APPENDIX I
CHAMA RECONSTRUCTED PRECIPITATION VALUES

Ronald H. Towner

Table I.1. Chama Reconstructed Precipitation Values.

Year	Annual Reconstructed Precipitation	20 Year Spline Reconstructed Precipitation
759	38.11	37.05
760	33.20	38.41
761	41.58	39.78
762	43.02	41.12
763	37.82	42.41
764	32.62	43.64
765	51.98	44.74
766	60.66	45.59
767	48.23	46.12
768	49.09	46.36
769	48.81	46.39
770	43.60	46.34
771	33.78	46.31
772	52.27	46.39
773	32.91	46.61
774	33.20	46.96
775	54.59	47.36
776	69.90	47.61
777	48.52	47.58
778	51.41	47.29
779	41.58	46.82
780	51.12	46.27
781	44.18	45.70
782	36.67	45.21
783	34.35	44.89
784	53.72	44.73
785	43.02	44.67
786	35.51	44.69
787	54.59	44.76
788	43.02	44.79
789	43.89	44.74
790	45.34	44.58
791	51.98	44.28
792	48.52	43.80
793	44.47	43.18
794	43.60	42.51
795	35.51	41.88
796	40.71	41.39
797	26.55	41.09
798	46.20	41.00
799	36.96	41.06
800	43.31	41.19

Year	Annual Reconstructed Precipitation	20 Year Spline Reconstructed Precipitation
801	43.02	41.31
802	45.92	41.37
803	47.65	41.29
804	44.47	41.09
805	44.47	40.81
806	37.53	40.53
807	33.20	40.36
808	38.11	40.40
809	25.97	40.67
810	37.82	41.14
811	39.27	41.71
812	50.54	42.18
813	61.81	42.39
814	51.70	42.22

APPENDIX K
SOIL HORIZON NOMENCLATURE, KEYS TO SYMBOLS USED IN DESCRIPTIONS OF SOIL MORPHOLOGY, AND SOIL PROPERTIES USED IN FIELD DESCRIPTIONS

Paul Drakos and Steve Reneau

SOIL HORIZON NOMENCLATURE (from Birkeland 1999)

Description of Master Horizon, Horizon, and Subhorizons

O horizon: Surface accumulations of mainly organic material; may or may not be, or has been, saturated with water. Subdivided on the degree of decomposition as measured by the fiber content after the material is rubbed between the fingers.

Oi horizon: Least decomposed organic materials; rubbed fiber content is greater than 40 percent by volume.

Oe horizon: Intermediate degree of decomposition; rubbed fiber content is between 17 and 40 percent by volume.

A horizon: Accumulation of humified organic matter mixed with mineral function; the latter is dominant. Occurs at the surface or below an O horizon; Ap is used for those horizons disturbed by cultivation.

E horizon: Usually underlies an O or A horizon, and can be used for eluvial horizons within or between parts of the B horizon (e.g., common above fragipan, x). Characterized by less organic matter and/or fewer sesquioxides (compounds or iron and aluminum) and/r less clay than the underlying horizon. Many are marked by a concentration of sand and silt. Horizon is light colored due mainly to the color of the primary mineral grains because secondary coatings on the grains are absent; relative to the underlying horizon, color value will be higher or chroma will be lower.

B horizon: Underlies and O, A., or E horizon, and shows little or no evidence of the original sediment or rock structure. Several kinds of B horizons are recognized, some based on the kinds of materials illuviated into them, others on residual concentrations of materials. Subdisvisions are:

> <u>Bh horizon</u>: Illuvial accumulation of amorphous organic matter-sesquioxide complexes that either coat grains or form sufficient coatings and pore fillings to cement the horizon.
>
> <u>Bhs horizon</u>: Illuvial accumulation of amorphous organic matter-sesquioxide complexes, and sesquioxide component is significant; both color value and chroma are three or less.

Bk horizon: Illuvial accumulation of alkaline earth carbonates, mainly calcium carbonate; the properties do not meet those for the K horizon.

Bl horizon: Illuvial concentrations primarily of silt. Used when silt cap development reaches Stages 5 and 6.

Bo horizon: Residual concentration of sesquioxides, the more soluble materials having been removed.

Bq horizon: Accumulation of secondary silica.

Bs horizon. Illuvial accumulation of amorphous organic matter-sesquioxide complexes if both color value and chroma are greater than three.

Bt horizon: Accumulation of silicate clay that has either formed in situ or is illuvial (clay translocated either within the horizon or into the horizon); hence it will have more clay than the assumed parent material and/or the overlying horizon. Illuvial clay can be recognized as grain coatings, bridges between grains, coatings on ped or grain surfaces or in pores, or thin, single or multiple near-horizontal descrete accumulation layers of pedogenic origin (clay bands or lamellae). In places, subsequent pedogenesis can destroy evidence of illuviation.

Bw horizon: Development of color (redder hue or higher chroma relative to C) or structure, or both, with little or no apparent illuvial accumulation of material.

By horizon: Accumulation of secondary gypsum.

Bz horizon: Accumulation of salts more soluble than gypsum.

K horizon: A subsurface horizon is so impregnated with carbonate that its morphology is determined by the carbonate. Authigenic carbonate coats or engulfs nearly all primary grains in a continuous medium. The uppermost part of a strongly developed horizon is laminated, brecciated, and/or pisolithic (Machette 1985). The cemented horizon corresponds to some caliches and calcretes.

C horizon: A subsurface horizon, excluding R, like or unlike materials from which the soil formed, or is presumed to have formed. Lacks properties of A and B horizons, but includes materials in various stages of weathering.

Cox and Cu horizons: In many unconsolidated deposits, the C horizon consists of oxidized material overlying seemingly unweathered C. The oxidized C does not meet the requirement of the Bw horizon. In stratigraphy, it is important to differentiate between these two kinds of C horizons. Here Cox is used for oxidized C horizons and Cu for unweathered C horizons. Alternatively, the Cox can be termed BC or CB.

Cr horizon: In soils formed on bedrock, there commonly will be a zone of weathered rock between the soil and the underlying rock. If it can be shown that the weathered rock has formed in place, and has not been transported, it is designated Cr. Such material is the saprolite of geologist; in situ formation is demonstrated by preservation of original rock features, such as grain-to-grain texture, layering, or dikes. If such material has been moved, however, the original structural features of the rock are lost, and the transported material may be the C horizon for the overlying soil. Those Cr horizons with translocated clay, as shown by clay films, are termed Crt.

R horizon: Consolidated bedrock underlying soil.

Selected Subordinate Departures

Lower-case letters follow the master horizon designation. Those that are mainly specific to a particular master horizon are given above. Some can be found in a variety of horizons; they are listed below.

b Buried soil horizon with major features formed prior to burial. May be deeply buried and not affected by subsequent pedogenesis; if shallow, they can be part of a younger soil profile.

c Concretion or nodules cemented by accumulations of iron, aluminum, manganeses, or titanium.

f Horizon cemented by permanent ice. Seasonally frozen horizons are not included, nor is dry permafrost material (material that lacks ice but is colder than 0° C).

g Horizon in which gleying is a dominant process that is, either iron has been removed during soil formation or saturation with stagnant water has preserved a reduced state. Common to these soils are neutral colors, with or without mottling. Most have chromas of 2 or less and many have redox concentrations. Strong gleying is indicated by chromas of one or less, and hues bluer than 10Y. Much of the above color is due to the color of reduced iron, or the color of uncoated grains from which iron pigment has been removed. Bg is used for horizons with pedogenic features in addition to gleying; however, if gleying is the only pedogenic feature, the horizon is designated Cg.

j Used in combination with other horizon designation (Btj, Ej) to denote incipient development of that particular feature or property. A rule for some desginations would be to use it for those horizons that do not meet criteria for diagnostic horizons (e.g., Ej for an eluvial horizon that does not meet the criteria of the albic horizon).

k Accumulation of alkaline earth carbonates, commonly $CaCO_3$.

m Horizon that is more than 90 percent cemented. Denote the cementing material (Km, carbonate; qm, silica; Kqm, carbonate and silica, etc.).

n Accumulation of exchangeable sodium.

ss Presence of slickensides.

v Has two uses: 1) One is plinthite, iron-rich, humus-poor, reddish material that hardens irreversibly when dried, and 2) If A horizons in arid environments have a vesicular structure (round voids), they are designated Av.

x Subsurface horizon characterized commonly by a bulk density greater than that of the adjacent horizons, firmness and brittleness, and very coarse prismatic structure with bleached vertical faces (fragipan character). An E horizon may overlie the fragipan horizon at depth as well as between the A and Bt horizons higher in the profile. If the E horizon nomenclature designations are identical, and both are pedogenic, a prime is applied to the lower E horizon. In this example, the profile would be A/E/Bt/E/Bx/Cox.

y Accumulation of gypsum.

z Accumulation of salts more soluble than gypsum (e.g., NaCl).

KEYS TO SYMBOLS USESD IN DESCRIPTIONS OF SOIL MORPHOLOGY

Structure

Grade	Size	Type	Other
1 = weak	vc = very coarse	sbk = subangular blocky	: = parting to (e.g. pr:pf)
2 = moderate	c = coarse	abk = angular blocky	
3 = strong	m = medium	pr = prismatic	
	f = fine	pl = platy

sl = sandy loam	sicl = silty clay loam
l = loam	cl = clay loam

SOIL PROPERTIES USED IN FIELD DESCRIPTIONS
(From Birkeland 1999)

Structure

Describe type, grade, and structure size. If the structure is not apparent, take a spade full of the soil and tap it horizontally on the ground and look for repeating patterns.

Type of Structure: Use Table 1.3 to define the type of soil structure.

Grade:

m—massive. Enough aggregation to maintain a vertical face but no formation of structure type (structureless).

sg—single grain. No aggregation (structureless). Loose grains of a sand dune are a good example.

1—weak. Peds barely observable in place, and, when disturbed, few entire peds are observed; much of the material is unaggregated.

2—moderate. Peds easily observable in place. When disturbed, there is a mixture of whole peds, broken peds, and some material not organized into peds.

3—strong. Peds are distinctly visible in place, and, when disturbed, nearly the entire mass consists of whole peds.

Size: Size differs with the kind of structure as shown in Table A1.4. Smaller structural units may be held together in such a way as to form larger units. For example, small subangular blocky units may combine in such a way to form larger prismatic units. The dominant structure is the primary structure when calculating PDI values, and the subordinate structure is the secondary structure.

Table 1.3 Description and Probable Origin of Soil Structure

Type	Sketch[a] and Description		Probable Origin[b]	Usual Associated Soil Horizon
Granular		Spheroidally shaped aggregates with faces that do not accommodate adjoining ped faces	Colloids, mainly organic, bind the particles together; clay and Fe and Al hydroxides may be responsible for some binding, and flocculating capacity of some ions, such as Ca^{2+}, may be helpful; periodic dehydration helps form more stable aggregates	A
Angular blocky		Approximately equidimensional blocks with planar faces that are accommodated to adjoining ped faces; face intersections are sharp with angular blocky, rounded with subangular blocky	Many faces may be intersecting shear planes developed during swelling and shrinkage that accompany changes in soil moisture	Bt
Subangular blocky				
Prismatic		Particles are arranged about a vertical line, and ped is bounded by planar vertical faces that accommodate adjoining faces; prismatic has a flat top, and columnar a rounded top.	Faces develop as a result of tensional forces during times of dehydration; rounded column tops may be due to some combination of erosion by percolating water and greater amounts of upward swelling of column centers on wetting	Bt
Columnar				Bn
Platy		Particles are arranged about a inherited horizontal plane	May be related to particle size orientation from parent material or induced by freeze–thaw processes	E, or those with fragipan
			May be related to layering in cementing material, induced during its precipitation(carbonate, silica, Fe hydroxides)	Km, Bqm, Bs

[a]Taken from Soil Survey Staff (1975).
[b]From Baver (1956), Black (1957), Rode (1962), and White (1966).

Gravel Content

Estimate volume percentage occupied by gravel (>2 mm). Weight percentage can be determined in the field with a screen (one can use an inexpensive 3-mm door screen) and a hand-held portable scale. Be watchful for shape and lithologic changes during the screening process, as they may indicate parent materials of more than one origin.

Consistence

Consistence is a measure of the adherence of the soil particles to the fingers, the cohesion of soil particles to one another, and the resistance of the soil mass to deformation. Soil Survey Division Staff (1993) has changed some of the terms, but the older terms are kept here as PDI values are based on them. Because this property varies with moisture content, it is taken when the soil is dry, moist, and wet. The wet consistence (natural or artificial wetness) is useful in determining texture classes in the field.

Dry Consistence (naturally dry in exposure):

lo—loose. Noncoherent, such as grains of a sand dune.
so—soft. Easily fails to powder or single grain, with very slight force between thumb and forefinger.
sh—slightly hard. Easily fails under slight force between thumb and forefinger.
h—hard. Fails in the hands without difficulty; requires strong force to fail between thumb and forefinger.
vh—very hard. Fails in hands with difficulty, but not between thumb and forefinger.
eh—extremely hard. Cannot be failed in hands.

Moist Consistence (usual moisture when one digs back into exposure):

lo—loose. Noncoherent.
vfr—very friable. Easily fails to powder or single grain, with very slight force between thumb and forefinger.
fr—friable. Fails under slight force between thumb and forefinger.
fi—firm. Fails under moderate force between thumb and forefinger.
vfi—very firm. Fails under strong force between thumb and forefinger.
efi—extremely firm. Fails under very strong force between hands but cannot be crushed between thumb and forefinger.

Wet Consistence (usually wetted artificially, but not so much the mass flows):

Stickiness is measured by pressing the wet soil between the thumb and forefinger and noting its adherence.

so—nonsticky. Practically no adherence to thumb and forefinger when pressure released.
ss—slightly sticky. After release of pressure, soil adheres to both thumb and forefinger but comes off one or the other rather cleanly. Does not appreciably stretch.
s—sticky. After release of pressure, soil adheres to both thumb and forefinger and tends to stretch somewhat before pulling apart from either digit.
vs—very sticky. After release of pressure, soil adheres strongly to both digits and is markedly stretched when they are separated.

Table A1.4 Classes of Soil Structure

0 20 40

Scale (in mm)

Size Class	Diameter of Granules (mm)	Thickness of Plates (mm)	Diameter of Blocks (mm)	Diameter of Prisms (mm)
vf—very fine	<1	<1	<5	<10
f—fine	1–2	1–2	5–10	10–20
m—medium	2–5	2–5	10–20	20–50
c—coarse	5—10	5–10	20–50	50–100
vc—very coarse	>10	>10	>50	>100

Plasticity is measured by rolling the wet soil between the thumb and forefinger and observing whether a roll can be formed and maintained.

po—nonplastic. No roll can be formed.

ps—slightly plastic. A roll 4 cm long and 6 mm thick can be formed and, if held on end, will support its own weight. A 4-mm-thick roll will not support its own weight. The roll is easily deformed and broken.

p—plastic. A roll 4 cm long and 4 mm thick can be formed and support its own weight. A 2-mm-thick roll will not support its own weight.

vp—very plastic. A roll 4 cm long and 2 mm thick can be formed and support its own weight. The roll is readily bent into a half or full circle.

Texture

Use established names from the textural triangle (Fig. A1.3). Screen out gravels and determine the textural class of the <2-mm fraction by noting the grittiness and wet consistence as shown in Fig. A1.4 (see also useful table of properties in Foss and others, 1975). Broad guidelines are given in the figure, but for more accuracy one should calibrate one's fingers by texturing samples with known particle-size distribution.

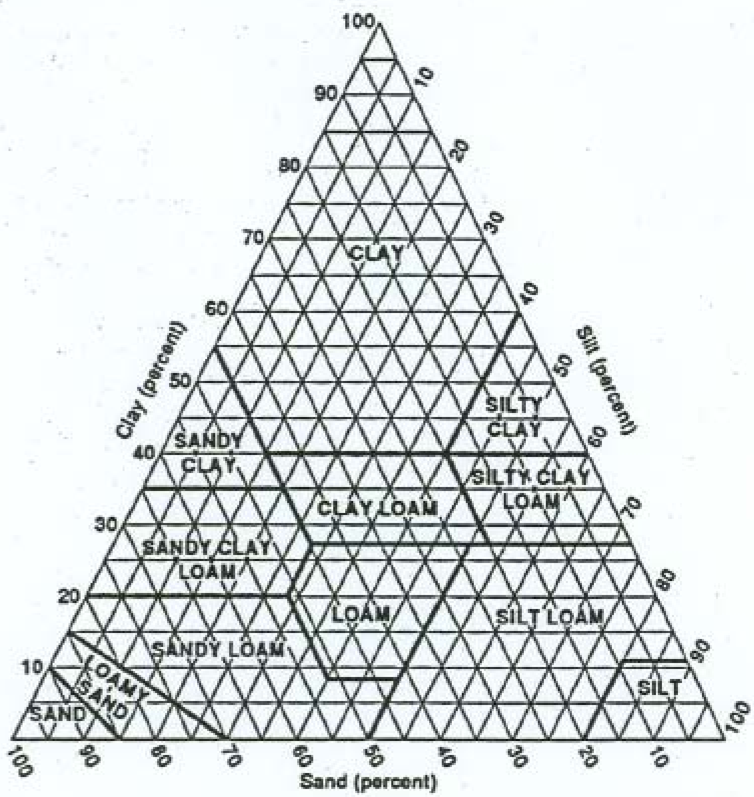

Figure A1.3 Textural names and abbreviations of names versus sand–silt–clay contents. *(Redrawn from Soil Survey Division Staff, 1993, Fig. 3.16.)*

TEXTURAL ABBREVIATIONS:				MODIFIER ABBREVIATIONS:	
C	Clay	SCL	Sandy Clay Loam	vf	very fine
CL	Clay Loam	SL	Sandy Loam	f	fine
L	Loam	Si	Silt	co	coarse
LS	Loamy Sand	SiC	Silty Clay	vco	very coarse
S	Sand	SiCL	Silty Clay Loam	g	gravelly
SC	Sandy Clay	SiL	Silt Loam		

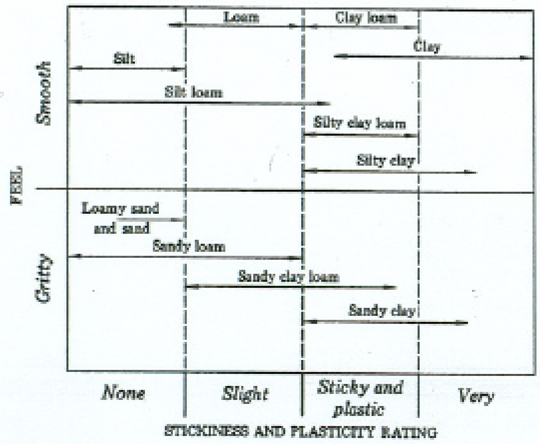

Figure A1.4 Approximate relations between texture class, grittiness, and wet consistence.

