heiau was left. The site specific significance of these valleys was categorized as either: 1) sites significant solely for information content which can undergo archaeological data recovery; or 2) sites significant for multiple criteria and merit preservation consideration. Those categorized as meriting preservation consideration would likely include large heiau, burial sites, and excellent examples of site types.	None
Overall Sensitivity: The overall sensitivity of a valley was ranked very high, high, moderate, low or unknown. Very high sensitivity areas have moderate or high densities of sites with little or no land alteration. They are extremely important archaeological and/or cultural areas. High sensitivity areas have moderate or high densities of sites with little or no land alteration. Moderate sensitivity areas have very few sites with the sites meriting preservation consideration due to multiple criteria or moderate densities of sites with moderate land alteration. Low sensitivity areas have very few sites due to normal site patterning or due to extensive land alteration. The sites present are significant solely for their informational content, which enable mitigation through data recovery. Those valleys where no surveying had been undertaken and the ability to predict what might be found was low were ranked unknown.	Moderate

Table 12 5. Cultural resource elements evaluated as part of the Hawaii Stream Assessment for Wailuanui Stream.

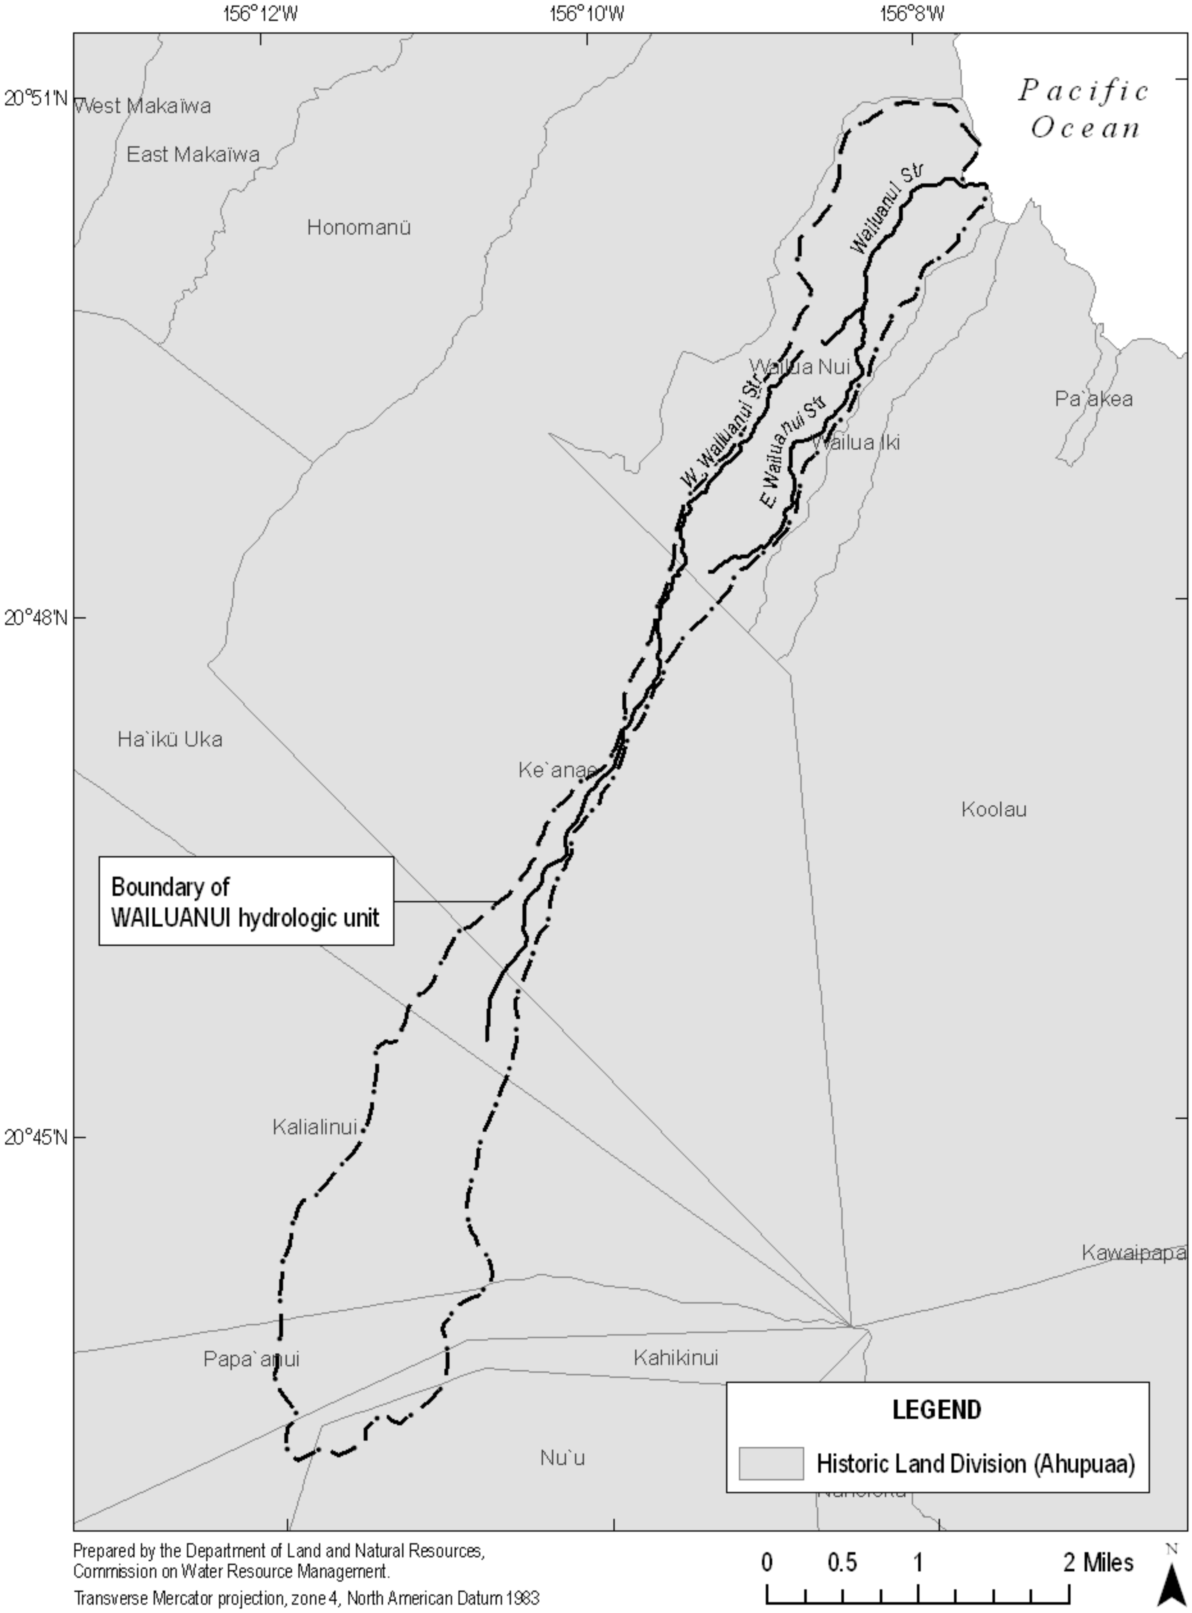
Category	Value
Historic Resources: Several types of sites were considered by inclusion in this section, particularly bridges, sugar mills and irrigation systems. Those that are listed on the State or National register were inventoried, but none of them assessed.	None
Taro Cultivation: Streams and stream water have been and continue to be an integral part of the Hawaiian lifestyle. The committee identified a number of factors important to current Hawaiian practices. These include current taro cultivation, the potential for taro cultivation, appurtenant rights, subsistence gathering areas, and stream-related mythology. The committee felt that a complete assessment of the cultural resources of Hawaii's streams should include these items but, due to limits of information, only the current cultivation of taro was included.	Up to 10 acres of taro

