Analytical Results From U.S. Bureau of Mines Investigations in the Colville Mining District, Alaska

By Mark P. Meyer¹

ABSTRACT

The U.S. Bureau of Mines, in cooperation with the Alaska Division of Geological and Geophysical Surveys and the U.S. Geological Survey, assessed the mineral resources and the mineral development potential of the Colville Mining District. This study is a continuation of the Bureau's statewide mining district evaluation program. The northern Alaska mining district study area includes the Colville River drainage basin along with the southern and eastern part of the National Petroleum Reserve in Alaska.

This report is a complete compilation of the geochemical data base that was generated as a result of the Bureau's (1990-93) field activities in the Colville Mining District. Also included in this report is a brief summary the Bureau's 1993 field season.

During the third year of the field program (1993) regional reconnaissance was conducted in the eastern section of the mining district between Monotis Creek and Atigun Pass. Anomalous U.S. Geological Survey geochemical sample values were investigated. Site-specific investigations were also conducted on lead-zinc-silver, manganese, and phosphate occurrences within the central and eastern part of the study area. As a result, twelve previously unreported and seven previously reported mineralized areas were examined and sampled during the 1993 field season. Work completed during the 1991-92 field seasons has been summarized in OFR 75-92 and OFR 12-93, respectively. A separate open-file report will be published detailing the work completed on the mineralized occurrences and mineralized areas identified during the 1990-93 field studies. An Executive Summary outlining the complete Colville Mining District study will also be published.

¹Physical Scientist, Alaska Field Operations Center, Anchorage, AK.

INTRODUCTION

In 1991, the U.S. Bureau of Mines (Bureau) initiated the Colville Mining District (CMD) study. Located in northern Alaska, the mining district is composed of the Colville River drainage basin as well as parts of the southern and eastern sections of the National Petroleum Reserve in Alaska (NPRA) (fig. 1). The study area contains 6.7 million hectares within the Colville River drainage and 0.35 million hectares within the NPRA (which also includes the eastern part of the Wainwright Mining District).

Ultimate objectives of this study are to; 1) identify mineral deposits of the CMD, 2) study the application of modern beneficiation technologies on known deposits, and 3) perform mining feasibility studies using hypothetical mine models. This investigation is a cooperative effort involving the Bureau, the Bureau of Land Management (BLM), the U.S. Geological Survey (USGS), and the Alaska Division of Geological and Geophysical Surveys (DGGS).

This CMD study is part of the Bureau's ongoing statewide mining district evaluation program. During 1991 through 1993, the Bureau conducted both reconnaissance sampling of the arctic foothills part of the study area and conducted detailed examinations and delineations of selected mineral occurrences in the study area. This report briefly summarizes the work completed during the 1993 field season and is the third in a series of annual summary reports covering the Bureau's CMD field work. Also contained in this report are the analytical results and sample locations for the entire 1990-93 project as well as an up-to-date bibliography. Work completed by the Bureau during the first two years of the study has been summarized in OFR 75-92 and OFR 12-93, respectively (248-249)².

LAND STATUS

Land ownership in the CMD includes those lands managed by the BLM, the National Park Service (NPS), the State of Alaska, Native regional and village corporations, and private parties. BLM manages the NPRA, which is open for oil and gas exploration but unavailable for mineral location and development. The NPS manages the Gates of the Arctic National Park, Preserve, and Wilderness, which is closed to oil, gas, and mineral exploration and development. The State of Alaska has made land selections within the area including some lands that are and are not available for mineral exploration and development. Native regional and village corporations have also made similar land selections in the area. Small parcels of private inholdings are located within the study area. Some of these lands may be available for mineral exploration and development subject to the management policies of the state and private land owners.

LOCATION AND ACCESS

Located in northern Alaska, the CMD comprises most of the west-central part of the northern slope of the Brooks Range (fig. 1). This area is bounded by the Colville River drainage

²Underlined numbers in parentheses refer to the references found in the bibliography preceding the appendix.