Clay Films

Clay films are thin layers of oriented clay and are described by recording their amount, distinctness, and locations. Study the peds with a hand lens in the field, or with a binocular microscope in the laboratory.

Amount:

v1—very few. Occupies less than 5% of the total area of the kind of surface described.
1—few. Occupies 5–25% of the total area of the kind of surface described.
2—common. Occupies 25–50% of the total area of the kind of surface described.
3—many. Occupies more than 50% of the total area of the kind of surface described.

The same classes are used to describe the amount of bridges connecting particles of structureless soil bodies. The amount is judged on the basis of the percentage of particles of the size designated that are joined to adjacent particles of similar size by bridges at contact points.

Distinctness: Distinctness refers to the ease and degree of certainty with which a surface feature can be identified. Distinctness is related to thickness, color contrast with the adjacent material, and other properties, but is not itself a measure of any one of them. Some thick films, for example, are faint, whereas some thin ones are prominent. The distinctness of some surface features changes markedly as the amount of moisture changes; therefore, the soil-water state might be specified. Clay films are difficult to recognize in wet soils. If classifying films on ped faces, compare features on a ped face with those on a nonstructural face broken across the ped. Three distinctness classes are used.

f—faint. Evident only on close examination with 10× magnification and cannot be identified positively in all places without greater magnification. The contrast with the adjacent material in color, texture, and other properties is small.

d—distinct. Can be detected without magnification, although magnification or tests may be needed for positive identification. The feature contrasts enough with the adjacent material that a difference in color, texture, or other properties is evident.

p—prominent. Conspicuous without magnification when compared with a surface broken through the soil. Color, texture, or some other property or combination of properties contrasts sharply with properties of the adjacent material, or the feature is thick enough to be conspicuous.

Location of Clay Films: Oriented clay is present as films on peds, inside of pores, or as bridges between grains and coats on grains. If films are preferential to some orientation (horizontal vs vertical), this should be noted.

pf—clay films occur on ped faces. Where the structure grade is weak or the soil is structureless, ped faces are indistinct or absent. It is probable that only when the structure grade is moderate or strong are the clay films on ped faces discernible.
po—clay films line tubular or interstitial pores.
br—oriented clay occurs as bridges holding mineral grains together. This is probably an initial step that occurs before clay films coat grains and is best observed in coarse-textured soils.
co—colloid coats mineral grains.
cobr—coats and bridges are present. This is probably more common than coats or bridges alone.

In describing clay films, care must be exercised not to confuse pressure faces with clay films. The former are common in soils with high clay content (Vertisols; shrink–swell clay such as smectite is best), and seasonal wetting and drying. Pressure faces arise when swelling pushes structural aggregates together and makes their sides smooth and, in places, reflective. At times these are difficult to differentiate from clay films, but some clay films can also be partly pressure faces. Slickensides are produced in the same manner, but are better developed, being polished and striated, and usually at >50 cm depth. Where slickensides are prominent, they are extensive and oriented at 20–30° from the horizontal to form wedges (Ahmad, 1983). If the shrinking and swelling that produce slickensides are extensive enough, wide and deep ground cracks will form during the dry season.

Examples of Clay-Film Descriptions:

3d po—many distinct clay films in pores.
2f pf and po—common faint clay films on peds and in pores.
3p pf, 2f po—many prominent clay films on ped faces, common faint clay films in pores.

It is important to record clay films because their presence is strong evidence for pedogenically illuviated clay. However, be warned that in places clay films can be original depositional (parent material) features. Waters charged with fine sediment that infiltrate a flood plain can produce clay films at depth (Walker and others, 1978), as can similar waters infiltrating till at the base of a glacier. If these latter parent-material films are present below the main soil-forming zone, their color will be closer to that of the parent material than to that of the soil.

Horizon Boundaries

Describe the lower boundary of each horizon, indicating distinctness and general topography.

Distinctness:

a—abrupt. Transition is less than 2 cm.
c—clear. Transition is 2–5 cm thick.
g—gradual. Transition is 5–15 cm thick.
d—diffuse. Transition is more than 15 cm thick.

Topography: Topography refers to the nature of the surface that separates the horizons. The modifiers sl (slightly) and v (very) may be used in combination with the following abbreviations.

s—smooth. Boundary is planar or parallel to the geomorphic surface.
w—wavy. Undulating surface with pockets wider than they are deep.
i—irregular. If pockets are deeper than their width.
b—broken. If one or both of the horizons separated by the boundary are discontinuous, so that boundary is interrupted.

Stages of Carbonate Morphology

Describe the stage of morphology (Fig. A1.5, Tables A1.5 and A1.6). In some places, there may not be stage II morphology in a sequence of nongravelly soils; rather, filaments of stage I become so common that the horizon meets the approximate percentage requirements for stage II. Holliday (1982) suggests that these latter occurrences be termed IIf to indicate their filamentous morphology.

I want to inject a word of caution on the recognition of carbonate morphological stages. In places, carbonate can be deposited on vertical faces by laterally seeping waters and thereby mask the pedogenic carbonate morphology (Lattman, 1973). In addition, M.N. Machette and R.E. Anderson (personal communication, 1991) have observed strong lateral (on contour) variations in carbonate morphology and accumulation along natural arroyos in arid parts of the eastern Great Basin. Hence, to study the morphology of pedogenic carbonate and avoid surficial cementation, one may have to dig back a meter or more.

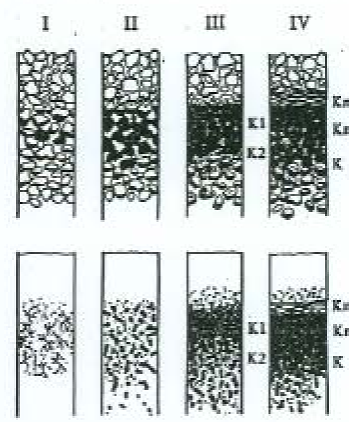

Figure A1.5 Sketch of carbonate buildup stages (I, II, III, IV) for gravelley (top) and nongravelley (bottom) parent materials. Machette (1985) added two more stages beyond stage IV (Table A1.5). In general, the stage morphologies merge to a common form at about stage III. *(Redrawn and modified from Gile and others, 1966, © 1966, The Williams & Wilkins Co., Baltimore.)*

Table A1.5 Stages of Carbonate Morphology

Stage	Gravelly Parent Material	Nongravelly Parent Material
I	Thin discontinuous clast coatings; some filaments; matrix can be calcareous next to stones; about 4% $CaCO_3$	Few filaments or coatings on sand grains; <10% $CaCO_3$
I+	Many or all clast coatings are thin and continuous	Filaments are common
II	Continuous clast coatings; local cementation of few to several clasts; matrix is loose and calcareous enough to give somewhat whitened appearance	Few to common nodules; matrix between nodules is slightly whitened by carbonate (15–50% by area), and the latter occurs in veinlets and as filaments; some matrix can be noncalcareous; about 10–15% $CaCO_3$ in whole sample, 15–75% in nodules
II+	Same as stage II, except carbonate in matrix is more pervasive	Common nodules; 50–90% of matrix is whitened; about 15% $CaCO_3$ in whole sample
Continuity of fabric high in carbonate		
III	Horizon has 50–90% K fabric with carbonate forming an essentially continuous medium; color mostly white; carbonate-rich layers more common in upper part; about 20–25% $CaCO_3$	Many nodules, and carbonate coats so many grains that over 90% of horizon is white; carbonate-rich layers more common in upper part; about 20% $CaCO_3$
III+	Most clasts have thick carbonate coats; matrix particles continuously coated with carbonate or pores plugged by carbonate; cementation more or less continuous; >40% $CaCO_3$	Most grains coated with carbonate; most pores plugged; >40% $CaCO_3$
Partly or entirely cemented		
IV	Upper part of K horizon is nearly pure cemented carbonate (75–90% $CaCO_3$) and has a weak platy structure due to the weakly expressed laminar depositional layers of carbonate; the rest of the horizon is plugged with carbonate (50–75% $CaCO_3$)	
V	Laminar layer and platy structure are strongly expressed; incipient brecciation and pisolith (thin, multiple layers of carbonate surrounding particles) formation	
VI	Brecciation and recementation, as well as pisoliths, are common	

Taken from Gile and others (1981) and Machette (1985), with further modification by R.R. Shroba (written communication, 1982).

Carbonate Effervescence

If dilute HCl (use a 1:10 ratio of concentrated HCl:water) is added to a soil containing $CaCO_3$, it will effervesce. The classes of effervescence are generally related to the amount of carbonate as well as to particle size (more rapid with smaller size) and mineralogy (slight with dolomite). Four classes are recognized:

Very slightly effervescent—few bubbles seen.
Slightly effervescent—bubbles readily seen.
Strongly effervescent—bubbles form low foam.
Violently effervescent—thick foam forms quickly.

For most geomorphic purposes, carbonate morphology stage is more useful than the classification of effervescence.

Salts and Silica Development

Pedogenic gypsum and silica have developmental stages that are similar to the stages of carbonate morphology (Table A1.7). One could devise a similar scheme for halite or any other accumulation of interest.

Cementation

Cementation refers to the brittle, hard consistence caused by some cementing agent, such as silica or $CaCO_3$, which, unlike clay, does not deform under pressure.

cw—weakly cemented. Mass is brittle and hard, but can be broken in hands.

APPENDIX L
DESCRIPTION OF SOIL MORPHOLOGY FROM C&T SITES

Table L.1. Summary of soil morphology for White Rock land transfer parcel soil profiles for geomorphic mapping units (described by Paul Drakos and Steven Reneau, May 2002).

Table L.2. Summary of soil morphology for White Rock land transfer parcel for geomorphic mapping units (described by Paul Drakos and Steven Reneau, May 2002): preliminary descriptions.

Depth (cm)	Horizon	Structure	Preliminary Age Estimate	Notes
Location 14, South gully wall, east of Location 15, confluence of gullies, south-central Parcel				
0-10	A		<1 ka (historic?)	loose fs, minor ms, young Qc or eroded top of old soil profile, reddish
10-17	Bt1b1	2f-msbk	>50-60 ka? (>30 ka?)	slightly grayish: some translocated clay; weak Bt; inferred pre-Qec soil, but not certain
17-30	Bt2b1	2-3msbk		abundant clay films
30-55	Bk1b1			few thin clay films; CaCO3 filaments; Stage 1; less developed Bk than Location 15
55-76	Ab2	2msbk	100-200 ka	grayish, buried A horizon
76-100	Bwb2	2msbk		
100-114+	Btb2	3fsbk		abundant clay films, moderate to thick, orange soil; presumed correlative with Bkb2 @ Location 15
Location 1, West of Bandelier Tuff mesa, thin Qc over Qec				
0-4	A		< 2 ka	loose vfs-ms + organics; pine needles @ surface
4-14	Bw1	1-2msbk		vfs + pumice
14-27	Bw2	1msbk		vfs + pumice; softer peds
27-40	C			loose fs + Qec pumice
40+	Cb1		50-60 ka	Qec pumice
Location 1A, West of Bandelier Tuff mesa, 5 m down gully from Location 1				
0-25	ABw		<2 ka (historic?)	top eroded; bioturbated pumice + fs; see Location 1 for subdivisions of Holocene
25-72	Cb1		50-60 ka	Qec pumice
72-88	Ab2		>50-60 ka (100-200 ka?)	vfs, well-sorted, eolian?; no soil structure; no organics
88-100+	Btb2	3msbk		reddened, moderate to thick clay films on ped faces and bridging grains
Location 2, Northwest of Bandelier Tuff mesa, down gully from Location 1				
0-60			?	tuff boulders to 25+ cm, sub-angular to sub-rounded; basal colluvial (?) layer
60-155				fine-grained pumice, coarse to very coarse sand to granule size, scattered larger Qbt pumice; Qbtt? (sample SLR-02-3)
Location 3b, Surface above east gully wall, northwest side Parcel				

Depth (cm)	Horizon	Structure	Preliminary Age Estimate	Notes
0-14	AC		< 500 yrs (historic?)	loose fs; slightly darkened
14-42	Ab1	2msbk	< 2-4 ka?	fs, darkened, buried A horizon
42-55	Bwb1	2f-msbk		minor CaCO3
55-70+	Btkb2	2-3msbk	>50-60 ka (100-200 ka?)	stage 1 CaCO3, filaments on ped faces; moderately thick clay films; fs
Location 3c, East gully wall 3 m west of Location 3b, 7 m east of Location 3a, eroded bank, northwest side Parcel				
0-5	A	pl	historic	darkened fs-vfs
5-12	Bkb1	2fabk	4-6 ka	darkened horizon with stage 1 CaCO3
12-37	Btkb1	2-3fsbk	20-40 ka?	stage 1 CaCO3; thin to moderate clay films, bridges between grains
37-52	Bt1b1	2msbk		thin clay films, bridges between grains (like overlying horizon, without CaCO3)
52-60	Bt2b1	1msbk		weak Bt
60-93	Ab2	2m-csbk	< 50 ka?	darkened horizon; thin clay films
93-112	Cox?b2	1msbk		fs
112+	Btb3	2-3msbk	100-200 ka?	abundant moderate to thick clay films, bridging grains, coating ped faces, very orange ("big orange")
Location 19, Site of active fan deposition, southwest side Parcel				
0-8	A		2-4 ka?	loose fs-vfs + minor organics
8-30	Bwt1	2pr to 2-3msbk		slightly reddish; some thin bridges and pore fillings (1nkpo: few very thin); vfs + scattered cs; slopewash colluvium
30-59	Bwt2	2m-csbk		slightly reddened, thin bridges, clay films mainly pore fillings; fs + scattered cs + vcs + granules
59-85	Ab1	1-2msbk	4-8 ka?	fs-vfs
85-100	Bkb1	2msbk		stage 1- CaCO3
Location 20, Outside area of active fan deposition, southwest side Parcel				
0-5	A		Late Pleistocene-Early Holocene?	loose fs + scattered granules + organic matter
5-26	Bt1	2mabk		thin bridges + pore fillings; hard; fs
26-44	Bt2	2-3msbk		very thin pore fillings; fs; basalt clast
44-68	Bk	2msbk		weak Bk, stage 1 CaCO3
68-86+	BCk	1mgr		loose, fs + fine pebbles
Location 4a, 10 m North of Location 4 Active Fan Below Gullies, Southwest Side Parcel				

Depth (cm)	Horizon	Structure	Preliminary Age Estimate	Notes
0-22	C		historic	stratified pumice + fines
22-33	Ab1	1msbk	late Holocene	fs; weak buried A horizon
33-44	Bwb1	pr to 2msbk		
44-73	Coxb1	1fsbk to sg		partially loose fine sand; eolian or fine-grained slopewash?
73-103	Bwb2	2msbk	mid-late Holocene?	fs-vfs
103+	Btb3		100-200 ka?	"big orange"; 0-103 cm is Holocene, possibly late Holocene
Location 4b, ~30 m north of Location 4a, south edge sagebrush, active fan below gullies, southwest side Parcel				
0-57	C1		late Holocene/historic?	stratified pumice and fines, fs+ms
57-78	C2			loose vfs
78-92	Bw1	2msbk	late Holocene	
Location 8a, North gully wall, 10 m east of Location 8, north-central Parcel				
0-9	A	1msbk	mid-Late Holocene	fs-vfs; distal slopewash
9-29	Bw	2msbk		vfs; minor CaCO3
29-49	Bk			stage 1- CaCO3; vfs
49+	Btb1		100-200 ka?	"big orange", above CaCO3, above basalt
Location 17, colluvial slope near LA-128805, southeast side Bandelier Tuff mesa				
0-10	A		late Holocene	loose fs + ms-cs, colluvial slopewash
10-25	Bw1	2msbk		vfs-cs; colluvium
25-42	Bw2	1msbk		vfs + ms-cs
42-72	C			fs + abundant fine Qec pumice
72-94+	Btkb1		100-200 ka?	good stage 1 CaCO3, filaments and coatings on ped faces; 2nbrpo clay films, thin; hard; orangeish, coarse sand ("big orange"?)
Location 21, Shallow soil over tuff, mesa top				
0-8	A		late Holocene	loose vfs + organic matter
8-13	Bw1	2fsbk		vfs
13-24	Bw2	2msbk		vfs; late Holocene slopewash ± eolian; finer texture than lower Qc slopes
24+	R			tuff
Location 11, South gully wall, south side Parcel, below power line, east of Location 9 and 10				
0-19	A	1msbk	late Holocene	fs-vfs, scattered granules

Depth (cm)	Horizon	Structure	Preliminary Age Estimate	Notes
19-30	Bw	1-2msbk		fs-vfs, scattered granules
30-61	Btb1	2fpr	late Pleistocene?	clay films (many) 3nbrpopf; vfs with scattered cs; presumed Pleistocene deposit
61-90	BCb1	1msbk		vfs
90-109	Btkb2	2msbk		stage 1- CaCO3, filaments, 1-2npobr clay films; vfs
109+	R			basalt cobbles
Location 10a, South gully wall, south side Parcel, below power line, east of Location 9				
0-8	A	1-2fgr	late Holocene	fs-vfs + organics
8-22	Bwk	2f-mabk		minor CaCO3, stage 1- (or Bw with minor CaCO3)
22-43	Bk1b1		late Pleistocene-early Holocene	stage 1 CaCO3, abundant filaments, vfs, 2npr
43-61	Bk2b1	2fpr to 2msbk		stage 1- CaCO3; vfs with minor ms; no clay films
61-92	Bw1b1 (Bwb2?)			vfs
92-121	Bw2b1	2m-csbk		fs + cs; mangans in peds (few)
121-140+	Bwb2	1-2msbk	Pleistocene (50-60 ka?)	vfs; fine Qec pumice (late-Pleistocene at base?)
Location 22, Colluvial slope near power station, east Parcel				
0-10	A		late Holocene	loose vfs
10-24	Bw1	2mgr		vfs + granules
24-43	Bw2	2msbk		vfs + scattered ms with some tuff clasts
43-65	BC	1msbk		vfs with some tuff clasts
65-110+	C			vfs; thick late Holocene slopewash deposit

APPENDIX M
RADIOCARBON DATES AND AGE CALIBRATIONS

Table M.1. Calibrated radiocarbon dates from samples used for reference soil stratigraphic descriptions in geoarchaeology investigation; calibrations conducted with CALIB 5.01.

