**Table 4–67 PSD Class II Increments Compared to INEEL Concentrations Associated with Alternative 2 (Use Only Existing Operational Facilities)—Option 2**

Pollutant	Averaging Period	Allowable PSD Increment (micrograms per cubic meter)	Modeled Increment (micrograms per cubic meter)
Nitrogen dioxide	Annual	25	$3.66 \times 10^{-4}$
Sulfur dioxide	Annual	20	0.024
	24 hours	91	0.19
	3 hours	512	0.43

**Key:** PSD, Prevention of Significant Deterioration.

**Source:** Modeled increments are based on the SCREEN3 computer code (EPA 1995).

Health effects from hazardous chemicals associated with this option are addressed in Section 4.4.2.1.9. The air quality impacts of transportation among SRS, INEEL, and LANL are presented in Section 4.4.2.1.11.

#### 4.4.2.1.4 Water Resources

Impacts on water resources at INEEL associated with operating ATR to irradiate neptunium-237 targets would be negligible as previously described in Section 4.4.1.1.4.

Building CPP-651 and/or FDPF, existing facilities in the INTEC area of INEEL, would be used for neptunium-237 storage; FDPF would also be used for the fabrication and processing of targets in support of plutonium-238 production. Impacts on water resources indicators at INEEL would be the same as those described in Section 4.3.2.1.4. In summary, a small increase in water use and sanitary wastewater generation would be anticipated, mainly attributable to increased staffing levels. Also, there would be a very small increase in process wastewater generation, but there would be no radiological liquid effluent discharge to the environment under normal operations.

#### 4.4.2.1.5 Geology and Soils

The irradiation of neptunium-237 targets in ATR would not be expected to result in impacts on geologic or soil resources at INEEL, nor be jeopardized by large-scale geologic conditions, for the reasons described in Section 4.4.1.1.5.

Building CPP-651 and/or FDPF would be used to store neptunium-237, and FDPF would be used to fabricate and process targets. Because both are existing facilities, there would be no disturbance to either geologic or soil resources at INTEC. Hazards from large-scale geologic conditions at INEEL, such as earthquakes and volcanoes, were previously evaluated as discussed in Section 4.2.3.2.5. The analysis determined that these hazards present a low risk for neptunium-237 storage in INTEC facilities. Likewise, large-scale geologic conditions do not present a substantial risk to use of the proposed facilities for neptunium-237 storage, target fabrication, and processing. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards would be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### 4.4.2.1.6 Ecological Resources

The irradiation of neptunium-237 targets in ATR would not result in impacts on ecological resources at INEEL for the reasons described in Section 4.4.1.1.6.

Because no new construction is planned, the use of Building CPP-651 and/or FDPF would not result in direct disturbance to ecological resources. As noted in Section 4.4.2.1.2, there would be no loud noises that would adversely impact wildlife. Because water usage and wastewater discharge would be small fractions of current values, there would be no impact on aquatic resources (Section 4.4.2.1.4). Due to the developed nature of the area and the fact that no new construction would take place, impacts on threatened and endangered species would not occur.

Consultation letters to comply with Section 7 of the Endangered Species Act were sent to the U.S. Fish and Wildlife Service and the Idaho Department of Fish and Game (see Table 5-3). Each agency was asked to provide information on potential impacts of the proposed action on threatened and endangered species. The Idaho Department of Fish and Game indicated that its database contained no known occurrences of special status plants or animals near the project area. While DOE has made additional contact with the U.S. Fish and Wildlife Service, a response is pending from this agency. Although no federally listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at INEEL prior to the receipt of input from the Service.

#### **4.4.2.1.7 Cultural and Paleontological Resources**

The irradiation of neptunium-237 targets in ATR would not result in impacts on cultural and paleontological resources at INEEL for the reasons described in Section 4.4.1.1.7.

Because no new construction would take place, impacts on cultural and paleontological resources at INTEC would not occur. Use of Building CPP-651 and/or FDPF to store neptunium-237 or FDPF to fabricate and process neptunium-237 targets would not change the status of six historic structures located at INTEC. Native American resources occurring in the vicinity of INTEC would not be impacted by neptunium-237 storage, target fabrication, or processing.

Consultation to comply with Section 106 of the National Historic Preservation Act was initiated with the State Historic Preservation Office (see Table 5-3). The State Historic Preservation Office indicated that Building CPP-651 and FDPF are likely to be eligible for the National Register of Historic Places as contributory properties in a potential historic district of exceptional significance. However, at this time, the State Historic Preservation Office has determined that more information is needed prior to assisting DOE in evaluating these properties. The State Historic Preservation Office also indicated that since there would be no new construction, there is little potential for effects on archaeological properties. DOE would provide additional information as required to the Idaho State Historic Preservation Office prior to the use of any facility at INEEL for the proposed project. Consultation was conducted with interested Native American tribes; however, responses are pending.

#### **4.4.2.1.8 Socioeconomics**

After facility modifications, startup, and testing of the plutonium-238 reactor operation and target fabrication/processing facilities at INEEL, approximately 24 additional workers would be required to operate these facilities (Hill et al. 1999). The socioeconomic impacts at INEEL are the same as those addressed in Section 4.3.2.1.8.

#### **4.4.2.1.9 Public and Occupational Health and Safety—Normal Operations**

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from operations are given in **Table 4-68** for INEEL: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

**Table 4–68 Incremental Radiological Impacts on the Public Around INEEL from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 2**

Receptor	INEEL ATR	INEEL FDPF	Total
<b>Population within 80 kilometers (50 miles) in the year 2020</b>			
Dose (person-rem)	0	$3.9 \times 10^{-6}$	$3.9 \times 10^{-6}$
35-year latent cancer fatalities	0	$6.7 \times 10^{-8}$	$6.7 \times 10^{-8}$
<b>Maximally exposed individual</b>			
Annual dose (millirem)	0	$2.6 \times 10^{-7}$	$2.6 \times 10^{-7}$
35-year latent cancer fatality risk	0	$4.6 \times 10^{-12}$	$4.6 \times 10^{-12}$
<b>Average exposed individual within 80 kilometers (50 miles)</b>			
Annual dose <sup>a</sup> (millirem)	0	$2.0 \times 10^{-8}$	$2.0 \times 10^{-8}$
35-year latent cancer fatality risk	0	$3.6 \times 10^{-13}$	$3.6 \times 10^{-13}$

a. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FDPF in the year 2020 (188,400).

**Source:** Model results, using the GENII computer code (Napier et al. 1988).

As a result of annual operations of both facilities, the projected total incremental population dose in the year 2020 would be  $3.9 \times 10^{-6}$  person-rem. The corresponding number of latent cancer fatalities in the population surrounding INEEL from 35 years of operations would be  $6.7 \times 10^{-8}$ . The total incremental dose to the maximally exposed member of the public from annual ATR operations would be 0 millirem because there would be no increase in radiological releases to the environment from ATR associated with this option. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would, therefore, be zero. The incremental dose to the maximally exposed member of the public from annual FDPF operations would be  $2.6 \times 10^{-7}$  millirem. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $4.6 \times 10^{-12}$ .

Incremental doses to involved workers from normal operations are given in **Table 4–69**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to ATR workers would be 0 millirem; for FDPF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities would be 0 and approximately 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–69. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–69 Incremental Radiological Impacts on Involved INEEL Workers from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 2**

Receptor—Involved Workers <sup>a</sup>	INEEL ATR	INEEL FDPF	Total
Total dose (person-rem per year)	0	12 <sup>b</sup>	12
35-year latent cancer fatalities	0	0.17	0.17
Average worker dose (millirem per year)	0	170	NA <sup>c</sup>
35-year latent cancer fatality risk	0	0.0023	NA <sup>c</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 75 badged workers.

c. Values cannot be given for the average worker because the workers would be at two different facilities.

**Key:** NA, not applicable.

**Source:** Mecham 1999; Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** At INEEL, both carcinogenic and noncarcinogenic health effects from exposure to hazardous chemicals were evaluated. It was assumed that under normal operating conditions, the primary exposure pathway for members of the public would be from air emissions released through the FDPF stack. Emissions of chemicals were estimated based on anticipated chemical usage. A worst-case dispersion modeling screening analysis was performed to estimate annual concentrations for each chemical, based on the emissions.

The annual concentration for each noncarcinogenic chemical was divided by the corresponding inhalation reference concentration to estimate the Hazard Quotient for each chemical. The Hazard Quotients were summed to give the Hazard Index from all noncarcinogenic chemicals associated with this option. A Hazard Index of less than one indicates that adverse health effects from non-cancer-causing agents are not expected. For carcinogens, the annual concentration was multiplied by the unit cancer risk to estimate the increased cancer risk from that chemical. Hazardous chemical health effects are summarized in **Table 4-70**.

**Table 4-70 Incremental Hazardous Chemical Impacts on the Public Around INEEL Under Alternative 2 (Use Only Existing Operational Facilities)—Option 2**

Chemical	Modeled Annual Increment (milligrams per cubic meter)	RfC - Inhalation (milligrams per cubic meter)	Unit Cancer Risk (risk per milligram per cubic meter)	Hazard Quotient	Cancer Risk
Diethyl benzene	$1.65 \times 10^{-5}$	1	0.0078	$1.65 \times 10^{-5}$	$1.29 \times 10^{-7}$
Methanol	$6.02 \times 10^{-7}$	1.75	NA	$3.44 \times 10^{-7}$	NA
Nitric acid	$1.21 \times 10^{-6}$	0.1225	NA	$9.86 \times 10^{-6}$	NA
Tributyl phosphate	$3.10 \times 10^{-5}$	0.01	NA	0.00310	NA
Hazard Index =				0.0031	

**Note:** For diethyl benzene, the reference concentration for ethyl benzene and the unit cancer risk for benzene were used to estimate Hazard Quotient and cancer risk because no information was available for diethyl benzene. For tributyl phosphate, the reference concentration for phosphoric acid was used to estimate the Hazard Quotient because no information was available for tributyl phosphate.

**Key:** NA, not applicable (the chemical is not a known carcinogen); RfC, reference concentration.

**Source:** DOE 1996a; EPA 1999; modeled increments are based on the SCREEN3 computer code (EPA 1995).

#### 4.4.2.1.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with ATR target irradiation and FDPF target processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Estimates of radiological consequences have been developed for the maximally exposed individual, the offsite population within 80 kilometers (50 miles) of the facility, and a noninvolved worker at a distance of 640 meters (0.4 mile) from the release point. Consequences are presented in terms of radiological dose (in rem) and the probability that the dose would result in a latent cancer fatality. Accident risk is defined as the product of the accident probability (i.e., accident frequency) and the accident consequence. In this NI PEIS, risk is expressed as the increased likelihood of a latent cancer fatality per year for an individual (the maximally exposed individual or a noninvolved worker), and as the increased number of latent cancer fatalities per year in the offsite population. The probability coefficients for determining the likelihood of a latent cancer fatality, given a dose, are given in Section 4.2.1.2.10. Consequences to involved workers are addressed in Section I.1.7.

To provide a better indication of risks from the postulated accidents, the risks are summed for each facility and also for each option. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk from accidents, a full-scope probabilistic risk analysis would be required for each facility. Since full-scope probabilistic risk analyses are not available to

incorporate in this NI PEIS, summing the spectrum of accident risks was considered appropriate for the purposes of this NI PEIS. Details of the risk summation calculations are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–71** and **4–72**, respectively. Because ATR is currently operating, the consequences and risks are presented for both the current reactor configuration without neptunium-237 targets and for the worst-case neptunium-237 target-loading reactor configuration.

**Table 4–71 ATR and FDPF Accident Consequences Under Alternative 2 (Use Only Existing Operational Facilities)—Option 2**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
<b>ATR accidents</b>						
Large-break LOCA with 0 kg/yr plutonium-238 production	0.465	$2.33 \times 10^{-4}$	$5.11 \times 10^4$	25.5	5.15	0.00206
Large-break LOCA with 5 kg/yr plutonium-238 production	0.604	$3.02 \times 10^{-4}$	$5.17 \times 10^4$	25.9	7.61	0.00304
Target handling with 0 kg/yr plutonium-238 production <sup>c</sup>	0.0	0.0	0.0	0.0	0.0	0.0
Target handling with 5 kg/yr plutonium-238 production	$2.05 \times 10^{-4}$	$1.03 \times 10^{-7}$	0.128	$6.41 \times 10^{-5}$	0.00324	$1.30 \times 10^{-6}$
<b>FDPF accidents</b>						
Ion exchange explosion during neptunium-237 target fabrication	$2.01 \times 10^{-9}$	$1.01 \times 10^{-12}$	$2.49 \times 10^{-5}$	$1.24 \times 10^{-8}$	$7.26 \times 10^{-9}$	$2.91 \times 10^{-12}$
Target dissolver tank failure during plutonium-238 separation	$6.11 \times 10^{-8}$	$3.05 \times 10^{-11}$	$5.65 \times 10^{-4}$	$2.82 \times 10^{-7}$	$2.17 \times 10^{-7}$	$8.69 \times 10^{-11}$
Ion exchange explosion during plutonium-238 separation	$1.63 \times 10^{-5}$	$8.13 \times 10^{-9}$	0.150	$7.51 \times 10^{-5}$	$5.79 \times 10^{-5}$	$2.31 \times 10^{-8}$
Processing facility beyond-design-basis earthquake	42.5	0.0425	$1.64 \times 10^5$	82.0	1,200	1.0 <sup>d</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

c. There would be no neptunium-237 targets for this zero-production case. Thus, there would be no associated accident consequences.

d. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4–72 ATR and FDPF Accident Risks Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 2**

Accident (Frequency)	Maximally Exposed Individual <sup>a</sup>	Population to 80 Kilometers (50 Miles) <sup>b</sup>	Noninvolved Worker <sup>a</sup>
<b>Annual ATR risks</b>			
Large-break LOCA with 0 kg/yr plutonium-238 production ( $1 \times 10^{-4}$ )	$2.33 \times 10^{-8}$	0.00255	$2.06 \times 10^{-7}$
Large-break LOCA with 5 kg/yr plutonium-238 production ( $1 \times 10^{-4}$ )	$3.02 \times 10^{-8}$	0.00259	$3.04 \times 10^{-7}$
Large-break LOCA incremental risks <sup>c</sup>	$6.90 \times 10^{-9}$	$4.00 \times 10^{-5}$	$9.80 \times 10^{-8}$
Neptunium-237 target handling with 5 kg/yr plutonium-238 production (0.001) <sup>d</sup>	$1.03 \times 10^{-10}$	$6.41 \times 10^{-8}$	$1.30 \times 10^{-9}$
<b>35-year ATR risk<sup>e</sup></b>	$2.45 \times 10^{-7}$	0.00140	$3.48 \times 10^{-6}$
<b>Annual FDPF risks</b>			
Ion exchange explosion during neptunium-237 target fabrication (0.01)	$1.01 \times 10^{-14}$	$1.24 \times 10^{-10}$	$2.91 \times 10^{-14}$
Target dissolver tank failure during plutonium-238 separation (0.01)	$3.05 \times 10^{-13}$	$2.82 \times 10^{-9}$	$8.69 \times 10^{-13}$
Ion exchange explosion during plutonium-238 separation (0.01)	$8.13 \times 10^{-11}$	$7.51 \times 10^{-7}$	$2.31 \times 10^{-10}$
Processing facility beyond-design-basis earthquake ( $1 \times 10^{-5}$ )	$4.25 \times 10^{-7}$	$8.20 \times 10^{-4}$	$1.00 \times 10^{-5(f)}$
<b>35-year FDPF risk</b>	$1.49 \times 10^{-5}$	0.0287	$3.50 \times 10^{-4}$
<b>35-year Option risk<sup>g</sup></b>	$1.51 \times 10^{-5}$	0.0301	$3.53 \times 10^{-4}$

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.

d. There would be no neptunium-237 targets for the zero-production case. Thus, the 5-kg/yr production rate target-handling risks are the incremental risks.

e. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.

f. Risk of an early fatality.

g. Individual risks are summed only for colocated individuals. The highest individual risk was used to represent the 35-year option risk.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

For 35 years of ATR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.45 \times 10^{-7}$  and  $3.48 \times 10^{-6}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.00140.

For 35 years of FDPF target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $1.49 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0287.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $1.51 \times 10^{-5}$  and  $3.53 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0301.

The irradiation of neptunium-237 targets to produce plutonium-238 at ATR would not introduce any additional operations that require the use of hazardous chemicals. Thus, there are no postulated hazardous chemical accidents attributable to the irradiation of neptunium-237 targets at ATR.

No chemical processing activities are currently performed at FDPF and no chemicals are stored in this facility. Processing activities in support of plutonium-238 production would require the introduction of hazardous chemicals, specifically nitric acid and nitric oxide. Potential health impacts from accidental releases of nitric acid were assessed by comparing estimated airborne concentrations of the chemicals to ERPG developed by the American Industrial Hygiene Association. The ERPG-1 value (0.5 part per million) is the maximum airborne concentration below which nearly all individuals could be exposed for up to one hour, resulting in only mild, transient, and reversible adverse health effects. The ERPG-2 value (10 parts per million) is protective of irreversible or serious health effects or impairment of an individual's ability to take protective action. The ERPG-3 value (25 parts per million) is indicative of potentially life-threatening health effects.

The maximum distances, in meters, needed to reach the ERPG values for nitric acid releases at FDPF for Stability Classes D and F are shown in **Table 4-73**. Two separate atmospheric conditions were evaluated, Stability Classes D and F. Stability Class D represents average meteorological conditions while Stability Class F represents worst-case meteorological conditions. The number of involved and noninvolved workers potentially exposed would vary with a number of factors such as the time of day and whether they are sheltered within buildings at the time of release. Individuals at the nearest highway (5,800 meters [3.8 miles]) and at the nearest site boundary (13,952 meters [8.7 miles]) from FDPF would be exposed to levels well below ERPG-1.

**Table 4-73 ERPG Distances for Nitric Acid Releases at FDPF Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 2**

Evaluation Parameter	Stability Class D (meters)	Stability Class F (meters)
ERPG-3	375	450
ERPG-2	500	600
ERPG-1	2,000	3,000

**Note:** To convert from meters to miles, multiply by  $6.22 \times 10^{-4}$ .

**Key:** ERPG, Emergency Response Planning Guideline.

There are no ERPG values for nitric oxide. For nitric oxide accidents, the level of concern has been estimated by using one-tenth of the “Immediately Dangerous to Life and Health” level published by the National Institute for Occupational Safety and Health. The Immediately Dangerous to Life and Health value for nitric oxide is 100 parts per million. The level of concern value used for this NI PEIS is 10 parts per million. The level of concern is defined as the concentration of an extremely hazardous substance in air above which there may be serious irreversible health effects as a result of a single exposure for a relatively short period of time.

For FDPF, the maximum distances needed to reach the level of concern for nitric oxide releases for Stability Classes D and F are 500 and 2,000 meters (0.31 and 1.24 miles), respectively. The number of involved and noninvolved workers potentially exposed would vary with a number of factors such as the time of day and whether they are sheltered within buildings at the time of release. Individuals at the nearest highway (5,800 meters [3.6 miles]) and at the nearest site boundary (13,952 meters [8.7 miles]) from FDPF would be exposed to levels well below the level of concern for nitric oxide.

Potential health impacts from the accidental release of the hazardous chemicals were assessed for a noninvolved worker, offsite individuals who are members of the public located at the nearest site boundary and onsite individuals who are members of the public located at the nearest highway access.

The impacts associated with the accidental release of nitric acid and nitric oxide at FDPF are presented in Table 4-74.

**Table 4-74 FDPF Hazardous Chemical Accident Impacts Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 2**

Receptor	Evaluation Parameter	Nitric Acid		Nitric Oxide	
		Stability Class D	Stability Class F	Stability Class D	Stability Class F
Noninvolved worker (640 meters)	Parts per million Level of concern Potential health effects	3.3 <ERPG-2 Mild, transient	8.4 <ERPG-2 Mild, transient	4.2 <LOC Mild, transient	67.5 >LOC Serious
Nearest highway maximally exposed individual	Parts per million Level of concern Potential health effects	0.05 < ERPG-1 None	0.15 ERPG-1 Mild, transient	0.09 < LOC None	0.87 < LOC None
Site boundary maximally exposed individual	Parts per million Level of concern Potential health effects	<<0.05 < ERPG-1 None	<<0.15 ERPG-1 Mild, transient	<<0.09 < LOC None	<<0.87 < LOC None

**Note:** < means “less than”; << means “much less than.”

**Key:** ERPG, Emergency Response Planning Guideline; LOC, level of concern.

**Source:** Model results.

#### 4.4.2.1.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to INEEL for target fabrication in FDPF. DOE would transport the unirradiated neptunium-237 targets from FDPF to ATR, also on the INEEL site. Following irradiation in ATR, the targets would be returned to FDPF for processing. After this processing, the plutonium-238 product would be shipped to LANL. The analysis is described in Appendix J.

Approximately 59 intersite shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 0.15 million kilometers (0.1 million miles).

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 1.3 person-rem; the dose to the public, 8 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.0005 latent cancer fatality among transportation workers and 0.004 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option is 0.0007.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident (probability of occurrence: 1 in 10 million per year) would not breach the transportation package. The consequences of more severe accidents that could breach the transportation package and release radioactive material were evaluated and estimated to have probabilities of less than 1 in 10 million per year.

Estimates of the total ground transportation accident risks under this option are as follows: a radiological dose to the population of 0.042 person-rem, resulting in  $2.1 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.0006 traffic fatality.

#### 4.4.2.1.12 Environmental Justice

**NORMAL OPERATIONS.** For 35 years of normal operations under this option, the number of expected latent cancer fatalities among populations residing within 80 kilometers (50 miles) of ATR and FDPF would be essentially zero (derived from information in Table 4–68). As shown in Table 4–70, the release of hazardous chemicals at INEEL would pose no significant risk of cancer or toxic effects among the public. As discussed in Section K.5.1, the likelihood that a latent cancer fatality would result from the ingestion of food that could be radiologically contaminated due to normal operations would be essentially zero at INEEL. No credible pattern of food consumption by persons residing in potentially affected areas would result in significant health risks due to radiological contamination of food supplies near INEEL. As discussed in Section 4.4.2.1.11, no fatalities due to transportation activities would be expected.

**ACCIDENTS.** The number of expected latent cancer fatalities among the populations at risk due to radiological accidents listed in Table 4–72 would be approximately 0.03. If a radiological accident were to occur at ATR or FDPF and northwesterly winds prevailed at the time of the accident, radiological contamination from the accident would be directed toward the Fort Hall Indian Reservation (see Figure K–2). However, accidents that could occur under the implementation of this option would not be expected to result in a latent cancer fatality among the population or maximally exposed individual residing within the boundary of the Fort Hall Indian Reservation.

As discussed in Section 4.4.2.1.11, no fatalities due to transportation accidents would be expected.

In summary, the implementation of this option would pose no significant radiological risk to persons residing in potentially affected areas or along representative transportation routes. Under the conservative assumption that all food consumed in potentially affected areas during the 35-year operational period would be radioactively contaminated, no credible pattern of food consumption would pose a significant radiological health risk due to the ingestion of contaminated food supplies. As discussed in other parts of Section 4.4.2.1, the implementation of this option would not result in significant nonradiological impacts on populations at risk. Thus, implementation would not pose significant and adverse environmental risks to persons residing within potentially affected areas, including minority and low-income persons.

#### 4.4.2.1.13 Waste Management

Only an extremely small amount of additional waste would be generated as a result of irradiating neptunium-237 targets in ATR (Section 4.4.1.1.13). However, waste would be associated with FDPF operations to fabricate and process neptunium-237 targets.

The impacts of managing waste associated with neptunium-237 target fabrication and processing in FDPF are assumed to be the same as for Option 2 under Alternative 1 (Section 4.3.2.1.13) because the same amount of plutonium-238 would be produced annually. As shown in that section, the impacts on the waste management systems at INEEL would be minimal.

#### 4.4.2.1.14 Spent Nuclear Fuel Management

No incremental impacts would be associated with the management of spent nuclear fuel (refer to Section 4.4.1.1.14).

#### **4.4.2.2 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.4.3 Alternative 2 (Use Only Existing Operational Facilities)—Option 3**

Option 3 involves operating ATR at INEEL to irradiate neptunium-237 targets, and operating FMEF at Hanford to fabricate and process these targets and to store the neptunium-237 transported to Hanford from SRS.

The transportation of the neptunium-237 from SRS to Hanford for processing and fabrication into neptunium-237 targets in FMEF, the transportation of these targets from Hanford to INEEL for irradiation in ATR, the transportation of the irradiated targets back to Hanford for postirradiation processing in FMEF, and the transportation of the plutonium-238 product from Hanford to LANL also constitute part of this option.

All options under this alternative include the permanent deactivation of FFTF at Hanford.

##### **4.4.3.1 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

###### **4.4.3.1.1 Land Resources**

**LAND USE.** The use of ATR to irradiate neptunium-237 targets would not result in impacts on land use at INEEL for the reasons described in Section 4.4.1.1.1.

FMEF, an existing facility in the 400 Area of Hanford, would be used for neptunium-237 storage, target fabrication, and processing. The use of FMEF would require the construction of a new 76-meter (250-foot) stack. Because the stack would be placed on previously disturbed land, and the use of FMEF for target fabrication and processing would be compatible with the mission for which it was designed, change in land use in the 400 Area would be minimal.

**VISUAL RESOURCES.** The use of ATR to irradiate neptunium-237 targets would not result in impacts on visual resources at INEEL for the reasons described in Section 4.4.1.1.1.

Neptunium-237 storage, target fabrication, and processing would take place in FMEF. Although FMEF is an existing facility, its use would require construction of a 76-meter (250-foot) stack. While the stack would be visible from surrounding areas, it would not change the overall appearance of the 400 Area or its Visual Resource Management Class IV rating. Thus, impacts on visual resources would be minimal.

###### **4.4.3.1.2 Noise**

The irradiation of neptunium-237 targets in ATR would not be expected to result in noise impacts at INEEL for the reasons described in Section 4.4.1.1.2.

A new 76-meter (250-foot) stack would be required for neptunium-237 target processing at FMEF. Noise associated with construction of the new stack would be typical of small construction projects and would be of short duration. During neptunium-237 target processing operations, sound levels would be similar to those associated with other operations in the 400 Area. Thus, the change in overall onsite noise impacts would be

minimal. Offsite noise impacts from these operations would also be minor because the nearest site boundary is 7 kilometers (4.3 miles) to the east and changes in traffic volume going to and from FMEF would be small. There would be no loud noises associated with neptunium-237 target processing that would adversely impact wildlife.

#### 4.4.3.1.3 Air Quality

It is estimated that there would be no measurable increases in nonradiological air pollutant emissions at INEEL associated with this option (Moor and Peterson 1999); therefore, no increased nonradiological air quality impacts would be expected.

The concentrations at Hanford attributable to this option are presented in **Table 4-75**. The concentrations for the option are based on a dispersion modeling screening analysis conducted with maximum expected emission rates and a set of worst-case meteorological conditions. Only those air pollutants expected to be emitted that have ambient air quality standards are presented in the table. The change in ambient concentrations were determined to be small, and would be below the applicable ambient air quality standards even when ambient monitoring values and the contributions from the other site activities are included.

**Table 4-75 Incremental Hanford Concentrations<sup>a</sup> Associated with Alternative 2  
(Use Only Existing Operational Facilities)—Option 3**

Pollutant	Averaging Period	Most Stringent Standard or Guideline (micrograms per cubic meter)	Modeled Increment (micrograms per cubic meter)
<b>Criteria pollutants</b>			
Nitrogen dioxide	Annual	100	$4.43 \times 10^{-5}$
Sulfur dioxide	Annual	50	0.0087
	24 hours	260	0.069
	3 hours	1,300	0.16
	1 hour	660	0.17
<b>Toxic air pollutants</b>			
Methanol	24 hours	870	0.0018
Nitric acid	24 hours	17	0.0022
Paraffin hydrocarbons	24 hours	7	0.16
Tributyl phosphate	24 hours	7.3	0.090

a. For comparison with ambient air quality standards.

**Source:** 40 CFR Part 50; WDEC 1998; modeled increments are based on the SCREEN3 computer code (EPA 1995).

The concentrations at Hanford attributed to this option are compared to the Prevention of Significant Deterioration Class II increments for nitrogen dioxide and sulfur dioxide in **Table 4-76**.

**Table 4-76 PSD Class II Increments Compared to Hanford Concentrations Associated with Alternative 2 (Use Only Existing Operational Facilities)—Option 3**

Pollutant	Averaging Period	Allowable PSD Increment (micrograms per cubic meter)	Modeled Increment (micrograms per cubic meter)
Nitrogen dioxide	Annual	25	$4.43 \times 10^{-5}$
Sulfur dioxide	Annual	20	0.0087
	24 hours	91	0.069
	3 hours	512	0.16

**Key:** PSD, Prevention of Significant Deterioration.

**Source:** Modeled increments are based on the SCREEN3 computer code (EPA 1995).

Health effects from hazardous chemicals associated with this option are addressed in Section 4.4.3.1.9. The air quality impacts of transportation among SRS, INEEL, Hanford, and LANL are presented in Section 4.4.3.1.11.

#### **4.4.3.1.4 Water Resources**

Impacts on water resources at INEEL associated with operating ATR to irradiate neptunium-237 targets would be negligible as previously described in Section 4.4.1.1.4.

Impacts on water resources at Hanford associated with the operation of FMEF for target material storage, target fabrication, and processing would be the same as those described in Section 4.3.3.1.4. Specifically, the operation of FMEF for this purpose is projected to require approximately 19 million liters (5 million gallons) of groundwater annually. This would include approximately 15 million liters (4 million gallons) per year to primarily support FMEF cooling needs, as well as material processing activities, and an additional 3.8 million liters (1 million gallons) per year for potable and sanitary water demands due to increased staffing. However, no impact on regional groundwater levels would be expected from increased withdrawals. FMEF groundwater usage would constitute an increase of about 10 percent over the 197 million liters (52 million gallons) withdrawn annually in the 400 Area during standby operations. Sanitary wastewater discharges from FMEF would also increase by roughly 3.8 million liters (1 million gallons) per year to the Energy Northwest treatment system, which has sufficient capacity. Also, the operation of FMEF for target fabrication and processing would generate approximately 15 million liters (4 million gallons) per year of process wastewater. This wastewater would be discharged to the 400 Area process sewer system and ultimately to the 400 Area Pond (i.e., 4608 B/C percolation ponds) (Chapin 2000; Nielsen 1999:38, 39, 41). Because discharges to the pond are regulated under State Waste Discharge Permit No. ST-4501 and there are no radiological liquid effluent pathways to the environment from FMEF, the impact on groundwater quality would be negligible.

It should be noted that the increase in water use and sanitary and process wastewater discharge for FMEF operations would essentially be negated by the larger reductions in water use and wastewater generation in the 400 Area associated with the permanent deactivation of FFTF (see Section 4.4.1.2.4).

Waste management aspects of this option and their effects are further discussed in Section 4.4.3.1.13.

#### **4.4.3.1.5 Geology and Soils**

The irradiation of neptunium-237 targets in ATR would not be expected to result in impacts on geologic or soil resources at INEEL, nor be jeopardized by large-scale geologic conditions, for the reasons described in Section 4.4.1.1.5.

Because the existing FMEF would be used for neptunium-237 storage, target fabrication, and processing and the new 76-meter (250-foot) stack would be built on previously disturbed land, impacts on geologic resources and native soils would be negligible. Hazards from large-scale geologic conditions at Hanford, such as earthquakes and volcanoes, were previously evaluated as discussed in Sections 4.2.4.2.5 and 4.3.3.1.5 and found to present a low risk to FMEF operations.

As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards would be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### 4.4.3.1.6 Ecological Resources

The irradiation of neptunium-237 targets in ATR would not result in impacts on ecological resources at INEEL for the reasons described in Section 4.4.1.1.6.

FMEF, an existing facility at Hanford, would be used for neptunium-237 target fabrication and processing. While a new 76-meter (250-foot) stack would be built, it would be placed on previously disturbed land in the 400 Area; thus, no natural terrestrial habitat would be lost. As noted in Section 4.4.3.1.2, there would be no sudden loud noises that would adversely impact wildlife. Because additional water usage and wastewater discharge would be small fractions of current values and discharge chemistry would not be expected to change, there would be no change in impacts on aquatic habitat or wetlands associated with the Columbia River (Section 4.4.3.1.4). Due to the developed nature of the area and the fact that construction would not disturb any natural habitat, impacts on threatened and endangered species would not occur.

Consultation letters concerning threatened and endangered species were sent to the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, the Washington State Department of Natural Resources, and the State of Washington Department of Fish and Wildlife (see Table 5–3). Each agency was asked to provide information on potential impacts of the proposed action on threatened and endangered species. Both the Washington State Department of Natural Resources and the State of Washington Department of Fish and Wildlife provided lists of state species of concern that occur in the vicinity of the project area. As noted above, no impacts to any threatened or endangered species are expected, including those of concern to these agencies. While DOE has made additional contacts with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service, responses are pending from these agencies. Although no federally listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at Hanford prior to the receipt of input from these Federal agencies.

#### 4.4.3.1.7 Cultural and Paleontological Resources

The irradiation of neptunium-237 targets in ATR would not result in impacts on cultural and paleontological resources at INEEL for the reasons described in Section 4.4.1.1.7.

Neptunium-237 storage, target fabrication, and processing would take place at FMEF, which is in the 400 Area of Hanford. Although a new 76-meter (250-foot) stack would be built, it would be placed on previously disturbed land in the 400 Area; thus, impacts on cultural and paleontological resources would not be expected. No prehistoric, historic, or paleontological sites have been identified either in the 400 Area or within 2 kilometers (1.2 miles) of the 400 Area. Six buildings in the 400 Area have been determined to be eligible for listing on the National Register of Historic Places as contributing properties within the Historic District recommended for mitigation. The use of FMEF for neptunium-237 target fabrication and processing would not affect the eligibility of these structures for the National Register of Historic Places. No Native American resources are known to occur in the 400 Area.

Consultation to comply with Section 106 of the National Historic Preservation Act was conducted with the State Historic Preservation Office (see Table 5–3) and resulted in concurrence by the State Historic Preservation Office that the proposed action would have no effect on historic properties at Hanford. Consultation was also conducted with interested Native American tribes that resulted in comments at public hearings by members representing the Nez Perce and Confederated Tribes of the Umatilla Indian Reservation. Responses to their specific comments are addressed in Volume 3.

#### **4.4.3.1.8 Socioeconomics**

After facility modifications, startup, and testing of the plutonium-238 reactor operation facilities at INEEL and target fabrication/processing facilities at Hanford, approximately 62 additional workers would be required to operate these facilities (none at INEEL and 62 at Hanford) (Hoyt et al. 1999). This level of employment would not generate any indirect jobs in the region around INEEL. At Hanford, as this option would also include deactivation of FFTF, the additional workers could potentially transfer from FFTF. If not, this option could generate about 157 indirect jobs in the region around Hanford. The potential total employment increase of 219 direct and indirect jobs in the Hanford region represents less than 0.1 percent of the projected regional economic area workforce. It would have no noticeable impact on the regional economic area.

Additional employment resulting from this option would not have any noticeable impact on community services in the Hanford region of influence. Assuming that 91 percent of the new employment associated with this option would reside in Hanford's region of influence (refer to Section 3.4.8), 199 new jobs could increase the region's population by approximately 383 persons. This increase, in conjunction with normal population growth forecasted by the State of Washington, would not have any noticeable effect on the availability of housing and/or the price of housing in the region of influence. Given the current population-to-student ratio in the region of influence, this would likely result in an increase of about 79 students, requiring local school districts to slightly increase the number of classrooms to accommodate them.

Community services in the region of influence would be expected to change to accommodate the population growth as follows: five new teachers would be needed to maintain the current student-to-teacher ratio of 16:1; one new police officer would need to be added to maintain the current officer-to-population ratio of 1.5:1000; one new firefighter would need to be added to maintain the current firefighter-to-population ratio of 3.4:1000; and one new doctor would be added to maintain the current physician-to-population ratio of 1.4:1000. Thus, an additional eight positions would have to be created to maintain community services at current levels. Hospitals in the region of influence would not experience any change from the 2.1 beds per 1,000 persons currently available. Additionally, the average school enrollment would not change. None of these projected changes should have a major impact on the level of community services currently offered in the region of influence.

#### **4.4.3.1.9 Public and Occupational Health and Safety—Normal Operations**

Assessments of incremental radiological and chemical impacts associated with Alternative 2, Option 3 are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from operations are given in **Table 4-77** for INEEL and Hanford: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

**Table 4–77 Incremental Radiological Impacts on the Public Around INEEL and Hanford from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 3**

Receptor	INEEL ATR	Hanford FMEF	Total
<b>Population within 80 kilometers (50 miles) in the year 2020</b>			
Dose (person-rem)	0	$4.4 \times 10^{-5}$	$4.4 \times 10^{-5}$
35-year latent cancer fatalities	0	$7.7 \times 10^{-7}$	$7.7 \times 10^{-7}$
<b>Maximally exposed individual</b>			
Annual dose (millirem)	0	$4.7 \times 10^{-7}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	$8.3 \times 10^{-12}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>			
Annual dose <sup>b</sup> (millirem)	0	$8.9 \times 10^{-8}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	$1.6 \times 10^{-12}$	NA <sup>a</sup>

a. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.

b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FMEF in the year 2020 (494,400).

**Key:** NA, not applicable.

**Source:** Model results, using the GENII computer code (Napier et al. 1988).

As a result of annual operations of ATR at INEEL and FMEF at Hanford, the projected total incremental population dose in the year 2020 would be  $4.4 \times 10^{-5}$  person-rem. The corresponding number of latent cancer fatalities in the populations surrounding INEEL and Hanford from 35 years of operations would be  $7.7 \times 10^{-7}$ . The total incremental dose to the maximally exposed member of the public from annual ATR operations would be 0 millirem because there would be no increase in radiological releases to the environment from ATR associated with this option. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would, therefore, be zero. The incremental dose to the maximally exposed member of the public from annual FMEF operations would be  $4.7 \times 10^{-7}$  millirem. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $8.3 \times 10^{-12}$ .

Incremental doses to involved workers from normal operations are given in **Table 4–78**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to ATR workers would be 0 millirem; for FMEF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities would be 0 and approximately 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–78. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–78 Incremental Radiological Impacts on Involved INEEL and Hanford Workers from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 3**

Receptor—Involved Workers <sup>a</sup>	INEEL ATR	Hanford FMEF	Total
Total dose (person-rem per year)	0	12 <sup>b</sup>	12
35-year latent cancer fatalities	0	0.17	0.17
Average worker dose (millirem per year)	0	170	NA <sup>c</sup>
35-year latent cancer fatality risk	0	0.0023	NA <sup>c</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 75 badged workers.

c. Values cannot be given for the average worker because the workers would be at two different facilities and sites.

**Key:** NA, not applicable.

**Source:** Mecham 1999; Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts at INEEL would be the same as those of ongoing site operations because no new chemicals would be emitted at ATR.

At Hanford, both carcinogenic and noncarcinogenic health effects from exposure to hazardous chemicals were evaluated. It was assumed that under normal operating conditions, the primary exposure pathway for members of the public would be from air emissions released through the process stack. Emissions of chemicals were estimated based on anticipated chemical usage. A worst-case dispersion modeling screening analysis was performed to estimate annual concentrations for each chemical, based on the emissions.

The annual concentration for each noncarcinogenic chemical was divided by the corresponding inhalation reference concentration to estimate the Hazard Quotient for each chemical. The Hazard Quotients were summed to give the Hazard Index from all noncarcinogenic chemicals associated with this option. A Hazard Index of less than one indicates that adverse health effects from non-cancer-causing agents are not expected. For carcinogens, the annual concentration was multiplied by the unit cancer risk to estimate the increased cancer risk from that chemical. Hazardous chemical health effects are summarized in **Table 4–79**.

**Table 4–79 Incremental Hazardous Chemical Impacts on the Public Around Hanford Under Alternative 2 (Use Only Existing Operational Facilities)—Option 3**

Chemical	Modeled Annual Increment (milligrams per cubic meter)	RfC - Inhalation (milligrams per cubic meter)	Unit Cancer Risk (risk per milligram per cubic meter)	Hazard Quotient	Cancer Risk
Diethyl benzene	$6.01 \times 10^{-6}$	1	0.0078	$6.01 \times 10^{-6}$	$4.69 \times 10^{-8}$
Methanol	$2.19 \times 10^{-7}$	1.75	NA	$1.25 \times 10^{-7}$	NA
Nitric acid	$2.73 \times 10^{-7}$	0.1225	NA	$2.22 \times 10^{-6}$	NA
Tributyl phosphate	$1.13 \times 10^{-5}$	0.01	NA	0.00113	NA
Hazard Index =				0.00114	

**Note:** For diethyl benzene, the reference concentration for ethyl benzene and the unit cancer risk for benzene were used to estimate Hazard Quotient and cancer risk because no information was available for diethyl benzene. For tributyl phosphate, the reference concentration for phosphoric acid was used to estimate the Hazard Quotient because no information was available for tributyl phosphate.

**Key:** NA, not applicable (the chemical is not a known carcinogen); RfC, reference concentration.

**Source:** DOE 1996a; EPA 1999; modeled increments are based on the SCREEN3 computer code (EPA 1995).

#### 4.4.3.1.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with ATR target irradiation and FMEF target processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Estimates of radiological consequences have been developed for the maximally exposed individual, the offsite population within 80 kilometers (50 miles) of the facility, and a noninvolved worker at a distance of 640 meters (0.4 mile) from the release point. Consequences are presented in terms of radiological dose (in rem) and the probability that the dose would result in a latent cancer fatality. Accident risk is defined as the product of the accident probability (i.e., accident frequency) and the accident consequence. In this NI PEIS, risk is expressed as the increased likelihood of a latent cancer fatality per year for an individual (the maximally exposed individual or a noninvolved worker), and as the increased number of latent cancer fatalities per year in the offsite population. The probability coefficients for determining the likelihood of a latent cancer fatality, given a dose, are given in Section 4.2.1.2.10. Consequences to involved workers are addressed in Section I.1.7.

To provide a better indication of risks from the postulated accidents, the risks are summed for each facility and also for each option. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk from accidents, a full-scope probabilistic risk analysis would be required for each facility. Since full-scope probabilistic risk analyses are not available to incorporate in this NI PEIS, summing the spectrum of accident risks was considered appropriate for the purposes of this NI PEIS. Details of the risk summation calculations are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–80** and **4–81**, respectively. Because ATR is currently operating, the consequences and risks are presented for both the current reactor configuration without neptunium-237 targets and for the worst-case neptunium-237 target-loading reactor configuration.

For 35 years of ATR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.45 \times 10^{-7}$  and  $3.48 \times 10^{-6}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.00140.

For 35 years of FMEF target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $2.88 \times 10^{-6}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.112.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $2.88 \times 10^{-6}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.114.

The irradiation of neptunium-237 targets to produce plutonium-238 at ATR would not introduce any additional operations that require the use of hazardous chemicals. Thus, there are no postulated hazardous chemical accidents attributable to the irradiation of neptunium-237 targets at ATR.

**Table 4–80 ATR and FMEF Accident Consequences Under Alternative 2 (Use Only Existing Operational Facilities)—Option 3**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
<b>ATR accidents</b>						
Large-break LOCA with 0 kg/yr plutonium-238 production	0.465	$2.33 \times 10^{-4}$	$5.11 \times 10^4$	25.5	5.15	0.00206
Large-break LOCA with 5 kg/yr plutonium-238 production	0.604	$3.02 \times 10^{-4}$	$5.17 \times 10^4$	25.9	7.61	0.00304
Target handling with 0 kg/yr plutonium-238 production <sup>c</sup>	0.0	0.0	0.0	0.0	0.0	0.0
Target handling with 5 kg/yr plutonium-238 production	$2.05 \times 10^{-4}$	$1.03 \times 10^{-7}$	0.128	$6.41 \times 10^{-5}$	0.00324	$1.30 \times 10^{-6}$
<b>FMEF accidents</b>						
Ion exchange explosion during neptunium-237 target fabrication	$2.02 \times 10^{-9}$	$1.01 \times 10^{-12}$	$7.26 \times 10^{-5}$	$3.63 \times 10^{-8}$	$6.65 \times 10^{-10}$	$2.66 \times 10^{-13}$
Target dissolver tank failure during plutonium-238 separation	$4.64 \times 10^{-8}$	$2.32 \times 10^{-11}$	0.00169	$8.47 \times 10^{-7}$	$1.95 \times 10^{-8}$	$7.81 \times 10^{-12}$
Ion exchange explosion during plutonium-238 separation	$1.24 \times 10^{-5}$	$6.18 \times 10^{-9}$	0.451	$2.25 \times 10^{-4}$	$5.20 \times 10^{-6}$	$2.08 \times 10^{-9}$
Processing facility beyond-design-basis earthquake	16.5	0.00823	$6.41 \times 10^5$	321	921	1.0 <sup>d</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

c. There would be no neptunium-237 targets for this zero-production case. Thus, there would be no associated accident consequences.

d. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4-81 ATR and FMEF Accident Risks Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 3**

Accident (Frequency)	Maximally Exposed Individual <sup>a</sup>	Population to 80 Kilometers (50 Miles) <sup>b</sup>	Noninvolved Worker <sup>a</sup>
<b>Annual ATR risks</b>			
Large-break LOCA with 0 kg/yr plutonium-238 production ( $1 \times 10^{-4}$ )	$2.33 \times 10^{-8}$	0.00255	$2.06 \times 10^{-7}$
Large-break LOCA with 5 kg/yr plutonium-238 production ( $1 \times 10^{-4}$ )	$3.02 \times 10^{-8}$	0.00259	$3.04 \times 10^{-7}$
Large-break LOCA incremental risks <sup>c</sup>	$6.90 \times 10^{-9}$	$4.00 \times 10^{-5}$	$9.80 \times 10^{-8}$
Neptunium-237 target handling with 5 kg/yr plutonium-238 production (0.001) <sup>d</sup>	$1.03 \times 10^{-10}$	$6.41 \times 10^{-8}$	$1.30 \times 10^{-9}$
<b>35-year ATR risk<sup>e</sup></b>	$2.45 \times 10^{-7}$	0.00140	$3.48 \times 10^{-6}$
<b>Annual FMEF risks</b>			
Ion exchange explosion during neptunium-237 target fabrication (0.01)	$1.01 \times 10^{-14}$	$3.63 \times 10^{-10}$	$2.66 \times 10^{-15}$
Target dissolver tank failure during plutonium-238 separation (0.01)	$2.32 \times 10^{-13}$	$8.47 \times 10^{-9}$	$7.81 \times 10^{-14}$
Ion exchange explosion during plutonium-238 separation (0.01)	$6.18 \times 10^{-11}$	$2.25 \times 10^{-6}$	$2.08 \times 10^{-11}$
Processing facility beyond-design-basis earthquake ( $1 \times 10^{-5}$ )	$8.23 \times 10^{-8}$	0.00321	$1.00 \times 10^{-5(f)}$
<b>35-year FMEF risk</b>	$2.88 \times 10^{-6}$	0.112	$3.50 \times 10^{-4}$
<b>35-year Option risk<sup>g</sup></b>	$2.88 \times 10^{-6}$	0.114	$3.50 \times 10^{-4}$

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.

d. There would be no neptunium-237 targets for the zero-production case. Thus, the 5-kg/yr production rate target-handling risks are the incremental risks.

e. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.

f. Risk of an early fatality.

g. Individual risks are summed only for colocated individuals. The highest individual risk was used to represent the 35-year option risk.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

No chemical processing activities are currently performed at FMEF and no chemicals are stored in this facility. Processing activities in support of plutonium-238 production would require the introduction of hazardous chemicals, specifically nitric acid and nitric oxide. Potential health impacts from accidental releases of nitric acid were assessed by comparing estimated airborne concentrations of the chemicals to ERPG developed by the American Industrial Hygiene Association. The ERPG-1 value (0.5 part per million) is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour, resulting in only mild, transient, and reversible adverse health effects. The ERPG-2 value (10 parts per million) is protective of irreversible or serious health effects or impairment of an individual’s ability to take protective action. The ERPG-3 value (25 parts per million) is indicative of potentially life-threatening health effects.

The maximum distances, in meters, needed to reach the ERPG values for nitric acid releases at FMEF for Stability Classes D and F are shown in **Table 4–82**. Two separate atmospheric conditions were evaluated, Stability Classes D and F. Stability Class D represents average meteorological conditions while Stability Class F represents worst-case meteorological conditions. The number of involved and noninvolved workers potentially exposed would vary with a number of factors such as the time of day and whether they are sheltered within buildings at the time of release. Individuals at the nearest highway (7,100 meters [4.4 miles]) and at the nearest site boundary (7,210 meters [4.5 miles]) from FMEF would be exposed to levels well below ERPG-1.

**Table 4–82 ERPG Distances for Nitric Acid Releases at FDPF Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 3**

Evaluation Parameter	Stability Class D (meters)	Stability Class F (meters)
ERPG-3	375	450
ERPG-2	500	600
ERPG-1	2,000	3,000

**Note:** To convert from meters to miles, multiply by  $6.22 \times 10^{-4}$ .

**Key:** ERPG, Emergency Response Planning Guideline.

There are no ERPG values for nitric oxide. For nitric oxide accidents, the level of concern has been estimated by using one-tenth of the “Immediately Dangerous to Life and Health” level published by the National Institute for Occupational Safety and Health. The Immediately Dangerous to Life and Health value for nitric oxide is 100 parts per million. The level of concern value used for this NI PEIS is 10 parts per million. The level of concern is defined as the concentration of an extremely hazardous substance in air above which there may be serious irreversible health effects as a result of a single exposure for a relatively short period of time.

For FMEF, the maximum distances needed to reach the level of concern for nitric oxide releases for Stability Classes D and F are 500 and 1,900 meters (0.31 and 1.18 miles), respectively. The number of involved and noninvolved workers potentially exposed would vary with a number of factors such as the time of day and whether they are sheltered within buildings at the time of release. Individuals at the nearest highway (7,100 meters [4.4 miles]) and at the nearest site boundary (7,210 meters [4.5 miles]) from FMEF would be exposed to levels well below the level of concern for nitric oxide.

Potential health impacts from the accidental release of the hazardous chemicals were assessed for a noninvolved worker, offsite individuals who are members of the public located at the nearest site boundary and onsite individuals who are members of the public located at the nearest highway access.

The impacts associated with the accidental release of nitric acid and nitric oxide at FMEF are presented in **Table 4–83**.

**Table 4–83 FMEF Hazardous Chemical Accident Impacts Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 3**

Receptor	Evaluation Parameter	Nitric Acid		Nitric Oxide	
		Stability Class D	Stability Class F	Stability Class D	Stability Class F
Noninvolved worker (640 meters)	Parts per million Level of concern Potential health effects	3.3 <ERPG-2 Mild, transient	8.6 <ERPG-2 Mild, transient	4.2 <LOC Mild, transient	66 >LOC Serious
Nearest highway maximally exposed individual	Parts per million Level of concern Potential health effects	0.03 < ERPG-1 None	0.1 ERPG-1 Mild, transient	0.09 < LOC None	0.55 < LOC None
Site boundary maximally exposed individual	Parts per million Level of concern Potential health effects	0.03 < ERPG-1 None	0.1 ERPG-1 Mild, transient	0.09 < LOC None	0.53 < LOC None

**Note:** < means “less than.”

**Key:** ERPG, Emergency Response Planning Guideline; LOC, level of concern.

**Source:** Model results.

#### 4.4.3.1.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the FMEF target fabrication facility at Hanford. DOE would transport the unirradiated neptunium-237 targets from FMEF to ATR at INEEL. Following irradiation in ATR, the targets would be returned to FMEF for processing. After this processing, the plutonium-238 product would be shipped to LANL. The analysis is described in Appendix J.

Approximately 689 shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 0.83 million kilometers (0.52 million miles).

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 5 person-rem; the dose to the public, 81 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.0020 latent cancer fatality among transportation workers and 0.040 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option is 0.0014.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FMEF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 were also evaluated and estimated to have a probability of less than 1 in 10 million per year.

Estimates of the total ground transportation accident risks under this option are as follows: a radiological dose to the population of 0.06 person-rem, resulting in  $3.0 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.017 traffic fatality.

#### **4.4.3.1.12 Environmental Justice**

**NORMAL OPERATIONS.** For 35 years of normal operations under this option, the likelihood of an incremental latent cancer fatality among the populations residing within 80 kilometers (50 miles) of ATR and FMEF would be essentially zero (derived from information in Table 4–77). As shown in Table 4–79, the release of hazardous chemicals at Hanford would pose no significant risk of cancer or toxic effects among the public. As discussed in Sections K.5.1 and K.5.3, the number of latent cancer fatalities that would result from the ingestion of food that could be radiologically contaminated due to normal operations would be essentially zero at INEEL and approximately 0.001 at Hanford. No credible pattern of food consumption by persons residing in potentially affected areas would result in significant health risks due to radiological contamination of food supplies near INEEL or Hanford. As discussed in Section 4.4.3.1.11, no fatalities would be expected from incident-free transportation activities.

**ACCIDENTS.** The number of expected latent cancer fatalities among the populations at risk due to radiological accidents listed in Table 4–81 would be approximately 0.11. If a radiological accident were to occur at ATR and northwesterly winds prevailed at the time of the accident, radiological contamination from the accident would be directed toward the Fort Hall Indian Reservation (see Figure K–2). However, accidents that could occur under the implementation of this option would not be expected to result in a latent cancer fatality among the population or maximally exposed individual residing within the boundary of the Fort Hall Indian Reservation. If a radiological accident were to occur at FMEF and northeasterly winds prevailed at the time of the accident, radiological contamination from the accident would be directed toward the Yakama Indian Reservation (see Figure K–11). However, accidents that could occur under the implementation of this option would not be expected to result in a latent cancer fatality among the population or maximally exposed individual residing within the boundary of Yakama Indian Reservation.

As discussed in Section 4.4.3.1.11, no fatalities would be expected to result from transportation accidents. In summary, the implementation of this option would pose no significant radiological risk to persons residing in potentially affected areas or along representative transportation routes. Under the conservative assumption that all food consumed in potentially affected areas during the 35-year operational period would be radioactively contaminated, no credible pattern of food consumption would pose a significant radiological health risk due to the ingestion of contaminated food supplies. As discussed in other parts of Section 4.4.3.1, the implementation of this option would not result in significant nonradiological impacts on populations at risk. Thus, implementation would not pose significant and adverse environmental risks to persons residing within potentially affected areas, including minority and low-income persons.

#### **4.4.3.1.13 Waste Management**

Only an extremely small amount of additional waste would be generated as a result of irradiating neptunium-237 targets in ATR (Section 4.4.1.1.13). Therefore, no impacts on the waste management systems at INEEL would be anticipated. However, there would be impacts on Hanford’s waste management systems as a result of FMEF operations to fabricate and process neptunium-237 targets for plutonium-238 production.

The expected generation rates of waste at Hanford that would be associated with the operation of FMEF for this target fabrication and processing are compared with Hanford’s treatment, storage, and disposal capacities in **Table 4–84**. The impacts on the Hanford waste management systems, in terms of managing the additional waste, are discussed in this section. Radiological and chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.4.3.1.9 through 4.4.3.1.11.

**Table 4–84 Incremental Waste Management Impacts of Operating FMEF at Hanford Under Alternative 2 (Use Only Existing Operational Facilities)—Option 3**

Waste Type <sup>a</sup>	Estimated Additional Waste Generation (cubic meters per year)	Estimated Additional Waste Generation as a Percent of <sup>b</sup>		
		Onsite Treatment Capacity	Onsite Storage Capacity	Onsite Disposal Capacity
Transuranic/High-level radioactive <sup>c</sup>	11	(c)	(c)	NA
<b>Low-level radioactive</b>				
Liquid	6	(d)	(d)	(d)
Solid	54	NA	NA	0.82
Mixed low-level radioactive	<5	0.27	1.0	1.2
Hazardous	18	NA	NA	NA
<b>Nonhazardous</b>				
Process wastewater	15,000	(d)	(d)	(d)
Sanitary wastewater	3,800	1.6 <sup>e</sup>	NA	NA
Solid	150	NA	NA	NA

a. See definitions in Section G.9.

b. The estimated additional amounts of waste generated annually are compared with the annual site treatment capacities. For nonhazardous liquid waste, the estimated additional annual generation rate is also compared with the annual site disposal capacity. The estimated total amounts of additional waste generated over the 35-year operational period are compared with the site's storage capacities, and, for other than nonhazardous liquid waste, with the site's disposal capacities.

c. Refer to the text for a discussion on waste classification and treatment. This waste would be stored at FMEF pending availability of a suitable repository. It is assumed that this waste would be remotely handled.

d. Refer to the text.

e. Percent of capacity of the Energy Northwest system.

**Note:** To convert from cubic meters per year to cubic yards per year, multiply by 1.308; < means "less than."

**Key:** NA, not applicable (i.e., the majority of this waste is not routinely treated or is not routinely stored or is not routinely disposed of on site; refer to the text).

**Source:** Chapin 2000; DOE 2000a; Hoyt et al. 1999; Nielsen 1999.

The canisters used to transport neptunium-237 to the site would constitute a very small additional amount of solid low-level radioactive waste—less than 10 cubic meters (13.1 cubic yards) over the 35-year operational period, even if no credit is taken for volume reduction by compaction (Brunson 1999a). The annual generation of this waste would fall within the range of accuracy of the solid low-level radioactive waste generation rate given in Table 4–84, and its management need not be addressed separately.

In accordance with the Records of Decision for the *Waste Management PEIS* (DOE 1997a), waste could be treated and disposed of on site at Hanford or at other DOE sites or commercial facilities. Based on the Record of Decision for high-level radioactive waste issued on August 12, 1999 (64 FR 46661), immobilized high-level radioactive waste would be stored on site until transfer to a geologic repository. Based on the Record of Decision for transuranic waste issued on January 20, 1998 (63 FR 3629), transuranic waste would be certified on site and eventually shipped to a suitable geologic repository for disposal. Based on the Record of Decision for hazardous waste issued on August 5, 1998 (63 FR 41810), nonwastewater hazardous waste would continue to be treated and disposed of at offsite commercial facilities. Based on the Record of Decision for low-level radioactive waste and mixed low-level radioactive waste issued on February 18, 2000 (65 FR 10061), minimal treatment of low-level radioactive waste will be performed at all sites and, to the extent practicable, onsite disposal of low-level radioactive waste will continue. Hanford and the Nevada Test Site will be made available to all DOE sites for disposal of low-level radioactive waste. Mixed low-level radioactive waste analyzed in the *Waste Management PEIS* will be treated at Hanford, INEEL, ORR, and SRS and will be disposed of at Hanford and the Nevada Test Site.

The analysis for the Draft NI PEIS assumed that the waste generated from the processing of irradiated neptunium-237 targets is transuranic waste. However, as a result of comments received during the public comment period, DOE is considering whether the waste from processing of irradiated neptunium-237 targets should be classified as high-level radioactive waste and not transuranic waste. Irrespective of how the waste is classified (i.e., transuranic or high-level radioactive waste), the composition and characteristics are the same, and the waste management activities (i.e., treatment and onsite storage) as described in this NI PEIS would be the same. In addition, either waste type would require disposal in a suitable repository. If it is transuranic waste, it would be nondefense waste and could not be disposed of at WIPP under current law. Because nondefense transuranic waste has no current disposal path, DOE Headquarters' approval would be necessary before a decision were made to generate such waste, as required by DOE Order 435.1. If the waste is classified as high-level radioactive waste, it is assumed for the purposes of this analysis that Yucca Mountain, Nevada, if approved, would be the final disposal site for DOE's high-level radioactive waste. The other differences between these two waste classifications are that a high-level radioactive waste repository requires a much more rigorous waste-form qualification process than a transuranic waste repository and there is a slightly different set of requirements for high-level radioactive waste than for transuranic waste delineated in DOE Manual 435.1.

Target fabrication and processing in FMEF would generate a total of 385 cubic meters (504 cubic yards) of transuranic or high-level radioactive waste over the 35-year operational period. As described in Section 3.4.5 of the *Preconceptual Design Planning for Chemical Processing to Support Pu-238 Production* (Wham 1998), the waste would be vitrified into a glass matrix at a glass melter installed within FMEF. The resulting glass matrix would be stored at FMEF pending availability of a repository for permanent disposal. The impacts of managing the additional quantities of this waste at Hanford would be minimal.

Solid low-level radioactive waste would be packaged, certified, and accumulated at FMEF before transfer for additional treatment and disposal in the existing onsite low-level radioactive Burial Grounds. Neptunium-237 target fabrication and processing would generate 1,890 cubic meters (2,470 cubic yards) of low-level radioactive waste over the 35-year operational period. This amount of low-level radioactive waste represents approximately 0.11 percent of the 1.74 million-cubic-meter (2.28 million-cubic-yard) capacity of the low-level radioactive waste Burial Grounds and 0.82 percent of the 230,000-cubic-meter (301,000-cubic-yard) capacity of the Grout Vaults. Using the 3,480-cubic-meter-per-hectare (1,842-cubic-yard-per-acre) disposal land usage factor for Hanford published in the *Storage and Disposition PEIS* (DOE 1996a:E-9), 1,890 cubic meters (2,470 cubic yards) of waste would require 0.54 hectares (1.3 acres) of disposal space at Hanford. The impacts of managing this additional low-level radioactive waste at Hanford would be minimal.

Liquid low-level radioactive waste associated with target fabrication and processing at FMEF would be transported to the 200 Area Effluent Treatment Facility for processing and ultimate disposal. Target fabrication and processing at FMEF would generate about 210 cubic meters (270 cubic yards) of liquid low-level radioactive waste over the 35-year operational period. This total amount of additional liquid low-level radioactive waste represents a small amount of waste which can be managed by the 200 Area Liquid Effluent Treatment Facility with an operating capacity of 0.57 cubic meter (0.75 cubic yard) per minute.

Mixed low-level radioactive waste would be stabilized, packaged, and stored on site for treatment and disposal in a manner consistent with the Tri-Party Agreement (EPA et al. 1989) for Hanford. Over the 35-year operational period, 175 cubic meters (229 cubic yards) of mixed low-level radioactive waste would be generated at FMEF associated with neptunium-237 target fabrication and processing. This mixed low-level radioactive waste is expected to be treated at a nearby commercial facility. However, if this waste were treated on site, it is estimated to be 0.27 percent of the 1,820-cubic-meter-per-year (2,380-cubic-yard-per-year) capacity of the Waste Receiving and Processing Facility. This waste also represents 1.0 percent of the 16,800-cubic-meter (22,000-cubic-yard) storage capacity of the Central Waste Complex and 1.2 percent of the

14,200-cubic-meter (18,600-cubic-yard) planned disposal capacity of the Radioactive Mixed Waste Disposal Facility. Therefore, this additional waste would only have a minimal impact on the management of mixed low-level radioactive waste at Hanford.

Hazardous waste generated during operation would be packaged in DOT-approved containers and shipped off site to permitted commercial recycling, treatment, and disposal facilities. The additional waste load generated during the operational period would have only a minimal impact on the Hanford hazardous waste management system.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Solid waste such as office paper, metal cans, and plastic and glass bottles that can be recycled would be sent off site for that purpose. The remaining solid sanitary waste would be sent for offsite disposal. This additional waste load would have only a minimal impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous process wastewater would be discharged into the 400 Area Ponds. This discharge is regulated by State Waste Discharge Permit ST-4501.

Nonhazardous sanitary wastewater would be discharged to the 400 Area sanitary sewer system, which connects to the Energy Northwest Sewage Treatment Facility. Nonhazardous sanitary wastewater generated from neptunium-237 target fabrication and processing in FMEF would represent 1.6 percent of the 235,000-cubic-meter-per-year (307,000-cubic-yard-per-year) capacity of the Energy Northwest Sewage Treatment Facility and would be well within the 138,000-cubic-meter-per-year (181,000-cubic-yard-per-year) excess capacity of this facility (DOE 1999a). Management of nonhazardous liquid waste at Hanford would only have a minimal impact on the treatment system.

The generation rates of waste at Hanford that would be associated with this option (refer to Table 4–84) can be compared with the current waste generation rates at the site, given in Table 3–34 (Section 3.4.11). The waste generation rates associated with plutonium-238 production would be much smaller than the current waste generation rates at the site.

#### **4.4.3.1.14 Spent Nuclear Fuel Management**

No incremental impacts would be associated with the management of spent nuclear fuel (refer to Section 4.4.1.1.14).

#### **4.4.3.2 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.4.4 Alternative 2 (Use Only Existing Operational Facilities)—Option 4**

Option 4 involves operating a CLWR at an unspecified location to irradiate neptunium-237 targets, and operating the REDC facility at ORR to fabricate and process these targets and to store the neptunium-237 transported to ORR from SRS.

The transportation of the neptunium-237 from SRS to ORR for processing and fabrication into neptunium-237 targets in REDC, the transportation of the targets from ORR to the generic CLWR site for irradiation, the transportation of the irradiated targets back to ORR for postirradiation processing in REDC, and the transportation of the plutonium-238 product from ORR to LANL also constitute part of this option.

All options under this alternative include the permanent deactivation of FFTF at Hanford.

#### **4.4.4.1 Operations and Transportation**

Environmental impacts associated with storage, processing, and irradiation operations and with all transportation activities are assessed in this section.

##### **4.4.4.1.1 Land Resources**

**LAND USE.** A currently operating CLWR would be used to irradiate neptunium-237 targets. There would be no impacts on land use because no new construction would be required, and use of the facility for target irradiation would be compatible with its current function.

There would be no impacts on land use at ORR from neptunium-237 storage, target fabrication, and processing at REDC for the reasons described in Section 4.4.1.1.1.

**VISUAL RESOURCES.** There would be no impacts on visual resources because use of a CLWR for neptunium-237 target irradiation would not require any external modifications that would alter the appearance of the facility.

There would be no impacts on visual resources at ORR from neptunium-237 storage, target fabrication, and processing at REDC for the reasons described in Section 4.4.1.1.1.

##### **4.4.4.1.2 Noise**

Noise associated with the irradiation of neptunium-237 targets at a CLWR site would be indistinguishable from other noises generated during normal operation of the facility. Noise associated with increased traffic going to and from the facility would be low and would result in only minor changes to existing onsite and offsite noise levels. Neptunium-237 target irradiation in a CLWR would not produce any sudden loud noises that would adversely affect wildlife.

Noise impacts at ORR would be minimal from neptunium-237 storage, target fabrication, and processing at REDC and changes in traffic noise would be minimal for the reasons described in Section 4.4.1.1.2.

##### **4.4.4.1.3 Air Quality**

It is expected that there would be no measurable increases in nonradiological air pollutant emissions at a CLWR site associated with this option; therefore, no changes in nonradiological air quality impacts would be expected.

Impacts for this option at ORR would be the same as those described for Option 1 (Section 4.4.1.1.3).

The air quality impacts of transportation among SRS, the generic site, ORR, and LANL are presented in Section 4.4.4.1.11.

##### **4.4.4.1.4 Water Resources**

No measurable impact on water resources at a CLWR site is expected under this option, because neptunium-237 target irradiation would not measurably increase water use or change the quantity or quality of effluent discharges. Information on water resources for the generic CLWR site is presented in Section 3.5.4.

Impacts for this option at ORR would be substantially the same as described for Option 1 (Section 4.4.1.1.4).

#### **4.4.4.1.5 Geology and Soils**

This option involves the irradiation of neptunium-237 targets in a CLWR. Because no new construction would take place, geologic and soil resources within the site area would not be disturbed. Assessment of hazards from large-scale geologic conditions for reactor sites, including assessment of seismic and nonseismic features, is governed by 10 CFR Part 100 and is beyond the scope of this analysis. Information on geology and soils for the generic CLWR site is presented in Section 3.5.5.

Neptunium-237 storage, target fabrication, and processing at REDC would not be expected to impact geologic and soil resources at ORR, nor be jeopardized by large-scale geologic conditions, for the reasons described in Sections 4.2.2.2.5 and 4.4.1.1.5. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards would be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.4.4.1.6 Ecological Resources**

A currently operating CLWR would be used to irradiate neptunium-237 targets. Terrestrial resources and wetlands would not be adversely affected because no new construction would be required. Further, as noted in Section 4.4.4.1.2, there would be no loud noises that would adversely affect wildlife. The irradiation of neptunium-237 targets would not impact aquatic resources because there would be no measurable change in water withdrawal or wastewater discharge (Section 4.4.4.1.4). Threatened and endangered species would not be impacted for the reasons noted above.

Impacts on ecological resources at ORR would not result from neptunium-237 storage, target fabrication, and processing at REDC for the reasons described in Section 4.4.1.1.6.

#### **4.4.4.1.7 Cultural and Paleontological Resources**

The irradiation of neptunium-237 targets would take place in a currently operating CLWR. Because no new construction would take place, impacts on cultural and paleontological resources would not occur.

Impacts on cultural and paleontological resources at ORR would not result from neptunium-237 storage, target fabrication, and processing at REDC for the reasons described in Section 4.4.1.1.7.

#### **4.4.4.1.8 Socioeconomics**

Reactor operations at a CLWR site would not require additional workers. Target fabrication and processing of plutonium-238 at ORR would require approximately 41 additional workers (Wham et al. 1998). The socioeconomic impacts at ORR are the same as those addressed in Section 4.3.1.1.8.

#### **4.4.4.1.9 Public and Occupational Health and Safety—Normal Operations**

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from operations are given in **Table 4–85** for the generic CLWR site and ORR: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

**Table 4–85 Incremental Radiological Impacts on the Public Around the Generic CLWR Site and ORR from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 4**

Receptor	Generic CLWR	ORR REDC	Total
<b>Population within 80 kilometers (50 miles) in the year 2020</b>			
Dose (person-rem)	0	$8.8 \times 10^{-5}$	$8.8 \times 10^{-5}$
35-year latent cancer fatalities	0	$1.5 \times 10^{-6}$	$1.5 \times 10^{-6}$
<b>Maximally exposed individual</b>			
Annual dose (millirem)	0	$1.9 \times 10^{-6}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	$3.3 \times 10^{-11}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>			
Annual dose <sup>b</sup> (millirem)	0	$7.8 \times 10^{-8}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	$1.4 \times 10^{-12}$	NA <sup>a</sup>

- a. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.  
 b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of REDC in the year 2020 (1,134,200).

**Key:** NA, not applicable.

**Source:** Model results, using the GENII computer code (Napier et al. 1988).

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

Target irradiation in a CLWR would not result in any incremental radiological emissions during normal operations or increased worker exposures. Therefore, the incremental impact of CLWR target irradiation is zero.

As a result of annual operations of the generic CLWR and REDC, the projected total incremental population dose in the year 2020 would be  $8.8 \times 10^{-5}$  person-rem. The corresponding number of latent cancer fatalities in the populations surrounding the generic CLWR site and ORR from 35 years of operations would be  $1.5 \times 10^{-6}$ . The total incremental dose to the maximally exposed member of the public from annual generic CLWR operations would be 0 millirem because there would be no increase in radiological releases to the environment from the generic CLWR associated with this option. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would, therefore, be zero. The incremental dose to the maximally exposed member of the public from annual REDC operations would be  $1.9 \times 10^{-6}$  millirem. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $3.3 \times 10^{-11}$ .

Incremental doses to involved workers from normal operations are given in **Table 4–86**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to generic CLWR workers would be 0 millirem; for REDC workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities would be 0 and approximately 12 person-rem, respectively. The risks and numbers of latent

cancer fatalities among the different workers from 35 years of operations are included in Table 4–86. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–86 Incremental Radiological Impacts on Involved CLWR and ORR Workers from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 4**

Receptor—Involved Workers <sup>a</sup>	Generic CLWR	ORR REDC	Total
Total dose (person-rem per year)	0	12 <sup>b</sup>	12
35-year latent cancer fatalities	0	0.17	0.17
Average worker dose (millirem per year)	0	170	NA <sup>c</sup>
35-year latent cancer fatality risk	0	0.0023	NA <sup>c</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with REDC operations at a DOE facility would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced at all facilities.

b. Based on an estimated 75 badged workers.

c. Values cannot be given for the average worker because the workers would be at two different facilities and sites.

**Key:** NA, not applicable.

**Source:** Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts at the generic CLWR site would be the same as those of ongoing site operations because no new chemicals would be emitted.

Hazardous chemical impacts for this option at ORR were determined to be the same as described for Option 1 (Section 4.4.1.1.9).

#### 4.4.4.1.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with target irradiation in a generic CLWR and REDC target processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Estimates of radiological consequences have been developed for the maximally exposed individual and the offsite population within 80 kilometers (50 miles) of the facility. Consequences to a noninvolved worker are not included for the generic CLWR analysis. Details regarding the exclusion of a noninvolved worker are provided in Section I.1.2.

Consequences are presented in terms of radiological dose (in rem) and the probability that the dose would result in a latent cancer fatality. Accident risk is defined as the product of the accident probability (i.e., accident frequency) and the accident consequence. In this NI PEIS, risk is expressed as the increased likelihood of a latent cancer fatality for an individual and as the increased number of latent cancer fatalities in the offsite population. The probability coefficients for determining the likelihood of a latent cancer fatality, given a dose, are given in Section 4.2.1.2.10. Consequences to involved workers are addressed in Section I.1.7.

To provide a better indication of risks from the postulated accidents, the risks are summed for each facility and also for each option. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk from accidents, a full-scope probabilistic risk analysis would be required for each facility. Since full-scope probabilistic risk analyses are plant specific,

summing the spectrum of accident risks was considered appropriate for the purposes of this NI PEIS. Details of the risk summation calculations are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–87** and **4–88**, respectively. Certain extremely unlikely or incredible severe accidents at commercial nuclear reactors could result in doses sufficiently high to cause early fatalities. The early fatality consequences and risks are presented in **Table 4–89**. The early fatalities shown in Table 4–89 are considered to be conservative estimates based upon the assumption that some individuals very close to the reactor do not evacuate. Because the generic CLWR is operational, the consequences and risks are presented for both the current reactor configuration without neptunium-237 targets and for the worst-case neptunium-237 target-loading reactor configuration. Baseline accident risks attributed to generic CLWR operations refer to accidents that could occur under the current CLWR configuration (without neptunium-237 targets). Baseline accident risks are obtained from the data in Tables 4–88 and 4–89 by summing the annual risks for the baseline CLWR configuration (0 kilograms per year plutonium-238 production), and then multiplying the sum by 35. The baseline CLWR accident risk to the public would be 0.073 latent cancer fatality. Baseline CLWR accident risks to the maximally exposed offsite individual would be  $5.7 \times 10^{-5}$  latent cancer fatality. Baseline risk to noninvolved workers is discussed in Appendix I.

For 35 years of CLWR target fabrication and irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual would be  $1.93 \times 10^{-9}$ . The increased number of latent cancer fatalities in the surrounding population would be 0.00305. The increased risk of an early fatality in the surrounding population would be  $2.07 \times 10^{-6}$ .

For 35 years of REDC target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $5.71 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.157.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $5.71 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.160.

The irradiation of neptunium-237 targets at the generic CLWR would not introduce any additional operations that require the use of hazardous chemicals. Thus, there are no postulated hazardous chemical accidents attributable to the irradiation of neptunium-237 targets at the generic CLWR.

Processing associated with the plutonium-238 production program at REDC, including storage of neptunium-237 and plutonium-238, neptunium-237 target fabrication, postirradiation processing to extract plutonium-238 and to recycle the unconverted neptunium-237 into new targets, does not require the introduction of hazardous chemicals that are not in current use in the facility. The quantities of in-process hazardous chemicals for the plutonium-238 production program are bounded by the quantities of the material currently stored in the facility. The impacts of in-process hazardous chemical accidents associated with the plutonium-238 production are bounded by the impacts of hazardous chemical accidents for existing storage facilities at REDC.

**Table 4–87 Generic CLWR and REDC Accident Consequences Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 4**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>

Late containment failure with 5 kg/yr plutonium-238 production	1.12	$5.60 \times 10^{-4}$	$1.06 \times 10^5$	53.6	NA	NA
Containment bypass with 0 kg/yr plutonium-238 production	1,540	1.00 <sup>d</sup>	$1.45 \times 10^6$	922	NA	NA
Containment bypass with 5 kg/yr plutonium-238 production	1,680	1.00 <sup>d</sup>	$1.52 \times 10^6$	978	NA	NA
<b>REDC accidents</b>						
Ion exchange explosion during neptunium-237 target fabrication	$6.13 \times 10^{-9}$	$3.06 \times 10^{-12}$	$8.58 \times 10^{-5}$	$4.29 \times 10^{-8}$	$5.60 \times 10^{-10}$	$2.24 \times 10^{-13}$
Target dissolver tank failure during plutonium-238 separation	$1.76 \times 10^{-7}$	$8.79 \times 10^{-11}$	0.00196	$9.82 \times 10^{-7}$	$1.69 \times 10^{-8}$	$6.74 \times 10^{-12}$
Ion exchange explosion during plutonium-238 separation	$4.68 \times 10^{-4}$	$2.34 \times 10^{-7}$	5.23	0.00261	$4.49 \times 10^{-5}$	$1.79 \times 10^{-8}$
Processing facility beyond-design-basis earthquake	163	0.163	$8.91 \times 10^5$	445	1,310	1.00 <sup>d</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities. The MACCS2 computer code calculates the dose to each exposed individual in the population, applies the appropriate cancer risk factor, and then sums the individual probabilities to determine the number of latent cancer fatalities.

c. Not applicable (refer to Appendix I). Evacuation of noninvolved workers and other noninvolved worker issues are addressed in Appendix I.

d. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident; NA, not applicable.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

- c. Not applicable (refer to Appendix I). Evacuation of noninvolved workers and other noninvolved worker issues are addressed in Appendix I.
- d. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.
- e. Risk of an early fatality.
- f. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.
- g. Individual risks are summed only for colocated individuals. The highest individual risk was used to represent the 35-year option risk.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident; NA, not applicable.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4-89 Generic CLWR Early Fatalities and Risks Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 4**

Accident (Frequency)	Population to 80 Kilometers (50 Miles)	
	Early Fatalities <sup>a</sup>	Annual Risk <sup>b</sup>
<b>Annual generic CLWR risks</b>		
Early containment failure with 0 kg/yr plutonium-238 production ( $7.92 \times 10^{-8}$ )	8.65	$6.85 \times 10^{-7}$
Early containment failure with 5 kg/yr plutonium-238 production ( $7.92 \times 10^{-8}$ )	8.76	$6.94 \times 10^{-7}$
Early containment failure incremental risk <sup>c</sup>	NA	$9.00 \times 10^{-9}$
Containment bypass with 0 kg/yr plutonium-238 production ( $1.53 \times 10^{-6}$ )	3.48	$5.32 \times 10^{-6}$
Containment bypass with 5 kg/yr plutonium-238 production ( $1.53 \times 10^{-6}$ )	3.51	$5.37 \times 10^{-6}$
Containment bypass incremental risk	NA	$5.00 \times 10^{-8}$
<b>35-year CLWR risk<sup>d</sup></b>	NA	$2.07 \times 10^{-6}$

a. Number of early fatalities assuming that the accident has occurred.

b. Risk of an early fatality.

c. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.

d. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; NA, not applicable.