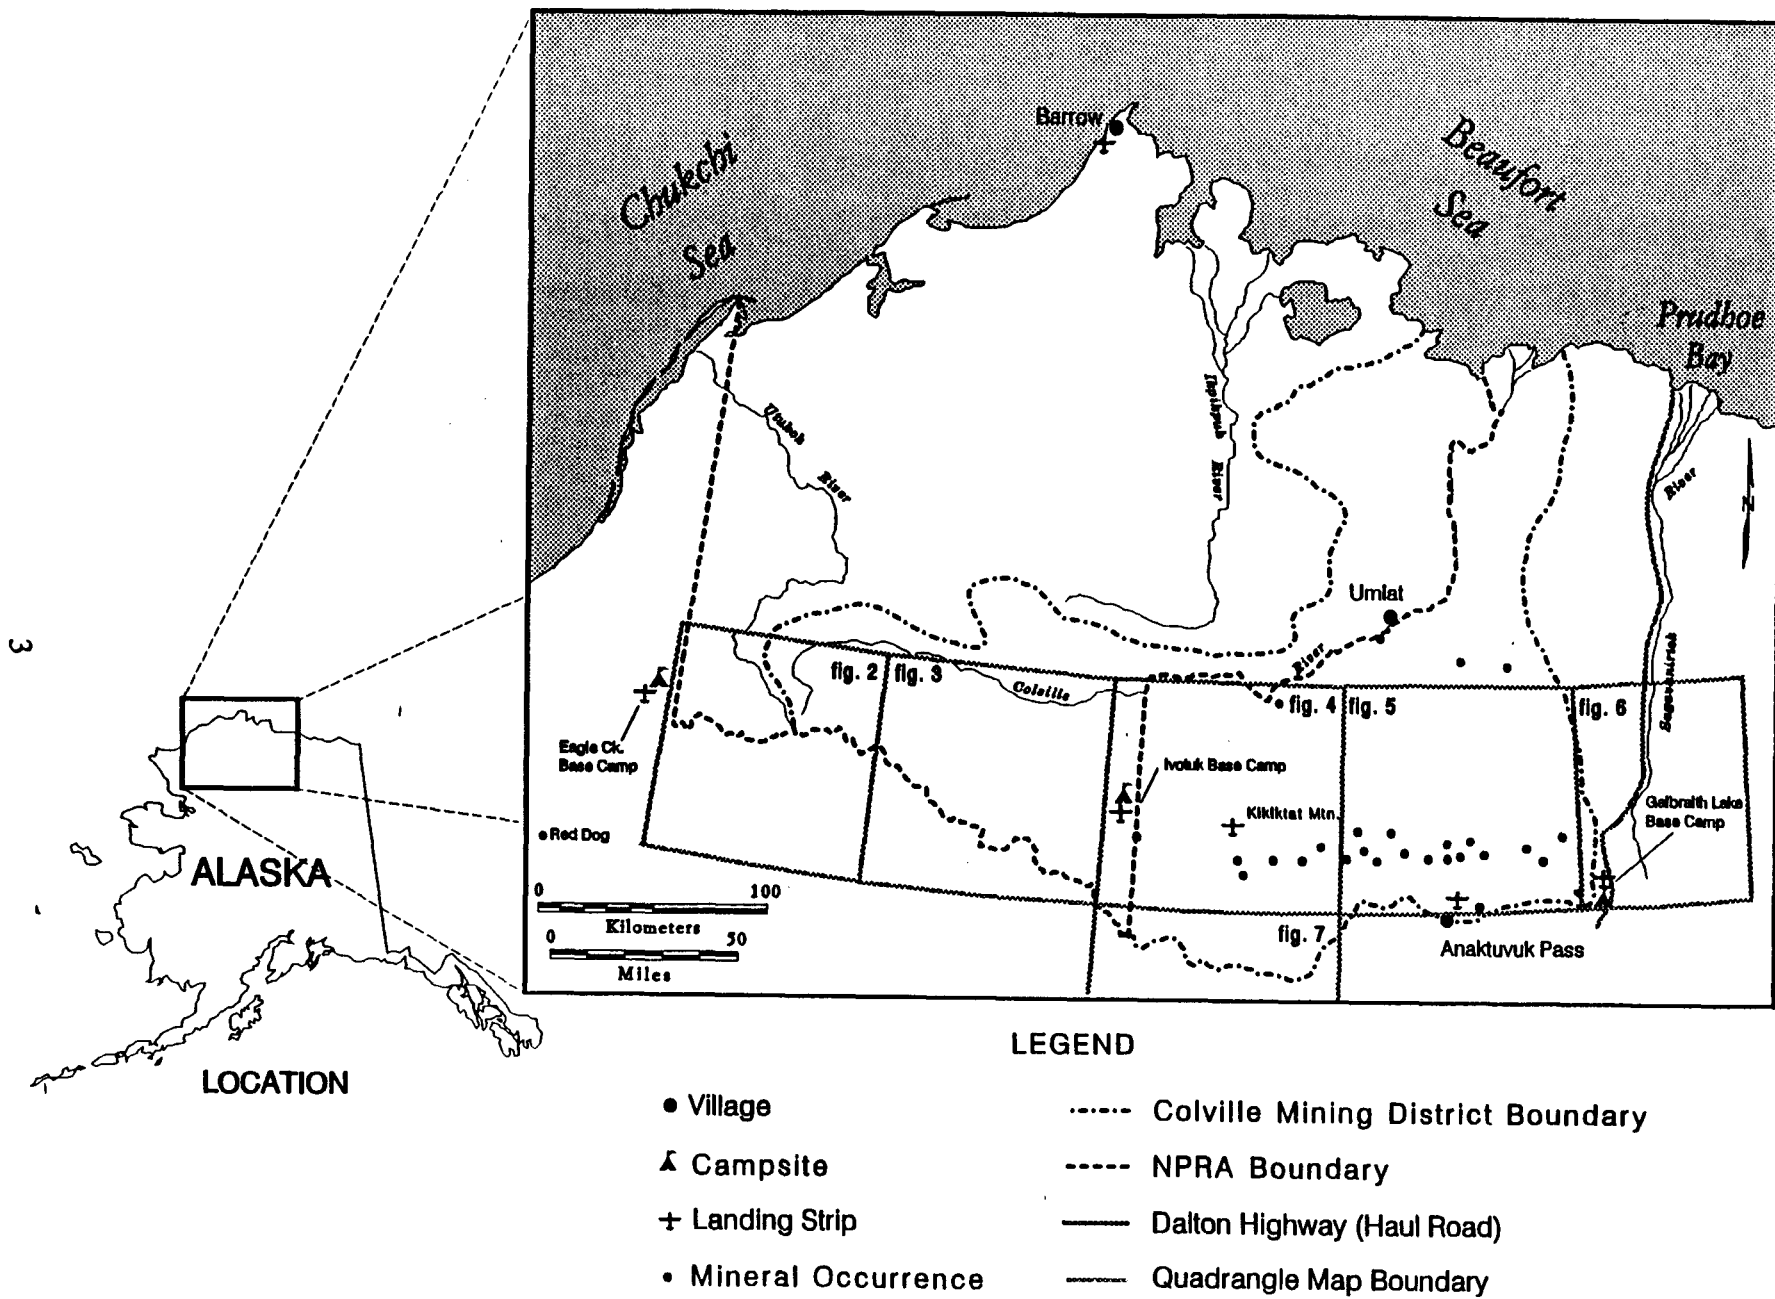

FIGURE 1. - Location Map of the CMD study area.

basin and the Arctic Ocean to the north. Three physiographic provinces covering the area include; 1) the Arctic Coastal Plain, 2) the Arctic Foothills, and 3) the Central and Eastern Brooks Range. The Arctic Coastal Plain physiographic division is characterized by a low lying plain rising to the south from the Arctic Ocean eventually reaching an elevation of 183 m. This area is poorly drained containing many marshes and braided meandering sluggish rivers. Numerous shallow lakes occur in the low lying areas. An occasional abrupt scarp, up to 61 m high, separates the coastal plain from the foothills. The Arctic Foothills physiographic division, consisting of rolling plateaus and low linear ridges, is subdivided into the northern and southern foothills. Rising in elevation from 183 to 1,068 m, the northern foothills have broad east-west-trending ridges dominated by mesa-like mountains. This area contains north-flowing swift braided rivers crossing broad gravel flats that locally contain extensive sheets of aufeis. Morainal lakes are located along the upper valleys of the major rivers as well as some divides. The southern foothills are characterized by irregular buttes, knobs, mesas, east-west-trending ridges ranging from 366 to 1,068 m, and intervening gently undulating tundra plains. The Central and Eastern Brooks Range physiographic division is composed of rugged, glaciated, east-west-trending ridges with elevations ranging from 915 to 2,135 m (396). The steep nature of the area creates swift moving streams and rivulets often occurring as waterfalls and cascades. Small cirque glaciers are common in the higher parts of this division and often contain tarn lakes. Higher elevations in the Brooks Range are devoid of trees, having only lichens covering the rocky slopes. At lower elevations, the vegetation grades into typical tundra species with stunted alder and willow along the river gravel bars.

Anaktuvuk Pass is the only year-round village within the study area while Umiat has a small summer population. Anaktuvuk Pass is located on the southeastern boundary of the study area at the headwaters of the John and Anaktuvuk Rivers. Umiat is located on the north bank of the Colville River 120 km south of the Beaufort Sea.