Field Number	Laboratory Number	14-C Date (yr BP)	14-C Date Corrected for delta-13C	Median Calibrated Age (yr BP)	1-sigma Calibrated Age Range (yr BP)	2-sigma Calibrated Age Range (yr BP)	Notes
Fence Canyon							
FC-9	Beta-113041	4380±50		4,953	4866–5034	4844–5268	0.45 m deep, pumice-rich non-stratified colluvium
FC-6	Beta-93925	4500±50		5,158	50525–287	4976–5310	0.65 m deep, colluvium, possible shallow channel fill
WR-44	Beta-75307	4660±50		5,405	5317–5465	5300–5579	Archaic hearth, 0.8-0.9 m deep below colluvium
FC-2	Beta-84489	6220±50		7,117	7021–7243	6996–7257	1.3 m deep, colluvium
FC-1	Beta-84488	7780±50		8,556	8463–8603	8428–8641	2.5 m deep, colluvium
FC-8	Beta-113040	7890±50		8,711	8597–8845	8588–8978	2.8 m deep, upper part of buried soil
FC-4	Beta-93924	12,330±70		14,281	14083–14435	14014–14718	3.5 m deep, colluvium, lower part of buried soil
FC-9 + FC-6		4440±35		5,046	4967–5267	4877–5281	samples statistically the same at 95% level; combined
FC-1 + FC-8		7835±35		8,612	8560–8641	8543–8721	samples statistically the same at 95% level; combined
EG&G Gully							
WR-9	Beta-55626 *	4020±80	4040±82	4,543	4418–4796	4297–4824	0.78-0.86 m deep; burn layer

Field Number	Laboratory Number	14-C Date (yr BP)	14-C Date Corrected for delta-13C	Median Calibrated Age (yr BP)	1-sigma Calibrated Age Range (yr BP)	2-sigma Calibrated Age Range (yr BP)	Notes
WR-1	Beta-55622 *	8050±130	8070±131	8,966	8720–9190	8596–9397	2.45-2.5 m deep; coarse sediments below buried soil
WR-5	Beta-59677 *	7875±85	7895 ± 87	8,745	8594–8971	8540–9002	3.55 m deep; 0.6+m above base
WR-1 & WR-5		7949±72		8,810	8656–8977	8607–8997	samples statistically the same at 95% level; combined

*Radiocarbon date was not corrected for d13C; for calibration, the d13C value was assumed to be -23.8±1.2 o/oo based on d13C values of 107 samples collected from the Pajarito Plateau.

Table M.2. Radiocarbon dates from Land Transfer parcels; calibrations conducted with CALIB 5.01.

APPENDIX N
A METAL DETECTION SURVEY OF LA 85864 AND LA 85869, LOS ALAMOS NATIONAL LABORATORY

Charles Haecker

INTRODUCTION

On September 30, 2003, historic archaeologist Charles Haecker conducted a comprehensive metal detector survey of two historic sites, LA 85864 and LA 85869, located on land administered by Los Alamos National Laboratory (LANL). Both sites were initially recorded during a 1991 archaeological survey of the vicinity around Rendija Canyon, as part of the LANL-Bolson Land Exchange archaeology project. At the time of this survey, LA 85864 reportedly consisted of a 5 m-diameter half-circle of tuff cobbles, two sherds, a chalcedony core, and a rhyolite tuff slab with a ground surface. David Hill, the archaeologist who recorded this site, noted that one sherd had a micaceous black paste, whereas the other sherd had a gray paste and tuffaceous temper. Hill noted on the site survey form that LA 85864 was either prehistoric Ancestral Pueblo or a Historic period site of unknown cultural affiliation. Later test excavations at LA 85864 identified the presence of a hearth inside the rock ring, which yielded a radiocarbon date of 130±60 BP (Beta-58428). This indicates that the feature dates to the 18^{th} or 19^{th} centuries.

Hill also recorded LA 85869, located approximately 120 m to the southeast of LA 85864. At the time of its discovery, LA 85869 reportedly consisted of one 4 m-diameter rock ring with an interior hearth, a lithic scatter, and a possible ramada. A concentration of cobbles in association with a mano and metate was situated to the west of the tipi ring. A light scattering of obsidian flakes were found over the surface of the site. Hill did not assign cultural affiliation but suspected that it dated to the "proto-historic" period (ARMS Sites Records; Peterson and Nightengale 1993).

In 2003, LANL archaeologists mapped, surface collected, and subsurface tested the two above-described sites. Three sherds were recovered from testing at LA 85864 but no metallic artifacts were found as a result of metal detecting this site. In contrast, the surface collecting of LA 85869 produced four metallic artifacts and two sherds. In addition, the comprehensive survey of this site prior to testing suggested there may be as many as four semi-permanent structures, consisting of tipis or wickiups and a ramada. Test excavations of LA 85869 in 2003 resulted in the recovery of several more metallic artifacts, as well as three sherds and 156 glass beads within Feature 2, which is a rock ring (see Chapter 42, Volume 2).

JICARILLA APACHE OCCUPATION OF NORTHERN NEW MEXICO

At least seven ethnic groups occupied northern New Mexico at least sporadically from the time of Spanish contact to the late 19^{th} and early 20^{th} centuries: the Utes, the Jicarilla Apache, Navajos, Tewa-speaking Puebloan peoples, the Comanches, the Hispanics, and the Genizaros.

Of these, the Comanches are not likely to have left structural evidence since their presence was in the form of small war parties that did not use structures of any types. The Navajos are reported to have raided throughout the region during 1700s up to the 1860s (Schaafsma 1976), but there is no documentation to suggest the Navajo occupied temporary structures that left rock rings as archaeological evidence of their presence.

Although there are data regarding Ute, Apache, and Plains Indian tipi morphology and size (cf., Adams et al. 2000; Earls et al. 1989; Smith 1974), there are too few consistently recorded attributes that can allow distinctions of ethnicity. The paucity of measurements, the lack of documentation on the subsistence-settlement systems of the group in question, and the difficulty involved in converting ethnographic/historic measurements to measurements on archaeological remains are problems in using ethnographic analogy. While there are enough general data on tipi rings that can be used as a comparative database, there are insufficient data to distinguish ethnicity of rings, and there are insufficient data to distinguish tipi rings from remains of brush structures, which are termed *wickiups*. Nonetheless, it is believed that both sites are the result of Jicarilla Apache occupation. This conclusion is based on what is generally known of the culture history of north-central New Mexico, combined with the significant discoveries of Jicarilla micaceous sherds at LA 85864 and LA 85869.

Prior to European contact, the Jicarilla Apache occupied a territory encompassing much of north-central New Mexico, southern Colorado, and the panhandle of Oklahoma. Historically they acted as itinerant traders and cultural brokers in an ecologically diverse region that linked Puebloan, Southern Plains and Hispanic cultures. These traditional roles changed during the 1800s due to Euro-American encroachment and US government frontier policies. Most of what is currently known about Jicarilla trade and economy comes from written documents that are often biased and incomplete. Little archaeological research has been carried out using Apache materials, and this has led to a critical gap in our understanding of culture contact dynamics along the frontier of New Mexico.

The Jicarilla Apaches occupied the west side of the Rio Grande, including the Jemez Mountains, more intensively and earlier than is commonly thought. The Jicarilla are reported with the Ute in Ute territory (Colorado San Juan Mountains and San Luis Valley) as early as 1818. The east end of the San Luis Valley was occupied even sooner by the Carlanas or Sierra Blancas. According to Thomas (1935), the Jicarillas also regularly traveled to Navajo country during the 18th century. During the 1840s, they were regularly reported to be in the Petaca/Ojo Caliente area and at Abiquiu, the Jicarilla most times in the company of the Utes. Emory (1848) names three of the principal chiefs of the Jicarilla "west of the Del Norte" in 1846. Ethno-historic records indicate that this area was inhabited by several Jicarilla bands by the 1850s, utilizing the mountains and heavily wooded valleys as a refuge during war and raiding campaigns. Hispanic farmers and sheepherders also occupied this area at the same time.

On May 30, 1849, Apaches raided the community of Abiquiu. A company of dragoons lead by Captain John Chapman went into the Jemez Mountains where they encountered these Apaches at the headwaters of the Rio Oso. The band had 40 to 50 lodges and between 200 or 400 members. In 1850, a small band of Jicarillas requested that they be allowed to live west of the Rio Grande, but they were attacked by Hispanics in Ojo Caliente and turned back. This attack was retaliation for an earlier assault on Ojo Caliente, presumably perpetrated by the Jicarilla. By 1853, Steck and Lane succeeded in moving Chacon's band to the Rio Puerco. However, when he explained this move to his superiors who believed it to be in Navajo or Ute territory, Lane argued that it was claimed by the Jicarilla as hunting grounds, and that he merely moved them farther into their existing range. Most of this information comes from Schroeder, Bender, and the compilations of primary document excerpts submitted on behalf of the government's side of the Land Claims.

The Jicarilla roamed the southern San Juan Mountains as early as the early 1800s and the Jemez Mountains before the 1840s. Just which bands is not clear during this early period, but the Jemez Mountains were the fall, summer, and winter hunting grounds of the Jicarilla bands who occupied the Abiquiu, El Rito, and Petaca districts in the 1870s. These mountains were sacred to them. Schroeder (1974:128) interviewed several Jicarilla as part of his Land Claims research report. Henry L. Vicente stated that the "Jemez Mountains were referred to as a ceremonial mountain." Mooney (1898:208) tells how Killer of the Enemies destroyed two giant bears that lived in the mountains west of Santa Clara, probably the Jemez Mountains. Pedernal Peak also is sacred; it forms the "nipple" of the earth that was fashioned in the form of a human body by Killer of the Enemies before he departed the people.

Severo Jaramillo, also interviewed by Schroeder, stated that the Jicarillas in the Jemez Mountains during the 1870s were the Sand People (Saitinde). Mooney (1928; see also Swanton 1952:371) states that the Saitinde, a Jicarilla band, claimed the vicinity of Española. Although the term "sand people" is thought to refer to the Jicarilla practice of mixing sand into their pottery clay, the term more likely makes reference to the band's traditional homeland. The Great Sand Dunes region in Colorado would be a likely candidate since it encompassed the range of the Sierra Blancas or Carlanas Apaches during 1700s. Sierra Blanca is adjacent to the great Sand Dunes on the east side of the San Luis Valley in Colorado. But the Jicarilla also report camping on the Arkansas at a place called "white sands" (Goddard 1911:245), which probably refers to the north branch of the Arkansas, called "the Big Sandy Fork" on an 1874-dated map.

Some of the Carlanas merged with the Jicarilla while they were all at Taos in the 1730s. Chacon usually traveled north to the Sierra Blanca area when fleeing troops or on hunting parties, and was one of the leaders of the Saitinde or Olleros in the 1850s. The Saitinde may constitute the remnant Carlanas band in part. Prior to occupying the Rio Puerco, Chacon and his band reportedly moved back and forth between Truchas and Anton Chico, where they hunted antelope and buffalo and had very good relations with Mexican settlements. The Saitinde farmed along the Chama, near Abiquiu, El Rito, and La Madera/Ojo Caliente on a more permanent basis starting in the 1850s.

John Mills Baltazar, a Jicarilla Apache who was 74 years old when Schroeder interviewed him in 1953, said he was born near Los Alamos. In his testimony before the Land Claims Commission, Hibben argued that births took place in permanent camps, suggesting that Jicarilla testimony regarding their birthplaces also record the locations of permanent camps. Hibben confirmed these locations with historical documents and archaeological survey. This land was annexed from San Ildefonso Pueblo during World War II. The Jicarillas had good connections with San Ildefonso and likely camped near the vicinity. Those fleeing Mescalero in 1886 sought refuge at San Ildefonso and San Juan Pueblos. Some of these Apaches were the disaffected *Olleros* at

Mescalero, who occupied the Jemez Mountains in previous times. Also, San Ildefonso pottery has been found at the Jicarilla sites in the Rio del Oso Valley (Sunday Eiselt, personal communication, October 2003).

PREVIOUS JICARILLA APACHE ARCHAEOLOGICAL STUDIES

Until recently, it was assumed by the archaeological community in the Desert Southwest that Apache encampments are too difficult to identify, thus generally not worthwhile as a subject of research. The apparent assumption was that the Apaches' fabled minimalist lifeways and a concomitant paucity of material possessions precluded discovery or recognition of their encampments via conventional archaeologist field methods (cf. Gregory 1981:266; Oakes 1996; Schaafsma 1981:299; Sebastian and Larralde 1989:93–94). However, recent work conducted by Adams et al. (2000), Haecker (2002, 2003), and by USFS-Carson Forest Archaeologist David Johnson (personal communications, 2002, 2003) indicate that Apache sites can be identified via predictive modeling as it pertains to specific types of landforms that were favored by Apaches. Furthermore, metal detection surveys in recent years of probable Apache encampment sites identified by such modeling often result in the discovery of an abundance of subsurface Apachean artifacts, as well as the identification of intra-site features such as rock rings, hearths, grinding stations, bedrock mortars, rock-stacked breastworks, and culturally modified trees.

Unfortunately, there is still a general lack of sustained research regarding Jicarilla Apache material culture in New Mexico, although much work has been conducted sporadically in a cultural resource management context (Biella and Wetherbee 1997; Earls et al. 1989; Girard 1988; Hammack 1965; Levine 1984; Levine and Mobley 1974; Levine et al. 1984; Mobley 1978; Schaafsma 1975; Winter 1988). The result is that, while potential Jicarilla Apache sites have been identified, few have attempted to interpret Jicarilla material culture. Isolating and interpreting Apache sites requires an interdisciplinary approach that combines historical documents, ethnographic research, archaeological methodologies that include remote sensing techniques such as metal detecting, and ceramic analytical techniques. According to Sunday Eiselt (personal communication, December 2003), it has been difficult for researchers to develop a holistic context for investigating Jicarilla Apache archaeological sites, and thus there has been little synthetic work in this area since the 1970s.

Much of what is presently known about the Jicarilla Apache archaeological record has been generated by James and Dolores Gunnerson on the Southern Plains and the foothills of New Mexico (Gunnerson 1979). J. Gunnerson described 12 potential Jicarilla encampments that were then compared to the historical materials collected by D. Gunnerson (1974). Two types of micaceous pottery have been identified as a result of this work: *Ocate Micaceous Type*, which dates from AD 1550–1750, and the *Cimarron Type,* dating from AD 1750 to the 1900s. The attributes of these ceramic types are described in detail by Brugge (1984), Franklin (1988), Gunnerson (1969), Gunnerson and Gunnerson (1971), Marshall (1987), and Warren (1976, 1981).

Artifacts and features associated with the Ocate pottery include adobe room blocks and ovoid pit houses, Desert Side-Notched projectile points, clay pipes, bone and shell artifacts, and small slab metates. Artifacts and features associated with the Cimarron pottery include rock-ring house features with central hearths, debitage, micaceous pipes, and ground stone, but artifacts are not generally abundant. Most of the sites excavated by Gunnerson lay east of the Sangre de Cristos Mountains, representing only half of the Jicarilla territory (Eiselt 1999:4).

The important research conducted by Anschuetz (1993, 1995b) and Eiselt (2001) in the Rio del Oso Valley, west of the town of Española, New Mexico, has renewed interest in the topic of Jicarilla Apache archaeology. Anschuetz recorded 48 rock ring sites that he attributes to the Jicarilla Apache within the Rio del Oso Valley, located approximately 35 km to the northeast of the LANL project area. He notes that the Jicarilla Apache history in the Rio del Oso Valley is the result of their migration from the Sangre de Cristo Mountains Front Range homeland, this due to economic, social, and cultural pressure first exerted by Comanche, then by Hispanic and Anglo-American populations, all of whom were competing for limited resources within the southwestern Plains. By the late 19th century, some Jicarilla Apache families of the Ollero band came to consider the Rio del Oso Valley as their homeland (Anschuetz 2000:3).