**Source:** Model results, using the MACCS2 computer code (Chanin and Young 1997).

#### 4.4.4.1.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the REDC target fabrication facility at ORR. DOE would transport the unirradiated neptunium-237 targets from REDC to a CLWR. Following irradiation in a CLWR, the targets would be returned to REDC for processing. After this processing, the plutonium-238 product would be shipped to LANL. The impact analysis, described in Appendix J, assumes the most distant CLWR is used for target irradiation.

Approximately 689 shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 2.6 million kilometers (1.6 million miles).

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 14 person-rem; the dose to the public, 299 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.006 latent cancer fatality among transportation workers and 0.15 latent cancer fatality in the total affected

population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option is 0.0056.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to REDC with a severity category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 were also evaluated and estimated to have a probability of lower than 1 in 10 million per year.

Estimates of the total ground transportation accident risks are as follows: a radiological dose to the population of 0.088 person-rem, resulting in  $4.4 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.074 traffic fatality.

#### **4.4.4.1.12 Environmental Justice**

Under this option, neptunium-237 targets would be irradiated in a CLWR at an unspecified site. Target fabrication and processing would be performed at REDC located at ORR. Activities at REDC were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.1.1.12) and found to pose no significant radiological or other risks to minority and low-income populations. The analysis of accidents at specific sites shows that accidents at the fabrication and target facilities would result in radiological risks to the public that are small, but which are several orders of magnitude larger than those that would result from accidents at specific reactor sites (see Section 2.7.1.1). It is plausible that a similar difference would exist between accident risks at an unspecified CLWR site and the fabrication and processing facilities. However, evaluations of environmental justice are necessarily site specific and cannot be performed for unspecified locations. In the event that this option were selected for implementation and a specific CLWR were selected for irradiation services, additional evaluation of environmental justice at the CLWR site would be performed prior to implementation.

#### **4.4.4.1.13 Waste Management**

There would be no change in the amounts of waste generated as the result of irradiating neptunium-237 targets in a CLWR. Thus, there would be no impact on the CLWR site's waste management systems as the result of target irradiation.

The impacts of managing waste associated with neptunium-237 target fabrication and processing in REDC are assumed to be the same as for Option 1 under Alternative 1 (Section 4.3.1.1.13) because the same amount of plutonium-238 would be produced annually. As shown in that section, the impacts on the waste management systems at ORR would be minimal.

#### **4.4.4.1.14 Spent Nuclear Fuel Management**

No incremental impacts would be associated with the management of spent nuclear fuel (refer to Section 4.4.1.1.14).

#### **4.4.4.2 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.4.5 Alternative 2 (Use Only Existing Operational Facilities)—Option 5**

This option involves operating a generic CLWR at a generic site to irradiate neptunium-237 targets, and operating FDPF at INEEL to fabricate and process these targets. This option also includes storage of the neptunium-237 transported to INEEL from SRS, in either Building CPP-651 or FDPF.

The transportation of the neptunium-237 from SRS to INEEL for processing and fabrication into neptunium-237 targets in FDPF, the transportation of the targets from INEEL to the generic CLWR site for irradiation in the CLWR, the transportation of the irradiated targets back to INEEL for postirradiation processing in FDPF, and the transportation of the plutonium-238 product from INEEL to LANL also constitute part of this option.

All options under this alternative include the permanent deactivation of FFTF at Hanford.

##### **4.4.5.1 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all intersite transportation activities, are assessed in this section.

###### **4.4.5.1.1 Land Resources**

**LAND USE.** The use of a CLWR to irradiate neptunium-237 targets would not be expected to result in impacts on land use for the reasons described in Section 4.4.4.1.1.

Impacts on land use at INEEL from neptunium-237 storage, target fabrication, and processing would not result for the reasons described in Section 4.4.2.1.1.

**VISUAL RESOURCES.** The use of a CLWR to irradiate neptunium-237 targets would not result in impacts on visual resources for the reasons described in Section 4.4.4.1.1.

Impacts on visual resources at INEEL from neptunium-237 storage, target fabrication, and processing would not result for the reasons described in Section 4.4.2.1.1.

###### **4.4.5.1.2 Noise**

The irradiation of neptunium-237 targets in a CLWR would not be expected to result in noise impacts for the reasons described in Section 4.4.4.1.2.

Noise impacts at INEEL would not be expected from neptunium-237 storage, target fabrication, and processing and changes in traffic noise would be small for the reasons described in Section 4.4.2.1.2.

###### **4.4.5.1.3 Air Quality**

Impacts for this option at a generic CLWR site would be the same as those described for Option 4 (Section 4.4.4.1.3).

Impacts for this option at INEEL would be the same as those described for Option 2 (Section 4.4.2.1.3).

The air quality impacts of transportation among SRS, the generic CLWR site, INEEL, and LANL are presented in Section 4.4.5.1.11.

#### **4.4.5.1.4 Water Resources**

Impacts for this option at a generic CLWR site would be negligible as described for Option 4 (Section 4.4.4.1.4).

Impacts for this option at INEEL would be the same as described for Option 2 (Section 4.4.2.1.4).

#### **4.4.5.1.5 Geology and Soils**

The irradiation of neptunium-237 targets in a CLWR would not be expected to result in impacts on geologic or soil resources for the reasons described in Section 4.4.4.1.5. Assessment of hazards from large-scale geologic conditions for reactor sites, including assessment of seismic and nonseismic features, is governed by 10 CFR 100 and is beyond the scope of this analysis.

Neptunium-237 storage, target fabrication, and processing would not be expected to impact geologic and soil resources at INEEL, nor be jeopardized by large-scale geologic conditions, for the reasons described in Sections 4.2.3.2.5 and 4.4.2.1.5. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards would be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.4.5.1.6 Ecological Resources**

The irradiation of neptunium-237 targets in a CLWR would not result in impacts on ecological resources for the reasons described in Section 4.4.4.1.6.

Impacts on ecological resources at INEEL would not result from neptunium-237 storage, target fabrication, and processing for the reasons described in Section 4.4.2.1.6.

#### **4.4.5.1.7 Cultural and Paleontological Resources**

The irradiation of neptunium-237 targets in a CLWR would not result in impacts on cultural and paleontological resources for the reasons described in Section 4.4.4.1.7.

Impacts on cultural and paleontological resources at INEEL would not result from neptunium-237 storage, target fabrication, and processing for the reasons described in Section 4.4.2.1.7.

#### **4.4.5.1.8 Socioeconomics**

Reactor operations at a CLWR site would not require additional workers. Target fabrication and processing of plutonium-238 at INEEL would require approximately 24 additional workers (Hill et al. 1999). The socioeconomic impacts at INEEL are the same as those assessed in Section 4.3.2.1.8.

#### 4.4.5.1.9 Public and Occupational Health and Safety—Normal Operations

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from operations are given in **Table 4-90** for the generic CLWR site and INEEL: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

**Table 4-90 Incremental Radiological Impacts on the Public Around the Generic CLWR Site and INEEL from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 5**

Receptor	Generic CLWR	INEEL FDPF	Total
<b>Population within 80 kilometers (50 miles) in the year 2020</b>			
Dose (person-rem)	0	$3.9 \times 10^{-6}$	$3.9 \times 10^{-6}$
35-year latent cancer fatalities	0	$6.7 \times 10^{-8}$	$6.7 \times 10^{-8}$
<b>Maximally exposed individual</b>			
Annual dose (millirem)	0	$2.6 \times 10^{-7}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	$4.6 \times 10^{-12}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>			
Annual dose <sup>b</sup> (millirem)	0	$2.0 \times 10^{-8}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	$3.6 \times 10^{-13}$	NA <sup>a</sup>

a. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.

b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FDFP in the year 2020 (188,400).

**Key:** NA, not applicable.

**Source:** Model results, using the GENII computer code (Napier et al. 1988).

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

Target irradiation in a CLWR would not result in any increased radiological emissions during normal operations or increased worker exposure. Therefore, the incremental impact of CLWR target irradiation is zero.

As a result of annual operations of the generic CLWR and FDFP, the projected total incremental population dose in the year 2020 would be  $3.9 \times 10^{-6}$  person-rem. The corresponding number of latent cancer fatalities in the populations surrounding the generic CLWR site and INEEL from 35 years of operations would be  $6.7 \times 10^{-8}$ . The total incremental dose to the maximally exposed member of the public from annual generic CLWR operations would be 0 millirem because there would be no increase in radiological releases to the environment from the generic CLWR associated with this option. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would, therefore, be zero. The incremental dose

to the maximally exposed member of the public from annual FDPF operations would be  $2.6 \times 10^{-7}$  millirem. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $4.6 \times 10^{-12}$ .

Incremental doses to involved workers from normal operations are given in **Table 4-91**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to CLWR workers would be 0 millirem; for FDPF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities would be 0 and approximately 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4-91. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4-91 Incremental Radiological Impacts on Involved CLWR and INEEL Workers from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 5**

Receptor—Involved Workers <sup>a</sup>	Generic CLWR	INEEL FDPF	Total
Total dose (person-rem per year)	0	12 <sup>b</sup>	12
35-year latent cancer fatalities	0	0.17	0.17
Average worker dose (millirem per year)	0	170	NA <sup>c</sup>
35-year latent cancer fatality risk	0	0.0023	NA <sup>c</sup>

- a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with FDPF operations at a DOE facility would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced at all facilities.
- b. Based on an estimated 75 badged workers.
- c. Values cannot be given for the average worker because the workers would be at two different facilities and sites.

**Key:** NA, not applicable.

**Source:** Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts at the generic CLWR site for this option would be the same as those of ongoing site operations because no new chemicals would be emitted.

Hazardous chemical impacts at INEEL for this option would be the same as those described for Option 2 (Section 4.4.2.1.9).

#### **4.4.5.1.10 Public and Occupational Health and Safety—Facility Accidents**

Impacts from postulated accidents associated with target irradiation in a generic CLWR and FDPF target processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Estimates of radiological consequences have been developed for the maximally exposed individual and the offsite population within 80 kilometers (50 miles) of the facility. Consequences to a noninvolved worker are not included for the generic CLWR analysis. Details regarding the exclusion of a noninvolved worker are provided in Appendix I.

Consequences are presented in terms of radiological dose (in rem) and the probability that the dose would result in a latent cancer fatality. Accident risk is defined as the product of the accident probability (i.e., accident frequency) and the accident consequence. In this NI PEIS, risk is expressed as the increased likelihood of a latent cancer fatality for an individual and as the increased number of latent cancer fatalities in the offsite population. The probability coefficients for determining the likelihood of a latent cancer fatality,

given a dose, are given in Section 4.2.1.2.10. Consequences to involved workers are addressed in Section I.1.7.

To provide a better indication of risks from the postulated accidents, the risks are summed for each facility and also for each option. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk from accidents, a full-scope probabilistic risk analysis would be required for each facility. Since full-scope probabilistic risk analyses are plant specific, summing the spectrum of accident risks was considered appropriate for the purposes of this NI PEIS. Details of the risk summation calculations are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4-92** and **4-93**, respectively. Certain extremely unlikely or incredible severe accidents at commercial nuclear reactors could result in doses sufficiently high to cause early fatalities. The early fatality consequences and risks are presented in **Table 4-94**. The early fatalities shown in Table 4-94 are considered to be conservative estimates based upon the assumption that some individuals very close to the reactor do not evacuate. Because the CLWR is currently operating, the consequences and risks are presented for both the current reactor configuration without neptunium-237 targets and for the worst-case neptunium-237 target-loading reactor configuration.

For 35 years of CLWR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual would be  $1.93 \times 10^{-9}$ . The increased number of latent cancer fatalities in the surrounding population would be 0.00305. The increased risk of an early fatality in the surrounding population would be  $2.07 \times 10^{-6}$ .

For 35 years of FDPF target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $1.49 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0287.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $1.49 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0318.

The irradiation of neptunium-237 targets at the generic CLWR would not introduce any additional operations that require the use of hazardous chemicals. Thus, there are no postulated hazardous chemical accidents attributable to the irradiation of neptunium-237 targets at the generic CLWR.

No chemical processing activities are currently performed at FDPF and no chemicals are stored in this facility. Processing activities in support of plutonium-238 production would require the introduction of hazardous chemicals, specifically nitric acid and nitric oxide. Potential health impacts from accidental releases of nitric acid were assessed by comparing estimated airborne concentrations of the chemicals to ERPG developed by the American Industrial Hygiene Association. The ERPG-1 value (0.5 part per million) is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour, resulting in only mild, transient, and reversible adverse health effects. The ERPG-2 value (10 parts per million) is protective of irreversible or serious health effects or impairment of an individual's ability to take protective action. The ERPG-3 value (25 parts per million) is indicative of potentially life-threatening health effects.

**Table 4-92 Generic CLWR and FDPF Accident Consequences Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 5**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
<b>Generic CLWR accidents</b>

<b>FDPF accidents</b>						
Ion exchange explosion during neptunium-237 target fabrication	$2.01 \times 10^{-9}$	$1.01 \times 10^{-12}$	$2.49 \times 10^{-5}$	$1.24 \times 10^{-8}$	$7.26 \times 10^{-9}$	$2.91 \times 10^{-12}$
Target dissolver tank failure during plutonium-238 separation	$6.11 \times 10^{-8}$	$3.05 \times 10^{-11}$	$5.65 \times 10^{-4}$	$2.82 \times 10^{-7}$	$2.17 \times 10^{-7}$	$8.69 \times 10^{-11}$
Ion exchange explosion during plutonium-238 separation	$1.63 \times 10^{-5}$	$8.13 \times 10^{-9}$	0.150	$7.51 \times 10^{-5}$	$5.79 \times 10^{-5}$	$2.31 \times 10^{-8}$
Processing facility beyond-design-basis earthquake	42.5	0.0425	$1.64 \times 10^5$	82.0	1,200	1.0 <sup>d</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities. The MACCS2 computer code calculates the dose to each exposed individual in the population, applies the appropriate cancer risk factor, and then sums the individual probabilities to determine the number of latent cancer fatalities.

c. Not applicable (refer to Appendix I). Evacuation of noninvolved workers and other noninvolved worker issues are addressed in Appendix I.

d. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

Containment bypass with 0 kg/yr plutonium-238 production ( $1.53 \times 10^{-6}$ )	3.48	$5.32 \times 10^{-6}$
Containment bypass with 5 kg/yr plutonium-238 production ( $1.53 \times 10^{-6}$ )	3.51	$5.37 \times 10^{-6}$
Containment bypass incremental risk	NA	$5.00 \times 10^{-8}$
<b>35-year CLWR risk<sup>d</sup></b>	NA	$2.07 \times 10^{-6}$

a. Number of early fatalities assuming that the accident has occurred.

b. Risk of an early fatality.

c. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.

d. The 35-year risk is determined by summing the incremental annual risks and multiplying by 35.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; NA, not applicable.

**Source:** Model results, using the MACCS2 computer code (Chanin and Young 1997).

The maximum distances, in meters, needed to reach the ERPG values for nitric acid releases at FDPF for Stability Classes D and F are shown in **Table 4-95**. Two separate atmospheric conditions were evaluated, Stability Classes D and F. Stability Class D represents average meteorological conditions, while Stability Class F represents worst-case meteorological conditions. The number of involved and noninvolved workers potentially exposed would vary with a number of factors, such as the time of day and whether they were sheltered within buildings at the time of release. Individuals at the nearest highway (5,800 meters [3.6 miles]) and at the nearest site boundary (13,952 meters [8.7 miles]) from FDPF would be exposed to levels well below ERPG-1.

**Table 4-95 ERPG Distances for Nitric Acid Releases at FDPF Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 5**

Evaluation Parameter	Stability Class D (meters)	Stability Class F (meters)
ERPG-3	375	450
ERPG-2	500	600
ERPG-1	2,000	3,000

**Note:** To convert from meters to miles, multiply by  $6.22 \times 10^{-4}$ .

**Key:** ERPG, Emergency Response Planning Guideline.

There are no ERPG values for nitric oxide. For nitric oxide accidents, the level of concern has been estimated by using one-tenth of the “Immediately Dangerous to Life and Health” level published by the National Institute for Occupational Safety and Health. The Immediately Dangerous to Life and Health value for nitric oxide is 100 parts per million. The level of concern value used for this NI PEIS is 10 parts per million. The level of concern is defined as the concentration of an extremely hazardous substance in air above which there may be serious irreversible health effects as a result of a single exposure for a relatively short period of time.

For FDPF, the maximum distances needed to reach the level of concern for nitric oxides releases for Stability Class D and F are 500 and 2,000 meters (0.31 and 1.24 miles), respectively. The number of involved and noninvolved workers potentially exposed would vary with a number of factors, such as the time of day and whether they were sheltered within buildings at the time of release. Individual at the nearest highway (5,800 meters [3.6 miles]) and the nearest site boundary (13,952 meters [8.7 miles]) from FDPF would be exposed to levels well below the level of concern for nitric oxide.

Potential health impacts from the accidental release of the hazardous chemicals were assessed for a noninvolved worker, offsite individuals who are members of the public located at the nearest site boundary and onsite individuals who are members of the public located at the nearest highway access.

The impacts associated with the accidental release of nitric acid and nitric oxide at FDPF are presented in **Table 4-96**.

**Table 4-96 FDPF Hazardous Chemical Accident Impacts Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 5**

Receptor	Evaluation Parameter	Nitric Acid		Nitric Oxide	
		Stability Class D	Stability Class F	Stability Class D	Stability Class F
Noninvolved worker (640 meters)	Parts per million Level of concern Potential health effects	3.3 <ERPG-2 Mild, transient	8.4 <ERPG-2 Mild, transient	4.2 <LOC Mild, transient	67.5 >LOC Serious
Nearest highway maximally exposed individual	Parts per million Level of concern Potential health effects	0.05 < ERPG-1 None	0.15 ERPG-1 Mild, transient	0.09 < LOC None	0.87 < LOC None
Site boundary maximally exposed individual	Parts per million Level of concern Potential health effects	<<0.05 < ERPG-1 None	<<0.15 ERPG-1 Mild, transient	<<0.09 < LOC None	<<0.87 < LOC None

**Note:** < means “less than”; << means “much less than.”

**Key:** ERPG, Emergency Response Planning Guideline; LOC, level of concern.

**Source:** Model results.

#### 4.4.5.1.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the target fabrication facility at INEEL. DOE would transport the unirradiated neptunium-237 targets from FDPF to a CLWR. Following irradiation in the CLWR, the targets would be returned to FDPF for processing. After this processing, the plutonium-238 product would be shipped to LANL. The impact analysis, described in Appendix J, assumes the most distant CLWR is used for target irradiation.

Approximately 689 shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 3.1 million kilometers (1.9 million miles).

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 17 person-rem; the dose to the public, 357 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.007 latent cancer fatality among transportation workers and 0.18 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option is 0.0066.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FDPF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 were also evaluated and estimated to have a probability of lower than 1 in 10 million per year.

Estimates of the total ground transportation accident risks under this option are as follows: a radiological dose to the population of 0.0042 person-rem, resulting in  $2.1 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.088 traffic fatality.

#### **4.4.5.1.12 Environmental Justice**

Under this option, neptunium-237 targets would be irradiated in a CLWR at an unspecified site. Target fabrication and processing would be performed at FDPF located at INEEL. Activities at FDPF were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.2.1.12) and found to pose no significant radiological or other risks to minority and low-income populations. The analysis of accidents at specific sites shows that accidents at the fabrication and target facilities would result in radiological risks to the public that are small, but which are several orders of magnitude larger than those that would result from accidents at specific reactor sites (see Section 2.7.1.1). It is plausible that a similar difference would exist between accident risks at an unspecified CLWR site and the fabrication and processing facilities. However, evaluations of environmental justice are necessarily site specific and cannot be performed for unspecified locations. In the event that this option were selected for implementation and a specific CLWR were selected for irradiation services, additional evaluation of environmental justice at the CLWR site would be performed prior to implementation.

#### **4.4.5.1.13 Waste Management**

There would be no change in the amounts of waste generated as the result of irradiating neptunium-237 targets in the CLWR. Thus, there would be no impact on the CLWR site's waste management systems as the result of target irradiation.

The impacts of managing waste associated with neptunium-237 target fabrication and processing in FDPF are assumed to be the same as for Option 2 under Alternative 1 (Section 4.3.2.1.13) because the same amount of plutonium-238 would be produced annually. As shown in that section, the impacts on the waste management systems at INEEL would be minimal.

#### **4.4.5.1.14 Spent Nuclear Fuel Management**

No incremental impacts would be associated with the management of spent nuclear fuel (refer to Section 4.4.1.1.14).

#### **4.4.5.2 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.4.6 Alternative 2 (Use Only Existing Operational Facilities)—Option 6**

This option involves operating a generic CLWR at a generic site to irradiate neptunium-237 targets, and operating FMEF at Hanford to both fabricate and process these targets and to store the neptunium-237 transported to Hanford from SRS.

The transportation of the neptunium-237 from SRS to Hanford for processing and fabrication into neptunium-237 targets in FMEF, the transportation of the targets from Hanford to the generic CLWR site for irradiation in the CLWR, the transportation of the irradiated targets back to Hanford for postirradiation processing in FMEF, and the transportation of the plutonium-238 product from Hanford to LANL also constitute part of this option.

All options under this alternative include the permanent deactivation of FFTF at Hanford.

#### **4.4.6.1 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all intersite transportation activities, are assessed in this section.

##### **4.4.6.1.1 Land Resources**

**LAND USE.** The use of a CLWR to irradiate neptunium-237 targets would not result in impacts on land use for the reasons described in Section 4.4.4.1.1.

Impacts on land use at Hanford from neptunium-237 storage, target fabrication, and processing at FMEF would be expected to be minimal for the reasons described in Section 4.4.3.1.1.

**VISUAL RESOURCES.** The use of a CLWR to irradiate neptunium-237 targets would not result in impacts on visual resources for the reasons described in Section 4.4.4.1.1.

Impacts on visual resources at Hanford from neptunium-237 target fabrication and processing at FMEF would be expected to be minimal for the reasons described in Section 4.4.3.1.1.

##### **4.4.6.1.2 Noise**

The irradiation of neptunium-237 targets in a CLWR would not result in noise impacts for the reasons described in Section 4.4.4.1.2.

Noise impacts at Hanford would be minimal from neptunium-237 storage, target fabrication, and processing at FMEF, and changes in traffic noise would be small for the reasons described in Section 4.4.3.1.2.

#### **4.4.6.1.3 Air Quality**

Impacts for this option at the generic CLWR site would be the same as those described for Option 4 (Section 4.4.4.1.3).

Impacts for this option at Hanford would be the same as those described for Option 3 (Section 4.4.3.1.3).

The air quality impacts of transportation among SRS, the generic CLWR site, Hanford, and LANL are presented in Section 4.4.6.1.1.1.

#### **4.4.6.1.4 Water Resources**

Impacts for this option at a generic CLWR site would be negligible as described for Option 4 (Section 4.4.4.1.4).

Impacts for this option at Hanford would be the same as described for Option 3 (Section 4.4.3.1.4). Groundwater withdrawals and the discharge of process and sanitary effluents by FMEF would increase.

#### **4.4.6.1.5 Geology and Soils**

The irradiation of neptunium-237 targets in a CLWR would not be expected to result in impacts on geologic or soil resources for the reasons described in Section 4.4.4.1.5. Assessment of hazards from large-scale geologic conditions for reactor sites, including assessment of seismic and nonseismic features, is governed by 10 CFR Part 100 and is beyond the scope of this analysis.

Neptunium-237 storage, target fabrication, and processing at FMEF would not be expected to impact geologic and soil resources at Hanford, nor be jeopardized by large-scale geologic conditions, for the reasons described in Sections 4.2.4.2.5 and 4.4.3.1.5. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards would be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.4.6.1.6 Ecological Resources**

The irradiation of neptunium-237 targets in a CLWR would not result impacts on ecological resources for the reasons described in Section 4.4.4.1.6.

Impacts on ecological resources at Hanford would not result from neptunium-237 storage, target fabrication, and processing at FMEF for the reasons described in Section 4.4.3.1.6.

#### **4.4.6.1.7 Cultural and Paleontological Resources**

The irradiation of neptunium-237 targets in a CLWR would not result in impacts on cultural and paleontological resources for the reasons described in Section 4.4.4.1.7.

Impacts on cultural and paleontological resources at Hanford would not result from neptunium-237 storage, target fabrication, and processing at FMEF for the reasons described in Section 4.4.3.1.7.

#### 4.4.6.1.8 Socioeconomics

Reactor operations at a CLWR site would not require additional workers. Target fabrication and processing of plutonium-238 at Hanford would require approximately 62 additional workers (Hoyt et al. 1999). The socioeconomic impacts at Hanford are the same as those addressed in Section 4.4.3.1.8.

#### 4.4.6.1.9 Public and Occupational Health and Safety—Normal Operations

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from operations are given in **Table 4-97** for the generic CLWR site and Hanford: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

**Table 4-97 Incremental Radiological Impacts on the Public Around the Generic CLWR Site and Hanford from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 6**

Receptor	Generic CLWR	Hanford FMEF	Total
<b>Population within 80 kilometers (50 miles) in the year 2020</b>			
Dose (person-rem)	0	$4.4 \times 10^{-5}$	$4.4 \times 10^{-5}$
35-year latent cancer fatalities	0	$7.7 \times 10^{-7}$	$7.7 \times 10^{-7}$
<b>Maximally exposed individual</b>			
Annual dose (millirem)	0	$4.7 \times 10^{-7}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	$8.3 \times 10^{-12}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>			
Annual dose <sup>b</sup> (millirem)	0	$8.9 \times 10^{-8}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	$1.6 \times 10^{-12}$	NA <sup>a</sup>

a. A "Total" cannot be given in this case because the same individual cannot be located at two different sites simultaneously.

b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FMEF in the year 2020 (494,400).

**Key:** NA, not applicable.

**Source:** Model results, using the GENII computer code (Napier et al. 1988).

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

Target irradiation in a CLWR would not result in any incremental radiological emissions during normal operations or in increased worker exposures. Therefore, the incremental impact of CLWR target irradiation is zero.

As a result of annual operations of the generic CLWR and FMEF, the projected total incremental population dose in the year 2020 would be  $4.4 \times 10^{-5}$  person-rem. The corresponding number of latent cancer fatalities in the populations surrounding the generic CLWR site and Hanford from 35 years of operations would be  $7.7 \times 10^{-7}$ . The total incremental dose to the maximally exposed member of the public from annual generic CLWR operations would be 0 millirem because there would be no increase in radiological releases to the environment from the generic CLWR associated with this option. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would, therefore, be zero. The incremental dose to the maximally exposed member of the public from annual FMEF operations would be  $4.7 \times 10^{-7}$  millirem. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $8.3 \times 10^{-12}$ .

Incremental doses to involved workers from normal operations are given in **Table 4-98**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to CLWR workers would be 0 millirem; for FMEF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities would be 0 and approximately 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4-98. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4-98 Incremental Radiological Impacts on Involved CLWR and Hanford Workers from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 6**

Receptor—Involved Workers <sup>a</sup>	Generic CLWR	Hanford FMEF	Total
Total dose (person-rem per year)	0	12 <sup>b</sup>	12
35-year latent cancer fatalities	0	0.17	0.17
Average worker dose (millirem per year)	0	170	NA <sup>c</sup>
35-year latent cancer fatality risk	0	0.0023	NA <sup>c</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with FMEF operations at DOE facilities would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced at all facilities.

b. Based on an estimated 75 badged workers.

c. Values cannot be given for the average worker because the workers would be at two different facilities and sites.

**Key:** NA, not applicable.

**Source:** Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts at the generic CLWR site for this option would be the same as those of current site operations because no new chemicals would be emitted.

Hazardous chemical impacts for this option at Hanford would be the same as those described for Option 3 (Section 4.4.3.1.9).

#### 4.4.6.1.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with target irradiation in a generic CLWR and FMEF target processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Estimates of radiological consequences have been developed for the maximally exposed individual and the offsite population within 80 kilometers (50 miles) of the facility. Consequences to a noninvolved worker are

not included for the generic CLWR analysis. Details regarding the exclusion of a noninvolved worker are provided in Appendix I.

Consequences are presented in terms of radiological dose (in rem) and the probability that the dose would result in a latent cancer fatality. Accident risk is defined as the product of the accident probability (i.e., accident frequency) and the accident consequence. In this NI PEIS, risk is expressed as the increased likelihood of a latent cancer fatality for an individual and as the increased number of latent cancer fatalities in the offsite population. The probability coefficients for determining the likelihood of a latent cancer fatality, given a dose, are given in Section 4.2.1.2.10. Consequences to involved workers are addressed in Section I.1.7.

To provide a better indication of risks from the postulated accidents, the risks are summed for each facility and also for each option. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk from accidents, a full-scope probabilistic risk analysis would be required for each facility. Since full-scope probabilistic risk analyses are plant specific, summing the spectrum of accident risks was considered appropriate for the purposes of this NI PEIS. Details of the risk summation calculations are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–99** and **4–100**, respectively. Certain extremely unlikely or incredible severe accidents at commercial nuclear reactors could result in doses sufficiently high to cause early fatalities. The early fatality consequences and risks are presented in **Table 4–101**. The early fatalities shown in Table 4–101 are considered to be conservative estimates based upon the assumption that some individuals very close to the reactor do not evacuate. Because the generic CLWR is currently operating, the consequences and risks are presented for both the current reactor configuration without neptunium-237 targets and for the worst-case neptunium-237 target-loading reactor configuration.

For 35 years of CLWR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual would be  $1.93 \times 10^{-9}$ . The increased number of latent cancer fatalities in the surrounding population would be 0.00305. The increased risk of an early fatality in the surrounding population would be  $2.07 \times 10^{-6}$ .

For 35 years of FMEF target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and of an early fatality to a noninvolved worker would be  $2.88 \times 10^{-6}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.112.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $2.88 \times 10^{-6}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.115.

The irradiation of neptunium-237 targets at the generic CLWR would not introduce any additional operations that require the use of hazardous chemicals. Thus, there are no postulated hazardous chemical accidents attributable to the irradiation of neptunium-237 targets at the generic CLWR.

**Table 4–99 Generic CLWR and FMEF Accident Consequences Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 6**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
<b>Generic CLWR accidents</b>						
Large-break LOCA with 0 kg/yr plutonium-238 production	0.0312	1.56×10 <sup>-5</sup>	186	0.0931	NA <sup>c</sup>	NA

Processing facility beyond-design-basis earthquake	16.5	0.00823	6.41×10 <sup>5</sup>	321	921	1.0 <sup>d</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities. The MACCS2 computer code calculates the dose to each exposed individual in the population, applies the appropriate cancer risk factor, and then sums the individual probabilities to determine the number of latent cancer fatalities.

c. Not applicable (refer to Appendix I). Evacuation of noninvolved workers and other noninvolved worker issues are addressed in Appendix I.

d. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident; NA, not applicable.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

<b>35-year Option risk<sup>g</sup></b>	$2.88 \times 10^{-6}$	0.115	$3.50 \times 10^{-4}$

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. Not applicable (refer to Appendix I). Evacuation of noninvolved workers and other noninvolved worker issues are addressed in Appendix I.

d. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.

e. Risk of an early fatality.

f. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.

g. Individual risks are summed only for collocated individuals. The highest individual risk was used to represent the 35-year option risk.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident; NA, not applicable.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4–101 Generic CLWR Early Fatalities and Risks Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 6**

Accident (Frequency)	Population to 80 Kilometers (50 Miles)	
	Early Fatalities <sup>a</sup>	Annual Risk <sup>b</sup>

Containment bypass incremental risks	NA	$5.00 \times 10^{-8}$
<b>35-year CLWR risk<sup>d</sup></b>	NA	$2.07 \times 10^{-6}$

a. Number of early fatalities assuming that the accident has occurred.

b. Risk of an early fatality.

c. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.

d. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; NA, not applicable.

**Source:** Model results, using the MACCS2 computer code (Chanin and Young 1997).

No chemical processing activities are currently performed at FMEF and no chemicals are stored in this facility. Processing activities in support of plutonium-238 production would require the introduction of hazardous chemicals, specifically nitric acid and nitric oxide. Potential health impacts from accidental releases of nitric acid were assessed by comparing estimated airborne concentrations of the chemicals to ERPG developed by the American Industrial Hygiene Association. The ERPG-1 value (0.5 part per million) is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour, resulting in only mild, transient, and reversible adverse health effects. The ERPG-2 value (10 parts per million) is protective of irreversible or serious health effects or impairment of an individual's ability to take protective action. The ERPG-3 value (25 parts per million) is indicative of potentially life-threatening health effects.

The maximum distances, in meters, needed to reach the ERPG values for nitric acid releases at FMEF for Stability Classes D and F are shown in **Table 4–102**. Two separate atmospheric conditions were evaluated, Stability Classes D and F. Stability Class D represents average meteorological conditions, while Stability Class F represents worst-case meteorological conditions. The number of involved and noninvolved workers potentially exposed would vary with a number of factors, such as the time of day and whether they were sheltered within buildings at the time of release. Individuals at the nearest highway (7,100 meters [4.4 miles]) and at the nearest site boundary (7,210 meters [4.5 miles]) from FMEF would be exposed to levels well below ERPG-1.

**Table 4–102 ERPG Distances for Nitric Acid Releases at FMEF Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 6**

Evaluation Parameter	Stability Class D (meters)	Stability Class F (meters)
ERPG-3	375	450
ERPG-2	500	600
ERPG-1	2,000	3,000

**Note:** To convert from meters to miles, multiply by  $6.22 \times 10^{-4}$ .

**Key:** ERPG, Emergency Response Planning Guideline.

There are no ERPG values for nitric oxide. For nitric oxide accidents, the level of concern has been estimated by using one-tenth of the “Immediately Dangerous to Life and Health” level published by the National Institute for Occupational Safety and Health. The Immediately Dangerous to Life and Health value for nitric oxide is 100 parts per million. The level of concern value used for this NI PEIS is 10 parts per million. The level of concern is defined as the concentration of an extremely hazardous substance in air above which there may be serious irreversible health effects as a result of a single exposure for a relatively short period of time.

For FMEF, the maximum distances needed to reach the level of concern for nitric oxides releases for Stability Classes D and F are 500 and 1,900 meters (0.31 and 1.18 miles), respectively. The number of involved and noninvolved workers potentially exposed would vary with a number of factors, such as the time of day and whether they were sheltered within buildings at the time of release. Individual at the nearest highway (7,100 meters [4.4 miles]) and the nearest site boundary (7,210 meters [4.5 miles]) from FMEF would be exposed to levels well below the level of concern for nitric oxide.

Potential health impacts from the accidental release of the hazardous chemicals were assessed for a noninvolved worker, offsite individuals who are members of the public located at the nearest site boundary and onsite individuals who are members of the public located at the nearest highway access. Two separate atmospheric conditions were evaluated, Stability Classes D and F. Stability Class D represents average meteorological conditions, while Stability Class F represents worst-case meteorological conditions.

The impacts associated with the accidental release of nitric acid and nitric oxide at FMEF are presented in **Table 4–103**.

**Table 4–103 FMEF Hazardous Chemical Accident Impacts Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 6**

Receptor	Evaluation Parameter	Nitric Acid		Nitric Oxide	
		Stability Class D	Stability Class F	Stability Class D	Stability Class F
Noninvolved worker (640 meters)	Parts per million	3.3	8.6	4.2	66

	Potential health effects	None	Mild, transient	None	None

**Note:** < means “less than.”

**Key:** ERPG, Emergency Response Planning Guideline; LOC, level of concern.

**Source:** Model results.

#### 4.4.6.1.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the FMEF target fabrication facility at Hanford. DOE would transport the unirradiated neptunium-237 targets from FMEF to a CLWR. Following irradiation in the CLWR, the targets would be returned to FMEF for processing. After this processing, the plutonium-238 product would be shipped to LANL. The impact analysis, described in Appendix J, assumes the most distant CLWR is used for target irradiation.

Approximately 689 shipments of radioactive materials would be made by DOE under this option. The total distance traveled on public roads by trucks carrying radioactive materials would be 3.6 million kilometers (2.2 million miles).

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 20 person-rem; the dose to the public, 411 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.008 latent cancer fatality among transportation workers and 0.21 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option is 0.0075.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FMEF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 were also evaluated and estimated to have a probability of lower than 1 in 10 million per year.

Estimates of the total ground transportation accident risks under this option are as follows: a radiological dose to the population of 0.06 person-rem, resulting in  $3.0 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.10 traffic fatality.

#### **4.4.6.1.12 Environmental Justice**

Under this option, neptunium-237 targets would be irradiated in a CLWR at an unspecified site. Target fabrication and processing would be performed at FMEF located at Hanford. Activities at FMEF were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.3.1.12) and found to pose no significant radiological or other risks to minority and low-income populations. The analysis of accidents at specific sites shows that accidents at the fabrication and target facilities would result in radiological risks to the public that are small, but which are several orders of magnitude larger than those that would result from accidents at specific reactor sites (see Section 2.7.1.1). It is plausible that a similar difference would exist between accident risks at an unspecified CLWR site and the fabrication and processing facilities. However, evaluations of environmental justice are necessarily site specific and cannot be performed for unspecified locations. In the event that this option were selected for implementation and a specific CLWR were selected for irradiation services, additional evaluation of environmental justice at the CLWR site would be performed prior to implementation.

#### **4.4.6.1.13 Waste Management**

There would be no change in the amounts of waste generated as the result of irradiating neptunium-237 targets in the CLWR. Thus, there would be no impact on the CLWR site's waste management systems as the result of target irradiation.

The impacts of managing waste associated with neptunium-237 target fabrication and processing in FMEF are assumed to be the same as for Option 3 (Section 4.4.3.1.13) because the same amount of plutonium-238 would be produced annually. As shown in that section, the impacts on the waste management systems at Hanford would be minimal.

#### **4.4.6.1.14 Spent Nuclear Fuel Management**

No incremental impacts would be associated with the management of spent nuclear fuel (refer to Section 4.4.1.1.14).

#### **4.4.6.2 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.4.7 Alternative 2 (Use Only Existing Operational Facilities)—Option 7**

This option involves operating both the High Flux Isotope Reactor (HFIR) at ORR and ATR at INEEL to irradiate neptunium-237 targets, and operating the REDC facility at ORR to both fabricate and process these targets and to store the neptunium-237 transported to ORR from SRS.

The transportation of the neptunium-237 from SRS to ORR for processing and fabrication into neptunium-237 targets in REDC, the transportation of a portion of these targets from ORR to INEEL for irradiation in ATR, the transportation of the irradiated targets back to ORR for postirradiation processing in REDC, and the transportation of the entire plutonium-238 product from ORR to LANL also constitute part of this option.

All options under this alternative include the permanent deactivation of FFTF at Hanford.

#### **4.4.7.1 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

##### **4.4.7.1.1 Land Resources**

**LAND USE.** The use of ATR to irradiate neptunium-237 targets would not result in impacts on land use at INEEL for the reasons described in Section 4.4.1.1.1.

The irradiation of neptunium-237 targets would also take place at HFIR. HFIR is an existing facility in the 7900 Area of ORNL. Use of the facility for target irradiation would not involve any new construction. Because no additional land would be disturbed and the target irradiation would be compatible with the present mission of the reactor, there would be no change in impacts on land use at ORR.

There would be no impacts on land use at ORR from neptunium-237 storage, target fabrication, and processing at REDC for the reasons described in Section 4.4.1.1.1.

**VISUAL RESOURCES.** The use of ATR to irradiate neptunium-237 targets would not result in visual impacts at INEEL for the reasons described in Section 4.4.1.1.1.

The irradiation of neptunium-237 targets would also take place within HFIR at ORR. Because HFIR is an existing facility that would require no external modifications, there would be no change in its appearance. Therefore, the current Visual Resource Management Class IV rating for the 7900 Area would not change. Because there would be no change in the appearance of HFIR or the 7900 Area, there would be no impact on visual resources.

Neptunium-237 storage, target fabrication, and processing at REDC would not impact visual resources at ORR for the reasons described in Section 4.4.1.1.1.

#### **4.4.7.1.2 Noise**

The irradiation of neptunium-237 targets in ATR would not result in noise impacts at INEEL for the reasons described in Section 4.4.1.1.2.

Noise generated during the irradiation of neptunium-237 targets in HFIR would be similar to sound levels associated with current reactor operations, as well as other operations conducted within the 7900 Area. Onsite noise impacts would be expected to be minimal, and changes in offsite noise levels would not be noticeable, because the nearest site boundary is 2.5 kilometers (1.6 miles) to the southeast. Changes in traffic volume going to and from HFIR would be small, and would result in only minor changes to onsite and offsite noise levels. There would be no loud noises associated with neptunium-237 target irradiation that would adversely impact wildlife.

Noise impacts at ORR would not be expected from neptunium-237 storage, target fabrication, and processing at REDC and changes in traffic noise would be small for the reasons described in Section 4.4.1.1.2.

#### **4.4.7.1.3 Air Quality**

Impacts for this option at INEEL would be the same as those described for Option 1 (Section 4.4.1.1.3).

Impacts for this option at ORR would be the same as those described for Option 1 (Section 4.4.1.1.3). There would be no measurable nonradiological air pollutant emissions associated with the operation of HFIR.

The air quality impacts of transportation among SRS, INEEL, ORR, and LANL are presented in Section 4.4.7.1.11.

#### **4.4.7.1.4 Water Resources**

The irradiation of neptunium-237 targets for plutonium-238 production in ATR at INEEL would have no measurable impact on water resources as previously described for Option 1 (Section 4.4.1.1.4). Under this option, neptunium-237 target irradiation would also be conducted in the HFIR at ORR. Similar to ATR, impacts on water resources associated with the dual operation of HFIR in the 7900 Area of ORR would not be expected to impact water resources as plutonium-238 production would not measurably increase water use or change the quality or quantity of effluents discharged. Both facilities would already be operating for other purposes so dual operation should not have any measurable cumulative impact.

REDC at ORR would be used for neptunium-237 storage, target fabrication, and processing. Impacts on water resources of this activity were determined to be the same as previously described for Option 1 (see Section 4.4.1.1.4). Impacts of this option on water resources are expected to be negligible overall.

#### **4.4.7.1.5 Geology and Soils**

The use of ATR to irradiate neptunium-237 targets would not be expected to result in impacts on geologic or soil resources, nor be jeopardized by large-scale geologic conditions, for the reasons described in Section 4.4.1.1.5.

HFIR would also be used to irradiate neptunium-237 targets. Because there would be no construction, there would be no disturbance to either geologic or soil resources in the 7900 Area of ORR. Impacts on geologic and soil resources at ORR would not be expected from neptunium-237 storage, target fabrication, and processing at REDC for the reasons described in Section 4.4.1.1.5. Hazards from large-scale geologic conditions at ORR, such as earthquakes and volcanoes, were evaluated as summarized in Section 4.2.2.2.5. The analysis determined that these hazards present a low risk to specially designed or upgraded facilities (such as HFIR and REDC), and is not revisited here.

As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards will be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.4.7.1.6 Ecological Resources**

The irradiation of neptunium-237 targets in ATR would not result in impacts on ecological resources at INEEL for the reasons described in Section 4.4.1.1.6.

The irradiation of neptunium-237 targets would also take place in the existing HFIR facility at ORR. No new construction would occur that could cause direct disturbance to ecological resources, including wetlands. As noted in Section 4.4.7.1.2, there would be no loud noises that would adversely impact wildlife. There would be no change in impacts on aquatic resources because additional water would not be withdrawn from or discharged to site surface waters and effluent chemistry would not measurably change (Section 4.4.1.1.4). Due to the developed nature of the area and because no new construction would take place, impacts on threatened and endangered species would not occur.

Consultation to comply with Section 7 of the Endangered Species Act was conducted with the U.S. Fish and Wildlife Service (see Table 5–3) and resulted in the Service concluding that it does not anticipate adverse effects to federally listed endangered species that occur near the project area. DOE has also consulted with the Tennessee Department of Environment and Conservation; a response concerning state-listed species is pending from this agency. Although no state-listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at ORR prior to the receipt of input from the state.

There would be no impacts on ecological resources at ORR from neptunium-237 storage, target fabrication, and processing at REDC for the reasons described in Section 4.4.1.1.6.

#### **4.4.7.1.7 Cultural and Paleontological Resources**

The use of ATR to irradiate neptunium-237 targets at INEEL would not result in impacts on cultural and paleontological resources for the reasons described in Section 4.4.1.1.7.

The irradiation of neptunium-237 targets would also take place in the existing HFIR facility at ORR. No new construction would take place. Therefore, direct impacts on cultural and paleontological resources would not occur. One structure located within ORNL, the Graphite Reactor, is listed on the National Register of Historic Places as a National Historic Landmark. Additionally, several other structures proposed for listing on the National Register of Historic Places are found within or near ORNL. However, neither the Graphite Reactor nor any of the other structures is located within the 7900 Area, and therefore, their status would not change by the use of HFIR for the irradiation of neptunium-237 targets.

Consultation to comply with Section 106 of the National Historic Preservation Act was initiated with the State Historic Preservation Office (see Table 5–3). While DOE has made additional contact with the State Historic Preservation Office, a response is pending from this office. Although impacts to cultural resources are not

expected as a result of the proposed action, no action would be taken relative to the use of facilities at ORR prior to the receipt of input from the State Historic Preservation Office.

Impacts on cultural and paleontological resources at ORR would not result from neptunium-237 target fabrication and processing at REDC for the reasons described in Section 4.4.1.1.7.

#### 4.4.7.1.8 Socioeconomics

After facility modifications, startup, and testing of the plutonium-238 reactor operation facilities at INEEL, and reactor operation and target fabrication/processing facilities at ORR, approximately 41 additional workers would be required to operate these facilities (none at INEEL and approximately 41 at ORR) (Wham et al. 1998). The socioeconomic impacts at ORR are the same as those addressed in Section 4.3.1.1.8.

#### 4.4.7.1.9 Public and Occupational Health and Safety—Normal Operations

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from operations are given in **Table 4–104** for INEEL and ORR: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

**Table 4–104 Incremental Radiological Impacts on the Public Around INEEL and ORR from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 7**

Receptor	INEEL ATR	ORR			Two-Site Total
		HFIR	REDC	Total	
<b>Population within 80 kilometers (50 miles) in the year 2020</b>					
Dose (person-rem)	0	0	$8.8 \times 10^{-5}$	$8.8 \times 10^{-5}$	$8.8 \times 10^{-5}$
35-year latent cancer fatalities	0	0	$1.5 \times 10^{-6}$	$1.5 \times 10^{-6}$	$1.5 \times 10^{-6}$
<b>Maximally exposed individual</b>					
Annual dose (millirem)	0	0	$1.9 \times 10^{-6}$	$1.9 \times 10^{-6}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	0	$3.3 \times 10^{-11}$	$3.3 \times 10^{-11}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>					
Annual dose <sup>b</sup> (millirem)	0	0	$7.8 \times 10^{-8}$	$7.8 \times 10^{-8}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	0	$1.4 \times 10^{-12}$	$1.4 \times 10^{-12}$	NA <sup>a</sup>

- a. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.  
 b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of HFIR and REDC in the year 2020 (1,134,200).

**Key:** NA, not applicable.

**Source:** Model results, using the GENII computer code (Napier et al. 1988).

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

As a result of annual operations of ATR at INEEL and HFIR and REDC at ORR, the projected incremental total population dose in the year 2020 would be  $8.8 \times 10^{-5}$  person-rem. The corresponding number of latent cancer fatalities in the populations surrounding INEEL and ORR from 35 years of operations would be  $1.5 \times 10^{-6}$ . The total incremental dose to the maximally exposed member of the public from annual ATR and HFIR operations would be 0 millirem because there would be no increase in radiological releases to the environment from either of these reactors associated with this option. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would, therefore, be zero. The incremental dose to the maximally exposed member of the public from annual HFIR and REDC operations would be  $1.9 \times 10^{-6}$  millirem. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $3.3 \times 10^{-11}$ .

Incremental doses to involved workers from normal operations are given in **Table 4–105**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to ATR workers would be 0 millirem; for HFIR workers, the incremental annual average dose would also be 0 millirem; for REDC workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities would be 0, 0, and approximately 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–105. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–105 Incremental Radiological Impacts on Involved INEEL and ORR Workers from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 7**

Receptor—Involved Workers <sup>a</sup>	INEEL ATR	ORR		Total
		HFIR	REDC	
Total dose (person-rem per year)	0	0	12 <sup>b</sup>	12
35-year latent cancer fatalities	0	0	0.17	0.17
Average worker dose (millirem per year)	0	0	170	NA <sup>c</sup>
35-year latent cancer fatality risk	0	0	0.0023	NA <sup>c</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 75 badged workers.

c. Values cannot be given for the average worker because the workers would be in three different facilities at two different sites.

**Key:** NA, not applicable.

**Source:** Mecham 1999; Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** No new hazardous chemicals would be emitted at HFIR. Therefore, impacts for this option at both INEEL and ORR would be the same as those described for Option 1 (Section 4.4.1.1.9).

#### 4.4.7.1.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with ATR and HFIR target irradiation and REDC target processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Estimates of radiological consequences have been developed for the maximally exposed individual, the offsite population within 80 kilometers (50 miles) of the facility, and a noninvolved worker at a distance of 640 meters (0.4 mile) from the release point. Consequences are presented in terms of radiological dose (in rem) and the

probability that the dose would result in a latent cancer fatality. Accident risk is defined as the product of the accident probability (i.e., accident frequency) and the accident consequence. In this NI PEIS, risk is expressed as the increased likelihood of a latent cancer fatality per year for an individual (the maximally exposed offsite individual or a noninvolved worker), and as the increased number of latent cancer fatalities per year in the offsite population. The probability coefficients for determining the likelihood of a latent cancer fatality, given a dose, are given in Section 4.2.1.2.10. Consequences to involved workers are addressed in Section I.1.7.

To provide a better indication of risks from the postulated accidents, the risks are summed for each facility and also for each option. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk from accidents, a full-scope probabilistic risk analysis would be required for each facility. Since full-scope probabilistic risk analyses are not available to incorporate in this NI PEIS, summing the spectrum of accident risks was considered appropriate for the purposes of this NI PEIS. Details of the risk summation calculations are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4-106** and **4-107**, respectively. Because ATR and HFIR are currently operating, the consequences and risks are presented for both the current reactor configurations without neptunium-237 targets and for the worst-case neptunium-237 target-loading reactor configurations. Baseline accident risks attributed to ATR and HFIR operations refer to accidents that could occur under the current ATR and HFIR configurations (without neptunium-237 targets). Baseline accident risks are obtained from the data in Table 4-107 by summing the annual risks for the baseline reactor configuration (0 kilogram per year plutonium-238 production), and then multiplying the sum by 35. The baseline ATR accident risk to the public would be 0.089 latent cancer fatality. Baseline ATR accident risks to the maximally exposed offsite individual and a noninvolved worker would be  $8.2 \times 10^{-7}$  and  $7.2 \times 10^{-6}$  latent cancer fatalities, respectively. Similarly, the baseline HFIR accident risk to the public would be 0.0052 latent cancer fatality. Baseline HFIR accident risks to the maximally exposed offsite individual and a noninvolved worker would be  $4.2 \times 10^{-6}$  and  $2.4 \times 10^{-5}$  latent cancer fatalities, respectively.

For 35 years of ATR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and to a noninvolved worker would be  $1.49 \times 10^{-7}$  and  $1.95 \times 10^{-6}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $7.01 \times 10^{-4}$ .

For 35 years of HFIR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and to a noninvolved worker would be  $8.68 \times 10^{-9}$  and  $3.43 \times 10^{-8}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $4.09 \times 10^{-5}$ .

For 35 years of REDC target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and of an early fatality to a noninvolved worker would be  $5.71 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.157.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $5.71 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.157.

The irradiation of neptunium-237 targets at ATR and HFIR would not introduce any additional operations that require the use of hazardous chemicals. Thus, there are no postulated hazardous chemical accidents attributable to the irradiation of neptunium-237 targets at ATR and HFIR.

**Table 4–106 ATR, HFIR, and REDC Accident Consequences Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 7**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>

Target dissolver tank failure during plutonium-238 separation	$1.76 \times 10^{-7}$	$8.79 \times 10^{-11}$	0.00196	$9.82 \times 10^{-7}$	$1.69 \times 10^{-8}$	$6.74 \times 10^{-12}$
Ion exchange explosion during plutonium-238 separation	$4.68 \times 10^{-4}$	$2.34 \times 10^{-7}$	5.23	0.00261	$4.49 \times 10^{-5}$	$1.79 \times 10^{-8}$
Processing facility beyond-design-basis earthquake	163	0.163	$8.91 \times 10^5$	445	1,310	1.00 <sup>d</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

c. There would be no neptunium-237 targets for this zero-production case. Thus, there would be not associated accident consequences.

d. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4–107 ATR, HFIR, and REDC Accident Risks Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 7**

Accident (Frequency)	Maximally Exposed Individual <sup>a</sup>	Population to 80 Kilometers (50 Miles) <sup>b</sup>	Noninvolved Worker <sup>a</sup>
<b>Annual ATR risks</b>

- a. Increased likelihood of a latent cancer fatality.
- b. Increased number of latent cancer fatalities.
- c. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.
- d. There would be no neptunium-237 targets for the zero-production case. Thus, the (3 kg/yr at ATR, 2 kg/yr at HFIR) production rate target-handling risks are the incremental risks.
- e. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.
- f. Risk of an early fatality.
- g. Individual risks are summed only for colocated individuals. The highest individual risk was used to represent the 35-year option risk.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

Processing associated with the plutonium-238 production program at REDC, including storage of neptunium-237 and plutonium-238, neptunium-237 target fabrication, postirradiation processing to extract plutonium-238 and to recycle the unconverted neptunium-237 into new targets, would not require the introduction of hazardous chemicals that are not in current use in the facility. The quantities of in-process hazardous chemicals for the plutonium-238 production program are bounded by the quantities of the material currently stored in the facility. The impacts of in-process hazardous chemical accidents associated with the plutonium-238 production are bounded by the impacts of hazardous chemical accidents for existing storage facilities at REDC.

#### 4.4.7.1.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the REDC target fabrication facility at ORR. DOE would transport the unirradiated neptunium-237 targets from REDC to HFIR, also at ORR, and to ATR at INEEL. Following irradiation in HFIR or ATR, the targets would be returned to REDC for processing. After this processing, the plutonium-238 product would be shipped to LANL. The analysis is described in Appendix J.

Approximately 563 intersite shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 1.8 million kilometers (1.1 million miles).

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 10 person-rem; the dose to the public, 192 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.004 latent cancer fatality among transportation workers and 0.096 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option is 0.0052.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to REDC with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 were also evaluated and estimated to have a probability of lower than 1 in 10 million per year.

Estimates of the total ground transportation accident risks under this option are as follows: a radiological dose to the population of 0.088 person-rem, resulting in  $4.4 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.048 traffic fatality.

#### 4.4.7.1.12 Environmental Justice

**NORMAL OPERATIONS.** For 35 years of normal operations under this option, the radiological risk among the population residing within 80 kilometers (50 miles) of ATR, HFIR, and REDC would be less than  $2 \times 10^{-6}$  latent cancer fatalities. As shown in Sections 4.4.1.1.9 and 4.4.7.1.9, the release of hazardous chemicals at ORR and at INEEL would pose no significant risk of cancer or toxic effects among the public. As discussed in Sections K.5.1 and K.5.2, the likelihood that a latent cancer fatality would result from the ingestion of food that could be radiologically contaminated due to normal operations would be essentially zero

at INEEL and ORR. No credible pattern of food consumption by persons residing in potentially affected areas would result in significant health risks due to radiological contamination of food supplies near INEEL or ORR. As discussed in Section 4.4.7.1.11, no fatalities would be expected to result from incident-free transportation.

**ACCIDENTS.** The number of expected latent cancer fatalities among populations at risk due to accidents listed in Table 4–107 would be approximately 0.16. If a radiological accident were to occur at ATR and northwesterly winds prevailed at the time of the accident, radiological contamination from the accident would be directed toward the Fort Hall Indian Reservation (see Figure K–2). However, accidents that could occur under the implementation of this option would not be expected to result in a latent cancer fatality among the population or maximally exposed individual residing within the boundary of the Fort Hall Indian Reservation. In the event a radiological accident were to occur at REDC or HFIR and southerly winds prevailed at the time of the accident, radiological contamination would be directed toward the predominately minority population of the Scarboro community adjacent to the northern boundary of ORR (see Figure K–6). If the winds were blowing from the west-southwest at the time of the accident, radiological contamination would be directed toward minority populations residing in Knoxville, Tennessee. Accidents that could occur under the implementation of this option would not be expected to result in a latent cancer fatality among the minority populations or maximally exposed individuals residing in the Scarboro community or Knoxville.

As discussed in Section 4.4.7.1.11, no fatalities would be expected to result from transportation accidents.

In summary, the implementation of this option would pose no significant radiological risk to persons residing in potentially affected areas or along representative transportation routes. Under the conservative assumption that all food consumed in potentially affected areas during the 35-year operational period would be radioactively contaminated, no credible pattern of food consumption would pose a significant radiological health risk due to the ingestion of contaminated food supplies. As discussed in other parts of Section 4.4.7.1, the implementation of this option would not result in significant nonradiological impacts on populations at risk. Thus, implementation would not pose significant and adverse environmental risks to persons residing within potentially affected areas, including minority and low-income persons.

#### **4.4.7.1.13 Waste Management**

Only very small amounts of additional waste would be generated as a result of irradiating neptunium-237 targets in ATR and HFIR because these reactors would already be operating for other purposes. The anticipated incremental generation of waste from ATR operations is discussed in Section 4.4.1.1.13. The operation of HFIR is expected to increase the generation of solid low-level radioactive waste by less than 1 cubic meter (1.3 cubic yards) per year. There would be virtually no impacts on either site's waste management systems as the result of neptunium-237 target irradiation.

The impacts of managing waste associated with neptunium-237 target fabrication and processing in REDC are assumed to be the same as for Option 1 under Alternative 1 (Section 4.3.1.1.13) because the same amount of plutonium-238 would be produced annually. As shown in that section, the impacts on the waste management systems at ORR would be minimal.

#### **4.4.7.1.14 Spent Nuclear Fuel Management**

No incremental impacts would be associated with the management of spent nuclear fuel (refer to Section 4.4.1.1.14).

#### 4.4.7.2 Permanent Deactivation of FFTF

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### 4.4.8 Alternative 2 (Use Only Existing Operational Facilities)—Option 8

This option involves operating both the HFIR at ORR and ATR at INEEL to irradiate neptunium-237 targets, and operating FDPF at INEEL to fabricate and process these targets. This option also includes storage of the neptunium-237 transported to INEEL from SRS, in either Building CPP-651 or FDPF.

The transportation of the neptunium-237 from SRS to INEEL for processing and fabrication into neptunium-237 targets in FDPF, the transportation of a portion of these targets from INEEL to ORR for irradiation in HFIR, the transportation of the irradiated targets back to INEEL for postirradiation processing in FDPF, and the transportation of the entire plutonium-238 product from INEEL to LANL also constitute part of this option.

All options under this alternative include the permanent deactivation of FFTF at Hanford.

##### 4.4.8.1 Operations and Transportation

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

###### 4.4.8.1.1 Land Resources

**LAND USE.** The irradiation of neptunium-237 targets in ATR would not result in impacts on land use at INEEL for the reasons described in Section 4.4.1.1.1.

The irradiation of neptunium-237 targets would also take place in the existing HFIR facility. There would be no impacts on land use at ORR for the reasons described in Section 4.4.7.1.1.

There would be no impacts on land use at INEEL from neptunium-237 storage, target fabrication, and processing for the reasons described in Section 4.4.2.1.1.

**VISUAL RESOURCES.** The irradiation of neptunium-237 targets in ATR would not result in impacts on visual resources at INEEL for the reasons described in Section 4.4.1.1.1.

The irradiation of neptunium-237 targets would also take place within the existing HFIR facility. There would be no impacts on visual resources at ORR for the reasons described in Section 4.4.7.1.1.

There would be no impacts on visual resources at INEEL from neptunium-237 storage, target fabrication, and processing for the reasons described in Section 4.4.2.1.1.

###### 4.4.8.1.2 Noise

The irradiation of neptunium-237 targets in ATR would not result in noise impacts at INEEL for the reasons described in Section 4.4.1.1.2.

The irradiation of neptunium targets would also take place in HFIR. No change in noise impacts at ORR would be expected for the reasons described in Section 4.4.7.1.2.

Noise impacts at INEEL would not be expected from neptunium-237 storage, target fabrication, and processing and changes in traffic noise would be small for the reasons described in Section 4.4.2.1.2.

#### **4.4.8.1.3 Air Quality**

Impacts for this option at INEEL would be the same as those described for Option 2 (Section 4.4.2.1.3).

It is expected that there would be no measurable increases in nonradiological air pollutant emissions at ORR associated with HFIR operations; therefore, no changes in nonradiological air quality impacts would be expected (Wham 1999a).

The air quality impacts of transportation among SRS, INEEL, ORR, and LANL are presented in Section 4.4.8.1.11.

#### **4.4.8.1.4 Water Resources**

Impacts for this option at INEEL would be the same as those described for Option 2 (Section 4.4.2.1.4).

The irradiation of neptunium-237 targets would also take place in the existing HFIR facility at ORR. No measurable impact on water resources at ORR would be expected for the same reasons as described in Section 4.4.7.1.4.

#### **4.4.8.1.5 Geology and Soils**

The use of ATR to irradiate neptunium-237 targets at INEEL would not be expected to result in impacts on geologic or soil resources, nor be jeopardized by large-scale geologic conditions, for the reasons described in Section 4.4.1.1.5.

Dual use of HFIR at ORR to irradiate neptunium-237 targets would also not be expected to result in impacts on geologic and soil resources, nor be jeopardized by large-scale geologic conditions, for the reasons described in Sections 4.2.2.2.5 and 4.4.7.1.5.

Neptunium-237 storage, target fabrication, and processing in FDPF would not be expected to impact geologic and soil resources at INEEL, nor be jeopardized by large-scale geologic conditions, for the reasons described in Sections 4.2.3.2.5 and 4.4.2.1.5.

As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards will be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.4.8.1.6 Ecological Resources**

The irradiation of neptunium-237 targets in ATR would not result in impacts on ecological resources at INEEL for the reasons described in Section 4.4.1.1.6.

The irradiation of neptunium targets would also take place in HFIR. There would be no impacts on ecological resources at ORR for the reasons described in Section 4.4.7.1.6.

There would be no impacts on ecological resources at INEEL from neptunium-237 storage, target fabrication, and processing for the reasons described in Section 4.4.2.1.6.

#### 4.4.8.1.7 Cultural and Paleontological Resources

The irradiation of neptunium-237 targets in ATR would not result in impacts on cultural and paleontological resources at INEEL for the reasons described in Section 4.4.1.1.7.

The irradiation of neptunium-237 targets would also take place in HFIR. Impacts on cultural and paleontological resources at ORR would not be expected for the reasons described in Section 4.4.7.1.7.

Impacts on cultural and paleontological resources at INEEL would not be expected from neptunium-237 storage, target fabrication, and processing for the reasons described in Section 4.4.2.1.7.

#### 4.4.8.1.8 Socioeconomics

After facility modifications, startup, and testing of the plutonium-238 reactor operation facilities at INEEL and ORR and target fabrication/processing facilities at INEEL, approximately 24 additional workers would be required to operate these facilities (24 at INEEL and none at ORR) (Hill et al. 1999). The socioeconomic impacts at INEEL are the same as those addressed in Section 4.3.2.1.8.

#### 4.4.8.1.9 Public and Occupational Health and Safety—Normal Operations

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from operations are given in **Table 4–108** for INEEL and ORR: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

As a result of annual operations of HFIR at ORR and ATR and FDPF at INEEL, the projected incremental total population dose in the year 2020 would be  $3.9 \times 10^{-6}$  person-rem. The corresponding number of latent cancer fatalities in the populations surrounding INEEL and ORR from 35 years of operations would be  $6.7 \times 10^{-8}$ . The incremental total dose to the maximally exposed member of the public from annual ATR and HFIR operations would be 0 millirem because there would be no increase in radiological releases to the environment from either of these reactors associated with this option. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would, therefore, be zero. The total incremental dose to the maximally exposed member of the public from annual ATR and FDPF operations would be  $2.6 \times 10^{-7}$  millirem. From 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $4.6 \times 10^{-12}$ .

**Table 4–108 Incremental Radiological Impacts on the Public Around ORR and INEEL from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 8**

Receptor	ORR HFIR	INEEL			Two-Site Total
		ATR	FDPF	Total	
<b>Population within 80 kilometers (50 miles) in the year 2020</b>					
Dose (person-rem)	0	0	$3.9 \times 10^{-6}$	$3.9 \times 10^{-6}$	$3.9 \times 10^{-6}$
35-year latent cancer fatalities	0	0	$6.7 \times 10^{-8}$	$6.7 \times 10^{-8}$	$6.7 \times 10^{-8}$
<b>Maximally exposed individual</b>					
Annual dose (millirem)	0	0	$2.6 \times 10^{-7}$	$2.6 \times 10^{-7}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	0	$4.6 \times 10^{-12}$	$4.6 \times 10^{-12}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>					
Annual dose <sup>b</sup> (millirem)	0	0	$2.0 \times 10^{-8}$	$2.0 \times 10^{-8}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	0	$3.6 \times 10^{-13}$	$3.6 \times 10^{-13}$	NA <sup>a</sup>

- a. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.  
 b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FDPF in the year 2020 (188,400).

**Key:** NA, not applicable.

**Source:** Model results, using the GENII computer code (Napier et al. 1988).

Incremental doses to involved workers from normal operations are given in **Table 4–109**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to ATR workers would be 0 millirem; for HFIR workers, the incremental annual average dose would also be 0 millirem; for FDPF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities would be 0, 0, and approximately 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–109. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–109 Incremental Radiological Impacts on Involved ORR and INEEL Workers from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 8**

Receptor—Involved Workers <sup>a</sup>	ORR HFIR	INEEL		Total
		ATR	FDPF	
Total dose (person-rem per year)	0	0	12 <sup>b</sup>	12
35-year latent cancer fatalities	0	0	0.17	0.17
Average worker dose (millirem per year)	0	0	170	NA <sup>c</sup>
35-year latent cancer fatality risk	0	0	0.0023	NA <sup>c</sup>

- a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.  
 b. Based on an estimated 75 badged workers.  
 c. Values cannot be given for the average worker because the workers would be in three different facilities at two different sites.

**Key:** NA, not applicable.

**Source:** Mecham 1999; Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts for this option at INEEL would be the same as those described for Option 2 (Section 4.4.2.1.9).

Hazardous chemical impacts at ORR would be the same as those of ongoing site operations because no new chemicals are expected to be emitted from operating HFIR.

#### 4.4.8.1.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with ATR and HFIR target irradiation and FDPF target processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Estimates of radiological consequences have been developed for the maximally exposed individual, the offsite population within 80 kilometers (50 miles) of the facility, and a noninvolved worker at a distance of 640 meters (0.4 mile) from the release point. Consequences are presented in terms of radiological dose (in rem) and the probability that the dose would result in a latent cancer fatality. Accident risk is defined as the product of the accident probability (i.e., accident frequency) and the accident consequence. In this NI PEIS, risk is expressed as the increased likelihood of a latent cancer fatality per year for an individual (the maximally exposed offsite individual or a noninvolved worker), and as the increased number of latent cancer fatalities per year in the offsite population. The probability coefficients for determining the likelihood of a latent cancer fatality, given a dose, are given in Section 4.2.1.2.10. Consequences to involved workers are addressed in Section I.1.7.

To provide a better indication of risks from the postulated accidents, the risks are summed for each facility and also for each option. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk from accidents, a full-scope probabilistic risk analysis would be required for each facility. Since full-scope probabilistic risk analyses are not available to incorporate in this NI PEIS, summing the spectrum of accident risks was considered appropriate for the purposes of this NI PEIS. Details of the risk summation calculations are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4-110** and **4-111**, respectively. Because ATR and HFIR are currently operating, the consequences and risks are presented for both the current reactor configurations without neptunium-237 targets and for the worst-case neptunium-237 target-loading reactor configurations.

For 35 years of ATR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and to a noninvolved worker would be  $1.49 \times 10^{-7}$  and  $1.95 \times 10^{-6}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $7.01 \times 10^{-4}$ .

For 35 years of HFIR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and to a noninvolved worker would be  $8.68 \times 10^{-9}$  and  $3.43 \times 10^{-8}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $4.09 \times 10^{-5}$ .

For 35 years of FDPF target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and an early fatality to a noninvolved worker would be  $1.49 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0287.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $1.50 \times 10^{-5}$  and  $3.52 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0295.

The irradiation of neptunium-237 targets at ATR and HFIR would not introduce any additional operations that require the use of hazardous chemicals. Thus, there are no postulated hazardous chemical accidents attributable to the irradiation of neptunium-237 targets at ATR and HFIR.

**Table 4–110 ATR, HFIR, and FDPF Accident Consequences Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 8**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker

Ion exchange explosion during plutonium-238 separation	1.63×10 <sup>-5</sup>	8.13×10 <sup>-9</sup>	0.150	7.51×10 <sup>-5</sup>	5.79×10 <sup>-5</sup>	2.31×10 <sup>-8</sup>
Processing facility beyond-design-basis earthquake	42.5	0.0425	1.64×10 <sup>5</sup>	82.0	1,200	1.0 <sup>d</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

c. There would be no neptunium-237 targets for this zero-production case. Thus, there would be no associated accident consequences.

d. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4–111 ATR, HFIR, and FDPF Accident Risks Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 8**

Accident (Frequency)	Maximally Exposed Individual <sup>a</sup>	Population to 80 Kilometers (50 Miles) <sup>b</sup>	Noninvolved Worker <sup>a</sup>

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.

d. There would be no neptunium-237 targets for the zero-production case. Thus, the (3 kg/yr at ATR, 2 kg/yr at HFIR) production rate target-handling risks are the incremental risks.

e. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.

f. Risk of an early fatality.

g. Individual risks are summed only for colocated individuals. The highest individual risk was used to represent the 35-year option risk.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

No chemical processing activities are currently performed at FDPF and no chemicals are stored in this facility. Processing activities in support of plutonium-238 production would require the introduction of hazardous chemicals, specifically nitric acid and nitric oxide. Potential health impacts from accidental releases of nitric acid were assessed by comparing estimated airborne concentrations of the chemicals to ERPG developed by the American Industrial Hygiene Association. The ERPG-1 value (0.5 part per million) is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour, resulting in only mild, transient, and reversible adverse health effects. The ERPG-2 value (10 parts per million) is protective of irreversible or serious health effects or impairment of an individual’s ability to take protective action. The ERPG-3 value (25 parts per million) is indicative of potentially life-threatening health effects.

The maximum distances, in meters, needed to reach the ERPG values for nitric acid releases at FDPF for Stability Classes D and F are shown in **Table 4–112**. Two separate atmospheric conditions were evaluated, Stability Classes D and F. Stability Class D represents average meteorological conditions while Stability Class F represents worst-case meteorological conditions. The number of involved and noninvolved workers potentially exposed would vary with a number of factors, such as the time of day and whether they were sheltered within buildings at the time of release. Individuals at the nearest highway (5,800 meters [3.6 miles]) and at the nearest site boundary (13,952 meters [8.7 miles]) from FDPF would be exposed to levels well below ERPG-1.

**Table 4–112 ERPG Distances for Nitric Acid Releases at FDPF Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 8**

Evaluation Parameter	Stability Class D (meters)	Stability Class F (meters)
ERPG-3	375	450
ERPG-2	500	600
ERPG-1	2,000	3,000

**Note:** To convert from meters to miles, multiply by  $6.22 \times 10^{-4}$ .

**Key:** ERPG, Emergency Response Planning Guideline.

There are no ERPG values for nitric oxide. For nitric oxide accidents, the level of concern has been estimated by using one-tenth of the “Immediately Dangerous to Life and Health” level published by the National Institute for Occupational Safety and Health. The Immediately Dangerous to Life and Health value for nitric oxide is 100 parts per million. The level of concern value used for this NI PEIS is 10 parts per million. The level of concern is defined as the concentration of an extremely hazardous substance in air above which there may be serious irreversible health effects as a result of a single exposure for a relatively short period of time.

For FDPF, the maximum distances needed to reach the level of concern for nitric oxides releases for Stability Classes D and F are 500 and 2,000 meters (0.31 and 1.24 miles), respectively. The number of involved and noninvolved workers potentially exposed would vary with a number of factors, such as the time of day and whether they were sheltered within buildings at the time of release. Individual at the nearest highway (5,800 meters [3.6 miles]) and the nearest site boundary (13,952 meters [8.7 miles]) from FDPF would be exposed to levels well below the level of concern for nitric oxide.

Potential health impacts from the accidental release of the hazardous chemicals were assessed for a noninvolved worker, offsite individuals who are members of the public located at the nearest site boundary and onsite individuals who are members of the public located at the nearest highway access.

The impacts associated with the accidental release of nitric acid and nitric oxide at FDPF are presented in **Table 4–113**.

**Table 4–113 FDFP Hazardous Chemical Accident Impacts Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 8**

Receptor	Evaluation Parameter	Nitric Acid		Nitric Oxide	
		Stability Class D	Stability Class F	Stability Class D	Stability Class F
Noninvolved worker (640 meters)	Parts per million Level of concern Potential health effects	3.3 <ERPG-2 Mild, transient	8.4 <ERPG-2 Mild, transient	4.2 <LOC Mild, transient	67.5 >LOC Serious
Nearest highway maximally exposed individual	Parts per million Level of concern Potential health effects	0.05 < ERPG-1 None	0.15 ERPG-1 Mild, transient	0.09 < LOC None	0.87 < LOC None
Site boundary maximally exposed individual	Parts per million Level of concern Potential health effects	<<0.05 < ERPG-1 None	<<0.15 ERPG-1 Mild, transient	<<0.09 < LOC None	<<0.87 < LOC None

**Note:** < means “less than”; << means “much less than.”

**Key:** ERPG, Emergency Response Planning Guideline; LOC, level of concern.

**Source:** Model results.

#### 4.4.8.1.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the FDFP target fabrication facility at INEEL. DOE would transport the unirradiated neptunium-237 targets from FDFP to HFIR at ORR, and to ATR at INEEL. Following irradiation in HFIR or ATR, the targets would be returned to FDFP for processing. After this processing, the plutonium-238 product would be shipped to LANL. The analysis is described in Appendix J.

Approximately 311 intersite shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 0.99 million kilometers (0.62 million miles).

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 6 person-rem; the dose to the public, 103 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.0024 latent cancer fatality among transportation workers and 0.052 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option is 0.0030.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FDFP with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 were also evaluated and estimated to have a probability of lower than 1 in 10 million per year.

Estimates of the total ground transportation accident risks are as follows: a radiological dose to the population of 0.088 person-rem, resulting in  $4.4 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.024 traffic fatality.

#### **4.4.8.1.12 Environmental Justice**

**NORMAL OPERATIONS.** For 35 years of normal operations under this option, the likelihood of an incremental latent cancer fatality among the population residing within 80 kilometers (50 miles) of HFIR, ATR, and FDPF would be essentially zero (derived from information in Table 4–108). As shown in Sections 4.4.2.1.9 and 4.4.8.1.9, the release of hazardous chemicals at INEEL would pose no significant risk of cancer or toxic effects among the public. As discussed in Sections K.5.1 and K.5.2, the likelihood that a latent cancer fatality would result from the ingestion of food that could be radiologically contaminated due to normal operations would be essentially zero at INEEL and ORR. No credible pattern of food consumption by persons residing in potentially affected areas would result in significant health risks due to radiological contamination of food supplies near INEEL or ORR. The likelihood of a latent cancer fatality among the public due to incident-free transportation during the 35-year project would be approximately 1 in 19, and the likelihood of a nonradiological fatality due to vehicular emissions would be approximately 1 in 330 (derived from information in Section 4.4.8.1.11).

**ACCIDENTS.** The number of expected latent cancer fatalities among the populations at risk due to accidents listed in Table 4–111 would be approximately 0.03. If a radiological accident were to occur at ATR or FDPF and northwesterly winds prevailed at the time of the accident, radiological contamination from the accident would be directed toward the Fort Hall Indian Reservation (see Figure K–2). However, accidents that could occur under the implementation of this option would not be expected to result in a latent cancer fatality among the population or maximally exposed individual residing within the boundary of the Fort Hall Indian Reservation. In the event a radiological accident were to occur at HFIR and southerly winds prevailed at the time of the accident, radiological contamination would be directed toward the predominately minority population of the Scarboro community adjacent to the northern boundary of ORR (see Figure K–6). If the winds were blowing from the west-southwest at the time of the accident, radiological contamination would be directed toward minority populations residing in Knoxville, Tennessee. Accidents that could occur under the implementation of this option would not be expected to result in a latent cancer fatality among the minority populations or maximally exposed individuals residing in the Scarboro community or Knoxville.