There are no roads, highways, or railroads located within the study area. A few useable gravel airstrips are located within the study area, and these are situated at Umiat, Ivotuk, Kikiktat Mountain, and Anaktuvuk Pass. An airstrip, located 32 km west of the study area, along Eagle Creek, is useful for access to the western part of the study area. Access to the villages and base camps within the study area is by aircraft from either Barrow, Bettles, Deadhorse, Fairbanks, or Kotzebue. Located just outside the eastern boundary of the study area, the Dalton Highway and the Galbraith Lake airstrip can be used for access to the eastern part of the CMD.

CLIMATE

The CMD lies within a zone of continuous permafrost (396). Average summer temperatures range between -2° and 7° C and winter temperatures average between -32° and -21° C in Barrow (194). Mid-day summer temperatures of 29° C have been experienced at both the Ivotuk and Eagle Creek airstrips. Strong winds blow persistently throughout the year, generally from either the southwest or northeast at Ivotuk and from the southwest or southeast at Eagle Creek. Summer afternoon rainstorms and thunderstorms arrive from the south and southwest while morning fog banks move in from the Arctic Ocean either from the northeast or the northwest.

Average annual precipitation at Anaktuvuk Pass is 25 cm with 145 cm falling as snow.

Precipitation occurs mostly as snow, but scattered light rain is common during the summer months, along with occasional afternoon thunderstorms (194). Occasional snow squalls and hail storms occur throughout the summer in the upper foothills area.

Due to the long winter season as well as the extreme weather conditions, field work is limited to the time period from early to mid June through early August. Early, spring snow creates conditions which include all north facing drainages being snow filled, numerous snowdrifts occurring within the drainages, aufeis conditions developing along several stream channels, and the higher elevations being snow covered. Most drainages and higher elevations, excluding glaciated areas, are snow-free by the end of June. Occasional snow flurries reach the lower elevations during the summer months but the snow usually melts quickly. Winter snow begins collecting at the higher elevations during the first two weeks of August.