Additional work by Eiselt within this valley has refined and expanded upon the findings of Anschuetz. Jicarilla encampments appear to be characterized by between 10 to 15 rock rings with clearly associated 19th century trash and Apache micaceous ceramics. These rock rings often occur as discrete clusters less than 50 m apart. Clusters consist on average of two- to- three closely spaced rings and often associated with possible corrals, garden plots, and water control devices. Metal artifacts such as barrel hoop fragments, buckles, buttons, cone tinklers made from strips of food cans, metal projectile points, and the detritus from making these points, are found associated with Rio del Oso tipi rings (Eiselt 1999:8).

Additionally, Haecker (2003) recovered a similar variety of metal objects during his investigation of late 19th and early 20th century Jicarilla tipi rings on Ghost Ranch, located approximately 60 km to the north of the LANL project area. Significantly, the material culture found at the Ghost Ranch sites indicates occasional Jicarilla occupation of this area perhaps as late as the first decade of the 20th century. Such occupation of the area around Abiquiu by Jicarilla families would have constituted an unauthorized, and thus illegal, leaving of the Jicarilla Reservation.

METAL DETECTION SURVEY OF LA 85864 AND 85869

A metal detection survey of the two sites was deemed appropriate given the likelihood that both sites date to the Historic period. If metallic artifacts were discovered, these artifacts would provide an accurate assessment as to the period of occupation. Also, discovery of surface finds of native-made ceramics, resulting from a close inspection of the ground surface during metal detection, would also provide information regarding the probable ethnicity of the sites' occupants.

Metal detection of the two sites adhered to field methods typically employed by archaeologists who utilize this remote sensing tool. Specifically, at LA 85869, the surveyor traversed a series of overlapping two meter-wide transects. The surveyor, using an overlapping sweeping motion with the machine coil, ultimately inspected virtually 100 percent of the site area. In addition, an estimated 15 meter-wide buffer around the site boundary was also inspected in this fashion. Once detected, a metal target was then excavated and exposed using a trowel. Objects that were of 20th century manufacture, for example, .22 rifle shell casings, were given to LANL archaeologists to discard off-site. Other objects that were likely or possibly associated with the site were assigned field specimen (FS) numbers and collected by LANL for later processing. Upon completing the survey, LANL archaeologists point-provenienced the artifacts locations and features via a total station established over a site datum.

SURVEY RESULTS

An intensive metal detector sweep of LA 85864 did not result in the discovery of any metallic artifacts. However, at LA 85869, 16 metal artifacts were discovered and collected. In addition, three sherds had been surface collected by LANL archaeologists from this site and prior to the metal detector survey. These artifacts are described as follows.

FS 129: The following describes the results of analysis conducted by Sunday Eiselt, a specialist in Jicarilla Apache ceramics:

The sherd is a body fragment made of primary micaceous clay. The sherd can be grouped with other historic micaceous types that are part of the ill-defined ware category of *Sangre de Cristos Micaceous* (Baugh and Eddy 1987). Without a rim, it is difficult to attribute it to the Apache, but given the character of the site, it probably is [prior to her analysis, Ms. Eiselt was given a general description of the site, including recovered metal artifacts, by Haecker]. There are a few other characteristics of the sherd that suggest an Apache origin:

- The Apache whole vessels dating to the turn of the century that I have analyzed as well as the fragmentary Cimarron ceramics from archaeological sites in the Chama district and elsewhere are relatively thin (4-6 mm). The interior surface is compacted and slightly faceted, indicating that the vessel interior surface is compacted and slightly faceted, indicating that the vessel interior was burnished with a recurved stick or stone or lightly sanded, but not polished to a high luster (unlike most Pueblo ceramics except Picuris).

- Interior surface texture remains rough. The exteriors commonly display scrape marks, and frequently these are smoothed over through the application of a thin mica slurry or wash, probably applied with the hands or with a chamois while the pot was leather hard. The exterior treatment tends to give the sherds a waxy texture, and this may be due to the application of the slurry, which floats small pieces of mica to the surface, but it also could be that the exterior pot was rag polished once dry. This would force larger mica fragments to bend over any rough edges or bumps caused by protruding aplastic inclusions. Relatively large and abundant aplastic inclusions are typical in Apache ceramic pastes. They only removed the aplastics that they could feel with the fingers (as did the Pueblos).

- The pot from which the sherd derives was thin (5.6 mm). It has a lightly burnished/sanded interior that is smudged either through use or during firing (pots were typically fired upside down). While relatively flat, the interior surface also is rough and compacted. The exterior may contain light corn-cob scrape marks, but aplastic bumps are also present. The exterior surface treatment is nonetheless consistent with Apache finishing practices. The surface is waxy, and aplastic bumps are smoothed over and lightly polished with something soft like leather or bare hands. A mica slurry was applied to the exterior only. The clay is primary micaceous clay of unknown origin although the extremely small size of mica flakes is consistent with U.S. Hill clays. Other inclusions include quartz primarily. Apache pottery techniques, and archaeological sherd description can be found in Opler (1971), and Gunnerson (1969).

- According to Guthe (1925), San Ildefonso produced micaceous pottery on a limited basis. The San Ildefonso potters called micaceous clay "Apache clay." They got the clay from Truchas or Santa Fe Canyon. The finishing techniques described by Guthe indicate the use of a gourd scraper or *kajepe* by San Ildefonso potters. "Finishing touches" are not described very well. A gourd scraper will produce a flat, smooth, and non-undulating vessel surface. No scraper will produce a flat, smooth, and non-undulating vessel surface. No corncob scraper marks will be visible, even if one was used during initial thinning. Apache pots, on the other hand, will almost always contain undulating surfaces because they did not use gourd scrapers. They smoothed vessels with the hands or cloth after scraping. Many Picuris and Taos pots that I have analyzed have been scraped with a gourd scraper, and this is a distinctive practice for Pueblo potters more generally. The exterior of FS 129 does not appear to have been scraped with a gourd. I have not analyzed San Ildefonso micaceous pottery, so I cannot comment any further on potential differences there. Richard Lang describes a type called Tewa Micaceous (1997:250), but this is a very thick micaceous ware that is similar to Vadito Micaceous described by Dick (1965).

An assignment as Apache based on surface treatment and wall construction alone is tentative at best, but taken with other evidence at the site, it is suggestive. If any quartz-muscovite and schist nodules are present on the site, this is very consistent with the mobile production practices of the Apache. The nodules are cleaning debris, and they are frequently associated with rings or can be found at lookout locations. The Jicarilla carried raw clay on horseback and produced pottery in locations distant from the sources.

The following artifacts were recovered as a result of metal detection at LA 85869:

FS 135: Metal strip, believed to be of tin/zinc alloy; 1 cm wide, 4.2 cm long, end bent together; oxidized; function unknown.

FS 197: Can fragments (10); portion of a can seam indicates the fragments are from a "sanitary seal" can, a post-1897 manufacturing innovation (Busch 1981:97).

FS 199: Can fragments (2); portion of a can seam indicates the fragments are from a "sanitary seal" can, post-1897.

FS 209: Bridle jingle or *coscojo*, two parts joined by a hook. Coscojos of this type are machine-manufactured, are Hispanic in origin. They have been found on both Jicarilla Apache and Ute encampments in north-central New Mexico, on Mescalero Apache sites in southeastern New Mexico, and Chiricahua Apache sites in southwestern New Mexico (Adams et al. 2000; Haecker 2003). Together, these sites have a date range of circa 1840–1900+.

FS 210: Straight pin or round wire fragment, ferrous; 3.0 cm long; 19th century to present.

FS 211: Trapezoidal-shaped white metal (tin?) sheet, folded, edges cut; 4.0 x 2.5 cm. Function unknown, although its shape and method of modification suggests that this is a cone tinkler, or the detritus resulting from making a cone tinkler; 19th century to present.

FS 212: White metal (tin?) fragment, cut on all sides; possibly detritus resulting from making a cone tinkler; oxidized; 19th century to present.

FS 213: Can fragment, cut into a strip; possible fastener hole; strip is "wavy" in profile; 3.0 x 1.0 cm. Function unknown.

FS 214: Lead/alloy rifle ball; .50 cal.; cast seam is visible; ball has an impact surface. The metal alloy is not known but either tin or antimony were alloyed with lead in the manufacture of bullets after the Civil War. Also, black powder firearms are presently used in the vicinity of the project area (Steve Hoagland, personal communication). It is believed that, since the ball has been fired, it is not associated with 19th century Native American occupation component of the site.

FS 215: Lead rifle ball; .50 cal.; sprue is present, indicating it was cast in a mold; dropped/not fired; relatively more oxidized than FS 214, suggesting greater age. The softness of the metal (object could be scratched with a fingernail) indicates it is unalloyed lead, which is characteristic of firearm projectiles prior to circa 1870. It is likely, therefore, that the artifact was deposited by Native American occupants of the site.

FS 216: Base fragment of a .30 cal. brass pistol shell casing; rim-fired; post-1871 (Suydam 1960:67).

FS 217: Lead fragment, presumably from a fired bullet; slightly oxidized; cannot determine if it is alloyed or unalloyed lead; 19th century to present.

FS 218: Brass fragment of a rifle shell, caliber unknown; 20th century to present.

FS 219: Fragment of white metal (tin?) sheet, cut on two sides; oxidized. Function unknown but possibly detritus resulting from making a cone tinkler; 19th century to present.

FS 220: Bridle jingle or *coscojo*, three parts joined. (See FS 209).

FS 221: Bridle jingle or *coscojo*, two parts joined. (See FS 209).

Bead Analysis

A total of 156 glass beads were discovered at LA 85869 during the excavation of a tipi ring (Feature 2) and sample areas immediately adjacent to this feature (see Table N.1). All but two of the beads (n = 154) are of the so-called "seed" bead category. The two anomalous beads include one-half of a blue "pony" bead (FS 304) and a red with white core bead (FS 232), termed a *cournaline d'Aleppo* or "Hudson's Bay Company" bead (Ross 2000:31). Pony beads are about 3/32 inch in diameter and almost always blue or white. The pony bead moved slowly west and did not reach the Plains in quantity until about 1800. It was followed in about 1840 in the west by a type of very small bead that were of a variety of colors and often faceted. This tiny "cut" bead and the pony bead continued together until the appearance about 1855 in the west of the "seed" bead. The pony beads then disappeared, except in Idaho, northwest Montana and eastern Washington. The cut beads continued, but always in the minority to seed beads (Douglas 1936:90–92, *in* Ross 2000:A-3). Pony beads were prized by Mescalero Apaches well into the 1870s (see Figure N.1), whereupon they were replaced in popularity by seed beads by the early 1880s.

Table N.1. Artifacts derived from test excavations from LA 85869.

FS #	ARTIFACT TYPE	NO.	DESCRIPTION
232	bead	2	White seed (1); red w/ white core, 3 mm dia. (1)
234	"	2	White seed (1); red seed (1)
238	Metal flake, possibly lead alloyed w/ tin or antimony	1	5 x 7 mm; function or source unknown
245	bead	12	White seed (8); blue seed (4)
250	"	1	White seed (1)
251	"	5	White seed (2); blue seed (2); Pink-red seed (1)
258	"	19	White seed (12); dark blue seed (3); blue seed (1); tan seed (3)
259	"	2	White seed (1); tan seed (1)
268	Rolled steel strip, 1.5" x 0.75"; 3 sides are cut, one side showing metal fatigue from bending back and forth; metal strip is "wavy" in profile	1	Function unknown
273	bead	13	White seed (7); blue seed (6); tan seed (1)
274	"	12	White seed (9); blue seed (1); tan seed (2)
275	"	2	White seed (2)
276	"	2	White seed (1); blue seed (1)
279	"	9	White seed (6); blue seed (3)
280	"	7	White seed (6); blue seed (1)

FS #	ARTIFACT TYPE	NO.	DESCRIPTION
281	"	15	White seed (5); blue seed (2); dark blue seed (4); tan seed (4)
284	"	2	White seed (1); blue seed (1)
289	"	2	White seed (1); tan seed (1)
290	"	7	White seed (4); blue seed (1); pink-red seed(1); tan seed (1)
292	"	5	White seed (4); blue seed (1)
298	"	10	White seed (8); blue seed (2)
300	"	1	Blue seed (1)
301	"	1	White seed (1)
303	"	8	White seed (3); blue seed (4); pink-red seed (1)
304	"	1	"pony"-type bead, half fragment, 20 mm dia.
310	Lead ball, out-of-round, split, approx. 0.30" dia.	1	Possible fish line weight
312	bead	7	White seed (5); blue seed (1); tan seed (1)
315	bead	4	White seed (2; one slightly larger w/ larger hole); blue seed (1); brown/tan seed (1)
316	"	3	White seed (2); blue seed (1)
317	"	1	White seed

The term *cornaline d'Aleppo* identifies a red, double-layered polychrome, cut-type bead. Since gold was used to make red or ruby-colored glass, red beads were expensive relative to the other beads offered to North American Indians during the 19th century. Thus, expensive red glass was layered on inexpensive white glass to reduce the production cost of red beads. Brilliant red beads cost almost five times as much as black beads, that is, the cheapest bead color type (Ross 2000:31).

Seed beads were supplied by traders in a number of sizes, all of them quite small. The largest are about one-sixteenth of an inch in diameter, about half the size of the next largest type of trade bead. According to Hanson (1989:2), citing various authors, traders introduced seed beads to the Northern Plains and Upper Missouri River Indian tribes around 1830. The popularity of seed beads for embroidery spread south and westward, reaching the Southern Cheyenne by around the mid-1830s, the western Sioux and Crow by the 1840s and, among the Blackfeet, seed beads became popular by 1875 (Ewers 1945:38). The Athapaskan-speaking tribes of Colorado, Utah, and Idaho began using seed beads in great numbers by 1890 (Duncan 1989:16).

Figure N.1. Jicarilla Apache maiden, 1873.
Note necklace of "pony" beads, and an absence of seed bead embroidery, which is dominant on Jicarilla Apache clothing by circa 1880.

The earliest type of seed beads are opaque and have softer colors than those introduced toward the end of the 19th century. From the analysis of over 430,000 beads archaeologically recovered from Fort Union, North Dakota, as well as from analyzing beads from 13 other regional trading post sites (Ross 2000), it is evident that there occurred a transition in native preference regarding bead colors. For hundreds of years the dominant bead color among Indians across North America had been white, reflecting a common use of shell in bead making. Blue was the second-most desired bead color. Later, with ever-increasing contact, Indians accepted a greater range of unfamiliar colors. With the arrival of Europeans and their glass beads, initial bead colors of choice among most Native Americans in western North America continued to be primarily white, followed by blue (Ross 2000:136).

Blue and white beads dominate archaeological assemblages that date to the 1830s, with limited occurrences of red, amber-colored, black, and green beads. By the 1840s, blue and white beads continued to dominate, but red and black beads were becoming more common, with limited amounts of green beads. By the 1850s, blue and white beads retained their popularity but continued to diminish in frequency, while red, black, and amber-colored beads increased in popularity. During the 1860s, the use of a wide range of colors became popular, including yellow, pink, green, light and dark blue, and light and dark purple. By the mid-1880s, virtually all Native American peoples employed almost exclusively the smallest of seed beads for their embroidery. By then seed beads had an even wider range of colors and possessed more brilliant hues, as compared to those available in previous decades. Old bead sample cards used by traders just prior to 1900 show more than 80 colors of seed beads from which Indian women could make selections (Douglas 1936:90–92; Ross 2000:167, A-6).

It is not statistically valid to compare and contrast the types and characteristics of the relatively few beads recovered from LA 85869 with the massive amounts found at, for example, Fort Union, North Dakota. However, it is noteworthy that the most common bead color represented at LA 85869 is white (n = 94, or 64%), followed by blue (n = 41, or 26%). This suggests that the occupants of the tipi site possessed the same general bead color preference as their fellow Native Americans throughout 19th century North America. Seed beads of the smallest size (i.e., 0.5-0.7 mm diameter), are well represented in the collection. This indicates that the site was occupied at least as early as circa 1880. And, as noted above, the tan, brown-tan, and pink-red seed beads are colors that likely would not have been introduced to the Jicarilla Apaches until the 1880s, or possibly even later.

The fragment of blue pony bead, and possibly also the *cornaline d'Aleppo* cut bead, likely pre-date the seed beads insofar as when these two beads were first acquired and used by an occupant(s) of LA 85869. The fragmented condition of the pony bead suggests it was deposited as a result of on-site breakage. The cut bead, given that it is red, would have possessed some intrinsic value greater than all the other beads found on the site. The size of this bead (2 mm in diameter) precludes its use on embroidery; rather, it likely would have been strung alongside other beads of similar or greater size, on a necklace or beaded tassel.

CONCLUSIONS

The rock ring features found at LA 85869 and the one rock ring feature of LA 85864 are characteristic of mid- to- late 19th and early 20th century Jicarilla encampments located within north-central New Mexico, and specifically within the Rio del Oso Valley. Also, several of the artifact types, which include micaceous sherds, *coscojos*, the cast rifle ball of pure lead, scraps of cut sheet metal, and glass beads, are duplicated by the artifacts found at two mid-19th century Jicarilla sites located east of Pilar, New Mexico (David Johnson, personal communication, October 2003), and on late 19th century Jicarilla Apache sites within the Rio del Oso Valley, New Mexico (Sunday Eiselt, personal communication, October 2003). Also, two Jicarilla Apache encampments have been identified on Ghost Ranch property, and have been dated to circa 1886–1910 (Haecker 2003). Just as at LA 85869, the Ghost Ranch sites also contain fragments of sanitary seal cans, which point to a post-1897 occupation. If Jicarilla Apaches deposited sanitary seal cans at LA 85869 and not the result of a later, non-Indian component, this would indicate a Post-Reservation occupation of lands that eventually became LANL property. Furthermore, this Jicarilla re-occupation would have constituted an unauthorized trespass onto lands that they had been forced to officially abandon after 1882 (Tiller 1992). Finally, it is reported by Tiller (1992:121–122) that, for many years after the establishment of the Jicarilla reservation in 1887, it was a common practice for some Jicarilla families to leave the reservation without official permission. These families would engage in trade with neighboring communities, visit friends, "or just to have something to do." Since there were few opportunities for wage work on the reservation, Jicarilla families sold or traded handcrafted articles such as baskets, buckskin moccasins, beaded accessories, bows and arrows, and pottery. The market for Jicarilla arts and crafts was limited due to the remoteness of the reservation. Therefore, it was necessary for those engaged in such endeavors to travel to, among other places, the various Rio Grande pueblos during their annual celebrations. Given that San Ildefonso had a provided temporary refuge for those Jicarilla families who had "illegally departed" the Mescalero reservation in 1886 (Tiller 1992:93), it is not surprising to find archaeologist evidence of late 19th century Jicarilla encampments on LANL property.