The radiological risk of a public fatality due to incident-free transportation of radioactive material would be approximately 0.052 latent cancer fatality and the risk of a fatal traffic collision during 35 years of shipments would be approximately 0.024 fatality (Section 4.4.8.1.11).

In summary, the implementation of this option would pose no significant radiological risk to persons residing in potentially affected areas or along representative transportation routes. Under the conservative assumption that all food consumed in potentially affected areas during the 35-year operational period would be radioactively contaminated, no credible pattern of food consumption would pose a significant radiological health risk due to the ingestion of contaminated food supplies. As discussed in other parts of Section 4.4.8.1, the implementation of this option would not result in significant nonradiological impacts on populations at risk. Thus, implementation would not pose significant and adverse environmental risks to persons residing within potentially affected areas, including minority and low-income persons.

#### **4.4.8.1.13 Waste Management**

Only very small amounts of additional waste would be generated as a result of irradiating neptunium-237 targets in ATR and HFIR because these reactors would already be operating for other purposes. The anticipated incremental generation of waste from ATR operations is discussed in Section 4.4.1.1.13. The anticipated incremental generation of waste from HFIR operations is discussed in Section 4.4.7.1.13. There would be virtually no impacts on either site's waste management system as the result of neptunium-237 target irradiation.

The impacts of managing waste associated with neptunium-237 target fabrication and processing in FDPF are assumed to be the same as for Option 2 under Alternative 1 (Section 4.3.2.1.13) because the same amount of plutonium-238 would be produced annually. As shown in that section, the impacts on the waste management systems at INEEL would be minimal.

#### **4.4.8.1.14 Spent Nuclear Fuel Management**

No incremental impacts would be associated with the management of spent nuclear fuel (refer to Section 4.4.1.1.14).

#### **4.4.8.2 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.4.9 Alternative 2 (Use Only Existing Operational Facilities)—Option 9**

This option involves operating HFIR at ORR and ATR at INEEL to irradiate neptunium-237 targets, and operating FMEF at Hanford to both fabricate and process these targets and to store the neptunium-237 transported to Hanford from SRS.

The transportation of the neptunium-237 from SRS to Hanford for processing and fabrication into neptunium-237 targets in FMEF, the transportation of targets from Hanford to both INEEL and ORR for irradiation in ATR and HFIR, respectively, the transportation of the irradiated targets back to Hanford for postirradiation processing in FMEF, and the transportation of the plutonium-238 product from Hanford to LANL also constitute part of this option.

All options under this alternative include the permanent deactivation of FFTF at Hanford.

#### **4.4.9.1 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

##### **4.4.9.1.1 Land Resources**

**LAND USE.** The irradiation of neptunium-237 targets in ATR would not result in impacts on land use at INEEL for the reasons described in Section 4.4.1.1.1.

The irradiation of neptunium-237 targets would also take place within the existing HFIR facility at ORR. Impacts on land use at ORR would not result for the reasons described in Section 4.4.7.1.1.

Impacts on land use at Hanford from neptunium-237 storage, target fabrication, and processing at FMEF would be expected to be minimal for the reasons described in Section 4.4.3.1.1.

**VISUAL RESOURCES.** The irradiation of neptunium-237 targets in ATR would not result in impacts on visual resources at INEEL for the reasons described in Section 4.4.1.1.1.

The irradiation of neptunium-237 targets would also take place within the existing HFIR facility at ORR. There would be no impacts on visual resources at ORR for the reasons described in Section 4.4.7.1.1.

Impacts on visual resources at Hanford from neptunium-237 storage, target fabrication, and processing at FMEF would be expected to be minimal for the reasons described in Section 4.4.3.1.1.

#### **4.4.9.1.2 Noise**

The irradiation of neptunium-237 targets in ATR would not result in a change in noise impacts at INEEL for the reasons described in Section 4.4.1.1.2.

The irradiation of neptunium targets would also take place in HFIR. No change in noise impacts at ORR would be expected for the reasons described in Section 4.4.7.1.2.

Noise impacts at Hanford would be expected to be minimal from neptunium-237 storage, target fabrication, and processing at FMEF and changes in traffic noise would be small for the reasons described in Section 4.4.3.1.2.

#### **4.4.9.1.3 Air Quality**

Impacts for this option at INEEL would be the same as those described for Option 3 (Section 4.4.3.1.3).

Impacts for this option at ORR would be the same as those described for Option 8 (Section 4.4.8.1.3).

Impacts for this option at Hanford would be the same as those described for Option 3 (Section 4.4.3.1.3).

The air quality impacts of transportation among SRS, INEEL, ORR, Hanford, and LANL are presented in Section 4.4.9.1.11.

#### **4.4.9.1.4 Water Resources**

Impacts for this option at INEEL would be the same as those described for Option 1 (Section 4.4.1.1.4).

Impacts for this option at ORR would be the same as those described for Option 7 (Section 4.4.7.1.4).

Impacts for this option at Hanford would be the same as those described for Option 3 (Section 4.4.3.1.4).

#### **4.4.9.1.5 Geology and Soils**

The use of ATR to irradiate neptunium-237 targets at INEEL would not be expected to result in impacts on geologic or soil resources, nor be jeopardized by large-scale geologic conditions, for the reasons described in Section 4.4.1.1.5.

Dual use of HFIR at ORR to irradiate neptunium-237 targets would also not be expected to result in impacts on geologic and soil resources, nor be jeopardized by large-scale geologic conditions, for the reasons described in Sections 4.2.2.2.5 and 4.4.7.1.5.

Impacts on geologic and soil resources at Hanford would not be expected from neptunium-237 storage, target fabrication, and processing at FMEF for the reasons described in Sections 4.3.3.1.5 and 4.4.3.1.5. Large-scale geologic conditions also present a low risk to FMEF operations, as further discussed in Section 4.2.4.2.5. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards will be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### 4.4.9.1.6 Ecological Resources

The irradiation of neptunium-237 targets in ATR would not result in impacts on ecological resources at INEEL for the reasons described in Section 4.4.1.1.6.

The irradiation of neptunium targets would also take place in HFIR. There would be no impacts on ecological resources at ORR for the reasons described in Section 4.4.7.1.6.

There would be no impacts on ecological resources at Hanford from neptunium-237 storage, target fabrication, and processing at FMEF for the reasons described in Section 4.4.3.1.6.

#### 4.4.9.1.7 Cultural and Paleontological Resources

The irradiation of neptunium-237 targets in ATR would not result in impacts on cultural and paleontological resources at INEEL for the reasons described in Section 4.4.1.1.7.

The irradiation of neptunium targets would also take place in HFIR. There would be no impacts on cultural and paleontological resources at ORR for the reasons described in Section 4.4.7.1.7.

There would be no impacts on cultural and paleontological resources at Hanford from neptunium-237 target fabrication and processing at FMEF for the reasons described in Section 4.4.3.1.7.

#### 4.4.9.1.8 Socioeconomics

After facility modifications, startup, and testing of the plutonium-238 reactor operation facilities at INEEL and ORR and target fabrication/processing facilities at Hanford, approximately 62 additional workers would be required to operate these facilities (none at INEEL and ORR and 62 at Hanford) (Hoyt et al. 1999). The socioeconomic impacts at Hanford are the same as those addressed in Section 4.3.3.1.8.

#### 4.4.9.1.9 Public and Occupational Health and Safety—Normal Operations

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from operations are given in **Table 4–114** for INEEL, ORR, and Hanford: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

**Table 4–114 Incremental Radiological Impacts on the Public Around INEEL, ORR, and Hanford from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 9**

Receptor	INEEL ATR	ORR HFIR	Hanford FMEF	Three-Site Total
<b>Population within 80 kilometers (50 miles) in the year 2020</b>				
Dose (person-rem)	0	0	$4.4 \times 10^{-5}$	$4.4 \times 10^{-5}$
35-year latent cancer fatalities	0	0	$7.7 \times 10^{-7}$	$7.7 \times 10^{-7}$
<b>Maximally exposed individual</b>				
Annual dose (millirem)	0	0	$4.7 \times 10^{-7}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	0	$8.3 \times 10^{-12}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>				
Annual dose <sup>b</sup> (millirem)	0	0	$8.9 \times 10^{-8}$	NA <sup>a</sup>
35-year latent cancer fatality risk	0	0	$1.6 \times 10^{-12}$	NA <sup>a</sup>

- a. A “Total” cannot be given in this case because the same individual cannot be located at three different sites simultaneously.  
 b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FMEF in the year 2020 (494,400).

**Key:** NA, not applicable.

**Source:** Model results, using the GENII computer code (Napier et al. 1988).

As a result of annual operations of ATR at INEEL, HFIR at ORR, and FMEF at Hanford, the projected incremental total population dose in the year 2020 would be  $4.4 \times 10^{-5}$  person-rem. The corresponding number of latent cancer fatalities in the populations surrounding INEEL, ORR, and Hanford from 35 years of operations would be  $7.7 \times 10^{-7}$ . The total incremental dose to the maximally exposed members of the public from annual ATR and HFIR operations would be 0 millirem because there would be no increase in radiological releases to the environment from either of these reactors associated with this option. From 35 years of operations, the corresponding risk of a latent cancer fatality to these individuals would, therefore, be zero. The incremental dose to the maximally exposed member of the public from annual FMEF operations would be  $4.7 \times 10^{-7}$  millirem. From 35 years of operations, the corresponding risk of a latent fatal cancer to this individual would be  $8.3 \times 10^{-12}$ .

Incremental doses to involved workers from normal operations are given in **Table 4–115**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to ATR and HFIR workers would be 0 millirem; for FMEF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities would be 0, 0, and approximately 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–115. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–115 Incremental Radiological Impacts on Involved INEEL, ORR, and Hanford Workers from Operational Facilities Under Alternative 2 (Use Only Existing Operational Facilities)—Option 9**

Receptor—Involved Workers <sup>a</sup>	INEEL ATR	ORR HFIR	Hanford FMEF	Three-Site Total
Total dose (person-rem per year)	0	0	12 <sup>b</sup>	12
35-year latent cancer fatalities	0	0	0.17	0.17
Average worker dose (millirem per year)	0	0	170	NA <sup>c</sup>
35-year latent cancer fatality risk	0	0	0.0023	NA <sup>c</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 75 badged workers.

c. Values cannot be given for the average worker because the workers would be at three different facilities and sites.

**Key:** NA, not applicable.

**Source:** Mecham 1999; Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts for this option at INEEL would be the same as those of ongoing site operations because no new chemicals are expected to be emitted at ATR.

Hazardous chemical impacts for this option at ORR were determined to be the same as those of ongoing site operations because no new chemicals are expected to be emitted at HFIR.

Hazardous chemical impacts for this option at Hanford would be the same as those described for Option 3 (Section 4.4.3.1.9).

#### 4.4.9.1.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with ATR and HFIR target irradiation and FMEF target processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Estimates of radiological consequences have been developed for the maximally exposed individual, the offsite population within 80 kilometers (50 miles) of the facility, and a noninvolved worker at a distance of 640 meters (0.4 mile) from the release point. Consequences are presented in terms of radiological dose (in rem) and the probability that the dose would result in a latent cancer fatality. Accident risk is defined as the product of the accident probability (i.e., accident frequency) and the accident consequence. In this NI PEIS, risk is expressed as the increased likelihood of a latent cancer fatality per year for an individual (the maximally exposed offsite individual or a noninvolved worker), and as the increased number of latent cancer fatalities per year in the offsite population. The probability coefficients for determining the likelihood of a latent cancer fatality, given a dose, are given in Section 4.2.1.2.10. Consequences to involved workers are addressed in Section I.1.7.

To provide a better indication of risks from the postulated accidents, the risks are summed for each facility and also for each option. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk from accidents, a full-scope probabilistic risk analysis would be required for each facility. Since full-scope probabilistic risk analyses are not available to incorporate in this NI PEIS, summing the spectrum of accident risks was considered appropriate for the purposes of this NI PEIS. Details of the risk summation calculations are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4-116** and **4-117**, respectively. Because ATR and HFIR are currently operating, the consequences and risks are presented for both the current reactor configurations without neptunium-237 targets and for the worst-case neptunium-237 target-loading reactor configurations.

For 35 years of ATR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and to a noninvolved worker would be  $1.49 \times 10^{-7}$  and  $1.95 \times 10^{-6}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $7.01 \times 10^{-4}$ .

**Table 4-116 ATR, HFIR, and FMEF Accident Consequences Under Alternative 2 (Use Only Existing Operational Facilities)—Option 9**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

c. There would be no neptunium-237 targets for this zero-production case. Thus, there would be no associated accident consequences.

d. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

<b>35-year FMEF risk</b>	$2.88 \times 10^{-6}$	0.112	$3.50 \times 10^{-4}$
<b>35-year Option risk<sup>g</sup></b>	$2.88 \times 10^{-6}$	0.113	$3.50 \times 10^{-4}$

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. The incremental risk from irradiation of neptunium-237 targets in a currently operating reactor is determined by subtracting the risk of operating without targets from the risk of operating with targets.

d. There would be no neptunium-237 targets for the zero-production case. Thus, the (3 kg/yr at ATR, 2kg/yr at HFIR) production rate target-handling risks are the incremental risks.

e. The 35-year risk is determined by summing the incremental annual risks and then multiplying by 35.

f. Risk of an early fatality.

g. Individual risks are summed only for colocated individuals. The highest individual risk was used to represent the 35-year option risk.

**Note:** To convert from kilograms per year to pounds per year, multiply by 2.20.

**Key:** kg/yr, kilograms per year; LOCA, loss-of-coolant accident.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

For 35 years of HFIR target irradiation, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and to a noninvolved worker would be  $8.68 \times 10^{-9}$  and  $3.43 \times 10^{-8}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $4.09 \times 10^{-5}$ .

For 35 years of FMEF target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed offsite individual and of an early fatality to a noninvolved worker would be  $2.88 \times 10^{-6}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.112.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $3.04 \times 10^{-6}$  and  $3.52 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.113.

The irradiation of neptunium-237 targets at ATR and HFIR would not introduce any additional operations that require the use of hazardous chemicals. Thus, there are no postulated hazardous chemical accidents attributable to the irradiation of neptunium-237 targets at ATR and HFIR.

No chemical processing activities are currently performed at FMEF and no chemicals are stored in this facility. Processing activities in support of plutonium-238 production would require the introduction of hazardous chemicals, specifically nitric acid and nitric oxide. Potential health impacts from accidental releases of nitric acid were assessed by comparing estimated airborne concentrations of the chemicals to ERPG developed by the American Industrial Hygiene Association. The ERPG-1 value (0.5 part per million) is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour, resulting in only mild, transient, and reversible adverse health effects. The ERPG-2 value (10 parts per million) is protective of irreversible or serious health effects or impairment of an individual's ability to take protective action. The ERPG-3 value (25 parts per million) is indicative of potentially life-threatening health effects.

The maximum distances, in meters, needed to reach the ERPG values for nitric acid releases at FMEF for Stability Classes D and F are shown in **Table 4–118**. Two separate atmospheric conditions were evaluated, Stability Classes D and F. Stability Class D represents average meteorological conditions while Stability Class F represents worst-case meteorological conditions. The number of involved and noninvolved workers potentially exposed would vary with a number of factors, such as the time of day and whether they were sheltered within buildings at the time of release. Individuals at the nearest highway (7,100 meters [4.4 miles]) and at the nearest site boundary (7,210 meters [4.5 miles]) from FDPF would be exposed to levels well below ERPG-1.

**Table 4–118 ERPG Distances for Nitric Acid Releases at FMEF Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 9**

Evaluation Parameter	Stability Class D (meters)	Stability Class F (meters)
ERPG-3	375	450
ERPG-2	500	600
ERPG-1	2,000	3,000

**Note:** To convert from meters to miles, multiply by  $6.22 \times 10^{-4}$ .

**Key:** ERPG, Emergency Response Planning Guideline.

There are no ERPG values for nitric oxide. For nitric oxide accidents, the level of concern has been estimated by using one-tenth of the “Immediately Dangerous to Life and Health” level published by the National Institute for Occupational Safety and Health. The Immediately Dangerous to Life and Health value for nitric oxide is 100 parts per million. The level of concern value used for this NI PEIS is 10 parts per million. The level of

concern is defined as the concentration of an extremely hazardous substance in air above which there may be serious irreversible health effects as a result of a single exposure for a relatively short period of time.

For FMEF, the maximum distances needed to reach the level of concern for nitric oxides releases for Stability Classes D and F are 500 and 1,900 meters (0.31 and 1.18 miles), respectively. The number of involved and noninvolved workers potentially exposed would vary with a number of factors, such as the time of day and whether they were sheltered within buildings at the time of release. Individual at the nearest highway (7,100 meters [4.4 miles]) and the nearest site boundary (7,210 meters [4.5 miles]) from FMEF would be exposed to levels well below the level of concern for nitric oxide.

Potential health impacts from the accidental release of the hazardous chemicals were assessed for a noninvolved worker, offsite individuals who are members of the public located at the nearest site boundary and onsite individuals who are members of the public located at the nearest highway access.

The impacts associated with the accidental release of nitric acid and nitric oxide at FMEF are presented in **Table 4–119**.

**Table 4–119 FMEF Hazardous Chemical Accident Impacts Under Alternative 2  
(Use Only Existing Operational Facilities)—Option 9**

Receptor	Evaluation Parameter	Nitric Acid		Nitric Oxide	
		Stability Class D	Stability Class F	Stability Class D	Stability Class F
Noninvolved worker (640 meters)	Parts per million	3.3	8.4	4.2	66
	Level of concern	<ERPG-2	<ERPG-2	<LOC	>LOC
	Potential health effects	Mild, transient	Mild, transient	Mild, transient	Serious
Nearest highway maximally exposed individual	Parts per million	0.03	0.1	0.09	0.55
	Level of concern	< ERPG-1	ERPG-1	< LOC	< LOC
	Potential health effects	None	Mild, transient	None	None
Site boundary maximally exposed individual	Parts per million	0.03	0.1	0.09	0.53
	Level of concern	< ERPG-1	ERPG-1	< LOC	< LOC
	Potential health effects	None	Mild, transient	None	None

**Note:** < means “less than.”

**Key:** ERPG, Emergency Response Planning Guideline; LOC, level of concern.

**Source:** Model results.

#### 4.4.9.1.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the FMEF target fabrication facility at Hanford. DOE would transport the unirradiated neptunium-237 targets from FMEF to HFIR at ORR, and to ATR at INEEL. Following irradiation in HFIR or ATR, the targets would be returned to FMEF for processing. After this processing, the plutonium-238 product would be shipped to LANL. The analysis is described in Appendix J.

Approximately 689 shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 1.6 million kilometers (0.99 million miles).

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 9 person-rem; the dose to the public, 167 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.0036 latent cancer fatality among transportation workers and 0.084 latent cancer fatality in the total affected

population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option is 0.0037.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FMEF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 were also evaluated and estimated to have a probability of lower than 1 in 10 million per year.

Estimates of the total ground transportation accident risks are as follows: a radiological dose to the population of 0.06 person-rem, resulting in  $3.0 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.04 traffic fatality.

#### **4.4.9.1.12 Environmental Justice**

**NORMAL OPERATIONS.** For 35 years of normal operations under this option, the likelihood of an incremental latent cancer fatality among the population residing within 80 kilometers (50 miles) of HFIR, ATR, and FMEF would be essentially zero (derived from information in Table 4-114). As shown in Sections 4.4.3.1.9 and 4.4.9.1.9, the release of hazardous chemicals at Hanford would pose no significant risk of cancer or toxic effects among the public. As discussed in Sections K.5.1, K.5.2, and K.5.3, the risk that would result from the ingestion of food that could be radiologically contaminated due to normal operations would be essentially zero at INEEL and ORR, and approximately 0.001 latent cancer fatality at Hanford. No credible pattern of food consumption by persons residing in potentially affected areas would result in significant health risks due to radiological contamination of food supplies near INEEL, ORR, and Hanford. As discussed in Section 4.4.9.1.11, no fatalities would be expected to result from incident-free transportation activities.

**ACCIDENTS.** The number of expected latent cancer fatalities among populations at risk due to accidents listed in Table 4-117 would be approximately 0.11. If a radiological accident were to occur at ATR and northwesterly winds prevailed at the time of the accident, radiological contamination from the accident would be directed toward the Fort Hall Indian Reservation (see Figure K-2). In the event a radiological accident were to occur at HFIR and southerly winds prevailed at the time of the accident, radiological contamination would be directed toward the predominately minority population of the Scarboro community adjacent to the northern boundary of ORR (see Figure K-6). If the winds were blowing from the west-southwest at the time of the accident, radiological contamination would be directed toward minority populations residing in Knoxville, Tennessee. If a radiological accident were to occur at FMEF and northeasterly winds prevailed at the time of the accident, radiological contamination from the accident would be directed toward the Yakama Indian Reservation (see Figure K-11). However, accidents that could occur under the implementation of this option would not be expected to result in a latent cancer fatality among the populations or maximally exposed individuals residing near or within the boundaries of the Fort Hall Indian Reservation, the Scarboro community, Knoxville, or the Yakama Indian Reservation.

As discussed in Section 4.4.9.1.11, no fatalities would be expected to result from transportation accidents.

In summary, the implementation of this option would pose no significant radiological risk to persons residing in potentially affected areas or along representative transportation routes. Under the conservative assumption that all food consumed in potentially affected areas during the 35-year operational period would be

radioactively contaminated, no credible pattern of food consumption would pose a significant radiological health risk due to the ingestion of contaminated food supplies. As discussed in other parts of Section 4.4.9.1, the implementation of this option would not result in significant nonradiological impacts on populations at risk. Thus, implementation would not pose significant and adverse environmental risks to persons residing within potentially affected areas, including minority and low-income persons.

#### **4.4.9.1.13 Waste Management**

Only very small amounts of additional waste would be generated as a result of irradiating neptunium-237 targets in ATR and HFIR because these reactors would already be operating for other purposes. The anticipated incremental generation of waste from ATR operations is discussed in Section 4.4.1.1.13. The anticipated incremental generation of waste from HFIR operations is discussed in Section 4.4.7.1.13. There would be virtually no impacts on either site's waste management systems as the result of neptunium-237 target irradiation.

The impacts of managing waste associated with neptunium-237 target fabrication and processing in FMEF are assumed to be the same as for Option 3 (Section 4.4.3.1.13) because the same amount of plutonium-238 would be produced annually. As shown in that section, the impacts on the waste management systems at Hanford would be minimal.

#### **4.4.9.1.14 Spent Nuclear Fuel Management**

No incremental impacts would be associated with the management of spent nuclear fuel (refer to Section 4.4.1.1.14).

#### **4.4.9.2 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.5 ALTERNATIVE 3—CONSTRUCT NEW ACCELERATOR(S)**

Under Alternative 3, one or two new accelerators would be used for target irradiation for the evaluation period of 35 years. The new accelerator(s) which would be constructed at an existing DOE site,<sup>1</sup> would be used to irradiate all of the targets (i.e., for production of plutonium-238, isotopes for medical and industrial uses, and materials testing for research and development). Ongoing operations at existing facilities as described in Chapter 3, Affected Environment, would continue.

The targets for plutonium-238 production would be fabricated in one of the three candidate facilities at ORNL, INEEL, or Hanford. The material needed for the target fabrication (neptunium-237) would be transported from SRS to the fabrication facilities. The targets would be irradiated at the new high-energy accelerator facility and transported back to the target fabrication facilities for postirradiation processing.

Targets for medical and industrial isotope production would be fabricated in a new support facility located at the same site as the low-energy accelerator. The targets would be irradiated in the low-energy accelerator and returned to the new support facility for postirradiation processing. Site selection for Alternative 3 is not evaluated as part of this NI PEIS. Because Alternative 3 is evaluated at a generic DOE site, no credit was taken for any support infrastructure existing at the site and it was postulated that a new support facility would be required to support operation of the low-energy accelerator and its missions and the high-energy accelerator civilian nuclear energy research and development missions if both accelerators are located on the same site. While this approach bounds the environmental impact assessment for the implementation of Alternative 3, it overstates the impacts because this NI PEIS integrates the impacts associated with constructing a new support facility and infrastructure that may be available at the existing DOE site. In the event that Alternative 3 or the low-energy accelerator alone is selected by the Record of Decision for subsequent consideration, follow-on NEPA assessments would evaluate potential locations for either both accelerators or one of the accelerators. It is unlikely that DOE would consider locating the new low-energy or high-energy accelerator on a DOE site that does not have existing infrastructure capable of supporting all or most of the mission requirements. If the accelerator(s) were built on a DOE site with existing support facilities, the environmental impacts of such implementation could be determined by subtracting the construction and decommissioning impacts associated with the new support facility from the total impacts given for this alternative.

Under Alternative 3, nonirradiated targets, irradiated targets, and processed materials would be transported between the locations selected for storage, target fabrication, target irradiation, postirradiation processing, and the final destination of the plutonium-238. Alternative 3 also would include decontamination and decommissioning of the accelerator(s) and the support facility when the missions are over, as well as deactivation of FFTF at Hanford.

The low-energy accelerator would serve as a dedicated isotope production facility. Due to the nature of this type of accelerator, it could only produce a limited number of isotopes (listed in Table 1–1), has no ability to satisfy the plutonium-238 needs, and a very limited ability to support the proposed nuclear-based research and development needs. The preconceptual design of the high-energy accelerator presented in Appendix F focused on supporting the plutonium-238 production mission. The design of the high-energy accelerator could be refined and expanded to perform additional missions such as the production of a select set of medical and industrial radioisotopes. In addition, DOE is aware of longer-term concepts that would apply high-energy accelerators to produce “tuneable” neutrons in a subcritical assembly. Such a facility could be used to address some of the missions more familiar to reactor facilities and may hold considerable promise for future science

---

<sup>1</sup> If two accelerators were constructed, they could be located at different sites. However, to bound the environmental impacts at a generic site, the assessments in this section assume their location at a single site.

and technology research. A facility of this nature could provide unique capabilities in areas such as the testing of many different nuclear system coolant, fuel, and material interactions. The changes required to add additional capability to the high-energy accelerator could be provided, but they would increase the size of the facility, add complexity to the facility design and operation, increase the cost of construction and operation, and potentially require more time for design and construction.

The three options under this alternative and their associated target fabrication, postirradiation processing, and transportation activities are discussed below.

- **Option 1.** REDC at ORNL would be used to fabricate and process the neptunium-237 targets required for plutonium-238 production. The neptunium-237 transported from SRS to ORNL would be stored at REDC. The plutonium-238 product would be transported from ORNL to LANL for use in radioisotope power systems for future U.S. space missions. A new support facility at an existing DOE site would be used to fabricate and process the targets required for the production of medical and industrial and research isotopes and to store the materials needed for target fabrication.
- **Option 2.** FDPF at INEEL would be used to fabricate and process the neptunium-237 targets associated with plutonium-238 production. The neptunium-237 transported from SRS to INEEL would be stored in FDPF or Building CPP-651 at INEEL. The plutonium-238 product would be transported from INEEL to LANL for use in radioisotope power systems for future U.S. space missions. A new support facility at an existing DOE site would be used to fabricate and process the targets required to produce medical and industrial and research isotopes and to store the materials needed for target fabrication.
- **Option 3.** FMEF at Hanford would be used to fabricate and process the neptunium-237 targets for plutonium-238 production. The neptunium-237 transported from SRS to Hanford would be stored in FMEF. The plutonium-238 product would be transported from Hanford to LANL. A new support facility at an existing DOE site would be used to fabricate and process the targets required for the production of medical and industrial and research isotopes and to store the materials needed for target fabrication.

The incremental environmental impacts associated with each option are presented separately for the high-energy accelerator, the low-energy accelerator, and the support facility because combinations of these facilities may be selected for implementation. This segmentation assists in the selection of facilities from any of the possible combinations.

#### 4.5.1 Alternative 3 (Construct New Accelerator[s])—Option 1

Option 1 involves constructing and operating one or two accelerators to irradiate all targets associated with plutonium-238 production, medical and industrial isotope production, and research and development; operating REDC at ORR to fabricate and process neptunium-237 targets and to process the plutonium-238 product; and conducting and operating the support facility to fabricate and process the other targets and materials and to process the associated products. This option includes storage in REDC of the neptunium-237 transported to ORR from SRS and storage in the new support facility of the other target materials transported to the generic site from other offsite facilities.

The transportation of the neptunium-237 from SRS to ORR and then to the generic site, the transportation of the other target materials to the generic site, and the transportation of plutonium-238 and other product materials following irradiation and postirradiation processing constitute part of this option.

All options under this alternative include the decontamination and decommissioning of the accelerator(s) and support facility at the generic site following their operational lifetimes, and also the permanent deactivation of FFTF at Hanford.

#### **4.5.1.1 Construction of the New Accelerator(s) and Support Facility**

The environmental impacts associated with the construction of one or two new accelerators and a support facility at the generic DOE site are assessed in this section. If the accelerator(s) were built on a site with existing support facilities, there would be no impacts associated with constructing a new support facility.

##### **4.5.1.1.1 Land Resources**

**LAND USE.** The construction of a low-energy accelerator, a high-energy accelerator, and a support facility would require 4 hectares (10 acres), 20.2 hectares (50 acres), and 2.4 hectares (6 acres), respectively (TechSource 2000; Herrington 2000; SAIC 2000). Since the exact nature of the construction site for any of these facilities is not known at this time (e.g., whether it has been previously disturbed or not), potential effects on land use cannot be determined. In general, if a location in a previously developed portion of a generic DOE site were selected, impacts on land use would be minimal. However, if an undisturbed location were chosen, land use would change from its present designation to industrial. If the accelerator(s) alternative were selected, tiered NEPA documentation would permit an exact determination of impacts on land use.

**VISUAL RESOURCES.** Impacts from construction of one or two accelerators and a support facility to visual resources at a generic DOE site would depend on the specific location selected. Impacts could include a change in the present Visual Resource Management rating of the site and/or increase in visibility of the site from offsite locations due to the presence of new structures. If construction took place on undeveloped land, the Visual Resource Management rating could change from Class II or III (ratings typical of undeveloped portions of many DOE sites) to Class IV. If a previously developed location were chosen for the accelerator(s), the Visual Resource Management rating would remain Class IV. In either case, new facilities may impact the view from offsite locations by increasing the industrial nature of the viewshed. This impact would be more likely at a western site due to the generally level terrain and sparse vegetation. Specific impacts on visual resources would be determined in tiered NEPA documentation if the accelerator(s) alternative were selected.

##### **4.5.1.1.2 Noise**

The construction of high-energy and/or low-energy accelerators would result in some increase in noise levels from the use of earthmoving, materials handling, and impact equipment; employee vehicles; and truck traffic. Noise from construction activities, especially impulsive noise, would be expected to disturb wildlife in the immediate area of the construction site. The change in noise levels in areas outside the DOE site would be dependent on the location selected and the exact nature of the construction location and activities required. However, generally if the location selected were within one of the larger DOE sites and more centrally located within the site, offsite noise impacts from construction activities would be small. Construction employee vehicles and truck traffic would result in an increase in traffic noise along roads used to access the site. However, this increase in traffic noise would be small unless the construction traffic volume were as large as the existing site traffic. Site-specific analysis would be conducted in tiered NEPA documentation if the accelerator(s) alternative were selected.

The construction of a support facility would result in some increase in noise levels from the use of earthmoving, materials handling, and impact equipment; employee vehicles; and truck traffic. Noise from construction activities, especially impulsive noise, would be expected to disturb wildlife in the immediate area of the construction site. The change in noise levels in areas outside the DOE site would be dependent on the

location selected and the exact nature of the construction location and activities required. However, generally if the location selected were within one of the larger DOE sites and more centrally located within the site, offsite noise impacts from construction activities would be small. Construction employee vehicles and truck traffic would result in an increase in traffic noise along roads used to access the site. However, this increase in traffic noise would be small unless the construction traffic volume were as large as the existing site traffic. Site-specific analysis would be conducted in tiered NEPA documentation if the accelerator(s) alternative were selected.

#### 4.5.1.1.3 Air Quality

**High-Energy Accelerator.** Construction of the high-energy accelerator would result in an increase in air quality impacts from employee vehicles, trucks, and construction equipment. Criteria pollutant concentrations for construction of the high-energy accelerator were modeled and compared to the most stringent standards (Table 4-120). The maximum ground-level concentrations that would result from high-energy accelerator construction would be well below the ambient air quality standards, although concentrations of some pollutants (i.e., PM<sub>10</sub> and nitrogen oxide) would be relatively high. Therefore, if the accelerator were in an area that already had high background pollutant concentrations, resultant pollutant concentrations could approach or exceed the ambient standards. Regulatory compliance would need to be assessed on a case-by-case basis. Hazardous chemical emissions from construction activities have not been identified.

**Table 4-120 Incremental Concentrations Associated with High-Energy Accelerator Construction Under All Options of Alternative 3 (Construct New Accelerator[s])**

Pollutant	Averaging Period	Most Stringent Standard or Guideline (microgram per cubic meter) <sup>a</sup>	Modeled Increment (microgram per cubic meter)
Carbon monoxide	8 hours	10,000	436
	1 hour	40,000	623
Nitrogen oxide	Annual	100	42
PM <sub>10</sub>	Annual	50	3
	24 hours	150	69
Sulfur dioxide	Annual	80	3
	24 hours	365	64
	3 hours	1,300	143

a. The more stringent of the Federal and state standards is presented if both exist for the averaging period. The National Ambient Air Quality Standards (NAAQS) (40 CFR Part 50), other than those based on annual averages, are not to be exceeded more than once per year. The annual arithmetic mean PM<sub>10</sub> standard is attained when the expected annual arithmetic mean concentration is less than or equal to the standard.

**Source:** Modeled increments are based on SCREEN3 computer code (EPA 1995); data from TechSource 2000.

Modeling was based on a construction area of 100,000 square meters (1,080,000 square feet). The site was modeled as an area source with emissions occurring at a height of 3 meters (9.8 feet). A boundary limit of 3,200 meters (2 miles) was assumed for a generic site.

**Low-Energy Accelerator.** Given the small size of the low-energy accelerator (about 20 percent of the construction size of the high-energy accelerator), emissions of air pollutants from construction would be very small in comparison with the high-energy accelerator. The maximum ground level concentrations that would result from low-energy accelerator construction would be well below the ambient air quality standards. Nevertheless, regulatory compliance would need to be assessed on a case-by-case basis.

**Support Facility for Accelerator(s).** Given the small size of the support facility in comparison with the accelerators (about 10 percent of the construction size of the high-energy accelerator), emissions of air

pollutants from construction would be very small in comparison with the high-energy accelerator construction. The maximum ground level concentrations that would result from accelerator support facility construction would be 10 percent of the values given in Table 4–120.

#### 4.5.1.1.4 Water Resources

The estimated effects on key water resource indicators associated with constructing the new accelerator(s) and support facility are presented in **Table 4–121**.

**Table 4–121 Estimated Water Use and Wastewater Generation Associated with Constructing New Accelerator(s) and Support Facility Under All Options of Alternative 3 (Construct New Accelerator[s])**

Indicator (million liters per year)	Accelerators <sup>a</sup>		New Support Facility <sup>a</sup>
	Low-Energy	High-Energy	
Water use	14.0	22.7	14.6
Sanitary wastewater generation	1.5	11.4	3.6

a. These estimates are annualized values based on projected construction/preoperational testing periods for the low-energy accelerator, high-energy accelerator, and new support facility of 3 years, 4.5 years, and 4.5 years, respectively.

**Note:** To convert from liters per year to gallons per year, multiply by 0.264.

**Source:** SAIC 2000; Snead 2000; TechSource 2000.

Water would be expected to be required for such uses as mixing concrete, dust control, washing activities, and for potable and sanitary needs. These estimates are annual average values over the forecasted construction periods; these values do not include dewatering of excavations that could be required at some sites. The exact impact of these withdrawals on the resource would depend on the water source (surface water or groundwater) and its relative abundance. These factors would be used to determine the impact on the local and/or regional availability of the resource. Impacts would be expected to be small to negligible due to the relatively small volumes of water required for construction compared to expected site availability.

Sanitary wastewater would be generated by construction personnel and also by facility staff during preoperational testing. Process wastewater could also be generated during construction, associated with facility cold-startup and testing of auxiliary systems as construction progresses (e.g., cooling towers). The site selected would use existing infrastructure; nearby wastewater treatment facilities would be used to the extent possible, supplemented by portable or temporary facilities during construction, as necessary. The potential impact on water resources would depend on the availability and capacity of appropriate treatment facilities. All wastewater would be disposed of in accordance with applicable regulatory requirements with discharges to surface waters in accordance with National Pollutant Discharge Elimination System (NPDES) effluent limitations.

Ground disturbance and runoff from denuded areas could potentially impact surface water quality near construction areas (Section 4.5.1.1.6). However, appropriate spill prevention practices and soil erosion and sediment control measures (e.g., silt fences, mulching disturbed areas) would be employed during construction to minimize water quality impacts.

Some locations on a generic DOE site could potentially be affected by flooding requiring appropriate siting decisions (Section 3.6.4). Applicable regulatory requirements would be followed in siting facilities including Executive Order 11988, *Floodplain Management*.

Although specific impacts on water resources cannot be determined at this time, site-specific analysis would be conducted in tiered NEPA documentation if the accelerator(s) alternative were selected.

#### 4.5.1.1.5 Geology and Soils

Construction of the high-energy accelerator would disturb a total of approximately 20.2 hectares (50 acres) of land, with construction of the low-energy accelerator disturbing about 4 hectares (10 acres) of land (TechSource 2000). Construction of the support facility would disturb an additional 2.4 hectares (6 acres) of land (Herrington 2000; SAIC 2000). Construction impacts on geologic and soil resources cannot be determined at this time since they are site specific in nature. However, impacts would be expected to be less if previously disturbed land were used than if an undeveloped area were selected for construction.

In general, construction activities would likely require appreciable quantities of sand and gravel and possibly other geologic materials and, depending on the site chosen, could temporarily deplete local deposits or stockpiles of these materials. Soil erosion potential is also closely related to the amount of land disturbed.

As discussed in Section 3.6.5, the proposed facilities could be located at a generic DOE site with seismic activity ranging from low to moderate. Known capable faults could be located within 19 kilometers (12 miles). However, no known large-scale geologic conditions are present at any generic DOE site that would preclude the construction and operation of properly designed facilities. Appropriate activities and subsurface investigations would be conducted to identify geologic hazards including seismic and volcanic features and other natural hazards (landslide areas, sinkholes, unstable soils) as part of the site selection process. As stated in DOE Order 420.1, DOE requires that nuclear or nonnuclear facilities be designed, constructed, and operated so that the public, the workers, and the environment are protected from the adverse impacts of natural phenomena hazards, including earthquakes. DOE Order 420.1, Section 4.4, as supplemented by DOE Guide 420.1-2, stipulates the natural phenomena hazards mitigation requirements for DOE facilities. Further, the natural phenomena hazards mitigation requirements of DOE Order 420.1 are consistent with the guidance for seismic design and construction contained in the National Earthquake Hazards Reduction Program 1997 provisions (BSSC 1997). In addition, DOE Guide 420.1-2 was recently issued to recognize the consolidation of the three previous U.S. model building codes, including the Uniform Building Code, into the *International Building Code* (ICC 2000). The DOE requirements for seismic engineering have followed the Uniform Building Code, unless the importance of achieving a high level of protection warrants the use of more demanding methods and criteria (DOE Guide 420.1-2). Thus, new facilities would be designed and sited in accordance with DOE Order 420.1.

Site-specific analysis would be conducted in tiered NEPA documentation if the accelerator(s) alternative were selected.

#### 4.5.1.1.6 Ecological Resources

If the accelerator(s) alternative were selected, tiered NEPA documentation would be undertaken to determine the exact nature of construction impacts on ecological resources. During that process, impacts on individual species and habitats that are sensitive to disturbance would be determined. This would include consideration of wetlands and threatened and endangered species. Wetland delineations and consultation with the U.S. Fish and Wildlife Service and state wildlife agency would take place, as necessary, to ensure that these resources would be protected.

Construction impacts on ecological resources are site specific. The nature of these impacts would be expected to vary depending on whether the site was located in the eastern or western portion of the United States. In fact, depending on the site location, impacts on some resources may not occur. Additionally, construction impacts on ecological resources would depend on whether the selected location was within an already disturbed portion of the site. In general impacts on terrestrial resources, wetlands, aquatic resources, and threatened and endangered species described below are applicable to an undeveloped site.

**Terrestrial Resources.** The construction of a low-energy accelerator, a high-energy accelerator, and a support facility would require 4 hectares (10 acres), 20.2 hectares (50 acres), and 2.4 hectares (6 acres), respectively (Herrington 2000; TechSource 2000; SAIC 2000). If these facilities were constructed at an undeveloped location, it is likely that woodland habitat would be lost at an eastern generic DOE site and shrubland would be disturbed at a western site. Land clearing activities would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area were already supporting the maximum number of individuals, the additional animals would compete for limited resources that could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the disturbed area may not survive.

**Wetlands.** Clearing and grading operations could result in the direct loss of wetlands, although proper placement of the accelerator(s) and support facility within the overall generic DOE site would eliminate or reduce the potential for such loss. Indirect impacts could also result from stormwater runoff carrying sediments to wetlands located adjacent to the site. Changes in hydrology, water quality, and soils could occur as a result of alterations in water levels, runoff, and the buildup of sediments. These changes could, in turn, alter the vegetative composition of the wetland. In general, both direct and indirect impacts would be more likely to occur at an eastern site due to the greater abundance of wetlands. If preliminary analysis determined that wetlands could be impacted by development, a wetland delineation would be required. Impacts on wetlands could also lead to the implementation of mitigation measures.

**Aquatic Resources.** During construction of the accelerator(s) and a support facility, impacts on aquatic resources could result from stormwater runoff. Runoff could alter flow rates, increase turbidity, and lead to sedimentation of streambeds. These impacts could, in turn, cause temporary and permanent changes in species composition and density, and alter breeding habitats. The implementation of erosion and sediment control procedures would lessen construction impacts.

**Threatened and Endangered Species.** The construction of one or two accelerators and a support facility would have the potential to impact threatened and endangered species. Sources of impacts would be similar to those discussed above for terrestrial resources, wetlands, and aquatic resources. The primary difference is that the resource of concern involves individual species that are sensitive to disturbance and whose existence may be threatened by development. Consultations with the U.S. Fish and Wildlife Service and appropriate state agency would be conducted at the site-specific level, as appropriate.

#### **4.5.1.1.7 Cultural and Paleontological Resources**

The construction of a low-energy accelerator, a high-energy accelerator, and a support facility would require 4 hectares (10 acres), 20.2 hectares (50 acres), and 2.4 hectares (6 acres), respectively (SAIC 2000; TechSource 2000). Since the exact nature of the construction site for any of these facilities is not known at this time (e.g., whether it has previously been disturbed or not), potential effects on cultural resources cannot be determined. In general, if a location in a previously developed portion of a DOE generic site were selected, impacts on cultural resources may not occur. However, if an undisturbed location were chosen, cultural resources could be impacted. If the accelerator(s) alternative were selected, prehistoric and historic resources, including those that are or may be eligible for listing on the National Register of Historic Places, would be identified. These resources would be identified through site surveys and consultation with the State Historic Preservation Officer. Specific concerns about the presence, type, and location of Native American resources would be addressed through consultation with the potentially affected tribes in accordance with the *National Historic Preservation Act*, the *Native American Graves Protection and Repatriation Act*, and the *American Indian Religious Freedom Act*.

#### **4.5.1.1.8 Socioeconomics**

It is estimated that 410 workers would be needed to construct the new accelerator(s) and a support facility at a generic DOE site during the peak year of construction. The impact from this influx of workers upon the site's region of influence and regional economic area would depend on whether the site were located near a large urbanized area or in a remote rural area. Since the population for the region of influence for a generic site could range from nearly 2.0 million people for a site in a large metropolitan area, to less than 200,000 for a site in a small rural community, the socioeconomic impacts of constructing new accelerator(s) and a support facility would vary greatly. Therefore, if DOE were to select the new accelerator(s) alternative, additional NEPA documentation would be required to select the specific DOE site to locate the new accelerator(s) and support facility. In that document, DOE would perform a thorough evaluation of the socioeconomic impacts of the sites under consideration.

#### **4.5.1.1.9 Public and Occupational Health and Safety—Normal Construction Activities**

Assessments of incremental radiological and chemical impacts associated with the construction of the new accelerator(s) and support facility are presented in this section. Supplemental information is provided in Appendix H.

**RADIOLOGICAL IMPACTS.** During construction operations, it is not anticipated that there would be any resulting radiological releases to the environment; therefore no additional dose to the public is expected. Furthermore, construction workers are not expected to receive exposures above natural background levels which exist within the construction areas. However, as a precautionary measure, workers would be badged as deemed appropriate.

**HAZARDOUS CHEMICAL IMPACTS.** No hazardous chemical releases have been identified for construction activities. The painting activities would result in very small emissions of noncarcinogenic chemicals, which would produce minimal impact. Therefore, minimal hazardous chemical impacts are associated with construction.

#### **4.5.1.1.10 Public and Occupational Health and Safety—Construction Accidents**

There are no radiological or hazardous chemical accidents postulated during the construction phases of the new accelerator(s) or the support facility. Workers could experience industrial accidents commonly associated with the construction of large facilities.

#### **4.5.1.1.11 Environmental Justice**

Environmental effects due to construction activities that would be expected to occur at an unspecified accelerator(s) and support facility site are addressed in Section 4.5.1.1. The analysis shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected areas would not be significant. Unless there are patterns of food consumption among minority or low-income residents surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that construction activities would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new accelerator(s) and support facility, an additional evaluation of environmental justice at the accelerator(s) and support facility site during construction would be performed prior to implementation.

#### 4.5.1.1.12 Waste Management

The expected generation rates of waste at a generic DOE site that would be associated with the construction of new accelerator(s) to irradiate targets and a support facility to fabricate and process medical and industrial isotope targets and to meet research and development needs are provided in **Table 4–122**. These estimates represent the total amount of waste generated during the construction period. These generation rates cannot be compared at this time with site treatment, storage, and disposal capacities because a DOE site has not yet been chosen for these facilities. Site-specific analyses would be conducted if this alternative were chosen, and appropriate NEPA documentation would be prepared.

**Table 4–122 Estimated Waste Generation Associated with Constructing New Accelerator(s) and Support Facility Under All Options of Alternative 3 (Construct New Accelerator[s])**

Waste Type <sup>a</sup>	Estimated Waste Generation for New Accelerator(s) (total cubic meters)		Estimated Waste Generation for New Support Facility (total cubic meters)
	Low-Energy	High-Energy	
<b>High-level radioactive</b>	0	0	0
<b>Transuranic</b>	0	0	0
<b>Low-level radioactive</b>			
Liquid	0	2	0
Solid	0	115	0
<b>Mixed low-level radioactive</b>	0	6	0
<b>Hazardous</b>			
Liquid	0	4	1
Solid	0	7	3
<b>Nonhazardous</b>			
Process wastewater	0	0	0
Sanitary wastewater	4,500	51,000	16,000
Solid	500	3,900	650

a. See definitions in Section G.9.

**Note:** To convert from cubic meters to cubic yards, multiply by 1.308.

**Source:** SAIC 2000; TechSource 2000.

Section 3.6.11.1 provides DOE site ranges for each waste type that include volume currently stored, projected generation, and for some types of waste, disposal volume. Radiological and chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.5.1.1.9 through 4.5.1.1.10.

#### 4.5.1.2 Operations and Transportation

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

##### 4.5.1.2.1 Land Resources

**LAND USE.** The operation of one or two accelerators and a support facility at a generic DOE site would not be expected to affect land use. This is because none of the anticipated operational impacts (e.g., air emissions) are expected to affect this resource.

REDC would be used for neptunium-237 storage, target fabrication, and processing. The use of REDC for this purpose would not change land use at the site since REDC is currently operating and its proposed use would be compatible with its present mission.

**VISUAL RESOURCES.** The primary source of impacts on visual resources from the operation of one or two accelerators and a support facility would be air emissions. Releases from stacks associated with this alternative would be controlled and, therefore, would be unlikely to exceed Bureau of Land Management Visual Resource Management objectives. However, the operation of cooling towers could result in a visible plume. The extent and visibility of the plume would depend on site meteorological conditions and terrain features. While plume formation would be favored by meteorological conditions at an eastern generic DOE site, terrain features would tend to mask it from offsite locations; the opposite would tend to be true at a western site. If the accelerator(s) alternative were selected, the visual impact of the cooling tower plume would be determined in tiered NEPA documentation.

All activities associated with neptunium-237 storage, target fabrication, and processing would take place within REDC. Operations associated with the proposed activities would not result in any impact on visual resources or change in the current Visual Resource Management Class IV rating of the 7900 Area. This is because none of the anticipated operational impacts (e.g., air emissions) would be expected to affect this resource.

#### 4.5.1.2.2 Noise

The operation of high-energy and/or low-energy accelerators at a generic DOE site would result in some increase in noise levels from equipment (e.g., cooling systems, vents, motors, generators, compressors, pumps, and material-handling equipment), employee vehicles, and truck traffic. Noise from operation activities could disturb wildlife outside the facility fence line. The change in noise levels in areas outside the DOE site would be dependent on the location selected and the equipment. However, generally if the location selected were within one of the larger DOE sites and were more centrally located within the site, offsite noise impacts from operation would be expected to be small. Operation employee vehicles and truck traffic would result in an increase in traffic noise along roads used to access the site. However, this increase in traffic noise would be small unless the operation traffic volume were as large as the existing site traffic. Site-specific analysis would be conducted in tiered NEPA documentation if the accelerator(s) alternative were selected.

The operation of a support facility at a generic DOE site would result in some increase in noise levels from equipment (e.g., cooling systems, vents, motors, generators, compressors, pumps, and material-handling equipment), employee vehicles, and truck traffic. Noise from operation activities could disturb wildlife outside the facility fence line. The change in noise levels in areas outside the DOE site would be dependent on the location selected and the equipment. However, generally if the location selected were within one of the larger DOE sites and were more centrally located within the site, offsite noise impacts from operation would be expected to be small. Operation employee vehicles and truck traffic would result in an increase in traffic noise along roads used to access the site. However, this increase in traffic noise would be small unless the operation traffic volume were as large as the existing site traffic. Site-specific analysis would be conducted in tiered NEPA documentation if the accelerator(s) alternative were selected.

This option also involves using REDC for neptunium-237 target material storage, target fabrication, and processing. Interior modifications of these facilities in the 7900 Area of ORNL would be expected to result in little change in noise impacts on wildlife around this area. The operation of REDC would not result in any change in noise impacts on wildlife around the 7900 Area and offsite noise impacts would be small because the nearest site boundary is 2.5 kilometers (1.6 miles) to the southeast. Operation would be expected to result in a minimal change in noise impacts on people near the ORR as a result of changes in employee and truck traffic levels.

#### 4.5.1.2.3 Air Quality

**High-Energy Accelerator.** The operation of a new high-energy accelerator would result in some increase in air quality impacts due to the operation of emergency diesel generators. Criteria pollutants were modeled and compared to the most stringent standards (**Table 4–123**). The maximum ground-level pollutant concentrations that would result from high-energy accelerator operation would be well below the ambient air quality standards. However, if the accelerator is in an area that already had high background pollutant concentrations, resultant pollutant concentrations could approach or exceed the ambient standards for some pollutants. As a result, regulatory compliance would need to be assessed on case-by-case basis. Hazardous chemical impacts are addressed in Section 4.5.1.2.9.

**Table 4–123 Incremental Concentrations Associated with High-Energy Accelerator Operation<sup>a</sup> Under Alternative 3 (Construct New Accelerator[s])—Option 1**

Pollutant	Averaging Period	Most Stringent Standard or Guideline (microgram per cubic meter) <sup>b</sup>	Modeled Increment (microgram per cubic meter)
Carbon monoxide	8 hours	10,000	94
	1 hour	40,000	135
Nitrogen oxide	Annual	100	0.47
PM <sub>10</sub>	Annual	50	0.03
	24 hours	150	17.7
Sulfur dioxide	Annual	80	0.03
	24 hours	365	16.5
	3 hours	1,300	37.2

- From operation of two emergency diesel generators.
- The more stringent of the Federal and state standards is presented if both exist for the averaging period. The National Ambient Air Quality Standards (NAAQS) (40 CFR Part 50), other than those based on annual averages, are not to be exceeded more than once per year. The annual arithmetic mean PM<sub>10</sub> standard is attained when the expected annual arithmetic mean concentration is less than or equal to the standard.

**Source:** Modeled increments are based on the SCREEN3 computer code (EPA 1995); TechSource 2000.

Modeling was based on design consideration of two emergency diesel generators. These were modeled as a point source with emissions occurring at a stack height of 3 meters (9.8 feet). A boundary limit of 3,200 meters (2 miles) was assumed for a generic site.

Air quality impacts at ORR from target fabrication and processing associated with this option were determined to be the same as described for Alternative 2, Option 1 (Section 4.4.1.1.3).

**Low-Energy Accelerator.** The operation of a low-energy accelerator would not require emergency diesel generators. Thus, there would be no increase in air quality impacts due to the operation of the low-energy accelerator.

**Support Facility for Accelerator(s).** The operation of the support facility would result in air pollutant emissions similar to FMEF operating in support of FFTF. Thus, there would be an increase in air quality impacts that would be assessed and appropriate NEPA documentation prepared if this option were selected for implementation.

#### 4.5.1.2.4 Water Resources

The estimated effects on key water resource indicators associated with operating the new accelerator(s) and support facility are presented in **Table 4–124**. Operation of the high-energy accelerator at a generic DOE site

would have the highest estimated water demand of any facility considered, requiring 1,904 million liters (503 million gallons) of water per year. In general, water would be required by the high-energy accelerator and other facilities to support such uses as process cooling, material processing, and potable and sanitary needs with the high water use of the high-energy accelerator attributable to cooling tower operation. The exact impact of these withdrawals on the resource would depend on the water source (surface water or groundwater) and its relative abundance. These factors would be used to determine the impact on the local and/or regional availability of the resource. For surface water, a dedicated surface water intake may have to be constructed if the generic site's existing distribution system is inadequate to meet the increased demands of the facilities. For groundwater, additional wells may have to be developed to supply the facilities (particularly the high-energy accelerator) directly or to provide increased production capacity for the generic site's existing supply system.

**Table 4-124 Estimated Water Use and Wastewater Generation Associated with Operating Accelerator(s) and Support Facility Under Alternative 3 (Construct New Accelerator[s])—Option 1**

Indicator (million liters per year)	Accelerators		New Support Facility
	Low-Energy	High-Energy	
Water use	1.9	1,904	6.92
Process wastewater generation	0	284	0.016 <sup>a</sup>
Sanitary wastewater generation	0.9	11.4	6.91

a. Assume process wastewater generated at the same incremental rate as the Hanford 300 Area facilities (RPL/306-E).

**Note:** To convert from liters per year to gallons per year, multiply by 0.264.

**Source:** SAIC 2000; TechSource 2000.

The operation of the high-energy accelerator is estimated to generate approximately 284 million liters (75 million gallons) of process wastewater per year. This process effluent would mainly consist of cooling tower blowdown. The operation of the low-energy accelerator would not generate process wastewater as process cooling water would be recirculated within a closed-loop system. The support facility would generate a very small quantity of process wastewater mainly as a result of material processing. There would be no radiological liquid effluent discharge to the environment under normal operations. Sanitary wastewater would be generated as a result of operation of the accelerator(s) and support facility based on facility staff use of lavatory, shower, and kitchen facilities, and from miscellaneous potable and sanitary uses. Waste management activities and their effects are further detailed in Section 4.5.1.2.13. The potential impact on water resources would depend on the availability and capacity of appropriate treatment facilities. Process and sanitary wastewater would be discharged to either existing site wastewater treatment facilities or to new facilities constructed specifically to serve the proposed facilities. All wastewater would be disposed of in accordance with applicable regulatory requirements with discharges to surface waters in accordance with NPDES effluent limitations.

Although specific impacts on water resources cannot be determined at this time, site-specific analysis would be conducted in tiered NEPA documentation if the accelerator(s) alternative were selected.

REDC, an existing facility in the 7900 Area of ORNL at ORR, would be used for neptunium-237 storage, target fabrication, and processing in support of plutonium-238 production with impacts on ORR water resources indicators the same as those described in Section 4.3.1.1.4. In summary, a small increase in water use and sanitary wastewater generation is anticipated, mainly attributable to increased staffing levels. Also, there would be a very small increase in process wastewater generation, but there would be no radiological liquid effluent discharge to the environment under normal operations.

#### **4.5.1.2.5 Geology and Soils**

The operation of the accelerator(s) and support facility would not be expected to result in impacts on geologic and soils resources at a generic DOE site. If cooling towers are used, the potential exists for salt deposition to alter soil chemistry. While high rainfall at an eastern site would tend to keep salt from accumulating in the soil, the potential exists that salt could accumulate at a western site where rainfall is sparse. If the accelerator(s) alternative were selected, impacts on geology and soils would be determined in tiered NEPA documentation. As discussed in Section 4.5.1.1.5, the proposed facilities would be designed and constructed in accordance with DOE Order 420.1 and sited to minimize the risk from geologic hazards. Thus, site geologic conditions would be unlikely to affect the facilities.

The use of REDC for neptunium-237 storage, target fabrication, and processing would not be expected to impact either geologic or soil resources, nor be jeopardized by large-scale geologic conditions. Hazards from large-scale geologic conditions at ORR, such as earthquakes, volcanoes, and sinkholes, were previously evaluated in the *Storage and Disposition PEIS* (DOE 1996a:4-260) as discussed in Section 4.2.2.2.5. The analysis determined that these hazards present a low risk to long-term storage facilities. Further review of the data and analyses presented in that document and the site-specific data presented in this NI PEIS indicates that the large-scale geologic conditions likewise present a low risk to REDC operations.

As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards will be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.5.1.2.6 Ecological Resources**

If the accelerator(s) alternative were selected, tiered NEPA documentation would be undertaken to determine the exact nature of operational impacts on ecological resources. During this process, impacts on individual species and habitats that are sensitive to disturbance would be determined. This would include consideration of wetlands and threatened and endangered species.

While the exact nature of operational impacts on ecological resources cannot be determined until a specific site is selected, certain general types of impacts are possible. The nature and extent of these impacts would be expected to vary depending on whether the selected site was located in the eastern or western portion of the United States.

**Terrestrial Resources.** Activities associated with operations, such as noise and human presence, could affect wildlife living adjacent to the accelerator(s) and support facility. These disturbances could cause some species to move from the area. Preventing workers from entering undisturbed areas would minimize impacts on wildlife living adjacent to the facilities. Emissions to the air and water, both nonradiological and radiological, could impact both plants and animals. Plants and animals could be exposed to pollutants via a number of pathways including direct exposure, contact with contaminated soil, ingestion, and inhalation. Further, bioaccumulation could affect species that consume exposed plants or animals. While regulatory limits would act to limit the effects of air emissions and effluent discharges, impacts would be analyzed once site and facility specific information became available.

**Wetlands.** Impacts from the operation of one or two accelerators and a support facility at a western generic DOE site would not be expected to affect wetlands since discharges would be to an evaporation pond. At an eastern site, wastewater and cooling tower blowdown would be discharged to an onsite water body. While these discharges would be through permitted outfalls, the potential exists that wetlands could be affected. Potential impacts, such as changes in water levels and plant species composition, would depend on outfall location, water volume, discharge temperature, and water chemistry. Since these factors depend on site

location and facility engineering design, operational impacts on onsite wetlands would have to be analyzed once these factors are known.

**Aquatic Resources.** Operational impacts on aquatic resources at a western site would not be expected because groundwater would be used and wastewater and cooling tower blowdown would be discharged to an evaporation pond. At an eastern site, potential impacts on aquatic resources could occur as a result of water withdrawal and discharge. Water withdrawal could lead to the loss of aquatic organisms through impingement and entrainment. The discharge of cooling water could result in alterations in aquatic communities. Alterations could include changes in aquatic vegetation and the loss of fish and benthic macroinvertebrates. Additionally, radionuclides and chemicals in the discharge water have the potential to impact aquatic organisms. The extent of potential impacts on the aquatic environment would depend on site and facility specific information.

**Threatened and Endangered Species.** The operation of one or two accelerators and a support facility would have the potential to impact threatened and endangered species. Sources of impacts would be similar to those discussed above for terrestrial resources, wetlands, and aquatic resources. The primary difference is that the resources of concern involve individual species that are sensitive to disturbance and whose existence may be threatened by development.

REDC would be used for neptunium-237 storage, target fabrication, and processing. As noted in Section 4.5.1.2.2, wildlife would not be adversely affected by noise associated with facility operation. There would be no change in impacts on wetlands or aquatic resources because additional water usage and wastewater discharge would be small fractions of current values. Further, this option would not result in any new contaminants in existing discharges (Section 4.5.1.2.4). No threatened and endangered species have been identified within the 7900 Area; therefore, operational impacts on this resource are not expected.

Consultation to comply with Section 7 of the Endangered Species Act was conducted with the U.S. Fish and Wildlife Service (see Table 5–3) and resulted in the Service concluding that it does not anticipate adverse effects to federally listed endangered species that occur near the project area. DOE has also consulted with the Tennessee Department of Environment and Conservation; a response concerning state-listed species is pending from this agency. Although no state-listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at ORR prior to the receipt of input from the state.

#### 4.5.1.2.7 Cultural and Paleontological Resources

Impacts on cultural and paleontological resources from the operation of one or two accelerators and a support facility at a generic DOE site would depend on the relative location of such resources to the site and/or transportation routes. While impacts would be expected to be nonexistent or small, they cannot be ruled out. For example, noise related to plant operation or traffic to and from the facility or alterations in the viewshed could adversely affect visitor enjoyment of an historic site. Since impacts on cultural resources are site dependent, specific operational impacts cannot be determined until a site were selected. The operation of the accelerator(s) and support facility would not be expected to impact paleontological resources.

The operation of REDC for neptunium-237 storage, target fabrication, and processing would not affect the status of cultural and paleontological resources at ORR. The Graphite Reactor, which is located within ORNL, is listed on the National Register of Historic Places as a National Historic Landmark. Additionally, several other structures proposed for listing on the National Register of Historic Places are found within or near ORNL. However, neither the Graphite Reactor nor any of the other structures is located within the 7900 Area, thus, the use of REDC for target fabrication and processing would not change their status.

Consultation to comply with Section 106 of the National Historic Preservation Act was initiated with the State Historic Preservation Office (see Table 5–3). While DOE has made additional contact with the State Historic Preservation Office, a response is pending from this office. Although impacts to cultural resources are not expected as a result of the proposed action, no action would be taken relative to the use of facilities at ORR prior to the receipt of input from the State Historic Preservation Office.

#### **4.5.1.2.8 Socioeconomics**

It is estimated that 325 workers would be needed to operate the new accelerator(s) and support facility at a generic DOE site. The impact from this influx of workers upon the site's region of influence and regional economic area would depend on whether the site were located near a large urbanized area or in a remote rural area. Since the population for the region of influence for a generic site could range from nearly 2.0 million people for a site in a large metropolitan area, to less than 200,000 for a site in a small rural community, the socioeconomic impacts of operating a new accelerator and support facility would vary greatly. Therefore, if DOE were to select this option, additional NEPA documentation would be required to determine the specific socioeconomic impacts.

The socioeconomic impacts associated with neptunium-237 target fabrication and processing at ORR are addressed in Section 4.3.1.1.8.

#### **4.5.1.2.9 Public and Occupational Health and Safety—Normal Operations**

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from startup and operations are given in **Table 4–125** for the generic DOE site and ORR: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

**Table 4–125 Incremental Radiological Impacts on the Public Around the Generic DOE Site and ORR from Operational Facilities Under Alternative 3 (Construct New Accelerator[s])—Option 1**

Receptor	ORR REDC	Accelerators Preoperational Startup <sup>a</sup>		Generic Site Operations				Two- Site Total
		Low-Energy	High-Energy	Accelerators		Accelerator(s) Support Facility	Total	
				Low-Energy	High- Energy			
<b>Population within 80 kilometers (50 miles) in the year 2020</b>								
Dose (person-rem)	$8.8 \times 10^{-5}$	0.0024	0.035	0.0043	0.055	0.14	0.20	0.20
35-year latent cancer fatalities	$1.5 \times 10^{-6}$	$2.4 \times 10^{-6(b)}$	$3.5 \times 10^{-5(b)}$	$7.5 \times 10^{-5}$	$9.6 \times 10^{-4}$	0.0025	0.0035	0.0035
<b>Maximally exposed individual</b>								
Annual dose (millirem)	$1.9 \times 10^{-6}$	$1.4 \times 10^{-5}$	$1.8 \times 10^{-4}$	$1.1 \times 10^{-4}$	$8.7 \times 10^{-4}$	0.0025	0.0035	NA <sup>c</sup>
35-year latent cancer fatality risk	$3.3 \times 10^{-11}$	$1.4 \times 10^{-11(b)}$	$1.8 \times 10^{-10(b)}$	$1.9 \times 10^{-9}$	$1.5 \times 10^{-8}$	$4.4 \times 10^{-8}$	$6.1 \times 10^{-8}$	NA <sup>c</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>								
Annual dose <sup>d</sup> (millirem)	$7.8 \times 10^{-8}$	$1.6 \times 10^{-6}$	$2.3 \times 10^{-5}$	$2.8 \times 10^{-6}$	$3.6 \times 10^{-5}$	$9.1 \times 10^{-5}$	$1.3 \times 10^{-4}$	NA <sup>c</sup>
35-year latent cancer fatality risk	$1.4 \times 10^{-12}$	$1.6 \times 10^{-12(b)}$	$2.3 \times 10^{-11(b)}$	$4.9 \times 10^{-11}$	$6.3 \times 10^{-10}$	$1.6 \times 10^{-9}$	$2.3 \times 10^{-9}$	NA <sup>c</sup>

a. For conservatism as well as consistency with other radiological impacts evaluated in this NI PEIS, these values were assessed for the year 2020 even though these activities would commence prior to that year.

b. Preoperational activities last 2 years. Number is a 2-year latent cancer fatality risk.

c. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.

d. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of REDC or the generic site in the year 2020 (1,134,200 and 1,538,100, respectively).

**Key:** NA, not applicable.

**Source:** SAIC 2000; TechSource 2000; model results, using the GENII computer code (Napier et al. 1988).

As a result of annual operations of the accelerator facilities (a high-energy accelerator, a low-energy accelerator, and an accelerator support facility) and REDC, the projected incremental total population dose in the year 2020 would be 0.20 person-rem; the corresponding number of latent cancer fatalities in the populations surrounding the generic DOE site and ORR from 35 years of operations would be 0.0035. The incremental total dose to the maximally exposed member of the public from annual operations of the accelerator(s) and support facility at the generic site would be 0.0035 millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $6.1 \times 10^{-8}$ . Estimated annual risks are also presented for preoperational testing and startup phase activities anticipated for the accelerator(s) and support facility. The incremental dose to the maximally exposed member of the public from annual REDC operations would be  $1.9 \times 10^{-6}$  millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $3.3 \times 10^{-11}$ .

Incremental doses to involved workers from normal operations are given in **Table 4–126**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to the high-energy and low-energy accelerator workers during startup and operations would be 150 millirem; for support facility workers, the incremental annual average dose operations would be 114 millirem for REDC workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities is estimated to be 30 (high-energy accelerator startup and operation), 15 (low-energy accelerator startup and operation), 11 (support facility operation), and 12 person-rem (REDC operation). The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–126. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–126 Incremental Radiological Impacts on Involved Workers at the Generic DOE Site and ORR from Operational Facilities Under Alternative 3 (Construct New Accelerator[s])—Option 1**

Receptor—Involved Workers <sup>a</sup>	ORR REDC	Accelerators Preoperational Startup		Generic Site Operations			Two-Site Total
		Low-Energy	High-Energy	Accelerators		Accelerator(s) Support Facility	
				Low-Energy	High-Energy		
Total dose (person-rem per year)	12 <sup>b</sup>	23 <sup>b</sup>	45 <sup>b</sup>	15 <sup>b</sup>	30 <sup>b</sup>	11 <sup>b</sup>	69
35-year latent cancer fatalities	0.17	0.018 <sup>c</sup>	0.036 <sup>c</sup>	0.21	0.42	0.16	0.96
Average worker dose (millirem per year)	170	150	150	150	150	114	NA <sup>d</sup>
35-year latent cancer fatality risk	0.0023	1.2×10 <sup>-4(c)</sup>	1.2×10 <sup>-4(c)</sup>	0.0021	0.0021	0.0016	NA <sup>d</sup>

- a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that facilities adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.
- b. Based on an estimated 75 badged workers at ORR REDC, 90 radiological workers (and 100 total workers) at the accelerator(s) support facility, 200 workers at the high-energy accelerator (300 during startup), and 100 workers at the low-energy accelerator (150 during startup).
- c. Preoperational startup testing lasts 2 years. Number is a 2-year latent cancer fatality risk.
- d. Values cannot be given for the average worker because the workers would be in three different facilities at two different sites.

**Key:** NA, not applicable.

**Source:** DOE 1999b; Nielsen 1999; Wham 1999b, 2000.

## HAZARDOUS CHEMICALS IMPACTS

**High-Energy Accelerator.** The operation of a high-energy accelerator would result in some increase in emissions of hazardous chemicals from diesel fuel burning equipment used for operation. The operation of the accelerator would require the emergency diesel generators to be tested approximately 1 hour each month and 12 hours once a year to ensure operability. Chemical releases were modeled based on 48 hours of operation. The source was modeled as a point source with emissions occurring at a stack height of 3 meters (9.8 feet). A boundary limit of 3,200 meters (2 miles) was assumed for a generic site. Resulting concentrations were determined to be very small and would have no incremental impact on the current conditions at the site (**Table 4–127**).

Hazardous chemical impacts at ORR from target fabrication and processing associated with this option were determined to be the same as described in Option 1 under Alternative 2 (Section 4.4.1.1.9).

**Low-Energy Accelerator.** The operation of a low-energy accelerator would not require emergency diesel generators. Thus, there would be no increase in hazardous chemical impacts due to the operation of the low-energy accelerator.

**Support Facility for Accelerator(s).** The operation of the support facility would result in air pollutant emissions similar to FMEF operating in support of FFTF. Thus, there would be an increase in hazardous chemical impacts that would be assessed and appropriate NEPA documentation prepared if this option were selected for implementation.

**Table 4–127 Incremental Hazardous Chemical Impacts on the Public Around a Generic Site from High-Energy Accelerator Operation Under Alternative 3 (Construct New Accelerator[s])—Option 1**

Chemicals	Modeled Annual Increment (microgram per cubic meter)	RfC (microgram per cubic meter)	Unit Cancer Risk (Risk per Microgram per cubic meter)	Hazard Quotient	Cancer Risk
Acetaldehyde	0.0000811	NA	$2.20 \times 10^{-6}$	NA	$1.79 \times 10^{-10}$
Benzene	0.0000987	NA	$7.80 \times 10^{-6}$	NA	$7.70 \times 10^{-10}$
Formaldehyde	0.000125	NA	$1.30 \times 10^{-5}$	NA	$1.62 \times 10^{-9}$
Toluene	0.0000433	400	NA	$1.08 \times 10^{-7}$	NA
Propylene	0.000273	NA	$3.70 \times 10^{-6}$	NA	$1.01 \times 10^{-9}$

**Note:** Propylene oxide cancer unit was used for propylene.

**Key:** RfC, Reference concentration; NA, not applicable; The chemical is not a known carcinogen, or it is a carcinogen and only unit cancer will apply.

**Source:** Data from TechSource 2000; EPA 1999; modeled increments are based on the SCREEN3 computer code (EPA 1995).

#### 4.5.1.2.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with accelerator target irradiation; support facility fabrication and processing of medical, industrial, and research and development isotopes; and REDC target fabrication and processing of neptunium-237 targets are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–128** and **4–129**, respectively.

For 35 years of high-energy accelerator target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.05 \times 10^{-6}$  and  $5.15 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0063.

For 35 years of low-energy accelerator target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.45 \times 10^{-9}$  and  $3.07 \times 10^{-8}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $3.66 \times 10^{-5}$ .

For 35 years of medical, industrial, and research and development target fabrication and processing at the support facility, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $3.26 \times 10^{-5}$  and  $9.85 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.056.

For 35 years of neptunium-237 target fabrication and processing at REDC, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $5.71 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.157.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $9.18 \times 10^{-5}$  and  $5.00 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.219.

**Table 4-128 New Accelerator(s), Support Facility, and REDC Accident Consequences Under Alternative 3 (Construct New Accelerator[s])—Option 1**

Accident	Maximally Exposed Individual		Population to 80 kilometers (50 miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
<b>High-energy accelerator accidents</b>						
Design-basis target accident	2.93×10 <sup>-4</sup>	1.47×10 <sup>-7</sup>	0.980	4.90×10 <sup>-4</sup>	9.35×10 <sup>-4</sup>	3.74×10 <sup>-7</sup>
Beyond-design-basis earthquake	11.7	0.00585	3.01×10 <sup>4</sup>	18	184	0.147
<b>Low-energy accelerator accidents</b>						
Design-basis target accident	8.05×10 <sup>-5</sup>	4.03×10 <sup>-8</sup>	17.7	0.00885	0.00112	4.48×10 <sup>-7</sup>
Beyond-design-basis earthquake	0.0132	6.60×10 <sup>-6</sup>	32.4	0.0162	0.208	8.32×10 <sup>-5</sup>
<b>Support facility accidents</b>

<b>Annual support facility risks</b>			
Medical and industrial isotopes localized solvent fire (0.044)	$4.32 \times 10^{-7}$	$6.91 \times 10^{-4}$	$9.41 \times 10^{-8}$
Medical and industrial isotopes unlikely seismic event (0.01)	$3.75 \times 10^{-7}$	$6.80 \times 10^{-4}$	$2.04 \times 10^{-6}$
Medical and industrial isotopes glovebox explosion ( $1.00 \times 10^{-4}$ )	$1.25 \times 10^{-7}$	$2.30 \times 10^{-4}$	$6.80 \times 10^{-7}$
<b>35-year support facility risk</b>	$3.26 \times 10^{-5}$	0.056	$9.85 \times 10^{-5}$
<b>Annual REDC risks</b>			
Ion exchange explosion during neptunium-237 target fabrication (0.01)	$3.06 \times 10^{-14}$	$4.29 \times 10^{-10}$	$2.24 \times 10^{-15}$
Target dissolver tank failure during plutonium-238 separation (0.01)	$8.79 \times 10^{-13}$	$9.82 \times 10^{-9}$	$6.74 \times 10^{-14}$
Ion exchange explosion during plutonium-238 separation (0.01)	$2.34 \times 10^{-9}$	$2.61 \times 10^{-5}$	$1.79 \times 10^{-10}$
Processing facility beyond-design-basis earthquake ( $1 \times 10^{-5}$ )	$1.63 \times 10^{-6}$	0.00445	$1.00 \times 10^{-5(c)}$
<b>35-year REDC risk</b>	$5.71 \times 10^{-5}$	0.157	$3.50 \times 10^{-4(c)}$
<b>35-year Option risk</b>	$9.18 \times 10^{-5}$	0.219	$5.00 \times 10^{-4}$

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. Risk of an early fatality.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

There are no hazardous chemical accidents associated with the new accelerator(s) or new support facility. The irradiation of neptunium-237, medical, industrial, and research and development isotopes in the new accelerator(s) would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The fabrication and processing of medical, industrial, and research and development isotopes at the new support facility would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The hazardous chemical accident impacts at REDC are the same as those presented in Section 4.4.4.1.10.

#### 4.5.1.2.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the REDC target fabrication facility at ORR. DOE would transport the unirradiated neptunium-237 targets from REDC to the accelerator(s) site. Following

irradiation in the accelerator(s), the targets would be returned to REDC for processing. After this processing, the plutonium-238 product would be shipped to LANL. Additionally, medical and industrial isotopes would be shipped from the accelerator(s) site to a local airport, and from there to locations throughout the country.

Approximately 37,000 shipments of radioactive materials would be made by DOE in support of the low-energy accelerator. The total distance traveled on public roads by trucks carrying radioactive materials would be 4.8 million kilometers (3.0 million miles); and in the air carrying medical and industrial isotopes, 23 million kilometers (14 million miles).

Approximately 269 shipments of radioactive materials would be made by DOE in support of the high-energy accelerator. The total distance traveled on public roads by trucks carrying radioactive materials would be 0.94 million kilometers (0.59 million miles).

The transportation impact analysis is described in detail in Appendix J.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION FOR THE LOW-ENERGY ACCELERATOR.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 15 person-rem; the dose to the public, 7 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.0059 latent cancer fatality among transportation workers and 0.0037 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.02.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION FOR THE HIGH-ENERGY ACCELERATOR.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 5 person-rem; the dose to the public, 101 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.0020 latent cancer fatality among transportation workers and 0.050 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.0022.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION FOR THE LOW-ENERGY ACCELERATOR.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: more than 1 in 10 million per year) would not breach the transportation package. The consequences of more severe accidents that could breach the transportation package and release radioactive material were evaluated and estimated to have probabilities of less than 1 in 10 million per year.

Estimates of the total ground transportation accident risks under this option are as follows: a radiological dose to the population of 1,063 person-rem, resulting in 0.53 latent cancer fatality; and traffic accidents resulting 0.11 traffic fatality.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION FOR THE HIGH-ENERGY ACCELERATOR.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FDPF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 was also evaluated and estimated to have a probability of less than 1 in 10 million per year.

Estimates of the total transportation accident risks under this option are as follows: a radiological dose to the population of 0.16 person-rem, resulting in  $8.1 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.025 traffic fatality.