ACKNOWLEDGMENTS

The author would like to acknowledge all of those Bureau and seasonal employees that helped make the 1993 field season a success. Bureau employees included Joe Kurtak along with the geologic field assistants Russ Hicks, Ed Klimasauskas, Allan Nakanishi, Matt Nelson, and Steve Oswald. The author would also like to thank Jennifer Claxton for her good cooking and cheerful disposition during the entire project.

GEOLOGIC SETTING

The southern part of the CMD is located within a fold and thrust belt which extends across northern Alaska and includes the western Brooks Range and the Arctic Foothills. This belt consists of Upper Devonian to Upper Cretaceous prodelta, deltaic, and shallow marine sedimentary rocks that have been subdivided into allochthons by thrust faulting. Imbricate and generally south-dipping thrust faulting and associated north-vergent folding have shortened and juxtaposed the sedimentary rocks obscuring their original depositional relationships. Various late Tertiary and Quaternary glacial and alluvial sediments overly the rocks (347).

The southern allochthon includes undifferentiated Mississippian to Cretaceous Nanushuk (Opikruak Formation), Etivluk, and Lisburne Groups. Thrust into this group are allochthonous rocks from the Upper Devonian to Lower Cretaceous Endicott (Hunt Fork Shale, Kanayut Conglomerate, and Kayak Shale) and Lisburne Groups. To the north and abutting the southern allochthon are the rocks from the Lower Cretaceous undifferentiated Nanushuk Group (Okpikruak, Kongakut, and Torok Formations interbedded with the Fortress Mountain Formation). Further northward and overlying the previous allochthons are rocks from the Middle to Upper Cretaceous Colville and Nanusuk Groups. The Colville Group outcrops eastward and the Nanusuk Group outcrops to the west (270).

Metallic mineral occurrences found within the CMD occur as either sediment-hosted stratiform massive sulfide deposits, sediment-hosted bedded barite deposits, breccia-vein deposits, or in metalliferous black shales (347). Only one known sediment-hosted stratiform sulfide deposit occurs within the Endicott Group. Sediment-hosted bedded barite deposits occur in the Etivluk Group. Breccia-vein deposits occur within the Endicott Group and metalliferous black shales occur within the Kayak Shale of the Endicott Group (347).

PREVIOUS STUDIES

Investigations of Alaska's northern slope were started by the USGS for mineral and fuel resources in the early 1900's (43-44, 225, 349-350). Additional investigations occurred during the 1920's (357), with a lull in exploration during the 1930's, followed by renewed interest during the 1940's and 1950's for oil (306). A USGS metallic mineral resource appraisal program was conducted between 1974 and 1982 (102, 241, 291-295, 382). Cobb published the first summary of metallic resources of northern Alaska in 1975 including mineral occurrences within the CMD study area (105). An update report of the metallic resources was published in 1981 (110).

Currently the USGS, with assistance from the DGGS, is conducting an Alaska Mineral Resource Appraisal Program (AMRAP) study on the Killik River quadrangle. The USGS completed an administrative report summarizing the historical geologic, geochemical, and geophysical work performed within the Howard Pass, western Killik River, and Misheguk Mountain quadrangles (347).

Private companies as well as Native corporations have carried out exploration programs within the NPRA and CMD study area. Regional reconnaissance studies were conducted during the late 1950's and early 1960's, while site-specific studies were conducted at Drenchwater Creek, Story Creek, and Kivliktort Mountain during the 1980's (347). The 1990's have brought a renewed interest by private industry and Native Corporations in the mineral potential of the central Brooks Range. This interest is a result of the opening of the world-class Red Dog lead-zinc-silver mine in 1990 in the southern DeLong Mountains.

Appraisal of the mineral resources in the southern part of the NPRA was conducted by the Bureau and the USGS during 1977 and 1978. During the field investigations, the USGS performed regional geological mapping to determine the geological setting of the NPRA, and mapped zones of mineral potential. Regional geochemical surveys were also conducted by the USGS (291-295). Eighty drainages with anomalous metal values were identified from the original USGS geochemical surveys. The Bureau used the analytical results and preliminary interpretation from these studies in selecting areas of anomalous concentrations of specific elements for further detailed mineral sampling and investigations. Bureau field work consisted of traversing those drainages containing the geochemical anomalies in search of the source rock. Stream sediments and select rock samples were collected from the drainages to define and identify further zones of mineralization. Due to time constraints, the Bureau examined only 25 of the drainages with lead-zinc anomalies during the two years of field work (192-196).

Additional sulfide mineralization was identified and sampled by the Bureau in widely scattered areas along the geochemical trends which track the region's east-west geological structure. Barium, chromium, fluorite, phosphate, rare-earth elements (e.g. lanthanum), scandium, yttrium, and vanadium were also noted within the NPRA (192-196).