APPENDIX O
REPORT FOR CERAMICS FROM LA 85864 AND LA 85869

B. Sunday Eiselt

The following descriptions are for micaceous clay ceramic fragments collected from sites LA 85869 and LA 85864 (non-micaceous fragments are listed but not described). Included in descriptions of micaceous ceramics are notes regarding surface finish and paste characteristics. Suggestions regarding ethnic affiliation and geological origin of clays are provided, but these identifications are tentative. Ethnic affiliation is difficult to determine from body sherds alone. The identification of clay sources for the unknown sherds also are tentative. These identifications are based on comparisons with sampled (known source) clays using a binocular microscope.

Primary micaceous clays are found decomposing from the Vadito Group, a Precambrian formation containing abundant muscovite mica and quartz-mica schist. Vadito Group outcrops are located in the vicinity of Petaca, Picuris, Cordova, Guadalupita, Pecos, and Las Vegas. Paste mineralogies for all micaceous sherds recovered from LA 85869 and LA 85864 are consistent with the general characteristics of Vadito Group micaceous clay deposits. Aplastic inclusions include angular and subangular translucent quartz and white quartz (dominant). Muscovite mica is dominant. Iron-stained quartz, quart-mica schist, hematite, and magnetite also are present. No exotic inclusions were noted in the current sample, suggesting that temper was not intentionally added to clays in order to create ceramic pastes.

The exact geographic locations of the primary clays used to make the ceramics is difficult to determine based on mineralogy alone. Vadito Group lithologies are similar throughout the northern Rio Grande, and the petrographic studies needed to separate clay districts or clay sources have not been carried out. Visual examination of a comparative collection of over 123 clay samples from Petaca, Picuris, Cordova, and Guadalupita do, however, suggest that some mineralogical differences may exist. The source determinations provided in this report are based on these comparisons.

LA 85864

FS 575 - Two small body fragments (one vessel) – primary micaceous clay.

Sherds contain only a moderate amount of mica. Rosy quartz and possible magnetite are present but rare. The presence of rosy quartz and magnetite in the same sample indicates a Cordova-Truchas origin. Exterior and interior sherd surfaces are compacted (probably scraped with a gourd scraper, sanded, or burnished towards the end of the production sequence) and display striations consistent with wiping with a wet object (cloth or hand) while the vessel was wet (during the final step in the production sequence). No corncob striations (from scraping vessel walls) are present. The vessel may be attributed to Taos, Picuris, or Jicarilla makers based on surface finish (Tewa micaceous vessels rarely display such compacted surfaces).

FS 572 – One body fragment origin unknown

This fragment appears to be made from an alluvial clay containing mica rather than a primary micaceous clay. Mica fragments are silt-to-clay-sized and larger fragments are rare. Aplastics are subangular to subrounded. Origin of clays unknown, although alluvial micaceous clays are present north of Abiquiu. Surface slip or float does not appear to be micaceous. Ethnic affiliation unknown.

FS 574 – Prehistoric, non-micaceous painted ware (Wiyo? Biscuit A?)

LA 85869

FS 309 – Two small body fragments (one vessel) – primary micaceous clay.

Sherds contain abundant muscovite mica in a gradient of sizes. Biotite and booked biotite also is common. Aplastics include translucent to white quartz (dominant) and magnetite (rare). The abundance of booked biotite in combination with the presence of magnetite suggest a Picuris, Cordova, or Guadalupita origin. If garnet is found, then Picuris is the likely source. If rosy quartz is found, then the clay may have come from Cordova or Guadalupita. A micaceous float (slurry) was applied to the exterior surface. Interior and exterior surfaces are compacted. No wipe or scrape marks are visible. Vessel may be attributed to the Taos, Picuris, or Jicarilla makers based on surface finish.

FS 328 - Four body fragments (one vessel) – primary micaceous clay.

Sherds contain abundant muscovite in a gradient of sizes. Quartz mica-schist also is common. Iron-stained quartz and magnetite present. One small fragment of hematite noted. The abundance of quartz-mica schist and the presence of iron-stained quartz and hematite strongly suggest a Petaca origin. Vessel was fired upside down (smudged exterior, oxidized exterior). Red surface color on exterior also suggests a Petaca origin for the clay. Interior and exterior surfaces are compacted, but wipe-marks also are visible. Vessel walls were sanded or burnished prior to the application of a mica slip or slurry. This is consistent with Jicarilla Apache techniques. Given that the clay most likely originated at Petaca and given the surface finish, this vessel probably was made by Jicarillas (Cimarron Micaceous). Surface color, surface finish, and paste characteristics are very similar to Jicarilla ceramic sherds recovered in the nearby Rio del Oso Valley.

FS 325 – Historic(?) plain ware ceramic

Conclusion

The small ceramic assemblage recovered from LA 85869 is consistent with other sherd assemblages found at 19^{th} century Jicarilla Apache sites in the Chama District and elsewhere.

The clays from each of the two recovered vessels came from different locations (Picuris-Cordova-Guadalupita and Petaca). Geochemical source analysis of Jicarilla sherd assemblages demonstrates that they typically contain a variety of clay sources. In particular, they contain clays obtained from widely distributed sources, unlike Pueblo assemblages, which tend to be more homogenous and regionally restricted. A heterogeneous sherd assemblage containing clays obtained at multiple sources (including those located in the Petaca, Picuris, and Cordova clay districts) is characteristic of Jicarilla pottery production.

The sherds from LA 85869 definitely were made from different clays based on paste mineralogy, even though exact source identifications are tentative. This in combination with ceramic surface finish helps to narrow down ethnic affiliation to the Jicarilla (probable). Jicarilla sites also contain historic plain or decorated ceramics obtained through trade from Pueblo potters, but these finds are rare. Ceramic assemblages are dominated by micaceous sherds. If quartz and quartz-mica schist nodules were (or are) found at this site in association with tipi rings, then this also is very characteristic of Apache ceramic production during the 19th century. Clay frequently was transported on horseback and cleaned at distant camps. Less can be said about LA 85864.

Santa Clara Pueblo potters utilized Cordova-Chimayo area clays according to Hill and Lang (1982:83). There also was a "supposed" micaceous source located near the pueblo that was covered by floods some time in the recent past, although there are no micaceous (Precambrian) outcrops in this area. However, the surface finish of vessels combined with the diversity of clay sources represented, is more consistent with Apache practices.

Petrographic analysis may be useful in separating regional clay districts and localized sources based on the relative abundances of rare minerals (as indicated above). It should be noted, however, that mineralogical information obtained from LA 85869 petrographic analysis will have limited utility until a comparative clay source study is completed.

APPENDIX P
RECONSTRUCTIBLE VESSEL ANALYSIS

Marlene Owens and Dean Wilson

As part of the Los Alamos Project ceramic analysis, whole vessels recovered during earlier excavations of sites near Los Alamos, and which were stored at MIAC (Museum of Indian Arts and Culture), were analyzed. This resulted in the examination of 23 reconstructible vessels from several sites in the area. Characteristics recorded for each of these vessels include: 1) the site and provenience (if known) from where the vessel was recovered; 2) the curation (catalog) number from the MIAC; 3) the vessel number assigned during the present study (this number is the order in which the vessel was analyzed); 4) basic information recorded for the analysis of most Los Alamos pottery ceramics including the pottery type, form, temper, interior and exterior surface manipulation and type of pigment, of the vessel; and 5) additional information recorded during vessels analysis including design motifs and layouts, size, reconstruction status, firing condition including sooting, post-firing wear and modifications, and the completeness and maximum volume

The maximum volume was calculated using the formula $V = \pi r^2 h$. Volume capacity was estimated from the profile of the vessel by measuring height divided into equal increments of two centimeters or four centimeters (depending on the size of the vessel) then multiplied by the radius of the increments subsequently multiplied by pi (3.141), then summed together into cubic centimeters, which then is converted to liters. One thousand cubic centimeters is equal to one liter. This is a tedious process but a slightly more accurate one. Vessel form was utilized in this case as a description between the types of pottery and function was implied. This analysis does not delve into the functions of the vessel due to the wide range of the potential usage of any vessel assemblage. Additional attributes were also recorded, such as modifications to the vessel possibly implying use. A description of each the vessels analyzed during the present study follow.

RECONSTRUCTIBLE VESSEL DESCRIPTIONS

Vessel 1

Vessel one was recovered from LA 169 (Otowi). The vessel was classified as Wiyo Black-on-white and is a shallow bowl, which is 80 percent complete (Figure P.1). The interior surface was highly polished with a white slip and the exterior was unpolished. Surface conditions indicated it was slightly oxidized. The base has slight to moderate abrasion with a few scattered fire clouds. Rim chipping is evident, but most likely not from use. Designs are boldly executed on the interior surface in an organic pigment. The interior design band is made up of hatchured lines with bold triangles in between the diamond panels. The diagonally placed panels have bold opposing triangles down the center and smaller bold triangles in opposite corners. Two framing lines are near the bottom of the band. There was no rim decoration. The band is approximately

12 cm in width. The center design has four isolated triangles with a spiraling line square. The dimensions of the bowl are shown in Table P.1.

Figure P.1. Santa Fe Black-on-white vessel from Otowi.

Table P.1. Dimensions for Vessel 1.

Rim Diameter	29.5 cm
Height	13.4 cm
Maximum Diameter	29.5 cm
Maximum volume	6.55 L

Vessel 2

Vessel two was recovered from LA 170 (Tsirege). The vessel is an unpolished miniature Mudware seed jar (Figure P.2). The exterior surface had variable portions reduced in firing and surfaces were oxidized. The exterior had a slight abrasion with poorly defined fire clouds. The dimensions of the jar are shown in Table P.2.

Table P.2. Measured dimensions for Vessel 2.

Rim Diameter	6.0 cm
Height	5.0 cm
Maximum Diameter	7.5 cm
Maximum volume	.16L

Figure P.2. Mudware seed jar from Tsirege.

Vessel 3

Vessel 3 was recovered from LA 170 (Tsirege). The vessel represents an unusually shaped Biscuit B (Bandelier Black-on-gray) shallow bowl (Figure P.3).

Figure P.3. Biscuit B vessel from Tsirege.

The interior and exterior of the bowl had an unevenly, but well-polished grayish cream slip. The surfaces are slightly oxidized and the exterior surface has abrasions in two places at the base of the bowl. Designs are executed on both sides in organic paint. The rim ticking consists of six isolated repetitions of 4 to 5 dots. The interior design consisted of isolated motifs of connecting line flags covering the whole bowl. The exterior design was organized as a band consisting of a zig-zag line with parallel ticked lines on both sides. This band had a single framing line on the top and bottom. The dimensions of the bowl are shown in Table P.3.

Table P.3. Measured dimensions for Vessel 3.

Rim Diameter	25.0 cm
Height	9.0 cm
Maximum Diameter	25.0 cm
Maximum volume	3.68 L

Vessel 4

Vessel 4 was recovered from LA 170 (Tsirege), and was identified as a shallow Biscuit B (Bandelier Black-on-gray) bowl. The interior and exterior surface is well polished over a cream slip. The surfaces were slightly oxidized with a moderate abrasion concentrated at the base. The exterior slip was spalled and had sporadic sooting. Designs are executed on both sides in organic paint. Rim decoration consisted of four occurrences of five dots. The interior of the bowl had a band down the center of the vessel consisting of triangles of dots with connecting line flags framed with a single line. There were stylized linear zoomorphs on the interior of the rim. Linear curving designs and isolated parallel line segments were on both sides of the center design band. The exterior portion of the bowl had a band of several panels of diagonal flag triangles framed on both sided by three different sizes of lines. The dimensions of the bowl are shown in Table P.4.

Figure P.4. Biscuit B vessel from Tsirege.

Table P.4. Measured dimensions for Vessel 4.

Rim Diameter	22.4 cm
Height	10.0 cm
Maximum Diameter	24.0 cm
Maximum volume	3/60 L

Vessel 5

It is not known from what site vessel five originated. It is a slightly lopsided Biscuitware jar. Because of its form, it was not assigned to a specific type. The interior is slightly polished and buff with a moderately polished exterior cream slip (Figure P.5). The jar was slightly oxidized with concentrated abrasions and fire clouds near the base. Designs are executed in the interior surface in organic paint. The design consists of rim ticking, with the top portion of the vessel having a band of several panels incorporated with zoomorphs, framed with single lines. The lower portion of the jar consists of several pairs of parallel perpendicular lines around the vessel. The dimensions of the jar are as shown in Table P.5.

Figure P.5. Biscuitware jar from the Pajarito Plateau.

Table P.5. Measured dimensions for Vessel 5.

Rim Diameter	10.9 cm
Height	8.3 cm
Maximum Diameter	13.5 cm
Maximum volume	0.74 L

Vessel 6

Vessel six was recovered from LA 170 (Tsirege). The vessel was identified as a Kotyiti Glaze F, glaze-on-red constricted bowl with a spout that was much like a tea kettle (Figure P.6). The interior and exterior surfaces are polished over a red slip. The exterior had a sporadic slip, mostly on the lower three-quarters of the bowl. The bowl was poorly oxidized and the exterior base of the bowl was moderately to heavily worn. The design was a band of a runny glaze consisting of "chevron" lines and triangles ending at a break. The dimensions of the bowl are shown in Table P.6.

Figure P.6. Kotyiti Glaze F vessel from Tsirege.

Table P.6. Measured dimensions for Vessel 6.

Rim Diameter	17.8 cm
Height	11.0 cm
Maximum Diameter	22.0 cm
Maximum volume	3.26 L

Vessel 7

Vessel 7 was recovered from LA 170 (Tsirege). The vessel was classified as an Espinosa Glaze C Polychrome and is a shallow bowl (Figure P.7). The exterior and interior surfaces are polished over a red slip with some areas of polished buff. The interior of the bowl was oxidized and the exterior is poorly oxidized. Extremely small fire clouds were evident on the exterior portion of the vessel (Figure P.8). There was no evidence of abrasion on the base. Designs were executed on both sides in a polychrome glaze paints. The interior design layout consisted of two parallel glaze lines; within the lines was a red slip. A zoomorphic figure was in the interior center. The exterior design band consists of four plain panels with four perpendicular panel lines, in between the panel lines is filled in with a red slip. This band was framed on top and bottom by a single line. These lines were also filled in with a red slip. The dimensions of the bowl are shown in Table P.7.

Table P.7. Measured dimensions for Vessel 7.

Rim Diameter	18.8 cm
Height	8.5 cm
Maximum Diameter	20.0 cm
Maximum volume	2.24 L

Figure P.7. Espinosa Glaze C Polychrome vessel from Tsirege.

Figure P.8. Fire clouds present on the exterior portion of the Espinosa Glaze C vessel.

Vessel 8

It is unknown where vessel eight came from. The vessel is a shallow Wiyo black-on-white bowl that is 40 percent complete (Figure P.9). The interior surface is highly polished with a cream slip. The exterior surface appears to have an unusual polished white slip and an unknown red stain. It is difficult to determine the extent of the exterior slip due to the high amount of surface exfoliation. The interior was slightly oxidized. The exterior had a single fire cloud with a slight to moderate abrasion of the base. The interior surface was decorated in organic pigment. The interior slip appears to be a band completely covered with a series of curvilinear spirals with hatchured and dotted filling. Three drill holes were observed near the rim; two of these were parallel. Due to 60 percent of the vessel missing, the dimensions were obtained by the using a template that measured the radius of the rim in one centimeter increments of the partial vessel. The approximate dimensions are shown in Table P.8.

Table P.8. Measured dimensions for Vessel 8.

Rim Diameter (approx.)	22.0 cm
Height (approx.)	10.0 cm
Maximum Diameter (approx.)	22.0 cm
Maximum volume (approx.)	2.67 L

Figure P.9. Wiyo Black-on-white vessel from an unknown site on the plateau.

Vessel 9

Vessel 9 was recovered from LA 170 (Tsirege). The vessel was classified as a shallow Sankawi Black-on-cream bowl. The interior and exterior surfaces are polished with cream slips, which were in shades of white to tarnished gray in color (Figures P.10 and P.11).

Table P.9. Measured dimensions for Vessel 9.

Rim Diameter	24.5 – 35.0 cm
Height	13.5 cm
Maximum Diameter	29.0 – 35.0 cm
Maximum volume (approx.)	8.71 L

Figure P.10. Sankawi Black-on-cream bowl from Tsirege.

Figure P.11. Interior of Sankawi Black-on-cream vessel from Tsirege.

There was slight oxidation of both surfaces and fire clouds on the exterior. The base of the vessel had slight abrasion. Both surfaces were decorated in organic pigment. Groups of rim ticking were observed along the rim of the vessel. The interior design consisted of what appears to be a double headed awanyu across the bowl consisting of parallel lines, ticked lines, dots, triangles and rectangular ribbons filled with dots (Figure P.11). Along the interior edge of the rim was a zig-zag line. The exterior design was a band consisting of rectangular ribbons filled with dots with bold diagonal flags. The band was framed with five multiple sized lines, two on top, three on the bottom. It is possible the shape of the bowl was caused by firing, or that the shape was intentional, to incorporate the interior design of the awanyu. Due to the irregular shape of the bowl, the minimum and maximum dimensions were recorded and are shown in Table P.9.