Fishponds are another integral part of traditional Hawaiian culture, which speaks volumes of Native Hawaiian skill and knowledge of aquaculture, which has also seen a resurgence of interest in recent years. Fishponds are found throughout the Hawaiian Islands and were either man-made or natural enclosures of water used for the raising and harvesting of fish and other aquatic organisms. Kikuchi (1973) identified six main types of fishponds, two of which are associated with streams (*loko wai*, *loko ia kalo*) and one type is associated with fresh water springs (*kaheka* or *hapunapuna*).

- Type III – *Loko Wai*: An inland fresh water fishpond which is usually either a natural lake or swamp, which can contain ditches connected to a river, stream, or the sea, and which can contain sluice grates. Although most frequently occurring inland, *loko wai* are also located along the coast near the outlet of a stream.
- Type IV – *Loko Ia Kalo*: A fishpond utilizing irrigated taro plots. *Loko ia kalo* are located inland along streams and on the coast in deltas and marshes.
- Type VI – *Kaheka* and *Hapunapuna*: A natural pool or holding pond. The majority, if not all of these types of ponds, are anchialine ponds with naturally occurring shrimp and mollusks.

According to a 1990 Hawaii Coastal Zone Management Program *Hawaiian Fishpond Study for the Islands of Hawaii, Maui, Lanai, and Kauai*, there are no fishponds present in the Wailuanui hydrologic unit (DHM, Inc., 1990).

Figure 12-2. Traditional ahupuaa boundaries in the vicinity of Wailuanui hydrologic unit. This hydrologic unit spans seven ahupuaa – Wailua Nui, Keanae, Haiku Uka, Kalialinui, Papaanui, Kahikinui, and Nuu (Source: State of Hawaii, Office of Planning, 2007a).



Prepared by the Department of Land and Natural Resources, Commission on Water Resource Management.

Transverse Mercator projection, zone 4, North American Datum 1983

13.0 Non-Instream Uses

Under the State Water Code, noninstream uses are defined as “water that is diverted or removed from its stream channel…and includes the use of stream water outside of the channel for domestic, agricultural, and industrial purposes.” In most cases, water is diverted from the stream channel via a physical diversion structure. Diversions take many forms, from small PVC pipes in the stream that remove relatively small amounts of water, to earthen auwai (ditches), hand-built rock walls, and concrete dams that remove relatively larger amounts of water. Water is most often used away from the stream channel and is not returned; however, as in the case of taro fields, water may be returned to the stream at some point downstream of its use. While the return of surface water to the stream would generally be considered a positive value, this introduces the need to consider water quality variables such as increased temperature, nutrients, and dissolved oxygen, which may impact other instream uses.

In addition to the amount of water currently (or potentially) being diverted offstream, the Commission must also consider the diversion structure and the type of use, all of which impact instream uses in different ways. The wide range of diversion structures, as noted above, is what makes regulation of surface water particularly difficult, since one standard method cannot be depended upon for monitoring and measuring flow. The ease of diverting streamflow, whether it be by gravity-flow PVC pipe, pump, or a dug channel, also plays a role in the convenience of diverting surface water and the abundance of illegal, non-permitted diversions.

Upon the enactment of the State Water Code and subsequent adoption of the Hawaii Administrative Rules, the Commission required the registration of all existing stream diversions statewide. The Commission categorized the diversions and filed registrations according to the registrant’s last name or company name. While it is recognized that the ownership and/or lease of many of the properties with diversions has changed since then, the file reference (FILEREF) remains the name of the original registrant file (Table 13-1). Locations are depicted in Figure 13-8.

In 2007, the Commission initiated a contract for the purpose of conducting statewide field investigation to verify and inventory surface water uses and stream diversions, and update existing surface water information. Priority 1 Areas, under this contract, include all east Maui streams that are part of the pending Petition to Amend Interim Instream Flow Standards. Data from this study are pending. Table 13-1 primarily contains information extracted from the original registration files.

For the Wailuanui hydrologic unit, East Maui Irrigation Co. (EMI) operates only the Koolau Ditch as part of the larger East Maui Irrigation System. Though EMI registered all of its “major” diversions (included in Table 13-1), EMI opted not to register their “minor” diversions and instead provided a map, lists and photographs. Though these minor diversions may vary widely in construction, one example consists of a small concrete basin collecting ground water seepage, which then transports the collected water via a gravity-flow PVC pipe to a larger ditch, ultimately joining one of the primary systems. The registration of these minor diversions is arguable since the contribution of these small seeps and springs to total streamflow is unknown. Information on EMI’s minor diversions are listed in Table 13-2. Locations are depicted in Figure 13-8.

Since the enactment of HAR Title 13 Chapter 168, stream diversion works permits are required for the construction of new diversions or alteration of existing diversions, with the exception of routine maintenance. These permitted (as opposed to “registered”) are not part of the Commission’s verification effort, nor have any been permitted in the Wailuanui hydrologic unit.

Table 13-1. Registered diversions in the Wailuanui hydrologic unit.