PRESENT BUREAU STUDY

In 1990, the Bureau conducted an orientation survey of the area. During 1991 through 1993, the Bureau in cooperation with the BLM - Arctic District Office, the USGS, and the DGGS, conducted exploration, geological, geochemical, geophysical, mineral resource, and

mineral potential investigations in the CMD and the southern part of the NPRA. Reconnaissance sampling in the southern part of the study area along with detailed examinations and delineations of selected mineral occurrences and mineralized areas were conducted by the Bureau (248-249). Mine feasibility studies were also conducted as were bulk sampling of various occurrences for beneficiation studies. Detailed geologic and gravity surveys as well as sampling were completed on several occurrences (217).

Locations of the samples taken during the 1990-93 field seasons are shown on figures 2 - 7. Mineral occurrences and mineralized areas examined are shown on figure 8. The attached appendix contains information on each sample taken during the study including: sample numbers with corresponding map numbers, name and/or location of the mineral occurrence or sample locality, the U.S. public land survey grid, year the sample was collected, sample site and type, basic rock type, and the analytical results.

In the discussion below, analytical results are referenced by their sample location and number as well as map number. Sample location refers to the actual geographic location or occurrence name where a sample was collected in the field. Sample number refers to the number that was assigned to a sample when it was collected in the field. Map number refers to the numbering system used on figures 2 through 7 that is used to geographically represent the locations of samples. Some map numbers represent more than one sample number due to the close spacing of sample locations.

SAMPLING

Rock samples consisted of fresh, altered, or mineralized material collected from either outcrop, rubblecrop, or float near real or apparent mineral occurrences. Rock samples collected were of seven types; 1) continuous chip: rock fragments broken in a continuous line for a measured distance across an exposure of an apparently homogenous mineral occurrence, 2) random chip: rock fragments collected at random points from an apparently homogenous mineralized occurrence, 3) spaced chip: rock fragments collected at measured points from an apparently homogenous mineral occurrence, 4) chip channel: rock fragments collected along a channel of uniform width and depth across the exposure of mineralized rock, 5) representative chip: rock fragments depicting an exposure of mineralized rock, 6) select: rock collected from the highest grade portion of a mineralized zone, and 7) grab: rock collected more or less at random from an outcrop or from float.

Soil samples were collected from the thin C horizon characteristic of arctic soils beneath a 0.3- to 0.8-m-thick tundra cover.

Stream sediment samples composed of silt-sized material were collected from the active part of stream beds.

ANALYTICAL PROCEDURES

Rock samples were ground to -140 mesh and analyzed by inductively coupled plasma (ICP) spectroscopy. Any sample suspected of containing elevated levels of either silver, copper, lead, zinc, or platinum-group metals (PGM) were fire assayed or analyzed by atomic absorption spectroscopy. Soil and stream sediment samples were sieved through an 80-mesh screen prior

to analysis. Detection limits for the elements that were analyzed by atomic emission spectroscopy - ICP, fire assay - directly coupled plasma (DCP), and quantitative analysis - fire assay (FA) methods are listed by year in tables 1 through 4. Fluorometric analysis was used to analyze for uranium. Specific gravity values for barite were determined by the USGS (207).

RESULTS

This report is a complete compilation of the geochemical data base generated as a result of the 1990-93 field seasons as listed in the appendix and shown on figures 2 - 7. A brief summary of the findings from the 1993 field seasons is also presented. Included in the back of this report is an up-to-date bibliography covering the CMD study area. This report is not a comprehensive or conclusive discussion of the entire CMD project, it should be used in conjunction with all the ancillary reports published on the CMD (247-248). An Executive Summary (250) and a detailed property summary open-file report (217) of the CMD study will be published at a later date.

1990 Field Program

In 1990, the Bureau conducted an 8-day field orientation of the southcentral CMD and its known mineralization (247). Nine anomalous areas and mineralized occurrences (figs. 3-4) were visited and sampled, including Drenchwater Creek, Isikut Mountain, Kivliktort Mountain East, Kivliktort Mountain West, Koiyaktot Mountain West, Lisburne Ridge, Otuk Creek, Safari Creek, and Story Creek.

1991 Field Program

A three-year CMD field-study program was started by the Bureau in 1991. Reconnaissance investigations were conducted between Rampart Creek to the west, and the Okokmilaga River to the east for lead, zinc, copper, silver, barium, manganese, chromium, as well as other types of minerals. Previously identified USGS geochemical stream sediment anomalies were investigated during the 56-day field season, and a total of 736 samples were collected. Nineteen mineral occurrences, including twelve occurrences that were previously unreported, were identified, examined, and sampled. Anomalously high concentrations of antimony, arsenic, barium, cadmium, manganese, nickel, strontium, and titanium were found in several drainages (248). Site-specific investigations of Drenchwater Creek, Kady, Kivliktort Mountain East, Kivliktort Mountain West, Koiyaktot Mountain East, Koiyaktot Mountain West, and Story Creek were also conducted (fig. 8). Table 1 lists the newly identified and previously identified mineral occurrences examined during the 1991 field season. Bulk samples were collected at Drenchwater Creek, Story Creek, and Ivotuk Hills for beneficiation studies (248).

1992 Field Program

During the 1992 field season, Bureau personnel conducted the second year of the CMD study. A total of 56 days were spent working in the area between Spike Creek to the west, and Ivotuk Creek to the east. A total of 350 rock, soil, and stream sediment samples were collected.