Vessel 10

The site of origin for Vessel 10 is unknown. The vessel was identified as San Lazaro Glaze D glaze-on-red shallow bowl (Figure P.12). The interior and exterior surfaces were polished over red slips. Both surfaces of the bowl were oxidized with fire clouds. The interior design was a band with panels that exhibit elements such as triangles and horizontal lines. The band was framed on both sides with a single line. The exterior band consisted of a masked figure near the rim edge (Figure P.13). Within the band was a series of opposing triangles with line segments in between. The dimensions of the bowl are shown in Table P.10.

Figure P.12. San Lazaro Glaze D glaze-on-red bowl from Tsirege.

Figure P.13. Masked figure on the exterior of a Glaze D bowl.

Table P.10. Measured dimensions for Vessel 10.

Rim Diameter	20.5 cm
Height	8.0 cm
Maximum Diameter	20.5 cm
Maximum volume	1.84 L

Vessel 11

Vessel 11 was recovered from LA 170 (Tsirege). The vessel was classified as a San Lazaro Glaze D glaze-on-red shallow bowl (Figure P.14). The interior and exterior surfaces were polished over a red slip. The interior was oxidized and the exterior poorly oxidized. There was slight abrasion on the exterior at the base of the bowl. Interior design layout had a band consisting of a scalloped line along the interior rim edge and three straight lines that connect to a large mask with feathers at the interior bottom of the bowl (Figure P.15). The exterior had a band of flagged triangles and horizontal lines. The dimensions of the bowl were recorded and are shown in Table P.11.

Figure P.14. San Lazaro Glaze D bowl from Tsirege.

Figure P.15. Interior decoration on a San Lazaro Glaze D bowl.

Table P.11. Measured dimensions for Vessel 11.

Rim Diameter	20.5 cm
Height	8.0 cm
Maximum Diameter	20.5 cm
Maximum volume	1.84 L

Vessel 12

Vessel 12 was recovered from LA 170 (Tsirege). The vessel was assigned to Sankawi Black-on-cream and is a wide mouth jar (Figure P.16). The interior of the jar was an unslipped polished buff with a polished cream slip. The exterior firing conditions were neutral, and very lightly oxidized. A moderate abrasion was observed at the base of the vessel. The exterior surface was decorated in organic paint. The bulge of the jar had a band of motifs that consisted of triangles and rectangular lines with dots, with two framing lines at the top and bottom. The underslope of the jar had a zig-zag line below the band. The rim decoration consisted of bold triangles angled downwards. The paint has faded in some areas, leaving a negative space. The dimensions of the jar are shown in Table P.12.

Figure P.16. Sankawi Black-on-cream jar from Tsirege.

Table P.12. Measured dimensions for Vessel 12.

Rim Diameter	22.0 cm
Height	30.0 cm
Maximum Diameter	38.0 cm
Maximum volume	21.50 L

Vessel 13

Vessel 13 was recovered from LA 170 (Tsirege). The vessel was classified as a Sankawi Black-on-cream wide mouth jar (Figure P.17). The interior of the jar was a polished buff; the exterior surface displayed a polished cream slip. The reflected conditions are neutral to slightly oxidizing with moderate to heavy abrasions along the high point of the concave base of the vessel. Fire clouds were present near the base. Designs were executed in an organic paint and formed a band consisting of three parallel lines in a zig-zag pattern. The center line had ticked lines on both sides. The band had two framing lines with a single thick zig-zag line on the underslope of the vessel. The rim decoration consisted of a band with a checkerboard pattern. The jar dimensions are presented in Table P.13.

Figure P.17. Sankawi Black-on-cream jar from Tsirege.

Table P.13. Measured dimensions for Vessel 13.

Rim Diameter	19.8 cm
Height	33.0 cm
Maximum Diameter	37.0 cm
Maximum volume	23.07 L

Vessel 14

Vessel 14 was recovered from LA 170 (Tsirege). The vessel is a Potsui'i Incised wide mouth jar that is 70 percent complete (Figure P.18). The lower portions of the jar were absent but reproduced with plaster, and thus the height of the vessel was estimated. The exterior surface was incised and polished with a light mica slip. The interior surface was plain and polished and was fired in reduced firing conditions and both surfaces were lightly sooted as indicated by the gray to brown color. The exterior had two bands of incised designs. The upper band consisted of several parallel lines in a zig-zag pattern with a couple of upper framing lines. The lower band had hatchured triangles. The dimensions of the jar are shown in Table P.14.

Figure P.18. Potsui'i Incised wide mouth jar from Tsirege.

Table P.14. Measured dimensions for Vessel 14.

Rim Diameter	22.5 cm
Height (approx.)	31.0 cm
Maximum Diameter	36.0 cm
Maximum volume	21.16 L

Vessel 15

The site of origin of Vessel 15 is unknown. The vessel was classified as an Ocate Micaceous wide mouth pitcher that was 80 percent complete (Figure P.19). The exterior surface had a very thin micaceous slip with numerous striations. The striations were present on both the interior and exterior surfaces with no apparent pattern. The interior striations were more pronounced on the upper portions of the neck. The pot displayed portions that were both reduced and slightly oxidized. The exterior surface had oxidation in areas that reflect use in cooking. There is a singe strap handle extending from the upper middle portion of the body. The bottom portion of the vessel is missing. Both the exterior and interior surfaces are sooted. The rim has abrasion and chipping is most likely from use. The surface manipulation and vessel shape suggest a very late form, circa 1900, which was most likely produced by Jicarilla Apache potters. The dimensions of the vessel are shown in Table P.15.

Figure P.19. Ocate Micaceous wide mouth pitcher from the plateau.

Table P.15. Measured dimensions for Vessel 15.

Rim Diameter	20.5 cm
Height (approx.)	23.5 cm
Maximum Diameter	30.0 cm
Maximum volume	10.99 L

Vessel 16

The site of origin of Vessel 16 is unknown. The vessel was a Sapawi Gray wide mouth utilityware jar (Figure P.20). The exterior consisted of a smeared plain corrugated surface and the interior was plain and unpolished. The paste does not appear to have any mica although a thin mica slip was observed. Surface conditions indicated reduced firing and it was sooted on the exterior surfaces most likely from cooking. The base of the jar had a highly abraded surface. The exterior surface manipulation was corrugated from the top ¾ and the lower portion was a plain unpolished surface. The dimensions of the jar are shown in Table P.16.

Table P.16. Measured dimensions for Vessel 16.

Rim Diameter	31.5 cm
Height	40.5 cm
Maximum Diameter	47.0 cm
Maximum volume	47.80 L

Figure P.20. Sapawi Gray wide mouth utilityware jar from the plateau.

Vessel 17

The site of origin of Vessel 17 is unknown. The vessel was identified as Sapawe Micaceous and is a wide-mouth utilityware jar (Figure P.21). The exterior consisted of a smeared plain corrugated surface and the interior was plain and unpolished. It did not appear to have a mica slip. The jar had reduced firing and was sooted on the exterior and is most likely from cooking. The base of the vessel had moderate to heavy abrasion. The exterior surface manipulation was corrugated from the top ¾ and the lower portions had a plain unpolished surface. The dimensions of the vessel are shown in Table P.17.

Figure P.21. Sapawe Micaceous utilityware jar from the plateau.

Table P.17. Measured dimensions for Vessel 17.

Rim Diameter	25.5 cm
Height	24.5 cm
Maximum Diameter	31.5 cm
Maximum volume	13.75 L

Vessel 18

It is not known where Vessel 18 was recovered. This vessel was identified as an indented-corrugated wide-mouth utilityware jar (Figure P.22). The exterior had an indented-corrugated surface manipulation and the interior was plain and unpolished. The jar was fired in reduced firing conditions and displays sooting on the exterior. The dimensions of the jar are shown in Table P.18.

Figure P.22. Indented corrugated utilityware jar from the plateau.

Table P.18. Measured dimensions for Vessel 18.

Rim Diameter	11.8 cm
Height	14.0 cm
Maximum Diameter	15.5 cm
Maximum volume	1.95 L

Vessel 19

Vessel 19 was recovered from LA 4631. The vessel was identified as a smeared-indented corrugated bowl that is 80 percent complete (Figure P.23). Portions of this bowl were reconstructed using plaster. The exterior had an indented-corrugated surface manipulation and the interior was plain and unpolished. It was fired in a reduced atmosphere and exhibited slight sooting on both surfaces. Slight to moderate abrasion was observed on the base of the bowl. The interior portion had stains in an unknown pigment. The dimensions of the bowl are shown in Table P.19.

Figure P.23. Smeared-indented corrugated vessel from LA 4631.

Table P.19. Measured dimensions for Vessel 19.

Rim Diameter	13.3 cm
Height	6.5 cm
Maximum Diameter	13.3 cm
Maximum volume	0.57 L

Vessel 20

Vessel 20 was recovered from LA 4712. The vessel was identified as a smeared-indented corrugated utilityware jar (Figure P.24). The exterior surface manipulation was smeared-indented corrugated and the interior was plain and unpolished. The vessel was fired in reduced conditions and had sooting on the exterior. The base had moderate abrasions. Patterns of sooting indicate probable use for cooking. Organic paint was observed on the interior surface. It consisted of four parallel organic lines that angle from the rim. The vessel dimensions are shown in Table P.20.

Figure P.24. Smeared-indented corrugated vessel from LA 4712.

Table P. 20. Measured dimensions for Vessel 20.

Rim Diameter	25.5 cm
Height	33.0 cm
Maximum Diameter	36.0 cm
Maximum volume	23.34 L

Vessel 21

There is no provenience information for Vessel 20. The vessel was identified as a smeared-indented corrugated wide mouth jar (Figure P.25). The exterior surface manipulation consisted of smeared-indented corrugated texture with the interior plain and unpolished. The firing conditions were mostly reduced with some areas oxidized. Post-firing conditions consisted of sooting and oxidation, probably from cooking. The base of the vessel had slight abrasion. Two pairs of repair holes were observed near the rim and another pair at the bottom of the vessel. The rim also had four pronounced fillets. The vessel dimensions are showing in Table P.21.

Figure P.25. Smeared-indented corrugated jar from the plateau.

Table P.21. Measured dimensions for Vessel 21.

Rim Diameter	23.5 cm
Height	29.0 cm
Maximum Diameter	33.0 cm
Maximum volume	17.68 L

Vessel 22

Vessel 22 was recovered from LA 4634. The vessel was unidentified as a highly unusual square Santa Fe black-on-white shallow bowl (Figure P.26), which was analyzed while on display at the museum. The interior and exterior surface consisted of a polished white slip. The bowl had neutral firing conditions. Some sooting was visible on the exterior surface, although the extent is unknown. The interior is decorated with organic pigment. The design band consisted of four panels; two of the panels were of the checkerboard pattern, opposite one another, the other two panels consisting of opposing parallel "chevron" lines with bold ticked triangles in the corners and in the center of the lines. There appears to be two repair holes near the rim. The dimensions of the bowl are taken from the cataloging card and are shown in Table P.22.

Table P.22. Measured dimensions for Vessel 22.

Rim Dimensions (l x w)	17.1 cm by 17.1 cm
Height	8.3 cm
Maximum Diameter	17.1 cm
Maximum volume	1.82 L

Figure P.26. Square Santa Fe Black-on-white bowl form LA 4634.

Vessel 23

Provenience information for Vessel 23 is unknown. The vessel was identified as a shallow Biscuit B (Bandelier Black-on-gray) bowl (Figure P.27). The analysis of this bowl occurred while it was on display at the museum. The surface manipulation appears to be a polished cream slip. The exterior design and surface could not be seen, and was not analyzed. The vessel had neutral firing conditions. The interior is decorated with organic pigment. The interior design layout consisted of a band that included panels of triangles and parallel lines with dots, which were divided into two distinct patterns. The band was framed with multiple sized lines on top and bottom. There were several groupings of ticked rim lines. The dimensions of the bowl were taken from the catalog card and are shown in Table P.23.

Table P.23. Measured dimensions for Vessel 23.

Rim Diameter	33.7 cm
Height	15.3 cm
Maximum Diameter	35.7 cm
Maximum volume	11.96 L

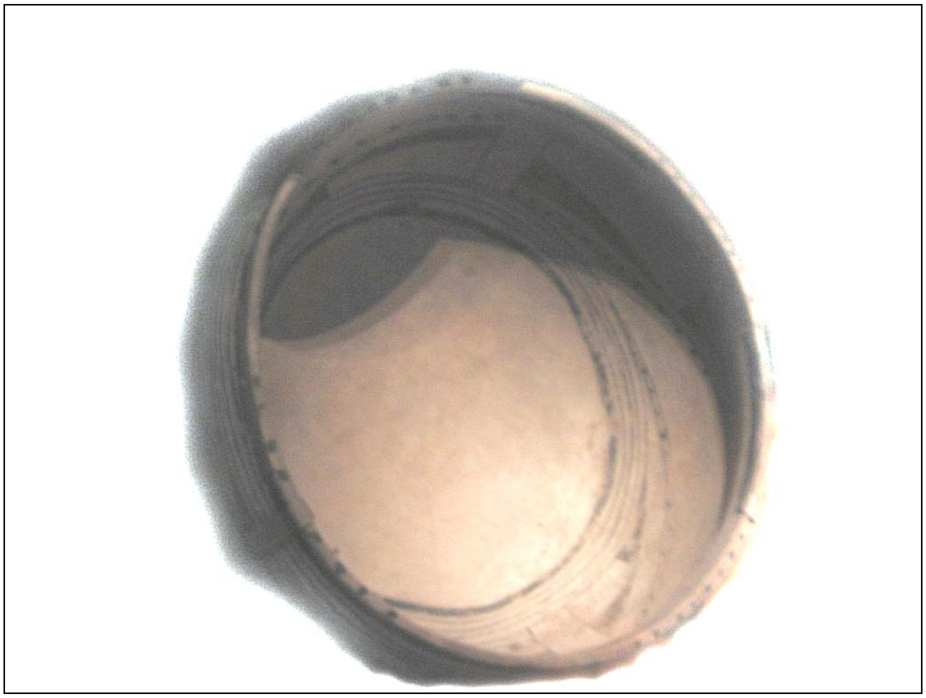

Figure P.27. Biscuit B bowl from an unknown site on the plateau.

Summary

All the vessels are recovered from the general Los Alamos area. Nine vessels had an unknown site number. According to the Museum of Indian Arts and Culture, these unknown vessels were recovered by Mike Burkheimer, Conway Smith, and John Marshall in 1964 and are on loan by the Department of Energy and the Los Alamos Historical Museum. Tables P.24 through P.27 summarize the information collected during the analyses of the whole vessels.

aSome sherds could not be thin-sectioned for size or other considerations, but this inventory preserves the complete original list of sherds sent for analysis.
bThis column contains object-specific identifier information, in the format "Site-Accession code-Catalog number" or "Site-Provenience code-Object number."

Table Q.2. Inventory of all sherds selected for petrographic analysis showing temper characterization.

[a]Paste parameters and related calculated parameters: P + V + T = Paste + Voids + Total. Paste percent = Paste/P + V + T. Sand percent = Total (from Table Q.4a)/P + V + T. Paste values are missing from some sherds. Mineral to Lithic Ratios: M = Total mineral grains (Q + F + sum of Px to Gar, Table Q.4b). Lv = Sum of volcanic lithic grains (Lv___). Lm = Sum of metamorphic lithic grains (Lm___). Ls = Sum of sedimentary lithic grains (Ls___). L = Lv + Lm + Ls. Bulk Composition and Feldspar Ratios: Q = Qtz + Sqtz. F = K + Tplag. Tkspar = Kspar + Skspar. K = Kspar + Skspar + Micr + Sanid. Tplag = Plag + Plagal + Plaggn + Splag.