K-20a	Koolau	Wailua-nui stream intake (#8 intake pipe). Concrete catchment basin with pipe.
K-21a	Koolau	8" steel pipe intake East of #9 intake
K-21b	Koolau	Filipino Ditch diversion to #9 intake

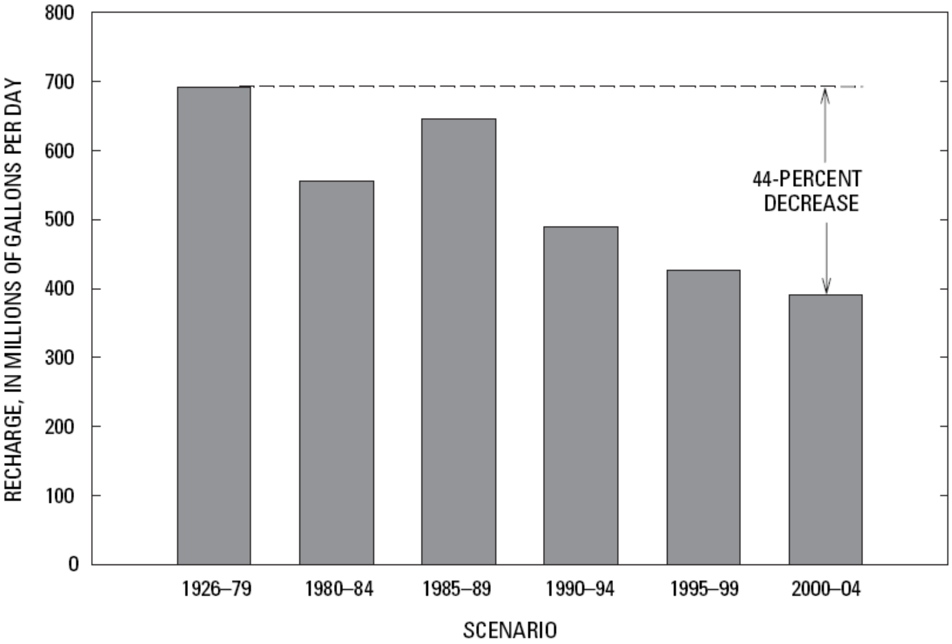
Following the establishment of instream flow standards, one of the proposed measures to increase streamflow may be to decrease the amount of water diverted from streams. Such measure has important implications to ground water recharge because it affects the amount of water available for irrigation. Decreasing the amount of water diverted at the ditches located in east Maui affects the amount of water available for the irrigation of crops in west and central Maui. Since the early 20th century, about 100 billion gallons of water (274 million gallons per day) have been diverted each year from Maui streams for irrigation in west and central Maui. More than half of this diverted water, 59 billion gallons per year (162 million gallons per day), comes from east Maui (Engott and Vana, 2007).

The effects of irrigation water on ground water recharge can be analyzed using the water budget equation[12]. Engott and Vana (2007) at the USGS conducted a study that estimated each of the water budget components for west and central Maui using data from 1926 to 2004. Components of the water budget include rainfall, fog drip, irrigation, runoff, evapotranspiration, and recharge. Results of the study were separated into six historical periods: 1926-79, 1980-84, 1985-89, 1990-94, 1995-99, and 2000-04. From 1979 to 2004, ground water recharge decreased 44 percent from 693 million gallons per day to 391 million gallons per day (Figure 13-1). The low recharge rate in 2004 coincides with the lowest irrigation and rainfall rates that were 46 percent and 11 percent lower than those in 1979, respectively. During this period, agricultural lands decreased 21 percent from 112,657 acres in 1979 to 88,847 acres in 2004. Further analysis revealed that a 20 percent decrease in irrigation rate could result in 9 percent reduction in recharge. A similar study by Izuka et al. (2005) reported that 34 percent decrease in irrigation rate constituted a 7 percent reduction in recharge in the Lihue basin in Kauai, Hawaii. Since over half of the irrigation water for west and central Maui comes from east Maui, a 20 percent decrease in the amount of water diverted from streams in the east can potentially reduce recharge in the west and central parts of Maui by 5 percent.

---

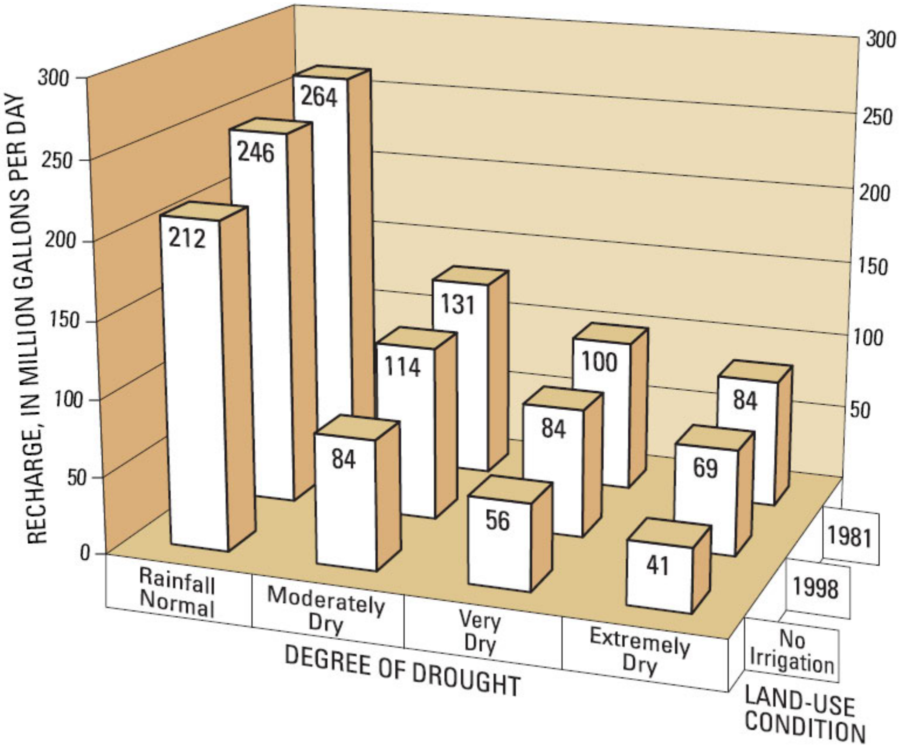
[12] Water-budget is a balance between the amount of water leaving, entering and being stored in the plant-soil system. The water budget method/equation is often used to estimate ground water recharge.

Figure 13-1. Estimated recharge for six historical periods between 1926 and 2004, central and west Maui, Hawaii (Source: Engott and Vana, 2007).



Droughts, or periods of lower than average rainfall, have been shown to drastically decrease ground water recharge (Figure 13-2). The period of drought that occurred in 1998-2002, where rainfall was at least 30 percent lower than the average annual rainfall, was estimated to reduce recharge by 27 percent in west and central Maui (Engott and Vana, 2007). For example, on the island of Kauai, the drought conditions reduced recharge in Lihue basin by 34-37 percent (Izuka et al., 2005). Even though droughts can have exacerbating effects on ground water recharge, these effects are transient and are usually mitigated by periods of higher than average rainfall (Engott and Vana, 2007). However, prolonged loss of irrigation water caused by a decrease in the amount of water diverted by irrigation ditches has greater effects on the long-term trends of ground water levels.