Outwash Creek West	

Two base camps were utilized by independent crews, one at Eagle Creek (56 days) and the other at Ivotuk (30 days). Eagle Creek crew members conducted a geologic reconnaissance sampling program of the area between Spike Creek and Bogie Creek (figs. 2-3) collecting 126 samples. No visible lead, zinc, or copper mineralization was noted. Although analytical results confirm that significant mineralization was not found in any of the samples, barite, phosphate, and quartz crystal mineralization may be worth additional study (249). Ivotuk crew members conducted site-specific investigations and geological and geochemical reconnaissance sampling in the area from Rolling Pin Creek to Ivotuk Creek (fig. 3) and collected 224 samples. Site-specific investigations of the Abby, Bion, Ekakevik, Lakeview, Longview, Stack, Tuck; Drenchwater, Safari, and Story Creeks; Story Creek West; and the Lisburne Ridge occurrences were conducted (249). Table 2 lists the newly identified and previously identified mineral occurrences examined during the 1992 field season.

1993 Field Program

Bureau personnel conducted the third and final year of field work in the eastern part of the CMD during the 1993 field season. A total of 56 days were spent conducting field investigations in the area between Monotis Creek to the west and Atigun Pass to the east (figs. 5-6). Several site-specific studies were conducted on lead-zinc-silver, manganese, and phosphate occurrences

TABLE 2. - Mineral occurrences examined during the 1992 field season

in this area and in the central Ivotuk area. Site-specific investigations of Cobblestone Mountain North, Kiruktagiak River, Monotis Creek, Safari Creek, Skimo Creek East, Skimo Creek West, and Tiglukpuk Creek North were conducted (figs. 4-6). Table 3 lists the newly and previously identified mineral occurrences and mineralized areas examined during the 1993 field season. A total of 487 rock, soil, and stream sediment samples were collected. One base camp was set up at Galbraith Lake 37 km north of Atigun Pass, and was utilized by both field crews.

Sampling in the CMD study area consisted of traversing both ridges and stream drainages in an attempt to verify anomalous values indicated from previous USGS geochemical sampling (383). Traverses were concentrated along the central and southeastern part of the CMD between Monotis Creek to the west, and Atigun Pass to the east.

Anomalous levels of lead, manganese, phosphate, silver, and zinc were identified during the 1993 field season (figs. 4-6). Anomalous zinc (sphalerite) levels were found in concretions within the Kayak Shale which extends from Chandler Lake eastward to the Itkillik River area. These high zinc localities include the Mt Stuver; Welcome Creek; Cockedhat, Fan, Oolah, and Three Mountains; and the Itkillik, Nanushuk, and Siksikpuk River areas. Anomalous levels of lead (galena) were noted in the Siksikpuk River area while anomalous manganese was found in siltstones at Cobblestone Mountain. Along the front of the Brooks Range, anomalous phosphate levels occur within interbedded Lisburne Group shale, chert, and limestone.

Mineralized Areas

Table 3 lists twelve previously unreported and seven previously reported mineralized areas which were examined and sampled during the 1993 field season (figs. 4-6). Previously reported mineralized areas include Cobblestone Mountain North, Kiruktagiak River, Monotis Creek,

TABLE 3. - Mineralized areas examined during the 1993 field season

Siksikpuk River West	

Skimo Creek East, Skimo Creek West, and Tiglukpuk Creek North. Previously unreported mineralized areas include Anaktuvuk River East, Cockedhat Mountain Southwest, Confusion Creek, Encampment Creek, Encampment Creek East, Encampment Creek West, Ikagiak Creek East, Ipnarik River East, Ipnarik River West, Itkillik River Northwest, Siksikpuk River, and Siksikpuk River West.

Anaktuvuk River East phosphate mineralization is located at the headwaters of the Anaktuvuk River along the south side of Fan Mountain (fig. 8). Phosphate occurs in Lisburne Group limestone. Two samples (4550-01; map nos. CL94, CL96) contained 0.17 and 0.06% P_2O_5 , respectively (fig. 5).

Cobblestone Mountain North manganese mineralization is located along Cobblestone Creek 16 km northeast of Nanushuk Lake (fig. 8). Manganese occurs in a greenish-brown silty mudstone with manganese oxide-coated quartz veinlets. The mineralized zone is 7-m-wide and trends northeast. Eleven samples (4442, 4444, 4446-55; map nos. CL 173-5) taken in the area contained 0.51 - 11.69% manganese, two samples (4442, 4448; map no. CL175) contained 1,229 - 1,780 ppm arsenic, and one sample (4449; map no. CL175) contained >2,000 ppm strontium (fig. 5).

Cockedhat Mountain Southwest zinc mineralization is located at the headwaters of a western tributary of the Itkillik River on the south side of Cockedhat Mountain (fig. 8). Visible sphalerite is associated with quartz and calcite in dark brown interbedded siltstone and mudstone

concretions of the Kayak Formation. Four samples (4605, 4625-26, 4629; map nos. CL136, CL143) taken in the area contain 1,214 - 11,962 ppm zinc and 27 - 101 ppm lead (fig. 5).