APPENDIX R:
DEBITAGE CODING SHEET

LA #
Area #
Room #
Feature #
Stratum #
Level #
FS #

Artifact Type

1. angular debris
2. core flake
3. blade
4. biface flake
5. uniface flake
6. notching flake
7. channel flake
8. bipolar flake
9. *piece esquillee*
10. core trimming flake
11. core tablet
12. burin spall
13. opposing core flake (struck from bottom of core)
14. change-of-orientation flake (overstruck core flake that removes bottom of core)
15. *outrepasse* (overstruck biface thinning flake)
16. pot lid
17. hammerstone flake
18. ground stone flake
19. manuport
20. microdebitage (< 10 mm)
21. und. Flake
22. fire-cracked rock

Material Type

See lithic material coding sheet

Material Grain

1. fine (glossy)
2. medium (smooth surface)
3. coarse (grainy to the touch)

Condition

1. whole (incl. angular debris, FCR, manuport)

2. proximal
3. midsection
4. distal
5. lateral
6. und. Fragment (includes microdebitage)

Measurements

length (mm for whole flakes and manuports that are river cobbles)
weight (0.1 gm; all)

Platform Type

1. absent
2. cortical
3. single-faceted
4. dihedral
5. multi-faceted
6. collapsed
7. crushed
8. battered (HS flakes)
9. non-applicable (angular debris, microdebitage, FCR, manuport)

Platform Preparation

1. none
2. abraded/crushed
3. ground
4. abraded/ground
5. retouched
6. retouched/abraded
7. retouched/ground
8.
9. und./non-applicable (collapsed, crushed, battered platform, flake frag) or (absent, angular debris, microdebitage, FCR, manuport)

Cortex Type (Raw Material Form)

1. absent
2. nodular
3. tabular
4. waterworn
5. quartz crystal
6. undetermined

Cortex Placement

1. absent
2. platform only
3. dorsal only
4. platform and partial dorsal

5. orange rind
6. platform and/or 100% dorsal
7. non-applicable (flake fragments, HS flakes, angular debris, microdebitage FCR, manuports)

Burning
1. absent
2. present

No. of Damaged Edges

Location of damage
1. end
2. lateral
3. projection
4. dorsal

Edge Outline
1. straight
2. concave
3. convex
4. straight/concave
5. straight/convex
6. concave/convex
7. projection (graver/perforator)
8. flat (abraded/ground surface)

Edge Angle (blank for projections and flat edge outlines)

CORES AND HEAVY-DUTY TOOLS

Artifact Type
20. core
21. tested material
22. cobble uniface
23. cobble biface
24. hammerstone
25. anvil

Material Type
See lithic material coding sheet

Material Grain
1. fine
2. medium

3. coarse

Condition
1. whole
2. fragment

Measurements
length (mm)
width (mm)
thickness (mm)
weight (gm; core fragments)

Core Type
1. single-directional (nodule blank)
2. bidirectional (nodule blank)
3. multi-directional (nodule blank)
4. bipolar core (nodule or flake blank)
5. core fragment (nodule or flake blank)
6. non-applicable (tm, cobbles, hammerstones)
7. flake core (flake blank)

Core platform orientation/shape
single-directional cores
1. single-face
2. multi-faces
3. prismatic
4. pyramidal

bidirectional cores
5. change of orientation
6. discoidal
7. bifacial
8. opposed same face
9. opposed different face
10. 90 degrees

multi-directional cores
11. globular
12. opposed/ 90 degrees
13. opposed same and different face

other cores
14. bipolar core
15. core fragment

non-applicable

16. non-cores (tm, cobbles, hammerstones)

Number of Core Platforms (zero for core fragments and non-cores, 1 for bipolar cores).

Core Platform type
1. cortical (e.g., cores on large flakes or angular debris)
2. single-faceted
3. cortical and single-faceted
4. multi-faceted
5. undetermined/non-applicable (core fragments, non-cores)

Core Platform Preparation
1. none
2. abraded/crushed
3. ground
4. abraded/ground
5.
6. undetermined/non-applicable (core fragments, non-cores)

Cortex Type (Raw Material Form)
1. absent
2. nodular
3. tabular
4. waterworn
5. quartz crystal
6. undetermined

Percent Cortical/Unflaked surface
1. <25%
2. 25-50%
3. 51-75%
4. >75%
5. undetermined (core frags)

Reason for Discard
1. broken: material flaw
2. broken: culturally induced fracture
3. extensive hinging/stepping
4. exhausted
5. still useable
6. extensive edge battering (e.g., core/hammerstone, cobble biface)
7. burned
8. undetermined
9. non-applicable (e.g., hammerstones)

Burning

1. absent
2. present

Number of Damaged Loci

Type of Damage (1-4)

1. battering
2. rounding
3. scarring
4. abrasion/ground

Location of Damage (1-4)

1. edge
2. convex surface
3. ridge
4. flat surface
5. flake scar ridge
6. all over

RETOUCHED TOOL CODING SHEET

Artifact Type

30. retouched pieces
31. notch (1-2 contiguous notches)
32. denticulate (>2 contiguous notches)
33. biface
34. projectile point
35. uniface
36. end scraper
37. side scraper
38. nosed scraper
39. circular scraper
40. transverse scraper
41.
42.
43. drill
44. perforator
45. graver
46. burin
47. ret. flake/perforator
48. perforator/notch
49. denticulate/notch
50. uniface/notch
51.

Material Type

See lithic material coding sheet

Material Gain

1. fine
2. medium
3. coarse

Condition (Note: manufacture, use, or undetermined for break type in comments)

1. whole
2. proximal
3. midsection
4. distal
5. lateral
6. und. fragment

Measurements (note also use separate form for projectile point metrics)

length (mm)
width (mm)
thickness (mm)
weight (gm; fragments)

Cortex Type (Raw Material Form)

1. absent
2. nodular
3. tabular
4. waterworn
5. quartz crystal
6. undetermined

Biface shape/Point Type

1-165. See list of point types
180. stemmed (shouldered or tanged)
181. contracting stem
182. corner-notched
183. side-notched
184. side-notched with basal-notch
185. fluted
186. und. fragment
201. ovoid
202. ovate
203. lanceolate
204. round
205. triangular
210. n/a (not a biface/pt)
211. cruciform

Burning
1. absent
2. present

Number of Separate Retouched Edges (1-formal tools; n- retouched pieces)

Retouch Type (1-4)
1. unidirectional ventral (inverse)
2. unidirectional dorsal (obverse)
3. bidirectional (both faces)
4. alternating (uni. ventral and dorsal along same edge)
5. alternate (uni. Ventral and dorsal along opposite edges)
6. beveled
7. alternate/beveled
8. use-wear
9. burination
10. backed
11. bidirectional/beveled

Edge Outline (1-4)
1. straight
2. concave
3. convex
4. straight/concave
5. straight/convex
6. concave/convex (denticulate or double notch)
7. projection (graver/perforator)
8. flat (abraded/ground surface)
9. undetermined (point frags)

Damage Present (1-4)
1. absent
2. present
3. undetermined (e.g., point base frags)

Edge Angle (1-4) (monitor on blade for pts and bifaces, scraper edges, and blank on point base frags)

PROJECTILE POINT CODING SHEET

1. Late Paleo-concave-based, convex blade: 1a (narrow) and 1b (wide)
2. Late Paleo-square-based; also may have convex blade
3. Jay (convex or straight base)
4. Bajada (concave base)

5. James Allen
6. Contracting stem: Gypsum Cave
7. Preform
8. Undetermined
9. Middle Archaic: San Jose
10. Late Archaic-Armijo
11. Foothill Mountain (convex blade, concave base/Angostura)
12. Late Paleo: Sierra Vista
13. Undetermined large side-notched
14. Long contracting stem (Hellgap/Agate Basin)
15. Great Basin
16. Large side-notched (straight base; Sudden or Northern)
17.
18. Large side-notched (concave base; San Rafael)
19. Late Archaic: corner-notched
20. Late Archaic: side-notched
21. Late Archaic: stemmed (straight or concave base)
22. Late Archaic: leaf-shaped
23. Late Archaic: contracting stem

Metrics

Overall length
Blade length
Blade width
Neck width
Stem length
Stem width
Max thickness
Basal depth
Weight

Condition

1. Whole
2. Proximal
3. Midsection
4. Distal
5. Lateral
6. Undetermined
7. Broken

Blade Shape

1. Straight (angled)
2. Parallel
3. Convex
4. Serrated
5. Concave
6. Irregular

7. Other
8. Undetermined

Base Shape

1. Straight
2. Concave
3. Notched
4. Convex (contracting)
5. Other
6. Undetermined

Ground

1. Base & lateral
2. Lateral
3. Base
4. Undetermined
5. Absent

Reworked

1. Absent
2. Blade
3. Base
4. Blade & Base
5. Undetermined

Beveling

1. Absent
2. Present
3. Undetermined

GROUND STONE CODING SHEET

Artifact Type

50. one-hand mano (<170 mm)
51. two-hand mano (>170 mm)
52. undetermined mano fragment
53. millingstone (>250 mm)
54. basin metate
55. formal slab metate
56. trough metate
57.
58. grinding slab (<250 mm)
59. undetermined metate fragment
60. polishing stone

61. palette
62. mortar
63. pestle
64. abrading stone (generalized)
65. grooved abrader
66. axe
67. maul
68. hoe
69. tchamajilla
70. ornament
71. pipe
72. stone ceramic lid
73. comal
74. misc. ground stone
75. vent plug (tiponi)
80. undetermined ground stone fragment
81. whet stone
82. shaped slab

Material Type
See lithic material coding sheet

Condition
1. whole
2. fragment

Measurements
length (mm)
width (mm)
thickness (mm)
weight (gm)

Primary Grinding Surface length (mm)

Primary Grinding Surface width (mm)

Use Location
1. single unopposed surface
2. two opposed surfaces
3. perimeter (e.g., abrading stone)
4. edge (e.g., axe)
5. other
6. undetermined (frags)
7. non-applicable (e.g., ornament, stone lids, shaped slab)

Grinding surface cross-section (single or double surfaces)

1. plano (flat)
2. concave
3. convex
4. bi-plano
5. plano-convex
6. plano-concave
7. bi-convex
8. wedge shaped
9. n/a (w/out grinding surfaces)
10. undetermined
11. beveled/flat
12. beveled/beveled
13. beveled (single surface)

Grinding Surface(s) Shape

1. ovoid
2. rectangular
3. n/a
4. undetermined
5. irregular (e.g., abrader)

Surface(s) modification

1. ground
2. pecked
3. ground/pecked
4. polished/ground
5. flaked (e.g., axe, hoe, shaped slab)
6. flaked/ground (e.g., axe)

Mano fingerholds

1. absent
2. one side
3. two sides
4. undetermined (mano frags)/ non-applicable (non-manos)

Other ground stone use-wear

1. absent
2. battering (mano/hammerstone, maul)
3. scarred/rounded edge (axe, tchamajilla)
4. core (e.g., 1-hand mano)
5. trough metate wear on mano

Burned

1. absent
2. present

LITHIC RAW MATERIAL TYPES

100. undetermined Igneous
110. basalt
    111. vesicular basalt
120. rhyolite
130. andesite
140. granite/diorite
150. dacite
180. obsidian
    181. black translucent (Jemez); also w/ white inclusions, banded and smokey.
    182. black opaque (with brown edges)
    183. black dusty (Polvadera)
    184. green (Jemez)
    185. brown (Jemez)
    186. gray (Cerro del Medio?)
    187. mahogany (Cerro del Medio?)
190. tuff
191. welded tuff
192.
193. pumice
200. Undetermined Sedimentary
    210. sandstone
    211. concretion
    212. fossil
    213. orthoquartzite
    214. conglomerate
    215. breccia
220. Siltstone
230. Shale
240. Jet
250. Limestone
260. Chalcedony
270. Chert
    271. Pedernal chert/chalcedony (with black, red and/or yellow)
    272. Alibates - 5RP 4/2, grayish/red/purple to 10R 4/2, grayish red
    273. Greenish/Gray/ mottled chert – N7, light gray to N4 medium dark gray
    274. Salmon pink chert – 10R 7/4, moderate orange pink
    275. Yellow/Butterscotch chert – 10YR 5/4, moderate yellowish brown to 10YR 6/6 dark yellow orange
    276. Jasper/red/burgundy chert – 10R 2/2,very dusky red
    277. Yellowish/brown, (w/fossil incl.) – 10YR 5/4, moderate yellowish brown
    278. Green mottled chert, w/rust colored incl. – 5Y 4/1, olive gray, 10Y 6/2 pale olive to 5GY 5/2, dusky yellow green

279. Mottled tan/white chert – 5YR 6/1, light brownish gray to N7 light gray (was #261).

290. Silicified Wood
400. Undetermined Metamorphic
410. Quartzite
420. Schist
430. Soapstone
440. Metaconglomerate
450. Greenstone
460. Gneiss
470. Slate
899. Undetermined mineral

900. Quartz	904. Selenite/gypsum	908. Kaolinite
901. Quartz Crystal	905. Calcite	909. Turquoise
902. Hematite	906. Mica	910. Augite
903. Limonite	907. Azurite	911. Malachite

APPENDIX S
C&T FLOTATION SAMPLE SUMMARY INFORMATION

Table S.1. C&T summary flotation information.

APPENDIX Z
TECHNICAL REPORT ON DATING OF CERAMIC MATERIALS FROM LOS ALAMOS, NEW MEXICO

Technical data on the luminescence analysis of 33 ceramic materials from sites near Los Alamos, New Mexico, were originally presented in a series of four reports. These are combined here to reduce repetition. Because table formats differed slightly from report to report, the original tables are maintained in this appendix, which should also facilitate keeping separate each set of analyses. The samples are listed in Tables Z.1 through Z.4. The general laboratory procedures are presented at the end of the appendix.

Table Z.1. TL samples from the 2002 excavations.

Lab #	Site	FS#	Room	Material	Context	Burial Depth (cm)
UW1030	LA12587	1274	2	B/W sherd	Room floor	43

Dose Rate

Dose rates were determined from radioactivity measurements using alpha counting (for U and Th) and flame photometry (for K). These results are given in Tables Z.5 through Z.8. Also given in these tables are the comparisons of beta dose rates measured directly by beta counting and derived analytically from alpha counting/flame photometry assuming secular equilibrium in the U and Th decay chains. Where these differ significantly, a possibility of disequilibrium is present. In the latter case, the more direct measure from beta counting is used in the age calculation. Otherwise the more precise alpha counting and flame photometry results are used. Average moisture contents through time for the samples were estimated at 70±30 percent of currently measured absorption values. Moisture contents of 10.5 percent were assumed for the associated sediments. Tables Z.9 through Z.12 give the total dose rates for TL. The OSL dose rates differ slightly because of differences in alpha efficiency.

Table Z.5. Dose rates from radioactivity measurements for 2002 samples.

Sample	U (ppm)	Th (ppm	K (%)	β dose rate (Gy/ka)	
				α-counting/flame phot.	β-counting

Equivalent Dose

Equivalent dose was measured by TL, OSL and IRSL, as described in the procedures section. Anomalous fading was measured for TL only. The correction for lower alpha efficiency, b-value, was measured for all three, except for the first two sets (UW1030-UW1037 and UW1236-UW1247) where it was only measured for TL. A b-value of 0.7 ± 0.3 was assumed for the OSL b-value for these samples (based on measurements of other samples). Tables Z.13 through Z.17 give equivalent dose values and b-values, as well as the TL plateau region, the fit to the TL growth curves and the slope ratio between additive dose and regeneration TL growth curves. Where no IRSL or OSL equivalent value is given, no measurable signal was obtained.

Table Z.13. Equivalent dose values and b-values for the 2002 TL samples.

Sample	Equivalent dose (Gy)			TL parameters		
	TL	IRSL	OSL	Plateau (°C)	Slope ratio*	b-value (Gy μm^2)
UW1030	6.06±0.46			240-300	1	1.47±0.10
UW1031	6.29±0.61	3.70±0.71	5.54±0.63	290-350	0.66±0.05	1.11±0.03
UW1032	7.46±0.53	5.64±0.45	6.78±1.29	None	1	1.12±0.11
UW1033	7.42±0.67		4.48±0.28	310-370	0.75±0.06	1.05±0.06
UW1034	4.25±0.46	3.92±0.41	4.25±0.13	300-340	1	0.83±0.06
UW1035	3.30±0.36	3.14±0.48	6.18±0.99	270-390	1.51±0.14	1.20±0.10
UW1036	4.26±1.33	4.18±0.44	4.43±0.21	320-360	1.90±0.28	1.34±0.11
UW1037	3.63±0.40	3.72±0.46		310-410	1.36±0.12	1.07±0.10

* Growth curve fits were linear for all samples except for UW1030, UW1031, UW1032 and UW1037 for which they were quadratic.

Table Z.14. Equivalent dose values and b-values for the 2003 TL samples.

Sample	Equivalent dose (Gy)			TL Parameters

* Growth curve fits were linear for all samples except UW1244. For UW1240 and UW1245, only an additive dose procedure was used because the regeneration growth curves resulted in a significant negative intercept, suggesting a growth curve of a different shape than for additive dose and therefore not amenable to the slide technique.

Age

Tables Z.19 through Z.22 give the derived ages and their bases. Discussion of the ages follows. For the sites excavated in 2002, the TL and OSL ages agreed on UW1031, UW1032, UW1034, UW1035, and UW1036, although the OSL age for UW1035 was based on only a single aliquot. On UW1032, even though the TL and OSL ages agreed, both produced anomalously old ages. The sample had no TL plateau, so it is probable the sample was not fired sufficiently in antiquity and therefore carries a small geological residual signal. UW1030 and UW1037 had no measurable OSL signal, so the age was based only on TL. Neither sample showed significant fading. For UW1033, the TL age was anomalously old, so the OSL age was taken as the best estimate. This sample may also have suffered from insufficient firing.

Table Z.19. Derived ages and bases for the 2002 TL data.

Sample	Basis	Years BP	% error	Years AD
UW1030	TL	777±68	8.7	1226±68
UW1031	TL/OSL	956±80	8.4	1047±80
UW1032	TL/OSL	1321±120	9.1	682±120
UW1033	OSL	943±109	11.6	1060±109
UW1034	TL/OSL	815±59	11.1	1188±59
UW1035	OSL/corrected TL	1202±201	16.7	801±201
UW1036	TL/OSL	821±42	5.1	1182±42
UW1037	TL	678±86	12.7	1325±86

In eight of the 2003 excavated samples, the TL and OSL ages were in agreement, for UW1238 only after the TL age was corrected for fading. On three samples, UW1241, UW1244 and UW1246, the TL age was younger than the OSL age, probably due to fading of the TL signal. This was verified by fading tests for UW1244 and UW1246, although an attempted correction produced an unrealistically old age. Fading was assumed for UW1241, for which no fading test was performed due to sample size. The OSL age was considered the best estimate for all three. For UW1243, the OSL produced an unreasonably old age (perhaps because of insufficient heating), so the TL age, corrected for fading, was taken as the best estimate. The sample had a relatively small TL plateau.

Table Z.20. Derived ages and bases for the 2003 TL samples.