Figure 13-2. Summary of estimated recharge, in million gallons per day, for various land-use and rainfall conditions in the Lihue Basin, Kauai, Hawaii (Source: Engott and Vana, 2007).



The Agricultural Lands of Importance to the State of Hawaii (ALISH) were completed by the State Department of Agriculture (HDOA) in 1977, with the assistance of the Soil Conservation Service (SCS), U.S. Department of Agriculture, and the College of Tropical Agriculture, University of Hawaii. Three classes of agriculturally important lands were established for Hawaii in conjunction with an SCS effort to inventory prime agricultural lands nationwide. Hawaii's effort resulted in the classification system of lands as: 1) Prime agricultural land; 2) Unique agricultural land; and 3) Other important agricultural land. Each classification was based on specific criteria such as soil characteristics, slope, flood frequency, and water supply. ALISH was intended to serve as a long-term planning guidance for land use decisions related to important agricultural lands. HDOA is currently in the process of developing agricultural incentives based on classifications of Important Agricultural Lands. Wailuanui is comprised of 1.5 percent of unique agricultural land (Table 13-3.

Table 13-3. Agricultural Lands of Importance to the State of Hawaii and area distributions in the Wailuanui hydrologic unit.

Density	Area (mi^2)	Percent of Unit
Unique agricultural land	0.09	1.5
Other important agricultural land	0.05	0.9

From 1978 to 1980, HDOA prepared agricultural land use maps (ALUM) based on data from its Planning and Development Section and from SCS. The maps identified key commodity areas (with subclasses) consisting of: 1) Animal husbandry; 2) Field crops; 3) Orchards; 4) Pineapple; 5) Aquaculture; 6) Sugarcane; and Wetlands (Table 13-4).

Table 13-4. Agricultural land uses and area distributions in the Wailuanui hydrologic unit.

Density	Area (mi^2)	Percent of Unit
Wetlands	0.10	1.7
Animal husbandry, grazing	0.12	2.1

Though both ALISH and ALUM datasets are considerably outdated, many of the same agricultural assumptions may still hold true. The information is presented here to provide the Commission with present or potential noninstream use information (Figure 13-9).

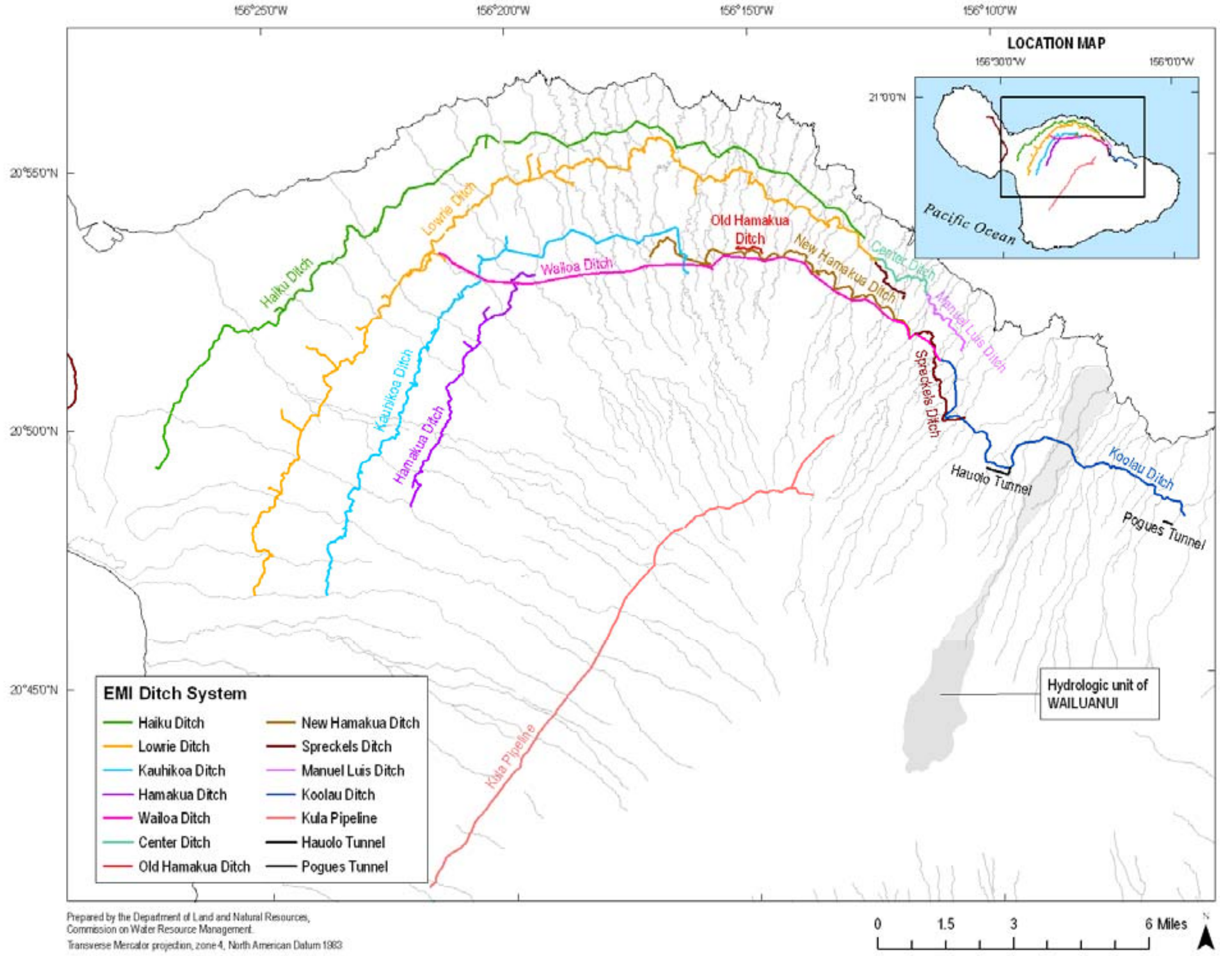
The presence of the EMI system adds considerable complexity to the Commission's role in weighing instream and noninstream uses. While this is largely due to the transfer of water from one hydrologic unit to another, the importance of the system to both agriculture and municipal water supply in Upcountry and Central Maui play a pivotal role in the consideration of economic impacts. The complexity of the EMI system is detailed in Table 13-5 and illustrated in Figure 13-3.