#### 4.5.1.2.12 Environmental Justice

Under this option, neptunium-237 targets would be irradiated in one or two new accelerators that would be constructed at a site yet to be specified. Fabrication and processing of neptunium-237 targets for plutonium-238 production would be performed at REDC located at ORR. A new support facility would be constructed at the same unspecified site for fabrication and processing targets not used for plutonium-238 production.

Activities at REDC were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.1.1.12) and found to pose no significant radiological or other risks to minority and low-income populations. The environmental analysis of operations at the new accelerator(s) and support facility site shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected area would not be significant. Unless there are patterns of food consumption among minority or low-income residents surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that operations at the site would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site-specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specified site selected for the new accelerator(s) and support facility, an additional evaluation of environmental justice at the accelerator(s) and support facility site during operation would be performed prior to implementation.

#### 4.5.1.2.13 Waste Management

The expected annual generation of waste that would be generated from the operation of new accelerator(s) to irradiate targets and a support facility to fabricate and process medical and industrial isotope targets and to meet research and development needs are provided in **Table 4-130**. These generation rates cannot be compared at this time with site treatment, storage, and disposal capacities because a DOE site has not yet been chosen for these facilities. Section 3.6.11.1 provides DOE site ranges for each waste type that include volume currently stored, projected generation, and for some types of waste, disposal volume. Radiological and chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.5.1.2.9 through 4.5.1.2.11.

In accordance with the Records of Decision for the *Waste Management PEIS* (DOE 1997a), waste could be treated and disposed of on site or at other DOE sites or commercial facilities. No high-level radioactive waste or transuranic waste would be generated from irradiating targets in the new accelerator(s) or from target fabrication or processing in the new support facility.

**Table 4–130 Estimated Waste Generation Rates of Operating New Accelerator(s) and Support Facility Under Alternative 3 (Construct New Accelerator[s])—Option 1**

Waste Type <sup>a</sup>	Estimated Waste Generation for New Accelerator(s) (cubic meters per year)		Estimated Waste Generation for New Support Facility (cubic meters per year)
	Low-Energy	High-Energy	
<b>High-level radioactive</b>	0	0	0
<b>Transuranic</b>	0	0	0
<b>Low-level radioactive</b>			
Liquid	0	1	0
Solid	5	54	20
<b>Mixed low-level radioactive</b>	0.20	3	4
<b>Hazardous</b>	0.10	2	<1
<b>Nonhazardous</b>			
Process wastewater	0	280,000	16 <sup>b</sup>
Sanitary wastewater	910	11,300	6,900
Solid	8	31	80

a. See definitions in Section G.9.

b. Assume process wastewater generated at the same incremental rate as the Hanford 300 Area facilities (RPL/306-E).

**Note:** To convert from cubic meters to cubic yards, multiply by 1.308, < mean “less than.”

**Source:** SAIC 2000; TechSource 2000.

Currently, DOE sites that manage low-level radioactive waste treat and/or dispose of the waste on site or off site, either at another DOE facility or a commercial facility. The low-level radioactive waste and mixed low-level radioactive waste Record of Decision issued on February 18, 2000 (65 FR 10061), states that for the management of low-level radioactive waste, minimal treatment will be performed at all sites, and disposal will continue, to the extent practicable, on site at INEEL, LANL, ORR, and SRS. In addition, Hanford and the Nevada Test Site will be available to all DOE sites for low-level radioactive waste disposal. An estimated 35 cubic meters (46 cubic yards) of liquid low-level radioactive waste and 2,100 cubic meters (2,750 cubic yards) of solid low-level radioactive waste would be generated over a 35-year period as a result of target irradiation at the new accelerator(s). Target fabrication and processing at the new support facility would generate about 700 cubic meters (920 cubic yards) of solid low-level radioactive waste. The minor amounts of low-level radioactive waste (less than 10 cubic meters [13.1 cubic yards]) (Brunson 1999a) generated from the decontamination of the shipping containers used to transport neptunium-237 from SRS to REDC (or FDPF or FMEF, depending on the option) for storage could easily be managed under the existing waste management practices and are not included in the table.

Most of DOE’s mixed low-level radioactive waste is being stored on site awaiting the development of treatment methods. DOE is subject to the requirements mandated by the Federal Facility Compliance Act of 1992, and most DOE facilities that currently store or generate mixed low-level radioactive waste have either a state-approved or EPA region-approved site treatment plan or another type of agreement. Each site treatment plan or agreement requires the treatment of mixed waste, including mixed low-level radioactive waste, in accordance with its provisions. The low-level radioactive waste and mixed low-level radioactive waste Record of Decision, issued on February 18, 2000 (65 FR 10061), states that mixed low-level radioactive waste will be treated at Hanford, INEEL, ORR, and SRS and disposed of at Hanford and the Nevada Test Site. Over the 35-year operational period, an estimated 110 cubic meters (140 cubic yards) of mixed low-level radioactive waste would be generated as a result of target irradiation at the new accelerator(s). Target fabrication and processing at the new support facility would generate about 140 cubic meters (180 cubic yards) of mixed low-level radioactive waste.

The hazardous waste Record of Decision, issued on August 5, 1998 (63 FR 41810), states that most DOE sites will continue to use offsite facilities for the treatment and disposal of major portions of nonwastewater hazardous waste, with ORR and SRS continuing to treat some of their own nonwastewater hazardous waste on site in existing facilities where this is economically favorable. Wastewater, which is about 99 percent of DOE's hazardous waste, is treated on site. An estimated 74 cubic meters (97 cubic yards) of hazardous waste would be generated during the 35-year operational period at the accelerator(s) and less than 35 cubic meters (46 cubic yards) at the new support facility.

DOE currently manages sanitary and industrial waste on a site-by-site basis. Some DOE sites dispose of this waste in onsite landfills that have permits issued by appropriate state agencies, while other sites use commercial landfills (DOE 1997a:1-29). Solid waste such as office paper, metal cans, and plastic and glass bottles that can be recycled would be sent off site for that purpose. Over the 35-year operational period, an estimated 9.8 million cubic meters (12.8 million cubic yards) of process wastewater, 427,000 cubic meters (558,000 cubic yards) of sanitary wastewater, and 1,400 cubic meters (1,800 cubic yards) of solid nonhazardous waste would be generated as a result of target irradiation at the new accelerator(s). Target fabrication and processing at the new support facility would generate about 560 cubic meters (730 cubic yards) of process wastewater, 241,500 cubic meters (316,000 cubic yards) of sanitary wastewater, and 2,800 cubic meters (3,700 cubic yards) of solid nonhazardous waste.

The impacts of managing waste associated with fabricating and processing neptunium-237 targets for plutonium-238 production in REDC at ORR are assumed to be the same as for Option 1 under Alternative 1 (Section 4.3.1.1.13). As shown in that section, the impacts on the waste management systems at ORR would be small.

#### **4.5.1.3 Decontamination and Decommissioning of the Accelerator(s) and Support Facility**

The environmental impacts associated with the decontamination and decommissioning of the accelerator(s) and support facility at the generic DOE site are assessed in this section. If the accelerator(s) were built on a site with existing support facilities, there would be no impacts associated with decommissioning a “new” support facility.

##### **4.5.1.3.1 Land Resources**

**LAND USE.** Decontamination and decommissioning of the accelerator(s) and a support facility would not involve the removal of any major structures, although some smaller facilities and pieces of equipment could be removed. Thus, the industrial nature of the land would not change.

**VISUAL RESOURCES.** Decontamination and decommissioning of the accelerator(s) and a support facility would not impact visual resources since no major structures would be removed. Thus, the Visual Resource Management Class IV rating of the site would remain unchanged.

##### **4.5.1.3.2 Noise**

Decontamination and decommissioning of the high-energy and/or low-energy accelerators and support facility would result in some increase in noise levels from the use of construction type equipment, materials handling and impact equipment, employee vehicles, and truck traffic. Actual noise levels would depend on the decontamination and decommissioning activities selected. Noise from these activities, especially impulsive noise, would be expected to disturb wildlife in the immediate area of the facilities. The change in noise levels in areas outside the DOE site would depend on the location selected and the exact nature of the activities required. However, generally if the accelerator(s) and support facility location were within one of the large

DOE sites and were more centrally located within the site, offsite noise impacts from decontamination and decommissioning would be expected to be small. Employee vehicles and truck traffic would result in an increase in traffic noise along roads used to access the site. However, this increase in traffic noise would be small unless the decontamination and decommissioning traffic volume were as large as the traffic from facility operation and other site activities. Site-specific analysis would be conducted in tiered NEPA documentation if the accelerator(s) alternative were selected.

#### **4.5.1.3.3 Air Quality**

The potential for air quality impacts due to decommissioning and deactivation of the accelerator(s) and support facility would not be expected to be any higher than those associated with their construction and operation. Some decrease in air quality impacts may occur when generators and pumps supporting operations of the accelerator(s) are shut down.

#### **4.5.1.3.4 Water Resources**

Decontamination and decommissioning of the accelerator(s) and support facility would involve permanent shutdown, stabilization, and monitoring of the deactivated facilities. As a result, processing and auxiliary systems would be shutdown and process and sanitary wastewater discharges would cease from the vacated facilities. This would eliminate the annual discharge of approximately 284 million liters (75 million gallons) of nonradioactive process wastewater from the high-energy accelerator and 0.016 million liters (0.004 million gallons) from the support facility to onsite treatment facilities. Also, the discharge of sanitary wastewater to onsite treatment facilities would be eliminated, including 11.4 million liters (3 million gallons) per year from the high-energy accelerator, 0.9 million liters (0.24 million gallons) from the low-energy accelerator, and 6.91 million liters (1.82 million gallons) annually from the support facility. The effects of decontamination and decommissioning on waste management are further detailed in Section 4.5.1.3.13. Site water withdrawals to supply the facilities would also be reduced by an estimated 1,904 million liters (503 million gallons) per year for the high-energy accelerator, 1.9 million liters (0.50 million gallons) for the low-energy accelerator, and 6.92 million liters (1.83 million gallons) annually for the support facility (SAIC 2000; TechSource 2000).

#### **4.5.1.3.5 Geology and Soils**

No major structures would be demolished to effect decontamination and decommissioning of the accelerator(s) and support facility. Some ground disturbance could occur associated with removal of some smaller facilities and pieces of equipment. However, ground disturbance would be confined to previously disturbed areas immediately adjacent to the accelerator(s) and support facility, with the impact on geologic and soil resources expected to be negligible overall.

#### **4.5.1.3.6 Ecological Resources**

Since no major structures would be demolished during the decontamination and decommissioning of the accelerator(s) and a support facility, the area would continue to be of limited value to wildlife. Noise from decontamination and decommissioning activities would be expected to disturb wildlife in the immediate area; however, this disturbance would be of limited duration. Water use would decrease at the generic site with the decommissioning of the accelerator(s) and support facility. This would result in a decrease in impingement and entrainment of aquatic organisms, as well as a decrease in impacts from effluent discharge at a site where surface water bodies are used. At a site where water is withdrawn from groundwater and discharged to an evaporation pond, the cessation of discharge from the accelerator(s) and support facility could result in a reduction in the size of the pond or its possible elimination. This could, in turn, result in the loss (or elimination) of associated aquatic and terrestrial wildlife, as well as wetland habitat. The response of any threatened or endangered species to decontamination and decommissioning of the accelerator(s) and support facility could vary from positive (e.g., due to a decrease in human presence and emissions) to negative (e.g., due to the elimination of aquatic or wetland habitat), depending on the species involved.

#### **4.5.1.3.7 Cultural and Paleontological Resources**

Decontamination and decommissioning of the accelerator(s) and a support facility would not change the status of cultural and paleontological resources. This is because any required ground disturbance would be confined to previously disturbed areas immediately adjacent to the accelerator(s) and support facility.

#### **4.5.1.3.8 Socioeconomics**

Decommissioning of the accelerator(s) and support facility would result in a negative impact on the socioeconomic characteristics of the DOE site at which they were located. This impact would depend on whether the candidate site was located near a large urbanized area or in a remote rural area. Since the population for the region of influence for a generic DOE site could range from nearly 2.0 million people for a site in a large metropolitan area, to less than 200,000 for a site in a small rural community, the socioeconomic impacts of decommissioning would vary greatly. Therefore, if DOE were to select the new accelerator(s) alternative, additional NEPA documentation would be required to evaluate the specific socioeconomic impacts of decommissioning.

#### **4.5.1.3.9 Public and Occupational Health and Safety—Normal Decontamination and Decommissioning Activities**

Assessments of incremental radiological and chemical impacts associated with the decontamination and decommissioning of the accelerator(s) and support facility are presented in this section. Supplemental information is provided in Appendix H.

During decontamination and decommissioning operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

**RADIOLOGICAL IMPACTS.** In the *Generic Environmental Impact Statement on Decommissioning of Nuclear Facilities*, NUREG-0586 (NRC 1988), NRC determined that the health impact to the public from the decommissioning of research reactors was “negligible.” In the same NUREG, NRC also concluded that the public health impact from radiological releases associated with the decommissioning and decontamination of the research reactor support facility was also “negligible.” Decommissioning and decontamination of the accelerator(s) and support facility would involve less radioactive materials and thus less radioactive emissions,

than those associated with the research reactor and support facility. Based on these conclusions, the environmental impact on the public health and safety from the routine release of radionuclides during the decontamination and decommissioning of the accelerator(s) and support facility addressed in this NI PEIS are deemed to be negligible.

Incremental doses to involved workers from decontamination and decommissioning operations are given in **Table 4–131**; these workers are defined as those directly associated with all decontamination and decommissioning activities. The incremental annual average dose to involved workers during decontamination and decommissioning operations at the accelerator(s) would be 160 millirem; for support facility workers, the incremental annual average dose during decontamination and decommissioning operations would be 100 millirem. The incremental annual dose received by the total site workforce for each of these facilities is estimated to be 17 (total for both accelerators) and 4 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from annual decontamination and decommissioning operations are included in Table 4–131; a probability coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem was applied for workers (ICRP 1991). Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–131 Incremental Radiological Impacts on Involved Workers at the Generic DOE Site from Accelerator(s) and Support Facility Decontamination and Decommissioning Activities Under All Options of Alternative 3 (Construct New Accelerator[s])**

Receptor—Involved Workers <sup>a</sup>	Generic Site Decontamination and Decommissioning Activities			
	Accelerators		Accelerator(s) Support Facility	Total
	Low-Energy	High-Energy		
Total dose (person-rem per year)	5.6 <sup>b</sup>	11 <sup>b</sup>	4 <sup>b</sup>	21
1-year latent cancer fatalities	0.0022	0.0045	0.0016	0.0083
Average worker dose (millirem per year)	160	160	100	143
1-year latent cancer fatality risk	$6.5 \times 10^{-5}$	$6.5 \times 10^{-5}$	0.0004	$5.7 \times 10^{-5}$

- a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.
- b. Based on 105 badged workers at the accelerator(s) (35 at low-energy and 70 at high-energy) and 40 badged workers at the support facility.

**Source:** Calculational results.

**HAZARDOUS CHEMICAL IMPACTS.** No additional hazardous chemical release is expected from activities associated with decontamination and decommissioning the accelerator(s) and its support facility.

#### **4.5.1.3.10 Public and Occupational Health and Safety—Decontamination and Decommissioning Accidents**

There are no radiological or hazardous chemical accidents postulated during the decontamination and decommissioning phases of the new accelerator(s) or the new support facility. Involved workers could experience industrial accidents commonly associated with these types of activities.

#### **4.5.1.3.11 Environmental Justice**

Environmental effects due to decontamination and decommissioning activities that would be expected to occur at an unspecified accelerator(s) and support facility site are addressed in Section 4.5.1.3. The environmental analysis of decontamination and decommissioning activities at the new accelerator(s) and support facility site shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected

areas would not be significant. Unless there are patterns of food consumption among minority or low-income residents surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that decontamination and decommissioning activities at the site would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new accelerator(s) and support facility, an additional evaluation of environmental justice at the accelerator(s) and support facility site during decontamination and decommissioning would be performed prior to implementation.

#### **4.5.1.3.12 Waste Management**

The decontamination and decommissioning of the new accelerator(s) and support facility could generate numerous types of waste. The materials that may be removed or stabilized as a result of decontamination and decommissioning would be managed and reused, recycled, or disposed of in accordance with applicable Federal and state regulations. No analysis of waste management impacts, however, can be formulated at this time. Once proposals concerning decontamination and decommissioning activities were developed, DOE would undertake any additional NEPA analysis that may be necessary or appropriate.

#### **4.5.1.4 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

### **4.5.2 Alternative 3 (Construct New Accelerator[s])—Option 2**

Option 2 involves constructing and operating one or two accelerators to irradiate all targets associated with plutonium-238 production, medical and industrial isotope production, and research and development; operating FDPF at INEEL to fabricate and process neptunium-237 targets and to process the plutonium-238 product; and conducting and operating the support facility to fabricate and process the other targets and materials and to process the associated products. This option includes storage in Building CPP-651 or FDPF of the neptunium-237 transported to INEEL from SRS and storage in the new support facility of the other target materials transported to the generic site from other offsite facilities.

The transportation of the neptunium-237 from SRS to INEEL and then to the generic site, the transportation of the other target materials to the generic site, and the transportation of plutonium-238 and other product materials following irradiation and postirradiation processing constitute part of this option.

All options under this alternative include the decontamination and decommissioning of the accelerator(s) and support facility at the generic DOE site following their operating lifetimes, and also the permanent deactivation of FFTF at Hanford.

#### **4.5.2.1 Construction of the New Accelerator(s) and Support Facility**

The environmental impacts associated with the construction of one or two new accelerators and a support facility at the generic DOE site are assessed in Section 4.5.1.1.

#### **4.5.2.2 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

#### **4.5.2.2.1 Land Resources**

**LAND USE.** Impacts on land use associated with the operation of one or two accelerators and a support facility are addressed in Section 4.5.1.2.1.

Building CPP-651 and/or FDPF, which are located at INTEC, would be used for neptunium-237 storage, and FDPF would be used for target fabrication and processing. Use of these facilities would not change land use at the site since both are currently operating and their proposed use would be compatible with their present mission.

**VISUAL RESOURCES.** Impacts on visual resources associated with the operation of one or two accelerators and a support facility are addressed in Section 4.5.1.2.1.

All activities associated with neptunium-237 storage would take place within Building CPP-651 and/or FDPF, and target fabrication and processing would be in FDPF. Operations associated with the proposed activities would not result in any impact on visual resources or change in the current Visual Resource Management Class IV designation of INTEC. This is because none of the anticipated operational impacts (e.g., air emissions) would be expected to affect this resource.

#### **4.5.2.2.2 Noise**

Noise impacts associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.2.

This option also involves using Building CPP-651 and/or FDPF, both in the INTEC area of INEEL, for neptunium-237 target material storage, and FDPF for target fabrication and processing. Interior modifications of these facilities would be expected to result in little change in noise impacts on wildlife around this area. The operation of these facilities would not be expected to result in any change in noise impacts on wildlife around the INTEC area and offsite noise impacts would be small because the nearest site boundary is 12 kilometers (7.5 miles) to the south. Operation would result in a minimal change in noise impacts on people near the INEEL as a result of changes in employee and truck traffic levels.

#### **4.5.2.2.3 Air Quality**

Air quality impacts associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.3.

Impacts associated with this option at INEEL were determined to be the same as under Option 2 of Alternative 2 (Section 4.4.2.1.3).

The air quality impacts of transportation are presented in Section 4.5.2.2.11.

#### **4.5.2.2.4 Water Resources**

Impacts on water resources associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.4.

Building CPP-651 and/or FDPF, existing facilities in the INTEC area of INEEL, would be used for neptunium-237 storage; FDPF would also be used for the fabrication and processing of targets in support of plutonium-238 production. Impacts on water resources indicators at INEEL would be the same as those

described in Section 4.3.2.1.4. In summary, a small increase in water use and sanitary wastewater generation would be anticipated, mainly attributable to increased staffing levels. Also, there would be a very small increase in process wastewater generation, but there would be no radiological liquid effluent discharge to the environment under normal operations.

#### **4.5.2.2.5 Geology and Soils**

Impacts on geology and soils associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.5. As discussed in Section 4.5.1.1.5, the proposed facilities would be designed and constructed in accordance with DOE Order 420.1 and sited to minimize the risk from geologic hazards. Thus, site geologic conditions would be unlikely to affect the facilities.

The use of Building CPP-651 and/or FDPF for neptunium-237 storage, and FDPF for target fabrication and processing would not be expected to impact geologic resources, nor be jeopardized by large-scale geologic conditions, at INEEL. Hazards from large-scale geologic conditions at INEEL, such as earthquakes and volcanoes, were previously evaluated in the *Storage and Disposition PEIS* (DOE 1996a:4-148) as discussed in Section 4.2.3.2.5. The analysis determined that these hazards present a low risk to long-term storage facilities. That analysis was reviewed in the *Surplus Plutonium Disposition EIS* (DOE 1999a:4-267-268). Further review of the data and analyses presented in these referenced documents and the site-specific data presented in this NI PEIS indicates that the large-scale geologic conditions likewise present a low risk to the proposed use of the INTEC facilities. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards will be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.5.2.2.6 Ecological Resources**

Impacts on ecological resources associated with the operation of one or two accelerators and a support facility are addressed in Section 4.5.1.2.6.

Building CPP-651 and/or FDPF would be used for neptunium-237 storage, and FDPF for target fabrication and processing. As noted in Section 4.5.2.2.2, there would be little change in noise impacts on wildlife. Because additional water usage and wastewater discharge would be small fractions of current values, there would be no impact on aquatic resources (Section 4.5.2.2.4). Threatened and endangered species would not be affected by operation because an existing facility(s) within an already developed area would be used.

Consultation letters to comply with Section 7 of the Endangered Species Act were sent to the U.S. Fish and Wildlife Service and the Idaho Department of Fish and Game (see Table 5-3). Each agency was asked to provide information on potential impacts of the proposed action on threatened and endangered species. The Idaho Department of Fish and Game indicated that its database contained no known occurrences of special status plants or animals near the project area. While DOE has made additional contact with the U.S. Fish and Wildlife Service, a response is pending from this agency. Although no federally listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at INEEL prior to the receipt of input from the Service.

#### **4.5.2.2.7 Cultural and Paleontological Resources**

Impacts on cultural and paleontological resources associated with the operation of one or two accelerators and a support facility are addressed in Section 4.5.1.2.7.

Although six historic structures are associated with INTEC, their status would not be affected by the operation of Building CPP-651 and/or FDPF for neptunium-237 storage, and FDPF for target fabrication and processing. Also, the status of Native American and paleontological resources occurring in the vicinity of INTEC would not be affected by operation of these facilities.

Consultation to comply with Section 106 of the National Historic Preservation Act was initiated with the State Historic Preservation Office (see Table 5-3). The State Historic Preservation Office indicated that Building CPP-651 and FDPF are likely to be eligible for the National Register of Historic Places as contributory properties in a potential historic district of exceptional significance. However, at this time, the State Historic Preservation Office has determined that more information is needed prior to assisting DOE in evaluating these properties. The State Historic Preservation Office also indicated that since there would be no new construction, there is little potential for effects on archaeological properties. DOE would provide additional information as required to the Idaho State Historic Preservation Office prior to the use of any facility at INEEL for the proposed project. Consultation was conducted with interested Native American tribes; however, responses are pending.

#### **4.5.2.2.8 Socioeconomics**

The socioeconomic impacts associated with the operation of the accelerator(s) and support facility at a generic DOE site are addressed in Section 4.5.1.2.8.

The socioeconomic impacts associated with neptunium-237 target fabrication and processing at INEEL are addressed in Section 4.3.2.1.8.

#### **4.5.2.2.9 Public and Occupational Health and Safety—Normal Operations**

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from startup and operations are given in **Table 4-132** for the generic DOE accelerator(s) site and INEEL: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

**Table 4–132 Incremental Radiological Impacts on the Public Around the Generic DOE Site and INEEL from Operational Facilities Under Alternative 3 (Construct New Accelerator[s])—Option 2**

Receptor	INEEL FDPF	Accelerators Preoperational Startup <sup>a</sup>		Generic Site Operations			Two- Site Total	
		Low-Energy	High-Energy	Accelerators		Accelerator(s) Support Facility		Total
				Low- Energy	High- Energy			
<b>Population within 80 kilometers (50 miles) in the year 2020</b>								
Dose (person-rem)	$3.9 \times 10^{-6}$	0.0024	0.035	0.0043	0.055	0.14	0.20	0.20
35-year latent cancer fatalities	$6.7 \times 10^{-8}$	$2.4 \times 10^{-6(b)}$	$3.5 \times 10^{-5(b)}$	$7.5 \times 10^{-5}$	$9.6 \times 10^{-4}$	0.0025	0.0035	0.0035
<b>Maximally exposed individual</b>								
Annual dose (millirem)	$2.6 \times 10^{-7}$	$1.4 \times 10^{-5}$	$1.8 \times 10^{-4}$	$1.1 \times 10^{-4}$	$8.7 \times 10^{-4}$	0.0025	0.0035	NA <sup>c</sup>
35-year latent cancer fatality risk	$4.6 \times 10^{-12}$	$1.4 \times 10^{-11(b)}$	$1.8 \times 10^{-10(b)}$	$1.9 \times 10^{-9}$	$1.5 \times 10^{-8}$	$4.4 \times 10^{-8}$	$6.1 \times 10^{-8}$	NA <sup>c</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>								
Annual dose <sup>d</sup> (millirem)	$2.0 \times 10^{-8}$	$1.6 \times 10^{-6}$	$2.3 \times 10^{-5}$	$2.8 \times 10^{-6}$	$3.6 \times 10^{-5}$	$9.1 \times 10^{-5}$	$1.3 \times 10^{-4}$	NA <sup>c</sup>
35-year latent cancer fatality risk	$3.6 \times 10^{-13}$	$1.6 \times 10^{-12(b)}$	$2.3 \times 10^{-11(b)}$	$4.9 \times 10^{-11}$	$6.3 \times 10^{-10}$	$1.6 \times 10^{-9}$	$2.3 \times 10^{-9}$	NA <sup>c</sup>

a. For conservatism as well as consistency with other radiological impacts evaluated in this NI PEIS, these values were assessed for the year 2020 even though these activities would commence prior to that year.

b. Preoperational activities last 2 years. Number is a 2-year latent cancer fatality risk.

c. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.

d. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FDPF or the generic site in the year 2020 (188,400 and 1,538,100, respectively).

**Key:** NA, not applicable.

**Source:** SAIC 2000; TechSource 2000; model results, using the GENII computer code (Napier et al. 1988).

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

As a result of annual operations of the accelerator facilities (a high-energy accelerator, a low-energy accelerator, and a support facility) and FDPF, the projected incremental total population dose in the year 2020 would be 0.20 person-rem; the corresponding number of latent cancer fatalities in the populations surrounding the generic DOE site and INEEL from 35 years of operations would be 0.0035. The incremental total dose to the maximally exposed member of the public from annual operations of the accelerator(s) and support facility at the generic DOE site would be 0.0035 millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $6.1 \times 10^{-8}$ . Estimated annual risks are also presented for pre-operational testing/startup phase activities anticipated for the accelerator(s) and support facility. The incremental dose to the maximally exposed member of the public from annual FDPF operations would be  $2.6 \times 10^{-7}$  millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $4.6 \times 10^{-12}$ .

Incremental doses to involved workers from normal operations are given in **Table 4–133**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to the high-energy and low-energy accelerator workers during startup and operations would be 150 millirem; for support facility workers, the incremental annual average dose during operations would be 114 millirem; for FDPF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities is estimated to be 30 (high-energy accelerator startup and operation), 15 (low-energy accelerator startup and operation), 11 (support facility operation), and 12 person-rem (FDPF operation). The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–133. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–133 Incremental Radiological Impacts on Involved Workers at the Generic DOE Site and INEEL from Operational Facilities Under Alternative 3 (Construct New Accelerator[s])—Option 2**

Receptor—Involved Workers <sup>a</sup>	INEEL FDPF	Accelerators Preoperational Startup		Generic Site Operations			Two-Site Total
		Low-Energy	High-Energy	Accelerators		Accelerator(s) Support Facility	
				Low-Energy	High-Energy		
Total dose (person-rem per year)	12 <sup>b</sup>	23 <sup>b</sup>	45 <sup>b</sup>	15 <sup>b</sup>	30 <sup>b</sup>	11 <sup>b</sup>	69
35-year latent cancer fatalities	0.17	0.018 <sup>c</sup>	0.036 <sup>c</sup>	0.21	0.42	0.16	0.96
Average worker dose (millirem per year)	170	150	150	150	150	114	NA <sup>d</sup>
35-year latent cancer fatality risk	0.0023	1.2×10 <sup>-4(c)</sup>	1.2×10 <sup>-4(c)</sup>	0.0021	0.0021	0.0016	NA <sup>d</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that each facility adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 75 badged workers at INEEL FDPF, 200 at the high-energy accelerator (300 during startup), 100 at the low-energy accelerator (150 during startup), and 100 total workers at the accelerator(s) support facility.

c. Preoperational startup testing lasts 2 years. Number is a 2-year latent cancer fatality risk.

d. Values cannot be given for the average worker because the workers would be in three different facilities at two different sites.

**Key:** NA, not applicable.

**Source:** DOE 1999b; Nielsen 1999; Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.9.

Impacts from hazardous chemicals at INEEL were determined to be the same as under Option 2 of Alternative 2 (Section 4.4.2.1.9).

#### 4.5.2.2.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with accelerator target irradiation; support facility fabrication and processing of medical, industrial, and research and development isotopes; and FDPF target fabrication and processing of neptunium-237 targets are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–134** and **4–135**, respectively.

For 35 years of high-energy accelerator target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.05 \times 10^{-6}$  and  $5.15 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0063.

For 35 years of low-energy accelerator target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.45 \times 10^{-9}$  and  $3.07 \times 10^{-8}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $3.66 \times 10^{-5}$ .

**Table 4–134 New Accelerator(s), Support Facility, and FDPF Accident Consequences Under Alternative 3 (Construct New Accelerator[s])—Option 2**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
<b>High-energy accelerator accidents</b>						
Design-basis target accident	$2.93 \times 10^{-4}$	$1.47 \times 10^{-7}$	0.980	$4.90 \times 10^{-4}$	$9.35 \times 10^{-4}$	$3.74 \times 10^{-7}$
Beyond-design-basis earthquake	11.7	0.00585	$3.01 \times 10^4$	18	184	0.147
<b>Low-energy accelerator accidents</b>						
Design-basis target accident	$8.05 \times 10^{-5}$	$4.03 \times 10^{-8}$	17.7	0.00885	0.00112	$4.48 \times 10^{-7}$
Beyond-design-basis earthquake	0.0132	$6.60 \times 10^{-6}$	32.4	0.0162	0.208	$8.32 \times 10^{-5}$
<b>Support facility accidents</b>						
Medical and industrial isotopes localized solvent fire	0.0194	$9.72 \times 10^{-6}$	31.1	0.0156	0.00530	$2.12 \times 10^{-6}$
Medical and industrial isotopes unlikely seismic event	0.0750	$3.75 \times 10^{-5}$	136	0.0680	0.510	$2.04 \times 10^{-4}$
Medical and industrial isotopes glovebox explosion	2.50	0.00125	4,600	2.30	17.0	0.00680
<b>FDPF accidents</b>						
Ion exchange explosion during neptunium-237 target fabrication	$2.01 \times 10^{-9}$	$1.01 \times 10^{-12}$	$2.49 \times 10^{-5}$	$1.24 \times 10^{-8}$	$7.26 \times 10^{-9}$	$2.91 \times 10^{-12}$
Target dissolver tank failure during plutonium-238 separation	$6.11 \times 10^{-8}$	$3.05 \times 10^{-11}$	$5.65 \times 10^{-4}$	$2.82 \times 10^{-7}$	$2.17 \times 10^{-7}$	$8.69 \times 10^{-11}$
Ion exchange explosion during plutonium-238 separation	$1.63 \times 10^{-5}$	$8.13 \times 10^{-9}$	0.150	$7.51 \times 10^{-5}$	$5.79 \times 10^{-5}$	$2.31 \times 10^{-8}$
Processing facility beyond-design-basis earthquake	42.5	0.0425	$1.64 \times 10^5$	82.0	1,200	1.00 <sup>c</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

c. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4–135 New Accelerator(s), Support Facility, and FDPF Accident Risks Under Alternative 3 (Construct New Accelerator[s])—Option 2**

Accident (Frequency)	Maximally Exposed Individual <sup>a</sup>	Population to 80 Kilometers (50 Miles) <sup>b</sup>	Noninvolved Worker <sup>a</sup>
<b>Annual high-energy accelerator risks</b>			
Design-basis target accident ( $1 \times 10^{-4}$ )	$1.47 \times 10^{-11}$	$4.90 \times 10^{-8}$	$3.74 \times 10^{-11}$
Beyond-design-basis earthquake ( $1 \times 10^{-5}$ )	$5.85 \times 10^{-8}$	$1.80 \times 10^{-4}$	$1.47 \times 10^{-6}$
<b>35-year high-energy accelerator risk</b>	$2.05 \times 10^{-6}$	0.00630	$5.15 \times 10^{-5}$
<b>Annual low-energy accelerator risks</b>

Beyond-design-basis earthquake ( $1 \times 10^{-5}$ )	$6.60 \times 10^{-11}$	$1.62 \times 10^{-7}$	$8.32 \times 10^{-10}$
<b>35-year low-energy accelerator risk</b>	$2.45 \times 10^{-9}$	$3.66 \times 10^{-5}$	$3.07 \times 10^{-8}$
<b>Annual support facility risks</b>			
Medical and industrial isotopes localized solvent fire (0.044)	$4.32 \times 10^{-7}$	$6.91 \times 10^{-4}$	$9.41 \times 10^{-8}$
Medical and industrial isotopes unlikely seismic event (0.01)	$3.75 \times 10^{-7}$	$6.80 \times 10^{-4}$	$2.04 \times 10^{-6}$
Medical and industrial isotopes glovebox explosion ( $1.00 \times 10^{-4}$ )	$1.25 \times 10^{-7}$	$2.30 \times 10^{-4}$	$6.80 \times 10^{-7}$
<b>35-year support facility risk</b>	$3.26 \times 10^{-5}$	0.056	$9.85 \times 10^{-5}$
<b>Annual FDPF risks</b>			
Ion exchange explosion during neptunium-237 target fabrication (0.01)	$1.01 \times 10^{-14}$	$1.24 \times 10^{-10}$	$2.91 \times 10^{-14}$
Target dissolver tank failure during plutonium-238 separation (0.01)	$3.05 \times 10^{-13}$	$2.82 \times 10^{-9}$	$8.69 \times 10^{-13}$
Ion exchange explosion during plutonium-238 separation (0.01)	$8.13 \times 10^{-11}$	$7.51 \times 10^{-7}$	$2.31 \times 10^{-10}$
Processing facility beyond-design-basis earthquake ( $1 \times 10^{-5}$ )	$4.25 \times 10^{-7}$	$8.20 \times 10^{-4}$	$1.00 \times 10^{-5(c)}$
<b>35-year FDPF risk</b>	$1.49 \times 10^{-5}$	0.0287	$3.50 \times 10^{-4(c)}$
<b>35-year Option risk</b>	$4.95 \times 10^{-5}$	0.0911	$5.00 \times 10^{-4}$

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. Risk of an early fatality.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

For 35 years of medical, industrial, and research and development target fabrication and processing at the support facility, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $3.26 \times 10^{-5}$  and  $9.85 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.056.

For 35 years of neptunium-237 target fabrication and processing at FDPF, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $1.49 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0287.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $4.95 \times 10^{-5}$  and  $5.00 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0911.

There are no hazardous chemical accidents associated with the new accelerator(s) or new support facility. The irradiation of neptunium-237, medical, industrial, and research and development isotopes in the new accelerator(s) would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The fabrication and processing of medical, industrial, and research and development isotopes at the new support facility would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The hazardous chemical accident impacts at FDPF are the same as those presented in Section 4.4.5.1.10.

#### **4.5.2.2.11 Public and Occupational Health and Safety—Transportation**

DOE would transport neptunium-237 from storage at SRS to the REDC target fabrication facility at ORR. DOE would transport the unirradiated neptunium-237 targets from REDC to the accelerator(s) site. Following irradiation in the accelerator(s), the targets would be returned to REDC for processing. After this processing, the plutonium-238 product would be shipped to LANL. Additionally, medical and industrial isotopes would be shipped from the accelerator(s) site to a local airport, and from there to locations throughout the country.

Approximately 37,000 shipments of radioactive materials would be made by DOE in support of the low-energy accelerator. The total distance traveled on public roads by trucks carrying radioactive materials would be 4.8 million kilometers (3.0 million miles); and in the air carrying medical and industrial isotopes, 23 million kilometers (14 million miles).

Approximately 269 shipments of radioactive materials would be made by DOE in support of the high-energy accelerator. The total distance traveled on public roads by trucks carrying radioactive materials would be 0.99 million kilometers (0.62 million miles).

The transportation impact analysis is described in detail in Appendix J.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION FOR THE LOW-ENERGY ACCELERATOR.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 15 person-rem; the dose to the public, 7 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.0059 latent cancer fatality among transportation workers and 0.0037 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.02.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION FOR THE HIGH-ENERGY ACCELERATOR.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 6 person-rem; the dose to the public, 107 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.002 latent cancer fatality among transportation workers and 0.054 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.0023.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION FOR THE LOW-ENERGY ACCELERATOR.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: more than 1 in 10 million per year) would not breach the transportation package. The consequences of more severe accidents

that could breach the transportation package and release radioactive material were evaluated and estimated to have probabilities of less than 1 in 10 million per year.

Estimates of the total ground transportation accident risks under this option are as follows: a radiological dose to the population of 1,063 person-rem, resulting in 0.53 latent cancer fatality; and traffic accidents resulting 0.11 traffic fatality.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION FOR THE HIGH-ENERGY ACCELERATOR.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FDPF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 was also evaluated and estimated to have a probability of less than 1 in 10 million per year.

Estimates of the total transportation accident risks under this option are as follows: a radiological dose to the population of 0.16 person-rem, resulting in  $8.1 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.025 traffic fatality.

#### **4.5.2.2.12 Environmental Justice**

Under this option, neptunium-237 targets would be irradiated in one or two new accelerators that would be constructed at a site yet to be specified. Fabrication and processing of neptunium-237 targets for plutonium-238 production would be performed at FDPF located at INEEL. A new support facility would be constructed at the same site for fabrication and processing targets not used for plutonium-238 production.

Activities at FDPF were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.2.1.12) and found to pose no significant radiological or other risks to minority and low-income populations. The environmental analysis of operations at the new accelerator(s) and support facility site shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected areas would not be significant. Unless there are patterns of food consumption among minority or low-income residents surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that operations at the site would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new accelerator(s) and support facility, an additional evaluation of environmental justice at the accelerator(s) and support facility site during operation would be performed prior to implementation.

#### **4.5.2.2.13 Waste Management**

The impacts of managing waste associated with the operation of new accelerator(s) to irradiate targets and a support facility to fabricate and process medical and industrial isotope targets and to meet research and development needs are assumed to be the same as for Option 1 (Section 4.5.1.2.13). Radiological and chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.5.2.2.9 through 4.5.2.2.11.

The impacts of managing waste associated with fabricating and processing neptunium-237 targets for plutonium-238 production in FDPF at INEEL are assumed to be the same as for Option 2 under Alternative 1 (Section 4.3.2.1.13). As shown in that section, the impacts on the waste management systems at INEEL would be small.

#### **4.5.2.3 Decontamination and Decommissioning of the Accelerator(s) and Support Facility**

The environmental impacts associated with the decontamination and decommissioning of the accelerator(s) and support facility at the generic DOE site are assessed in Section 4.5.1.3.

#### **4.5.2.4 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

### **4.5.3 Alternative 3 (Construct New Accelerator[s])—Option 3**

Option 3 involves constructing and operating one or two accelerators to irradiate all targets associated with plutonium-238 production, medical and industrial isotope production, and research and development; operating FMEF at Hanford to fabricate and process neptunium-237 targets and to process the plutonium-238 product; and conducting and operating the support facility to fabricate and process the other targets and materials and to process the associated products. This option includes storage in FMEF of the neptunium-237 transported to Hanford from SRS and storage in the new support facility of the other target materials transported to the generic site from other offsite facilities.

The transportation of the neptunium-237 from SRS to Hanford and then to the generic site, the transportation of the other target materials to the generic site, and the transportation of plutonium-238 and other product materials following irradiation and postirradiation processing constitute part of this option.

All options under this alternative include the decontamination and decommissioning of the accelerator(s) and support facility at the generic site following their operating lifetimes, and also the permanent deactivation of FFTF at Hanford.

#### **4.5.3.1 Construction of the New Accelerator(s) and Support Facility**

Environmental impacts associated with the construction of one or two new accelerators and support facility at the generic DOE site are assessed in Section 4.5.1.1.

#### **4.5.3.2 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

##### **4.5.3.2.1 Land Resources**

**LAND USE.** Impacts on land use associated with the operation of the accelerator(s) and a support facility are addressed in Section 4.5.1.2.1.

FMEF would be used for neptunium-237 storage, target fabrication, and processing. Land use within the 400 Area would not change since the use of FMEF would be compatible with the mission for which it was designed.

**VISUAL RESOURCES.** Impacts on visual resources associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.1.

All activities associated with neptunium-237 storage, target fabrication, and processing would take place within FMEF. Operations associated with the proposed activities would not result in any change to visual resources; thus, the current Visual Resource Management Class IV rating of the 400 Area. This is because none of the anticipated operational impacts (e.g., air emissions) would be expected to affect this resource.

#### **4.5.3.2.2 Noise**

Noise impacts associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.2.

This option also involves using FMEF for target material storage, target fabrication, and processing. Activities associated with construction of a new stack would be typical of small construction projects and would result in some temporary increase in noise. Noise sources associated with this construction would not be expected to be loud impulsive sources and are not expected to result in disturbance of wildlife around the 400 Area. The operation of FMEF would not be expected to result in any change in noise impacts on wildlife around the 400 Area and offsite noise impacts would also be minor because the nearest site boundary is 7 kilometers (4.3 miles) to the east. Operation would be expected to result in a minimal change in noise impacts on people near the Hanford site as a result of changes in employee and truck traffic levels.

#### **4.5.3.2.3 Air Quality**

Air quality impacts associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.3.

Air quality impacts at Hanford associated with this option were determined to be the same as under Option 3 of Alternative 2 (Section 4.4.3.1.3).

The air quality impacts of transportation are presented in Section 4.5.3.2.11.

#### **4.5.3.2.4 Water Resources**

Impacts on water resources associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.4.

FMEF in the 400 Area of Hanford would be used for neptunium-237 storage, target fabrication, and processing in support of plutonium-238 production. The operation of FMEF for this purpose is projected to require approximately 19 million liters (5 million gallons) of groundwater annually. This includes approximately 15 million liters (4 million gallons) per year to support FMEF cooling needs and an additional 3.8 million liters (1 million gallons) per year for potable and sanitary water demands due to increased staffing. However, no impact on regional groundwater levels would be expected from increased withdrawals. FMEF groundwater usage would constitute an increase of about 10 percent over the 197 million liters (52 million gallons) withdrawn annually in the 400 Area during standby operations. Sanitary wastewater discharges from FMEF would also increase by roughly 3.8 million liters (1 million gallons) per year to the Energy Northwest treatment system, which has sufficient capacity. Also, the operation of FMEF for target fabrication and processing would generate approximately 15 million liters (4 million gallons) per year of process wastewater. This wastewater would be discharged to the 400 Area process sewer system and ultimately to the 400 Area Pond (i.e., 4608 B/C percolation ponds) (Chapin 2000; Nielsen 1999:38, 39, 41). As discharges to the pond are

regulated under State Waste Discharge Permit No. ST-4501 and there are no radiological liquid effluent pathways to the environment from FMEF, the impact on groundwater quality would be negligible.

It should be noted that the increase in water use and sanitary and process wastewater discharge for FMEF operations would essentially be negated by the larger reductions in water use and wastewater generation in the 400 Area associated with the permanent deactivation of FFTF (see Section 4.4.1.2.4).

#### **4.5.3.2.5 Geology and Soils**

Impacts on geology and soils associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.5. As discussed in Section 4.5.1.1.5, the proposed facilities would be designed and constructed in accordance with DOE Order 420.1 and sited to minimize the risk from geologic hazards. Thus, site geologic conditions would be unlikely to affect the facilities.

The use of FMEF for neptunium-237 storage, target fabrication, and processing would not be expected to impact geologic resources, nor be jeopardized by large-scale geologic conditions. Hazards from large-scale geologic conditions at Hanford, such as earthquakes and volcanoes, were previously evaluated in the *Storage and Disposition PEIS* (DOE 1996a:4-45) as discussed in Section 4.2.4.2.5. The analysis determined that these hazards present a low risk to long-term storage facilities. That analysis was reviewed in the *Surplus Plutonium Disposition EIS* (DOE 1999a:4-260). Further review of the data and analyses presented in these referenced documents and the site-specific data presented in this NI PEIS indicates that the large-scale geologic conditions likewise present a low risk to FMEF operations. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards will be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.5.3.2.6 Ecological Resources**

Impacts on ecological resources associated with the operation of the accelerator(s) and a support facility are addressed in Section 4.5.1.2.6.

This option also involves using FMEF for neptunium-237 storage, target fabrication, and processing. As noted in Section 4.5.3.2.2, there would be no change in noise impacts on wildlife. Because additional water usage and wastewater discharge would be small fractions of current values, there would be no change in impacts on aquatic habitat or wetlands associated with the Columbia River (Section 4.5.3.2.4). Threatened and endangered species would not be affected by operation because an existing facility within an already developed area would be used.

Consultation letters concerning threatened and endangered species were sent to the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, the Washington State Department of Natural Resources, and the State of Washington Department of Fish and Wildlife (see Table 5-3). Each agency was asked to provide information on potential impacts of the proposed action on threatened and endangered species. Both the Washington State Department of Natural Resources and the State of Washington Department of Fish and Wildlife provided lists of state species of concern that occur in the vicinity of the project area. As noted above, no impacts to any threatened or endangered species are expected, including those of concern to these agencies. While DOE has made additional contacts with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service, responses are pending from these agencies. Although no federally listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at Hanford prior to the receipt of input from these Federal agencies.

#### **4.5.3.2.7 Cultural and Paleontological Resources**

Impacts on cultural and paleontological resources associated with the operation of the accelerator(s) and a support facility are addressed in Section 4.5.1.2.7.

Neptunium-237 storage, target fabrication, and processing would take place at FMEF, which is in the 400 Area. No prehistoric, historic, or paleontological sites have been identified either within the 400 Area or within 2 kilometers (1.2 miles) of the 400 Area. Six buildings located within the 400 Area, including two FFTF structures (the Reactor Containment Building and FFTF Control Building), have been determined to be eligible for the National Register as contributing properties within the Historic District recommended for mitigation. The operation of FMEF would not affect the status of these structures. No Native American resources are known to occur within the 400 Area.

Consultation to comply with Section 106 of the National Historic Preservation Act was conducted with the State Historic Preservation Office (see Table 5–3) and resulted in concurrence by the State Historic Preservation Office that the proposed action would have no effect on historic properties at Hanford. Consultation was also conducted with interested Native American tribes that resulted in comments at public hearings by members representing the Nez Perce and Confederated Tribes of the Umatilla Indian Reservation. Responses to their specific comments are addressed in Volume 3.

#### **4.5.3.2.8 Socioeconomics**

The socioeconomic impacts associated with the operation of the new accelerator(s) and support facility at a generic DOE site are addressed in Section 4.5.1.2.8.

Target fabrication and processing of neptunium-237 targets at FMEF at Hanford would require about 62 additional workers (Hoyt et al. 1999). The socioeconomic impacts at Hanford are the same as those addressed in Section 4.4.3.1.8.

#### **4.5.3.2.9 Public and Occupational Health and Safety—Normal Operations**

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from startup and operations are given in **Table 4–136** for the generic DOE site and Hanford: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

**Table 4–136 Incremental Radiological Impacts on the Public Around the Generic DOE Site and Hanford from Operational Facilities Under Alternative 3 (Construct New Accelerator[s])—Option 3**

Receptor	Hanford FMEF	Accelerators Preoperational Startup <sup>a</sup>		Generic Site Operations				Two-Site Total
		Low-Energy	High-Energy	Accelerators		Accelerator(s) Support Facility	Total	
				Low-Energy	High-Energy			
<b>Population within 80 kilometers (50 miles) in the year 2020</b>								
Dose (person-rem)	$4.4 \times 10^{-5}$	0.0024	0.035	0.0043	0.055	0.14	0.20	0.20
35-year latent cancer fatalities	$7.7 \times 10^{-7}$	$2.4 \times 10^{-6(b)}$	$3.5 \times 10^{-5(b)}$	$7.5 \times 10^{-5}$	$9.6 \times 10^{-4}$	0.0025	0.0035	0.0035
<b>Maximally exposed individual</b>								
Annual dose (millirem)	$4.7 \times 10^{-7}$	$1.4 \times 10^{-5}$	$1.8 \times 10^{-4}$	$1.1 \times 10^{-4}$	$8.7 \times 10^{-4}$	0.0025	0.0035	NA <sup>c</sup>
35-year latent cancer fatality risk	$8.3 \times 10^{-12}$	$1.4 \times 10^{-11(b)}$	$1.8 \times 10^{-10(b)}$	$1.9 \times 10^{-9}$	$1.5 \times 10^{-8}$	$4.4 \times 10^{-8}$	$6.1 \times 10^{-8}$	NA <sup>c</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>								
Annual dose <sup>d</sup> (millirem)	$8.9 \times 10^{-8}$	$1.6 \times 10^{-6}$	$2.3 \times 10^{-5}$	$2.8 \times 10^{-6}$	$3.6 \times 10^{-5}$	$9.1 \times 10^{-5}$	$1.3 \times 10^{-4}$	NA <sup>c</sup>
35-year latent cancer fatality risk	$1.6 \times 10^{-12}$	$1.6 \times 10^{-12(b)}$	$2.3 \times 10^{-11(b)}$	$4.9 \times 10^{-11}$	$6.3 \times 10^{-10}$	$1.6 \times 10^{-9}$	$2.3 \times 10^{-9}$	NA <sup>c</sup>

a. For conservatism as well as consistency with other radiological impacts evaluated in this NI PEIS, these values were assessed for the year 2020 even though these activities would commence prior to that year.

b. Preoperational activities last 2 years. Number is a 2-year latent cancer fatality risk.

c. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.

d. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FMEF or the generic site in the year 2020 (494,400 and 1,538,100, respectively).

**Key:** NA, not applicable.

**Source:** SAIC 2000; TechSource 2000; model results, using the GENII computer code (Napier et al. 1988).

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

As a result of annual operations of the accelerator facilities (the high- and low-energy accelerators and the support facility) and FMEF, the projected incremental total population dose in the year 2020 would be 0.20 person-rem; the corresponding number of latent cancer fatalities in the populations surrounding the generic DOE site and Hanford from 35 years of operations would be 0.0035. The incremental total dose to the maximally exposed member of the public from annual operations of the accelerator(s) and support facility at the generic DOE site would be 0.0035 millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $6.1 \times 10^{-8}$ . Estimated annual risks are also presented for preoperational testing/startup phase activities anticipated for the accelerator(s) and support facility. The incremental dose to the maximally exposed member of the public from annual FMEF operations would be  $4.7 \times 10^{-7}$  millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $8.3 \times 10^{-12}$ .

Incremental doses to involved workers from normal operations are given in **Table 4–137**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to the high-energy and low-energy accelerator workers during startup and operations would be 150 millirem; for support facility workers, the incremental annual average dose during operations would be 114 millirem; for FMEF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities is estimated to be 45 (total for both accelerators), 11, and 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–137. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–137 Incremental Radiological Impacts on Involved Workers at the Generic DOE Site and Hanford from Operational Facilities Under Alternative 3 (Construct New Accelerator[s])—Option 3**

Receptor—Involved Workers <sup>a</sup>	Hanford FMEF	Accelerators Preoperational Startup		Generic Site Operations			Two-Site Total
		Low-Energy	High-Energy	Accelerators		Accelerator(s) Support Facility	
				Low-Energy	High-Energy		
Total dose (person-rem per year)	12 <sup>b</sup>	23 <sup>b</sup>	45 <sup>b</sup>	15 <sup>b</sup>	30 <sup>b</sup>	11 <sup>b</sup>	69
35-year latent cancer fatalities	0.17	0.018 <sup>c</sup>	0.036 <sup>c</sup>	0.21	0.42	0.16	0.96
Average worker dose (millirem per year)	170	150	150	150	150	114	NA <sup>d</sup>
35-year latent cancer fatality risk	0.0023	1.2×10 <sup>-4(c)</sup>	1.2×10 <sup>-4(c)</sup>	0.0021	0.0021	0.0016	NA <sup>d</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that each facility adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 75 badged workers at FMEF, 200 at the high-energy accelerator (300 during startup), 100 at the low-energy accelerator (150 during startup), and 100 at the accelerator(s) support facility.

c. Preoperational startup testing lasts 2 years. Number is a 2-year latent cancer fatality risk.

d. Values cannot be given for the average worker because the workers would be in three different facilities at two different sites.

**Key:** NA, not applicable.

**Source:** Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts associated with the operation of the accelerator(s) and support facility are addressed in Section 4.5.1.2.9.

Impacts from hazardous chemicals at Hanford were determined to be the same as under Option 3 of Alternative 2 (Section 4.4.3.1.9).

#### 4.5.3.2.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with accelerator target irradiation; support facility fabrication and processing of medical, industrial, and research and development isotopes; and FMEF target fabrication and processing of neptunium-237 targets are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–138** and **4–139**, respectively.

For 35 years of high-energy accelerator target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.05 \times 10^{-6}$  and  $5.15 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0063.

**Table 4-138 New Accelerator(s), Support Facility, and FMEF Accident Consequences Under Alternative 3 (Construct New Accelerator[s])—Option 3**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
<b>High-energy accelerator accidents</b>						
Design-basis target accident	$2.93 \times 10^{-4}$	$1.47 \times 10^{-7}$	0.980	$4.90 \times 10^{-4}$	$9.35 \times 10^{-4}$	$3.74 \times 10^{-7}$
Beyond-design-basis earthquake	11.7	0.00585	$3.01 \times 10^4$	18	184	0.147
<b>Low-energy accelerator accidents</b>						
Design-basis target accident	$8.05 \times 10^{-5}$	$4.03 \times 10^{-8}$	17.7	0.00885	0.00112	$4.48 \times 10^{-7}$
Beyond-design-basis earthquake	0.0132	$6.60 \times 10^{-6}$	32.4	0.0162	0.208	$8.32 \times 10^{-5}$
<b>Support facility accidents</b>						
Medical and industrial isotopes localized solvent fire	0.0194	$9.72 \times 10^{-6}$	31.1	0.0156	0.00530	$2.12 \times 10^{-6}$
Medical and industrial isotopes unlikely seismic event	0.0750	$3.75 \times 10^{-5}$	136	0.0680	0.510	$2.04 \times 10^{-4}$
Medical and industrial isotopes glovebox explosion	2.50	0.00125	4,600	2.30	17.0	0.00680
<b>FMEF accidents</b>						
Ion exchange explosion during neptunium-237 target fabrication	$2.02 \times 10^{-9}$	$1.01 \times 10^{-12}$	$7.26 \times 10^{-5}$	$3.63 \times 10^{-8}$	$6.65 \times 10^{-10}$	$2.66 \times 10^{-13}$
Target dissolver tank failure during plutonium-238 separation	$4.64 \times 10^{-8}$	$2.32 \times 10^{-11}$	0.00169	$8.47 \times 10^{-7}$	$1.95 \times 10^{-8}$	$7.81 \times 10^{-12}$
Ion exchange explosion during plutonium-238 separation	$1.24 \times 10^{-5}$	$6.18 \times 10^{-9}$	0.451	$2.25 \times 10^{-4}$	$5.20 \times 10^{-6}$	$2.08 \times 10^{-9}$
Processing facility beyond-design-basis earthquake	16.5	0.00823	$6.41 \times 10^5$	321	921	1.00 <sup>c</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

c. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4–139 New Accelerator(s), Support Facility, and FMEF Accident Risks Under Alternative 3 (Construct New Accelerator[s])—Option 3**

Accident (Frequency)	Maximally Exposed Individual <sup>a</sup>	Population to 80 Kilometers (50 Miles) <sup>b</sup>	Noninvolved Worker <sup>a</sup>
<b>Annual high-energy accelerator risks</b>

<b>35-year FMEF risk</b>	$2.88 \times 10^{-6}$	0.112	$3.50 \times 10^{-4(c)}$
<b>35-year Option risk</b>	$3.76 \times 10^{-5}$	0.175	$5.00 \times 10^{-4}$

- a. Increased likelihood of a latent cancer fatality.
- b. Increased number of latent cancer fatalities.
- c. Risk of an early fatality.

Source: Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

For 35 years of low-energy accelerator target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.45 \times 10^{-9}$  and  $3.07 \times 10^{-8}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $3.66 \times 10^{-5}$ .

For 35 years of medical, industrial, and research and development target fabrication and processing at the support facility, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $3.26 \times 10^{-5}$  and  $9.85 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.056.

For 35 years of neptunium-237 target fabrication and processing at FMEF, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $2.88 \times 10^{-6}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.112.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $3.76 \times 10^{-5}$  and  $5.00 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.175.

There are no hazardous chemical accidents associated with the new accelerator(s) or new support facility. The irradiation of neptunium-237, medical, industrial, and research and development isotopes in the new accelerator(s) would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The fabrication and processing of medical, industrial, and research and development isotopes at the new support facility would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The hazardous chemical accident impacts at FMEF are the same as those presented in Section 4.4.6.1.10.

#### **4.5.3.2.11 Public and Occupational Health and Safety—Transportation**

DOE would transport neptunium-37 from storage at SRS to the REDC target fabrication facility at ORR. DOE would transport the unirradiated neptunium-237 targets from REDC to the accelerator(s) site. Following irradiation in the accelerator(s), the targets would be returned to REDC for processing. After this processing, the plutonium-238 product would be shipped to LANL. Additionally, medical and industrial isotopes would be shipped from the accelerator(s) site to a local airport, and from there to locations throughout the country.

Approximately 37,000 shipments of radioactive materials would be made by DOE in support of the low-energy accelerator. The total distance traveled on public roads by trucks carrying radioactive materials would be 4.8 million kilometers (3.0 million miles); and in the air carrying medical and industrial isotopes, 23 million kilometers (14 million miles).

Approximately 269 shipments of radioactive materials would be made by DOE in support of the high-energy accelerator. The total distance traveled on public roads by trucks carrying radioactive materials would be 1.1 million kilometers (0.71 million miles).

The transportation impact analysis is described in detail in Appendix J.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION FOR THE LOW-ENERGY ACCELERATOR.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 15 person-rem; the dose to the public, 7 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.0059 latent cancer fatality among transportation workers and 0.0037 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.02.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION FOR THE HIGH-ENERGY ACCELERATOR.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 7 person-rem; the dose to the public, 123 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.003 latent cancer fatality among transportation workers and 0.0061 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.0026.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION FOR THE LOW-ENERGY ACCELERATOR.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: more than 1 in 10 million per year) would not breach the transportation package. The consequences of more severe accidents that could breach the transportation package and release radioactive material were evaluated and estimated to have probabilities of less than 1 in 10 million per year.

Estimates of the total ground transportation accident risks under this option are as follows: a radiological dose to the population of 1,063 person-rem, resulting in 0.53 latent cancer fatality; and traffic accidents resulting 0.11 traffic fatality.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION FOR THE HIGH-ENERGY ACCELERATOR.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FDPF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 was also evaluated and estimated to have a probability of less than 1 in 10 million per year.

Estimates of the total transportation accident risks under this option are as follows: a radiological dose to the population of 0.14 person-rem, resulting in  $7.2 \times 10^{-5}$  latent cancer fatality; and traffic accidents resulting in 0.03 traffic fatality.

#### **4.5.3.2.12 Environmental Justice**

Under this option, neptunium-237 targets would be irradiated in one or two new accelerators that would be constructed at a site yet to be specified. Fabrication and processing of neptunium-237 targets for plutonium-238 production would be performed at FMEF located at Hanford. A new support facility would be constructed at the same unspecified site for fabrication and processing targets not used for plutonium-238 production.

Activities at FMEF were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.3.1.12) and found to pose no significant radiological or other risks to minority and low-income populations. The environmental analysis of operations at the new accelerator(s) and support facility site shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected area would not be significant. Unless there are patterns of food consumption among minority or low-income residents surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that operations at the site would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site-specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new accelerator(s) and support facility, an additional evaluation of environmental justice at the accelerator(s) and support facility site during operation would be performed prior to implementation.

#### **4.5.3.2.13 Waste Management**

The impacts of managing waste associated with the operation of new accelerator(s) to irradiate targets and a support facility to fabricate and process medical and industrial isotope targets and to meet research and development needs are assumed to be the same as for Option 1 (Section 4.5.1.2.13). Radiological and

chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.5.3.2.9 through 4.5.3.2.11.

The impacts of managing waste associated with fabricating and processing neptunium-237 targets for plutonium-238 production in FMEF at Hanford are assumed to be the same as for Option 3 under Alternative 2 (Section 4.4.3.1.13). As shown in that section, the impacts on the waste management systems at Hanford would be small.

#### **4.5.3.3 Decontamination and Decommissioning of the Accelerator(s) and Support Facility**

The environmental impacts associated with the decontamination and decommissioning of the accelerator(s) and support facility at the generic DOE site are assessed in Section 4.5.1.3.

#### **4.5.3.4 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.6 ALTERNATIVE 4—CONSTRUCT NEW RESEARCH REACTOR**

Under Alternative 4, a new research reactor would be used for target irradiation for the evaluation period of 35 years. The new research reactor, to be constructed at an existing DOE site, would be used to irradiate all targets (i.e., for the production of plutonium-238, isotopes for medical and industrial uses, and materials testing for civilian nuclear energy research and development). Ongoing operations at existing facilities as described in Chapter 3, Affected Environment, would continue.

The targets for plutonium-238 production would be fabricated in one of the three candidate facilities at ORNL, INEEL, or Hanford. The material needed for the target fabrication (neptunium-237) would be transported from SRS to the fabrication facilities. The targets would be irradiated at the new research reactor facility and transported back to the target fabrication facilities for postirradiation processing.

Targets for medical and industrial isotope production would be fabricated in a new support facility located at the same site as the new research reactor. The targets would be irradiated in the new research reactor and returned to the new support facility for postirradiation processing.

Alternative 4 site selection is not evaluated as part of this NI PEIS. Because Alternative 4 is evaluated at a generic DOE site, no credit was taken for any existing support infrastructure existing at the site and it was postulated that a new support facility would be required to support operation of the new research reactor and its missions. While this approach bounds the environmental impact assessment for the implementation of Alternative 4, it overstates the impacts because this NI PEIS integrates the impacts associated with constructing a new support facility and infrastructure that may be available at the existing DOE site. In the event that Alternative 4 is selected by the Record of Decision for subsequent consideration, follow-up NEPA assessments would evaluate potential locations for the new research reactor. It is unlikely that DOE would consider locating the new research reactor on a DOE site that does not have existing infrastructure capable of supporting all or most of the medical and industrial isotope production and civilian nuclear energy research and development mission requirements. If the reactor were built on a DOE site with existing support facilities, the environmental impacts of such implementation could be determined by subtracting the construction and decommissioning impacts associated with the new support facility from the total impacts given for this alternative.

Under Alternative 4, nonirradiated targets, irradiated targets, and processed materials would be transported between the locations selected for storage, target fabrication, target irradiation, postirradiation processing, and the final destination of the plutonium-238. Alternative 4 also would include the decontamination and decommissioning of both the research reactor and the support facility when the missions are over, as well as deactivation of FFTF at Hanford.

The proposed new research reactor would provide ample neutrons for the production of plutonium-238 and for many of the isotopes listed in Table 1–1. The thermal flux would limit the new research reactor's ability to produce a number of isotopes requiring fast or high-energy neutrons. Its lower flux levels ( $10^{13}$  neutrons per square centimeter per second) and predominantly thermal flux would limit its ability to support many of the projected nuclear-based research and development needs.

The three options under this alternative and their associated target fabrication, postirradiation processing, and transportation activities are discussed below.

- **Option 1.** REDC at ORNL would be used to fabricate and process the neptunium-237 targets associated with plutonium-238 production. The neptunium-237 transported from SRS to ORNL would be stored at REDC. The plutonium-238 product would be transported from ORNL to LANL.

A new support facility at an existing DOE site would be used to fabricate and process the targets required for the production of medical and industrial and research isotopes and to store the materials needed for target fabrication.

- **Option 2.** FDPF at INEEL would be used to fabricate and process the neptunium-237 targets associated with plutonium-238 production. The neptunium-237 transported from SRS to INEEL would be stored in FDPF or Building CPP-651. The plutonium-238 product would be transported from INEEL to LANL. A new support facility at an existing DOE site would be used to fabricate and process the targets required for the production of medical and industrial and research isotopes and to store the materials needed for target fabrication.
- **Option 3.** FMEF at Hanford would be used to fabricate and process neptunium-237 targets for plutonium-238 production. The neptunium-237 transported from SRS to Hanford would be stored in FMEF. The plutonium-238 product would be transported from Hanford to LANL. A new support facility at an existing DOE site would be used to fabricate and process the targets required for the production of medical and industrial and research isotopes and to store the materials needed for target fabrication.

The incremental environmental impacts associated with each option are presented separately for the research reactor and the support facility because both facilities may not be selected together. This segmentation assists in the selection of facilities from the two possible combinations, that is, research reactor plus support facility or research reactor only.

As described in Section 1.2.3, the civilian nuclear energy research and development initiatives requiring an enhanced DOE nuclear infrastructure fall into three basic categories: materials research, nuclear fuels research, and advanced reactor development.

- Materials research involves irradiating materials in a high-flux field to determine the radiation effect during reactor normal operating conditions or to perform accelerated life-cycle testing. This form of testing would not introduce material into the research reactor that would result in additional releases during normal operation or accident conditions.
- Nuclear fuels research involves irradiating test fuel pellets, fuel pins, and fuel assemblies in high-temperature environments expected in future reactor designs. When the test specimens are inserted into the research reactor, there would be no significant increase of fissile material in the reactor core inventory that would result in additional releases during normal operation or accident conditions.
- Advanced reactor development involves test loop experiments under prototypical reactor conditions. When the test loop is operating in the research reactor core, there would be no significant increase of fissile material in the reactor core inventory that would result in additional releases during normal operation or accident conditions.

The environmental impacts associated with implementation of the proposed civilian nuclear energy research and development mission cannot be distinguished from the impacts of operating the new research reactor without the civilian nuclear energy research and development mission.

#### **4.6.1 Alternative 4 (Construct New Research Reactor)—Option 1**

Option 1 involves constructing and operating the research reactor to irradiate all targets associated with plutonium-238 production, medical and industrial isotope production, and research and development; operating

REDC at ORR to fabricate and process neptunium-237 targets and to process the plutonium-238 product; and constructing and operating the support facility to fabricate and process the other targets and materials and to process the associated products. This option includes storage in REDC of the neptunium-237 transported to ORR from SRS and storage in the new support facility of the other target materials transported to the generic site from other offsite facilities.

The transportation of the low-enriched uranium fuel for use in the research reactor, the transportation of the neptunium-237 to ORR and then to the generic site, the transportation of the other target materials to the generic site, and the transportation of all product materials following irradiation and postirradiation processing are also part of the option.

All options under this alternative include the decontamination and decommissioning of the research reactor and support facility at the generic DOE site following their operating lifetimes, and also the permanent deactivation of FFTF at Hanford.

#### **4.6.1.1 Construction of the New Research Reactor and Support Facility**

The environmental impacts associated with the construction of a new research reactor and support facility at the generic DOE site are assessed in this section. If the research reactor were built on a site with existing support facilities, there would be no impacts associated with constructing a new support facility.

##### **4.6.1.1.1 Land Resources**

**LAND USE.** The construction of a research reactor and support facility at a generic DOE site would disturb 1.6 hectares (4 acres) and 2.4 hectares (6 acres), respectively. Since the exact nature of the construction site is not known at this time (e.g., whether it has been previously disturbed or not), potential effects on land use cannot be determined. In general, if a location in a previously developed portion of a generic DOE site were selected, impacts on land use would be minimal. However, if an undisturbed location were chosen, land use would change from its present designation to industrial. If the reactor alternative were selected, tiered NEPA documentation would permit an exact determination of impacts on land use.

**VISUAL RESOURCES.** Impacts from construction of a research reactor and support facility to visual resources at a generic DOE site would depend on the specific location selected. Impacts could include a change in the present Visual Resource Management rating of the site and/or increase in visibility of the site from offsite locations due to the presence of new structures. If construction took place on undeveloped land, the Visual Resource Management rating could change from Class II or III (ratings typical of undeveloped portions of many DOE sites) to Class IV. If a previously developed location were chosen for the reactor, the Visual Resource Management rating would remain Class IV. In either case, new facilities may impact the view from off site locations by increasing the industrial nature of the viewshed. This impact would be more likely at a western site due to the generally level terrain and sparse vegetation. Specific impacts on visual resources would be determined in tiered NEPA documentation if the reactor alternative were selected.

##### **4.6.1.1.2 Noise**

Construction of a research reactor and support facility would result in some increase in noise levels from the use of earthmoving, materials handling, and impact equipment; employee vehicles; and truck traffic. Noise from construction activities, especially impulsive noise, would be expected to disturb wildlife in the immediate area of the construction site. The change in noise levels in areas outside the DOE site would be dependent on the location selected and the exact nature of the construction location and activities required. However, generally if the location selected were within one of the larger DOE sites and more centrally located within

the site, offsite noise impacts from construction activities can be expected to be small. Construction employee vehicles and truck traffic would result in an increase in traffic noise along roads used to access the site. However, this increase in traffic noise would be small unless the construction traffic volume is as large as the existing site traffic. Site-specific analysis would be conducted in tiered NEPA documentation if the reactor alternative were selected.

#### 4.6.1.1.3 Air Quality

Construction of the new research reactor and support facility would result in an increase in employee vehicles and truck traffic. Criteria pollutants were modeled and compared to the most stringent standards (**Table 4–140**). The maximum ground-level concentrations that would result from reactor construction would be below the ambient air quality standards, although concentrations of some pollutants (i.e., PM<sub>10</sub>) would be relatively high. Therefore, if the reactor were in an area that already had high background pollutant concentrations, resultant pollutant concentrations could approach or exceed the ambient standards. As a result, regulatory compliance would need to be assessed on case-by-case basis. Hazardous chemical emissions from construction have not been identified.

**Table 4–140 Incremental Concentrations Associated with Research Reactor Construction Under All Options of Alternative 4 (Construct New Research Reactor)**

Pollutant	Averaging Period	Most Stringent Standard or Guideline (microgram per cubic meter) <sup>a</sup>	Modeled Increment (microgram per cubic meter)
Carbon monoxide	8 hours	10,000	72
	1 hour	40,000	103
Nitrogen oxide	Annual	100	1
PM <sub>10</sub>	Annual	50	3
	24 hours	150	88

a. The more stringent of the Federal and state standards is presented if both exist for the averaging period. The National Ambient Air Quality Standards (NAAQS) (40 CFR Part 50), other than those based on annual averages, are not to be exceeded more than once per year. The annual arithmetic mean PM<sub>10</sub> standard is attained when the expected annual arithmetic mean concentration is less than or equal to the standards.

**Source:** Modeled increments are based on the SCREEN3 computer code (EPA 1995); data from Appendix E.

#### 4.6.1.1.4 Water Resources

The impacts on key water resource indicators associated with constructing the new research reactor and support facility are presented in **Table 4–141**. Water is expected to be required for such uses as mixing concrete, dust control, washing activities, and potable and sanitary needs. These estimates are annual average values over the forecasted construction periods; these values do not include dewatering of excavations that could be required at some sites. The exact impact of these withdrawals on the resource would depend on the water source (surface water or groundwater) and its relative abundance. These factors would be used to determine the impact on the local and/or regional availability of the resource. Impacts would be expected to be small to negligible due to the relatively small volumes of water required for construction compared to expected site availability.

Sanitary wastewater would be generated by construction personnel and also by facility staff during preoperational testing. Process wastewater could also be generated during construction associated with facility cold-startup and testing of auxiliary systems as construction progresses (e.g., cooling towers). Site selection would make use of existing infrastructure and nearby wastewater treatment facilities would be used to the

**Table 4–141 Estimated Water Use and Wastewater Generation Associated with Constructing a New Research Reactor and Support Facility Under All Options of Alternative 4 (Construct New Research Reactor)**

Indicator (million liters per year)	New Research Reactor <sup>a</sup>	New Support Facility <sup>a</sup>
Water use	11.7	14.6
Sanitary wastewater generation	11.4	3.6

a. These estimates are annualized values based on projected construction/preoperational testing periods for the new research reactor and the new support facility of 4 years and 4.5 years, respectively.

**Note:** To convert from liters per year to gallons per year, multiply by 0.264.

**Source:** Appendix E; SAIC 2000.

extent possible and would be supplemented by portable or temporary facilities during construction as necessary. The potential impact on water resources would depend on the availability and capacity of appropriate treatment facilities. All wastewater would be disposed of in accordance with applicable regulatory requirements with discharges to surface waters in accordance with NPDES effluent limitations.

Ground disturbance and runoff from denuded areas could potentially impact surface water quality near construction areas (Section 4.6.1.1.6). However, appropriate spill prevention practices and soil erosion and sediment control measures (e.g., silt fences, mulching disturbed areas) would be employed during construction to minimize water quality impacts.

Some locations on a generic DOE site could potentially be affected by flooding requiring appropriate siting decisions (refer to Section 3.6.4). Applicable regulatory requirements would be followed in siting facilities including Executive Order 11988, *Floodplain Management*.

Although specific impacts on water resources cannot be determined at this time, site-specific analysis would be conducted in tiered NEPA documentation if the research reactor alternative were selected.

#### **4.6.1.1.5 Geology and Soils**

Construction of the research reactor would disturb a total of approximately 1.6 hectares (4 acres) of land. Construction of the support facility would disturb an additional 2.4 hectares (6 acres) of land (Appendix E; Herrington 2000; SAIC 2000). Related impacts on geologic and soil resources cannot be determined at this time since they are site specific in nature. However, impacts would be expected to be less if previously disturbed land were used than if an undeveloped area were selected for construction. In general, construction activities would likely require appreciable quantities of sand and gravel and possibly other geologic materials and, depending on the site chosen, could temporarily deplete local deposits or stockpiles of these materials. Soil erosion potential is also closely related to the amount of land disturbed.

As discussed in Section 3.6.5, the proposed facilities could be located at a generic DOE site with seismic activity ranging from low to moderate. Known capable faults could be located within 19 kilometers (12 miles). However, no known large-scale geologic conditions are present at any generic DOE site that would preclude the construction and operation of properly designed facilities. Appropriate activities and subsurface investigations would be conducted to identify geologic hazards including seismic and volcanic features and other natural hazards (landslide areas, sinkholes, unstable soils) as part of the site selection process. As stated in DOE Order 420.1, DOE requires that nuclear or nonnuclear facilities be designed, constructed, and operated so that the public, the workers, and the environment are protected from the adverse impacts of natural phenomena hazards, including earthquakes. DOE Order 420.1, Section 4.4, as supplemented by DOE Guide 420.1-2, stipulates the natural phenomena hazards mitigation requirements for DOE facilities. Further, the natural phenomena hazards mitigation requirements of DOE Order 420.1 are consistent with the

guidance for seismic design and construction contained in the National Earthquake Hazards Reduction Program (NEHRP) 1997 provisions (BSSC 1997). In addition, DOE Guide 420.1-2 was recently issued to recognize the consolidation of the three previous U.S. model building codes, including the Uniform Building Code (UBC), into the International Building Code (ICC 2000). The DOE requirements for seismic engineering have followed the UBC, unless the importance of achieving a high level of protection warrants the use of more demanding methods and criteria (DOE Guide 420.1-2). Thus, new facilities would be designed and sited in accordance with DOE Order 420.1.

Site-specific analysis would be conducted in tiered NEPA documentation if the research reactor alternative were selected.

#### **4.6.1.1.6 Ecological Resources**

If the research reactor alternative were selected, tiered NEPA documentation would be undertaken to determine the exact nature of construction impacts on ecological resources. During that process, impacts on individual species and habitats that are sensitive to disturbance would be determined. This would include consideration of wetlands and threatened and endangered species. Wetland delineations and consultation with the U.S. Fish and Wildlife Service and state wildlife agency would take place, as necessary, to ensure that these resources would be protected.

Construction impacts on ecological resources are site specific. The nature of these impacts would be expected to vary depending on whether the site was located in the eastern or western portion of the United States. In fact, depending on the site location, impacts on some resources may not occur. Additionally, construction impacts on ecological resources would depend on whether the selected location was within an already disturbed portion of the site. In general impacts on terrestrial resources, wetlands, aquatic resources, and threatened and endangered species described below are applicable to an undeveloped site.

**Terrestrial Resources.** Construction of a research reactor and support facility would disturb 1.6 hectares (4 acres) and 2.4 hectares (6 acres), respectively, of terrestrial habitat. If these facilities were constructed at an undeveloped location, it is likely that woodland habitat would be lost at an eastern generic DOE site and shrubland would be disturbed at a western site. Land clearing activities would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area were already supporting the maximum number of individuals, the additional animals would compete for limited resources that could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the disturbed area may not survive.

**Wetlands.** Clearing and grading operations could result in the direct loss of wetlands, although proper placement of the research reactor and support facility within the overall generic DOE site would eliminate or reduce the potential for such loss. Indirect impacts could also result from stormwater runoff carrying sediments to wetlands located adjacent to the site. Changes in hydrology, water quality, and soils could occur as a result of alterations in water levels, runoff, and the buildup of sediments. These changes could, in turn, alter the vegetative composition of the wetland. In general, both direct and indirect impacts would be more likely to occur at an eastern site due to the greater abundance of wetlands. If preliminary analysis determined that wetlands could be impacted by development, a wetland delineation would be required. Impacts on wetlands could also lead to the implementation of mitigation measures.