Confusion Creek zinc mineralization is located near the headwaters of Confusion Creek 6 km east of Invalurak Mtn (fig. 8). Visible sphalerite is associated with quartz and calcite in dark brown interbedded siltstone and mudstone concretions of the Kayak Formation. Two samples (4753, 4759; map nos. CL53, CL55) taken in the area contained 13,120 and 16,172 ppm zinc, respectively (fig. 5).

Zinc mineralization was located at three areas of Encampment Creek. Visible sphalerite is associated with quartz and calcite in dark brown interbedded siltstone and mudstone concretions of the Kayak Formation. The first mineralized area is located near the headwaters of the main fork of Encampment Creek 3 km northwest of Invalurak Mtn (fig. 8). Two samples (4771-72; map nos. CL46-7) from the area contained 4,094 and 5,249 ppm zinc (fig. 5). Encampment Creek East is located near the headwaters of Encampment Creek on the north side of Invalurak Mtn (fig. 8). Three samples (4495, 4754, 4757; map nos. CL48-9) taken in the area contain 3,131 - 11,254 ppm zinc (fig. 5). Encampment Creek West is located on the divide between Encampment Creek and the Siksikpuk River 5 km northwest of Invalurak Mtn (fig. 8). Three samples (4768-70; map no. CL45) taken in the area contained 1,187 - 12,108 ppm zinc (fig. 5).

Ikagiak Creek East lead-zinc-manganese mineralization is located at the headwaters of Ikagiak Creek 11 km east of Little Chandler Lake (fig. 8). Visible sphalerite and galena is associated with quartz and calcite in dark brown interbedded siltstone and mudstone concretions of the Kayak Formation. Seven samples (4485, 4809-14; map nos. CL31-5) contained 18 ppm - 0.02% lead, 13 ppm - 0.74% zinc, and from 318 - 15,788 ppm manganese (fig. 5).

Lead-zinc-silver mineralization was located in two areas of the Ipnarik River. Ipnarik River East is located near the headwaters of the Ipnarik River 12 km west of Kavaksurak Mountain (fig. 8). Disseminated sphalerite and galena is associated with quartz veinlets in a gray silicified sandstone. Five samples (6005, 6042-45; map nos. HP78-80) from the area contained 177 ppm - 1,920 ppm lead, 56 ppm - 3.39% zinc, and up to 9.2 g/mt silver (fig. 3). Ipnarik River West is located near the headwaters of the Ipnarik River 16 km west of Kavaksurak Mountain (fig. 8). Visible sphalerite and/or galena occurs within quartz stringers that cut silicified, bleached, and/or brecciated sandstones of the Kanuyut Formation. Fourteen samples (6001-02, 6008, 6026-36; map nos. HP83-4, HP86-7, HP91) taken in the area contain 55 ppm - 36.44% lead, 86 ppm - 3.99% zinc, up to 438.8 g/mt silver, and 13 - 3,688 ppm copper (fig. 3).

Itkillik River Northwest lead-zinc-silver mineralization is located at the headwaters of an eastern tributary of the Itkillik River 18 km east of Marshmallow Mountain (fig. 8). Visible galena is associated with calcite and quartz veinlets in siltstone. Three samples (4552-53, 4578; map nos. CL147, CL149) taken in the area contain 24 ppm - 0.67% lead, 3 ppm - 0.01% zinc and up to 1.7 g/mt silver (fig. 5).

Kiruktagiak River phosphate mineralization is located on the Kiruktagiak River upstream from the junction with Monotis Creek 8 km northwest of White Lake (fig. 8). Oölitic phosphate is associated with a 25-cm-thick paper shale interbedded with limestone and chert on the north limb of the east-west-trending Monotis anticline. Eighteen samples (4502-13, 4525-30; map nos. CL10-3) taken along the anticline contained from 0.16 - 26.28% P₂O₅ (fig. 5).

Monotis Creek phosphate mineralization is located on Monotis Creek upstream from the junction with Kiruktagiak River 9 km northwest of White Lake (fig. 8). Oölitic phosphate is associated with black shales, limestones, and cherts on the north limb of the east-west-trending Monotis anticline. Fifteen samples (4381-84, 4514-24; map nos. CL14-5) taken along the anticline contained 0.11 - 30.68% P_2O_5 and up to 1,258 ppm zinc (fig. 5).

The Safari Creek lead-zinc-silver occurrence is located at the headwaters of eastern Safari Creek 20 km southwest of Mount Bupto (fig. 8). Safari Creek was located in 1992 (248) and revisited in 1993. Visible galena is associated with quartz veins that form a northwest trending 10-m-wide stockwork zone in sandstone. A high-grade sample (6047; map no. HP96) taken from the zone contained 53.36% lead, 2.05% zinc, and 310.96 g/mt silver (fig. 3).