Table 13-5. Historic Timeline of the East Maui Irrigation System (Source: Wilcox, 1996)

1869 -	Samuel Alexander and Henry Baldwin partner to purchase 11.94 acres of Bush Ranch.
1876 -	Alexander and Baldwin form the Hamakua Ditch Company on Maui.
1878 -	Construction of the Hamakua Ditch is completed (not to be confused with the Upper and Lower Hamakua Ditches on the island of Hawaii).
1894 -	Alexander & Baldwin (A&B) is established as an agency.
1898 -	A&B gain control of Hawaiian Commercial & Sugar (HC&S), then become its agent shortly thereafter.
-	Construction of Lowrie Ditch is started about this time. The Lowrie Ditch emanates from the Kailua watershed in the Makawao District, and receives water from a reservoir in Papaaea and Kailua Stream where the diversion intercepts the source of the older Haiku Ditch.
1900 -	A&B is incorporated with accumulated assets of $1.5 million, compared with a net profit of just $2,627.20 in 1895
-	Lowrie Ditch is completed with a capacity of 60 million gallons per day and is able to irrigate 6,000 acres. The 22-mile system is 75 percent open ditch, but also includes 74 tunnels, 19 flumes, and a total of 4760 feet of siphons.
1904 -	Construction begins on Koolau Ditch, which extends the system 10 miles toward Hana.
1905 -	Koolau Ditch is completed with a capacity of 85 million gallons per day, and consists of 7.5 miles of tunnel and 2.5 miles of open ditch and flume.
1908 -	The East Maui Irrigation Company (EMI) is formed to develop and administer the surface water for all the plantations owned, controlled, or managed by A&B.
-	A&B gains control of Kihei Plantation.
1912 -	The old Haiku Ditch is abandoned between 1912 and 1929.
1914 -	New Haiku Ditch is completed with a capacity of 100 million gallons per day. The system is mostly tunnel, partially lined, with a length of 54,044 feet.
1915 -	Kauhikoa Ditch is completed with a capacity of 110 million gallons per day and a length of 29,910 feet.
1918 -	Construction of Wailoa Ditch is started.
1923 -	Wailoa Ditch is completed with a capacity of 160 million gallons per day. The system is mostly tunnel, completely lined, with a length of 51,256 feet. Capacity was later increased to 195 million gallons per day (date unknown).

In total, the EMI system consists of 388 separate intakes, 24 miles of ditch, 50 miles of tunnel, twelve inverted siphons, and numerous small feeders, dams, intakes, pipes, and flumes (Figure 13-3). Supporting infrastructure includes 62 miles of private roads and 15 miles of telephone lines. The system primarily captures surface water from multiple watersheds in east Maui with a combined area of approximately 56,000 acres, of which 18,000 acres are owned by EMI, and the rest by the State of Hawaii (Wilcox, 1996).

Figure 13-3. East Maui Irrigation System.



Prepared by the Department of Land and Natural Resources, Commission on Water Resource Management.
Transverse Mercator projection, zone 4, North American Datum 1983

The EMI system has a delivery capacity of 450 million gallons per day, but delivers an average of 165 million gallons per day. However, the average water delivery can vary considerably due to variable climate conditions that affect surface water availability. Approximately 70 percent of the water delivered via the EMI system emanates from State lands, for which Alexander & Baldwin (A&B) and EMI have obtained water leases pursuant to four license areas (Table 13-6).

Table 13-6. Revocable permits issued to A&B/EMI.

Revocable Permit No.	License Area	Acres
S-7264	Huelo	8,752.69
S-7263	Honomanu	3,381.00
S-7265	Keanae	10,768.00
S-7266	Nahiku	10,111.22

The last water license agreement expired in 1986, after which all four agreements were extended as revocable permits that were renewed annually, alternating in issuance to EMI and A&B. In 2001, a request was made to the State Board of Land and Natural Resources (BLNR) to enter into a long-term lease rather than continue with year-to-year revocable permits. A contested case before the BLNR is currently pending; however, the existing permits continue to be renewed on a holdover basis (A&B, 2007).

There have been few changes to the EMI system since the Wailoa Ditch was completed in 1923. EMI continues to provide water to HC&S, which is the largest producer of raw sugar in Hawaii, and only one of two remaining sugar plantations in the state. In 2006, HC&S produced about 81 percent of the total raw sugar in Hawaii, or approximately 173,600 tons, amounting to about 3 percent of total U.S. sugar produced (A&B, 2007). HC&S also produces molasses, a by-product of sugar production, and specialty food-grade sugars sold under their Maui Brand® trademark. Table 13-7 summarizes the harvest and production yields for HC&S from 2000 through 2006.

Table 13-7. Summary of sugar-related harvests by HC&S for 2000-2006 (Source: A&B, 2002; 2003; 2005; 2007).
[* Data were not reported]

Year	Raw sugar produced (tons)	Percent of total raw sugar produced In Hawaii	Area harvested (acres)	Yield per acre (tons)	Average cost per ton (dollars)	Molasses produced (tons)	Specialty food-grade sugar produced (tons)
2006	173,600	81.0	16,950	10.2	*	55,900	15,500
2005	192,700	76.0	16,639	11.6	*	57,100	18,900
2004	198,800	77.0	16,890	11.8	435	65,100	15,500
2003	205,700	79.0	15,660	13.1	422	72,500	12,100
2002	215,900	79.0	16,557	13.0	332	74,300	11,000
2001	191,500	70.0	15,101	12.7	371	71,200	8,848
2000	210,269	*	17,266	12.2	331	70,551	*

The HC&S sugar plantation currently consists of approximately 43,300 acres of land. Sugar is cultivated on roughly 35,100 acres, while the balance is leased to third parties, is not suitable for cultivation, or is used for plantation purposes (A&B, 2006). Approximately 30,000 acres are irrigated with water delivered by EMI, with 5,000 acres irrigated solely with EMI water, and the remaining 25,000 acres are irrigated with a mix of EMI water and supplemental ground water pumped by HC&S.

The total amount of water HC&S needs from EMI varies largely with weather and seasonal conditions, but ranges from a low of 134 million gallons per day in the winter months to a high of 268 million gallons per day during peak usage in the months of May to October (Findings of Fact, Conclusions of Law, and Decision and Order, 2007). From 2002 to 2004, HC&S received 71 percent of its water supply from EMI (surface water), while the remaining 29 percent was supplemental ground water. The EMI system was designed and constructed to take full advantage of the gravity flow of water from higher to lower elevations, thus minimizing pumping and the additional consumption of electrical power. As a result, HC&S attempts to divert the maximum possible amount of water into the EMI system at the Wailoa Ditch, which has a capacity of 195 million gallons per day.