**Aquatic Resources.** During construction of a research reactor and support facility, impacts on aquatic resources could result from stormwater runoff. Runoff could alter flow rates, increase turbidity, and lead to sedimentation of streambeds. These impacts could, in turn, cause temporary and permanent changes in species composition and density, and alter breeding habitats. The implementation of erosion and sediment control procedures would lessen construction impacts.

**Threatened and Endangered Species.** Construction of a research reactor and support facility would have the potential to impact threatened and endangered species. Sources of impacts would be similar to those discussed above for terrestrial resources, wetlands, and aquatic resources. The primary difference is that the resource of concern involves individual species that are sensitive to disturbance and whose existence may be threatened by development. Consultations with the U. S. Fish and Wildlife Service and appropriate state agency would be conducted at the site-specific level, as appropriate.

#### **4.6.1.1.7 Cultural and Paleontological Resources**

The construction of a research reactor and support facility at a generic DOE site would disturb 1.6 hectares (4 acres) and 2.4 hectares (6 acres), respectively. Since the exact nature of the construction site is not known at this time (e.g., whether it has previously been disturbed or not), potential effects on cultural resources cannot be determined. In general, if a location in a previously developed portion of a DOE generic site were selected, impacts on cultural resources may not occur. However, if an undisturbed location were chosen, cultural resources could be impacted. If the reactor alternative were selected, prehistoric and historic resources, including those that are or may be eligible for listing on the National Register of Historic Places, would be identified. These resources would be identified through site surveys and consultation with the State Historic Preservation Officer. Specific concerns about the presence, type, and location of Native American resources would be addressed through consultation with the potentially affected tribes in accordance with the *National Historic Preservation Act*, the *Native American Graves Protection and Repatriation Act*, and the *American Indian Religious Freedom Act*.

#### **4.6.1.1.8 Socioeconomics**

It is estimated that 160 workers would be needed each of the 4 years required to construct the research reactor and support facility at a generic DOE site. The impact of this influx of workers upon the site's region of influence and regional economic area would depend on whether the site were located near a large urbanized area or in a remote rural area. Since the population for the region of influence for a generic site could range from nearly 2.0 million people for a site in a large metropolitan area, to less than 200,000 for a site in a small rural community, the socioeconomic impacts of constructing a new research reactor and support facility would vary greatly. Therefore, if DOE were to select the new research reactor alternative, additional NEPA documentation would be required to select the specific DOE site to locate the new research reactor and support facility. In that document, DOE would perform a thorough evaluation of the socioeconomic impacts of the sites under consideration.

#### **4.6.1.1.9 Public and Occupational Health and Safety—Normal Construction Activities**

**RADIOLOGICAL IMPACTS.** During construction operations, it is not anticipated that there would be any resulting radiological releases to the environment; therefore, no additional dose to the public is expected. Furthermore, construction workers are not expected to receive exposures above natural background levels that exist within the construction areas. However, as a precautionary measure, workers would be badged as deemed appropriate.

**HAZARDOUS CHEMICAL IMPACTS.** No hazardous chemical releases have been identified from construction activities. Therefore, minimal hazardous chemical impacts would be associated with construction.

#### **4.6.1.1.10 Public and Occupational Health and Safety—Construction Accidents**

There are no radiological or hazardous chemical accidents postulated during the construction phases of the new research reactor or support facility. Workers could experience industrial accidents commonly associated with the construction of large facilities.

#### **4.6.1.1.11 Environmental Justice**

Section 4.6.1.1 addresses environmental effects due to construction activities that would be expected to occur at an unspecified reactor and support facility site. The analysis shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected areas are not significant. Unless there are patterns of food consumption among minority or low-income residents surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that construction activities would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site-specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new research reactor and support facility, an additional evaluation of environmental justice at the research reactor and support facility site during construction would be performed prior to implementation.

#### **4.6.1.1.12 Waste Management**

The expected generation rates of waste at a generic DOE site that would be associated with the construction of a new research reactor to irradiate targets and a support facility to fabricate and process medical and industrial isotope targets and to meet research and development needs are provided in **Table 4-142**. These estimates represent the total amount of waste generated during the construction period. These generation rates cannot be compared at this time with site treatment, storage, and disposal capacities because a DOE site has not yet been chosen for these facilities. Site-specific analyses would be conducted if this alternative were chosen, and appropriate NEPA documentation would be prepared.

Section 3.6.11.1 provides DOE site ranges for each waste type that include volume currently stored, projected generation, and for some types of waste, disposal volume. Radiological and chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.6.1.1.9 through 4.6.1.1.11.

#### **4.6.1.2 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

##### **4.6.1.2.1 Land Resources**

**LAND USE.** The operation of a research reactor and support facility at a generic DOE site would not be expected to affect land use. This is because none of the anticipated operational impacts (e.g., air emissions) are expected to affect this resource.

**Table 4–142 Estimated Waste Generation Associated with Constructing a New Research Reactor and Support Facility Under All Options of Alternative 4 (Construct New Research Reactor)**

Waste Type <sup>a</sup>	Estimated Waste Generation for New Research Reactor (total cubic meters)	Estimated Waste Generation for New Support Facility (total cubic meters)
<b>High-level radioactive</b>	0	0
<b>Transuranic</b>	0	0
<b>Low-level radioactive</b>		
Liquid	0	0
Solid	0	0
<b>Mixed low-level radioactive</b>	0	0
<b>Hazardous</b>		
Liquid	1	1
Solid	3	3
<b>Nonhazardous</b>		
Process wastewater	0	0
Sanitary wastewater	44,000	16,000
Solid (kilograms)	1,230,000	230,000

a. See definitions in Section G.9.

**Note:** To convert from cubic meters to cubic yards, multiply by 1.308.

**Source:** Appendix E; SAIC 2000.

REDC would be used for neptunium-237 storage, target fabrication, and processing. The use of REDC for this purpose would not change land use at the site since REDC is currently operating and its proposed use would be compatible with its present mission.

**VISUAL RESOURCES.** The primary source of impacts on visual resources from the operation of a research reactor and support facility would be air emissions. Releases from stacks associated with this alternative would be controlled and, therefore, would be unlikely to exceed Bureau of Land Management Visual Resource Management objectives. However, the operation of cooling towers could result in a visible plume. The extent and visibility of the plume would depend on site meteorological conditions and terrain features. While plume formation would be favored by meteorological conditions at an eastern generic DOE site, terrain features would tend to mask it from offsite locations; the opposite would tend to be true at a western site. If the reactor alternative were selected, the visual impact of the cooling tower plume would be determined in tiered NEPA documentation.

All activities associated with neptunium-237 storage, target fabrication, and processing would take place within REDC. Operations associated with the proposed activities would not result in any impact on visual resources or change in the current Visual Resource Management Class IV rating of the 7900 Area. This is because none of the anticipated operational impacts (e.g., air emissions) would be expected to affect this resource.

#### 4.6.1.2.2 Noise

The operation of a reactor and support facility at a generic DOE site would result in some increase in noise levels from equipment (e.g., cooling systems, vents, motors, generators, compressors, pumps, and material-handling equipment), employee vehicles, and truck traffic. Noise from operation activities could disturb wildlife outside the facility fence line. The change in noise levels in areas outside the DOE site would be dependent on the location selected and the equipment. However, generally if the location selected is within one of the larger DOE sites and is more centrally located within the site, offsite noise impacts from operation can be expected to be small. Operation employee vehicles and truck traffic would result in an increase in traffic noise along roads used to access the site. However, this increase in traffic noise would be small unless

the operation traffic volume were as large as the existing site traffic. Site-specific analysis would be conducted in tiered NEPA documentation if the reactor alternative were selected.

This option also involves using REDC for neptunium-237 target material storage, target fabrication, and processing. Interior modifications of these facilities in the 7900 Area of ORNL would be expected to result in little change in noise impacts on wildlife around this area. The operation of REDC would not be expected to result in any change in noise impacts on wildlife around the 7900 Area and offsite noise impacts would be small because the nearest site boundary is 2.5 kilometers (1.6 miles) to the southeast. Operation would be expected to result in a minimal change in noise impacts on people near ORR as a result of changes in employee and truck traffic levels.

#### 4.6.1.2.3 Air Quality

The operation of a new research reactor and support facility would result in some increase in air quality impacts due to operation of emergency diesel generators. Criteria pollutants were modeled and compared to the most stringent standards (**Table 4–143**). The maximum ground-level pollutant concentrations that would result from reactor operation would be well below the ambient air quality standards. However, if the reactor were in an area that already had high background pollutant concentrations, resultant pollutant concentrations could approach or exceed the ambient standards for some pollutants. As a result, regulatory compliance would need to be assessed on case-by-case basis. Hazardous chemical impacts are addressed in Section 4.6.1.2.9.

**Table 4–143 Incremental Concentrations Associated with Research Reactor Operation<sup>a</sup> Under Alternative 4 (Construct New Research Reactor)—Option 1**

Criteria Pollutant	Averaging Period	Most Stringent Standard or Guideline (micrograms per cubic meter) <sup>b</sup>	Modeled Increment (micrograms per cubic meter)
Carbon monoxide	8 hours	10,000	89.5
	1 hour	40,000	128
Nitrogen oxide	Annual	100	0.198
PM <sub>10</sub>	Annual	50	0.0035
	24 hours	150	3.46
Sulfur dioxide	Annual	80	0.062
	24 hours	365	61.2
	3 hours	1,300	138

a. From operation of two emergency diesel generators.

b. The more stringent of the Federal and state standards is presented if both exist for the averaging period. The National Ambient Air Quality Standards (NAAQS) (40 CFR Part 50), other than those based on annual averages, are not to be exceeded more than once per year. The annual arithmetic mean PM<sub>10</sub> standard is attained when the expected annual arithmetic mean concentration is less than or equal to the standard.

**Source:** Modeled increments are based on the SCREEN3 computer code (EPA 1995); data from Appendix E.

Air quality impacts associated with this option at ORR were determined to be the same as under Option 1 of Alternative 2 (Section 4.4.1.1.3).

The air quality impacts of transportation are presented in Section 4.6.1.2.11.

#### 4.6.1.2.4 Water Resources

The estimated impacts on key water resource indicators associated with operating the new research reactor and support facility are presented in **Table 4–144**. Operation of the research reactor at a generic DOE site would have the highest water demand under this alternative and the second highest of any production facility

considered, requiring 807 million liters (213.2 million gallons) of water per year. In general, water would be required by the new research reactor and support facility to support such uses as process cooling, potable, and sanitary needs. For the new research reactor, the single largest system use would be for cooling tower operation and associated evaporative losses. The exact impact of these withdrawals on the resource would depend on the water source (surface water or groundwater) and its relative abundance. These factors would be used to determine the impact on the local and/or regional availability of the resource. For surface water, a dedicated surface water intake may have to be constructed if the generic site's existing distribution system is inadequate to meet the increased demands of the facilities. For groundwater, additional wells may have to be developed to supply the facilities directly or to provide increased production capacity for the generic site's existing supply system.

**Table 4-144 Estimated Water Use and Wastewater Generation Associated with Operating a New Research Reactor and Support Facility Under Alternative 4 (Construct New Research Reactor)—Option 1**

Indicator (million liters per year)	New Research Reactor <sup>a</sup>	New Support Facility <sup>a</sup>
Water use	807	6.92
Process wastewater generation	7.9	0.016 <sup>a</sup>
Sanitary wastewater generation	11.6	6.91

a. Assume process wastewater generated at the same incremental rate as the Hanford 300 Area facilities (RPL/306-E).

**Note:** To convert from liters per year to gallons per year, multiply by 0.264.

**Source:** Appendix E; SAIC 2000.

The operation of the research reactor is estimated to generate approximately 7.9 million liters (2.1 million gallons) of process wastewater per year. It is expected that this process effluent would mainly consist of cooling tower blowdown. The support facility would generate a very small amount of process wastewater, mainly as a result of material processing. There would be no radiological liquid effluent discharge to the environment from either facility under normal operations. Sanitary wastewater would be generated as a result of operations of the new research reactor and support facility based on facility staff use of lavatory, shower, and kitchen facilities and from miscellaneous potable and sanitary uses. Waste management activities and their effects are further detailed in Section 4.6.1.2.13. The potential impact on water resources would depend on the availability and capacity of appropriate treatment facilities. Process and sanitary wastewater would be discharged to either existing site wastewater treatment facilities or to new facilities constructed specifically to serve the proposed facilities. All wastewater would be disposed of in accordance with applicable regulatory requirements with discharges to surface waters in accordance with NPDES effluent limitations.

Although specific impacts on water resources cannot be determined at this time, site-specific analysis would be conducted in tiered NEPA documentation if the research reactor alternative were selected.

REDC, an existing facility in the 7900 Area of ORNL at ORR, would be used for neptunium-237 storage, target fabrication, and processing in support of plutonium-238 production with impacts on ORR water resources indicators the same as those described in Section 4.3.1.1.4. In summary, a small increase in water use and sanitary wastewater generation is anticipated, mainly attributable to increased staffing levels. Also, there would be a very small increase in process wastewater generation, but there would be no radiological liquid effluent discharge to the environment under normal operations.

#### **4.6.1.2.5 Geology and Soils**

The operation of a research reactor and support facility would not be expected to result in impacts on geologic and soils resources at a generic DOE site. If cooling towers are used, the potential exists for salt deposition

to alter soil chemistry. While high rainfall at an eastern site would tend to keep salt from accumulating in the soil, the potential exists that salt could accumulate at a western site where rainfall is sparse. If the reactor alternative were selected, impacts on geology and soils would be determined in tiered NEPA documentation. As discussed in Section 4.6.1.1.5, the proposed facilities would be designed and constructed in accordance with DOE Order 420.1 and sited to minimize the risk from geologic hazards. Thus, site geologic conditions would be unlikely to affect the facilities.

The use of REDC for neptunium-237 storage, target fabrication, and processing would not be expected to impact either geologic or soil resources, nor be jeopardized by large-scale geologic conditions. Hazards from large-scale geologic conditions at ORR, such as earthquakes, volcanoes, and sinkholes, were previously evaluated in the *Storage and Disposition PEIS* (DOE 1996a:4-260) as discussed in Section 4.2.2.2.5. The analysis determined that these hazards present a low risk to long-term storage facilities. Further review of the data and analyses presented in that document and the site-specific data presented in this NI PEIS indicates that the large-scale geologic conditions likewise present a low risk to REDC operations.

As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards would be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### **4.6.1.2.6 Ecological Resources**

If the new research reactor alternative were selected, tiered NEPA documentation would be undertaken to determine the exact nature of operational impacts on ecological resources. During this process, impacts on individual species and habitats that are sensitive to disturbance would be determined. This would include consideration of wetlands and threatened and endangered species.

While the exact nature of operational impacts on ecological resources cannot be determined until a specific site is selected, certain general types of impacts are possible. The nature and extent of these impacts would be expected to vary depending on whether the selected site was located in the eastern or western portion of the United States.

**Terrestrial Resources.** Activities associated with operations, such as noise and human presence, could affect wildlife living adjacent to the research reactor and support facility. These disturbances could cause some species to move from the area. Preventing workers from entering undisturbed areas would minimize impacts on wildlife living adjacent to the facilities. Emissions to the air and water, both nonradiological and radiological, could impact both plants and animals. Plants and animals could be exposed to pollutants via a number of pathways including direct exposure, contact with contaminated soil, ingestion, and inhalation. Further, bioaccumulation could affect species that consume exposed plants or animals. While regulatory limits would act to limit the effects of air emissions and effluent discharges, impacts would be analyzed once site and facility specific information became available.

**Wetlands.** Impacts from the operation of a research reactor and support facility at a western generic DOE site would not be expected to affect wetlands since discharges would be to an evaporation pond. At an eastern site, wastewater and cooling tower blowdown would be discharged to an onsite waterbody. While these discharges would be through permitted outfalls, the potential exists that wetlands could be affected. Potential impacts, such as changes in water levels and plant species composition, would depend on outfall location, water volume, discharge temperature, and water chemistry. Since these factors depend on site location and facility engineering design, operational impacts on site wetlands would have to be analyzed once these factors are known.

**Aquatic Resources.** Operational impacts on aquatic resources at a western site would not be expected since groundwater would be used and wastewater and cooling tower blowdown would be discharged to an evaporation pond. At an eastern site, potential impacts on aquatic resources could occur as a result of water withdrawal and discharge. Water withdrawal could lead to the loss of aquatic organisms through impingement and entrainment. The discharge of cooling water could result in alterations in aquatic communities. Alterations could include changes in aquatic vegetation and the loss of fish and benthic macroinvertebrates. Additionally, radionuclides and chemicals in the discharge water have the potential to impact aquatic organisms. The extent of potential impacts on the aquatic environment would depend upon site and facility specific information.

**Threatened and Endangered Species.** The operation of a research reactor and support facility would have the potential to impact threatened and endangered species. Sources of impacts would be similar to those discussed above for terrestrial resources, wetlands, and aquatic resources. The primary difference is that the resources of concern involve individual species that are sensitive to disturbance and whose existence may be threatened by development.

REDC would be used for neptunium-237 storage, target fabrication, and processing. As noted in Section 4.6.1.2.2, there would be little change in noise impacts on wildlife. There would be no change in impacts on wetlands or aquatic resources because additional water usage and wastewater discharge would be small fractions of current values. Further, this option would not result in any new contaminants in existing discharges (Section 4.6.1.2.4). Threatened and endangered species would not be affected by operation because an existing facility within an already developed area would be used.

Consultation to comply with Section 7 of the Endangered Species Act was conducted with the U.S. Fish and Wildlife Service (see Table 5–3) and resulted in the Service concluding that it does not anticipate adverse effects to federally listed endangered species that occur near the project area. DOE has also consulted with the Tennessee Department of Environment and Conservation; a response concerning state-listed species is pending from this agency. Although no state-listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at ORR prior to the receipt of input from the state.

#### **4.6.1.2.7 Cultural and Paleontological Resources**

Impacts on cultural and paleontological resources from the operation of a research reactor and support facility at a generic DOE site would depend on the relative location of such resources to the site and/or transportation routes. While impacts would be expected to be nonexistent or small, they cannot be ruled out. For example, noise related to plant operation or traffic to and from the facility or alterations in the viewshed could adversely affect visitor enjoyment of an historic site. Since impacts on cultural resources are site dependent, specific operational impacts cannot be determined until a site were selected. The operation of a reactor and support facility would not be expected to impact paleontological resources.

The operation of REDC for neptunium-237 storage, target fabrication, and processing would not change the status of cultural and paleontological resources at ORR. The Graphite Reactor, which is located within ORNL, is listed on the National Register of Historic Places as a National Historic Landmark. Additionally, several other structures proposed for listing on the National Register of Historic Places are found within or near ORNL. However, neither the Graphite Reactor nor any of the other structures is located within the 7900 Area; thus, the use of REDC for target fabrication and processing would not change their status.

Consultation to comply with Section 106 of the National Historic Preservation Act was initiated with the State Historic Preservation Office (see Table 5–3). While DOE has made additional contact with the State Historic Preservation Office, a response is pending from this office. Although impacts to cultural resources are not

expected as a result of the proposed action, no action would be taken relative to the use of facilities at ORR prior to the receipt of input from the State Historic Preservation Office.

#### 4.6.1.2.8 Socioeconomics

It is estimated that 220 workers would be needed each year to operate the research reactor and support facility at a generic DOE site. The impact of this influx of workers upon the site's region of influence and regional economic area would depend on whether the site were located near a large urbanized area or in a remote rural area. Since the population for the region of influence for a generic site could range from nearly 2.0 million people for a site in a large metropolitan area, to less than 200,000 for a site in a small rural community, the socioeconomic impacts of operating a new research reactor and support facility would vary greatly. Therefore, if DOE were to select this option, additional NEPA documentation would be required to determine the specific socioeconomic impacts.

The socioeconomic impacts associated with neptunium-237 target fabrication and processing at ORR are addressed in Section 4.3.1.1.8.

#### 4.6.1.2.9 Public and Occupational Health and Safety—Normal Operations

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from startup and operations are given in **Table 4-145** for the generic DOE site and ORR: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. Radiological impacts from startup operations prior to fuel loading would be zero. After fuel loading, these impacts would be expected to be bounded by normal operation impacts. Therefore, startup impacts have not been treated separately from normal operational impacts. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

As a result of annual operations of the research reactor facilities and REDC, the projected incremental total population dose in the year 2020 would be 0.14 person-rem; the corresponding number of latent cancer fatalities in the populations surrounding the generic DOE site and ORR from 35 years of operations would be 0.0025. The incremental total dose to the maximally exposed member of the public from annual operations of the research reactor and support facility at the generic DOE site would be 0.0026 millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $4.5 \times 10^{-8}$ .

**Table 4–145 Incremental Radiological Impacts on the Public Around the Generic DOE Site and ORR from Operational Facilities Under Alternative 4 (Construct New Research Reactor)—Option 1**

Receptor	ORR REDC	Generic Site			Two-Site Total
		Research Reactor Operations	Reactor Support Facility Operations	Total	
<b>Population within 80 kilometers (50 miles) in the year 2020</b>					
Dose (person-rem)	$8.8 \times 10^{-5}$	0.0023	0.14	0.14	0.14
35-year latent cancer fatalities	$1.5 \times 10^{-6}$	$4.0 \times 10^{-5}$	0.0025	0.0025	0.0025
<b>Maximally exposed individual</b>					
Annual dose (millirem)	$1.9 \times 10^{-6}$	$6.8 \times 10^{-5}$	0.0025	0.0026	NA <sup>a</sup>
35-year latent cancer fatality risk	$3.3 \times 10^{-11}$	$1.2 \times 10^{-9}$	$4.4 \times 10^{-8}$	$4.5 \times 10^{-8}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>					
Annual dose <sup>b</sup> (millirem)	$7.8 \times 10^{-8}$	$1.5 \times 10^{-6}$	$9.1 \times 10^{-5}$	$9.3 \times 10^{-5}$	NA <sup>a</sup>
35-year latent cancer fatality risk	$1.4 \times 10^{-12}$	$2.6 \times 10^{-11}$	$1.6 \times 10^{-9}$	$1.6 \times 10^{-9}$	NA <sup>a</sup>

- a. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.  
 b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of REDC or the generic site in the year 2020 (1,134,200 and 1,538,100, respectively).

**Key:** NA, not applicable.

**Source:** Appendix E; model results, using the GENII computer code (Napier et al. 1988).

Incremental doses to involved workers from normal operations are given in **Table 4–146**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to research reactor workers during startup and operations would be 100 millirem; for support facility workers, the incremental annual average dose during startup and operations would be 114 millirem; for REDC workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities is estimated to be 12, 11, and 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–146. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–146 Incremental Radiological Impacts on Involved Workers at the Generic DOE Site and ORR from Operational Facilities Under Alternative 4 (Construct New Research Reactor)—Option 1**

Receptor—Involved Workers <sup>a</sup>	ORR REDC	Generic Site		Two-Site Total
		Research Reactor Operations	Reactor Support Facility Operations	
Total dose (person-rem per year)	12 <sup>b</sup>	12 <sup>b</sup>	11 <sup>b</sup>	36
35-year latent cancer fatalities	0.17	0.17	0.16	0.50
Average worker dose (millirem per year)	170	100	114	NA <sup>c</sup>
35-year latent cancer fatality risk	0.0023	0.0014	0.0016	NA <sup>c</sup>

- a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that each facility adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.  
 b. Based on an estimated 75 badged workers at REDC, 120 research reactor workers, and 100 workers at the reactor support facility.

c. Values cannot be given for the average worker because the workers would be in three different facilities at two different sites.

**Key:** NA, not applicable.

**Source:** Nielsen 1999; Wham 1999b, 2000.

**HAZARDOUS CHEMICALS IMPACTS.** The operation of a new reactor and associated support facility would result in some increase in emissions of hazardous chemicals due to diesel fuel burning from different sources of equipment used for operation. The operation of the reactor would require the emergency diesel generators to be tested approximately 1 hour each month and 24 hours once a year to ensure operability. Chemical releases were modeled based on 72 hours of operation. Resulting concentrations were determined to be very small and would have no incremental impact on the site current conditions (**Table 4–147**).

**Table 4–147 Incremental Hazardous Chemical Impacts from New Research Reactor Diesel Generator Operation Under Alternative 4 (Construct New Research Reactor)—Option 1**

Chemicals	Modeled Annual Increment (micrograms per cubic meter)	RfC (micrograms per cubic meter)	Unit Cancer Risk (risk per micrograms per cubic meter)	Hazard Quotient	Cancer Risk
Benzene	$4.83 \times 10^{-5}$	NA	0.0000078	NA	$3.77 \times 10^{-10}$
Naphthalene	$6.83 \times 10^{-6}$	3	NA	$2.28 \times 10^{-6}$	NA
Toluene	$1.75 \times 10^{-5}$	400	NA	$4.38 \times 10^{-8}$	NA
Propylene	$1.73 \times 10^{-4}$	NA	0.0000037	NA	$6.42 \times 10^{-10}$

**Note:** Propylene oxide cancer unit was used for propylene.

**Key:** NA, not applicable (the chemical is not a known carcinogen, or it is a carcinogen and only unit cancer would apply); RfC, Reference Concentration.

**Source:** Data from Appendix E; EPA 1999; modeled increments are based on the SCREEN3 computer code (EPA 1995).

Hazardous chemicals impacts for this option at ORR were determined to be the same as described in Alternative 2, Option 1 (Section 4.4.1.1.9).

#### 4.6.1.2.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with research reactor target irradiation; support facility medical, industrial, and research and development isotope fabrication and processing; and REDC neptunium-237 target fabrication and processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–148** and **4–149**, respectively.

For 35 years of research reactor target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.49 \times 10^{-9}$  and  $8.41 \times 10^{-9}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $2.26 \times 10^{-5}$ .

For 35 years of support facility medical, industrial, and research and development target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $3.26 \times 10^{-5}$  and  $9.85 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.056.

For 35 years of REDC neptunium-237 target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $5.71 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.157.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $8.98 \times 10^{-5}$  and  $4.49 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.213.

**Table 4–148 New Research Reactor, Support Facility, and REDC Accident Consequences Under Alternative 4 (Construct New Research Reactor)—Option 1**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. Risk of an early fatality.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

There are no hazardous chemical accidents associated with the new research reactor or new support facility. The irradiation of neptunium-237, medical, industrial, and research and development isotopes in the new research reactor would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The fabrication and processing of medical, industrial, and research and development isotopes at the new support facility would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The hazardous chemical accident impacts at REDC are the same as those presented in Section 4.4.4.1.10.

#### **4.6.1.2.11 Public and Occupational Health and Safety—Transportation**

DOE would transport neptunium-237 from storage at SRS to the REDC target fabrication facility at ORR. DOE would transport the unirradiated neptunium-237 targets from REDC to the reactor site. Following irradiation in the reactor, the targets would be returned to REDC for processing. After this processing, the plutonium-238 product would be shipped to LANL. The reactor would receive low enriched uranium fuel from a U.S. fuel fabrication facility. Additionally, medical and industrial isotopes would be shipped from the reactor site to a local airport, and from there to locations throughout the country.

Approximately 37,000 shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 7.5 million kilometers (4.7 million miles); and in the air carrying medical isotopes, 23 million kilometers (14 million miles).

The transportation impact analysis is described in detail in Appendix J.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 28.6 person-rem; the dose to the public, 308 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.011 latent cancer fatality among transportation workers and 0.15 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.026. About half of the crew risk, about 2 percent of the public risk, and most of the emissions risk would result from shipping medical and industrial isotopes.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FDPF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 was also evaluated and estimated to have a probability of less than 1 in 10 million per year.

Estimates of the total transportation accident risks under this option are as follows: a radiological dose to the population of 1,063 person-rem, resulting in 0.53 latent cancer fatality; and traffic accidents resulting in 0.19 traffic fatality. Nearly all of the radiological and about 59 percent of the traffic accident risk would result from shipping medical and industrial isotopes.

#### **4.6.1.2.12 Environmental Justice**

Under this option, neptunium-237 targets would be irradiated in a new reactor that would be constructed at a site yet to be specified. Fabrication and processing of neptunium-237 targets for plutonium-238 production would be performed at REDC located at ORR. A new support facility would be constructed at an unspecified site for fabrication and processing targets not used for plutonium-238 production.

Activities at REDC were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.1.1.12) and found to pose no significant radiological or other risks to minority and low-income populations. The environmental analysis of operations at the new research reactor and support facility site shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected

area would not be significant. Unless there are patterns of food consumption among minority or low-income resident surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that operations at the site would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site-specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new research reactor and support facility, an additional evaluation of environmental justice at the reactor and support facility site during operation would be performed prior to implementation.

#### 4.6.1.2.13 Waste Management

The expected annual generation of waste that would be generated from the operation of a new research reactor to irradiate targets and a support facility to fabricate and process medical and industrial isotope targets and to meet research and development needs are provided in **Table 4–150**. These generation rates cannot be compared at this time with site treatment, storage, and disposal capacities because a DOE site has not yet been chosen for these facilities. Section 3.6.11.1 provides DOE site ranges for each waste type that include volume currently stored, projected generation, and for some types of waste, disposal volume. Radiological and chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.6.1.2.9 through 4.6.1.2.11.

**Table 4–150 Estimated Waste Generation Rates of Operating a New Research Reactor and Support Facility Under Alternative 4 (Construct New Research Reactor)—Option 1**

Waste Type <sup>a</sup>	Estimated Waste Generation for New Research Reactor (cubic meters per year)	Estimated Waste Generation for New Support Facility (cubic meters per year)
High-level radioactive	0	0
Transuranic	0	0
<b>Low-level radioactive</b>		
Liquid	<6	0
Solid	50	20
Mixed low-level radioactive	<0.5	4
Hazardous	4	<1
<b>Nonhazardous</b>		
Process wastewater	7,950	16 <sup>b</sup>
Sanitary wastewater	11,600	6,900
Solid	250	80

a. See definitions in Section G.9.

b. Assumes process wastewater generated at the same incremental rate as Hanford 300 facilities.

**Note:** To convert from cubic meters per year to cubic yards per year, multiply by 1.308; < means “less than.”

**Source:** Appendix E; SAIC 2000.

Depending in part on decisions in the Records of Decision for the *Waste Management PEIS* (DOE 1997a), waste could be treated and disposed of on site or at other DOE sites or commercial facilities. No high-level radioactive waste or transuranic waste would be generated from irradiating targets in the new research reactor or from target fabrication or processing in the new support facility.

Currently, DOE sites that manage low-level radioactive waste treat and/or dispose of the waste on site or off site, either at another DOE facility or a commercial facility. The low-level radioactive waste and mixed low-level radioactive waste Record of Decision issued on February 18, 2000 (65 FR 10061), states that for the management of low-level radioactive waste, minimal treatment will be performed at all sites, and disposal will

continue, to the extent practicable, on site at INEEL, LANL, ORR, and SRS. In addition, Hanford and the Nevada Test Site will be available to all DOE sites for low-level radioactive waste disposal. Less than 210 cubic meters (275 cubic yards) of liquid low-level radioactive waste and 1,750 cubic meters (2,300 cubic yards) of solid low-level radioactive waste would be generated over a 35-year period as a result of target irradiation at the new research reactor. Target fabrication and processing at the new support facility would generate about 700 cubic meters (920 cubic yards) of solid low-level radioactive waste. The minor amounts of low-level radioactive waste (less than 10 cubic meters [13.1 cubic yards]) (Brunson 1999a) generated from the decontamination of the shipping containers used to transport neptunium-237 from SRS to REDC (or FDPF or FMEF, depending on the option) for storage could easily be managed under the existing waste management practices and are not included in the table.

Most of DOE's mixed low-level radioactive waste is being stored on site awaiting the development of treatment methods. DOE is subject to the requirements mandated by the Federal Facility Compliance Act of 1992, and most DOE facilities that currently store or generate mixed low-level radioactive waste have either a state-approved or EPA region-approved site treatment plan or another type of agreement. Each site treatment plan or agreement requires the treatment of mixed waste, including mixed low-level radioactive waste, in accordance with its provisions. The low-level radioactive waste and mixed low-level radioactive waste Record of Decision, issued on February 18, 2000 (65 FR 10061), states that mixed low-level radioactive waste will be treated at Hanford, INEEL, ORR, and SRS and disposed of at Hanford and the Nevada Test Site. Over the 35-year operational period, less than 18 cubic meters (24 cubic yards) of mixed low-level radioactive waste would be generated as a result of target irradiation at the new research reactor. Target fabrication and processing at the new support facility would generate about 140 cubic meters (180 cubic yards) of mixed low-level radioactive waste.

The hazardous waste Record of Decision, issued on August 5, 1998 (63 FR 41810), states that most DOE sites will continue to use offsite facilities for the treatment and disposal of major portions of nonwastewater hazardous waste, with ORR and SRS continuing to treat some of their own nonwastewater hazardous waste on site in existing facilities where this is economically favorable. Wastewater, which is about 99 percent of DOE's hazardous waste, is treated on site. An estimated 140 cubic meters (180 cubic yards) of hazardous waste would be generated during the 35-year operational period at the research reactor and less than 35 cubic meters (46 cubic yards) at the new support facility.

DOE currently manages sanitary and industrial waste on a site-by-site basis. Some DOE sites dispose of this waste in onsite landfills that have permits issued by appropriate state agencies, while other sites use commercial landfills (DOE 1997a:1-29). Solid waste such as office paper, metal cans, and plastic and glass bottles that can be recycled would be sent off site for that purpose. Over the 35-year operational period, an estimated 280,000 cubic meters (370,000 cubic yards) of process wastewater, 406,000 cubic meters (531,000 cubic yards) of sanitary wastewater, and 8,800 cubic meters (12,000 cubic yards) of solid nonhazardous waste would be generated as a result of target irradiation at the new research reactor. Target fabrication and processing at the new support facility would generate about 560 cubic meters (730 cubic yards) of process wastewater, 241,500 cubic meters (316,000 cubic yards) of sanitary wastewater, and 2,800 cubic meters (3,700 cubic yards) of solid nonhazardous waste.

The impacts of managing waste associated with fabricating and processing neptunium-237 targets for plutonium-238 production in REDC at ORR are assumed to be the same as for Option 1 under Alternative 1 (Section 4.3.1.1.13). As shown in that section, the impacts on the waste management systems at ORR would be minimal.

#### **4.6.1.2.14 Spent Nuclear Fuel Management**

The operation of the proposed new research reactor would generate about 0.31 metric ton heavy metal (682 pounds) of spent nuclear fuel per year, a total of about 11 metric tons heavy metal (24,200 pounds) from 35 years of operation. This spent nuclear fuel would be stored at the spent nuclear fuel pool at the reactor site. The spent nuclear fuel pool would be designed to provide enough capacity for 35 years of operation, that is, have a total capacity of about 11 metric tons (24,200 pounds). No dry fuel storage is anticipated at the site; therefore there are no environmental impacts associated with the construction of a dry fuel storage facility. The environmental impacts associated with the normal operation of the proposed new research reactor (which includes spent nuclear fuel storage) would result in an annual dose to the maximally exposed individual member of the public of  $6.8 \times 10^{-5}$  millirem from total site operations. This dose is well below the EPA's Clean Air Act standard of 10 millirem per year that is cited in DOE Order 5400.5. The environmental impacts associated with spent nuclear fuel management would be small.

#### **4.6.1.3 Decontamination and Decommissioning of the Research Reactor and Support Facility**

The environmental impacts associated with the decontamination and decommissioning of the research reactor and support facility at the generic DOE site are assessed in this section. If the research reactor were built on a site with existing support facilities, there would be no impacts associated with decommissioning a “new” support facility.

##### **4.6.1.3.1 Land Resources**

**LAND USE.** Decontamination and decommissioning of a research reactor and support facility would not involve the removal of any major structures, although some smaller facilities and pieces of equipment could be removed. Thus, the industrial nature of the land would not change.

**VISUAL RESOURCES.** Decontamination and decommissioning of a research reactor and support facility would not impact visual resources since no major structures would be removed. Thus, the Visual Resource Management Class IV rating of the site would remain unchanged.

##### **4.6.1.3.2 Noise**

Decontamination and decommissioning of a reactor and support facility would result in some increase in noise levels from the use of construction type equipment, materials handling and impact equipment, employee vehicles, and truck traffic. Actual noise levels would depend on the decontamination and decommissioning activities selected. Noise from these activities, especially impulsive noise, would be expected to disturb wildlife in the immediate area of the facilities. The change in noise levels in areas outside the DOE site would depend on the location selected and the exact nature of the activities required. However, generally if the reactor and support facility location were within one of the larger DOE sites and were more centrally located within the site, offsite noise impacts from decontamination and decommissioning activities would be expected to be small. Employee vehicles and truck traffic would result in an increase in traffic noise along roads used to access the site. However, this increase in traffic noise would be small unless the decontamination and decommissioning traffic volume were as large as the traffic from facility operation and other site activities. Site-specific analysis would be conducted in tiered NEPA documentation if the reactor alternative were selected.

#### **4.6.1.3.3 Air Quality**

Deactivation and decommissioning of the new reactor and support facility would result in some change in the air quality impacts. However, they would not be expected to be higher than the impacts associated with construction and operation.

#### **4.6.1.3.4 Water Resources**

Decontamination and decommissioning of the research reactor and support facility would involve permanent shutdown, stabilization, and monitoring of the deactivated facilities. As a result, processing and auxiliary systems would be shutdown and process and sanitary wastewater discharges would cease from the vacated facilities. This would eliminate the annual discharge of approximately 7.9 million liters (2.1 million gallons) of nonradioactive process wastewater from the research reactor and 0.016 million liters (0.004 million gallons) from the support facility on an annual basis. The discharge of 11.6 million liters (3.07 million gallons) per year of sanitary wastewater from the research reactor and 6.91 million liters (1.82 million gallons) from the support facility would be eliminated to onsite treatment facilities. The effects of decontamination and decommissioning on waste management are further detailed in Section 4.6.1.3.13. Site water withdrawals to supply the facilities would also be reduced by approximately 807 million liters (213.2 million gallons) per year for the research reactor and 6.92 million liter (1.83 million gallons) annually for the support facility (Appendix E; SAIC 2000).

#### **4.6.1.3.5 Geology and Soils**

No major structures would be demolished to effect decontamination and decommissioning of the research reactor and support facility. Some ground disturbance could occur associated with removal of some smaller facilities and pieces of equipment. However, ground disturbance would be confined to previously disturbed areas immediately adjacent to the reactor complex and support facility, with the impact on geologic and soil resources expected to be negligible overall.

#### **4.6.1.3.6 Ecological Resources**

Since no major structures would be demolished during decontamination and decommissioning of a research reactor and support facility, the area would continue to be of limited value to wildlife. Noise from decontamination and decommissioning activities would be expected to disturb wildlife in the immediate area; however, this disturbance would be of limited duration. Water use would decrease at the generic site with the decommissioning of a research reactor and support facility. This would result in a decrease in impingement and entrainment of aquatic organisms, as well as a decrease in impacts from effluent discharge at a site where surface water bodies are used. At a site where water is withdrawn from groundwater and discharged to an evaporation pond, the cessation of discharge from a reactor and support facility could result in a reduction in the size of the pond or its possible elimination. This could, in turn, result in the loss (or elimination) of associated aquatic and terrestrial wildlife, as well as wetland habitat. The response of any threatened or endangered species to decontamination and decommissioning of a reactor and support facility could vary from positive (e.g., due to a decrease in human presence and emissions) to negative (e.g., due to the elimination of aquatic or wetland habitat), depending on the species involved.

#### **4.6.1.3.7 Cultural and Paleontological Resources**

Decontamination and decommissioning of a research reactor and support facility would not change the status of cultural and paleontological resources. Any required ground disturbance would be confined to previously disturbed areas immediately adjacent to the reactor and support facility.

#### 4.6.1.3.8 Socioeconomics

Decommissioning of the research reactor and support facility would result in a negative impact on the socioeconomic characteristics of the DOE site at which they were located. This impact would depend on whether the candidate site was located near a large urbanized area or in a remote rural area. Since the population for the region of influence for a generic DOE site could range from nearly 2.0 million people for a site in a large metropolitan area, to less than 200,000 for a site in a small rural community, the socioeconomic impacts of decommissioning would vary greatly. If DOE were to select the new research reactor alternative, additional NEPA documentation would be required to evaluate the specific socioeconomic impacts of the decommissioning.

#### 4.6.1.3.9 Public and Occupational Health and Safety—Normal Decontamination and Decommissioning Activities

Assessments of incremental radiological and chemical impacts associated with the decontamination and decommissioning of the research reactor and support facility are presented in this section. Supplemental information is provided in Appendix H.

During decontamination and decommissioning operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

**RADIOLOGICAL IMPACTS.** In the *Final Generic Environmental Impact Statement on Decommissioning of Nuclear Facilities*, NUREG-0586, (NRC 1988), NRC determined that the health impact to the public from the decommissioning of research reactors was “negligible.” This statement was based on the analysis of a 60-megawatt thermal light water pool reactor fueled with TRIGA fuel. The generic reactor facility used in the analysis of generic research reactor environmental impacts is a 50-megawatt thermal light water pool reactor fueled with TRIGA fuel. In the same NUREG, NRC also concluded that the public health impact from radiological releases associated with the decommissioning and decontamination of process facilities similar to the generic research reactor support facility was also “negligible.” Based on these NRC conclusions, the environmental impact on the public health and safety from the routine release of radionuclides during the decontamination and decommissioning of the generic research reactor and its support facility addressed in this NI PEIS are deemed to be negligible.

Incremental doses to involved workers from decontamination and decommissioning operations are given in **Table 4-151**; these workers are defined as those directly associated with all decontamination and decommissioning activities. The incremental annual average dose to involved workers during decontamination and decommissioning operations at the research reactor would be 275 millirem; for support facility workers, the incremental annual average dose during decontamination and decommissioning operations would be 25 millirem. The incremental annual dose received by the total site workforce for each of these facilities is estimated to be 11 and 1 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from annual decontamination and decommissioning operations are included in **Table 4-151**; a probability coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem was applied for workers (ICRP 1991). Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–151 Incremental Radiological Impacts on Involved Workers at the Generic DOE Site from the Research Reactor and Support Facility Decontamination and Decommissioning Activities Under All Options of Alternative 4 (Construct New Research Reactor)**

Receptor—Involved Workers <sup>a</sup>	Generic Site Decontamination and Decommissioning Activities		
	Research Reactor	Research Reactor Support Facility	Total
Total dose (person-rem per year)	11 <sup>b</sup>	1 <sup>b</sup>	12
4-year latent cancer fatalities	0.018	0.0016	0.019
Average worker dose (millirem per year)	275	25	150
4-year latent cancer fatality risk	$4.4 \times 10^{-4}$	$4.0 \times 10^{-5}$	$2.4 \times 10^{-4}$

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that each facility adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 40 badged workers.

Source: NRC 1988.

**HAZARDOUS CHEMICAL IMPACTS.** Limited impacts would result from hazardous chemicals associated with deactivation and decommissioning activities.

#### 4.6.1.3.10 Public and Occupational Health and Safety—Decontamination and Decommissioning Accidents

Impacts from postulated accidents associated with the decontamination and decommissioning of the research reactor and support facility are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–152** and **4–153**, respectively.

**Table 4–152 Research Reactor and Support Facility Decontamination and Decommissioning Accident Consequences Under All Options of Alternative 4 (Construct New Research Reactor)**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
Spent nuclear fuel cask drop	$7.01 \times 10^{-12}$	$3.51 \times 10^{-15}$	$2.78 \times 10^{-8}$	$1.39 \times 10^{-11}$	$1.30 \times 10^{-11}$	$5.20 \times 10^{-15}$
Reactor core tank vaporization	$1.55 \times 10^{-5}$	$7.75 \times 10^{-9}$	0.346	$1.73 \times 10^{-4}$	$5.23 \times 10^{-5}$	$2.09 \times 10^{-8}$

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

Source: Model results using MACCS2 (Chanin and Young 1997).

**Table 4–153 Research Reactor and Support Facility Decontamination and Decommissioning Accident Risks Under All Options of Alternative 4 (Construct New Research Reactor)**

Accident (Frequency)	Maximally Exposed Individual <sup>a</sup>	Population to 80 Kilometers (50 Miles) <sup>b</sup>	Noninvolved Worker <sup>a</sup>
Spent nuclear fuel cask drop ( $5.0 \times 10^{-6}$ )	$1.75 \times 10^{-20}$	$6.95 \times 10^{-17}$	$2.60 \times 10^{-20}$
Reactor core tank vaporization ( $1.0 \times 10^{-4}$ )	$7.75 \times 10^{-13}$	$1.73 \times 10^{-8}$	$2.09 \times 10^{-12}$

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

Source: Model results using MACCS2 (Chanin and Young 1997).

For a spent nuclear fuel cask drop, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $1.75 \times 10^{-20}$  and  $2.60 \times 10^{-20}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $6.95 \times 10^{-17}$ .

For a reactor core tank vaporization accident, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $7.75 \times 10^{-13}$  and  $2.09 \times 10^{-12}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $1.73 \times 10^{-8}$ .

There are no hazardous chemical accidents postulated during the decontamination and decommissioning phases of the new research reactor or the new support facility. Involved workers could experience industrial accidents commonly associated with these types of activities.

#### 4.6.1.3.11 Environmental Justice

Environmental effects due to decontamination and decommissioning activities that would be expected to occur at the unspecified reactor and support facility site are addressed in Section 4.6.1.3. The environmental analysis of decontamination and decommissioning activities at the new reactor and support facility site shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected area are not significant. Unless there are patterns of food consumption among minority or low-income residents surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that decontamination and decommissioning activities at the site would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site-specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new research reactor and support facility, an additional evaluation of environmental justice at the reactor and support facility site during decontamination and decommissioning would be performed prior to implementation.

#### 4.6.1.3.12 Waste Management

The decontamination and decommissioning of the new research reactor and support facility would generate numerous types of waste. The materials that may be removed or stabilized as a result of decontamination and decommissioning would be managed and reused, recycled, or disposed of in accordance with applicable Federal and state regulations. No analysis of waste management impacts, however, can be formulated at this time. Once proposals concerning decontamination and decommissioning activities are developed, DOE will undertake any additional NEPA analysis that may be necessary or appropriate.

#### **4.6.1.3.13 Spent Nuclear Fuel Management**

The Nuclear Waste Policy Act of 1982, as amended, assigned to the Secretary of Energy the responsibility for the development of a geologic repository for the ultimate disposal of high-level radioactive waste and spent nuclear fuel. When such a repository is available, spent nuclear fuel would be transferred from nuclear reactor sites to the repository for disposal. Until a repository becomes available, spent nuclear fuel associated with the operation of the research reactor would be stored in the reactor pool. Upon cessation of research reactor operations, the reactor would be decontaminated and decommissioned. At that time, spent nuclear fuel stored in the pool would be packaged in acceptable containers and shipped to the geologic repository for disposal.

#### **4.6.1.4 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.6.2 Alternative 4 (Construct New Research Reactor)—Option 2**

Option 2 involves constructing and operating the research reactor to irradiate all targets associated with plutonium-238 production, medical and industrial isotope production, and research and development; operating FDFP at INEEL to fabricate and process neptunium-237 targets and to process the plutonium-238 product; and constructing and operating the support facility to fabricate and process the other targets and materials and to process the associated products. This option includes storage in Building CPP-651 or FDFP of the neptunium-237 transported to INEEL from SRS and storage in the new support facility of the other target materials transported to the generic site from other offsite facilities.

The transportation of the low enriched uranium fuel for use in the research reactor, the transportation of the neptunium-237 to INEEL and then to the generic site, the transportation of the other target materials to the generic site, and the transportation of all product materials following irradiation and postirradiation processing are also part of this option.

All options under this alternative include the decontamination and decommissioning of the research reactor and support facility at the generic site following their operating lifetimes, and also the permanent deactivation of FFTF at Hanford.

##### **4.6.2.1 Construction of the New Research Reactor and Support Facility**

The environmental impacts associated with the construction of a new research reactor and support facility at the generic DOE site are assessed in Section 4.6.1.1.

##### **4.6.2.2 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

###### **4.6.2.2.1 Land Resources**

**LAND USE.** Impacts on land use associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.1.

Building CPP-651 and/or FDFP, which are located at INTEC, would be used for neptunium-237 storage, and FDFP would be used for target fabrication and processing. Use of these facilities would not change land use

at the site since both are currently operating and their proposed use would be compatible with their present mission.

**VISUAL RESOURCES.** Impacts on visual resources associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.1.

All activities associated with neptunium-237 storage would take place within Building CPP-651 and/or FDPF, and target fabrication and processing in FDPF. Operations associated with the proposed activities would not result in any impact on visual resources or change in the current Visual Resource Management Class IV rating of INTEC. This is because none of the anticipated operational impacts (e.g., air emissions) would be expected to affect this resource.

#### **4.6.2.2.2 Noise**

Noise impacts associated with operation of a research reactor and support facility are addressed in Section 4.6.1.2.2.

This option also involves using the Building CPP-651 and/or FDPF, both in the INTEC area of INEEL, for neptunium-237 target material storage, and FDPF for target fabrication and processing. Interior modifications of these facilities would be expected to result in little change in noise impacts on wildlife around this area. The operation of this facility would not be expected to result in any change in noise impacts on wildlife around the INTEC area and offsite noise impacts would be small because the nearest site boundary is 12 kilometers (7.5 miles) to the south. Operation would be expected to result in minimal change in noise impacts on people near the INEEL as a result of changes in employee and truck traffic levels.

#### **4.6.2.2.3 Air Quality**

Air quality impacts associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.3.

Impacts associated with this option at INEEL were determined to be the same as under Option 2 of Alternative 2 (Section 4.4.2.1.3).

The air quality impacts of transportation are presented in Section 4.6.2.2.11.

#### **4.6.2.2.4 Water Resources**

Impacts on water resources associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.4.

Building CPP-651 and/or FDPF, existing facilities in the INTEC area of INEEL, would be used for neptunium-237 storage; FDPF would also be used for the fabrication and processing of targets in support of plutonium-238 production. Impacts on water resources indicators at INEEL would be the same as those described in Section 4.3.2.1.4. In summary, a small increase in water use and sanitary wastewater generation would be anticipated, mainly attributable to increased staffing levels. Also, there would be a very small increase in process wastewater generation, but there would be no radiological liquid effluent discharge to the environment under normal operations.

#### 4.6.2.2.5 Geology and Soils

Impacts on geology and soils associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.5. As discussed in Section 4.6.1.1.5, the proposed facilities would be designed and constructed in accordance with DOE Order 420.1 and sited to minimize the risk from geologic hazards. Thus, site geologic conditions would be unlikely to affect the facilities.

The use of Building CPP-651 and/or FDPF for neptunium-237 storage, and FDPF for target fabrication and processing would not be expected to impact geologic resources, nor be jeopardized by large-scale geologic conditions. Hazards from large-scale geologic conditions at INEEL, such as earthquakes and volcanoes, were previously evaluated in the *Storage and Disposition PEIS* (DOE 1996a:4-148) as discussed in Section 4.2.3.2.5. The analysis determined that these hazards present a low risk to long-term storage facilities. That analysis was reviewed in the *Surplus Plutonium Disposition EIS* (DOE 1999a:4-267-268). Further review of the data and analyses presented in these referenced documents and the site-specific data presented in this NI PEIS indicates that the large-scale geologic conditions likewise present a low risk to the proposed use of the INTEC facilities. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards would be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### 4.6.2.2.6 Ecological Resources

Impacts on ecological resources associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.6.

Building CPP-651 and/or FDPF would be used for neptunium-237 storage, and FDPF for target fabrication and processing. As noted in Section 4.6.2.2.2, there would be no change in noise impacts on wildlife. Because additional water usage and wastewater discharge would be small fractions of current values, there would be no impact on aquatic resources (Section 4.6.2.2.4). Threatened and endangered species would not be affected by operation because an existing facility(s) within an already developed area would be used.

Consultation letters to comply with Section 7 of the Endangered Species Act were sent to the U.S. Fish and Wildlife Service and the Idaho Department of Fish and Game (see Table 5-3). Each agency was asked to provide information on potential impacts of the proposed action on threatened and endangered species. The Idaho Department of Fish and Game indicated that its database contained no known occurrences of special status plants or animals near the project area. While DOE has made additional contact with the U.S. Fish and Wildlife Service, a response is pending from this agency. Although no federally listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at INEEL prior to the receipt of input from the Service.

#### 4.6.2.2.7 Cultural and Paleontological Resources

Impacts on cultural and paleontological resources associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.7.

Although six historic structures are associated with INTEC, their status would not be affected by operation of Building CPP-651 and/or FDPF for neptunium-237 storage, and FDPF for target fabrication and processing. Also, the status of Native American and paleontological resources occurring in the vicinity of INTEC would not be affected by the operation of these facilities.

Consultation to comply with Section 106 of the National Historic Preservation Act was initiated with the State Historic Preservation Office (see Table 5–3). The State Historic Preservation Office indicated that Building CPP–651 and FDPF are likely to be eligible for the National Register of Historic Places as contributory properties in a potential historic district of exceptional significance. However, at this time, the State Historic Preservation Office has determined that more information is needed prior to assisting DOE in evaluating these properties. The State Historic Preservation Office also indicated that since there would be no new construction, there is little potential for effects on archaeological properties. DOE would provide additional information as required to the Idaho State Historic Preservation Office prior to the use of any facility at INEEL for the proposed project. Consultation was conducted with interested Native American tribes; however, responses are pending.

#### 4.6.2.2.8 Socioeconomics

The socioeconomic impacts associated with the operation of the new research reactor and support facility at a generic DOE site are addressed in Section 4.6.1.2.8.

The socioeconomic impacts associated with neptunium-237 target fabrication and processing at INEEL are addressed in Section 4.3.2.1.8.

#### 4.6.2.2.9 Public and Occupational Health and Safety—Normal Operations

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from startup and operations are given in **Table 4–154** for the generic DOE site and INEEL: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public.

Radiological impacts from startup operations prior to fuel loading would be zero. After fuel loading, these impacts would be expected to be bounded by the normal operation impacts. Therefore, startup impacts have not been treated separately from normal operational impacts. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

As a result of annual operations of the research reactor facilities and FDPF, the projected incremental total population dose in the year 2020 would be 0.14 person-rem; the corresponding number of latent cancer fatalities in the populations surrounding the generic DOE site and INEEL from 35 years of operations would be 0.0025. The incremental total dose to the maximally exposed member of the public from annual operations of the research reactor and support facility at the generic DOE site would be 0.0026 millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $4.5 \times 10^{-8}$ .

**Table 4–154 Incremental Radiological Impacts on the Public Around the Generic DOE Site and INEEL from Operational Facilities Under Alternative 4 (Construct New Research Reactor)—Option 2**

Receptor	INEEL FDPF	Generic Site			Two-Site Total
		Research Reactor Operations	Reactor Support Facility Operations	Total	
<b>Population within 80 kilometers (50 miles) in the year 2020</b>					
Dose (person-rem)	$3.9 \times 10^{-6}$	0.0023	0.14	0.14	0.14
35-year latent cancer fatalities	$6.7 \times 10^{-8}$	$4.0 \times 10^{-5}$	0.0025	0.0025	0.0025
<b>Maximally exposed individual</b>					
Annual dose (millirem)	$2.6 \times 10^{-7}$	$6.8 \times 10^{-5}$	0.0025	0.0026	NA <sup>a</sup>
35-year latent cancer fatality risk	$4.6 \times 10^{-12}$	$1.2 \times 10^{-9}$	$4.4 \times 10^{-8}$	$4.5 \times 10^{-8}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>					
Annual dose <sup>b</sup> (millirem)	$2.0 \times 10^{-8}$	$1.5 \times 10^{-6}$	$9.1 \times 10^{-5}$	$9.3 \times 10^{-5}$	NA <sup>a</sup>
35-year latent cancer fatality risk	$3.6 \times 10^{-13}$	$2.6 \times 10^{-11}$	$1.6 \times 10^{-9}$	$1.6 \times 10^{-9}$	NA <sup>a</sup>

- a. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.  
 b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FDPF or the generic site in the year 2020 (188,400 and 1,538,100, respectively).

**Key:** NA, not applicable.

**Source:** Appendix E; model results, using the GENII computer code (Napier et al. 1988).

Incremental doses to involved workers from normal operations are given in **Table 4–155**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to research reactor workers during operations would be 100 millirem; for support facility workers, the incremental annual average dose during operations would be 114 millirem; for FDPF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities is estimated to be 12, 11, and 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–155. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–155 Incremental Radiological Impacts on Involved Workers at the Generic DOE Site and INEEL from Operational Facilities Under Alternative 4 (Construct New Research Reactor)—Option 2**

Receptor—Involved Workers <sup>a</sup>	INEEL FDPF	Generic Site		Two-Site Total
		Research Reactor Operations	Reactor Support Facility Operations	
Total dose (person-rem per year)	12 <sup>b</sup>	12 <sup>b</sup>	11 <sup>b</sup>	36
35-year latent cancer fatalities	0.17	0.17	0.16	0.50
Average worker dose (millirem per year)	170	100	114	NA <sup>c</sup>
35-year latent cancer fatality risk	0.0023	0.0014	0.0016	NA <sup>c</sup>

- a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that each facility adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 75 badged workers at FDPF, 120 research reactor workers, and 100 workers at the reactor support facility.

c. Values cannot be given for the average worker because the workers would be in three different facilities at two different sites.

**Key:** NA, not applicable.

**Source:** Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts associated with the operation of the research reactor and support facility are addressed in Section 4.6.1.2.9.

Impacts from hazardous chemicals at INEEL were determined to be the same as in Alternative 2, Option 2 (Section 4.4.2.1.9).

#### 4.6.2.2.10 Public and Occupational Health and Safety—Facility Accidents

Impacts from postulated accidents associated with research reactor target irradiation; support facility medical, industrial, and research and development isotope fabrication and processing; and FDPF neptunium-237 target fabrication and processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–156** and **4–157**, respectively.

**Table 4–156 New Research Reactor, Support Facility, and FDPF Accident Consequences Under Alternative 4 (Construct New Research Reactor)—Option 2**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>
<b>New research reactor accidents</b>						
Design-basis accident	$1.33 \times 10^{-6}$	$6.65 \times 10^{-10}$	0.00241	$1.20 \times 10^{-6}$	$5.49 \times 10^{-6}$	$2.20 \times 10^{-9}$
Beyond-design-basis earthquake	0.00373	$1.87 \times 10^{-6}$	27.6	0.0138	0.0531	$2.12 \times 10^{-5}$
Fuel-handling accident	$1.90 \times 10^{-9}$	$9.50 \times 10^{-13}$	$6.79 \times 10^{-6}$	$3.40 \times 10^{-9}$	$5.83 \times 10^{-9}$	$2.33 \times 10^{-12}$
Neptunium-237 target-handling accident	$5.42 \times 10^{-8}$	$2.71 \times 10^{-11}$	$8.95 \times 10^{-5}$	$4.47 \times 10^{-8}$	$2.43 \times 10^{-7}$	$9.72 \times 10^{-11}$
Medical isotope target-handling accident	$1.04 \times 10^{-5}$	$5.20 \times 10^{-9}$	0.101	$5.06 \times 10^{-5}$	$6.76 \times 10^{-6}$	$2.70 \times 10^{-9}$
<b>Support facility accidents</b>						
Medical and industrial isotopes localized solvent fire	0.0194	$9.72 \times 10^{-6}$	31.1	0.0156	0.00530	$2.12 \times 10^{-6}$
Medical and industrial isotopes unlikely seismic event	0.0750	$3.75 \times 10^{-5}$	136	0.0680	0.510	$2.04 \times 10^{-4}$
Medical and industrial isotopes glovebox explosion	2.50	0.00125	4,600	2.30	17.0	0.00680
<b>FDPF accidents</b>						
Ion exchange explosion during neptunium-237 target fabrication	$2.01 \times 10^{-9}$	$1.01 \times 10^{-12}$	$2.49 \times 10^{-5}$	$1.24 \times 10^{-8}$	$7.26 \times 10^{-9}$	$2.91 \times 10^{-12}$
Target dissolver tank failure during plutonium-238 separation	$6.11 \times 10^{-8}$	$3.05 \times 10^{-11}$	$5.65 \times 10^{-4}$	$2.82 \times 10^{-7}$	$2.17 \times 10^{-7}$	$8.69 \times 10^{-11}$
Ion exchange explosion during plutonium-238 separation	$1.63 \times 10^{-5}$	$8.13 \times 10^{-9}$	0.150	$7.51 \times 10^{-5}$	$5.79 \times 10^{-5}$	$2.31 \times 10^{-8}$
Plutonium-238 processing facility beyond-design-basis earthquake	42.5	0.0425	$1.64 \times 10^5$	82.0	1,200	1.0 <sup>c</sup>

a. Likelihood of a latent cancer fatality.

b. Number of latent cancer fatalities.

c. Early fatality due to radiation dose. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

**Table 4-157 New Research Reactor, Support Facility, and FDPF Accident Risks Under Alternative 4 (Construct New Research Reactor)—Option 2**

Accident (Frequency)	Maximally Exposed Individual <sup>a</sup>	Population to 80 Kilometers (50 Miles) <sup>b</sup>	Noninvolved Worker <sup>a</sup>
<b>Annual new research reactor risks</b>			
Design-basis accident ( $1 \times 10^{-4}$ )	$6.65 \times 10^{-14}$	$1.20 \times 10^{-10}$	$2.20 \times 10^{-13}$
Beyond-design-basis earthquake ( $1 \times 10^{-5}$ )	$1.87 \times 10^{-11}$	$1.38 \times 10^{-7}$	$2.12 \times 10^{-10}$
Fuel-handling accident (0.01)	$9.50 \times 10^{-15}$	$3.40 \times 10^{-11}$	$2.33 \times 10^{-14}$
Neptunium-237 target-handling accident (0.01)	$2.71 \times 10^{-13}$	$4.47 \times 10^{-10}$	$9.72 \times 10^{-13}$
Medical isotope target-handling accident (0.01)	$5.20 \times 10^{-11}$	$5.06 \times 10^{-7}$	$2.70 \times 10^{-11}$
<b>35-year new research reactor risk</b>	$2.49 \times 10^{-9}$	$2.26 \times 10^{-5}$	$8.41 \times 10^{-9}$
<b>Annual support facility risks</b>			
Medical and industrial isotopes localized solvent fire (0.044)	$4.32 \times 10^{-7}$	$6.91 \times 10^{-4}$	$9.41 \times 10^{-8}$
Medical and industrial isotopes unlikely seismic event (0.01)	$3.75 \times 10^{-7}$	$6.80 \times 10^{-4}$	$2.04 \times 10^{-6}$
Medical and industrial isotopes glovebox explosion ( $1.00 \times 10^{-4}$ )	$1.25 \times 10^{-7}$	$2.30 \times 10^{-4}$	$6.80 \times 10^{-7}$
<b>35-year support facility risk</b>	$3.26 \times 10^{-5}$	0.056	$9.85 \times 10^{-5}$
<b>Annual FDPF risks</b>			
Ion exchange explosion during neptunium-237 target fabrication (0.01)	$1.01 \times 10^{-14}$	$1.24 \times 10^{-10}$	$2.91 \times 10^{-14}$
Target dissolver tank failure during plutonium-238 separation (0.01)	$3.05 \times 10^{-13}$	$2.82 \times 10^{-9}$	$8.69 \times 10^{-13}$
Ion exchange explosion during plutonium-238 separation (0.01)	$8.13 \times 10^{-11}$	$7.51 \times 10^{-7}$	$2.31 \times 10^{-10}$
Plutonium-238 processing facility beyond-design-basis earthquake ( $1 \times 10^{-5}$ )	$4.25 \times 10^{-7}$	$8.20 \times 10^{-4}$	$1.00 \times 10^{-5(c)}$
<b>35-year FDPF risk</b>	$1.49 \times 10^{-5}$	0.0287	$3.50 \times 10^{-4(c)}$
<b>35-year Option risk</b>	$4.75 \times 10^{-5}$	0.0848	$4.49 \times 10^{-4}$

a. Increased likelihood of a latent cancer fatality.

b. Increased number of latent cancer fatalities.

c. Risk of an early fatality.

**Source:** Model results, using the MACCS2 (Chanin and Young 1997) and GENII (Napier et al. 1988) computer codes.

For 35 years of research reactor target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.49 \times 10^{-9}$  and  $8.41 \times 10^{-9}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $2.26 \times 10^{-5}$ .

For 35 years of support facility medical, industrial, and research and development target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $3.26 \times 10^{-5}$  and  $9.85 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.056.

For 35 years of FDPF neptunium-237 target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be

$1.49 \times 10^{-5}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0287.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $4.75 \times 10^{-5}$  and  $4.49 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.0848.

There are no hazardous chemical accidents associated with the new research reactor or new support facility. The irradiation of neptunium-237, medical, industrial, and research and development isotopes in the new research reactor would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The fabrication and processing of medical, industrial, and research and development isotopes at the new support facility would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The hazardous chemical accident impacts at FDPF are the same as those presented in Section 4.4.5.1.10.

#### 4.6.2.2.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the FDPF target fabrication facility at INEEL. DOE would transport the unirradiated neptunium-237 targets from FDPF to the reactor site. Following irradiation in the reactor, the targets would be returned to FDPF for processing. After this processing, the plutonium-238 product would be shipped to LANL. The reactor would receive low enriched uranium fuel from a U.S. fuel fabrication facility. Additionally, medical and industrial isotopes would be shipped from the reactor site to a local airport, and from there to locations throughout the country.

Approximately 37,000 shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 7.5 million kilometers (4.7 million miles); and in the air carrying medical isotopes, 23 million kilometers (14 million miles).

The transportation impact analysis is described in detail in Appendix J.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 29.2 person-rem; the dose to the public, 315 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.012 latent cancer fatality among transportation workers and 0.16 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.026. About half of the crew risk, about 2 percent of the public risk, and most of the emissions risk would result from shipping medical and industrial isotopes.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FDPF with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying

neptunium-237 (unirradiated) or plutonium-238 was also evaluated and estimated to have a probability of less than 1 in 10 million per year.

Estimates of the total transportation accident risks under this option are as follows: a radiological dose to the population of 1,063 person-rem, resulting in 0.53 latent cancer fatality; and traffic accidents resulting in 0.19 traffic fatality. Nearly all of the radiological and about 59 percent of the traffic accident risk would result from shipping medical and industrial isotopes.

#### **4.6.2.2.12 Environmental Justice**

Under this option, neptunium-237 targets would be irradiated in a new reactor that would be constructed at a site yet to be specified. Fabrication and processing of neptunium-237 targets for plutonium-238 production would be performed at FDPF at INEEL. A new support facility would be constructed at an unspecified site for fabrication and processing targets not used for plutonium-238 production.

Activities at FDPF were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.2.1.12) and found to pose no significant radiological or other risks to minority and low-income populations. The environmental analysis of operations at the new research reactor and support facility site shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected areas would not be significant. Unless there are patterns of food consumption among minority or low-income resident surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that operations at the site would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site-specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new research reactor and support facility, an additional evaluation of environmental justice at the reactor and support facility site during operation would be performed prior to implementation.

#### **4.6.2.2.13 Waste Management**

The impacts of managing waste generated from the operation of a new research reactor to irradiate targets and a support facility to fabricate and process medical and industrial isotope targets and to meet research and development needs are assumed to be the same as for Option 1 (Section 4.6.1.2.13). Radiological and chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.6.2.2.9 through 4.6.2.2.11.

The impacts of managing waste associated with fabricating and processing neptunium-237 targets for plutonium-238 production in FDPF at INEEL are assumed to be the same as for Option 2 under Alternative 1 (Section 4.3.2.1.13). As shown in that section, the impacts on the waste management systems at INEEL would be minimal.

#### **4.6.2.2.14 Spent Nuclear Fuel Management**

The impacts associated with spent nuclear fuel management under this option would be the same as for Option 1, and are given in Section 4.6.1.2.14.

### **4.6.2.3 Decontamination and Decommissioning of the Research Reactor and Support Facility**

The environmental impacts associated with the decontamination and decommissioning of the research reactor and support facility at the generic DOE site are assessed in Section 4.6.1.3.

#### **4.6.2.4 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.6.3 Alternative 4 (Construct New Research Reactor)—Option 3**

Option 3 involves construction and operating the research reactor to irradiate all targets associated with plutonium-238 production, medical and industrial isotope production, and research and development; operating FMEF at Hanford to fabricate and process neptunium-237 targets and to process the plutonium-238 product; and constructing and operating the support facility to fabricate and process the other targets and materials and to process the associated products. This option includes storage in FMEF of the neptunium-237 transported to Hanford from SRS and storage in the new support facility of the other target materials transported to the generic site from other offsite facilities.

The transportation of the low enriched uranium fuel for use in the research reactor, the transportation of the neptunium-237 to Hanford and then to the generic site, the transportation of the other target materials to the generic site, and the transportation of the product materials following irradiation and postirradiation processing are also part of this option.

All options under this alternative include the contamination and decommissioning of the research reactor and support facility at the generic DOE site following their operating lifetimes, and also the permanent deactivation of FFTF at Hanford.

##### **4.6.3.1 Construction of the New Research Reactor and Support Facility**

Environmental impacts associated with the construction of a new research reactor and support facility at the generic DOE site are assessed in Section 4.6.1.1.

##### **4.6.3.2 Operations and Transportation**

The environmental impacts associated with storage, processing, and irradiation operations, and with all transportation activities, are assessed in this section.

###### **4.6.3.2.1 Land Resources**

**LAND USE.** Impacts on land use associated with the operation of a reactor and support facility are addressed in Section 4.6.1.2.1.

FMEF would be used for neptunium-237 storage, target fabrication, and processing. Land use within the 400 Area would not change since the use of FMEF would be compatible with the mission for which it was designed.

**VISUAL RESOURCES.** Impacts on visual resources associated with the operation of a reactor and support facility are addressed in Section 4.6.1.2.1.

All activities associated with neptunium-237 storage, target fabrication, and processing would take place within FMEF. Operations associated with the proposed activities would not result in any impact on visual resources or change in the current Visual Resource Management Class IV rating of the 400 Area. This is because none of the anticipated operational impacts (e.g., air emissions) would be expected to affect this resource.

#### **4.6.3.2.2 Noise**

Noise impacts associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.2.

This option also involves using FMEF for target material storage, target fabrication, and processing. Activities associated with construction of a new stack would be typical of small construction projects and would result in some temporary increase in noise. Noise sources associated with this construction would not be expected to be loud impulsive sources and would not be expected to result in disturbance of wildlife around the 400 Area. The operation of FMEF would not be expected to result in any change in noise impacts on wildlife around the 400 Area and offsite noise impacts would also be minor because the nearest site boundary is 7 kilometers (4.3 miles) to the east. Operation would be expected to result in minimal change in noise impacts on people near Hanford as a result of changes in employee and truck traffic levels.

#### **4.6.3.2.3 Air Quality**

Air quality impacts associated with the operation of the new research reactor and support facility are addressed in Section 4.6.1.2.3.

Air quality impacts at Hanford associated with this option were determined to be the same as in Alternative 2, Option 3 (Section 4.4.3.1.3).

The air quality impacts of transportation are presented in Section 4.6.3.2.11.

#### **4.6.3.2.4 Water Resources**

Impacts on water resources associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.4.

FMEF in the 400 Area of Hanford would be used for neptunium-237 storage, target fabrication, and processing in support of plutonium-238 production. The operation of FMEF for this purpose is projected to require approximately 19 million liters (5 million gallons) of groundwater annually. This includes approximately 15 million liters (4 million gallons) per year to support FMEF cooling needs and an additional 3.8 million liters (1 million gallons) per year for potable and sanitary water demands due to increased staffing. However, no impact on regional groundwater levels would be expected from increased withdrawals. FMEF groundwater usage would constitute an increase of about 10 percent over the 197 million liters (52 million gallons) withdrawn annually in the 400 Area during standby operations. Sanitary wastewater discharges from FMEF would also increase by roughly 3.8 million liters (1 million gallons) per year to the Energy Northwest treatment system, which has sufficient capacity. Also, the operation of FMEF for target fabrication and processing would generate approximately 15 million liters (4 million gallons) per year of process wastewater. This wastewater would be discharged to the 400 Area process sewer system and ultimately to the 400 Area Pond (i.e., 4608 B/C percolation ponds) (DOE 2000a:B-3; Nielsen 1999:38, 39, 41). As discharges to the pond are regulated under State Waste Discharge Permit No. ST-4501 and there are no radiological liquid effluent pathways to the environment from FMEF, the impact on groundwater quality would be negligible.

It should be noted that the increase in water use and sanitary and process wastewater discharge for FMEF operations would essentially be negated by the larger reductions in water use and wastewater discharge associated with the permanent deactivation of FFTF (see Section 4.4.1.2.4).

#### 4.6.3.2.5 Geology and Soils

Impacts on geology and soils associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.5. As discussed in Section 4.6.1.1.5, the proposed facilities would be designed and constructed in accordance with DOE Order 420.1 and sited to minimize the risk from geologic hazards. Thus, site geologic conditions would be unlikely to affect the facilities.

The use of FMEF for neptunium-237 storage, target fabrication, and processing would not be expected to impact geologic resources, nor be jeopardized by large-scale geologic conditions. Hazards from large-scale geologic conditions at Hanford, such as earthquakes and volcanoes, were previously evaluated in the *Storage and Disposition PEIS* (DOE 1996a:4-45) as discussed in Section 4.2.4.2.5. The analysis determined that these hazards present a low risk to long-term storage facilities. That analysis was reviewed in the *Surplus Plutonium Disposition EIS* (DOE 1999a:4-260). Further review of the data and analyses presented in these referenced documents and the site-specific data presented in this NI PEIS indicates that the large-scale geologic conditions likewise present a low risk to FMEF operations. As necessary, the need to evaluate and upgrade existing DOE facilities with regard to natural geologic hazards would be assessed in accordance with DOE Order 420.1, which is described in Section 4.2.1.2.5.

#### 4.6.3.2.6 Ecological Resources

Impacts on ecological resources associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.6.

This option also involves using FMEF for neptunium-237 storage, target fabrication, and processing. As noted in Section 4.6.3.2.2, there would be no loud noises that would disturb wildlife. Because additional water usage and wastewater discharge would be small fractions of current values, there would be no change in impacts on aquatic habitat or wetlands associated with the Columbia River (Section 4.6.3.2.4). Threatened and endangered species would not be affected by operation because an existing facility within an already developed area would be used.

Consultation letters concerning threatened and endangered species were sent to the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, the Washington State Department of Natural Resources, and the State of Washington Department of Fish and Wildlife (see Table 5–3). Each agency was asked to provide information on potential impacts of the proposed action on threatened and endangered species. Both the Washington State Department of Natural Resources and the State of Washington Department of Fish and Wildlife provided lists of state species of concern that occur in the vicinity of the project area. As noted above, no impacts to any threatened or endangered species are expected, including those of concern to these agencies. While DOE has made additional contacts with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service, responses are pending from these agencies. Although no federally listed species are expected to be impacted by the proposed action, no action would be taken relative to the use of facilities at Hanford prior to the receipt of input from these Federal agencies.

#### 4.6.3.2.7 Cultural and Paleontological Resources

Impacts on cultural and paleontological resources associated with the operation of a research reactor and support facility are addressed in Section 4.6.1.2.7.

Neptunium-237 storage, target fabrication, and processing would take place at FMEF, which is in the 400 Area. No prehistoric, historic, or paleontological sites have been identified either within the 400 Area or within 2 kilometers (1.2 miles) of the 400 Area. Six buildings located within the 400 Area, including two

FFTF structures (the Reactor Containment Building and FFTF Control Building), have been determined to be eligible for the National Register as contributing properties within the Historic District recommended for mitigation. The operation of FMEF would not affect the status of these structures. No Native American resources are known to occur within the 400 Area.

Consultation to comply with Section 106 of the National Historic Preservation Act was conducted with the State Historic Preservation Office (see Table 5–3) and resulted in concurrence by the State Historic Preservation Office that the proposed action would have no effect on historic properties at Hanford. Consultation was also conducted with interested Native American tribes that resulted in comments at public hearings by members representing the Nez Perce and Confederated Tribes of the Umatilla Indian Reservation. Responses to their specific comments are addressed in Volume 3.

#### **4.6.3.2.8 Socioeconomics**

The socioeconomic impacts associated with the operation of a new research reactor and support facility at a generic DOE site are addressed in Section 4.6.1.2.8.

The socioeconomic impacts associated with neptunium-237 target fabrication and processing at Hanford are the same as those addressed in Section 4.4.3.1.8.

#### **4.6.3.2.9 Public and Occupational Health and Safety—Normal Operations**

Assessments of incremental radiological and chemical impacts associated with this option are presented in this section. Supplemental information is provided in Appendix H.

During normal operations, there would be incremental radiological and hazardous chemical releases to the environment and also incremental direct in-plant exposures. The resulting doses and potential health effects to the public and workers for this option are described below.

**RADIOLOGICAL IMPACTS.** Incremental radiological doses to three receptor groups from startup and operations are given in **Table 4–158** for the generic DOE site and Hanford: the population within 80 kilometers (50 miles) in the year 2020, the maximally exposed member of the public, and the average exposed member of the public. Radiological impacts from startup operations prior to fuel loading would be zero. After fuel loading, these impacts would be expected to be bound by the normal operational impacts. Therefore, startup impacts have not been treated separately from normal operational impacts. The projected number of latent cancer fatalities in the surrounding population and the latent cancer fatality risk to the maximally and average exposed individuals are also presented in the table.

A probability coefficient of  $5 \times 10^{-4}$  latent cancer fatality per rem is applied for the public, and a coefficient of  $4 \times 10^{-4}$  latent cancer fatality per rem is applied for workers (ICRP 1991). The value for workers is lower due to the absence of children and the elderly, who are more radiosensitive.