Zinc mineralization was located in two areas of the Siksikpuk River. Visible sphalerite is associated with quartz and calcite in dark brown interbedded siltstone and mudstone concretions of the Kayak Formation. The Siksikpuk River is located at the headwaters of the central fork of Siksikpuk River 13 km east of Little Chandler Lake (fig. 8). One sample (4829; map no. CL38) taken in the area contained 13,152 ppm zinc (fig. 5). Siksikpuk River West is located on a western tributary of the central fork of Siksikpuk River 10 km east of Little Chandler Lake (fig. 8). Four samples (4777-78, 4825, 4833; map nos. CL30, CL36-7) taken in the area contained 1,827 - 7,107 ppm zinc (fig. 5).

Phosphate was located at two locations on Skimo Creek. Skimo Creek East phosphate is located on the east side of Skimo Creek 16 km northeast of Invalurak Mtn (fig. 8). Oölitic phosphatic rock occurs in calcareous and fossiliferous black shale interbedded with chert and limestone on the north limb of an east-west-trending anticline. Twenty two samples (4581-83, 4593-94, 4597, 4652-55, 4657-68; map nos. CL57-9) taken along the anticline contained 0.03 - 23.72% P_2O_5 and up to 2,047 ppm zinc (fig. 5). Skimo Creek West phosphate is located on the west side of Skimo Creek 14 km northeast of Invalurak Mtn (fig. 8). Oölitic phosphatic rock occurs in interbedded calcareous shale and limestone on the north limb of east-west-trending anticline. Eight samples (4639-44, 4646-47; map no. CL56) taken along the anticline contained 1.23 - 22.50% P_2O_5 and up to 1,995 ppm zinc (fig. 8).

Tiglukpuk Creek North phosphate is located on Tiglukpuk Creek 17 km northeast of Invalurak Mtn (fig. 8). Oölitic phosphatic rock occurs in interbedded carbonaceous black chert and limestone on the north limb of an east-west-trending anticline. Eight samples (4612-17, 4637-38; map no. CL60) taken along the anticline contained 0.94 - 25.46% P_2O_5 and up to 2,044 ppm zinc (fig. 5).

SUMMARY

A relatively small amount of mineral related investigative work had been conducted in the CMD prior to this study. The Bureau had the opportunity to conduct reconnaissance and site-specific investigations in the southern part of the CMD during the 1990-93 field seasons while the USGS has been conducting AMRAP investigations along the southern CMD.

During 1990, the Bureau conducted an orientation field program to obtain an overview of the study area and its mineralization. Nine mineral occurrences were visited including Drenchwater Creek, Isiktut Mountain, Kivliktort Mountain East and West, Koiyaktot Mountain West, Lisburne Ridge, Otuk Creek, Safari Creek, and Story Creek.

The 1991 field season was the first year of an intense field program. The Bureau identified, located, and sampled nineteen mineral occurrences including Drenchwater Creek, Ivtuk Hills, Kady, Kakivilak Creek, Kakivilak Creek North, Kivliktort Mountain East and West, Koiyaktot Mountain East and West, Kurupa River Southwest, Outwash Creek North, Outwash Creek Northeast, Outwash Creek South, Outwash Creek Southeast, Outwash Creek South-Southwest, Outwash Creek Southwest, Outwash Creek West, Story Creek, and Vidlee. Anomalous mineral values were also noted in the Cutaway Creek, Koiyaktot Mountain, Kurupa River, Mt. Bupto, Outwash Creek, Rampart Creek, Twistem Creek, and the Wager Creek areas.

The 1992 field season identified, located, and sampled twelve mineral occurrences including Abby, Bion, Drenchwater Creek, Ekakevik, Lakeview, Lisburne Ridge, Longview, Safari Creek, Stack, Story Creek, Story Creek West, and Tuck. Other areas containing anomalous mineralization include the Eagle Creek, Lisburne Ridge, and Twistem Creek areas.

Field work, during 1993, resulted in the discovery of twelve new mineralized areas as well as examining six previously identified mineral occurrences. Areas of interest include those mineralized areas at Anaktuvuk River East, Cobblestone Mountain Southwest, Confusion Creek, Encampment Creek, Encampment Creek East and West, Ikagiak Creek East, Ipnarik River East and West, Itkillik River Northwest, Siksikpuk River, and Siksikpuk River West. Previously identified mineralized occurrences examined include Cobblestone Mountain North, Kiruktagiak River, Monotis Creek, Skimo Creek East and West, and Tiglukpuk Creek North. Anomalous mineralization was noted in the upper Kayak Shale which extends from Chandler Lake area eastward to the Itkillik River area.

Due to the lack of historical mineral investigations in the CMD, the Bureau was able to identify fifteen new mineral occurrences and twelve new mineralized areas during the 1991-93 field seasons. Because of the time constraints and vastness of the area only cursory examinations and sampling were conducted on most of these locations. Those mineral occurrence which were deemed significant had detailed site-specific examinations conducted on them. More detailed examinations are needed on the smaller mineral occurrences and mineralized areas identified during the 1991-93 field seasons. These examinations need to better delineate and define the existing deposits as well as further delineate their identifiable resources.

TABLE 4. - 1990 Sample Analysis Lower Detection Limits

Element	Lower limit (ppm)	Upper limit (ppm)	Element	Lower limit (ppm)	Upper limit (ppm)
ICP-Atomic Emission Spectroscopy			Nb	1	2,000