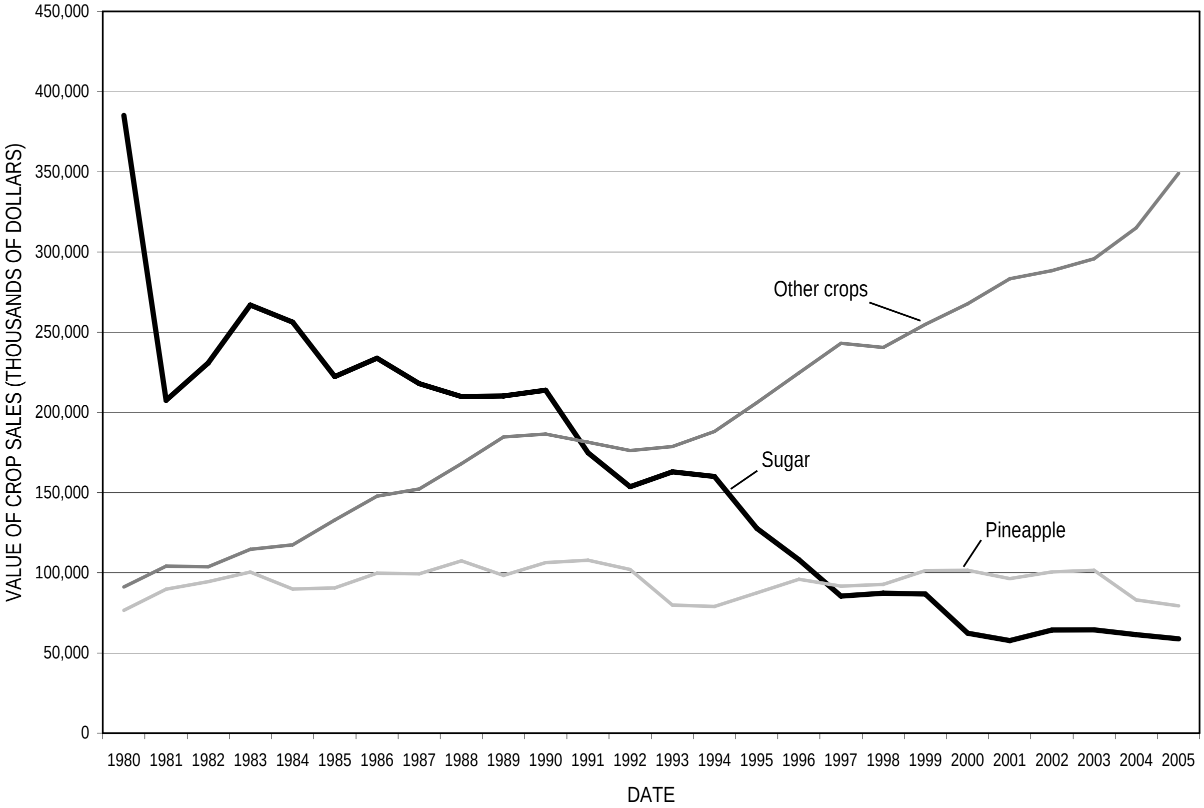
Of the estimated 1,750 agriculture-related jobs on Maui (Department of Business, Economic Development & Tourism [DBEDT], 2007), HC&S employs approximately 800 full-time workers, while EMI employs an additional 17 workers. The Agribusiness sector of HC&S saw a revenue increase of 3 percent, or $4.2 million, in 2006 over the previous year. This increase was attributed to higher revenues in repair services and trucking, higher-power sales, higher equipment rentals and soil sales, and higher specialty sugar and molasses sales. In comparison, lower revenues were reported in the bulk sugar sales (A&B, 2007). Table 13-8 provides a summary of HC&S' agribusiness revenues for 2000 through 2006.

Table 13-8. Summary of HC&S' agribusiness revenues for 2000 to 2006 (Source: A&B, 2002; 2005; 2007).

Year	Revenue (dollars)	Operating Profit (dollars)	Operating Profit Margin (percent)
2006	$ 127,400,000	$ 6,900,000	5.4
2005	$ 123,200,000	$ 11,200,000	9.1
2004	$ 112,800,000	$ 4,800,000	4.3
2003	$ 112,900,000	$ 5,100,000	4.5
2002	$ 112,700,000	$ 13,800,000	12.2
2001	$ 105,976,000	$ 5,660,000	5.3
2000	$ 107,510,000	$ 7,522,000	7.0

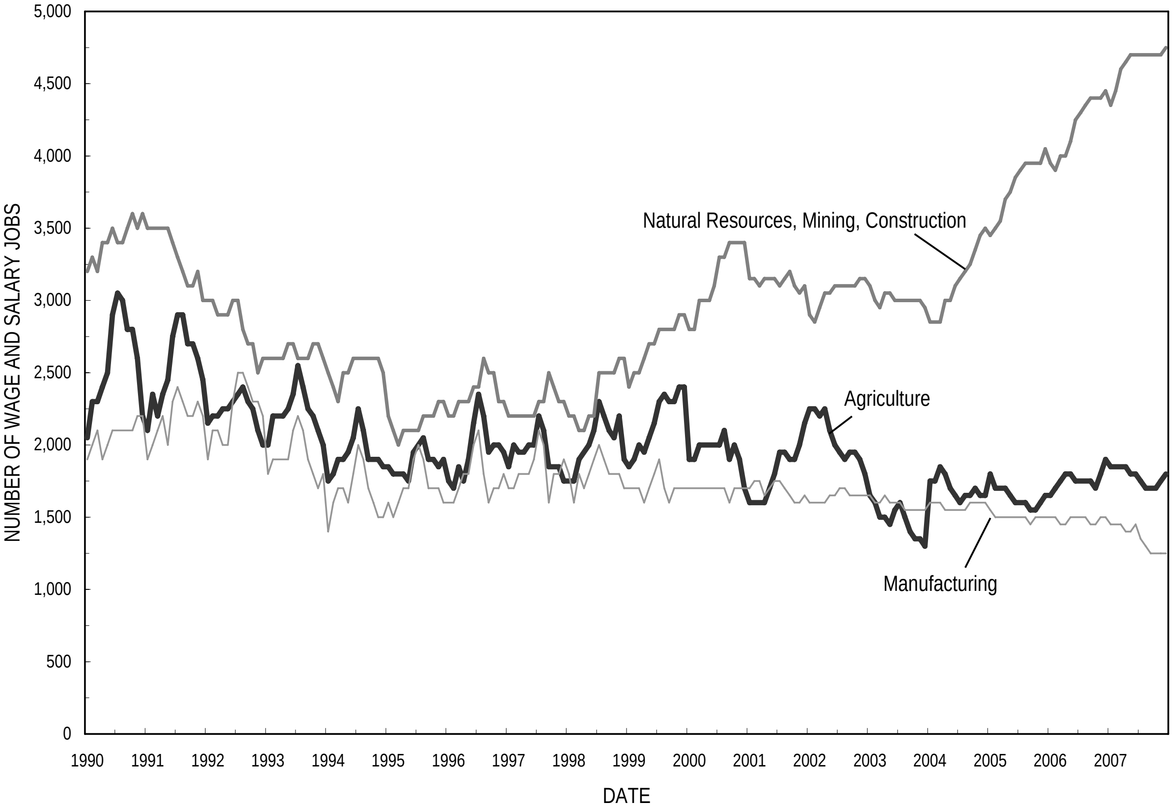
Overall, Hawaii sugar growers produce more sugar per acres than most other sugar-producing areas of the world; however, this advantage is offset by Hawaii's higher labor costs and higher transportation costs resulting from the longer distance to the U.S. mainland market. The DBEDT *State of Hawaii Data Book* shows the dramatic decline in sugar crop sales as plantations have closed over the last 25 years (DBEDT, 2006). Figure 13-4 illustrates the decline of sugar, the steady value of pineapple sales, and the increase of other crops generally considered as diversified agriculture.