As a result of annual operations of the research reactor facilities and FMEF, the projected incremental total population dose in the year 2020 would be 0.14 person-rem; the corresponding number of latent cancer fatalities in the populations surrounding the generic DOE site and Hanford from 35 years of operations would be 0.0025. The incremental total dose to the maximally exposed member of the public from annual operations of the research reactor and support facility at the generic DOE site would be 0.0026 millirem; from 35 years of operations, the corresponding risk of a latent cancer fatality to this individual would be  $4.5 \times 10^{-8}$ .

**Table 4–158 Incremental Radiological Impacts on the Public Around the Generic DOE Site and Hanford from Operational Facilities Under Alternative 4 (Construct New Research Reactor)—Option 3**

Receptor	Hanford FMEF	Generic Site			Two-Site Total
		Research Reactor Operations	Reactor Support Facility Operations	Total	
<b>Population within 80 kilometers (50 miles) in the year 2020</b>					
Dose (person-rem)	$4.4 \times 10^{-5}$	0.0023	0.14	0.14	0.14
35-year latent cancer fatalities	$7.7 \times 10^{-7}$	$4.0 \times 10^{-5}$	0.0025	0.0025	0.0025
<b>Maximally exposed individual</b>					
Annual dose (millirem)	$4.7 \times 10^{-7}$	$6.8 \times 10^{-5}$	0.0025	0.0026	NA <sup>a</sup>
35-year latent cancer fatality risk	$8.3 \times 10^{-12}$	$1.2 \times 10^{-9}$	$4.4 \times 10^{-8}$	$4.5 \times 10^{-8}$	NA <sup>a</sup>
<b>Average exposed individual within 80 kilometers (50 miles)</b>					
Annual dose <sup>b</sup> (millirem)	$8.9 \times 10^{-8}$	$1.5 \times 10^{-6}$	$9.1 \times 10^{-5}$	$9.3 \times 10^{-5}$	NA <sup>a</sup>
35-year latent cancer fatality risk	$1.6 \times 10^{-12}$	$2.6 \times 10^{-11}$	$1.6 \times 10^{-9}$	$1.6 \times 10^{-9}$	NA <sup>a</sup>

a. A “Total” cannot be given in this case because the same individual cannot be located at two different sites simultaneously.

b. Obtained by dividing the population dose by the number of people projected to live within 80 kilometers (50 miles) of FMEF or the generic site in the year 2020 (494,400 and 1,538,100, respectively).

**Key:** NA, not applicable.

**Source:** Appendix E; model results, using the GENII computer code (Napier et al. 1988).

Incremental doses to involved workers from normal operations are given in **Table 4–159**; these workers are defined as those directly associated with all process activities. The incremental annual average dose to research reactor workers during operations would be 100 millirem; for support facility workers, the incremental annual average dose during startup and operations would be 114 millirem; for FMEF workers, the incremental annual average dose would be approximately 170 millirem. The incremental annual dose received by the total site workforce for each of these facilities is estimated to be 12, 11, and 12 person-rem, respectively. The risks and numbers of latent cancer fatalities among the different workers from 35 years of operations are included in Table 4–159. Doses to individual workers would be kept to minimal levels by instituting badged monitoring and ALARA programs.

**Table 4–159 Incremental Radiological Impacts on Involved Workers at the Generic DOE Site and Hanford from Operational Facilities Under Alternative 4 (Construct New Research Reactor)—Option 3**

Receptor—Involved Workers <sup>a</sup>	Hanford FMEF	Generic Site		One- or Two-Site Total
		Research Reactor Operations	Reactor Support Facility Operations	
Total dose (person-rem per year)	12 <sup>b</sup>	12 <sup>b</sup>	11 <sup>b</sup>	36
35-year latent cancer fatalities	0.17	0.17	0.16	0.50
Average worker dose (millirem per year)	170	100	114	NA <sup>c</sup>
35-year latent cancer fatality risk	0.0023	0.0014	0.0016	NA <sup>c</sup>

a. The radiological limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, the maximum dose to a worker involved with operations would be kept below the DOE Administrative Control Level of 2,000 millirem per year (DOE 1999j). Further, DOE recommends that each facility adopt a more limiting, 500 millirem per year, Administrative Control Level (DOE 1999j). To reduce doses to levels that are as low as is reasonably achievable (ALARA), an effective ALARA program would be enforced.

b. Based on an estimated 75 badged workers at FMEF, 120 research reactor workers, and 100 workers at the reactor support facility.

c. Values cannot be given for the average worker because the workers would be in three different facilities at two different sites.

**Key:** NA, not applicable.

**Source:** Wham 1999b, 2000.

**HAZARDOUS CHEMICAL IMPACTS.** Hazardous chemical impacts associated with the operation of the research reactor and support facility are addressed in Section 4.6.1.2.9.

Impacts from hazardous chemicals at Hanford were determined to be the same as in Alternative 2, Option 3 (Section 4.4.3.1.9).

#### **4.6.3.2.10 Public and Occupational Health and Safety—Facility Accidents**

Impacts from postulated accidents associated with research reactor target irradiation; support facility medical, industrial, and research and development isotope fabrication and processing; and FMEF neptunium-237 target fabrication and processing are presented in this section. Detailed descriptions of the accident analyses are provided in Appendix I.

Consequences and associated risks are presented in **Tables 4–160** and **4–161**, respectively.

For 35 years of research reactor target irradiation, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $2.49 \times 10^{-9}$  and  $8.41 \times 10^{-9}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be  $2.26 \times 10^{-5}$ .

For 35 years of support facility medical, industrial, and research and development target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and to a noninvolved worker would be  $3.26 \times 10^{-5}$  and  $9.85 \times 10^{-5}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.056.

For 35 years of FMEF neptunium-237 target fabrication and processing, the increased risk of a latent cancer fatality to the maximally exposed individual and of an early fatality to a noninvolved worker would be  $2.88 \times 10^{-6}$  and  $3.50 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.112.

For 35 years under this option, the increased risk of a latent cancer fatality to the maximally exposed individual and of a fatality to a noninvolved worker would be  $3.55 \times 10^{-5}$  and  $4.49 \times 10^{-4}$ , respectively. The increased number of latent cancer fatalities in the surrounding population would be 0.168.

There are no hazardous chemical accidents associated with the new research reactor or new support facility. The irradiation of neptunium-237, medical, industrial, and research and development isotopes in the new research reactor would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The fabrication and processing of medical, industrial, and research and development isotopes at the new support facility would not require the use of hazardous chemicals in amounts that exceed the Threshold Planning Quantities on the Extremely Hazardous Substances List (EPA 1998).

The hazardous chemical accident impacts at FMEF are the same as those presented in Section 4.4.6.1.10.

**Table 4–160 New Research Reactor, Support Facility, and FMEF Accident Consequences Under Alternative 4 (Construct New Research Reactor)—Option 3**

Accident	Maximally Exposed Individual		Population to 80 Kilometers (50 Miles)		Noninvolved Worker	
	Dose (rem)	Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Latent Cancer Fatalities <sup>b</sup>	Dose (rem)	Latent Cancer Fatality <sup>a</sup>

#### 4.6.3.2.11 Public and Occupational Health and Safety—Transportation

DOE would transport neptunium-237 from storage at SRS to the FMEF target fabrication facility at Hanford. DOE would transport the unirradiated neptunium-237 targets from FMEF to the reactor site. Following irradiation in the reactor, the targets would be returned to FMEF for processing. After this processing, the plutonium-238 product would be shipped to LANL. The reactor would receive low enriched uranium fuel from a U.S. fuel fabrication facility. Additionally, medical and industrial isotopes would be shipped from the reactor site to a local airport, and from there to locations throughout the country.

Approximately 37,000 shipments of radioactive materials would be made by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 7.9 million kilometers (4.9 million miles); and in the air carrying medical isotopes, 23 million kilometers (14 million miles).

The transportation impact analysis is described in detail in Appendix J.

**IMPACTS OF INCIDENT-FREE TRANSPORTATION.** The dose to transportation workers from all transportation activities entailed by this option has been estimated at 31 person-rem; the dose to the public, 354 person-rem. Accordingly, incident-free transportation of radioactive material associated with this option would result in 0.012 latent cancer fatality among transportation workers and 0.18 latent cancer fatality in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this option would be 0.027. About half of the crew risk, about 2 percent of the public risk, and most of the emissions risk would result from shipping medical and industrial isotopes.

**IMPACTS OF ACCIDENTS DURING TRANSPORTATION.** The maximum foreseeable offsite transportation accident under this option (probability of occurrence: 1 in 10 million per year) is a shipment of irradiated neptunium-237 targets to FDFP with a severity Category V accident in an urban population zone under neutral (average) weather conditions. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatality, and 2.6 millirem to the hypothetical maximally exposed individual with a latent cancer fatality risk of  $1.3 \times 10^{-6}$ . No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of the accident, or occurrence while carrying neptunium-237 (unirradiated) or plutonium-238 was also evaluated and estimated to have a probability of less than 1 in 10 million per year.

Estimates of the total transportation accident risks under this option are as follows: a radiological dose to the population of 1,063 person-rem, resulting in 0.53 latent cancer fatality; and traffic accidents resulting in 0.19 traffic fatality. Nearly all of the radiological and about 58 percent of the traffic accident risk would result from shipping medical and industrial isotopes.

#### 4.6.3.2.12 Environmental Justice

Under this option, neptunium-237 targets would be irradiated in a new reactor that would be constructed at a site yet to be specified. Fabrication and processing of neptunium-237 targets for plutonium-238 production would be performed at FMEF at Hanford. A new support facility would be constructed at an unspecified site for fabrication and processing targets not used for plutonium-238 production.

Activities at FMEF were evaluated under other alternatives and options in this NI PEIS (e.g., Section 4.4.3.1.12) and were found to pose no significant radiological or other risks to minority and low-income populations. The environmental analysis of operations at the new research reactor and support facility site shows that radiological and nonradiological risks to persons residing in the (hypothetical) potentially affected areas would not be significant. Unless there are patterns of food consumption among minority or low-income residents surrounding the actual site (yet to be determined) that would result in a significant ingestion of radiologically contaminated food, it is plausible that operations at the site would pose no significant risks to minority and low-income persons. However, evaluations of environmental justice are necessarily site-specific and cannot be performed in detail for unspecified locations. In the event that this option were selected for implementation and a specific site selected for the new research reactor and support facility, then an additional evaluation of environmental justice at the reactor and support facility site during operation would be performed prior to implementation.

#### **4.6.3.2.13 Waste Management**

The impacts of managing waste generated from the operation of a new research reactor to irradiate targets and a support facility to fabricate and process medical and industrial isotope targets and to meet research and development needs are assumed to be the same as for Option 1 (Section 4.6.1.2.13). Radiological and chemical impacts on workers and the public from waste management activities are included in the public and occupational health and safety impacts that are given in Sections 4.6.3.2.9 through 4.6.3.2.11.

The impacts of managing waste associated with fabricating and processing neptunium-237 targets for plutonium-238 production in FMEF at Hanford are assumed to be the same as for Option 3 under Alternative 1 (Section 4.3.3.1.13). As shown in that section, the impacts on the waste management systems at Hanford would be minimal.

#### **4.6.3.2.14 Spent Nuclear Fuel Management**

The impacts associated with spent nuclear fuel management under this option would be the same as for Option 1, and are given in Section 4.6.1.2.14.

#### **4.6.3.3 Decontamination and Decommissioning of the Research Reactor and Support Facility**

The environmental impacts associated with the decontamination and decommissioning of the research reactor and support facility at the generic DOE site are assessed in Section 4.6.1.3.

#### **4.6.3.4 Permanent Deactivation of FFTF**

The environmental impacts associated with permanently deactivating FFTF are addressed in Section 4.4.1.2.

#### **4.7 ALTERNATIVE 5—PERMANENTLY DEACTIVATE FFTF (WITH NO NEW MISSIONS)**

Under Alternative 5, DOE would permanently deactivate FFTF at Hanford with no new missions. Medical and industrial isotope production and civilian nuclear energy research and development missions at the existing facilities, as described in Chapter 3, Affected Environment, would continue. DOE's nuclear facilities infrastructure would not be enhanced. The environmental impacts associated with FFTF deactivation are addressed in Section 4.4.1.2.

## 4.8 CUMULATIVE IMPACTS

The projected incremental environmental impacts of (1) constructing (as necessary) and operating the proposed facilities to store, fabricate, irradiate, and process the various targets addressed in this NI PEIS for 35 years, and (2) deactivating FFTF were added to the environmental impacts of other present and reasonably foreseeable future actions at or near the identified candidate sites to obtain cumulative site impacts under normal conditions. The other present and reasonably foreseeable future actions at or near the candidate sites are included in the baseline impacts presented in Chapter 3. Cumulative transportation impacts were determined by analyzing the impacts along the various routes used to transport the materials associated with nuclear infrastructure activities over the 35-year period. The methodology for assessing cumulative impacts is presented in Section G.10.

In this section, cumulative site impacts are presented only for those “resources” at a site that may reasonably be expected to be affected by the storage, fabrication, irradiation, and processing of the various targets. These include site employment, electrical consumption, water usage, air quality, waste management, and public and occupational health and safety. This section also includes the cumulative impacts associated with intersite transportation.

Impacts of the following are considered in the cumulative site impacts assessment:

- Current (baseline) activities at or in the vicinity of the candidate sites
- Other onsite and offsite activities that are reasonably foreseeable and documented
- Construction (as necessary), operation, and deactivation (as necessary) of the proposed nuclear infrastructure facilities to fabricate, irradiate, and process targets

Activities whose impacts are contained in cumulative site impacts include, but are not limited to, operation of the Spallation Neutron Source Facility at ORR, implementation of the Advanced Mixed Waste Treatment Project at INEEL, and remediation of the high-level waste tanks at Hanford.

Details of activities that may be implemented in the foreseeable future at any of the nuclear infrastructure candidate sites and evaluated in the cumulative impact assessment are given in the following documents:

- *Surplus Plutonium Disposition Final Environmental Impact Statement* (DOE 1999a) (Record of Decision issued)
- *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (DOE 1996a) (Record of Decision issued)
- *Disposition of Surplus Highly Enriched Uranium Final Environmental Impact Statement* (DOE 1996b) (Record of Decision issued)
- *Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling* (DOE 1995b) (Record of Decision issued)
- *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DOE 1997a) (Final EIS issued; Records of Decision issued for the various waste types)

- *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DOE 1995c) (Record of Decision issued)
- *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel* (DOE 1996c) (Record of Decision issued)
- *Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (DOE 1996d) (Record of Decision issued)
- *Final Environmental Impact Statement Management of Spent Nuclear Fuel from the K Basins at the Hanford Site* (DOE 1996h) (Record of Decision issued)
- *Advanced Mixed Waste Treatment Project Final Environmental Impact Statement* (DOE 1999c) (Record of Decision issued)
- *Final Environmental Impact Statement for the Tank Waste Remediation System, Hanford Site, Richland, Washington* (DOE 1996e) (Record of Decision issued)
- *Hanford Reach of the Columbia River Comprehensive River Conservation Study and Environmental Impact Statement* (NPS 1994) (Record of Decision issued)
- *Final Hanford Comprehensive Land-Use Plan Environmental Impact Statement* (DOE 1999d) (Record of Decision issued)
- *Final Environmental Impact Statement for the Treatment and Management of Sodium-Bonded Spent Nuclear Fuel* (DOE 2000b) (Record of Decision issued)
- *Final Environmental Impact Statement, Construction and Operation of the Spallation Neutron Sources* (DOE 1999e) (Record of Decision issued)
- *Final Programmatic Environmental Impact Statement for Alternative Strategies for the Long-Term Management and Use of Depleted Uranium Hexafluoride* (DOE 1999f) (Record of Decision issued)
- *Idaho High-Level Waste and Facilities Disposition Draft Environmental Impact Statement* (DOE 1999g)
- *Final Environmental Impact Statement for Treating Transuranic (TRU)/Alpha Low-Level Waste at the Oak Ridge National Laboratory* (DOE 2000c) (Record of Decision issued)
- *Environmental Assessment Melton Valley Storage Tanks Capacity Increase Project—Oak Ridge National Laboratory* (DOE/EA-1044 and FONSI, DOE 1995d)
- *Management of Spent Nuclear Fuel on the Oak Ridge Reservation* (DOE/EA-1117 and FONSI, DOE 1996f)
- *Environmental Assessment - Management of Hanford Site Non-Defense Production Reactor Spent Nuclear Fuel* (DOE/EA-1185 and FONSI, DOE 1997c)

- *Environmental Assessment for Transportation of Low-Level Radioactive Waste from the Oak Ridge Reservation to Off-Site Treatment or Disposal Facilities* (DOE 2000d)
- *Environmental Assessment for Transportation of Mixed Low-Level Radioactive Waste from the Oak Ridge Reservation to Off-Site Treatment or Disposal Facilities* (DOE 2000e)
- *Environmental Assessment for Selection and Operation of the Proposed Field Research Centers for the Natural and Accelerated Bioremediation Field Research (NABIR) Program* (DOE 2000f) (FONSI issued April 2000).

The related programs included in the cumulative impact assessment for the potentially affected candidate sites are identified in **Table 4-162**.

**Table 4-162 Other Present and Reasonably Foreseeable Actions Considered in the Cumulative Impact Assessment**

**Source:** Literature review.

In the tables that are included in the following sections, all relevant activities at each site are identified to the extent possible. They include existing and reasonably foreseeable activities, and those associated with nuclear infrastructure operations. The impacts associated with the latter are specifically shown as “New Nuclear Infrastructure Operations.” They include the impacts from construction (as necessary), operation, and deactivation (as necessary) of the proposed target fabrication, irradiation, and processing facilities assessed in this NI PEIS.

A bounding option was analyzed for each site. The bounding option is the option that would involve the greatest amounts of operational activities and associated environmental impacts at the candidate site. For example, the bounding option for ORR is Option 7 of Alternative 2, under which both HFIR and REDC operations would be involved in plutonium-238 production.

In addition to reasonably foreseeable site activities, other activities within the regions of the candidate sites were considered in the cumulative impact analysis for the selected resources. However, because of the distances between the candidate sites and these other existing and planned facilities, there is little opportunity for interactions among them.

#### 4.8.1 Cumulative Impacts at ORR

For ORR, the bounding option for this NI PEIS is Option 7 of Alternative 2. This option calls for the operation of HFIR to irradiate neptunium-237 targets and the operation of REDC to fabricate and process these targets and other neptunium-237 targets irradiated in ATR. The impacts associated with HFIR and REDC operations for other missions are included under “existing site activities.”

##### 4.8.1.1 Resource Requirements

Cumulative impacts on resource requirements at ORR are presented in **Table 4–163**. ORR would remain within its site capacity for all major resources. If Option 7 of Alternative 2 were implemented, the proposed nuclear infrastructure facilities would require essentially no change in the site’s use of electricity or water. Cumulatively, ORR would use approximately 10 percent of its electrical capacity and 37 percent of its water capacity. Site employment would increase by approximately 41 workers.

**Table 4–163 Maximum Cumulative Resource Use and Impacts at ORR**

Activities <sup>a</sup>	Site Employment	Electrical Consumption (megawatt-hours per year)	Water Usage (million liters per year)
<b>Existing site activities<sup>b</sup></b>	14,215	726,000	14,210
Storage and Disposition PEIS	Included above	7,260	0.24
Waste Management PEIS	1,259	84,160	394
Spallation Neutron Source	744	543,120	1,592
Treatment and Shipment of Transuranic Waste	17	3,000	3.8
<b>New nuclear infrastructure operations<sup>c</sup></b>	41 <sup>d</sup>	Negligible <sup>e</sup>	2.86
<b>Total</b>	16,276	~1,363,540	16,203
<b>Total site capacity</b>	NA	13,880,000	44,348

a. See Section 4.8 and Table 4–162 for a listing of past, present, and reasonably foreseeable actions considered.

b. Reflects current sitewide activities that are anticipated to continue during all or part of the 35-year period evaluated for proposed nuclear infrastructure operations.

c. Nuclear infrastructure activities from Alternative 2, Option 7.

d. Some, or all, of these worker requirements may be filled by the reassignment of the existing site workforce.

e. Additional electricity consumption associated with this option would be negligible compared to that associated with existing facility activities.

**Note:** To convert from liters per year to gallons per year, multiply by 0.264; to convert from megawatt-hours to British thermal units, multiply by  $3.42 \times 10^6$ ; ~ means “approximately” and indicates that new nuclear infrastructure operations would contribute only minimally.

**Key:** NA, not applicable.

**Source:** DOE 1996a:4-246, 4-255; 1997a:10-18, 10-32, 10-45, 10-58; 1999a:3-185; 1999e:4-45, 5-21, 5-177; 2000c:S-34, 4-60, 4-93; LMER 1997; Wham 1999a; Sections 4.4.7.1.4 and 4.4.7.1.8 of this NI PEIS.

#### 4.8.1.2 Air Quality

Cumulative impacts on air quality at ORR are presented in **Table 4–164**. ORR is currently in compliance with all Federal and State ambient air quality standards, and would continue to be in compliance even if the cumulative effects of all activities are included. As shown in the table, the contributions of nuclear infrastructure operations to overall site concentrations would be very small.

**Table 4–164 Maximum Cumulative Air Pollutant Concentrations at ORR for Comparison with Ambient Air Quality Standards**

Parameter	Carbon Monoxide		Nitrogen Dioxide	PM <sub>10</sub>		Sulfur Dioxide		
	8 hours	1 hour	Annual	Annual	24 hours	Annual	24 hours	3 hours
<b>Averaging Period</b>	8 hours	1 hour	Annual	Annual	24 hours	Annual	24 hours	3 hours
<b>Activities</b>								
Existing site activities <sup>a</sup> (micrograms per cubic meter)	7.75	26.5	0.98	1.6	12.6	4.76	33.4	106.4
HEU disposition <sup>b</sup> (micrograms per cubic meter)	11.5	53	1.33	0.03	0.37	2.46	29.3	161
Waste management program (micrograms per cubic meter)	0	0	0	3	9	2.4	11	39
Spallation Neutron Source (micrograms per cubic meter)	69	99	16	1.9	23	0.1	1	2.4
New nuclear infrastructure operations <sup>c</sup> (micrograms per cubic meter)	0	0	1.99×10 <sup>-4</sup>	0	0	0.04	0.31	0.7
Total concentration (micrograms per cubic meter)	88.3	179	18.3	6.53	45	9.76	75	310
<b>Standard</b>								
Most stringent standard <sup>d</sup> (micrograms per cubic meter)	10,000	40,000	100	50	150	80	365	1,300

a. Environmental impacts associated with existing site activities (based on 1998 emissions from the *Oak Ridge Reservation Annual Site Environmental Report 1998* [Hamilton et al. 1999]) that are anticipated to continue during part or all of the 35-year period evaluated for proposed nuclear infrastructure operations. The values in this row reflect a curtailment of stockpile stewardship management activities during this time period.

b. Highly enriched uranium disposition activities.

c. Nuclear infrastructure activities from Alternative 2, Option 7.

d. The more stringent of the Federal and state standards is presented if both exist for the averaging period.

Source: DOE 1996b; 1996d; 1997a; 1999e:5-27; Hamilton et al. 1999; modeled results from nuclear infrastructure operations are based on the SCREEN3 computer code (EPA 1995); Sections 4.4.1.1.3 and 4.4.7.1.3 of this NI PEIS.

#### 4.8.1.3 Public and Occupational Health and Safety—Normal Operations

Cumulative impacts in terms of radiation exposure to the public and workers at ORR are presented in **Table 4–165**. There would be no increase expected in the number of latent cancer fatalities in the population from ORR site operations if nuclear infrastructure operations were to occur at HFIR and REDC. The dose limits for individual members of the public are given in DOE Order 5400.5. As discussed in that order, the dose limit from airborne emissions is 10 millirem per year, as required by the Clean Air Act; the dose limit from drinking water is 4 millirem per year, as required by the Safe Drinking Water Act; and the dose limit from all pathways combined is 100 millirem per year. Therefore, as is evident in Table 4–165, the dose to the maximally exposed individual would be expected to remain well within the regulatory limits. Onsite workers would be expected to see an increase of approximately 0.17 latent cancer fatality due to radiation from nuclear infrastructure operations over the 35-year operational period.

**Table 4–165 Maximum Cumulative Radiation Impacts at ORR**

Impact	Maximally Exposed Individual		Population Dose Within 80 Kilometers (50 Miles) (Year 2020)		Total Site Workforce	
	Annual Dose (millirem per year)	Risk of a Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Number of Latent Cancer Fatalities <sup>a</sup>	Dose (person-rem per year)	Number of Latent Cancer Fatalities <sup>a</sup>
Existing site activities <sup>b</sup>	4.4	$7.7 \times 10^{-5}$	60.3	1.1	103	1.4
HEU disposition	0.039	$6.8 \times 10^{-7}$	0.16	0.0028	11	0.16
Stockpile stewardship and management	0.2	$3.5 \times 10^{-6}$	0.6	0.011	-1.8	-0.025
Waste management	0.35	$6.1 \times 10^{-6}$	1.2	0.021	0.45	0.0063
New nuclear infrastructure operations at ORR <sup>c</sup>	$1.9 \times 10^{-6}$	$3.3 \times 10^{-11}$	$8.8 \times 10^{-5}$	$1.5 \times 10^{-6}$	12	0.168
Total	5.0 <sup>d</sup>	$8.7 \times 10^{-5(d)}$	62	1.1	125	1.7

a. These values are calculated based on a 35-year exposure period.

b. Environmental impacts associated with present activities at ORR that are anticipated to continue during all or part of the 35-year period evaluated for proposed nuclear infrastructure operations.

c. Impacts are bounded by Option 7 of Alternative 2.

d. The same individual would not be expected to be the maximally exposed individual for all activities at ORR. The location of the maximally exposed individual depends upon where on the site an activity is performed. However, to provide an upper bound of the cumulative impacts to the maximally exposed individual, the impacts from each activity have been summed.

**Source:** (1) Hamilton et al. 1999:chap. 6 for impacts to the public from existing site activities and DOE 1999k:table B-1c for impacts to the site workforce from existing site activities; (2) DOE 1996a:chap. 4 and DOE 1997a:chap. 11 for all impacts associated with each of the other activities listed in the first column, except nuclear infrastructure operations; and (3) Section 4.4.7.1.9 of this NI PEIS for all impacts associated with nuclear infrastructure operations. Impacts presented in the source documents have been adjusted, as appropriate, to reflect the Records of Decision for waste management, as discussed in Chapter 3.

#### 4.8.1.4 Waste Management

Cumulative amounts of waste generated at ORR are presented in **Table 4–166**. It is unlikely that there would be major impacts on waste management at ORR because sufficient capacity would exist to manage the site wastes. As discussed in Section 4.3.1.1.13, irrespective of how the waste from processing irradiated neptunium-237 targets is classified (i.e., transuranic or high-level radioactive), the waste composition and characteristics are the same, and the management (i.e., treatment and onsite storage), as described in this NI PEIS, would be the same. In addition, either waste type would require disposal in a suitable repository. None of the options assessed in this NI PEIS would generate more than a small amount of additional waste at ORR.

#### 4.8.2 Cumulative Impacts at INEEL

For INEEL, the bounding option for this NI PEIS is Option 2 of Alternative 2. This option calls for the operation of ATR to irradiate neptunium-237 targets and the operation of FDPF to fabricate and process these targets. The impacts associated with ATR and FDPF operations for other missions are included under “existing site activities.”

**Table 4–166 Cumulative Impacts on Waste Management Activities at ORR Over 35-Year Period (cubic meters)**

Waste Type	Existing Site Activities <sup>a</sup>	Treatment and Shipment of Transuranic Waste <sup>b</sup>	Surplus Plutonium Disposition <sup>c</sup>	Spallation Neutron Source <sup>d</sup>	New Nuclear Infrastructure Operations <sup>e</sup>	Total	Site Capacity <sup>f</sup>		
							Treatment (cubic meters/year)	Storage	Disposal
Transuranic (High-level radioactive) <sup>g</sup>	766 (0)	607 (0)	11 (0)	0 (0)	385 (385)	1,769 (385)	4,050/5 years (0)	2,845 (0)	NA (NA)
Low-level radioactive	335,755	2,778	140	612,000	<2,145	~952,818	440,405	87,776	NA
Mixed low-level radioactive	28,035	23	1	623	<175	~28,857	263,560	234,226	NA
Hazardous <sup>h</sup> (kilograms)	1,260,000	0	1	1,435,000	227,500	2,922,501	1,738,803	7,312	NA
Nonhazardous									
Liquid	23,845,500	1,560	1,500	2,415	99,925	23,950,900	3,395,918	NA	NA
Solid	2,590,000	5,500	130	47,215	5,180	2,648,025	NA	NA	1,219,000

- a. Total 35-year waste generation estimate was derived from annual waste generation rates based on historical data obtained from Wham 1999c.
- b. Data from the *Final Environmental Impact Statement for Treating Transuranic (TRU)/Alpha Low-Level Waste at the Oak Ridge National Laboratory* (DOE 2000c:S-31) Low-Temperature Drying Alternative and selected in the Record of Decision (65 FR 48683).
- c. Data from the *Surplus Plutonium Disposition Final EIS* (DOE 1999a: 4-394) postirradiation examination (2006 through 2009) and selected in Record of Decision (65 FR 1608).
- d. Data from the *Spallation Neutron Source Final EIS* (DOE 1999e:3-31).
- e. Option 7 of Alternative 2. This alternative would generate the most waste for all waste types.
- f. Total 35-year and annual capacity derived from Table 3–13.
- g. Refer to Section 4.3.1.1.13 for a discussion on the classification of waste from processing irradiated neptunium-237 targets. Volumes in parentheses represent high-level radioactive waste.
- h. Assumes for hazardous waste that 353 kilograms equal 1 cubic meter (22 pounds equal 1 cubic foot).
- Note:** To convert from cubic meters to cubic yards, multiply by 1.308; < means “less than”; ~ means “approximately;” NA, not applicable (i.e., the majority of the waste is not routinely treated, stored, or disposed of on site).
- Source:** DOE 1999a:4-394; 65 FR 1608; DOE 1999e:3-31; DOE 2000c:S-31; 65 FR 48683; Wham 1999c; Sections 4.3.1.1.13 and 4.4.7.1.13 of this NI PEIS.

#### 4.8.2.1 Resource Requirements

Cumulative impacts on resource requirements at INEEL are presented in **Table 4–167**. INEEL would remain within its site capacity for all major resources. If Option 2 of Alternative 2 were implemented, the proposed nuclear infrastructure facilities would require essentially no change in the site’s use of electricity or water.

Cumulatively, INEEL would use 80 percent of its electrical capacity and 13 percent of its water capacity. Site employment would increase by approximately 24 workers.

**Table 4–167 Maximum Cumulative Resource Use and Impacts at INEEL**

Activities <sup>a</sup>	Site Employment	Electrical Consumption (megawatt-hours per year)	Water Usage (million liters per year)
<b>Existing site activities<sup>b</sup></b>	7,993	232,500	4,830
SNF Management and INEL Environmental Restoration and Waste Management	–	2,200	2
Foreign Research Reactor SNF Management	–	1,000	2
Waste Management PEIS	–	13,980	194
Advanced Mixed Waste Treatment Project	–	33,000	16
High-Level Waste and Facilities Disposition	–	33,000	351
<b>New nuclear infrastructure operations<sup>c</sup></b>	24 <sup>d</sup>	Negligible <sup>e</sup>	1.68
<b>Total</b>	8,017	~315,680	5,397
<b>Total site capacity</b>	NA	394,200	43,000

- a. See Section 4.8 and Table 4–162 for descriptions of past, present, and reasonably foreseeable actions considered.
- b. Reflects current sitewide activities (except that “Site Employment” value also reflects projected employment from other activities) that are anticipated to continue during all or part of the 35-year period evaluated for proposed nuclear infrastructure operations.
- c. Nuclear infrastructure activities from Alternative 2, Option 2.
- d. Some, or all, of those worker requirements may be filled by the reassignment of the existing workforce.
- e. Additional electricity consumption associated with this option would be negligible compared to that associated with existing facility activities.

**Note:** To convert from liters per year to gallons per year, multiply by 0.264; to convert from megawatt-hours to British thermal units, multiply by  $3.42 \times 10^6$ ; ~ means “approximately,” and indicates that new nuclear infrastructure operations would contribute only minimally.

**Key:** NA, not applicable; SNF, spent nuclear fuel.

**Source:** DOE 1995c:K-16; 1996c:4-53, 4-54, F-164; 1997a:6-18, 6-32, 6-45, 6-55, 6-67; 1999a:3-85, 4-379; 1999c:5.13-2; 1999g:5-86; French, Tallman, and Taylor 1999:v; Sections 4.4.2.1.4 and 4.4.2.1.8 of this NI PEIS.

#### 4.8.2.2 Air Quality

Cumulative impacts on air quality at INEEL are presented in **Table 4–168**. INEEL is currently in compliance with all Federal and state ambient air quality standards, and would continue to remain in compliance, even with consideration of the cumulative effects of all activities. The contributions of nuclear infrastructure operations to overall site concentrations are expected to be very small.

**Table 4–168 Maximum Cumulative Air Pollutant Concentrations at INEEL for Comparison with Ambient Air Quality Standards**

Parameter	Carbon Monoxide		Nitrogen Dioxide	PM <sub>10</sub>		Sulfur Dioxide		
	8 hours	1 hour	Annual	Annual	24 hours	Annual	24 hours	3 hours
<b>Activities</b>								
Existing site activities <sup>a</sup> (micrograms per cubic meter)	78	206	0.46	0.49	12	0.14	5.3	24
ANL–W contribution <sup>b</sup> (micrograms per cubic meter)	41	59	13	0.14	1.1	3.3	27	60
Advanced Mixed Waste Treatment Project <sup>c</sup> (micrograms per cubic meter)	0.85	115	0.34	0.006	4.6	0.012	4.5	25
HLW & FD <sup>d</sup> (micrograms per cubic meter)	4.2	10	0.19	0.02	0.28	0.57	8.9	42
New nuclear infrastructure operations <sup>e</sup> (micrograms per cubic meter)	0	0	3.66×10 <sup>-4</sup>	0	0	0.024	0.19	0.43
Total concentration (micrograms per cubic meter)	124	390	14	0.656	18	4.05	45.9	151
<b>Standard</b>								
Most stringent standard <sup>f</sup> (micrograms per cubic meter)	10,000	40,000	100	50	150	80	365	1,300

- a. Environmental impacts associated with existing site activities (excluding activities at ANL–W) as shown in the *Idaho High-Level Waste and Facilities Disposition Draft EIS*, Table C.2-14 (DOE 1999g) and in the *Final EIS for the Treatment and Management of Sodium-Bonded Spent Nuclear Fuel*, Table 3–2 (DOE 2000b). The activities whose concentrations are given in this row, are anticipated to continue during part or all of the 35-year period evaluated for proposed nuclear infrastructure operations.
- b. The contribution from existing ANL–W sources as shown the *Final EIS for the Treatment and Management of Sodium-Bonded Spent Nuclear Fuel*, Table 3–2 (DOE 2000b).
- c. *Advanced Mixed Waste Treatment Project Final EIS* activities—proposed action with microencapsulation or vitrification, Table 5.7-6 (DOE 1999c).
- d. High-level waste and facilities disposition site boundary contribution for planning basis option, Table C.2-14 (DOE 1999g).
- e. Nuclear infrastructure activities from Alternative 2, Option 2.
- f. The more stringent of the Federal and state standards is presented if both exist for the averaging period.

**Key:** HLW & FD = high-level waste and facilities disposition.

**Source:** DOE 1999c:5.7-15, 1999g, 2000b:sec. 4.11; modeled results for nuclear infrastructure operations are based on the SCREEN3 computer code (EPA 1995); Section 4.4.2.1.3 of this NI PEIS.

#### 4.8.2.3 Public and Occupational Health and Safety—Normal Operations

Cumulative impacts in terms of radiation exposure to the public and workers at INEEL are presented in **Table 4–169**. There would be no increase expected in the number of latent cancer fatalities in the population from INEEL site operations if nuclear infrastructure operations were to occur at ATR and FDPF. The dose limits for individual members of the public are given in DOE Order 5400.5. As discussed in that order, the dose limit from airborne emissions is 10 millirem per year, as required by the Clean Air Act; the dose limit from drinking water is 4 millirem per year, as required by the Safe Drinking Water Act; and the dose limit from all pathways combined is 100 millirem per year. Therefore, as is evident in Table 4–169, the dose to the maximally exposed individual would be expected to remain well within the regulatory limits. Onsite workers would be expected to see an increase of approximately 0.17 latent cancer fatality due to radiation from nuclear infrastructure operations over the 35-year operational period.

**Table 4–169 Maximum Cumulative Radiation Impacts at INEEL**

Impact	Maximally Exposed Individual		Population Dose Within 80 Kilometers (50 Miles) (Year 2020)		Total Site Workforce	
	Annual Dose (millirem per year)	Risk of a Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Number of Latent Cancer Fatalities <sup>a</sup>	Dose (person-rem per year)	Number of Latent Cancer Fatalities <sup>a</sup>
Existing site activities <sup>b</sup>	0.008	$1.7 \times 10^{-7}$	0.075	0.0013	64.9	0.91
Storage and disposition	$1.6 \times 10^{-6}$	$2.8 \times 10^{-11}$	$1.8 \times 10^{-5}$	$3.2 \times 10^{-7}$	25	0.35
Foreign research reactor spent nuclear fuel	$5.6 \times 10^{-4}$	$9.8 \times 10^{-9}$	0.0045	$7.9 \times 10^{-5}$	33	0.46
Spent nuclear fuel	0.008	$1.4 \times 10^{-7}$	0.19	0.0033	5.4	0.076
Advanced Mixed Waste Treatment Project	0.022	$3.9 \times 10^{-7}$	0.009	$1.6 \times 10^{-4}$	4.1	0.057
High-level waste and facilities disposition	0.002	$3.5 \times 10^{-8}$	0.10	0.0018	59	0.83
Sodium-bonded spent nuclear fuel	0.002	$3.5 \times 10^{-8}$	0.012	$2.1 \times 10^{-4}$	22	0.31
New nuclear infrastructure operations at ATR and FDPF <sup>c</sup>	$2.6 \times 10^{-7}$	$4.6 \times 10^{-12}$	$3.9 \times 10^{-6}$	$6.8 \times 10^{-8}$	12	0.17
Total	0.043 <sup>d</sup>	$7.4 \times 10^{-7(d)}$	0.39	0.0068	225.4	3.16

a. These values are calculated based on a 35-year exposure period.

b. Environmental impacts associated with present activities at INEEL that are anticipated to continue during all or part of the 35-year period evaluated for proposed nuclear infrastructure operations.

c. Impacts are bounded by Option 2 of Alternative 2.

d. The same individual would not be expected to be the maximally exposed individual for all activities at INEEL. The location of the maximally exposed individual depends upon where on the site an activity is performed. However, to provide an upper bound of the cumulative impacts to the maximally exposed individual, the impacts from each activity have been summed.

**Source:** (1) Saffle et al. 2000 for impacts to the public from existing site activities and DOE 1999k for impacts to the workforce from existing site activities; (2) DOE 1995c and DOE 1996a for all impacts associated with storage and disposition activities, foreign research reactor spent nuclear fuel activities, spent nuclear fuel activities, advanced mixed waste treatment activities, and high-level waste activities; (3) DOE 2000b for all impacts associated with sodium-bonded spent nuclear fuel activities; and (4) Section 4.4.2.1.9 of this NI PEIS for all impacts associated with infrastructure operations.

#### 4.8.2.4 Waste Management

Cumulative amounts of waste generated at INEEL are presented in **Table 4–170**. It is unlikely that there would be major impacts on waste management at INEEL because sufficient capacity would exist to manage the site waste. As discussed in Section 4.3.2.1.13, irrespective of how the waste from processing of irradiated neptunium-237 targets is classified (i.e., transuranic or high-level radioactive), the waste composition and characteristics are the same, and the management (i.e., treatment and onsite storage), as described in this NI PEIS, would be the same. In addition, either waste type would require disposal in a suitable repository. None of the alternatives assessed in this NI PEIS would generate more than a small amount of additional waste at INEEL.

**Table 4–170 Cumulative Impacts on Waste Management Activities at INEEL Over 35-Year Period (cubic meters)**

Waste Type	Existing Site Activities <sup>a</sup>	Idaho HLW and Facility Disposition EIS <sup>b</sup>	Treatment and Management of Sodium-Bonded SNF <sup>c</sup>	New Nuclear Infrastructure Operations <sup>d</sup>	Total	Site Capacity <sup>e</sup>		
						Treatment (cubic meters/ year)	Storage	Disposal (cubic meter/ year)
Transuranic (High-level <sup>f</sup> radioactive)	65,000 <sup>g</sup> (0)	110 (0)	14 (0)	245 (245)	65,369 (245)	57,794 (6,434)	190,319 (19,483)	NA (NA)
Low-level radioactive	135,600	15,325	862	<2,320	~154,107	42,363	177,493	69,530
Mixed low-level radioactive	3,767	12,837	40	<175	~16,819	157,092	187,761	NA
Hazardous	1,180	2,457	0	227,500 kilograms (644 cubic meters) <sup>h</sup>	4,281	NA	9,619	NA
Nonhazardous	124,905	145,262	4,960	64,015	339,142	3,200,000	NA	3,062,000

- a. DOE 2000b:table 4–67 and figures 5.4–1 through 5.4–3 and input values for those figures through year 2035.
  - b. DOE 2000b:table 4–67, Separations Alternative. Maximum quantities for any alternative.
  - c. DOE 2000b:table 4–18, Alternative 1, electrometallurgically treat blanket and driver fuel at ANL–W; 12 years of operation and selected in the Record of Decision (65 FR 56565).
  - d. Option 2 of Alternative 2 would generate the most waste for all waste types.
  - e. Total 35-year and annual capacity derived from Table 3–27.
  - f. Refer to Section 4.3.2.1.13 for a discussion on the classification of waste from processing irradiated neptunium-237 targets. Volumes in parentheses represent high-level radioactive waste.
  - g. This 65,000 cubic meters is in storage at the Radioactive Waste Management Complex.
  - h. Assumes for hazardous waste that 353 kilograms equals 1 cubic meter (22.0 pounds equals 1 cubic foot).
- Note:** To convert from cubic meters to cubic yards, multiply by 1.308; HLW means high-level radioactive waste; SNF means spent nuclear fuel; < means “less than”; ~ means “approximately;” NA, not applicable (i.e., the majority of the waste is not routinely treated, stored, or disposed of on site).
- Source:** DOE 2000b:table 4–67 and figures 5.4–1 through 5.4–3 and input values for those figures through year 2035; Sections 4.3.2.1.13 and 4.4.1.1.13 of this NI PEIS.

### 4.8.3 Cumulative Impacts at Hanford

For Hanford, the bounding option for this NI PEIS depends on the parameter assessed. For example, under Public and Occupational Health and Safety, the highest radiological doses and associated latent cancer fatalities to the public would be associated with Option 1 of Alternative 1, whereas the highest doses and latent cancer fatalities to workers would be associated with Option 3 of this same alternative. Processing of targets in RPL versus processing in FMEF accounts for there being different bounding options (refer to Tables 4–41, 4–42, 4–17, and 4–18). For each of the parameters addressed in this section, a footnote is included in each of the cumulative impact tables, as necessary, to indicate the bounding alternative/option.

#### 4.8.3.1 Resource Requirements

Cumulative impacts on resource requirements at Hanford are presented in **Table 4–171**. Hanford would remain within its site capacity for all major resources. If any of the options under Alternative 1 were implemented, the proposed nuclear infrastructure facilities would require a small increase in the site’s use of electricity and water. For the bounding options identified in Table 4–171, this would reflect an increase of about 2 and 1 percent, respectively, over current baseline utilization for these resources. There would be no additional land disturbance or development. Cumulatively, Hanford would use approximately 23 percent of its electrical capacity and 38 percent of its water capacity. Site employment would increase by approximately 130 workers.

**Table 4–171 Maximum Cumulative Resource Use and Impacts at Hanford**

Activities <sup>a</sup>	Site Employment	Electrical Consumption (megawatt-hours per year)	Water Usage (million liters per year)
<b>Existing site activities<sup>b</sup></b>	16,005	323,128	2,754 <sup>c</sup>
Tank Waste Remediation System	–	170,000	200
Waste Management PEIS	–	13,920	133
<b>New nuclear infrastructure operations<sup>d</sup></b>	130 <sup>e</sup>	55,000	80
<b>Total</b>	16,135	562,048	3,167
<b>Total site capacity</b>	NA	2,484,336	8,263 <sup>c</sup>

a. See Section 4.8 and Table 4–162 for descriptions of past, present, and reasonably foreseeable actions considered.

b. Reflects current sitewide activities. The “Site Employment” value also reflects projected employment from other activities that are anticipated to continue during all or part of the 35-year period evaluated for proposed nuclear infrastructure operations.

c. Reflects domestic/potable water only and not raw water usage or availability.

d. Electrical consumption and water usage are bounded by Option 3 or 6 of Alternative 1, with the values reflecting the increase over standby operations from restart of FFTF and associated support activities in FMEF.

e. Some, or all, of these worker requirements may be filled by the reassignment of the existing site workforce.

**Note:** To convert from liters per year to gallons per year, multiply by 0.264; to convert from megawatt-hours to British thermal units, multiply by  $3.42 \times 10^6$ .

**Key:** NA, not applicable.

**Source:** DOE 1996e:5-284; 1997a:5-18, 5-32, 5-45, 5-55, 5-67; 1999a:3-45, 4-376; Sections 4.3.3.1.4 and 4.3.3.1.8 of this NI PEIS.

#### 4.8.3.2 Air Quality

Cumulative impacts on air quality at Hanford are presented in **Table 4–172**. Hanford is currently in compliance with all Federal and state ambient air quality standards, and would continue to be in compliance even with consideration of the cumulative effects of all activities. The nuclear infrastructure contributions to overall site concentrations are expected to be very small.

#### 4.8.3.3 Public and Occupational Health and Safety—Normal Operations

Cumulative impacts in terms of radiation exposure to the public and workers at Hanford are presented in **Table 4–173**. There would be no increase expected in the number of latent cancer fatalities in the population from Hanford site operations if nuclear infrastructure operations were to occur at FMEF. The dose limits for individual members of the public are given in DOE Order 5400.5. As discussed in that order, the dose limit from airborne emissions is 10 millirem per year, as required by the Clean Air Act; the dose limit from drinking water is 4 millirem per year, as required by the Safe Drinking Water Act; and the dose limit from all pathways combined is 100 millirem per year. Therefore, as is evident in Table 4–173, the dose to the maximally exposed individual would be expected to remain well within the regulatory limits. Onsite workers would be expected to see an increase of approximately 0.26 latent cancer fatality due to radiation from nuclear infrastructure operations over the 35-year operational period.

Radiation doses listed under site activities in Table 4–173 include exposures due to activities associated with waste management (as estimated in the *Hanford Comprehensive Land-Use Plan* (DOE 1999d), the tank waste remediation system (DOE 1996e), management of spent nuclear fuel from the K Basins (DOE 1996h), disposal of decommissioned naval reactor plants (Navy 1996), and the Plutonium Finishing Plant Stabilization (DOE 1996g).

**Table 4–172 Maximum Cumulative Air Pollutant Concentrations at Hanford for Comparison with Ambient Air Quality Standards**

Parameter	Carbon Monoxide		Nitrogen Dioxide	PM <sub>10</sub>		Sulfur Dioxide			
	8 hours	1 hour	Annual	Annual	24 hours	Annual	24 hours	3 hours	1 hour
<b>Activities</b>									
Existing site activities <sup>a</sup> (micrograms per cubic meter)	27.3	63.3	0.666	0.0182	1.01	0.175	30.17	69.4	79.4
Hanford tank waste remediation <sup>b</sup> (micrograms per cubic meter)	34	48	0.12	0.0079	0.75	0.020	1.6	3.6	4
Spent nuclear fuel management <sup>c</sup> (micrograms per cubic meter)	0	0	0.1	0	0	0	0	0	0
New nuclear infrastructure FFTF operations <sup>d</sup> (micrograms per cubic meter)	52.1	74.4	0.0118	8.39×10 <sup>-4</sup>	9.84	0.00785	9.11	20.5	22.8
New nuclear infrastructure FMEF operations <sup>d</sup> (micrograms per cubic meter)	0	0	4.43×10 <sup>-5</sup>	0	0	0.0087	0.069	0.16	0.17
Total concentration (micrograms per cubic meter)	113.4	185.7	0.90	0.027	11.6	0.212	40.9	93.7	106
<b>Standard</b>									
Most stringent standard <sup>e</sup> (micrograms per cubic meter)	10,000	40,000	100	50	150	50	260	1,300	660

- Environmental impacts associated with existing site activities as described in Section 3.4.3 of this NI PEIS. The values listed are the summed values presented in Table 3–29. These activities are anticipated to continue during part or all of the 35-year period evaluated for proposed nuclear infrastructure operations.
- Hanford Tank Waste Remediation Final EIS* activities, vitrification facilities from Table 5.3-1, Phased Implementation – Phase II Operation (DOE 1996e).
- Spent Nuclear Fuel Management* – regionalization alternative (DOE 1995c:vol. 1, app. A, p. 5-43).
- Nuclear infrastructure contributions are bounded by Alternative 1, Option 3. Periodic testing of emergency diesel generators would result in higher values for certain pollutants and time periods (Section 4.3.3.1.3).
- The more stringent of the Federal and State standards is presented if both exist for the averaging period.

**Note:** The contribution from activities in the *Final Waste Management Programmatic EIS* (DOE 1997a) are small and are not shown.

**Source:** DOE 1995c, 1996e, 1997a; Wisness 2000; modeled results for nuclear infrastructure operations are based on the SCREEN3 computer code (EPA 1995); Sections 3.4.3 and 4.3.3.1.3 of this NI PEIS.

**Table 4–173 Maximum Cumulative Radiation Impacts at Hanford**

Impact	Maximally Exposed Individual		Population Dose Within 80 Kilometers (50 Miles) (Year 2020)		Total Site Workforce	
	Annual Dose (millirem per year)	Risk of a Latent Cancer Fatality <sup>a</sup>	Dose (person-rem)	Number of Latent Cancer Fatalities <sup>a</sup>	Dose (person-rem per year)	Number of Latent Cancer Fatalities <sup>a</sup>
Existing site activities <sup>b</sup>	0.02	$3.5 \times 10^{-7}$	0.60	0.011	181	2.5
Waste management	0.0057	$2.9 \times 10^{-9}$	0.28	0.0014	1,300	5.2
Tank remediation	(c)	$2.4 \times 10^{-6}$	(c)	0.19	(c)	3.27
Spent nuclear fuel management	(c)	$1.4 \times 10^{-8}$	(c)	$8.0 \times 10^{-4}$	(c)	0.057
Burial of low-level waste	0	0	0	0	1,018	0.41
Plutonium Finishing Plant stabilization	0.13	$3.9 \times 10^{-7}$	2.3	0.007	157	0.38
New nuclear infrastructure operations at FFTF and FMEF or RPL <sup>d</sup>	0.0054	$9.5 \times 10^{-8}$	0.25	0.0044	18	0.26
Total	(e)	$3.3 \times 10^{-6(f)}$	(e)	0.21	(e)	12

- These values are calculated based on a 35-year exposure period except for waste management (project duration for waste transfer of 10 years) and Plutonium Finishing Plant stabilization (a 6-year project).
- Environmental impacts associated with present activities at Hanford (including activities at other non-DOE facilities at, or near, Hanford) that are anticipated to continue during all or part of the 35-year period evaluated for proposed nuclear infrastructure operations.
- Source document provides project total; annual values are not constant.
- Impacts on the public are bounded by Option 1 of Alternative 1; impacts on workers are bounded by Option 3 of Alternative 1.
- Some source documents did not provide dose values, only expected latent cancer fatalities. Therefore, total dose estimates have not been developed.
- The same individual would not be expected to be the maximally exposed individual for all activities at Hanford. The location of the maximally exposed individual depends upon where an activity is performed on the site. However, to provide an upper bound cumulative impact for the maximally exposed individual, the impacts from each activity have been summed.

**Source:** (1) Dirkes, Hanf, and Poston 1999:chap. 5 and DOE 1997a for impacts to the public from existing site activities and DOE 1999k:table B-1c for impacts to the workforce from existing site activities; (2) DOE 1996a:chap. 4, 1996e:table 5.11.1, 1996g:table 3-12a, 1997a:table 11.6-2, 1999d:sec. 5.6.4; Navy 1996:sec. 4.3.3.5 for impacts associated with each of the other activities listed in the first column, except nuclear infrastructure operations; and (3) Sections 4.3.1.1.9 and 4.3.3.1.9 of this NI PEIS for all impacts associated with nuclear infrastructure operations.

#### 4.8.3.4 Waste Management

Cumulative amounts of waste generated at Hanford are presented in **Table 4–174**. It is unlikely that there would be major impacts on waste management at Hanford because sufficient capacity would exist to manage the site waste. As discussed in Sections 4.3.3.1.13 and 4.4.3.1.13, irrespective of how the waste from processing of irradiated neptunium-237 targets is classified (i.e., transuranic or high-level radioactive), the waste composition and characteristics are the same, and the management (i.e., treatment and onsite storage), as described in this NI PEIS, would be the same. In addition, either waste type would require disposal in a suitable repository. None of the alternatives assessed in this NI PEIS would generate more than a relatively small amount of additional waste at Hanford.

**Table 4-174 Cumulative Impacts on Waste Management Activities at Hanford Over 35-Year Period (cubic meters)**

Waste Type	Existing Site Activities <sup>a</sup>	New Nuclear Infrastructure Operations	Total	Site Capacity <sup>b</sup>		
				Treatment (cubic meters/year)	Storage	Disposal
Transuranic (High-level radioactive) <sup>c</sup>	9,880 (0)	385 <sup>d</sup> (385)	10,265 (385)	98,520 (50,000)	17,216 (146,000)	NA (NA)
Low-level radioactive	95,666	5,015 <sup>d</sup>	100,681	398,112	99,910	1,970,000
Mixed low-level radioactive	46,207	315 <sup>d</sup>	46,522	413,211	100,483	14,200
Hazardous	19,600	3,100 <sup>e</sup>	22,700	NA	NA	NA
Nonhazardous						
Liquid	7,000,000	1,494,500 <sup>d</sup>	8,494,500	120,000	NA	4,807,720
Solid	1,505,000	10,500 <sup>d</sup>	1,515,500	NA	NA	NA

a. Total 35-year waste generation derived from DOE 1999h, except for hazardous and nonhazardous waste, which were derived from Table 3-34.

b. Total 35-year and annual capacity derived from Table 3-36.

c. Refer to Section 4.3.3.1.13 and 4.4.3.1.13 for a discussion on the classification of waste from processing irradiated neptunium-237 targets. Volumes in parentheses represent high-level radioactive waste.

d. The bounding alternative for this waste type is Alternative 1, Option 3 or 6.

e. The bounding alternative for this waste type is Alternative 2, Option 3, 6, or 9; Alternative 3, Option 3; or Alternative 4, Option 3; which all include the deactivation of FFTF and neptunium-237 target fabrication and processing at FMEF. The inventory of bulk metallic sodium (Section 4.4.1.2.13) is not included because alternative sponsors and/or users will be found for its disposition.

**Note:** To convert from cubic meters to cubic yards, multiply by 1.308.

**Source:** DOE 1996a; DOE 1999h; Sections 4.3.3.1.13 and 4.4.1.2.13 of this NI PEIS.

#### 4.8.3.5 Spent Nuclear Fuel Management

As discussed in Section 4.3.1.1.14, the operation of FFTF for the proposed activities at 100 megawatts for 35 years under Alternative 1 would produce a total of about 16 metric tons of heavy metal (35,200 pounds) of spent nuclear fuel. The existing spent nuclear fuel at Hanford is about 2,133 metric tons of heavy metal (4,700,000 pounds) (DOE 1995c). The environmental impacts associated with the existing spent nuclear fuel management at Hanford are addressed in the following documents:

- DOE 1996a—*Storage and Disposition of Weapons-Usable Fissile Materials Fuel Programmatic Environmental Impact Statement*
- DOE 1995c—*Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho Nuclear Engineering Laboratory Environmental Restoration and Waste Management Final Environmental Impact Statement*
- DOE 1997c—*Environmental Assessment - Management of Hanford Site, Non-Defense Production Reactor Spent Nuclear Fuel*
- DOE 1996h—*Final Environmental Impact Statement, Management of Spent Nuclear Fuel from the K Basins at the Hanford Site*

The management of the existing spent fuel at Hanford results in a dose of less than 0.1 millirem per year to the maximally exposed member of the public. This dose is well within the DOE dose limits cited in

Section 4.8.3.3. DOE has committed to remove the spent fuel at Hanford for ultimate disposition in a geologic repository. The restart of FFTF under Alternative 1 would generate 16 metric tons of heavy metal of spent nuclear fuel, which is less than 1 weight-percent of the total spent nuclear fuel inventory presently at Hanford. Only a small fraction of the dose shown for nuclear infrastructure operations would be attributable to the management of this spent fuel at FFTF. The doses at Hanford, including those associated with spent nuclear fuel management, would remain within the DOE dose limits.

#### **4.8.4 Cumulative Impacts at the Generic CLWR Site**

No incremental environmental impacts at the generic site would be expected from the normal operation of a CLWR to irradiate targets (refer to Sections 4.4.4 through 4.4.6). Therefore, the cumulative impacts at the generic CLWR site would not be affected by any action assessed in this NI PEIS, and are not addressed further.

#### **4.8.5 Cumulative Impacts at the New Accelerator(s) Generic DOE Site**

Cumulative impacts cannot be presented for a generic site. If Alternative 3 were selected for implementation, a subsequent site-specific analysis would be conducted for the DOE site chosen for the combination of new accelerator(s) and support facility (refer to Section 4.5), and appropriate NEPA documentation would be prepared to address the cumulative impacts for that site.

#### **4.8.6 Cumulative Impacts at the New Research Reactor Generic DOE Site**

Cumulative impacts cannot be presented for a generic site. If Alternative 4 were selected for implementation, a subsequent site-specific analysis would be conducted for the DOE site chosen for the new research reactor and support facility or research reactor only (refer to Section 4.6), and appropriate NEPA documentation would be prepared to address the cumulative impacts for that site.

#### **4.8.7 Cumulative Impacts of Transportation**

The cumulative impacts from transportation associated with nuclear infrastructure activities are identified in Appendix J. Because likely transportation routes cross many states, cumulative impacts are compared on a national basis. Under all alternatives assessed in this NI PEIS, occupational radiation exposure to transportation workers and exposure to the public are estimated to each represent less than 0.05 percent of the cumulative exposures from nationwide transportation (DOE 1999i) over the 35-year period of nuclear infrastructure activities. No additional traffic fatality is expected; the incremental increase in traffic fatalities would be less than 0.0001 percent per year.

#### **4.9 MITIGATION MEASURES**

As shown throughout Chapter 4, the impacts of all the alternatives would be small. No specific mitigation measures would be necessary because all potential environmental impacts would be below acceptable levels or applicable standards.

Nevertheless, DOE would maintain all public and worker exposures, both direct exposures and indirect exposures via airborne emissions, as low as is reasonably achievable. This is a long-standing DOE policy to control or manage radiation exposures and releases of radioactive material to the environment as low as social, technical, economic, practical, and public policy considerations permit. This DOE policy is not a dose limit but rather a process that has as its objective the attainment of dose levels as far below the applicable limits as practical.

Similarly, DOE has a long-standing policy to minimize waste generation. Thus, DOE would conduct all operations in a manner that generates the smallest amount of waste practical. This policy applies to all types of waste, including solid and liquid radioactive waste, hazardous waste, and mixed waste.

Alternatives 3 and 4 involve the construction of major new facilities. In these alternatives, DOE would employ modern construction practices that minimize the environmental impacts.

#### **4.10 UNAVOIDABLE ADVERSE ENVIRONMENTAL IMPACTS**

Regardless of the option selected by DOE, there may be some associated unavoidable adverse environmental impacts, although the impacts would be small. Some health risks to workers and the public would be unavoidable were the option implemented. Workers at operating sites and involved in truck shipments would be subject to the same types and frequencies of injuries and accidental deaths that workers experience across the industrial sector of the nation. Workers would also be exposed to the specific health risks of exposures to radiation and hazardous chemicals. The public would generally be at a lower risk than any of the workers involved in processing activities. During processing operations, air quality would be unavoidably affected as the result of criteria and hazardous and toxic air pollutant emissions at the site, and from worker vehicles and truck shipment vehicles. Nonradiological air quality impacts at any particular site are not expected to affect attainment status of the site's air quality control region for each criteria air pollutant.

Construction activities associated with several options (including construction of a new 76-meter (250-foot) stack at Hanford, one or two new DOE accelerators and support facility, and a new DOE nuclear research reactor and support facility) would result in short term elevated levels of particulate matter in localized areas. In addition, portions of nonsensitive terrestrial habitats would be lost when these new facilities were constructed. None of these habitat losses is expected to constitute a significant impact on the resident plant and animal species because these species have broad ranges and the amount of lost habitat would comprise only a small fraction of these communities.

If an alternative were selected which involved a DOE site not yet selected for implementation (generic DOE site), the issue of unavoidable adverse environmental impacts would be assessed as part of the site selection process. Appropriate NEPA documentation would be prepared.

#### **4.11 RELATIONSHIP BETWEEN SHORT-TERM USE OF THE ENVIRONMENT AND LONG-TERM PRODUCTIVITY**

Short-term environmental impacts are those that would occur during construction and operation of target fabrication, storage, irradiation, or processing facilities. Impacts that extend beyond the period of facility operations are considered to be long-term impacts.

The implementation of any of the options assessed in this NI PEIS would result either in the short-term use of existing facilities and environmental resources, or in the construction of new facilities and their operation and ultimate decontamination and decommissioning. Facility modifications would be required for the implementation of neptunium-237 target fabrication and postirradiation plutonium-238 processing technologies at ORR, INEEL, and Hanford. In addition, facility modifications would be required at Hanford to support target fabrication and postirradiation processing for civilian nuclear energy research and industrial and medical isotope production in FFTF and perhaps at other DOE sites for targets irradiated in either one or two new DOE accelerators or a new DOE research reactor. Some new target fabrication and postirradiation processing facilities might be required to support targets irradiated in either one or two new DOE accelerators or a new DOE research reactor.

The implementation of options that require construction of new facilities would require short-term use of the environment and a variety of resources such as land, construction materials, and labor. Development of these facilities would commit lands to those uses from the beginning of the construction period through the duration of the operation period and until such facility would be fully decommissioned. Depending upon the specific locations at sites selected for these facilities, some terrestrial habitat may be lost when the area is cleared for construction. Disturbance of this acreage would eliminate the natural productivity of the land. At the end of the operational period, these facilities could be converted to other uses or decontaminated and decommissioned and the land returned to its original use or a condition compatible with future uses.

Transportation between SRS and the candidate neptunium-237 target fabrication sites; between the candidate sites for neptunium-237 target fabrication and processing and the irradiation sites; between the candidate postirradiation plutonium-238 processing sites and LANL; between an east coast port and Hanford for shipment of mixed oxide fuel; and between a U.S. fuel fabrication facility and Hanford for shipment of highly enriched uranium fuel would occur on existing roadways. Most target fabrication and postirradiation processing for industrial and medical isotopes and for civilian nuclear energy research and development would occur on the same site as the irradiation of those targets; however, there would be air and truck transport of the irradiation products to certain distribution centers. There would also be some transport of targets containing hazardous materials to the irradiation sites. These activities would result in emissions to the atmosphere that would not measurably affect regional or global air quality. Short-term uses of the environment would have no appreciable beneficial or adverse effects on long-term productivity of the environment on, or in the vicinity of, any of the sites assessed in this NI PEIS.

#### **4.12 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES**

This section describes the major irreversible and irretrievable commitments of resources that can be identified at this programmatic level of analysis. A commitment of resources is irreversible when primary or secondary impacts limit the future options for a resource. An irretrievable commitment refers to the use or consumption of resources neither renewable nor recoverable for future use.

Processing activities related to the production of plutonium-238 described in this NI PEIS would be conducted at existing facilities. In addition, the fabrication and processing of targets used to produce industrial and medical isotopes and to conduct civilian nuclear energy research and development using FFTF at Hanford would also be conducted in existing facilities. Modifications to existing facilities would consist of improvements required to meet current environmental standards or the installation of new processing equipment. In addition, the use of FMEF at Hanford would require construction of a 76-meter (250-foot) stack.

The implementation of several alternatives described in this NI PEIS would require the construction of new facilities to fabricate, irradiate, or process targets to produce plutonium-238 for space missions, industrial and medical isotopes, or to conduct civilian nuclear energy research and development. These alternatives would include those using one or two new accelerators or a new research reactor to irradiate the targets. To limit the cost and environmental impacts of these alternatives, DOE would consider modifying existing appropriate facilities at the irradiation sites rather than constructing new facilities.

The land that is currently occupied by either existing or new processing or irradiation facilities could ultimately be returned to open space uses if buildings, roads, and other structures were removed, areas cleaned up, and the land revegetated. Alternatively, the facilities could be modified for use in other DOE programs. The commitment of such land is irreversible in the short term, but not necessarily irreversible in the long term.

The irreversible and irretrievable commitment of material resources during the life-cycles of the activities described in this NI PEIS includes construction materials that cannot be recovered or recycled, materials that are rendered radioactive and cannot be decontaminated, and materials consumed or reduced to unrecoverable forms of waste. Where construction would be necessary, materials required include wood, concrete, sand, gravel, plastics, steel, aluminum, and other metals. These construction resources, except for those that can be recovered and recycled with present technology, would be irretrievably lost. However, none of those identified construction resources is in short supply, and all are readily available in the vicinity of locations being considered for new facilities. Materials required for the processing equipment, utilities, and fuel required for transportation options comprise the irretrievable resources required to implement the various options that use either new or existing facilities. None of the alternatives requires resources that would noticeably affect local or national supplies, or that would noticeably affect the quality of the local or global environment.

### 4.13 INDUSTRIAL SAFETY

Estimates of potential industrial impacts to workers during construction, irradiation, fabrication, and processing were evaluated based on DOE and Bureau of Labor Statistics data. Impacts are classified into two groups: total recordable cases and fatalities. A recordable case includes work-related death, illness, or injury which resulted in loss of consciousness, restriction of work or motion, transfer to another job, or required medical treatment beyond first aid. The industrial safety evaluation is discussed in more detail in Section I.3.

The average occupational total recordable cases and fatality rates for construction and operation activities are presented in **Table 4-175**.

**Table 4-175 Average Occupational Total Recordable Cases and Fatality Rates (per worker-year)**

Labor Category	Total Recordable Cases	Fatalities
Construction	0.053	$1.39 \times 10^{-4}$
Operation	0.033	$1.3 \times 10^{-5}$

Source: Section I.3.

The expected impacts (both annual and for the duration of the activity) to workers at each facility for construction and operation are presented in **Table 4-176**.

**Table 4-176 Industrial Safety Impacts from Construction and Operation**

Facility	Estimated Number of Workers	Construction or Operation Duration (years)	Expected Annual Total Recordable Cases	Expected Activity Duration Total Recordable Cases	Annual Fatalities	Activity Duration Fatalities
<b>Construction</b>						
Low-energy accelerator	75	3	4.0	12	0.010	0.030
High-energy accelerator	410	5	22	110	0.057	0.285
New research reactor	160	7	8.5	59.5	0.022	0.154
<b>Operation</b>						
ATR <sup>a</sup>	0	35	–	–	–	–
HFIR <sup>a</sup>	0	35	–	–	–	–
CLWR <sup>a</sup>	0	35	–	–	–	–
FFTF	242	35	8.0	280	0.0031	0.109
Low-energy accelerator	13	35	0.4	14	$1.7 \times 10^{-4}$	0.00595
High-energy accelerator	225	35	7.4	259	0.0029	0.102
New research reactor	120	35	4.0	140	0.0016	0.056
REDC	116	35	3.8	133	0.0015	0.0525
FDPF	75	35	2.5	87.5	$9.8 \times 10^{-4}$	0.0343
FMEF	105	35	3.5	123	0.0014	0.049
RPL/306-E	30	35	1.0	35	$3.9 \times 10^{-4}$	0.0137
New support facility	100	35	3.3	116	0.0013	0.0455

a. No additional workers would be required at these facilities for the proposed activities evaluated in this NI PEIS.

Source: Section I.3.

No fatalities would be expected from either construction or operation of any facility.

## Chapter 5

# Applicable Laws, Regulations, and Other Requirements

Chapter 5 presents the laws, regulations, and other requirements that apply to the proposed action and alternatives. Federal, state, and U.S. Department of Energy environmental, safety, and health laws, regulations, and Executive and DOE orders are summarized in Section 5.1. Radioactive material packaging and transportation laws and regulations are discussed in Section 5.2. Emergency management and response laws, regulations, and Executive orders are discussed in Section 5.3. Consultations with Federal, state, and local agencies and federally recognized Native American groups are discussed in Section 5.4.

### 5.1 ENVIRONMENTAL, SAFETY, AND HEALTH LAWS, REGULATIONS, EXECUTIVE ORDERS, AND U.S. DEPARTMENT OF ENERGY ORDERS

There are a number of Federal environmental laws that affect environmental protection, compliance, or consultation at every U.S. Department of Energy (DOE) location and at commercial light water reactors (CLWRs). In addition, certain environmental requirements have been delegated to state authorities for enforcement and implementation. It is DOE policy to conduct its operations in a manner that ensures the protection of public health, safety, and the environment through compliance with all applicable Federal and state laws, regulations, orders, and other requirements.

The various action alternatives analyzed in this *Final Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS])* involve the operation of existing DOE and commercial facilities, the construction and operation of new DOE facilities, and the transportation of materials. Compliance with statutes, regulations, and other Federal and state requirements may be dependent on whether a facility is newly built (preoperational) or has already been operating, as well as dependent on who owns the facility (i.e., DOE or a private entity). A brief summary of the alternatives is provided below to help the reader understand the statutory, regulatory, and other requirements that are discussed later in this chapter. Chapter 2 provides a more detailed discussion of these alternatives.

- **No Action Alternative** includes maintaining an existing facility (the Fast Flux Text Facility [FFTF]) in standby status and purchasing plutonium-238 from Russia. The continued use of existing DOE facilities to produce medical and industrial isotopes and conduct nuclear research and development activities at current operating levels is also included in this alternative, as well as the storage of neptunium-237.
- **Alternative 1** includes the use of existing DOE facilities to store nuclear materials (the Radiochemical Engineering Development Center [REDC], the Fluorinel Dissolution Process Facility [FDPF], the Fuels and Materials Examination Facility [FMEF], the Hanford Radiochemical Processing Laboratory [RPL/306-E], or the Idaho Nuclear Technology and Engineering Center [INTEC] Building 651 [CPP-651]); fabricate and process targets for plutonium-238 production, medical and industrial isotope production, and nuclear research and development needs (FMEF, REDC, Hanford RPL/306-E, FDPF); and irradiate all targets at FFTF.
- **Alternative 2** includes the use of existing operating DOE facilities to store nuclear materials (REDC, FDPF, CPP-651, or FMEF), fabricate and process neptunium-237 targets (REDC, FDPF, FMEF), and irradiate neptunium-237 targets (the Advanced Test Reactor [ATR], the High Flux Isotope Reactor [HFIR]). In addition to existing DOE facilities, the use of an existing operating CLWR to irradiate neptunium-237 targets was analyzed. The permanent deactivation of an existing DOE facility (FFTF) also is included in this alternative. Under this alternative, existing DOE facilities would

continue medical and industrial isotope production and nuclear research and development activities at current operating levels.

- **Alternative 3** includes the construction and operation of a new support facility at an existing DOE site to fabricate and process medical and industrial targets and nuclear materials for research and development purposes, and one or two new accelerators at an existing DOE site to irradiate these targets and materials, as well as neptunium-237 targets for plutonium-238 production. The use of existing DOE facilities for neptunium-237 target fabrication and processing (REDC, FDPF, FMEF) and materials storage (REDC, FDPF, CPP-651, FMEF) also was analyzed. The decontamination and decommissioning of the new accelerator(s) and support facility and the permanent deactivation of FFTF, an existing DOE facility, are included in this alternative.
- **Alternative 4** includes the construction and operation of a new support facility at an existing DOE site to fabricate and process medical and industrial targets and nuclear materials for research and development purposes, and a new research reactor at an existing DOE site to irradiate these targets and materials, as well as neptunium-237 targets for plutonium-238 production. Neptunium-237 target fabrication and processing at existing DOE facilities (REDC, FDPF, FMEF) and materials storage (REDC, FDPF, CPP-651, FMEF) were analyzed in this alternative as well. The decontamination and decommissioning of the new research reactor and support facility and the permanent deactivation of FFTF, an existing DOE facility, also are included in this alternative.
- **Alternative 5** includes the permanent deactivation of FFTF, an existing DOE facility, with no new missions at existing facilities.

The addition of plutonium-238 production, research and development, and industrial and medical isotope production missions at existing facilities would necessitate few, if any, physical or substantive changes to current activities at these sites. Continued compliance with applicable laws, regulations, and other requirements, including permits and licenses, would be required. Based on projections for air emissions and liquid effluent, no changes to the permits at these existing facilities should be necessary to accommodate the nuclear energy research and development and isotope production missions. Waste generated as a result of the expanded missions would be managed consistent with current site waste management practices and existing permits, agreements, and orders. However, as with any project, it should be noted that regulatory requirements can change over time and may impact current practices, possibly requiring changes or modifications to facility operations and applicable permits or licenses.

The construction and operation of one or two new accelerators or the research reactor and support facility at an existing DOE site would require major physical changes. These new facilities would require the appropriate licenses and permits necessary for construction and operation.

This section describes the environmental, safety, and health laws, regulations, and orders that may apply to the proposed action and alternatives. A more detailed analysis for new facilities (i.e., new accelerator(s) or new research reactor) would be needed if either of these alternatives is selected in the Record of Decision.

### **5.1.1 Federal Environmental, Safety, and Health Laws and Regulations**

**National Environmental Policy Act of 1969, as amended (42 United States Code (U.S.C.) 4321 *et seq.*)**—The National Environmental Policy Act (NEPA) establishes a national policy promoting awareness of the environmental consequences of human activity on the environment and consideration of environmental impacts during the planning and decision-making stages of a project. It requires Federal

agencies to prepare a detailed environmental impact statement (EIS) for any major Federal action with potentially significant environmental impact.

This NI PEIS has been prepared in accordance with NEPA requirements, the Council on Environmental Quality regulations (40 Code of Federal Regulations (CFR) Part 1500 *et seq.*), and DOE (10 CFR Part 1021, DOE Order 451.1B) provisions for implementing the procedural requirements of NEPA. It discusses reasonable alternatives and their potential environmental consequences.

**Atomic Energy Act of 1954 (42 U.S.C. 2011 *et seq.*)**—The Atomic Energy Act authorizes DOE to establish standards to protect health or minimize dangers to life or property for activities under DOE’s jurisdiction. Through a series of DOE orders, an extensive system of standards and requirements was established to ensure safe operation of DOE facilities. DOE regulations are found in 10 CFR.

The Atomic Energy Act also requires entities that operate nuclear power plants, such as CLWRs, to have a plant license issued by the U.S. Nuclear Regulatory Commission (NRC). The NRC regulations that implement this requirement provide for permits to be issued for the construction or alteration of such facilities. Operating licenses are applied for after completion of the construction or alteration of the facilities. Construction permits and operating licenses include detailed provisions regarding their duration and the design, safety, and quality assurance requirements for the subject facilities. The NRC regulations for permits and operating licenses are found in 10 CFR.

For alternatives involving existing DOE facilities and the construction and operation of one or two new DOE accelerators or a research reactor and support facility, an NRC license is not required and the facilities would need to comply with the appropriate DOE orders. A list of applicable DOE orders is provided in Section 5.1.3.

For the alternative involving the existing generic CLWR, the existing operating license would need to be amended to address neptunium-237 target irradiation. NRC must approve the generic CLWR’s license amendment before this plant can irradiate these targets to produce plutonium-238.

For nuclear facilities in the United States, annual exposure limits to the public and radiation workers are established by NRC in 10 CFR Part 20 (“Standards for Protection Against Radiation”) and 10 CFR Part 50, Appendix I (“Numerical Guides for Design Objectives and Limiting Conditions for Operation to Meet the Criterion ‘As Low as is Reasonably Achievable’ for Radioactive Material in Light-Water-Cooled Nuclear Power Reactor Effluent”).

**Clean Air Act of 1970, as amended (42 U.S.C. 7401 *et seq.*)**—The Clean Air Act is intended to “protect and enhance the quality of the Nation’s air resources so as to promote the public health and welfare and the productive capacity of its population.” Section 118 of the Clean Air Act (42 U.S.C. 7418) requires that each Federal agency with jurisdiction over any property or facility engaged in any activity that might result in the discharge of air pollutants comply with “all Federal, state, interstate, and local requirements” with regard to the control and abatement of air pollution.

The Clean Air Act: (1) requires the U.S. Environmental Protection Agency (EPA) to establish National Ambient Air Quality Standards as necessary to protect the public health, with an adequate margin of safety, from any known or anticipated adverse effects of a regulated pollutant (42 U.S.C. 7409 *et seq.*); (2) requires establishment of national standards of performance for new or modified stationary sources of atmospheric pollutants (42 U.S.C. 7411); (3) requires specific emission increases to be evaluated so as to prevent a significant deterioration in air quality (42 U.S.C. 7470 *et seq.*); and (4) requires specific standards for releases of hazardous air pollutants (including radionuclides) (42 U.S.C. 7412). These standards are implemented

through state implementation plans developed by each state with EPA approval. The Clean Air Act requires sources to meet standards and obtain permits to satisfy these standards.