Sample	Basis	Age (ka)	% error	Date (years AD)
UW1236	OSL/TL	0.970±0.072	7.4	1035 ± 73
UW1237	OSL/TL	0.871±0.079	9.1	1134 ± 79
UW1238	OSL/TL	0.891±0.085	9.6	1114± 85
UW1239	OSL/TL	0.788±0.056	7.0	1217 ± 56
UW1240	OSL/TL	0.955±0.090	9.4	1050 ± 90
UW1241	OSL	1.189±0.133	11.2	816 ± 133
UW1242	OSL/TL	1.117±0.062	5.6	888 ± 62
UW1243	TL	0.932±0.135	14.5	1073 ± 135
UW1244	OSL	1.154±0.125	10.8	851 ± 125
UW1245	OSL/TL	0.146±0.021	9.1	1859 ± 13
UW1246	OSL	1.169±0.134	11.5	836 ± 134
UW1247	OSL/TL	0.847±0.062	7.4	1158 ± 63

For the sites excavated in 2004, the TL and OSL ages for UW1416 were in agreement, after a correction for TL fading. For UW1417 and UW1418, the OSL age was taken as the best estimate because of fading of the TL signal. This was verified for UW1417, but a correction still underestimated the age in comparison with OSL. A fading test produced too scattered data to be conclusive for UW1418. OSL produced a Pleistocene age for UW1419, so the TL age was taken to be the estimate. No significant fading was detected for this sample. It is uncertain why the OSL signal was so large.

Table Z.21. Derived ages and bases for the 2004 TL samples.

Sample	Age (ka)	% error	Calendar date	Basis for age
UW1416	0.623±0.039	6.2	AD 1383 ± 39	OSL/corrected TL
UW1417	0.542±0.033	6.1	AD 1464 ± 33	OSL
UW1418	0.512±0.028	5.5	AD 1494 ± 28	OSL
UW1419	0.753±.108	14.3	AD 1253 ± 108	TL

For the sites excavated in 2005, the TL and OSL ages were in agreement for UW1502, UW1504, UW1505 UW1507 and UW1586. In the case of UW1504, the IRSL age agreed as well. For UW1586, the TL age was first corrected for fading. On UW1503, the IRSL age agreed with the fading-corrected TL age. The OSL age was slightly older, but the TL and IRSL were judged to be the best estimate. The age could be underestimated. For UW1506, no OSL age was obtained and the IRSL age is probably too young because of fading. The TL signal also faded, but correction produced a rather old, imprecise date, so the uncorrected TL was taken as the best estimate, although possibly underestimated. UW1508 behaved similarly to UW1506 but the fading correction produced a reasonably precise date. For UW1509 both TL and IRSL produced younger dates. Fading was evident for TL but the correction was still young. OSL was taken as the best estimate.

Procedures for Thermoluminescence Analysis of Pottery

Sample Preparation -- fine grain

The sherd is broken to expose a fresh profile. Material is drilled from the center of the cross-section, more than 2 mm from either surface, using a tungsten carbide drill tip. The material retrieved is ground gently by a corundum mortar and pestle, treated with HCl, and then settled in acetone for 2 and 20 minutes to separate the 1-8 µm fraction. This is settled onto a maximum of 72 stainless steel discs.

Glow-Outs

Thermoluminescence is measured by a Daybreak reader using a 9635Q photomultiplier with a Corning 7-59 blue filter, in N_2 atmosphere at 1°C/s to 450°C. A preheat of 240°C with no hold time precedes each measurement. Artificial irradiation is given with a ^{241}Am alpha source and a ^{90}Sr beta source, the latter calibrated against a ^{137}Cs gamma source. Discs are stored at room temperature for at least one week after irradiation before glow out. Data are processed by Daybreak TLApplic software.

Fading Test

Several discs are used to test for anomalous fading. The natural luminescence is first measured by heating to 450°C. The discs are then given an equal alpha irradiation and stored at room temperature for varied times: 10 min, 2 hours, 1 day, 1 week and 8 weeks. The irradiations are staggered in time so that all of the second glows are performed on the same day. The second glows are normalized by the natural signal and then compared to determine any loss of signal with time (on a log scale). If the sample shows fading and the signal versus time values can be reasonably fit to a logarithmic function, an attempt is made to correct the age following procedures recommended by Huntley and Lamothe (2001).

Equivalent Dose

The equivalent dose is determined by a combination additive dose and regeneration (Aitken 1985). Additive dose involves administering incremental doses to natural material. A growth curve plotting dose against luminescence can be extrapolated to the dose axis to estimate an equivalent dose, but for pottery this estimate is usually inaccurate because of errors in extrapolation due to nonlinearity. Regeneration involves zeroing natural material by heating to 450°C and then rebuilding a growth curve with incremental doses. The problem here is sensitivity change caused by the heating. By constructing both curves, the regeneration curve can be used to define the extrapolated area and to correct for sensitivity change by comparing it with the additive dose curve. This works where the shapes of the curves differ only in scale (i.e., the sensitivity change is independent of dose). The curves are combined using the "Australian slide" method in a program developed by David Huntley of Simon Fraser University (Prescott et al. 1993). The equivalent dose is taken as the horizontal distance between the two curves after a scale adjustment for sensitivity change. Where the growth curves are not linear, they are fit to quadratic functions. Dose increments (usually five) are determined so that the maximum additive dose results in a signal about three times that of the natural and the maximum regeneration dose about five times the natural. If the regeneration curve has a significant negative intercept, which is not expected given current understanding, the additive dose intercept is taken as the best, if not fully reliable approximation.

A plateau region is determined by calculating the equivalent dose at temperature increments between 240° and 450°C and determining over which temperature range the values do not differ significantly. This plateau region is compared with a similar one constructed for the b-value (alpha efficiency), and the overlap defines the integrated range for final analysis.

Alpha Effectiveness

Alpha efficiency is determined by comparing additive dose curves using alpha and beta irradiations. The slide program is also used in this regard, taking the scale factor (which is the ratio of the two slopes) as the b-value (Aitken 1985).

Radioactivity

Radioactivity is measured by alpha counting in conjunction with atomic emission for ^{40}K. Samples for alpha counting are crushed in a mill to flour consistency, packed into plexiglass containers with ZnS:Ag screens, and sealed for one month before counting. The pairs technique is used to separate the U and Th decay series. For atomic emission measurements, samples are dissolved in HF and other acids and analyzed by a Jenway flame photometer. K concentrations for each sample are determined by bracketing between standards of known concentration.

Conversion to ^{40}K is by natural atomic abundance. Radioactivity is also measured, as a check, by beta counting, using a Risø low level beta GM multicounter system. About 0.5 g of crushed sample is placed on each of four plastic sample holders. All are counted for 24 hours. The average is converted to dose rate following Bøtter-Jensen and Mejdahl (1988) and compared with the beta dose rate calculated from the alpha counting and flame photometer results.

Both the sherd and an associated soil sample are measured for radioactivity. Additional soil samples are analyzed where the environment is complex, and gamma contributions determined by gradients (after Aitken 1985: Appendix H). Cosmic radiation is determined after Prescott and Hutton (1988). Radioactivity concentrations are translated into dose rates following Adamiec and Aitken (1998).

Moisture Contents

Water absorption values for the sherds are determined by comparing the saturated and dried weights. For temperate climates, moisture in the pottery is taken to be 80 ± 20 percent of total absorption, unless otherwise indicated by the archaeologist. Again for temperate climates, soil moisture contents are taken from typical moisture retention quantities for different textured soils (Brady 1974:196), unless otherwise measured. For drier climates, moisture values are determined in consultation with the archaeologist.

Procedures for Optically Stimulated or Infrared Stimulated Luminescence of Fine-Grained Pottery

Optically stimulated luminescence (OSL) or infrared stimulated luminescence (IRSL) on fine-grain (1-8µm) pottery samples is carried out on single aliquots following procedures adapted from Banerjee et al. (2001) and Roberts and Wintle (2001). Equivalent dose is determined by the single-aliquot regenerative dose (SAR) method (Murray and Wintle 2000).

The SAR method measures the natural signal and the signal from a series of regeneration doses on a single aliquot. The method uses a small test dose to monitor and correct for sensitivity changes brought about by preheating, irradiation or light stimulation. SAR consists of the following steps: 1) preheat, 2) measurement of natural signal (OSL or IRSL), L(1), 3) test dose, 4) cut heat, 5) measurement of test dose signal, T(1), 6) regeneration dose, 7) preheat, 8) measurement of signal from regeneration, L(2), 9) test dose, 10) cut heat, 11) measurement of test dose signal, T(2), 12) repeat of steps 6 through 11 for various regeneration doses. A growth curve is constructed from the L(i)/T(i) ratios and the equivalent dose is found by interpolation of L(1)/T(1). Usually a zero regeneration dose and a repeated regeneration dose are employed to insure the procedure is working properly. For fine-grained ceramics, a preheat of 240°C for 10s, a test dose of 1.8 Gy, and a cut heat of 160°C are currently being used, although these parameters may be modified from sample to sample.

The luminescence, L(i) and T(i), is measured on a Risø TL-DA-15 automated reader by a succession of two stimulations. First, 100s at 60°C of IRSL (880nm diodes), and second 100s at 125°C of OSL (470nm diodes). The OSL is also called blue stimulated luminescence (BSL). Detection is through 7.5mm of Hoya U340 (ultra-violet) filters. The stimulations are used to construct IRSL and OSL growth curves, so that two estimations of equivalent dose are available. Only feldspars are sensitive to IRSL, but they are also sensitive to blue light. Nevertheless, the IRSL exposure is expected to greatly reduce the feldspar contribution, so that the OSL signal is mainly from quartz. The procedure is still undergoing study.

Alpha efficiency for IRSL and OSL is measured by adding two alpha regeneration doses to the SAR sequence, retaining the beta irradiation for the test dose. The slope of the alpha growth curve is compared to the slope of the beta growth curve to determine a b-value.

APPENDIX CC

Description of Ceramic Methodology

The following is the list of ceramic attributes that the Museum of New Mexico uses to perform basic pottery analyses. This includes sorting by pottery ware and type, vessel form, pigment type, interior and exterior modifications, temper and paste composition, rim sherd size and diameter, and vessel wall thickness.

Museum of New Mexico
Office of Archaeological Studies
Ceramic Analysis Coding List
Updated November 2005

TEMPER TYPE

0	Not examined
1	Indeterminate
2	Sand
3	Granite with abundant mica
4	Granite without abundant mica
5	Highly micaceous (residual) paste
6	Sherd
7	Sherd and sand
8	Fine tuff or ash
9	Large tuff fragments (vitric tuff)
10	Fine tuff and sand
11	Leucocratic igneous or granite (El Paso area)
12	Fine sandstone
13	Fine Jornada leucocratic igneous
14	Gray crystalline basalt
15	Sand and mica
16	Crushed andesite or diorite
17	Andesite diorite with sherd
18	Andesite diorite with sand and sherd
19	San Marcos latite
20	Fine sand or silt, and mica
21	Indeterminate dark igneous
22	Self tempered
23	Dark igneous and sherd (Chupadero)
24	Taos granite
25	Dark igneous and sand
26	Trachyte (Chuska area)
27	Mogollon volcanics
28	Coarse sand and fine igneous
29	Latite
30	Trachyte and sherd
31	Ant hill sand
32	Shale, sand, and sherd
33	Dark feldspar
34	Sherd and calcium carbonate
35	Fine feldspar, quartz, and hornblende
36	Dark igneous (southern origin)
37	Calcium carbonate
38	Micaceous schist (Gran Quivara)
39	Hornblende tuff
40	Fine Jornada leucocratic igneous and sherd
42	Sand and Mogollon volcanics
43	Basalt and sand
44	Oblate shale and sand
45	Dark crystalline particles and tuff
47	Tuff and mica
48	Andesite or diorite, sand, and shale
50	Vitrified
51	Casas Grandes igneous
52	Shale, dark particles, and mica
53	Tuff, mica and sand
54	Dark sand
55	Quartz and sandstone
56	Shale and sherd
57	Shale
58	Latite and Sand
59	Mica, quartz, and sandstone
60	Very Fine Sand (silt)
61	Quartzite (Leucocratic Igneous)
62	Multi-lithic sand
63	Dark matrix sandstone
64	Andesite or diorite with sand
65	Basalt (Zia)
70	Tuff and Phenocrysts (anthill)
71	Scoria (reddish porous basalt)
75	Quartz, Tuff, Mica in micaceous paste
76	Oblate shale and tuff
77	Large tuff predominate with anthill sand
78	Sapawe (Schist w/ mica, late Rio Grande)
79	Jemez Ash (predominately large ash and/or tuff)
80	Jemez Basalt (predominately basalt w/ash or tuff)

ADDITIONAL TEMPER TYPES (Duwe)

90	Tuff w/quartz sand
91	Tuff w/quartz sand and volcanics
92	Tuff w/quartz sand and plutonics
93	Tuff w/quartz sand and volcanics and plutonics

POTTERY TYPE

INDETERMINATE TRADITION

1101	Indeterminate Utility Ware
1201	Unpainted Undifferentiated White
1202	Mineral Paint Undifferentiated
1203	Indeterminate Organic Paint
1302	Indeterminate Red Ware
1401	Indeterminate Black Ware

NORTHERN RIO GRANDE (TEWA) TRADITION

Prehistoric White Ware

2201	Unpainted Undifferentiated White
2202	Mineral Paint Undifferentiated
2203	San Marcial Black-on-white
2204	Pueblo II Indeterminate Mineral
2205	Red Mesa Black-on-white Rio Grande Paste
2206	Red Mesa Black-on-white Squiggle Hatchure
2207	Kwahe'e Black-on-white Solid Designs

2208 Kwahe'e Black-on-white Thin Parallel Lines
2210 Kwahe'e Black-on-white Hatchured Gallup Style
2211 Kwahe'e Black-on-white Solid and Hatchure
2212 Kwahe'e Black-on-white Checkerboard
2213 Kwahe'e Black-on-white Other Design
2216 Organic Paint Undifferentiated
2217 Indeterminate Organic Coalition Paste
2218 Santa Fe Black-on-white
2219 Wiyo Black-on-white
2229 Biscuit Ware Unpainted Slipped Both Sides
2230 Biscuit Ware Painted Unspecified
2231 Biscuit A Abiquiu Black-on-white
2232 Biscuit B Bandelier Black-on-white
2233 Sankawi Black-on-cream
2234 Unpainted Santa Fe Paste (Seldom Used)
2236 Galisteo Black-on-white
2237 Unpainted Galisteo Paste
2238 Unpainted Biscuit Ware Slipped One Side
2240 Jemez-Santa Fe Vallecitos Black-on-white
2241 Jemez Paste, slipped, unpainted
2250 Organic Slipped Red
2251 Gallina Black-on-white
2252 Biscuit Ware, Slip and Paint Not Observable

Northern Rio Grande (Tewa) Historic Decorated and Polychrome Ware

2533 Tewa Polychrome (type)
2534 Ogapoge Polychrome
2535 Pojoaque Polychrome
2536 Tewa Polychrome Painted Undifferentiated (Two Slips)
2537 Black-on-cream Undifferentiated
2538 Historic Organic Paint Undifferentiated No Slip
2539 Powhoge Polychrome
2540 Historic White\Cream Slipped Unpainted
2541 Red-on-tan Unpainted
2542 Historic Unpainted Red and Cream Slipped
2543 San Juan Red-on-tan
2544 Historic Tewa Black-on-red
2545 Sakona Polychrome
2550 Jemez Black-on-white
2551 Jemez Unpainted
2552 Casitas Red-on-brown
2553 Tewa Paste With Mineral Paint
2554 Powhoge-like Late Polychrome

Prehistoric Utility Ware

3101 Plain Gray Rim
3102 Unknown Gray Rim
3103 Plain Gray Body
3104 Wide Neckbanded
3105 Wide Neckbanded Wiped
3106 Incised Neckbanded
2209 Kwahe'e Black-on-white Thick Parallel Lines
3107 Coiled Neckbanded
3108 Clapboard Neck
3109 Plain Scored Gray
3110 Basket Impressed Gray
3111 Indented Corrugated
3112 Incised Corrugated
3113 Plain Corrugated
3114 Smeared Plain Corrugated
3115 Alternating Corrugated
3116 Punched Corrugated
3117 Incised Plain Corrugated
3118 Smeared Indented Corrugated
3119 Patterned Corrugated
3120 Polished Gray
3121 Neck Corrugated
3122 Plain Incised
3126 Low Relief Corrugated
3130 Mica Utility Undifferentiated
3131 Sapawe Micaceous (Early Form)
3132 Potsuwi'i Incised
3133 Thin Plain Non Micaceous -Classic period
3134 Brushed
3140 Mud Ware
3141 Punctated Gray
3401 Local Brown Ware

Historic Plain Ware

3151 Tewa Buff Undifferentiated
3152 Tewa Polished Gray
3153 Tewa Polished Black
3154 Highly Micaceous Paste
3155 Smudged Interior Mica Slip Exterior
3156 Tewa Polished Red
3157 Polished Interior with Mica Slip
3158 Smudged Micaceous
3159 Smudged Interior Buff Exterior
3160 Tewa Unpolished Black
3161 Wide Neckbanded Wiped
3162 Tewa Unpolished Buff
3163 Smudged Exterior Buff Interior
3166 Unpolished Micaceous Slip
3167 Incised Utility Unpolished
3170 Micaceous Utility Undifferentiated (Temper not examined)
3171 Sapawe Micaceous (Late Variety)
3172 Potsuwi=i Incised
3173 Striated Micaceous
3179 Historic Plain Neck Banded
3180 Smudged Interior Unpolished Exterior
3181 Smudged Interior Corrugated Exterior
3185 Tewa Polished Gray with Mica Slip

3186 Tewa Polished Black with Mica Slip
3187 Polished with Highly Micaceous Paste
3401 Local Brown Ware

Sand Tempered Gray Wares
4101 Plain Gray Rim
4102 Unknown Gray Rim
4103 Plain Gray Body