Figure 13-4. Value of crop sales for sugar, pineapple and other crops from 1980 to 2005 (Source: DBEDT, 2006).



Examination of monthly economic indicators shows that, in general, agricultural jobs have slowly decreased on the island of Maui over the past 15 years. This trend is illustrated in Figure 13-5 along with trends for: 1) Natural resources, mining, and construction; and 2) Manufacturing.

Figure 13-5. Monthly number of wage and salary jobs, for three sectors including agriculture, for the island of Maui from 1990 to 2007 (Source: DBEDT, 2008).



In addition to sugar crops, HC&S receives revenue from its sale of electricity to Maui Electric Company (MECO). The HC&S Puunene Sugar Mill continues to provide a renewable energy alternative in the form of sugar cane bagasse, a fibrous byproduct of the sugar extraction process. Bagasse is the primary fuel used in boilers to generate steam, a requirement for sugar processing and for driving steam turbine generators to produce electricity. The electricity that is not used by the sugar mill is sold to MECO for distribution. HC&S is under contract with MECO to supply, at specified rates, 12 megawatts of power from 7:00 a.m. to 9:00 p.m. daily except Sunday and 8 megawatts at all other times. The contract provides for monetary penalties if these requirements are not met by HC&S. The approximate oil savings is 44,700 barrels per year (MECO, 2008).

HC&S also receives revenue from the delivery of water to the County of Maui Department of Water Supply's (DWS) Upcountry system, and to Maui Land and Pineapple Company, Inc. (MLP) for its east Maui pineapple fields. MLP cultivates roughly 6,000 acres of pineapple, of which over 2,800 are situated in east Maui and rely on the EMI system for water. While there are indications that MLP has leased, or is planning to lease, 400 additional acres in east Maui to expand their pineapple growing operations (Findings of Fact, Conclusions of Law, and Decision and Order, 2007), MLP has also expressed their intention of shifting plantings from Upcountry Maui to agricultural land in west Maui due to the susceptibility of their east Maui fields to drought conditions. MLP states that their west Maui lands are less susceptible to drought and irrigation storage capacity is being increased (MLP, 2007).

MLP estimates their water requirements from the EMI system at 4.5 million gallons per day from 2004 through 2009, and a reduction to approximately 4.4 million gallons per day from 2009 to 2016. Under a

License and Water Agreement between MLP and EMI, two "classes" of water are transported via the EMI system. The first class of water, which represents the majority of MLP's usage, is pumped by Maui Pineapple Co., Ltd. into the Koolau Ditch from Hanawi Stream at Nahiku near the start of the EMI system. The second class of water is what MLP is contractually allowed to withdraw, for a fee, from the EMI system when flow exceeds 100 million gallons per day.

According to MLP's Annual Reports to the U.S. Securities and Exchange Commission, the last year that MLP had an operating profit for their pineapple operations was in 1999. Table 13-9 provides a summary of revenue and operating losses from 1999 to 2006. Some of the revenue losses can be attributed to increased importation of oversees pineapple products (specifically from Thailand); though it appears that the U.S. had begun imposing antidumping duties, as canned pineapple imports had decreased in 2001. Regardless, in June 2007, MLP ceased pineapple canning operations on Maui, attributing the closure to increased imports of cheaper canned pineapple. MLP is instead choosing to focus on the production of pineapple juice and fresh fruit. The closure of Hawaii's last canned pineapple producer resulted in the loss of 120 jobs, or 27 percent of the company's workforce (Hao, 2007).

Table 13-9. Summary of MLP's revenues and operating losses for 1999 to 2006 (Source: MLP, 2002; 2004; 2005; 2007).
[Numbers in parentheses indicate operating losses; numbers not in parentheses are gains.]

Year	Revenue (dollars)	Operating Loss (dollars)
2006	$ 65,200,000	$ (18,600,000)
2005	$ 74,500,000	$ (11,400,000)
2004	$ 80,000,000	$ (10,800,000)
2003	$ 105,000,000	$ (921,000)
2002	$ 92,500,000	$ (8,500,000)
2001	$ 92,000,000	$ (3,000,000)
2000	$ 85,900,000	$ (2,900,000)
1999	$ 94,400,000	$ 6,100,000

The other major user of EMI surface water, Maui DWS, receives approximately 8.2 million gallons per day, a portion of which goes directly to the Kula Agricultural Park. Under a December 31, 1973 agreement between EMI, HC&S, and the County of Maui, EMI agreed to collect and deliver to the County 12 million gallons per 24-hour period for a term of 20 years, with an option for the County to receive an additional 4 million gallons after giving one year's written notice to EMI. Set to expire in 1993, this agreement was extended on several occasions, with the last extension expiring on April 30, 2000.

EMI currently delivers water to the County under a Memorandum of Understanding (MOU) that was executed on April 13, 2000, which provides for the County to continue to receive 12 million gallons per day from the Wailoa Ditch with an option to receive an additional 4 million gallons. However, the MOU also includes stipulations for periods of low flow, whereby the County will receive a minimum allotment of 8.2 million gallons per day while HC&S will also receive 8.2 millions gallons per day, or 9.4 million gallons per day should fire flow be required (Maui DWS, 2007b). The MOU has a term of 25 years and sets water delivery rates at $0.06 per thousand gallons. For the 2006 fiscal year, Maui DWS reported purchasing a total of 2,601 million gallons from EMI, at a cost of $156,848, which includes various other sources in addition to the Wailoa Ditch (Maui DWS, 2007a).