Emissions of air pollutants are regulated by EPA under 40 CFR Parts 50 through 99. Radionuclide emissions from DOE facilities are regulated under the National Emission Standards for Hazardous Air Pollutants Program under 40 CFR Part 61. Approval to construct a new facility or to modify an existing one may be required by these regulations under 40 CFR Section 61.07. These standards are not applicable to NRC-licensed facilities such as CLWRs. As cited in EPA's final rule (60 Federal Register 46206), compliance with the NRC regulations constitutes compliance with 40 CFR Part 61, Subparts H and I.

EPA also establishes radiation protection standards for members of the public from the general environment and from radioactive materials introduced into the general environment as a result of nuclear fuel cycle operations. These standards, which are applicable to CLWRs, are found in 40 CFR Part 190, "Environmental Radiation Protection Standards for Nuclear Power Operations."

For alternatives involving an existing DOE facility or an existing generic CLWR, no amendments to current air permits are expected, nor would approvals be needed to modify an existing facility, as required under 40 CFR Section 61.07. As discussed in the Air Resource sections of Chapter 4, the air quality standards are not expected to be exceeded.

For the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, air permits for construction and operation would need to be obtained.

**Clean Water Act of 1972, as amended (33 U.S.C. 1251 *et seq.*)**—The Clean Water Act, which amended the Federal Water Pollution Control Act, was enacted to "restore and maintain the chemical, physical, and biological integrity of the Nation's water." The Clean Water Act prohibits the "discharge of toxic pollutants in toxic amounts" to navigable waters of the United States. Section 313 of the Clean Water Act requires all branches of the Federal Government engaged in any activity that might result in a discharge or runoff of pollutants to surface waters to comply with Federal, state, interstate, and local requirements.

The Clean Water Act provides water quality standards for the Nation's waterways, guidelines and limitations for effluent discharges from point-source discharges, and the National Pollutant Discharge Elimination System (NPDES) permit program. The NPDES program is administered by EPA, pursuant to regulations in 40 CFR Part 122 *et seq.* Sections 401 through 405 of the Water Quality Act of 1987 added Section 402(p) to the Clean Water Act requiring that EPA establish regulations for permits for storm-water discharges associated with industrial activities. Storm-water provisions of the NPDES program are set forth at 40 CFR Section 122.26. Permit modifications are required if discharge effluent is altered.

For the alternatives involving an existing DOE facility or an existing generic CLWR, no amendments to NPDES permits are expected. As discussed in the Water Resource sections of Chapter 4, the water quality standards are not expected to be exceeded.

For the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, NPDES permits may be required.

**Safe Drinking Water Act of 1974, as amended (42 U.S.C. 300(f) *et seq.*)**—The primary objective of the Safe Drinking Water Act is to protect the quality of public drinking water supplies and sources of drinking water. The implementing regulations, administered by EPA unless delegated to states, establish standards applicable to public water systems. These regulations include maximum contaminant levels (including those for radioactivity) in public water systems, which are defined as water systems that have at least 15 service

connections used by year-round residents or regularly serve at least 25 year-round residents. The EPA regulations implementing the Safe Drinking Water Act are found under 40 CFR Parts 100 through 149. For radioactive material, the regulations specify that the average annual concentration of manmade radionuclides in drinking water, as delivered to the user by such a system, shall not produce a dose equivalent to the total body or an internal organ greater than 4 millirem per year beta activity (40 CFR Section 141.16(a)). Other programs established by the Safe Drinking Water Act include the Sole Source Aquifer Program, the Wellhead Protection Program, and the Underground Injection Control Program.

Activities conducted under all of the alternatives must be in compliance with the standards specified under the Safe Drinking Water Act, particularly the standard for radionuclides. As discussed in the Water Resources sections of Chapter 4, these standards are not expected to be exceeded.

**Low-Level Radioactive Waste Policy Act of 1980, as amended (42 U.S.C. 2021 *et seq.*)**—This act amended the Atomic Energy Act to specify that the Federal Government is responsible for disposal of low-level radioactive waste generated by its activities, and states are responsible for disposal of other low-level radioactive waste. It provides for and encourages interstate compacts to carry out the state responsibilities.

Low-level radioactive waste is expected to be generated from activities conducted under all of the alternatives. Therefore, this waste must be managed in compliance with this act. The Waste Management sections of Chapter 4 provide information on the generation and management of low-level radioactive waste for each of the alternatives.

**Solid Waste Disposal Act of 1965, as amended by the Resource Conservation and Recovery Act of 1976 and the Hazardous and Solid Waste Amendments of 1984 (42 U.S.C. 6901 *et seq.*)**—The Solid Waste Disposal Act of 1965, as amended, governs the transportation, treatment, storage, and disposal of hazardous and nonhazardous waste. Under the Resource Conservation and Recovery Act of 1976 (RCRA), which amended the Solid Waste Disposal Act of 1965, EPA defines and identifies hazardous waste; establishes standards for its transportation, treatment, storage, and disposal; and requires permits for persons engaged in hazardous waste activities. Section 3006 of the act (42 U.S.C. 6926) allows states to establish and administer these permit programs with EPA approval. The EPA regulations implementing RCRA are found in 40 CFR Parts 260 through 283.

Regulations imposed on a generator or on a treatment, storage, and/or disposal facility vary according to the type and quantity of material or waste generated, treated, stored, and/or disposed. The method of treatment, storage, and/or disposal also impacts the extent and complexity of the requirements.

Hazardous and mixed waste is expected to be generated from activities conducted for all of the alternatives. Therefore, these waste types must be managed in compliance with this act. The Waste Management sections of Chapter 4 provide information on the generation and management of hazardous and mixed waste for each of the alternatives.

**Federal Facility Compliance Act of 1992 (42 U.S.C. 6961 *et seq.*)**—The Federal Facility Compliance Act, enacted on October 6, 1992, amended RCRA. Section 102(a)(3) of the Federal Facility Compliance Act waives sovereign immunity for Federal facilities from fines and penalties for violations of RCRA, state, interstate, and local hazardous and solid waste management requirements. This waiver was delayed for 3 years following enactment for violations of the land disposal restrictions storage and prohibition (RCRA Section 3004(j)) involving mixed waste at DOE facilities. The act further delays the waiver of sovereign immunity beyond the 3-year period at a facility if DOE is in compliance with an approved plan for developing treatment capacity and technologies for mixed waste generated or stored at the facility, as well as an order requiring compliance with the plan.

Mixed low-level radioactive waste is expected to be generated from activities conducted for all of the alternatives. Therefore, this waste must be managed in compliance with this act. The Waste Management sections of Chapter 4 provide more information on the generation and management of mixed waste for each of the alternatives.

**Nuclear Waste Policy Act of 1982 as amended (U.S.C. 10101 through 10271)**—The Nuclear Waste Policy Act provides for research, development, and demonstration activities regarding disposal of high-level radioactive waste and spent nuclear fuel. As originally enacted, the Nuclear Waste Policy Act called for the Secretary of Energy to recommend candidate repository sites, but in 1987 it was amended to require DOE to proceed only with characterization of the Yucca Mountain Site (42 U.S.C. 10133 and 10172). The Nuclear Waste Policy Act also established the Office of Civilian Radioactive Waste Management (42 U.S.C. 10224), the Office of Nuclear Waste Negotiator (42 U.S.C. 10242), and the Nuclear Waste Fund (42 U.S.C. 10222); and it provides authority (along with the Atomic Energy Act) for EPA to develop standards for protection of the general environment from the management and disposal of spent nuclear fuel, transuranic, and high-level radioactive waste (40 CFR Part 191).

As discussed in Chapter 4, Sections 4.3.1.1.13, 4.3.2.1.13, 4.3.3.1.13, and 4.4.3.1.13, DOE is considering whether the waste from processing irradiated neptunium-237 targets should be classified as high-level radioactive waste. If this waste were to be classified as high-level radioactive waste, then this act would be applicable. In addition, the spent nuclear fuel expected to be generated under the alternatives to restart or deactivate FFTF, as discussed in Sections 4.3.1.1.14 and 4.4.1.2.14, must be managed in compliance with this act.

**Pollution Prevention Act of 1990 (42 U.S.C. 13101 *et seq.*)**—The Pollution Prevention Act establishes a national policy for waste management and pollution control. Source reduction is given first preference, followed by environmentally safe recycling, with disposal or releases to the environment as a last resort. In response to the policies established by the act, DOE committed to participation in the Superfund Amendments and Reauthorization Act, Section 313, EPA 33/50 Pollution Prevention Program. The goal for facilities involved in compliance with Section 313 is to achieve a 33 percent reduction (from a 1993 baseline) in the release of 17 priority chemicals by 1997. On August 3, 1993, President Clinton issued Executive Order 12856 requiring DOE to achieve a 50 percent reduction in total releases of all toxic chemicals by December 31, 1999. On November 12, 1999, U.S. Secretary of Energy Bill Richardson issued 14 pollution prevention and energy efficiency goals for DOE. These goals are designed to build environmental accountability and stewardship into DOE's decision-making process. Under these goals, DOE will strive to minimize waste and maximize energy efficiency as measured by continuous cost-effective improvements in the use of materials and energy, with the years 2005 and 2010 as interim measurement points.

Radioactive, hazardous, and nonhazardous waste types are expected to be generated from all the alternatives; therefore, efforts must be made to minimize their generation. The Waste Management sections of Chapter 4 provide more information on the generation and management of these wastes.

**Toxic Substances Control Act of 1976 (15 U.S.C. 2601 *et seq.*)**—The Toxic Substances Control Act provides EPA with the authority to require testing of chemical substances entering the environment and to regulate them as necessary. The law complements and expands existing toxic substance laws, such as Section 112 of the Clean Air Act and Section 307 of the Clean Water Act. The Toxic Substances Control Act requires compliance with inventory reporting and chemical control provisions of the act to protect the public from the risks of exposure to chemicals. The act also imposes strict limitations on the use and disposal of polychlorinated biphenyls, chlorofluorocarbons, asbestos, dioxins, certain metal-working fluids, and hexavalent chromium.

Activities under all of the alternatives would need to be in compliance with this act.

**National Historic Preservation Act of 1996, as amended (16 U.S.C. 470 *et seq.*)**—The National Historic Preservation Act provides that sites with significant national historic value be placed on the *National Register of Historic Places*, which is maintained by the Secretary of the Interior. The major provisions of the act for DOE are Sections 106 and 110. Both sections aim to ensure that historic properties are appropriately considered in planning Federal initiatives and actions. Section 106 is a specific, issue-related mandate to which Federal agencies must adhere. It is a reactive mechanism that is driven by a Federal action. Section 110, in contrast, sets out broad Federal agency responsibilities with respect to historic properties. It is a proactive mechanism with emphasis on ongoing management of historic preservation sites and activities at Federal facilities. No permits or certifications are required under the act.

Section 106 requires the head of any Federal agency having direct or indirect jurisdiction over a proposed Federal or federally assisted undertaking to ensure compliance with the provisions of the act. It compels Federal agencies to “take into account” the effect of their projects on historical and archaeological resources and to give the Advisory Council on Historic Preservation the opportunity to comment on such effects. Section 106 mandates consultation during Federal actions if the undertaking has the potential to have an effect on a historic property. This consultation normally involves the State and/or Tribal Historic Preservation Officers and may include other organizations and individuals, such as local governments, Native American tribes, and Native Hawaiian organizations. If an adverse effect is found, the consultation often ends with the execution of a memorandum of agreement that states how the adverse effects will be resolved.

The regulations implementing Section 106, found in 30 CFR Part 800, were revised on May 18, 1999 (64 FR 27043), effective June 17, 1999. This revision introduced new flexibility and options for agencies to use to meet their obligations to comply with the act.

As discussed in the Cultural and Paleontological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, no historic property resources would be impacted. Two FFTF structures (the Reactor Containment Building and FFTF Control Building) at Hanford have been determined to be eligible for the National Register of Historic Places as contributing properties within the Historic District recommended for mitigation; however, as discussed in Section 4.3.1.1.7, the restart of FFTF would be consistent with the purpose for which the reactor was built and would not affect the status of the aforementioned structures. In addition, the Materials Test Reactor, the Engineering Test Reactor, and ATR, as well as a number of support facilities at the Idaho National Engineering and Environmental Laboratory (INEEL), are potentially eligible for nomination to the National Register. However, as discussed in Section 4.4.1.1.7, the use of ATR would not affect the potential eligibility of these structures for listing.

For the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, additional information would be required to determine if there are any historic resources, including those that are eligible for listing on the National Register of Historic Places. These resources would be identified through site surveys and consultations with the State Historic Preservation Officer.

**American Antiquities Act of 1906, as amended (16 U.S.C 431 to 433)**—This act protects historic and prehistoric ruins, monuments, and antiquities, including paleontological resources, on federally controlled lands from appropriation, excavation, injury, and destruction without permission. On June 9, 2000, the Hanford Reach was designated as a national monument under this act.

As discussed in the Cultural and Paleontological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, no historic or prehistoric property resources would be impacted.

For the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, additional information would be required to determine whether there are any historic or prehistoric resources and the potential impacts.

**Archaeological and Historic Preservation Act of 1974, as amended (16 U.S.C 469 to 469c)**—This act protects sites that have historic and prehistoric importance.

As discussed in the Cultural and Paleontological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, no historic or prehistoric property resources would be impacted.

For the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, additional information would be required to determine whether there are any historic or prehistoric resources and the potential impacts.

**Archaeological and Resources Protection Act of 1979, as amended (16 U.S.C. 470 *et seq.*)**—This act requires a permit for any excavation or removal of archaeological resources from Federal or Native American lands. Excavations must be undertaken for the purpose of furthering archaeological knowledge in the public interest, and resources removed are to remain the property of the United States. The law requires that whenever any Federal agency finds that its activities may cause irreparable loss or destruction of significant scientific, prehistoric, or archaeological data, the agency must notify the U.S. Department of the Interior and may request that the Department undertake the recovery, protection, and preservation of such data. Consent must be obtained from the Native American tribe or the Federal agency having authority over the land on which a resource is located before issuance of a permit; the permit must contain terms and conditions requested by the tribe or Federal agency.

As discussed in the Cultural and Paleontological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new construction, except for the new 76-meter (250-foot) stack at FMEF, or land disturbance is expected, a permit would not be required.

However, for alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information would be needed to determine whether a permit would be required.

**Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*)**—The Endangered Species Act is intended to prevent the further decline of endangered and threatened species and to restore these species and habitats. Section 7 of the act requires Federal agencies having reason to believe that a prospective action may affect an endangered or threatened species or its habitat to consult with the U.S. Fish and Wildlife Service of the U.S. Department of the Interior or the National Marine Fisheries Service of the U.S. Department of Commerce to ensure that the action does not jeopardize the species or destroy its habitat (50 CFR Part 17). If, despite reasonable and prudent measures to avoid or minimize such impacts, the species or its habitat would be jeopardized by the action, a review process is specified to determine whether the action may proceed.

As discussed in the Ecological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new

construction, except for the new 76-meter (250-foot) stack at FMEF, or land disturbance is expected, impacts to threatened and endangered species are not expected.

However, for alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information would be needed to determine whether threatened or endangered species would be impacted.

**Migratory Bird Treaty Act of 1918, as amended (16 U.S.C. 703 *et seq.*)**—The Migratory Bird Treaty Act, as amended, is intended to protect birds that have common migration patterns between the United States and Canada, Mexico, Japan, and Russia. It regulates the harvest of migratory birds by specifying conditions such as the mode of harvest, hunting seasons, and bag limits. The act stipulates that it is unlawful at any time, by any means, or in any manner, to “kill ... any migratory bird.” Although no permit for this project is required under the act, DOE is required to consult with the U.S. Fish and Wildlife Service regarding impacts to migratory birds, and to avoid or minimize these effects in accordance with the U.S. Fish and Wildlife Service Mitigation Policy.

As discussed in the Ecological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new construction, except for the new 76-meter (250-foot) stack at FMEF, or land disturbance is expected, impacts to migratory birds are not expected.

However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information would be needed to determine whether migratory birds would be impacted.

**Bald and Golden Eagle Protection Act of 1973, as amended (16 U.S.C. 668 through 668d)**—The Bald and Golden Eagle Protection Act, as amended, makes it unlawful to take, pursue, molest, or disturb bald (American) and golden eagles, their nests, or their eggs anywhere in the United States (Section 668, 668c). A permit must be obtained from the U.S. Department of the Interior to relocate a nest that interferes with resource development or recovery operations.

As discussed in the Ecological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new construction, except for the new 76-meter (250-foot) stack at FMEF, or land disturbance is expected, impacts to migratory birds are not expected.

However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information would be needed to determine whether bald or golden eagles would be impacted and whether a permit would be required.

**Fish and Wildlife Coordination Act (16 U.S.C. 661 *et seq.*)**—The Fish and Wildlife Coordination Act promotes more effectual planning and cooperation between Federal, state, public, and private agencies for the conservation and rehabilitation of the Nation’s fish and wildlife and authorizes the U.S. Department of the Interior to provide assistance. This act requires consultation with the U.S. Fish and Wildlife Service on the possible effects on wildlife if there is construction, modification, or control of bodies of water in excess of 10 acres in surface area.

As discussed in the Ecological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new

construction, except for the 76-meter (250-foot) stack at FMEF, or land disturbance is expected, impacts to the Nation's fish and wildlife are not expected.

However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information would be needed to determine whether there would be any impacts to the Nation's fish and wildlife.

**Wild and Scenic Rivers Act of 1968, as amended (16 U.S.C. 1271 *et seq.*)**—This act requires consultation before construction of any new Federal project associated with a river designated as wild and scenic or under study to minimize and mitigate any adverse effects on the physical and biological properties of the river.

As discussed in Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new construction, except for the 76-meter (250-foot) stack at FMEF, or land disturbance is expected, impacts to any rivers designated as wild and scenic or under study are not expected. In addition, impacts on visual resources as a result of constructing a new stack at FMEF are expected to be minimal.

However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information would be needed to determine whether there would be any impacts to rivers designated as wild and scenic or under study.

**Farmland Protection Act of 1981 (7 U.S.C. 4201 *et seq.*)**—This act requires the avoidance of any adverse effects on prime and unique farmlands.

As discussed in Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new construction, except for the 76-meter (250-foot) stack at FMEF, or land disturbance is expected, impacts to any prime and unique farmlands are not expected.

However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information would be needed to determine whether there would be any impacts to prime or unique farmlands.

**American Indian Religious Freedom Act of 1978 (42 U.S.C. 1996)**—This act reaffirms Native American religious freedom under the First Amendment, and sets U.S. policy to protect and preserve the inherent and constitutional right of Native Americans to believe, express, and exercise their traditional religions. The act requires that Federal actions avoid interfering with access to sacred locations and traditional resources that are integral to the practice of religions.

As discussed in the Cultural and Paleontological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new construction, except for the 76-meter (250-foot) stack at FMEF, or land disturbance is expected, impacts to Native American resources are not expected.

However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information about the presence, type, and location of Native American resources would be needed to determine whether there would be any impacts to these resources.

**Religious Freedom Restoration Act of 1993 (42 U.S.C. 2000(bb) *et seq.*)**—This act prohibits the U.S. Government, including Federal departments, from substantially burdening the exercise of religion unless the Government demonstrates a compelling governmental interest, the action furthers a compelling government interest, and it is the least restrictive means of furthering that interest.

As discussed in the Cultural and Paleontological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new construction, except for the 76-meter (250-foot) stack at FMEF, or land disturbance is expected, impacts to Native American resources are not expected.

However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information about the presence, type, and location of Native American resources would be needed to determine whether there would be any impacts to these resources.

**Native American Graves Protection and Repatriation Act of 1990 (25 U.S.C. 3001)**—This act established a means for Native Americans to request the return or “repatriation” of human remains and other cultural items presently held by Federal agencies or federally assisted museums or institutions. The act also contains provisions regarding the intentional excavation and removal of, inadvertent discovery of, and illegal trafficking in Native American human remains and cultural items. Major actions under this law include: (a) establishing a review committee with monitoring and policy-making responsibilities, (b) developing regulations for repatriation, including procedures for identifying lineal descent or cultural affiliation needed for claims, (c) providing oversight of museum programs designed to meet the inventory requirements and deadlines of this law, and (d) developing procedures to handle unexpected discoveries of graves or grave goods during activities on Federal or tribal lands. All Federal agencies that manage land and/or are responsible for archaeological collections from their lands or generated by their activities must comply with the act. DOE managers of ground-disturbing activities on Federal and tribal lands should make themselves aware of the statutory provisions treating inadvertent discoveries of Native American remains and cultural objects. Regulations implementing the act are found at 43 CFR Part 10.

As discussed in the Cultural and Paleontological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities and the existing generic CLWR, due to the developed nature of these areas and the fact that no new construction, except for the 76-meter (250-foot) stack at FMEF, or land disturbance is expected, it is unlikely that human remains or other cultural items would be uncovered.

However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, disturbance of land would occur and, therefore, additional information about the presence, type, and location of Native American resources would be needed to determine whether there would be any impacts to these resources.

**Occupational Safety and Health Act of 1970 (29 U.S.C. 651 *et seq.*)**—The Occupational Safety and Health Act establishes standards for safe and healthful working conditions in places of employment throughout the United States. The act is administered and enforced by the Occupational Safety and Health Administration (OSHA), a U.S. Department of Labor agency. Although OSHA and EPA both have a mandate to reduce exposures to toxic substances, OSHA’s jurisdiction is limited to safety and health conditions that exist in the workplace environment.

Under the act, it is the duty of each employer to furnish employees a place of employment free of recognized hazards likely to cause death or serious physical harm. Employees have a duty to comply with the occupational safety and health standards and rules, regulations, and orders issued under the act. OSHA regulations

(29 CFR Part 1910) establish specific standards telling employers what must be done to achieve a safe and healthful working environment. Government agencies, including DOE, are not technically subject to OSHA regulations, but are required under 29 U.S.C. 668 to establish their own occupational safety and health programs for their places of employment which are consistent with OSHA standards. DOE places emphasis on compliance with these regulations at its facilities, and prescribes, through DOE orders, the Occupational Safety and Health Act standards that contractors shall meet, as applicable to their work at government-owned, contractor-operated facilities (DOE Order 440.1A). DOE keeps and makes available the various records of minor illnesses, injuries, and work-related deaths as required by OSHA regulations.

Activities under all the alternatives would need to be conducted in compliance with this act.

**Noise Control Act of 1972, as amended (42 U.S.C. 4901 *et seq.*)**—Section 4 of the Noise Control Act of 1972, as amended, directs all Federal agencies to carry out “to the fullest extent within their authority” programs within their jurisdictions in a manner that furthers a national policy of promoting an environment free from noise jeopardizing health and welfare.

As discussed in the Noise sections of Chapter 4, the operation of existing DOE facilities and existing CLWR would not result in any impacts because of increased noise levels. The construction and operation of new DOE facilities would require compliance with this requirement.

### **5.1.2 Environmental, Safety, and Health Executive Orders**

**Executive Order 11514 (Protection and Enhancement of Environmental Quality)**—This order (regulated by 40 CFR Parts 1500 through 1508) requires Federal agencies to continually monitor and control their activities to: (1) protect and enhance the quality of the environment, and (2) develop procedures to ensure the fullest practicable provision of timely public information and understanding of the Federal plans and programs that may have potential environmental impact so that views of interested parties can be obtained. DOE has issued regulations (10 CFR Part 1021) and DOE Order 451.1B for compliance with this Executive order.

As previously discussed under Section 5.1.1, this NI PEIS has been prepared in accordance with NEPA requirements (i.e., 40 CFR Parts 1500 through 1508, 10 CFR Part 1021, and DOE Order 451.1B).

**Executive Order 11593 (National Historic Preservation, May 13, 1971)**—This order directs Federal agencies to locate, inventory, and nominate properties under their jurisdiction or control to the *National Register of Historic Places*, if those properties qualify. This process requires DOE to provide the Advisory Council on Historic Preservation the opportunity to comment on the possible impacts of the proposed activity on any potential eligible or listed resources. Compliance with this Executive order is discussed in Section 5.1.1, National Historic Preservation Act of 1996, as amended.

**Executive Order 11988 (Floodplain Management)**—This order (regulated by 10 CFR Part 1022) requires Federal agencies to establish procedures to ensure that the potential effects of flood hazards and floodplain management are considered for any action undertaken in a floodplain, and that floodplain impacts be avoided to the extent practicable. As discussed in the Water Resource sections of Chapter 3, for the alternatives involving existing DOE facilities and the existing generic CLWR, compliance with this order has already been met. However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, additional information would be needed to determine compliance with this order.

**Executive Order 11990 (Protection of Wetlands)**—This order (regulated by 10 CFR Part 1022) requires Federal agencies to avoid any short- or long-term adverse impacts on wetlands wherever there is a practicable

alternative. As discussed in the Ecological Resource sections of Chapter 4, for the alternatives involving existing DOE facilities, impacts to wetlands are not expected because either there are no wetlands in the vicinity of the facility or because water usage and water discharge would not change or would be small fractions of current values, and discharge chemistry would not be expected to change. However, for the alternatives involving the construction and operation of one or two new DOE accelerators or a research reactor and support facility, additional information would be needed to determine whether there would be impacts to wetlands.

**Executive Order 12088 (Federal Compliance with Pollution Control Standards, October 13, 1978, as amended by Executive Order 12580, Federal Compliance with Pollution Control Standards, January 23, 1987)**—This order directs Federal agencies to comply with applicable administrative and procedural pollution control standards established by, but not limited to, the Clean Air Act, the Noise Control Act, the Clean Water Act, the Safe Drinking Water Act, the Toxic Substances Control Act, and RCRA.

Activities under all of the alternatives involving DOE facilities would need to be in compliance with this order.

**Executive Order 12580 (Superfund Implementation)**—This order delegates to the heads of executive departments and agencies the responsibility of undertaking remedial actions for releases or threatened releases that are not on the National Priorities List, and removal actions, other than emergencies, where the release is from any facility under the jurisdiction or control of executive departments and agencies.

Activities under all of the alternatives involving DOE facilities would need to be in compliance with this order.

**Executive Order 12898 (Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations)**—This order requires each Federal agency to identify and address disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations. The Environmental Justice sections of Chapter 4 provide information on the compliance with this order.

**Executive Order 12902 (Energy Efficiency and Water Conservation at Federal Facilities)**—This order requires Federal agencies to develop and implement a program for conservation of energy and water resources.

Activities under all of the alternatives involving DOE facilities would need to be in compliance with this order.

**Executive Order 13101 (Greening the Government Through Waste Prevention, Recycling, and Federal Acquisition)**—This order requires each Federal agency to incorporate waste prevention and recycling in its daily operations and work to increase and expand markets for recovered materials. This order states that it is national policy to prefer pollution prevention, whenever feasible. Pollution that cannot be prevented should be recycled; pollution that cannot be prevented or recycled should be treated in an environmentally safe manner. Disposal should be employed only as a last resort.

Activities under all of the alternatives involving DOE facilities would need to be in compliance with this order.

**Executive Order 13112 (Invasive Species)**—This order requires Federal agencies to prevent the introduction of invasive species and provide for their control and to minimize the economic, ecological, and human health impacts that invasive species cause.

Activities under all of the alternatives involving DOE facilities would need to be in compliance with this order.

**Executive Order 13148 (Greening the Government Through Leadership in Environmental Management)**—This order sets new goals for pollution prevention, requires all Federal facilities to have an environmental management system, and requires compliance or environmental management system audits.

Activities under all alternatives involving DOE facilities would need to be in compliance with this order.

### **5.1.3 DOE Environmental, Safety, and Health Regulations and Orders**

The Atomic Energy Act authorizes DOE to establish standards to protect health or minimize dangers to life or property from activities under DOE’s jurisdiction. Through a series of DOE orders and regulations, an extensive system of standards and requirements has been established to ensure safe operation of DOE facilities. DOE regulations and orders do not apply to activities regulated by NRC (10 CFR Sections 830.2(a) and 835.1(b)). Thus, DOE regulations and orders would not apply to CLWR facilities.

DOE regulations are found in 10 CFR. These regulations address such areas as energy conservation, administrative requirements and procedures, nuclear safety, and classified information. For the purpose of this NI PEIS, relevant regulations include: “Procedural Rules for DOE Nuclear Activities” (10 CFR Part 820), “Nuclear Safety Management” (10 CFR Part 830), “Occupational Radiation Protection” (10 CFR Part 835), “Compliance with the National Environmental Policy Act” (10 CFR Part 1021), and “Compliance with Floodplains/Wetlands Environmental Review Requirements” (10 CFR Part 1022).

DOE orders are issued in support of environmental, safety, and health programs. Many DOE orders have been revised and reorganized to reduce duplication and to eliminate obsolete provisions. The new DOE order organization is by series, with each number identified by three digits, and is intended to include all DOE orders, policies, manuals, requirement documents, notices, and guides. The remaining DOE orders, which are identified by four digits, are expected to be revised and converted to the new DOE numbering system. The major DOE orders pertaining to the alternatives are listed in **Table 5–1**.

**Table 5–1 Relevant DOE Orders (as of October 26, 2000)**

<b>DOE Order</b>	<b>Subject</b>
<b>Leadership/Management Planning</b>	
O 151.1	Comprehensive Emergency Management System (09/25/95; Change 2, 08/21/96)
<b>Information and Analysis</b>	
O 231.1	Environment, Safety and Health Reporting (09/30/95; Change 2, 11/07/96)
O 232.1A	Occurrence Reporting and Processing of Operations Information (07/21/97)
<b>Work Processes</b>	
O 414.1A	Quality Assurance (09/29/99)
O 420.1	Facility Safety (10/13/95; Change 2, 10/24/96)
O 430.1A	Life Cycle Asset Management (10/14/98)
O 435.1	Radioactive Waste Management (07/09/99)
O 440.1A	Worker Protection Management for DOE Federal and Contractor Employees (03/27/98)
O 451.1B	National Environmental Policy Act Compliance Program (10/26/00)
O 460.1A	Packaging and Transportation Safety (10/02/96)
O 460.2	Departmental Materials Transportation and Packaging Management (09/27/95; Change 1, 10/26/95)
O 470.1	Safeguards and Security Program (09/28/95; Change 1, 06/21/96)
O 470.2A	Oversight and Performance Assurance Program (03/01/00)
O 473.2	Protective Force Program (06/30/00)
O 474.1	Control and Accountability of Nuclear Materials (08/11/99)
<b>External Relationships</b>	
1230.2	American Indian Tribal Government Policy (04/08/92)
<b>Personnel Relations and Services</b>	
3790.1B	Federal Employee Occupational Safety and Health Program (01/07/93)
<b>Real Property Management</b>	
4330.4B	Maintenance Management Program (02/10/94)
<b>Project Management</b>	
4700.1	Project Management System (03/06/87; Change 1, 06/02/92)
<b>Environmental Quality and Impact</b>	
5400.1	General Environmental Protection Program (11/09/88; Change 1, 06/29/90)
5400.5	Radiation Protection of the Public and the Environment (02/08/90; Change 2, 01/07/93)
5480.4	Environmental Protection, Safety, and Health Protection Standards (05/15/84; Change 4, 01/07/93)
5480.19	Conduct of Operations Requirements for DOE Facilities (07/09/90; Change 1, 05/18/92)
5480.20A	Personnel Selection, Qualification, and Training Requirements for DOE Nuclear Facilities (11/15/94)
5480.21	Unreviewed Safety Questions (12/24/91)
5480.22	Technical Safety Requirements (02/25/92; Change 2, 01/23/96)
5480.23	Nuclear Safety Analysis Reports (04/10/92; Change 1, 03/10/94)
5480.30	Nuclear Reactor Safety Design Criteria (01/19/93)
<b>Emergency Preparedness</b>	
5530.3	Radiological Assistance Program (01/14/92; Change 1, 04/10/92)
5530.5	Federal Radiological Monitoring and Assessment Center (07/10/92; Change 1, 12/02/92)
<b>Defense Programs</b>	
5610.14	Transportation Safeguards System Program Operations (05/12/93)
5632.1C	Protection and Control of Safeguards and Security Interests (07/15/94)
5660.1B	Management of Nuclear Materials (05/26/94)
<b>Design</b>	
6430.1A	General Design Criteria (04/06/89)

### 5.1.4 State Environmental Laws, Regulations, and Agreements

Certain environmental requirements, including many discussed in Section 5.1.1, have been delegated to state authorities for implementation and enforcement. It is DOE policy to conduct its operations in an environmentally safe manner, in compliance with all applicable laws, regulations, and standards, including state laws and regulations. A list of applicable state laws, regulations, and agreements is provided in **Table 5–2**. This list is not exhaustive and other state laws and regulations may be applicable. In addition, other state laws and regulations may be applicable for the CLWR and the construction and operation of new accelerator(s) or a research reactor and support facilities, but are not specifically identified in Table 5–2 because the specific locations of these facilities have not been determined.

**Table 5–2 State Environmental Laws, Regulations, and Agreements**

Law/Regulation/Agreement	Citation	Requirements
<b>HANFORD, WASHINGTON</b>		
Washington Clean Air Act	Revised Code of Washington (RCW), Chapter 70.94	Provides for development of air pollution control and permitting regulations.
Washington State Air Pollution Control Regulations	Washington Administrative Code (WAC), Chapters 173-400 through 173-495	Requires permitting of source and control of toxic air pollutants, radionuclides, and other pollutants.
Water Pollution Control Act of 1945	RCW, Chapter 90.48	Establishes a permit system to license and control the discharge of pollutants into waters of the state. Permits are required for both point-source and non-point-source discharges.
Surface Water Quality Standards	WAC, Chapter 173-201A	Establishes water quality standards for surface waters at levels protective of aquatic life.
Washington State Department of Health Radiation Protection Requirements	WAC, Chapter 246-247	Establishes requirements for all facilities with the potential to emit airborne radioactivity, including Federal facilities.
Hazardous Waste Management Act	RCW, Chapter 70.105	Requires permits for various activities involving hazardous waste.
Radioactive Waste Storage and Transport Act of 1980	RCW, Chapter 70.99	Establishes various requirements for handling, storage, and transportation of radioactive waste.
Dangerous Waste Regulations	WAC, Chapter 173-303	Establishes hazardous waste treatment, storage, and disposal standards and permit requirements. These requirements cover a larger universe of materials than the Federal hazardous waste program.
Department of Fish and Wildlife	WAC, Chapter 232-12	Defines the requirements that the Department of Game must take to protect endangered or threatened wildlife.

<b>Law/Regulation/Agreement</b>	<b>Citation</b>	<b>Requirements</b>
Hanford Federal Facility Agreement and Consent Order (Tri-Party Agreement)	May 15, 1989 (amended December 31, 1998)	An enforceable agreement, which details work necessary to comply with state and Federal hazardous waste management requirements and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). This is an agreement among DOE, EPA, and the Washington State Department of Ecology.
<b>IDAHO NATIONAL ENGINEERING AND ENVIRONMENTAL LABORATORY, IDAHO</b>		
Idaho Environmental Protection and Health Act	ID Code, Title 39, Chapter 1	Provides for development of air pollution control permitting regulations.
Rules for the Control of Air Pollution in Idaho	Idaho Administrative Procedure Act (IDAPA) 58, Title 1, Chapter 1	Requires permitting of sources and control of toxic air pollutants and other pollutants.
Idaho Water Pollution Control Act	ID Code, Title 39, Chapter 36	Establishes a program to enhance and preserve the quality and the value of water resources.
Idaho Hazardous Waste Management Act	ID Code, Title 39, Chapter 44	Requires permit prior to construction or modification of a hazardous waste disposal facility.
Rules and Standards for Hazardous Waste	IDAPA 58, Title 1, Chapter 5 (58.01.03)	Requires permit prior to construction or modification of a hazardous waste disposal facility.
Various Acts Regarding Fish and Game	ID Code, Title 36, Chapters 9, 11, and 24	Requires consultation with responsible agency.
Idaho Historic Preservation Act	ID Code, Title 67, Chapter 46	Requires consultation with responsible local governing body.
Spent Fuel Settlement Agreement (also known as the Governor's Agreement)	October 16, 1995	Allows INEEL to receive spent nuclear fuel and mixed waste from off site and establishes schedules for the treatment of existing high-level radioactive waste, transuranic waste, mixed waste, and removal of spent nuclear fuel from the state. (This agreement is not applicable to the alternatives because only new waste will be generated by the proposed action. This newly generated waste, if determined to be mixed waste, will be covered by the INEEL Site Treatment Plan.)
Consent Order for Federal Facility Compliance Plan	November 1, 1995	Addresses compliance with the Federal Facility Compliance Act and mixed waste treatment issues by implementing the INEEL Site Treatment Plan.

<b>Law/Regulation/Agreement</b>	<b>Citation</b>	<b>Requirements</b>
<b>OAK RIDGE NATIONAL LABORATORY, TENNESSEE</b>		
Tennessee Air Pollution Control Act	TN Code, Title 68, Chapter 201 (Part 1)	Provides for permitting to construct, modify, or operate an air contaminant source.
Tennessee Air Pollution Control Regulations	TN Rule, Chapter 1200-3	Requires a permit to construct, modify, or operate an air contaminant source. Also sets fugitive dust requirements.
Tennessee Water Quality Control Act	TN Code, Title 69, Chapter 3	Provides authority to issue new or modify existing NPDES permits required for a water discharge source.
Tennessee Water Pollution Control Regulations	TN Rule, Chapter 1200-4	Requires a new or modification of an existing NPDES permit for a water discharge source.
Tennessee Hazardous Waste Management Act	TN Code, Title 68, Chapter 212 (Part 1)	Requires permit for any construction or modification of a hazardous waste facility.
Tennessee State Executive Order on Wetlands	TN State Wetlands Conservation Strategy	Provides guidance from the Governor's Interagency Wetlands Committee.
Tennessee Nongame and Endangered or Threatened Wildlife Species Conservation Act of 1974	TN Code, Title 70, Chapter 8 (Part 1)	Requires consultation with responsible agency.
Tennessee Department of Environmental Conservation Order	October 1, 1995	Requires DOE to comply with the Site Treatment Plan for the management and treatment of mixed radioactive waste.

## **5.2 RADIOACTIVE MATERIAL PACKAGING AND TRANSPORTATION REGULATIONS**

Transportation of hazardous and radioactive materials and substances is governed by the U.S. Department of Transportation (DOT) and NRC. The Hazardous Material Transportation Act of 1975 (49 U.S.C. 5105 *et seq.*) requires DOT to prescribe uniform national regulations for transportation of hazardous materials (including radioactive materials). Most state and local regulations regarding such transportation that are not substantively the same as DOT regulations are preempted (i.e., rendered void) (49 U.S.C. 5125). This, in effect, allows state and local governments only to enforce the Federal regulations, not to change or expand upon them.

This program is administered by the Research and Special Programs Administration of DOT, which coordinates its regulations with those of NRC (under the Atomic Energy Act) and with EPA (under RCRA) when covering the same activities.

DOT regulations, which may be found under 49 CFR Parts 171 through 178, and 49 CFR Parts 383 through 397, contain requirements for identifying a material as hazardous or radioactive. These regulations interface with the NRC regulations for identifying material, but DOT hazardous material regulations govern the hazard communication (such as marking, hazard labeling, vehicle placarding, and emergency response telephone number) and shipping requirements.

The NRC regulations applicable to radioactive materials transportation may be found under 10 CFR Part 71. These regulations include detailed packaging design requirements and package certification testing requirements. Complete documentation of design and safety analysis, and the results of the required testing, are submitted to NRC to certify the package for use. This certification testing involves the following components: heat, physical drop onto an unyielding surface, water submersion, puncture by dropping the package onto a steel bar, and gas tightness.

Transportation casks, which are used to transport radioactive material, are subject to numerous inspections and tests (10 CFR Section 71.87). These tests are designed to ensure that cask components are properly assembled and meet applicable safety requirements. Tests and inspections are clearly identified in the Safety Analysis Report for Packaging and/or the Certificate of Compliance for each cask. Casks are loaded and inspected by registered users in compliance with approved quality assurance programs. Operations involving the casks are conducted in compliance with 10 CFR Section 71.91. Reports of defects or accidental mishandling are submitted to NRC.

### **5.3 EMERGENCY MANAGEMENT AND RESPONSE LAWS, REGULATIONS, AND EXECUTIVE ORDERS**

This section discusses the laws, regulations, and Executive orders that address the protection of public health and worker safety and require the establishment of emergency plans. These laws, regulations, and Executive orders relate to the operation of facilities, including DOE facilities and CLWRs that engage directly or indirectly in the production of special nuclear material.

#### **5.3.1 Emergency Management and Response Federal Laws**

**Emergency Planning and Community Right-to-Know Act of 1986 (U.S.C. 11001 *et seq.*) (also known as “SARA Title III”)**—This act requires emergency planning, and notice to communities and government agencies, of the presence and release of specific chemicals. EPA implements this act under regulations found in 40 CFR Parts 355, 370, and 372. Under Subtitle A of this act, Federal facilities are required to provide various information (such as inventories of specific chemicals used or stored and releases that occur from these sites) to the state emergency response commission and to the local emergency planning committee to ensure that emergency plans are sufficient to respond to unplanned releases of hazardous substances. Implementation of the provisions of this act began voluntarily in 1987, and inventory and annual emissions reporting began in 1988. DOE requires compliance with Title III as a matter of DOE policy at its contractor-operated facilities.

**Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (42 U.S.C. 9604(I) (also known as “Superfund”)**—This act provides authority for Federal and state governments to respond directly to hazardous substance incidents. The act requires reporting of spills, including radioactive spills, to the National Response Center.

**Robert T. Stafford Disaster Relief and Emergency Assistance Act of 1988 (42 U.S.C. 5121)**—This act, as amended, provides an orderly and continuing means of assistance by the Federal Government to state and local governments in managing their responsibilities to alleviate suffering and damage resulting from disasters. The President, in response to a state Governor’s request, may declare an “emergency” or “major disaster” to provide Federal assistance under this act. The President, in Executive Order 12148, delegated all functions, except those in Sections 301, 401, and 409, to the Director of the Federal Emergency Management Agency. The act provides for the appointment of a Federal coordinating officer who will operate in the designated area with a state coordinating officer for the purpose of coordinating state and local disaster assistance efforts with those of the Federal Government.

**Justice Assistance Act of 1984 (42 U.S.C. 3701-3799)**—This act establishes the Emergency Federal Law Enforcement Assistance, which provides assistance to state and local governments in responding to a law enforcement emergency. The act defines the term “law enforcement emergency” as an uncommon situation which requires law enforcement, which is or threatens to become of serious or epidemic proportions, and with respect to which state and local resources are inadequate to protect the lives and property of citizens or to enforce the criminal law. Emergencies that are not of an ongoing or chronic nature (for example, the Mount Saint Helens volcanic eruption) are eligible for Federal law enforcement assistance. This assistance includes funds, equipment, training, intelligence information, and personnel.

**Price-Anderson Act (42 U.S.C. 2210)**—This act allows DOE to indemnify its contractors if the contract involves the risk of public liability from a nuclear incident.

### **5.3.2 Emergency Management and Response Federal Regulations**

**Quantities of Radioactive Materials Requiring Consideration of the Need for an Emergency Plan for Responding to a Release (10 CFR Section 30.72, Schedule C)**—This section of the regulations provides a list which is the basis for both the public and private sector to determine if the radiological materials they handle must have an emergency response plan for unscheduled releases, and is one of the threshold criteria documents for DOE hazards assessments required by DOE Order 5500.3A, “Planning and Preparedness for Operational Emergencies.” The “Federal Radiological Emergency Response Plan,” dated November 1995, primarily discusses offsite Federal response in support of state and local governments with jurisdiction during a peacetime radiological emergency.

**Commercial Nuclear Power Plant Emergency Preparedness Planning (44 CFR Part 352)**—These regulations generally establish the policies, procedures, and responsibilities of the Federal Emergency Management Agency, NRC, and DOE as guidance for implementing a federal emergency preparedness program.

**Occupational Safety and Health Administration Emergency Response, Hazardous Waste Operations, and Worker Right to Know (29 CFR Part 1910)**—This regulation establishes OSHA requirements for employee safety in a variety of working environments. It addresses employee emergency and fire prevention plans (Section 1910.38), hazardous waste operations and emergency response (Section 1920.120), and hazards communication (Section 1910.1200) that enable employees to be aware of the dangers they face from hazardous materials at their workplace. These regulations do not directly apply to Federal agencies. However, Section 19 of the Occupational Safety and Health Act (29 U.S.C. 668) requires all Federal agencies to have occupational safety programs “consistent” with Occupational Safety and Health Act standards.

**Emergency Management and Assistance (44 CFR Section 1.1)**—This regulation contains the policies and procedures for the Federal Emergency Management Act, National Flood Insurance Program, Federal Crime Insurance Program, Fire Prevention and Control Program, Disaster Assistance Program, and Preparedness Program, including radiological planning and preparedness.

**Hazardous Materials Tables and Communications, Emergency Response Information Requirements (49 CFR Part 172)**—This regulation defines the regulatory requirements for marking, labeling, placarding, and documenting hazardous material shipments. The regulation also specifies the requirements for providing hazardous material information and training.

### **5.3.3 Emergency Response and Management Executive Orders**

**Executive Order 12148 (Federal Emergency Management, July 20, 1979)**—This order transfers functions and responsibilities associated with Federal emergency management to the Director of the Federal Emergency Management Agency. The order assigns the Director the responsibility to establish Federal policies for, and to coordinate all civil defense and civil emergency planning, management, mitigation, and assistance functions of, Executive agencies.

**Executive Order 12656 (Assignment of Emergency Preparedness Responsibilities, November 1988)**—This order assigns emergency preparedness responsibilities to Federal departments and agencies.

#### 5.4 CONSULTATIONS WITH FEDERAL, STATE, AND LOCAL AGENCIES AND FEDERALLY RECOGNIZED NATIVE AMERICAN GROUPS

Certain laws, such as the Endangered Species Act, the Fish and Wildlife Coordination Act, and the National Historic Preservation Act, require consultation and coordination by DOE with other governmental entities including other Federal agencies, state and local agencies, and federally recognized Native American groups. These consultations must occur on a timely basis and are generally required before any land disturbance can begin. Most of these consultations are related to biotic resources, cultural resources, and Native American rights.

The biotic resource consultations generally pertain to the potential for activities to disturb sensitive species or habitats. Cultural resource consultations relate to the potential for disruption of important cultural resources and archaeological sites. Native American consultations are concerned with the potential for disturbance of ancestral Native American sites and the traditional practices of Native Americans.

DOE initiated the required consultations with the appropriate State Historic Preservation Officers, as required by NEPA and Section 106 of the National Historic Preservation Act; the U.S. Fish and Wildlife Service and the National Marine Fisheries Service, as required by the Endangered Species Act of 1973, the Bald and Golden Eagle Protection Act, and the Migratory Bird Treaty Act; and the appropriate state regulators, as required by state laws or regulations. DOE also initiated the required consultations with the appropriate Native American tribal governments, as required by the Executive Memorandum (dated April 29, 1994) entitled “Government-to-Government Relations with Native American Tribal Governments” and DOE Order 1230.2, “American Indian Tribal Government.” A list of those organizations contacted is included in **Table 5-3**. No major issues were identified as a result of the consultation process. The specific results of the consultation process are presented in Chapter 4.

**Table 5-3 Organizations Contacted During the Consultation Process**

<b>DOE Site</b>	<b>Subject</b>	<b>Addressed To (Date of Letter)</b>
ORR	Ecological resources	Mr. James Widlak U.S. Fish and Wildlife Service (July 10, 2000)
	Ecological resources	Mr. Reginald G. Reeves Tennessee Department of Environment and Conservation (July 10, 2000)
	Cultural resources	Mr. Ollie Keller State Historic Preservation Officer (July 10, 2000)
INEEL	Ecological resources	Mr. Mike Donahoo U.S. Fish and Wildlife Service (July 10, 2000)
	Ecological resources	Mr. George Stephens Idaho Department of Fish and Game (July 10, 2000)
	Cultural resources	Dr. Robert M. Yohe State Historic Preservation Officer (July 10, 2000)
	Native American	The Honorable Lionel Boyer Shoshone-Bannock Tribes (July 10, 2000)
	Native American	Ms. Diana Yupe Shoshone-Bannock Tribes (July 10, 2000)
Hanford	Ecological resources	Mr. James Michaels U.S. Fish and Wildlife Service (July 10, 2000)
	Ecological resources	Mr. Steve Landino National Marine Fisheries Service (July 10, 2000)
	Ecological resources	Ms. Sandy Swope Moody Washington Department of Natural Resources (July 10, 2000)
	Ecological resources	Ms. Lori Guggenmos Washington Department of Wildlife (July 10, 2000)
	Cultural resources	Dr. Allyson Brooks State Historic Preservation Officer (July 10, 2000)
	Native American	Ms. Lenora Seelatsee Wanapum Band (July 10, 2000)
	Native American	Mr. Russell Jim Yakama Nation (July 10, 2000)
	Native American	The Honorable William Burke Confederated Tribes of the Umatilla Indian Reservation (July 10, 2000)
	Native American	Mr. Patrick Sobotta Nez Perce Tribe (July 10, 2000)

## Chapter 6

### List of Preparers

**Benjamin, Richard, *Accelerator Design and Operations, TechSource, Inc.***

B.S., Mechanical Engineering, Lamar University  
M.S., Mechanical Engineering, Southern Methodist University  
Ph.D., Physics, University of Texas  
Years of Experience: 41

**Benromdhane, Souad A., *Air Quality, SAIC***

B.S. & M.S., Civil Engineering, École Nationale d'Ingenieurs de Tunis  
M.S., Geotechnical Engineering, École Nationale d'Ingenieurs de Tunis  
Ph.D., Environmental Engineering, Michigan State University  
Years of Experience: 10

**Brown, Colette E., *PEIS Document Manager, U.S. Department of Energy***

B.S., Nuclear Engineering, University of Virginia  
Years of Experience: 14

**Cavanaugh, Sydel S., *Public Outreach, Comment Response Document, SAIC***

B.A., Interdisciplinary Studies - Personnel and Sociology, University of Maryland Baltimore County  
Years of Experience: 15

**Collins, Alva L., *Affected Environment Lead, SAIC***

A.B., Chemistry, Oberlin College  
M.A., Inorganic Chemistry, Duke University  
M.B.A., Business Administration, Wharton Graduate School, University of Pennsylvania  
Ph.D., Inorganic Chemistry, Duke University  
Years of Experience: 30

**DeMoss, Gary M., *Transportation, SAIC***

B.S., Mechanical Engineering, University of Virginia  
M.S., Engineering Administration, Virginia Polytechnic Institute  
Years of Experience: 17

**Drake, Darrell, *Accelerator Design and Operations, TechSource, Inc.***

B.S., Engineering Physics, University of Oklahoma  
Ph.D., Nuclear Physics, University of Washington  
Years of Experience: 41

**Elia, Ellen, *Socioeconomics, SAIC***

B.A., Mathematics, College of the Holy Cross  
Years of Experience: 11

**Folk, Kevin T., *Water Resources, Geology and Soils, SAIC***

B.A., Geoenvironmental Studies, Shippensburg University  
M.S., Environmental Biology, Hood College  
Years of Experience: 10

**Gallagher, Daniel W., *Public and Occupational Health and Safety, SAIC***

B.S., Nuclear Engineering, Rensselaer Polytechnic Institute  
M.E., Nuclear Engineering, Rensselaer Polytechnic Institute  
Years of Experience: 20

**Gilden, Grace D., *Technical Editing, SAIC***

B.S., Journalism, University of Maryland  
Years of Experience: 22

**Grand, Pierre, *Accelerator Design and Operations, TechSource, Inc.***

B.S.M., CFF Technicum, Yverdon, Switzerland  
Dip. Eng. Ecole Polytechniques, University of Lausanne, Switzerland  
Years of Experience: 41

**Harms, Diane E., *Technical Editing, SAIC***

B.F.A., University of Connecticut  
Years of Experience: 15

**Haupt, Cathy G., *Comment Response Document, Research Support, SAIC***

B.S., Secondary Education, Clarion University  
M.S., Science Education, Clarion University  
Years of Experience: 14

**Herrington, William N., *Medical and Industrial Isotope Target Fabrication and Processing Operations, SAIC***

B.S., Radiation Protection Engineering, Texas A&M University  
Years of Experience: 23

**Hirrlinger, Diana N., *Summary, Laws and Regulations, Waste Management, SAIC***

B.S., Conservation of Natural Resources, University of California  
M.B.A., Marketing and Organizational Behavior, University of Maryland  
Years of Experience: 19

**Hoffman, Robert G., *Introduction, Program Alternatives, SAIC***

B.S., Environmental Resource Management, Pennsylvania State University  
Years of Experience: 15

**Hogroian, Paul, *Cost Study, Project Engineering and Management, Inc.***

B.S., Chemical Engineering, City College of New York  
M.S., Nuclear Engineering, Catholic University of America  
Years of Experience: 33

**Holian, O. James, *Comment Response Document, SAIC***

B.S., Meteorology, Pennsylvania State University  
M.S., Meteorology, Pennsylvania State University  
Years of Experience: 18

**Hummer, James, *Generic Support Facility, SAIC***

B.S., Chemical Engineering, Clarkson University  
M.S., Industrial Management, Clarkson University  
Years of Experience: 25

**Johnson, Charlotte L., *Deputy Project Manager, SAIC***

B.S., Chemistry, University of Maryland  
M.S., Technology Management, University of Maryland  
Years of Experience: 20

**Karimi, Roy, *Generic Reactor Operations, SAIC***

B.Sc., Chemical Engineering, Abadan Institute of Technology  
M.S., Nuclear Engineering, Massachusetts Institute of Technology  
N.E., Nuclear Engineering, Massachusetts Institute of Technology  
Sc.D., Nuclear Engineering, Massachusetts Institute of Technology  
Years of Experience: 24

**Lawrence, George, *Accelerator Design and Operations, TechSource, Inc.***

B.S., Physics, Massachusetts Institute of Technology  
Ph.D., Nuclear Physics, Australian National University, Canberra  
Years of Experience: 36

**Maltese, Jasper G., *Environmental Consequences, Parallax, Inc.***

B.S., Mathematics, Fairleigh Dickinson University  
M.S., Operations Research, George Washington University  
Years of Experience: 37

**Martin, Guy, *Generic Support Facility, SAIC***

B.S., Mechanical Engineering, City College of New York  
M.S., Nuclear Engineering, Polytechnic Institute of New York  
Years of Experience: 25

**Mirsky, Steven M., *Generic Reactor Operations, SAIC***

B.S., Mechanical Engineering, Cooper Union  
M.S., Nuclear Engineering, Pennsylvania State University  
Years of Experience: 24

**Mixon, Steven E., *Technical Editing, SAIC***

B.S., Communications, University of Tennessee  
Years of Experience: 15

**Nestor, Barry, *Document Production, SAIC***

B.A., Economics, Providence College  
M.A., American Government and Urban Affairs, American University  
Years of Experience: 21

**Papadopoulos, Aris, *Program Alternatives, SAIC***

B.S., Physics, Hamline University  
M.S., Nuclear Engineering, University of Utah  
Years of Experience: 29

**Rhone, Jacquelyn, *Administrative Record, Document Production, SAIC***

A.Sc., Radiological Health Technology, Central Florida Community College  
Years of Experience: 27

**Rikhoff, Jeffrey J., *Cost Study, SAIC***

B.A., English, DePauw University  
M.S., International/Economic Development and Appropriate Technology, University of Pennsylvania  
M.R.P., Regional/Environmental Planning, University of Pennsylvania  
Years of Experience: 14

**Sawyer, Cheri A., *Document Production, SAIC***

B.S., Journalism, University of Maryland  
Years of Experience: 20

**Schinner, James R., *Natural Resources, Cultural and Paleontological Resources, SAIC***

B.S., Zoology, University of Cincinnati  
M.S., Zoology, University of Cincinnati  
Ph.D., Wildlife Management, Michigan State University  
Years of Experience: 27

**Schlegel, Robert L., *Environmental Consequences Lead, Pu-238 Target Irradiation Operations, SAIC***

B.S., Chemical Engineering, Massachusetts Institute of Technology  
M.S., Nuclear Engineering, Columbia University  
Degree of Nuclear Engineering, Columbia University  
Years of Experience: 38

**Schwab, Patrick R., *FFTF Operations, Generic Accelerator Operations, SAIC***

B.S., Nuclear Engineering, Kansas State University  
M.S., Nuclear Engineering, University of Wisconsin  
Ph.D., Nuclear Engineering, University of Wisconsin  
Years of Experience: 18

**Shayer, Zeev, *Generic Reactor Operations, SAIC***

B.Sc., Engineering, Ben-Gurion University  
M.Sc., Nuclear Engineering, Ben-Gurion University  
Ph.D., Engineering Science, Tel-Aviv University  
Years of Experience: 25

**Shum, Edward Y., *Spent Nuclear Fuel, SAIC***

B.S., Chemistry, University of California  
M.S., Chemistry, Oregon State University  
Ph.D., Nuclear Chemistry, Oregon State University  
Years of Experience: 26

**Smith, Barry H., *Responsible Corporate Manager, SAIC***

B.A., Indiana University  
J.D., George Washington University National Law Center  
Years of Experience: 25

**Snead, Lewis, *Accelerator Design and Operations*, TechSource, Inc.**

B.S., Physics, University of Richmond  
Ph.D., Physics, University of North Carolina, Chapel Hill  
Years of Experience: 35

**Snyder, Carl A., *Accident Analysis*, SAIC**

B.S., Mathematics, University of Maryland  
B.S., Nuclear Engineering, University of Maryland  
Years of Experience: 10

**Soffer, Leonard, *Accident Analysis*, Parallax, Inc.**

B.S., Physics, City College of New York  
Years of Experience: 46

**Spivey, Mary Alice, *Laws and Regulations, Waste Management*, SAIC**

B.S., Environmental Sciences, Florida Institute of Technology  
Years of Experience: 18

**Sullivan, Barry D., *Project Manager*, SAIC**

B.S., Electrical Engineering, Rutgers University  
M.B.A., Business Administration, Hofstra University  
Years of Experience: 40

**Waldman, Gilbert H., *Radiological Assessment Operations*, SAIC**

B.S., Nuclear Engineering, University of Florida  
M.S., Technical Management, John Hopkins University  
Years of Experience: 8

**Werth, Robert H., *Noise Impacts, Air Quality*, SAIC**

B.A., Physics, Gordon College  
Years of Experience: 25

**Williams, John W., *Geographical Information Systems*, SAIC**

B.S., Mathematics, North Texas State University  
M.S., Physics, New Mexico State University  
Ph.D., Physics, New Mexico State University  
Years of Experience: 24

**Wilson, Mahlon T., *Accelerator Design and Operations*, TechSource, Inc.**

B.S., Mechanical Engineering, University of Colorado  
M.S., Mechanical Engineering, University of Colorado  
M.S., Nuclear Engineering, University of New Mexico  
Ph.D., Nuclear and Mechanical Engineering, University of New Mexico  
Years of Experience: 44

## **Chapter 7**

### **Distribution List**

The U.S. Department of Energy is providing copies of this *Final Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS])* (or Summary) to Federal, state, and local elected and appointed government officials and agencies; Native American representatives; Federal, state, and local environmental and public interest groups; and other organizations and individuals as listed. Approximately 1,500 copies of the NI PEIS and 7,500 copies of the Summary of the NI PEIS were sent to interested parties. Copies will be provided to others on request.

#### **UNITED STATES CONGRESS**

##### **U.S. Senate**

Larry Craig, R-Idaho  
Michael Crapo, R-Idaho  
Bill Frist, R-Tennessee  
Slade Gorton, R-Washington

Patty Murray, D-Washington  
Gordon Smith, R-Oregon  
Fred Thompson, R-Tennessee  
Ron Wyden, D-Oregon

##### **U.S. Senate Committees**

Jeff Bingaman, Committee on Energy and Natural Resources  
Pete Domenici, Subcommittee on Energy and Water Development  
Bob Graham, Subcommittee on Energy Research, Development, Production and Regulation  
Frank Murkowski, Committee on Energy and Natural Resources  
Don Nickles, Subcommittee on Energy Research, Development, Production and Regulation  
Harry Reid, Subcommittee on Energy and Water Development

##### **U.S. House of Representatives**

Brian Baird, D-Washington  
Earl Blumenauer, D-Oregon  
Helen Chenoweth-Hage, R-Idaho  
Peter DeFazio, D-Oregon  
Norm Dicks, D-Washington  
John Duncan, Jr., R-Tennessee  
Jennifer Dunn, R-Washington  
Bart Gordon, D-Tennessee  
Doc Hastings, R-Washington  
Van Hilleary, R-Tennessee  
Darlene Hooley, D-Oregon

Jay Inslee, D-Washington  
Jim McDermott, D-Washington  
Jack Metcalf, R-Washington  
George Nethercuff, R-Washington  
Deborah Pryce, R-Ohio  
Mike Simpson, R-Idaho  
Adam Smith, D-Washington  
John Tanner, D-Tennessee  
Greg Walden, R-Oregon  
Zach Wamp, R-Tennessee  
David Wu, D-Oregon

##### **U.S. House of Representatives Committees**

Joe Barton, Subcommittee on Energy and Power  
Tom Bliley, Committee on Commerce  
Rick Boucher, Subcommittee on Energy and Power  
Ken Calvert, Subcommittee on Energy and Environment

Jerry Costello, Subcommittee on Energy and Environment  
John Dingell, Committee on Commerce  
Ralph Hall, Committee on Science  
Ron Packard, Subcommittee on Energy and Water Development  
James Sensenbrenner, Jr., Committee on Science  
Pete Visclosky, Subcommittee on Energy and Water Development

## Chapter 8

### Glossary

**absorbed dose** – For ionizing radiation, the energy imparted to matter by ionizing radiation per unit mass of the irradiated material (e.g., biological tissue). The units of absorbed dose are the rad and the gray. (See rad and gray.)

**accelerator** – A device that accelerates charged particles (e.g., electrons or protons) to high velocities so they have high kinetic energy (i.e., the energy associated with motion); it focuses the charged particles into a beam and directs them against a target.

**accident sequence** – With regard to nuclear facilities, an initiating event followed by system failures or operator errors, which can result in significant core damage, confinement system failure, and/or radionuclide releases.

**actinide** – Any member of the group of elements with atomic numbers from 89 (actinium) to 103 (lawrencium) including uranium and plutonium. All members of this group are radioactive.

**activation products** – Nuclei, usually radioactive, formed by the bombardment and absorption in material with neutrons, protons, or other nuclear particles.

**Advanced Test Reactor** – A light-water cooled and moderated test reactor located within the Test Reactor Area of Idaho National Engineering and Environmental Laboratory. It is fueled with uranium enriched with uranium-235 and has a full power level of 250 megawatts, but typically operates at 140 megawatts or less.

**air pollutant** – Generally, an airborne substance that could, in high enough concentrations, harm living things or cause damage to materials. From a regulatory perspective, an air pollutant is a substance for which emissions or atmospheric concentrations are regulated or for which maximum guideline levels have been established due to potential harmful effects on human health and welfare.

**air quality control region** – Geographic subdivisions of the United States, designed to deal with pollution on a regional or local level. Some regions span more than one state.

**alpha activity** – The emission of alpha particles by radioactive materials.

**alpha particle** – A positively charged particle ejected spontaneously from the nuclei of some radioactive elements. It is identical to a helium nucleus and has a mass number of 4 and an electrostatic charge of +2. It has low penetrating power and a short range (a few centimeters in air). (See alpha radiation.)

**alpha radiation** – A strongly ionizing, but weakly penetrating, form of radiation consisting of positively charged alpha particles emitted spontaneously from the nuclei of certain elements during radioactive decay. Alpha radiation is the least penetrating of the three common types of ionizing radiation (alpha, beta, and gamma). Even the most energetic alpha particle generally fails to penetrate the dead layers of cells covering the skin and can be easily stopped by a sheet of paper. Alpha radiation is most hazardous when an alpha-emitting source resides inside an organism. (See alpha particle.)

**ambient** – Surrounding.

**ambient air** – The surrounding atmosphere as it exists around people, plants, and structures.

**ambient air quality standards** – The level of pollutants in the air prescribed by regulations that may not be exceeded during a specified time in a defined area. Air quality standards are used to provide a measure of the health-related and visual characteristics of the air.

**aquatic** – Living or growing in, on, or near water.

**aquatic biota** – The sum total of living organisms within any designated aquatic area.

**aquifer** – An underground geological formation, group of formations, or part of a formation that is capable of yielding a significant amount of water to wells or springs.

**aquitard** - A less-permeable geologic unit that inhibits the flow of water.

**archaeological sites (resources)** – Any location where humans have altered the terrain or discarded artifacts during either prehistoric or historic times.

**artifact** – An object produced or shaped by human workmanship of archaeological or historical interest.

**as low as is reasonably achievable (ALARA)** – An approach to radiation protection to manage and control worker and public exposures (both individual and collective) and releases of radioactive material to the environment to as far below applicable limits as social, technical, economic, practical, and public policy considerations permit. ALARA is not a dose limit but a process for minimizing doses to as far below limits as is practicable.

**attainment area** – An area that the U.S. Environmental Protection Agency has designated as being in compliance with one or more of the National Ambient Air Quality Standards for sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and particulate matter. An area may be in attainment for some pollutants but not for others. (See National Ambient Air Quality Standards, nonattainment area, and particulate matter.)

**atmospheric dispersion** – The process of air pollutants being dispersed in the atmosphere. This occurs by the wind that carries the pollutants away from their source, by turbulent air motion that results from solar heating of the Earth's surface, and air movement over rough terrain and surfaces.

**Atomic Energy Act** – A law originally enacted in 1946 and amended in 1954 that placed nuclear production and control of nuclear materials within a civilian agency, originally the Atomic Energy Commission. The functions of the Atomic Energy

Commission were replaced by the U.S. Nuclear Regulatory Commission and the U.S. Department of Energy.

**Atomic Energy Commission** – A five-member commission, established by the Atomic Energy Act of 1946, to supervise nuclear weapons design, development, manufacturing, maintenance, modification, and dismantlement. In 1974, the Atomic Energy Commission was abolished, and all functions were transferred to the Nuclear Regulatory Commission and the Administrator of the Energy Research and Development Administration. The Energy Research and Development Administration was later terminated, and functions vested by law in the Administrator were transferred to the Secretary of Energy.

**atomic number** – The number of positively charged protons in the nucleus of an atom or the number of electrons on an electrically neutral atom.

**background radiation** – Radiation from (1) cosmic sources, (2) naturally occurring radioactive materials, including radon (except as a decay product of source or special nuclear material), and (3) global fallout as it exists in the environment (e.g., from the testing of nuclear explosive devices).

**badged worker** – A worker who has the potential to be exposed to occupational radiation, and is equipped with a dosimeter to measure his/her dose.

**barrier** – Any material or structure that prevents or substantially delays movement of radionuclides toward the accessible environment.

**baseline** – The existing environmental conditions against which impacts of the proposed action and its alternatives can be compared. For this NI PEIS, the environmental baseline is the site environmental conditions as they exist or are estimated to exist in the absence of the proposed action.

**beam expander** – A device designed to expand the proton beam in an accelerator to a larger cross-sectional area.

**beamstop** – A device designed to absorb the full beam of an accelerator.

**becquerel** – A unit of radioactivity equal to one disintegration per second. Thirty-seven billion becquerels is equal to 1 curie.

**BEIR V** – Biological Effects of Ionizing Radiation; referring to the fifth in a series of committee reports from the National Research Council.

**benthic** – Plants and animals dwelling at the bottom of oceans, lakes, rivers, and other surface waters.

**beryllium** – An extremely lightweight element with the atomic number 4. It is metallic and is used in reactors as a neutron reflector.

**beta emitter** – A radioactive substance that decays by releasing a beta particle.

**beta particle** – A particle emitted in the radioactive decay of many radionuclides. A beta particle is identical to an electron. It has a short range in air and a small ability to penetrate other materials.

**beyond-design-basis accident** – An accident postulated for the purpose of generating large consequences by exceeding the functional and performance requirements for safety structures, systems, and components. (See design-basis accident.)

**beyond-design-basis events** – Postulated disturbances in process variables due to external events or multiple component or system failures that can potentially lead to beyond-design-basis accidents. (See design-basis events.)

**biodiversity** – The diversity of life in all its forms and all levels of organization. Also termed "biological diversity."

**biota (biotic)** – The plant and animal life of a region (pertaining to biota).

**blanket** – Blanket assembly in an accelerator is a material where the generated neutrons would be moderated to be absorbed (captured) in the target material to produce a new isotope.

**block** – U.S. Bureau of the Census term describing small areas bounded on all sides by visible features or political boundaries; used in tabulation of census data.

**boron-10** – An isotope of the element boron that has a high capture cross section for neutrons. It is used in reactor absorber rods for reactor control.

**bounded** – Producing the greatest consequences of any assessment of impacts associated with normal or abnormal operations.

**burial ground** – With regard to radioactive wastes, a place for burying unwanted (i.e., radioactive) materials in which the Earth acts as a receptacle to prevent the escape of radiation and the dispersion of wastes into the environment.

**calcination** – A process in which a material is heated to a high temperature to drive off volatile matter (to remove organic material) or to effect changes (as oxidation or pulverization, or to convert to nodular form). The temperature is kept below the fusion point.

**cancer** – The name given to a group of diseases characterized by uncontrolled cellular growth with cells having invasive characteristics such that the disease can transfer from one organ to another.

**canister** – A general term for a container, usually cylindrical, used in handling, storage, transportation, or disposal of waste.

**capable fault** – A fault that has exhibited one or more of the following characteristics: (1) movement at or near the ground surface at least once within the past 35,000 years, or movement of a recurring nature within the past 500,000 years; (2) macro-seismicity instrumentally determined with records of sufficient precision to demonstrate a direct relationship with the fault; (3) a structural relationship to a capable fault according to characteristic (1) or (2) above, such that movement

on one could be reasonably expected to be accompanied by movement on the other.

**capacity factor** – The ratio of the annual average power production of a power plant to its rated capacity.

**carbon dioxide** – A colorless, odorless gas that is a normal component of ambient air; it results from fossil fuel combustion, and is an expiration production.

**carbon monoxide** – A colorless, odorless, poisonous gas produced by incomplete fossil fuel combustion.

**cask** – A heavily shielded container used to store or ship radioactive materials.

**cation** – A positively charged ion.

**cell** – See hot cell.

**Chalfont container 9975** – A shielded Type B container with primary and secondary containment features that is used to store or ship radioactive materials. (See cask and Type B packaging.)

**cladding** – The outer metal jacket of a nuclear fuel element or target. It prevents fuel corrosion and retains fission products during reactor operation and subsequent storage, as well as providing structural support. Zirconium alloys, stainless steel, and aluminum are common cladding materials. In general, a metal coating bonded onto another metal.

**Class I areas** – A specifically designated area where the degradation of air quality is stringently restricted (e.g., many national parks, wilderness areas). (See Prevention of Significant Deterioration.)

**Class II areas** – Most of the country not designated as Class I is designated as Class II. Class II areas are generally cleaner than air quality standards require, and moderate increases in new pollution are allowed after a regulatory mandated impacts review.

**Clean Air Act** – This act mandates and provides for enforcement of regulations to control air pollution from various sources.

**Clean Air Act Amendments of 1990** – Expands the U.S. Environmental Protection Agency's enforcement powers, and adds restrictions on air toxics, ozone depleting chemicals, stationary and mobile emissions sources, and emissions implicated in acid rain and global warming.

**Clean Water Act of 1972, 1987** – This act regulates the discharge of pollutants from a point source into navigable waters of the United States in compliance with a National Pollutant Discharge Elimination System permit, and regulates discharges to or dredging of wetlands.

**Code of Federal Regulations** – All Federal regulations in effect are published in codified form in the Code of Federal Regulations.

**collective dose** – The sum of the individual doses received in a given period of time by a specified population from exposure to a specified source of radiation. Collective dose is expressed in units of person-rem or person-sievert.

**commercial light water reactor** – The term used to describe commercially operated power producing U.S. reactors that use “light” (as opposed to heavy) water for cooling and neutron moderation.

**committed dose equivalent** – The dose equivalent to organs or tissues that will be received by an individual during the 50-year period following the intake of radioactive material. It does not include contributions from radiation sources external to the body. Committed dose equivalent is expressed in units of rems or sieverts.

**committed effective dose equivalent** – The dose value obtained by (1) multiplying the committed dose equivalents for the organs or tissues that are irradiated and the weighting factors applicable to those organs or tissues and (2) summing all the resulting products. Committed effective dose equivalent is expressed in units of rem or sievert.

(See committed dose equivalent and weighting factor.)

**community (biotic)** – All plants and animals occupying a specific area under relatively similar conditions.

**community (environmental justice definition)** – A group of people or a site within a spatial scope exposed to risks that potentially threaten health, ecology, or land values; or are exposed to industry that stimulates unwanted noise, smell, industrial traffic, particulate matter, or other nonaesthetic impacts.

**conformity** – Conformity is defined in the Clean Air Act as the action's compliance with an implementation plan's purpose of eliminating or reducing the severity and number of violations of the National Ambient Air Quality Standards, and achieving expeditious attainment of such standards; and that such activities will not: (1) cause or contribute to any new violation of any standard in any area; (2) increase the frequency or severity of any existing violation of any standard in any area; or (3) delay timely attainment of any standard or any required interim emission reduction, or other milestones in any area.

**contact-handled waste** – Radioactive waste or waste packages whose external dose rate is low enough to permit contact handling by humans during normal waste management activities, (e.g., waste with a surface dose rate not greater than 200 millirem per hour). (See remote-handled waste.)

**container** – With regard to radioactive wastes, the metal envelope in the waste package that provides the primary containment function of the waste package, which is designed to meet the containment requirements of 10 CFR Part 60.

**containment design basis** – For a nuclear reactor, those bounding conditions for the design of the containment, including temperature, pressure, and leakage rate. Because the containment is provided as an additional barrier to mitigate the consequences of accidents involving the release of radioactive materials, the containment design basis

may include an additional specified margin above those conditions expected to result from the plant design-basis accidents to ensure that the containment design can mitigate unlikely or unforeseen events.

**contamination** – The deposition of undesirable radioactive material on the surfaces of structures, areas, objects, or personnel.

**control rod** – A rod containing material such as boron that is used to control the power of a nuclear reactor. By absorbing excess neutrons, a control rod prevents the neutrons from causing further fissions, i.e., increasing power.

**coolant** – A substance, either gas or liquid, circulated through a nuclear reactor or processing plant to remove heat.

**cooperating agency** – Any Federal agency other than a lead agency which has jurisdiction by law or special expertise with respect to any environmental impact involved in a proposal (or a reasonable alternative) for legislation or other major Federal action significantly affecting the quality of the human environment.

**credible accident** – An accident that has a probability of occurrence greater than or equal to once in a one million year time period.

**criteria pollutants** – An air pollutant that is regulated by National Ambient Air Quality Standards. The U.S. Environmental Protection Agency must describe the characteristics and potential health and welfare effects that form the basis for setting, or revising, the standard for each regulated pollutant. Criteria pollutants include sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and two size classes of particulate matter, less than or equal to 10 micrometers (0.0004 inch) in diameter, and less than or equal to 2.5 micrometers (0.0001 inch) in diameter. New pollutants may be added to, or removed from, the list of criteria pollutants as more information becomes available. (See National Ambient Air Quality Standards.)

**critical habitat** – Habitat essential to the conservation of an endangered or threatened species that has been designated as critical by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service following the procedures outlined in the Endangered Species Act and its implementing regulations (50 CFR Part 424). (See endangered species and threatened species.) The lists of Critical Habitats can be found in 50 CFR Section 17.95 (fish and wildlife), 50 CFR Section 17.96 (plants), and 50 CFR Part 226 (marine species).

**criticality** – The condition in which a system is capable of sustaining a nuclear chain reaction.

*chain reaction*: A reaction that initiates its own repetition. In nuclear fission, a chain reaction occurs when a neutron induces a nucleus to fission and the fissioning nucleus releases one or more neutrons which induce other nuclei to fission.

*critical mass*: The smallest mass of fissionable material that will support a self-sustaining nuclear chain reaction.

**cultural resources** – Archaeological sites, historical sites, architectural features, traditional use areas, and Native American sacred sites.

**cumulative impacts** – The impacts on the environment that result from the incremental impacts of the action when added to other past, present, and reasonably foreseeable future actions, regardless of the agency or person who undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. (40 CFR Section 1508.7)

**curie** – A unit of radioactivity equal to 37 billion disintegrations per second (i.e., 37 billion becquerels); also a quantity of any radionuclide or mixture of radionuclides having 1 curie of radioactivity.

**day-night average sound level** – The 24-hour, A-weighted equivalent sound level expressed in decibels. A 10-decibel penalty is added to sound levels between 10:00 p.m. and 7:00 a.m. to account

for increased annoyance due to noise during night hours.

**deactivation** – The placement of a facility in a radiologically and industrially safe shutdown condition that is suitable for a long-term surveillance and maintenance phase prior to final decontamination and decommissioning.

**decay (radioactive)** – The decrease in the amount of any radioactive material with the passage of time, due to spontaneous nuclear disintegration (i.e., emission from atomic nuclei of charged particles, photons, or both).

**decay heat (radioactivity)** – The heat produced by the decay of radionuclides.

**decibel** – A unit for expressing the relative intensity of sounds on a logarithmic scale where zero is below human perception and 130 is above the threshold of pain to humans. For traffic and industrial noise measurements, the A-weighted decibel, a frequency-weighted noise unit, is widely used. The A-weighted decibel scale corresponds approximately to the frequency response of the human ear and thus correlates well with loudness.

**deciduous** – Trees which shed leaves at a certain season.

**decommissioning** – Retirement of a facility, including any necessary decontamination and/or dismantlement.

**decontamination** – The actions taken to reduce or remove substances that pose a substantial present or potential hazard to human health or the environment, such as radioactive or chemical contamination from facilities, equipment, or soils by washing, heating, chemical or electrochemical action, mechanical cleaning, or other techniques.

**depleted uranium** – Uranium whose content of the fissile isotope uranium-235 is less than the 0.7 percent (by weight) found in natural uranium, so that it contains more uranium-238 than natural uranium.