Of the five separate water systems operated by DWS, the Upcountry Maui (sometimes referred to as Makawao) system is the second largest system and is supported by Maui's largest surface water treatment facility (WTF), the Kamole Weir WTF. Surface water, for the most part, supplements the primary ground water sources (Haiku and Kuapakalua wells) for the region, but serves as backup in the event of pump failure or drought. The Kamole Weir WTF produces an average 3.6 million gallons per day, but is capable of producing 8 million gallons per day at maximum capacity. DWS also plans to increase capacity by 2.3 million gallons per day in 2015 (Findings of Fact, Conclusions of Law, and Decision and Order, 2007; Maui DWS, 2007e).

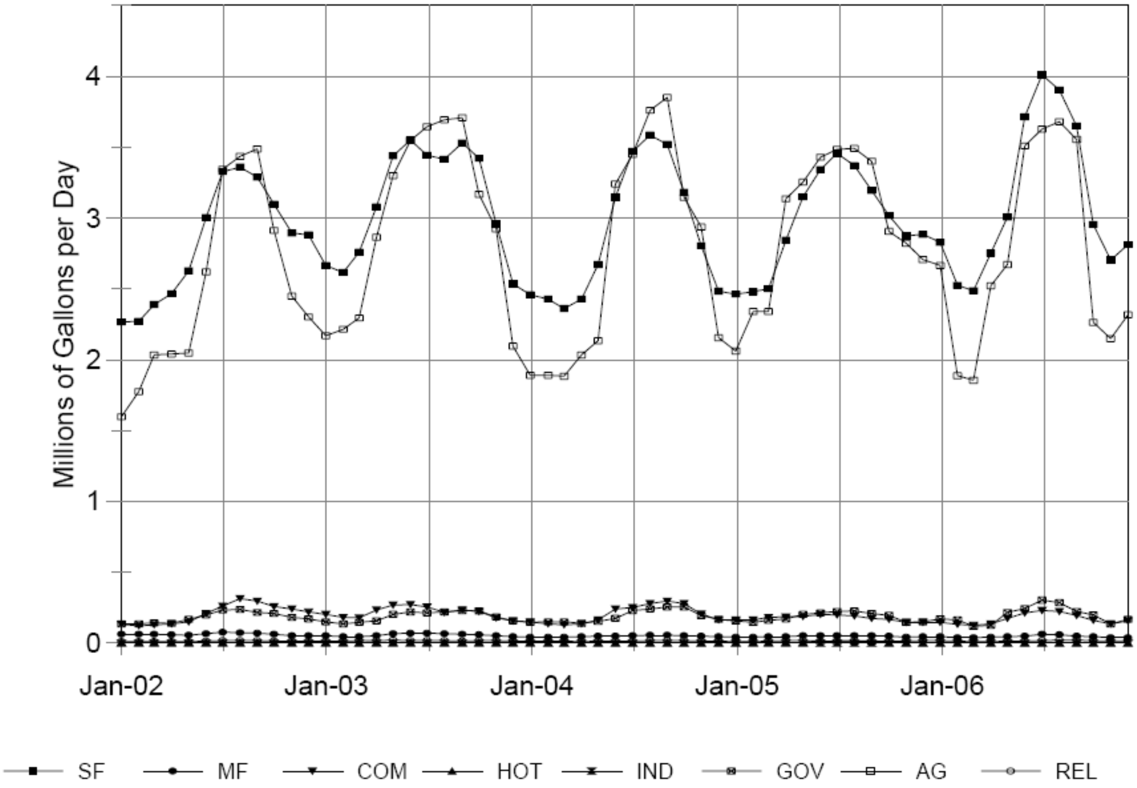
The Kamole Weir WTF receives water from the Wailoa Ditch and supplies water to approximately 6,571 water service connections and is capable of providing water to the entire Upcountry region (9,708 connections) if necessary (Maui DWS, 2007e). The Upcountry system includes the communities of Kula, Pukalani, Makawao, and Haiku, with an estimated population of 30,981 people (Findings of Fact, Conclusions of Law, and Decision and Order, 2007). Metered water usage in the Upcountry system has steadily climbed over the past 10 years, with the largest portion going towards potable water use (Table 13-10).

Table 13-10. Historical metered consumption for the Upcountry system, Maui (Source: Maui DWS, 2007d).
[Data reported in million gallons per day]

Year	General	Agriculture Potable	Total Potable	Agriculture Non-potable	Total
2005	4.441	2.378	6.820	0.571	7.391
2004	4.387	2.138	6.525	0.575	7.100
2003	4.778	2.320	7.098	0.582	7.680
2002	4.461	1.908	6.368	0.433	6.801
2001	4.823	2.563	7.387	0.690	8.077
2000	4.370	2.504	6.873	0.505	7.379
1999	4.146	2.474	6.620	0.555	7.175
1998	4.003	2.382	6.384	0.512	6.897
1997	3.693	1.829	5.521	0.374	5.895
1996	4.083	1.923	6.007	0.481	6.487
1995	4.382	2.300	6.682	0.634	7.317
1994	3.871	1.931	5.802	0.504	6.306

For the Makawao-Pukalani-Kula Community Plan District, water use for agriculture and single-family residences has been very similar over the past 5 years. The two uses also have strong annual patterns, with water use rising approximately 1.5 million gallons per day during summer months versus winter months (Figure 13-6). Other water uses within the district are relatively low (Maui DWS, 2007d).

Figure 13-6. Historical monthly water consumption by use class code for the Makawao-Pukalani-Kula Community Plan District, Maui (Source: Maui DWS, 2007d).
[SF is single family residential; MF is multi-family residential; COM is commercial; HOT is hotel; IND is industry; GOV is government; AG is agricultural; REL is religious)



The County of Maui, as part of its current effort to update the Maui County Water Use and Development Plan, is examining various resource options to meet the forecasted water needs and planning objectives of the Upcountry district over a 25-year planning period. Expansion of the Kamole Weir WTF is the primary long-term option affecting water delivered via the Wailoa Ditch; however, other options for the entire district include developing additional ground water sources, expanding/upgrading interconnections (booster pumps) between systems, and increasing water storage capacity (Maui DWS, 2007c). Upcountry water demands are expected to increase, as depicted in Figure 13-7, based upon five water-demand projections derived from varying growth scenarios (low, medium low, base, medium high, and high) to the year 2030.

Figure 13-7. Actual and projected water demands of all metered use classes for the Upcountry District, Maui (Source: Maui DWS, 2007d).