**deposition** – In geology, the laying down of potential rock-forming materials; sedimentation. In atmospheric transport, the settling out on ground and building surfaces of atmospheric aerosols and particles ("dry deposition"), or their removal from the air to the ground by precipitation ("wet deposition" or "rainout").

**design basis** – For nuclear facilities, information that identifies the specific functions to be performed by a structure, system, or component, and the specific values (or ranges of values) chosen for controlling parameters for reference bounds for design. These values may be: (1) restraints derived from generally accepted state-of-the-art practices for achieving functional goals; (2) requirements derived from analysis (based on calculation and/or experiments) of the effects of a postulated accident for which a structure, system, or component must meet its functional goals; or (3) requirements derived from Federal safety objectives, principles, goals, or requirements.

**design-basis accident** – An accident postulated for the purpose of establishing functional and performance requirements for safety structures, systems, and components. (See beyond-design-basis accident.)

**design-basis events** – Postulated disturbances in process variables that can potentially lead to design-basis accidents. (See beyond-design-basis events.)

**direct jobs** – The number of workers required at a site to implement an alternative.

**disposition** – The ultimate "fate" or end use of a surplus U.S. Department of Energy facility following the transfer of the facility to the Office of the Assistant Secretary for Environmental Waste Management.

**DOE orders** – Requirements internal to the U.S. Department of Energy that establish Department policy and procedures, including those for compliance with applicable laws.

**dose (or radiation dose)** – A generic term that means absorbed dose, effective dose equivalent,

committed effective dose equivalent, or total effective dose equivalent, as defined elsewhere in this glossary.

**dose equivalent** – A measure of radiological dose that correlates with biological effect on a common scale for all types of ionizing radiation. Defined as a quantity equal to the absorbed dose in tissue multiplied by a quality factor (the biological effectiveness of a given type of radiation) and all other necessary modifying factors at the location of interest. The units of dose equivalent are the rem and sievert.

**dose rate** – The radiation dose delivered per unit of time (e.g., rem per year).

**dosimeter** – A small device (instrument) carried by a radiation worker that measures cumulative radiation dose (e.g., a film badge or ionization chamber).

**drinking water standards** – The level of constituents or characteristics in a drinking water supply specified in regulations under the Safe Drinking Water Act as the maximum permissible.

**ecology** – A branch of science dealing with the interrelationships of living organisms with one another and with their nonliving environment.

**ecosystem** – A community of organisms and their physical environment interacting as an ecological unit.

**effective dose equivalent** – The dose value obtained by multiplying the dose equivalents received by specified tissues or organs of the body by the appropriate weighting factors applicable to the tissues or organs irradiated, and then summing all of the resulting products. It includes the dose from radiation sources internal and external to the body. The effective dose equivalent is expressed in units of rems or sieverts. (See committed dose equivalent and committed effective dose equivalent.)

**effluent** – A waste stream flowing into the atmosphere, surface water, ground water, or soil.

Most frequently the term applies to wastes discharged to surface waters.

**electron** – An elementary particle with a mass of  $9.107 \times 10^{-28}$  gram (or 1/1,837 of a proton) and a negative charge. Electrons surround the positively charged nucleus and determine the chemical properties of the atom.

**emission** – A material discharged into the atmosphere from a source operation or activity.

**emission standards** – Legally enforceable limits on the quantities and/or kinds of air contaminants that can be emitted into the atmosphere.

**endangered species** – Plants or animals that are in danger of extinction through all or a significant portion of their ranges and that have been listed as endangered by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service following the procedures outlined in the Endangered Species Act and its implementing regulations (50 CFR Part 424). (See threatened species.) The lists of endangered species can be found in 50 CFR Section 17.11 for wildlife, 50 CFR Section 17.12 for plants, and 50 CFR Section 222.23(a) for marine organisms.

**engineered safety features** – For a nuclear facility, features that prevent, limit, or mitigate the release of radioactive material from its primary containment.

**enriched uranium** – Uranium whose content of the fissile isotope uranium-235 is greater than the 0.7 percent (by weight) found in natural uranium. (See uranium, natural uranium, and highly enriched uranium.)

**entrainment** – The involuntary capture and inclusion of organisms in streams of flowing water, a term often applied to the cooling water systems of power plants and reactors. The organisms involved may include phyto- and zooplankton, fish eggs and larvae (ichthyoplankton), shellfish larvae, and other forms of aquatic life.

**Environment, Safety, and Health Program** – In the context of the U.S. Department of Energy,

encompasses those requirements, activities, and functions in the conduct of all Department and Department-controlled operations that are concerned with: impacts to the biosphere; compliance with environmental laws, regulations, and standards controlling air, water, and soil pollution; limiting the risks to the well-being of both the operating personnel and the general public; and protecting property against accidental loss and damage. Typical activities and functions related to this program include, but are not limited to, environmental protection, occupational safety, fire protection, industrial hygiene, health physics, occupational medicine, process and facilities safety, nuclear safety, emergency preparedness, quality assurance, and radioactive and hazardous waste management.

**environmental impact statement** – The detailed written statement that is required by section 102(2)(C) of the National Environmental Policy Act for a proposed major Federal action significantly affecting the quality of the human environment. A U.S. Department of Energy environmental impact statement is prepared in accordance with applicable requirements of the Council on Environmental Quality National Environmental Policy Act regulations in 40 CFR Parts 1500–1508 and the U.S. Department of Energy National Environmental Policy Act regulations in 10 CFR Part 1021. The statement includes, among other information, discussions of the environmental impacts of the proposed action and all reasonable alternatives, adverse environmental effects that can not be avoided should the proposal be implemented, the relationship between short-term uses of the human environment and enhancement of long-term productivity, and any irreversible and irretrievable commitments of resources.

**environmental justice** – The fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no group of people, including racial, ethnic, or socioeconomic groups, should bear a disproportionate share of the negative

environmental consequences resulting from industrial, municipal, and commercial operations or the execution of Federal, state, local, and tribal programs and policies. Executive Order 12898 directs Federal agencies to make achieving environmental justice part of their missions by identifying and addressing disproportionately high and adverse effects of agency programs, policies, and activities on minority and low-income populations. (See minority population and low-income population.)

**epidemiology** – Study of the occurrence, causes, and distribution of disease or other health-related states and events in human populations, often as related to age, sex, occupation, ethnic, and economic status, in order to identify and alleviate health problems and promote better health.

**exposure limit** – The level of exposure to a hazardous chemical (set by law or a standard) at which or below which adverse human health effects are not expected to occur.

*Reference dose* is the chronic-exposure dose (milligram or kilogram per day) for a given hazardous chemical at which or below which adverse human non-cancer health effects are not expected to occur.

*Reference concentration* is the chronic exposure concentration (milligram per cubic meter) for a given hazardous chemical at which or below which adverse human non-cancer health effects are not expected to occur.

**extrusion** – A type of process in which a material (e.g., metal or plastic) is forced through a die or very small hole to give it a certain shape.

**Fast Flux Test Facility** – A liquid-metal (sodium) cooled test reactor and moderated test reactor at the Hanford Site. It is fueled with a mixture of plutonium-uranium dioxide, and has a power level of 400 megawatts. It is presently in a standby status.

**fault** – A fracture or a zone of fractures within a rock formation along which vertical, horizontal, or transverse slippage has occurred. A normal fault

occurs when the hanging wall has been depressed in relation to the footwall. A reverse fault occurs when the hanging wall has been raised in relation to the footwall.

**fissile materials** – Although sometimes used as a synonym for fissionable material, this term has acquired a more restricted meaning, namely, any material fissionable by thermal (slow) neutrons. The three primary fissile materials are uranium-233, uranium-235, and plutonium-239.

**fission products** – Nuclei (fission fragments) formed by the fission of heavy elements, plus the nuclides formed by the fission fragments' radioactive decay.

**fissionable material** – Commonly used as a synonym for fissile material, the meaning of this term has been extended to include material that can be fissioned by fast neutrons, such as uranium-238.

**floodplain** – The lowlands and relatively flat areas adjoining inland and coastal waters and the flood prone areas of offshore islands. Floodplains include, at a minimum, that area with at least a 1.0 percent chance of being inundated by a flood in any given year.

The *base floodplain* is defined as the area which has a 1.0 percent or greater chance of being flooded in any given year. Such a flood is known as a 100-year flood.

The *critical action floodplain* is defined as the area which has at least a 0.2 percent chance of being flooded in any given year. Such a flood is known as a 500-year flood. Any activity for which even a slight chance of flooding would be too great (e.g., the storage of highly volatile, toxic, or water reactive materials) should not occur in the critical action floodplain.

The *probable maximum flood* is the hypothetical flood that is considered to be the most severe reasonably possible flood, based on the comprehensive hydrometeorological application of maximum precipitation and other hydrological factors favorable for maximum flood runoff (e.g., sequential storms and snowmelts). It is usually

several times larger than the maximum recorded flood.

**Fluorinel Dissolution Process Facility** – A processing facility at the Idaho Nuclear Technology and Engineering Center on the Idaho National Engineering and Environmental Laboratory that is designed to handle highly radioactive material using remote handling equipment. This facility was originally intended to process spent nuclear fuel.

**flux** – Rate of flow through a unit area; in reactor operation, the apparent flow of neutrons in a defined energy range (see neutron flux).

**formation** – In geology, the primary unit of formal stratigraphic mapping or description. Most formations possess certain distinctive features.

**fuel assembly** – A cluster of fuel rods or plates. Also called a fuel element. Approximately 200 fuel assemblies make up a reactor core.

**fuel rod** – A nuclear reactor component that includes the fissile material.

**Fuels and Materials Examination Facility** – A processing facility at the Hanford Site that is designed to handle highly radioactive materials using remote handling equipment. This facility was originally intended to process spent nuclear fuel and irradiated targets from the Fast Flux Test Facility.

**fugitive emissions** – (1) Emissions that do not pass through a stack, vent, chimney, or similar opening where they could be captured by a control device. (2) Any air pollutant emitted to the atmosphere other than from a stack. Sources of fugitive emissions include pumps; valves; flanges; seals; area sources such as ponds, lagoons, landfills, piles of stored material (e.g., coal); and road construction areas or other areas where earthwork is occurring.

**gamma radiation** – High-energy, short wavelength, electromagnetic radiation emitted from the nucleus of an atom during radioactive decay. Gamma radiation frequently accompanies

alpha and beta emissions and always accompanies fission. Gamma rays are very penetrating and are best stopped or shielded by dense materials, such as lead or depleted uranium. Gamma rays are similar to, but are usually more energetic than, x-rays.

**genetic effects** – Inheritable changes (chiefly mutations) produced by exposure, to ionizing radiation or other chemical or physical agents, of the parts of cells that control biological reproduction and inheritance.

**geologic repository** – A place to dispose of radioactive waste deep beneath the Earth's surface.

**geology** – The science that deals with the Earth: the materials, processes, environments, and history of the planet, including rocks and their formation and structure.

**gigaelectron volts** – 1,000 million electron volts (MeV). (See MeV.)

**glovebox** – Large enclosure that separates workers from equipment used to process hazardous material, while allowing the workers to be in physical contact with the equipment; normally constructed of stainless steel, with large acrylic/lead glass windows. Workers have access to equipment through the use of heavy-duty, lead-impregnated rubber gloves, the cuffs of which are sealed in portholes in the glovebox windows.

**gray** – The SI (International System of Units) unit of absorbed dose. One gray is equal to an absorbed dose of 1 joule per kilogram (1 gray is equal to 100 rads). (The joule is the SI unit of energy.) (See absorbed dose.)

**ground shine** – The radiation dose received from an area on the ground where radioactivity has been deposited by a radioactive plume or cloud.

**groundwater** – Water below the ground surface in a zone of saturation.

**habitat** – The environment occupied by individuals of a particular species, population, or community.

**half-life** – The time in which one-half of the atoms of a particular radioactive isotope disintegrate to another nuclear form. Half-lives vary from millionths of a second to billions of years.

**Hazard Index** – A summation of the Hazard Quotients for all chemicals now being used at a site, and those proposed to be added, to yield cumulative levels for a site. A Hazard Index value of 1.0 or less means that no adverse human health effects (noncancer) are expected to occur.

**Hazard Quotient** – The value used as an assessment of non-cancer associated toxic effects of chemicals, e.g., kidney or liver dysfunction. It is a ratio of the estimated exposure to that exposure at which it would be expected that adverse health effects would begin to be produced. It is independent of a cancer risk, which is calculated only for those chemicals identified as carcinogens.

**hazardous air pollutants** – Air pollutants not covered by ambient air quality standards but which may present a threat of adverse human health effects or adverse environmental effects. Those specifically listed in 40 CFR Section 61.01 are asbestos, benzene, beryllium, coke oven emissions, inorganic arsenic, mercury, radionuclides, and vinyl chloride. More broadly, hazardous air pollutants are any of the 189 pollutants listed in or pursuant to section 112(b) of the Clean Air Act. Very generally, hazardous air pollutants are any air pollutants that may realistically be expected to pose a threat to human health or welfare.

**hazardous chemical** – Under 29 CFR Part 1910, Subpart Z, hazardous chemicals are defined as “any chemical which is a physical hazard or a health hazard.” Physical hazards include combustible liquids, compressed gases, explosives, flammables, organic peroxides, oxidizers, pyrophorics, and reactives. A health hazard is any chemical for which there is good evidence that acute or chronic health effects occur in exposed employees. Hazardous chemicals include carcinogens, toxic or highly toxic agents, reproductive toxins, irritants, corrosives, sensitizers, hepatotoxins, nephrotoxins, agents that act on the hematopoietic system, and agents that

damage the lungs, skin, eyes, or mucous membranes.

**hazardous material** – A material, including a hazardous substance, as defined by 49 CFR Section 171.8, which poses a risk to health, safety, and property when transported or handled.

**hazardous substance** – Any substance subject to the reporting and possible response provisions of the Clean Water Act and the Comprehensive Environmental Response, Compensation, and Liability Act.

**hazardous waste** – A category of waste regulated under the Resource Conservation and Recovery Act. To be considered hazardous, a waste must be a solid waste under the Resource Conservation and Recovery Act and must exhibit at least one of four characteristics described in 40 CFR Section 261.20 through 40 CFR Section 261.24 (i.e., ignitability, corrosivity, reactivity, or toxicity) or be specifically listed by the U.S. Environmental Protection Agency in 40 CFR Section 261.31 through 40 CFR Section 261.33.

**high-efficiency particulate air filter** – An air filter capable of removing at least 99.97 percent of particles 0.3 micrometer (about 0.00001 inch) in diameter. These filters include a pleated fibrous medium (typically fiberglass) capable of capturing very small particles.

**High Flux Isotope Reactor** – A light-water cooled and moderated test reactor in the Oak Ridge National Laboratory area of the Oak Ridge Reservation. It is fueled with uranium highly enriched with uranium-235 and has a full authorized power level of 85 million watts.

**high-level radioactive waste** – High-level waste is the highly radioactive waste material resulting from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing and any solid material derived from such liquid waste that contains fission products in sufficient concentrations; and other highly radioactive material that is determined, consistent with existing law, to require permanent isolation.

**HIGHWAY** – A computer code used for predicting routes for transporting radioactive material in the United States and calculating route-specific population density statistics.

**highly enriched uranium** – Uranium whose content of the fissile isotope uranium-235 has been increased through enrichment to 20 percent or more (by weight). (See natural uranium, enriched uranium, and depleted uranium.)

**historic resources** – Archaeological sites, architectural structures, and objects produced after the advent of written history, dating to the time of the first Euro-American contact in an area.

**hot cell** – A shielded facility that requires the use of remote manipulators for handling radioactive materials.

**hydrology** – The science dealing with the properties, distribution, and circulation of natural water systems.

**impingement** – The process by which aquatic organisms too large to pass through the screens of a water intake structure become caught on the screens and are unable to escape.

**incident-free risk** – The radiological or chemical impacts resulting from emissions during normal operations and packages aboard vehicles in normal transport. This includes the radiation or hazardous chemical exposure of specific population groups and workers.

**indirect jobs** – Within a regional economic area, jobs generated or lost in related industries as a result of a change in direct employment.

**injection wells** – A well that takes water from the surface into the ground, either through gravity or by mechanical means.

**injector** – A device that provides protons for an accelerator by heating hydrogen gas to a plasma state in which the hydrogen atoms lose their electrons, thereby giving the hydrogen nuclei (protons) a positive charge. An electric voltage removes the protons from the injector.

**ion** – An atom that has too many or too few electrons, causing it to be electrically charged.

**ion exchange** – A unit physiochemical process that removes anions and cations, including radionuclides, from liquid streams (usually water) for the purpose of purification or decontamination.

**ion exchange resin** – An organic polymer that functions as an acid or base. These resins are used to remove ionic material from a solution. Cation exchange resins are used to remove positively charged particles (cations), and anion exchange resins are used to remove negatively charged particles (anions).

**ionizing radiation** – Alpha particles, beta particles, gamma rays, high-speed electrons, high-speed protons, and other particles or electromagnetic radiation that can displace electrons from atoms or molecules, thereby producing ions.

**irradiated** – Exposure to ionizing radiation. The condition of reactor fuel elements and other materials in which atoms bombarded with nuclear particles have undergone nuclear changes.

**isotopes** – Any of two or more variations of an element in which the nuclei have the same number of protons (i.e., the same atomic number) but different numbers of neutrons so that their atomic masses differ. Isotopes of a single element possess almost identical chemical properties, but often different physical properties (e.g., carbon-12 and -13 are stable, carbon-14 is radioactive).

**joule** – A metric unit of energy, work, or heat, equivalent to one watt-second, 0.737 foot-pound, or 0.239 calories.

**landscape character** – The arrangement of a particular landscape as formed by the variety and intensity of the landscape features (land, water, vegetation, and structures) and the four basic elements (form, line, color, and texture). These factors give an area a distinctive quality that distinguishes it from its immediate surroundings.

**latent cancer fatalities** – Deaths from cancer occurring some time after, and postulated to be due to, exposure to ionizing radiation or other carcinogens.

**license amendment** – Changes to an existing reactor's operating license that are approved by the U.S. Nuclear Regulatory Commission.

**light water** – The common form of water (a molecule with two hydrogen atoms and one oxygen atom, H<sub>2</sub>O), in which the hydrogen atom consists completely of the normal hydrogen isotope (one proton).

**light water reactor** – A nuclear reactor in which circulating light water is used to cool the reactor core and to moderate (reduce the energy of) the neutrons created in the core by the fission reactions.

**long-lived radionuclides** – Radioactive isotopes with half-lives greater than 30 years.

**loss-of-coolant accident** – An accident that results from the loss of reactor coolant because of a break in the reactor coolant system.

**low-enriched uranium** – Uranium whose content of the fissile isotope uranium-235 has been increased through enrichment to more than 0.7 percent but less than 20 percent by weight. Most nuclear power reactor fuel contains low-enriched uranium containing 3 to 5 percent uranium-235.

**low-income population** – Low-income populations, defined in terms of Bureau of the Census annual statistical poverty levels (Current Population Reports, Series P-60 on Income and Poverty), may consist of groups or individuals who live in geographic proximity to one another or who are geographically dispersed or transient (such as migrant workers or Native Americans), where either type of group experiences common conditions of environmental exposure or effect. (See environmental justice and minority population.)

**low-level radioactive waste** – Waste that contains radioactivity but is not classified as high-level waste, transuranic waste, spent nuclear fuel, or by-product material as defined by Section 11e (2) of the Atomic Energy Act of 1954, as amended. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level waste, provided the concentration of transuranic waste is less than 100 nanocuries per gram.

**maximally exposed offsite individual** – A hypothetical individual whose location and habits result in the highest total radiological or chemical exposure (and thus dose) from a particular source for all exposure routes (e.g., inhalation, ingestion, direct exposure).

**maximum contaminant level** – The designation for U.S. Environmental Protection Agency standards for drinking water quality under the Safe Drinking Water Act. The maximum contaminant level for a given substance is the maximum permissible concentration of that substance in water delivered by a public water system. The primary maximum contaminant levels (40 CFR Part 141) are intended to protect public health and are federally enforceable. They are based on health factors, but are also required by law to reflect the technological and economic feasibility of removing the contaminant from the water supply. Secondary maximum contaminant levels (40 CFR Part 143) are set by the U.S. Environmental Protection Agency to protect the public welfare. The secondary drinking water regulations control substances in drinking water that primarily affect aesthetic qualities (such as taste, odor, and color) relating to the public acceptance of water. These regulations are not federally enforceable, but are intended as guidelines for the states.

**megawatt** – A unit of power equal to 1 million watts. Megawatt thermal is commonly used to define heat produced, while megawatt electric defines electricity produced.

**meteorology** – The science dealing with the atmosphere and its phenomena, especially as relating to weather.

**MeV (million electron volts)** – A unit used to quantify energy. In this NI PEIS, it describes a particle's kinetic energy, which is an indicator of particle speed.

**micron** – One-millionth of one meter.

**migration** – The natural movement of a material through the air, soil, or groundwater; also, seasonal movement of animals from one area to another.

**Migratory Bird Treaty Act** – This act states that it is unlawful to pursue, take, attempt to take, capture, possess, or kill any migratory bird, or any part, nest, or egg of any such bird other than permitted activities.

**millirem** – One-thousandth of one rem.

**minority population** – Minority populations exist where either: (a) the minority population of the affected area exceeds 50 percent or (b) the minority population percentage of the affected area is meaningfully greater than in the general population or other appropriate unit of geographic analysis (such as a governing body's jurisdiction, a neighborhood, census tract, or other similar unit). "Minority" refers to individuals who are members of the following population groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic. "Minority populations" include either a single minority group or the total of all minority persons in the affected area. They may consist of groups of individuals living in geographic proximity to one another or a geographically dispersed/transient set of individuals (such as migrant workers or Native Americans), where either type of group experiences common conditions of environmental exposure or effect. (See environmental justice and low-income population.)

**mitigate** – Mitigation includes: (1) avoiding an impact altogether by not taking a certain action or parts of an action; (2) minimizing impacts by

limiting the degree or magnitude of an action and its implementation; (3) rectifying an impact by repairing, rehabilitating, or restoring the affected environment; (4) reducing or eliminating the impact over time by preservation and maintenance operations during the life of an action; or (5) compensating for an impact by replacing or providing substitute resources or environments.

**mixed oxide fuel** – Reactor fuel made with a physical blend of different fissionable materials, such as uranium dioxide and plutonium dioxide.

**mixed waste** – Waste that contains both nonradioactive hazardous waste and radioactive waste, as defined in this glossary.

**moderator** – A material used to decelerate neutrons in a reactor from high energies to low energies.

**molar** – A chemical term relating to the mole, or gram-molecular weight. A 1-molar solution would have 1 mole of solute per liter of solution.

**National Ambient Air Quality Standards** – Standards defining the highest allowable levels of certain pollutants in the ambient air (i.e., the outdoor air to which the public has access). Because the U.S. Environmental Protection Agency must establish the criteria for setting these standards, the regulated pollutants are called *criteria* pollutants. Criteria pollutants include sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and two size classes of particulate matter (less than or equal to 10 micrometers [0.0004 inch] in diameter and less than or equal to 2.5 micrometers [0.0001 inch] in diameter). Primary standards are established to protect public health; secondary standards are established to protect public welfare (e.g., visibility, crops, animals, buildings). (See criteria pollutant.)

**National Emission Standards for Hazardous Air Pollutants** – Emissions standards set by the U.S. Environmental Protection Agency for air pollutants which are not covered by National Ambient Air Quality Standards and which may, at sufficiently high levels, cause increased fatalities, irreversible health effects, or incapacitating illness.

These standards are given in 40 CFR Parts 61 and 63. National Emission Standards for Hazardous Air Pollutants are given for many specific categories of sources (e.g., equipment leaks, industrial process cooling towers, dry cleaning facilities, petroleum refineries). (See hazardous air pollutants.)

**National Environmental Policy Act of 1969** –

This act is the basic national charter for protection of the environment. It establishes policy, sets goals (Section 101), and provides means (Section 102) for carrying out policy. Section 102(2) contains “action-forcing” provisions to ensure that Federal agencies follow the letter and spirit of the act. For major Federal actions significantly affecting the quality of the human environment, Section 102(2)(C) of the National Environmental Policy Act requires Federal agencies to prepare a detailed statement that includes the environmental impacts of the proposed action and other specified information.

**National Historic Preservation Act** – This act provides that property resources with significant national historic value be placed on the National Register of Historic Places. It does not require any permits, but pursuant to Federal code, if a proposed action might impact a historic property resource, it mandates consultation with the proper agencies.

**National Pollutant Discharge Elimination System** –

A provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by the U.S. Environmental Protection Agency, a state, or, where delegated, a tribal government on an Indian reservation. The National Pollutant Discharge Elimination System permit lists either permissible discharges, the level of cleanup technology required for wastewater, or both.

**National Register of Historic Places** –

The official list of the Nation’s cultural resources that are worthy of preservation. The National Park Service maintains the list under direction of the Secretary of the Interior. Buildings, structures, objects, sites, and districts are included in the

National Register for their importance in American history, architecture, archeology, culture, or engineering. Properties included on the National Register range from large-scale, monumentally proportioned buildings to smaller scale, regionally distinctive buildings. The listed properties are not just of nationwide importance; most are significant primarily at the state or local level. Procedures for listing properties on the National Register are found in 36 CFR Part 60.

**natural phenomena accidents** – Accidents that are initiated by phenomena such as earthquakes, tornadoes, floods, etc.

**natural uranium** – Uranium with the naturally occurring distribution of uranium isotopes (approximately 0.7-weight percent uranium-235, and the remainder essentially uranium-238). (See uranium, depleted uranium, enriched uranium, highly enriched uranium, and low-enriched uranium.)

**neptunium** – An element, mostly manmade, with the atomic number 93. Pure neptunium is a silvery metal. The neptunium-237 isotope has a half-life of 2.14 million years. When neptunium-237 is bombarded by neutrons, it is transformed to neptunium-238, which in turn undergoes radioactive decay to become plutonium-238. When neptunium-237 undergoes radioactive decay, it emits alpha particles and gamma rays.

**neutron** – An uncharged elementary particle with a mass slightly greater than that of the proton. Neutrons are found in the nucleus of every atom heavier than hydrogen-1.

**neutron flux** – The product of neutron number density and velocity (energy), giving an apparent number of neutrons flowing through a unit area per unit time.

**nitrogen** – A natural element with the atomic number 7. It is diatomic in nature and is a colorless and odorless gas that constitutes about four-fifths of the volume of the atmosphere.

**nitrogen oxides** – Refers to the oxides of nitrogen, primarily nitrogen oxide and nitrogen dioxide.

These are produced in the combustion of fossil fuels and can constitute an air pollution problem. Nitrogen dioxide emissions contribute to acid deposition and formation of atmospheric ozone.

**noise** – Any sound that is undesirable because it interferes with speech and hearing, or is intense enough to damage hearing, or is otherwise annoying or undesirable.

**nonattainment area** – An area that the U.S. Environmental Protection Agency has designated as not meeting (i.e., not being in attainment of) one or more of the National Ambient Air Quality Standards for sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and particulate matter. An area may be in attainment for some pollutants, but not for others. (See attainment area, National Ambient Air Quality Standards, and particulate matter.)

**normal operation** – All normal (incident-free) conditions and those abnormal conditions that frequency estimation techniques indicate occur with a frequency greater than 0.1 events per year.

**Notice of Intent** – Announces the scoping process. The Notice of Intent is usually published in the Federal Register and a local newspaper. The scoping process includes holding at least one public meeting and requesting written comments on issues and environmental concerns that an environmental impact statement should address.

**nuclear criticality** – See criticality.

**nuclear facility** – A facility that is subject to requirements intended to control potential nuclear hazards. Defined in DOE directives as any nuclear reactor or any other facility whose operations involve radioactive materials in such form and quantity that a significant nuclear hazard potentially exists to the employees or the general public.

**nuclear fuel cycle** – The path followed by the nuclear fuel in its various states from mining the ore to waste disposal. The basic fuel materials for the generation of nuclear power are the elements uranium and thorium.

**nuclear grade** – Material of a quality adequate for use in a nuclear application.

**nuclear material** – Composite term applied to: (1) special nuclear material; (2) source material such as uranium or thorium or ores containing uranium or thorium; and (3) by-product material, which is any radioactive material that is made radioactive by exposure to the radiation incident to the process of producing or using special nuclear material.

**nuclear radiation** – Particles (alpha, beta, neutrons) or photons (gamma) emitted from the nucleus of unstable radioactive atoms as a result of radioactive decay.

**nuclear reactor** – A device that sustains a controlled nuclear fission chain reaction that releases energy in the form of heat.

**Nuclear Regulatory Commission** – The Federal agency that regulates the civilian nuclear power industry in the United States.

**nuclide** – A species of atom characterized by the constitution of its nucleus and hence by the number of protons, the number of neutrons, and the energy content.

**Occupational Safety and Health Administration** – Oversees and regulates workplace health and safety; created by the Occupational Safety and Health Act of 1970.

**offsite** – The term denotes a location, facility, or activity occurring outside of the site boundary.

**outfall** – The discharge point of a drain, sewer, or pipe as it empties into a body of water.

**ozone** – The triatomic form of oxygen; in the stratosphere, ozone protects the Earth from the sun's ultraviolet rays, but in lower levels of the atmosphere, ozone is considered an air pollutant.

**package** – For radioactive materials, the packaging, together with its radioactive contents, as presented for transport (the packaging plus the radioactive contents equals the package).

**packaging** – With regard to hazardous or radionuclide materials, the assembly of components necessary to ensure compliance with Federal regulations. It may consist of one or more receptacles, absorbent materials, spacing structures, thermal insulation, radiation shielding, and devices for cooling or absorbing mechanical shocks. The vehicle tie-down system and auxiliary equipment may be designated as part of the packaging.

**particulate matter** – Any finely divided solid or liquid material, other than uncombined (i.e., pure) water. A subscript denotes the upper limit of the diameter of particles included. Thus, PM<sub>10</sub> includes only those particles equal to or less than 10 micrometers (0.0004 inch) in diameter; PM<sub>2.5</sub> includes only those particles equal to or less than 2.5 micrometers (0.0001 inch) in diameter.

**permeability** – In geology, the ability of rock or soil to transmit a fluid.

**person-rem** – A unit of collective radiation dose applied to populations or groups of individuals (see collective dose); that is, a unit for expressing the dose when summed across all persons in a specified population or group. One person-rem equals 0.01 person-sieverts.

**phenolic protective coating** – A coating material made from the chemical, phenol.

**plume** – The elongated volume of contaminated water or air originating at a pollutant source such as an outlet pipe or a smokestack. A plume eventually diffuses into a larger volume of less contaminated material as it is transported away from the source.

**plutonium** – A heavy, radioactive, metallic element with the atomic number 94. It is produced artificially by neutron bombardment of uranium. Plutonium has 15 isotopes with atomic masses ranging from 232 to 246 and half-lives from 20 minutes to 76 million years.

**plutonium-238** – An isotope with a half-life of 87.74 years used as the heat source for radioisotope power systems. When plutonium-238

undergoes radioactive decay, it emits alpha particles and gamma rays.

**plutonium-239** – An isotope with a half-life of 24,110 years and is the primary radionuclide in weapons-grade plutonium. When plutonium-239 decays, it emits alpha particles.

**population dose** – See collective dose.

**pounds per square inch** – A measure of pressure; atmospheric pressure is about 14.7 pounds per square inch.

**Prevention of Significant Deterioration** – Regulations established to prevent significant deterioration of air quality in areas that already meet National Ambient Air Quality Standards. Specific details of Prevention of Significant Deterioration are found in 40 CFR Section 51.166. Among other provisions, cumulative increases in sulfur dioxide, nitrogen dioxide, and PM<sub>10</sub> levels after specified baseline dates must not exceed specified maximum allowable amounts. These allowable increases, also known as increments, are especially stringent in areas designated as Class I areas (e.g., national parks, wilderness areas) where the preservation of clean air is particularly important. All areas not designated as Class I are currently designated as Class II. Maximum increments in pollutant levels are also given in 40 CFR Section 51.166 for Class III areas, if any such areas should be so designated by EPA. Class III increments are less stringent than those for Class I or Class II areas. (See National Ambient Air Quality Standards.)

**primary system** – With regard to nuclear reactors, the system that circulates a coolant (e.g., water) through the reactor core to remove the heat of reaction.

**prime farmland** – Land that has the best combination of physical and chemical characteristics for producing food, feed, fiber, forage, oil-seed, and other agricultural crops with minimum inputs of fuel, fertilizer, pesticides, and labor, without intolerable soil erosion, as determined by the Secretary of Agriculture

(Farmland Protection Act of 1981, 7 CFR Part 7, paragraph 658).

**probabilistic risk assessment** – A comprehensive, logical, and structured methodology that accounts for population dynamics and human activity patterns at various levels of sophistication, considering time-space distributions and sensitive subpopulations. The probabilistic method results in a more complete characterization of the exposure information available, which is defined by probability distribution functions. This approach offers the possibility of an associated quantitative measure of the uncertainty around the value of interest.

**process** – Any method or technique designed to change the physical or chemical character of the product.

**protactinium** – An element that is produced by the radioactive decay of neptunium-237. The pure metal has a bright metallic luster. The protactinium-233 isotope has a half-life of 27 days and emits beta particles and gamma rays during radioactive decay.

**proton** – An elementary nuclear particle with a positive charge equal in magnitude to the negative charge of the electron; it is a constituent of all atomic nuclei, and the atomic number of an element indicates the number of protons in the nucleus of each atom of that element.

**PUREX** – An acronym for Plutonium-Uranium Extraction, the name of the chemical process usually used to remove plutonium and uranium from spent nuclear fuel, irradiated targets, and other nuclear materials.

**purpose-built vessel** – A vessel specifically designed to carry nuclear fuel casks.

**rad** – See radiation absorbed dose.

**radiation (ionizing)** – See ionizing radiation.

**radiation absorbed dose (rad)** – The basic unit of absorbed dose equal to the absorption of 0.01 joule

per kilogram (100 ergs per gram) of absorbing material.

**radioactive waste** – In general, waste that is managed for its radioactive content. Waste material that contains source, special nuclear, or by-product material is subject to regulation as radioactive waste under the Atomic Energy Act. Also, waste material that contains accelerator-produced radioactive material or a high concentration of naturally occurring radioactive material may be considered radioactive waste.

**radioactivity** – *Defined as a process:* The spontaneous transformation of unstable atomic nuclei, usually accompanied by the emission of ionizing radiation.

*Defined as a property:* The property of unstable nuclei in certain atoms to spontaneously emit ionizing radiation during nuclear transformations.

**Radiochemical Engineering Development Center** – A chemical processing facility at the Oak Ridge National Laboratory used for processing highly radioactive materials in hot cells using remote handling equipment. The REDC complex consists of Buildings 7920 and 7930.

**radioisotope or radionuclide** – An unstable isotope that undergoes spontaneous transformation, emitting radiation. (See isotopes.)

**radon** – A gaseous, radioactive element with the atomic number 86, resulting from the radioactive decay of radium. Radon occurs naturally in the environment and can collect in unventilated enclosed areas, such as basements. Large concentrations of radon can cause lung cancer in humans.

**RADTRAN** – A computer code combining user-determined meteorological, demographic, transportation, packaging, and material factors with health physics data to calculate the expected radiological consequences and accident risk of transporting radioactive material.

**reactor accident** – See design-basis accident and severe accident.

**reactor coolant system** – The system used to transfer energy from the reactor core either directly or indirectly to the heat rejection system.

**reactor core** – The fuel assemblies, fuel and target rods, control rods, blanket assemblies, and coolant/moderator. Fissioning takes place in this part of the reactor.

**reactor facility** – Unless it is modified by words such as containment, vessel, or core, the term reactor facility includes the housing, equipment, and associated areas devoted to the operation and maintenance of one or more reactor cores. Any apparatus that is designed or used to sustain nuclear chain reactions in a controlled manner, including critical and pulsed assemblies and research, tests, and power reactors, is defined as a reactor. All assemblies designed to perform subcritical experiments that could potentially reach criticality are also considered reactors.

**Record of Decision** – A document prepared in accordance with the requirements of 40 CFR Section 1505.2 and 10 CFR Section 1021.315 that provides a concise public record of the U.S. Department of Energy's decision on a proposed action for which an environmental impact statement was prepared. A Record of Decision identifies the alternatives considered in reaching the decision, the environmentally preferable alternative, factors balanced by the U.S. Department of Energy in making the decision, whether all practicable means to avoid or minimize environmental harm have been adopted, and, if not, the reason why they were not.

**reductant** – A chemical that is used to reduce the oxidation state (ionic charge) of another chemical.

**reference concentration** – It is an estimate of a toxic chemical daily inhalation of the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Those effects are both to the respiratory system (portal-of-entry) and the peripheral to the respiratory system (extra-respiratory effects). It is expressed in units of microgram per cubic meter.

**refueling outage** – The period of time that a reactor is shut down for refueling operations.

**region of influence** – A site-specific geographic area in which the principal direct and indirect effects of actions are likely to occur, and are expected to be of consequence for local jurisdictions.

**regional economic area** – A geographic area consisting of an economic node and the surrounding counties that are economically related, and include the places of work and residences of the labor force. Each regional economic area is defined by the U.S. Bureau of Economic Analysis.

**regulated substances** – A general term used to refer to materials other than radionuclides that may be regulated by other applicable Federal, state, or local requirements.

**rem (roentgen equivalent man)** – A unit of dose equivalent. The dose equivalent in rems equals the absorbed dose in rads in tissue multiplied by the appropriate quality factor and possibly other modifying factors. Derived from “roentgen equivalent man,” referring to the dosage of ionizing radiation that will cause the same biological effect as one roentgen of x-ray or gamma-ray exposure. One rem equals 0.01 sievert. (See absorbed dose and dose equivalent.)

**remediation** – The process, or a phase in the process, of rendering radioactive, hazardous, or mixed waste environmentally safe, whether through processing, entombment, or other methods.

**remote-handled waste** – In general, refers to radioactive waste that must be handled at a distance to protect workers from unnecessary exposure (e.g., waste with a dose rate of 200 millirem per hour or more at the surface of the waste package). (See contact-handled waste.)

**resin** – See ion exchange resin.

**Resource Conservation and Recovery Act, as Amended** – A law that gives the U.S. Environmental Protection Agency the

authority to control hazardous waste from “cradle to grave” (i.e., from the point of generation to the point of ultimate disposal), including its minimization, generation, transportation, treatment, storage, and disposal. The Resource Conservation and Recovery Act also sets forth a framework for the management of nonhazardous solid wastes. (See hazardous waste.)

**riparian** – Of, on, or relating to the banks of a natural course of water.

**risk** – The probability of a detrimental effect from exposure to a hazard. Risk is often expressed quantitatively as the probability of an adverse event occurring multiplied by the consequence of that event (i.e., the product of these two factors). However, separate presentation of probability and consequence is often more informative.

**risk assessment (chemical or radiological)** – The qualitative and quantitative evaluation performed in an effort to define the risk posed to human health and/or the environment by the presence or potential presence and/or use of specific chemical or radiological materials.

**roentgen** – A unit of exposure to ionizing x- or gamma radiation equal to or producing one electrostatic unit of charge per cubic centimeter of air.

**runoff** – The portion of rainfall, melted snow, or irrigation water that flows across the ground surface, and eventually enters streams.

**Safe Drinking Water Act** – This act protects the quality of public water supplies, water supply and distribution systems, and all sources of drinking water.

**safe, secure trailer** – A specially modified semi-trailer, pulled by an armored tractor truck, which DOE uses to transport nuclear weapons, nuclear weapons components, or special nuclear material over public highways.

**safeguards** – An integrated system of physical protection, material accounting, and material control measures designed to deter, prevent, detect,

and respond to unauthorized access, possession, use, or sabotage of nuclear materials.

**safety analysis report** – A report that systematically identifies potential hazards within a nuclear facility, describes and analyzes the adequacy of measures to eliminate or control identified hazards, and analyzes potential accidents and their associated risks. Safety analysis reports are used to ensure that a nuclear facility can be constructed, operated, maintained, shut down, and decommissioned safely and in compliance with applicable laws and regulations. Safety analysis reports are required for the U.S. Department of Energy nuclear facilities and as a part of applications for U.S. Nuclear Regulatory Commission licenses. The U.S. Nuclear Regulatory Commission regulations or DOE orders and technical standards that apply to the facility type provide specific requirements for the content of safety analysis reports. (See nuclear facility.)

**safety evaluation report** – A document prepared by the U.S. Nuclear Regulatory Commission that evaluates documentation (i.e., technical specifications, safety analysis reports, and special safety reviews and studies) submitted by a reactor licensee for its approval. This ensures all of the safety aspects of part or all of the activities conducted at a reactor are formally and thoroughly analyzed, evaluated, and recorded.

**sanitary waste** – Wastes generated by normal housekeeping activities, liquid or solid (includes sludge), which are not hazardous or radioactive.

**scope** – In a document prepared pursuant to the National Environmental Policy Act of 1969, the range of actions, alternatives, and impacts to be considered.

**scoping** – An early and open process for determining the scope of issues to be addressed in an environmental impact statement and for identifying the significant issues related to a proposed action. The scoping period begins after publication in the Federal Register of a Notice of Intent to prepare an environmental impact statement. The public scoping process is that portion of the process where the public is invited to

participate. The U.S. Department of Energy also conducts an early internal scoping process for environmental assessments or environmental impact statements. For environmental impact statements, this internal scoping process precedes the public scoping process. The U.S. Department of Energy's scoping procedures are found in 10 CFR Section 1021.311.

**security** – An integrated system of activities, systems, programs, facilities, and policies for the protection of restricted data and other classified information or matter, nuclear materials, nuclear weapons and nuclear weapons components, and/or DOE contractor facilities, property, and equipment.

**seismic** – Pertaining to any Earth vibration, especially an earthquake.

**severe accident** – An accident with a frequency rate of less than  $10^{-6}$  per year that would have more severe consequences than a design-basis accident, in terms of damage to the facility, offsite consequences, or both. Also called “beyond-design-basis reactor accidents” in this NIPeIS.

**sewage** – The total organic waste and wastewater generated by an industrial establishment or a community.

**shielding** – With regard to radiation, any material of obstruction (bulkheads, walls, or other construction) that absorbs radiation in order to protect personnel or equipment.

**short-lived activation products** – An element formed from neutron interaction that has a relatively short half-life, which is not produced from the fission reaction (e.g., a cobalt isotope formed from impurities in the metal of the reactor piping).

**short-lived nuclides** – Radioactive isotopes with half-lives no greater than about 30 years (e.g., cesium-137 and strontium-90).

**shutdown** – For a U.S. Department of Energy reactor, the condition in which a reactor has ceased operation, and DOE has officially declared that it does not intend to operate it further.

**sievert** – The SI (International System of Units) unit of radiation dose equivalent. The dose equivalent in sieverts equals the absorbed dose in grays multiplied by the appropriate quality factor (1 sievert is equal to 100 rem). (See gray.)

**silica gel** – An amorphous, highly adsorbent form of silicon dioxide.

**silt** – A sedimentary material consisting of fine mineral particles, intermediate in size between sand and clay.

**sinter** – A process in which particles are bonded together by pressure and heating below the melting point.

**solvent extraction** – A process that uses two solvents that do not mix (usually water and an organic solvent) to separate chemicals. An organic soluble chemical is usually added to the organic solvent to selectively extract a chemical from the aqueous solution into the organic solution when they are mixed. After the settling, the two solvents are separated from one another, and the desired chemical is removed from the organic solvent.

**source term** – The amount of a specific pollutant (e.g., chemical, radionuclide) emitted or discharged to a particular environmental medium (e.g., air, water) from a source or group of sources. It is usually expressed as a rate (i.e., amount per unit time).

**spallation** – A nuclear reaction in which light particles are ejected as the result of bombardment (as by high-energy protons).

**special nuclear materials** – As defined in Section 11 of the Atomic Energy Act of 1954, special nuclear material means: (1) plutonium, uranium enriched in the isotope 233 or in the isotope 235, and any other material which the U.S. Nuclear Regulatory Commission determines to be special nuclear material; or (2) any material artificially enriched by any of the above. Tritium is not a special nuclear material.

**sulfur oxides** – Common air pollutants, primarily sulfur dioxide, a heavy, pungent, colorless gas

(formed in the combustion of fossil fuels, considered a major air pollutant) and sulfur trioxide. Sulfur dioxide is involved in the formation of acid rain. It can also irritate the upper respiratory tract and cause lung damage.

**supernatant** – The liquid that stands over a precipitated material.

**surface water** – All bodies of water on the surface of the earth and open to the atmosphere, such as rivers, lakes, reservoirs, ponds, seas, and estuaries.

**target** – A tube, rod, or other form containing material that on being irradiated in a nuclear reactor or an accelerator would produce a desired end product.

**technical specifications** – With regard to U.S. Nuclear Regulatory Commission regulations, part of a U.S. Nuclear Regulatory Commission license authorizing the operation of a nuclear reactor facility. A technical specification establishes requirements for items such as safety limits, limiting safety system settings, limiting control settings, limiting conditions for operation, surveillance requirements, design features, and administrative controls.

**threatened species** – Any plants or animals that are likely to become endangered species within the foreseeable future throughout all or a significant portion of their ranges and which have been listed as threatened by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service following the procedures set out in the Endangered Species Act and its implementing regulations (50 CFR Part 424). (See endangered species.)

The lists of threatened species can be found at 50 CFR Sections 17.11 (wildlife), 17.12 (plants), and 227.4 (marine organisms).

**threshold limit values** – The recommended highest concentrations of contaminants to which workers may be exposed according to the American Conference of Governmental Industrial Hygienists.

**total effective dose equivalent** – The sum of the effective dose equivalent from external exposures and the committed effective dose equivalent from internal exposures.

**Toxic Substances Control Act of 1976** – This act authorizes the U.S. Environmental Protection Agency to secure information on all new and existing chemical substances and to control any substances determined to cause an unreasonable risk to public health or the environment. This law requires that the health and environmental effects of all new chemicals be reviewed by the U.S. Environmental Protection Agency before they are manufactured for commercial purposes.

**transients** – Events that could cause a change or disruption of plant thermal, hydraulic, or neutronic behavior.

**transuranic** – Refers to any element whose atomic number is higher than that of uranium (atomic number 92), including neptunium, plutonium, americium, and curium. All transuranic elements are produced artificially and are radioactive.

**transuranic waste** – Radioactive waste that is not classified as high-level radioactive waste and that contains more than 100 nanocuries (3700 becquerels) per gram of alpha-emitting transuranic isotopes with half-lives greater than 20 years.

**Type B packaging** – A regulatory category of packaging for transportation of radioactive material. The U.S. Department of Transportation and U.S. Nuclear Regulatory Commission require Type B packaging for shipping highly radioactive material. Type B packages must be designed and demonstrated to retain their containment and shielding integrity under severe accident conditions, as well as under the normal conditions of transport. The current U.S. Nuclear Regulatory Commission testing criteria for Type B package designs (10 CFR Part 71) are intended to simulate severe accident conditions, including impact, puncture, fire, and immersion in water. The most widely recognized Type B packages are the massive casks used for transporting spent nuclear fuel. Large-capacity cranes and mechanical lifting

equipment are usually needed to handle Type B packages.

**Type B shipping cask** – A U.S. Nuclear Regulatory Commission-certified cask with a protective covering that contains and shields radioactive materials, dissipates heat, prevents damage to the contents, and prevents criticality during normal shipment and accident conditions. It is used for transport of highly radioactive materials and is tested under severe, hypothetical accident conditions that demonstrate resistance to impact, puncture, fire, and submersion in water.

**unit cancer risk** – The likelihood that the substance is a human carcinogen and quantitatively gives an estimate of risk from oral exposure or from inhalation exposure. This estimate can be in terms of either risk per microgram per liter of drinking water or risk per microgram per cubic meter of air breathed.

**uranium** – A radioactive, metallic element with the atomic number 92; one of the heaviest naturally occurring elements. Uranium has 14 known isotopes, of which uranium-238 is the most abundant in nature. Uranium-235 is commonly used as a fuel for nuclear fission. (See natural uranium, enriched uranium, highly enriched uranium, and depleted uranium.)

**viewshed** – The extent of an area that may be viewed from a particular location. Viewsheds are generally bounded by topographic features such as hills or mountains.

**visual resource management class** – Any of the classifications of visual resources established through application of the Visual Resources Management process of the Bureau of Land Management. Four classifications are employed to describe different degrees of modification to landscape elements: Class I, areas where the natural landscape is preserved, including national wilderness areas and the wild sections of national wild and scenic rivers; Class II, areas with very limited land development activity, resulting in visual contrasts that are seen but do not attract attention; Class III, areas in which development may attract attention, but the natural landscape still

dominates; Class IV, areas in which development activities may dominate the view and may be the major focus in the landscape.

**volatile organic compounds** – A broad range of organic compounds, often halogenated, that vaporize at ambient or relatively low temperatures, such as benzene, chloroform, and methyl alcohol. With regard to air pollution, any organic compound that participates in atmospheric photochemical reaction, except for those designated by the U.S. Environmental Protection Agency administrator as having negligible photochemical reactivity.

**waste acceptance criteria** – The requirements specifying the characteristics of waste and waste packaging acceptable to a disposal facility, and the documents and processes the generator needs to certify that the waste meets applicable requirements.

**waste classification** – Wastes are classified according to DOE Order 435.1, *Radioactive Waste Management*, and include high-level, transuranic, and low-level wastes.

**Waste Isolation Pilot Plant** – A U.S. Department of Energy facility designed and authorized to permanently dispose of transuranic radioactive waste in a mined underground facility in deep geologic salt beds. It is located in southeastern New Mexico, 42 kilometers (26 miles) east of the city of Carlsbad.

**waste management** – The planning, coordination, and direction of those functions related to generation, handling, treatment, storage, transportation, and disposal of waste, as well as associated surveillance and maintenance activities.

**waste minimization and pollution prevention** – An action that economically avoids or reduces the generation of waste and pollution by source reduction, reducing the toxicity of hazardous waste and pollution, improving energy use, or recycling. These actions will be consistent with the general goal of minimizing present and future threats to human health, safety, and the environment.

**weighting factor** – Generally, a method of attaching different importance values to different items or characteristics. In the context of radiation protection, the proportion of the risk of effects resulting from irradiation of a particular organ or tissue to the total risk of effects when the whole body is irradiated uniformly (e.g., the organ dose weighting factor for the lung is 0.12, compared to 1.0 for the whole body). Weighting factors are used for calculating the effective dose equivalent.

**whole-body dose** – With regard to radiation, dose resulting from the uniform exposure of all organs and tissues in a human body. (See effective dose equivalent.)

**wind rose** – A circular diagram showing, for a specific location, the percentage of the time the wind is from each compass direction. A wind rose for use in assessing consequences of airborne releases also shows the frequency of different wind speeds for each compass direction.

**Zircaloy** – An alloy of zirconium containing tin, iron, chromium, and nickel.

## Chapter 9

### Index

#### 300 Area of Hanford

2-43, 3-1, 3-90–3-92, 3-94, 3-95, 3-98,  
3-101, 3-102, 3-105, 3-109, 3-113, 3-116,  
3-119–3-122, 3-124–3-126, 3-128, 3-131,

# FINAL Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility

## Volume 2 Appendixes

Cover photograph and illustration identification, beginning at top center and going clockwise:

- Radioisotope tagged monoclonal antibodies, “smart bullets,” target malignant cells for diagnosis and treatment of diseases
- The Fast Flux Test Facility at the Hanford Site near Richland, Washington
- Illustration of a satellite that could use radioisotope power systems
- The High Flux Isotope Reactor at the Oak Ridge National Laboratory near Oak Ridge, Tennessee
- The Advanced Test Reactor at the Idaho National Engineering and Environmental Laboratory near Idaho Falls, Idaho
- Tip of a remote-handling arm, used for work in developing industrial and medical isotopes

### **AVAILABILITY OF THE FINAL NI PEIS**

General questions regarding this PEIS or for a copy of this PEIS, please contact:

Colette E. Brown, Document Manager  
Office of Space and Defense Power Systems (NE-50)  
Office of Nuclear Energy, Science and Technology  
U.S. Department of Energy  
19901 Germantown Road  
Germantown, MD 20874  
Attention: NI PEIS  
Telephone: (877) 562-4593  
E-mail: Nuclear.Infrastructure-PEIS@hq.doe.gov

This PEIS is accessible on the Office of Nuclear Energy, Science and Technology web site at [www.nuclear.gov](http://www.nuclear.gov).

*Printed with soy ink on recycled paper*

## Cover Sheet

**Responsible Agency:** United States Department of Energy (DOE)

**Title:** *Final Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (NI PEIS)*

**Locations:** Idaho, Tennessee, Washington

**Contacts:** For copies of this programmatic environmental impact statement (PEIS), call toll-free (877) 562-4593

For additional information on this Final PEIS, contact:

Colette E. Brown, Document Manager  
Office of Space and Defense Power  
Systems (NE-50)  
Office of Nuclear Energy, Science and Technology  
U.S. Department of Energy  
19901 Germantown Road  
Germantown, MD 20874  
Attention: NI PEIS  
Telephone: (877) 562-4593

For general information on the DOE National Environmental Policy Act (NEPA) process, contact:

Carol M. Borgstrom, Director  
Office of NEPA Policy and Compliance (EH-42)

Telephone: (202) 586-4600, or leave a message  
at (800) 472-2756

**Abstract:** Under the authority of the Atomic Energy Act of 1954, as amended, the DOE is responsible for ensuring the availability of isotopes for medical, industrial and research applications, meeting the nuclear material needs of other Federal agencies, and undertaking research and development activities related to development of nuclear power for civilian use. To meet these responsibilities, DOE maintains nuclear infrastructure capabilities that support various missions. Current estimates for the future needs of medical and industrial isotopes, plutonium-238, and research requirements indicate that the current infrastructure may soon be insufficient to meet the projected demands. DOE proposes to enhance these capabilities to provide for: (1) production of isotopes for medical and industrial uses, (2) production of plutonium-238 for use in advanced radioisotope power systems for future National Aeronautics and Space Administration (NASA) space exploration missions, and (3) the Nation's nuclear research and development needs for civilian application.

This NI PEIS evaluates the environmental impacts of a No Action Alternative (maintaining status quo), four alternative strategies to accomplish this mission, and an alternative to permanently deactivate the Fast Flux Test Facility (FFTF), with no new missions. Alternatives 2, 3, and 4 also include permanent deactivation of FFTF. The alternatives are:

- No Action
1. Restart FFTF at Hanford, Washington
  2. Use only existing operational facilities
  3. Construct one or two new accelerators
  4. Construct a new research reactor
  5. Permanently deactivate FFTF (with no new missions)

The Preferred Alternative is Alternative 2, Option 7, Use Only Existing Operational Facilities. DOE would reestablish domestic production of plutonium-238, as needed, using the Advanced Test Reactor in Idaho and the High Flux Isotope Reactor in Tennessee, and would process irradiated plutonium-238 targets at the Radiochemical Engineering Development Center in Tennessee. DOE would permanently deactivate FFTF under the Preferred Alternative.

**Public Comments:** The Draft NI PEIS was issued for public review and comment on July 21, 2000. The comment period ended on September 18, 2000, although late comments were considered to the extent practicable. Public hearings were held to obtain comments on the Draft NI PEIS in Oak Ridge, Tennessee; Idaho Falls, Idaho; Hood River and Portland, Oregon; Seattle and Richland, Washington; and Arlington, Virginia. All comments were considered by DOE in preparing the Final NI PEIS, which also incorporates any new information received since issuance of the Draft NI PEIS. In response to comments on the Draft NI PEIS and as a result of information that was unavailable at the time of the issuance of the Draft PEIS, the Final PEIS contains revisions and new information, indicated by a sidebar in the margin. Volume 3 contains the comments received during the public review period for the Draft NI PEIS and DOE's responses to these comments. DOE will use the analyses presented in the Final NI PEIS as well as other information, including public input, costs, nonproliferation impacts, schedules, technical assurance, and other policy and programmatic objectives, in preparing the Record of Decision for accomplishing expanded civilian nuclear energy research and development and isotope production missions in the United States, including the role of FFTF. DOE will issue the Record of Decision no sooner than 30 days after the U.S. Environmental Protection Agency publishes a notice of availability of the Final NI PEIS in the Federal Register.

#### Appendix A

<b>Neptunium-237 Target Fabrication and Processing Operations for Plutonium-238 Production .....</b>	<b>A-1</b>
A.1 Radiochemical Engineering Development Center .....	A-1
A.1.1 Facility Description .....	A-1
A.1.2 Neptunium-237 Storage .....	A-4
A.1.3 Neptunium-237 Target Fabrication Process Description .....	A-5
A.1.3.1 Neptunium-237 Purification .....	A-5
A.1.3.2 Neptunium Oxide Production .....	A-6
A.1.3.3 Neptunium-237 Target Fabrication .....	A-7
A.1.4 Postirradiation Target Processing Description .....	A-7
A.1.4.1 Target Dissolution .....	A-7
A.1.4.2 Plutonium Separation and Neptunium Recycling .....	A-9
A.1.4.3 Plutonium Purification and Preparation of Plutonium Oxide .....	A-9
A.1.5 Plutonium-238 Storage Description .....	A-10
A.2 Fluorinel Dissolution Process Facility .....	A-10
A.2.1 Facility Description .....	A-10
A.2.2 Neptunium Storage .....	A-11
A.2.3 Neptunium-237 Target Fabrication Process Description .....	A-11
A.2.3.1 Neptunium-237 Purification .....	A-11
A.2.3.2 Neptunium Oxide Production .....	A-14
A.2.3.3 Neptunium-237 Target Fabrication .....	A-14
A.2.4 Postirradiation Processing Description .....	A-14
A.2.4.1 Target Dissolution .....	A-14
A.2.4.2 Plutonium Separation and Neptunium Recycling .....	A-15
A.2.4.3 Preparation of Plutonium Oxide .....	A-15
A.2.5 Plutonium-238 Storage Description .....	A-16
A.3 Fuels and Materials Examination Facility .....	A-16
A.3.1 Facility Description .....	A-16
A.3.2 Neptunium Storage .....	A-18
A.3.3 Neptunium-237 Target Fabrication Process Description .....	A-18
A.3.3.1 Neptunium-237 Purification .....	A-18
A.3.3.2 Neptunium Oxide Production .....	A-19
A.3.3.3 Neptunium-237 Target Fabrication .....	A-19
A.3.4 Postirradiation Processing Description .....	A-19
A.3.4.1 Target Dissolution .....	A-19
A.3.4.2 Plutonium Separation and Neptunium Recycling .....	A-19
A.3.4.3 Preparation of Plutonium Oxide .....	A-20

A.3.5	Plutonium-238 Storage Description .....	A-20
A.4	References .....	A-21

**Appendix B**

	<b>Neptunium-237 Target Irradiation Operations in Currently Operating Reactors for Plutonium-238 Production</b> .....	B-1
B.1	Advanced Test Reactor .....	B-1
B.1.1	Facility Description .....	B-1
B.1.2	Process Description .....	B-6
B.2	High Flux Isotope Reactor .....	B-6
B.2.1	Facility Description .....	B-6
B.2.2	Process Description .....	B-13
B.3	Commercial Light Water Reactor .....	B-14
B.3.1	Facility Description .....	B-14
B.3.2	Process Description .....	B-18
B.4	References .....	B-21

## List of Acronyms

AAA	Advanced Accelerator Applications
ALARA	as low as is reasonably achievable
ALOHA	Area Locations of Hazardous Atmospheres
ATR	Advanced Test Reactor
ATW	Accelerator Transmutation of Waste
BEIR	Biological Effects of Ionizing Radiation
BLIP	Brookhaven LINAC Isotope Producer
CEQ	Council on Environmental Quality
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
CFR	Code of Federal Regulations
CLWR	commercial light water reactor
CPP-651	Chemical Processing Plant 651 (Building CPP-651)
dBa	decibels A-weighted
DOD	U.S. Department of Defense
DOE	U.S. Department of Energy
DOT	U.S. Department of Transportation
EIS	environmental impact statement
EPA	U.S. Environmental Protection Agency
FDPF	Fluorinel Dissolution Process Facility
FFTF	Fast Flux Test Facility
FMEF	Fuels and Materials Examination Facility
FONSI	Finding of No Significant Impact
FPF	Fuel Processing Facility
FR	Federal Register
g	gravitational acceleration
Hanford	Hanford Site
HB	horizontal beam
HEPA	high-efficiency particulate air (filter)
HFIR	High Flux Isotope Reactor
HVAC	heating, ventilating, and air conditioning
I <sup>4</sup>	International Isotopes Idaho, Inc.
IAEA	International Atomic Energy Agency
IEM	Interim Examination and Maintenance Cell
INEEL	Idaho National Engineering and Environmental Laboratory
INTEC	Idaho Nuclear Technology and Engineering Center
IPF	Isotope Production Facility
ISC3	Industrial Source Complex
ISCST3	Industrial Source Complex (short-term model)
LANL	Los Alamos National Laboratory
LANSCE	Los Alamos Neutron Science Center
LCF	latent cancer fatality
LINAC	linear accelerator
MASF	Maintenance and Storage Facility

### Neptunium-237 Target Irradiation Operations in Currently Operating Reactors for Plutonium-238 Production

Neptunium-237 targets can be irradiated with neutrons to produce the plutonium-238 used in heat sources that support National Aeronautics and Space Administration (NASA) missions. The U.S. Department of Energy (DOE) has identified two of its currently operating reactors that have the potential to provide these irradiation services—the Advanced Test Reactor (ATR) at the Idaho National Engineering and Environmental Laboratory (INEEL) and the High Flux Isotope Reactor (HFIR) at the Oak Ridge Reservation (ORR). A currently operating commercial light water reactor (CLWR) of generic pressurized water reactor design has also been proposed by DOE as a possible source for the irradiation of the neptunium-237 targets. This possibility evolved as a result of DOE's request for Expressions of Interest posted in the January 4, 1999, issue of *Commerce Business Daily* (DOE 1999a).

It is anticipated that the plutonium-238 needed for the NASA missions would be produced for a period of approximately 35 years. The production of this plutonium-238 would not affect the capability of the DOE reactors to support other existing DOE missions or of the CLWR to produce commercial electricity.

Each of the reactor sites has security measures in place, including access control, and procedures to ensure the adequate protection of all materials processed and stored. Descriptions of the reactors and the plutonium-238 production processes specific to each reactor are provided in this appendix.

#### B.1 ADVANCED TEST REACTOR

##### B.1.1 Facility Description

ATR, located at INEEL, is one of the world's largest and most technologically advanced reactor test facilities. Special features of ATR include high neutron flux levels (ranging from  $1 \times 10^{15}$  neutrons per square centimeter per second in the flux traps to  $1 \times 10^{13}$  neutrons per square centimeter per second in the outer reflector positions) and the ability to vary power to fit different experiment needs in different test positions. The main purpose of ATR is to provide a prototypical reactor test environment for the study of radiation effects on materials and fuel. It is also used to produce radioisotopes for medical, industrial, and research uses. This facility description is based on information provided in the *Advanced Test Reactor, Upgraded Final Safety Analysis Report* (LMIT 1997) and *Capabilities of the Test Reactor Area Featuring the Advanced Test Reactor* (LMIT 1995).

ATR is located within the Test Reactor Area in the southwest portion of INEEL. The reactor, its primary coolant system, control room, and much of its auxiliary and experimental support equipment are located in Building 670. ATR began operation in 1967 and is expected to continue operating for several decades. The reactor vessel is entirely stainless steel and the core internals are replaced every 7 to 9 years, bringing the reactor to an essentially like-new condition (the most recent changeout was completed in 1994 [LMIT 1995]). Buildings and structures in other parts of the Test Reactor Area provide additional support functions.

ATR is a light-water-moderated and -cooled reactor with a design thermal power of 250 megawatts. The reactor typically operates at approximately 140 megawatts or less. Typical operating cycles are 42 days or 49 days at power followed by a 7-day outage for refueling and changeout of experiments and isotope production targets. The core is 1.2 meters (4 feet) high and is surrounded by a 1.3-meter-diameter (4.25-foot-diameter) beryllium reflector. Beryllium is an excellent neutron reflector and is used to enhance the neutron flux essential to a test reactor. The location of the core in the ATR vessel is shown in **Figure B-1**. ATR has nine flux traps in its core and achieves a close integration of flux traps and fuel by means of a

Figure B-1 Vertical Cross Section of the ATR Vessel

serpentine fuel arrangement (**Figure B-2**). When viewed from above, the ATR fuel region resembles a four-leaf clover. The four flux traps positioned within the four lobes of the reactor core are almost entirely surrounded by fuel, as is the center position. Four other flux trap positions between the lobes of the core have fuel on three sides. The ATR's unique control device design permits large power shifts among the nine flux traps. Testing can be performed in test loops installed in some flux traps with individual flow and temperature control or in reflector irradiation positions with primary fluid as coolant. The curved fuel arrangement brings the fuel closer on all sides of the test loops than is possible in a rectangular grid.

Of the nine flux traps, five are configured with pressurized-water loops that allow for individual temperature, pressure, flow, and chemistry controls. The five test loops are used by the Naval Reactors program. Of the remaining four flux traps, one is dedicated to the Naval Reactors program, one is used for isotope production, one is used for low-specific-activity cobalt production, and the fourth has recently had the Irradiation Test Vehicle installed. The Irradiation Test Vehicle can be described as three small pressurized-gas test loops. Use of one of these three has recently been purchased by a British corporation; negotiations for use of the other two are currently under way.

In addition to the primary flux trap irradiation positions, there are some 70 irradiation positions in the beryllium reflector (and aluminum support structure) that are available for experiment irradiation and isotope production. These position diameters range from 1.6 to 12.7 centimeters (0.625 to 5 inches) with thermal neutron flux levels ranging from  $1 \times 10^{15}$  to  $1 \times 10^{13}$  neutrons per square centimeter per second.

Approximately 25 percent of the high-flux test positions (A holes, B holes, and H holes) are currently used for iridium-192 production. The majority of the remaining high-flux test positions are used for cobalt-60 production. Occasionally, additional isotopes (e.g., strontium-89, nickel-63) are generated in small quantities. A private company leases the space for the production of these isotopes. A small number of positions are used by other companies or Government programs for other material irradiation projects. For the production of plutonium-238, neptunium-237 targets would be placed in the beryllium reflector positions. The proposed target design consists of neptunium dioxide blended with aluminum powder, pressed into a target core, and clad with aluminum. The basic ATR target should be similar in appearance to, but longer than, the typical transuranic isotope production target shown in **Figure B-3**. The ATR target length would be sized for the 1.2-meter (4-foot) active core length of ATR rather than the 0.51-meter (20-inch) active length of the HFIR target. Beryllium reflector position sizes range from 1.6 to 12.7 centimeters (0.625 to 5 inches) in diameter.

ATR is equipped with numerous safety features, including extensive plant protective systems, standby power sources, experiment interlocks, computerized surveillance, confinement systems, safety rods, and an emergency firewater injection system. ATR's six safety rods provide fast shutdown of the reactor if potentially damaging conditions develop. A sudden rise in power or coolant temperature, a sudden drop in coolant flow or pressure, or the overheating of a test sample are examples of approximately 360 conditions that would automatically drop the safety rods into the core. The firewater injection system provides emergency core cooling and flooding of the reactor vessel in the event of a loss of primary coolant.

ATR is connected by a water canal to the ATR Critical Facility. The ATR Critical Facility is a low-power, full-size nuclear duplicate of ATR, and is used to provide data, as needed, for experiment loadings prior to irradiation of the actual experiments in ATR.

Figure B-2 ATR Core Configuration

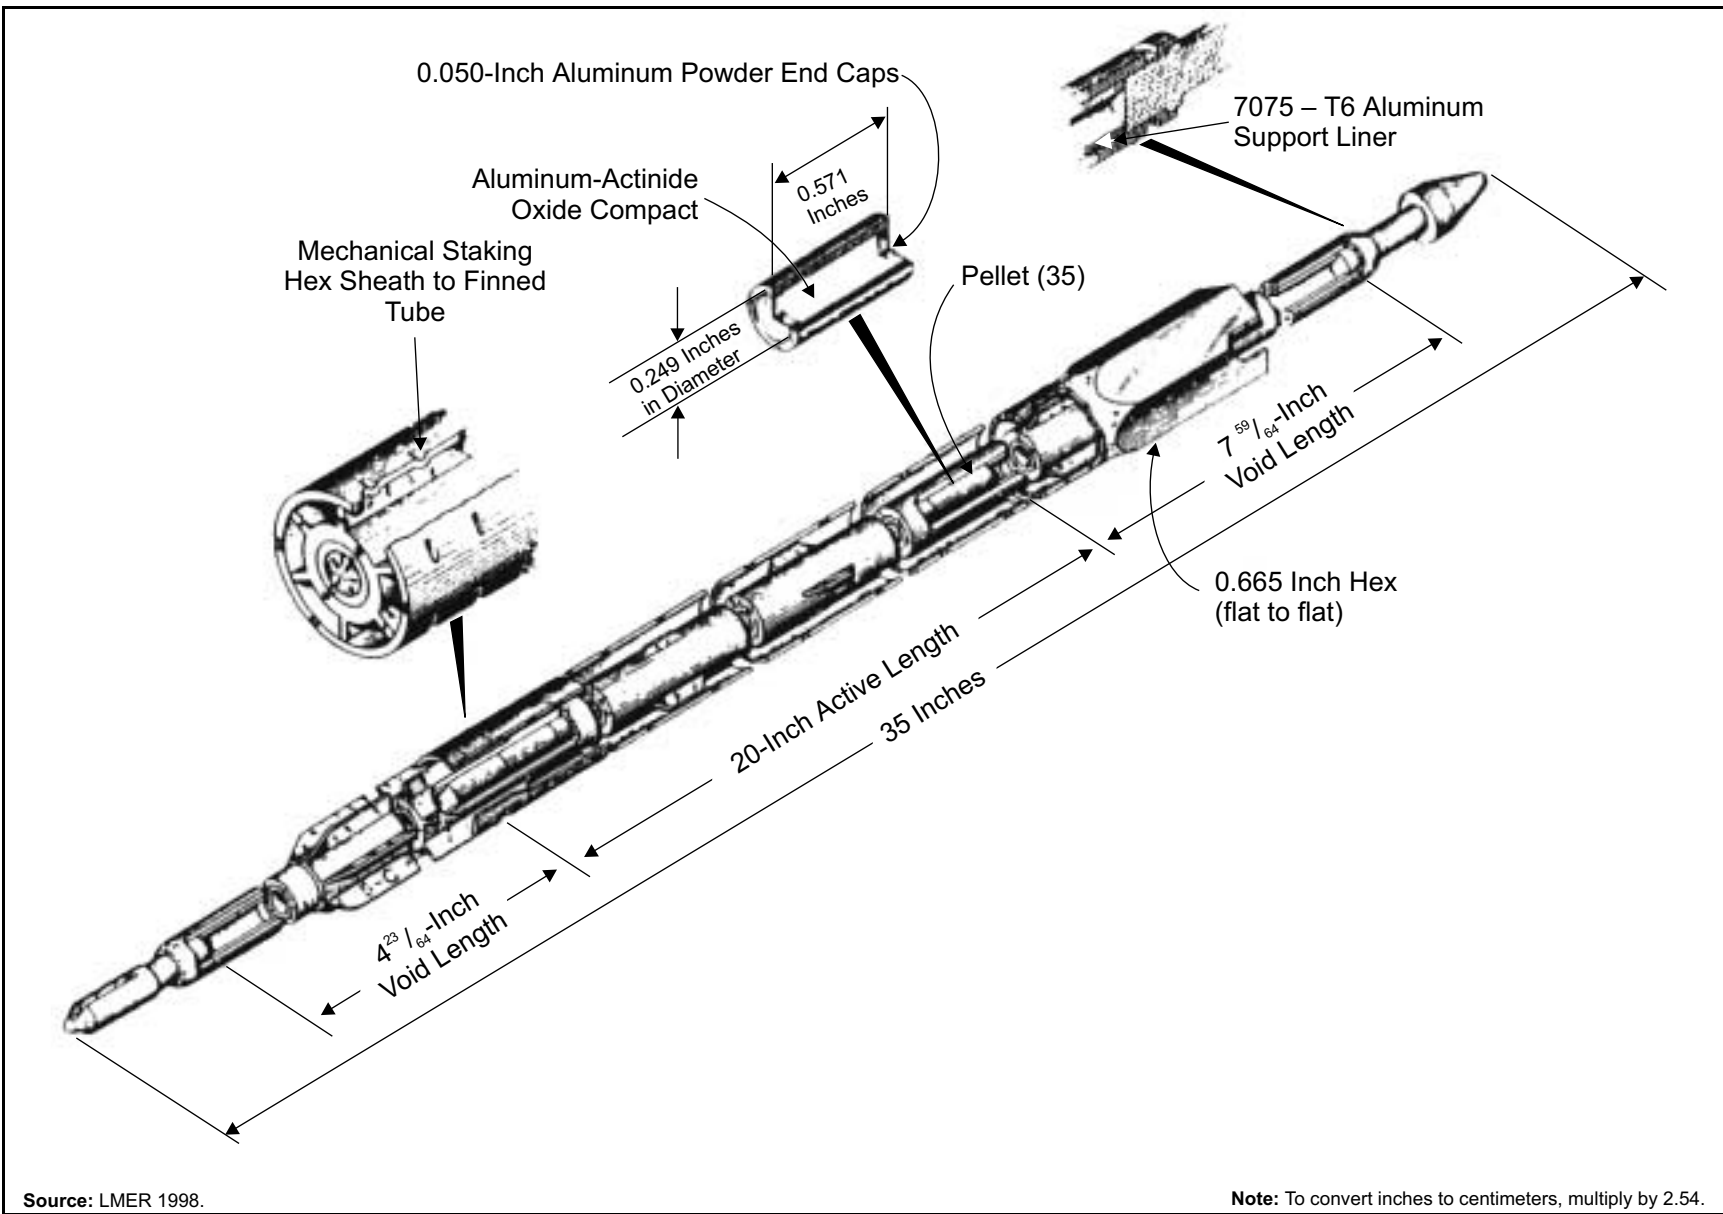

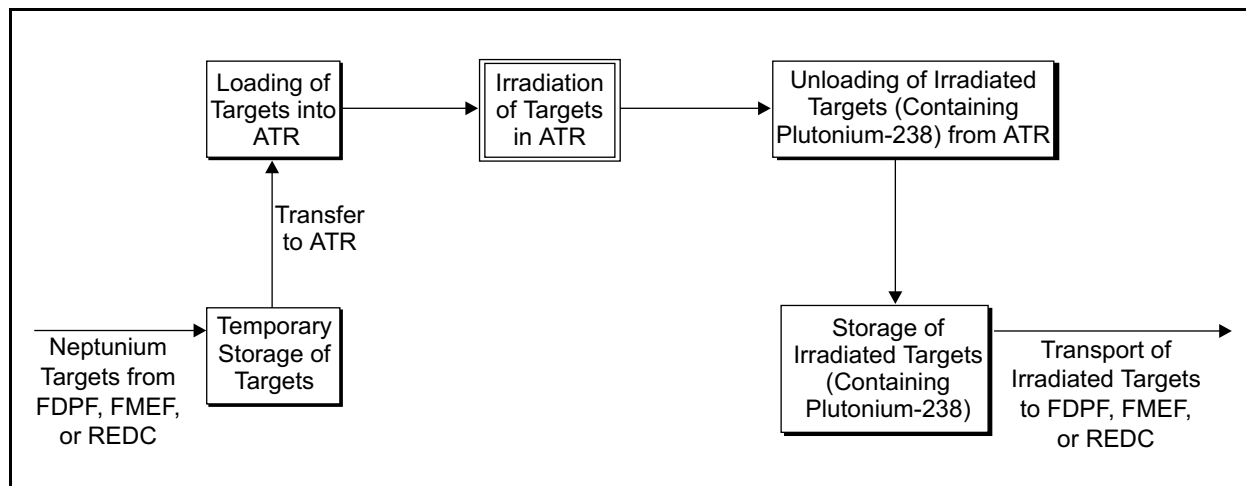

Figure B-3 Typical Transuranic Isotope Production Target

### B.1.2 Process Description

The target irradiation operations using ATR at INEEL are illustrated in **Figure B-4**.

**Figure B-4 Target Irradiation Operations Using ATR at INEEL**

Following neptunium target fabrication at the Fluorinel Dissolution Process Facility (FDPF) at INEEL, the Fuels and Materials Examination Facility (FMEF) at Hanford, or the Radiochemical Engineering Development Center (REDC) at ORR (Appendix A), the targets would be transported to INEEL for temporary underwater storage in the ATR reactor canal pending insertion into the reactor. Each target would contain, on average, approximately 750 grams (26 ounces) (approximately 0.5 curie) of neptunium-237 and up to an equivalent curie amount of protactinium-233, depending on the elapsed time following the neptunium-237 purification. The targets then would be manually transferred underwater to ATR and inserted into the beryllium reflector area of the reactor. This loading would take about 2 to 4 hours to complete. Nominally, 94 targets would be irradiated concurrently in ATR for a period of about 6 months to 2 years. The length of irradiation depends on the positions of the targets in the reactor. Following irradiation, the targets, each nominally containing, on average, 63 grams (2 ounces) of plutonium-238, smaller amounts of plutonium isotopes with higher atomic weights, and larger amounts of neptunium-237 (Schnitzler 1999), would be removed from ATR using the same underwater manual transfer system used during loading and would be stored in the reactor canal. This unloading would take approximately 2 to 4 hours to complete. The irradiated targets would be stored for a period of approximately 4 to 6 months to allow for the decay of short-lived radionuclides generated during irradiation.

After storage, the irradiated targets would be transported to FDPF, FMEF, or REDC for processing to separate the plutonium-238 product. A discussion of the postirradiation activities at these facilities is provided in Appendix A.

## B.2 HIGH FLUX ISOTOPE REACTOR

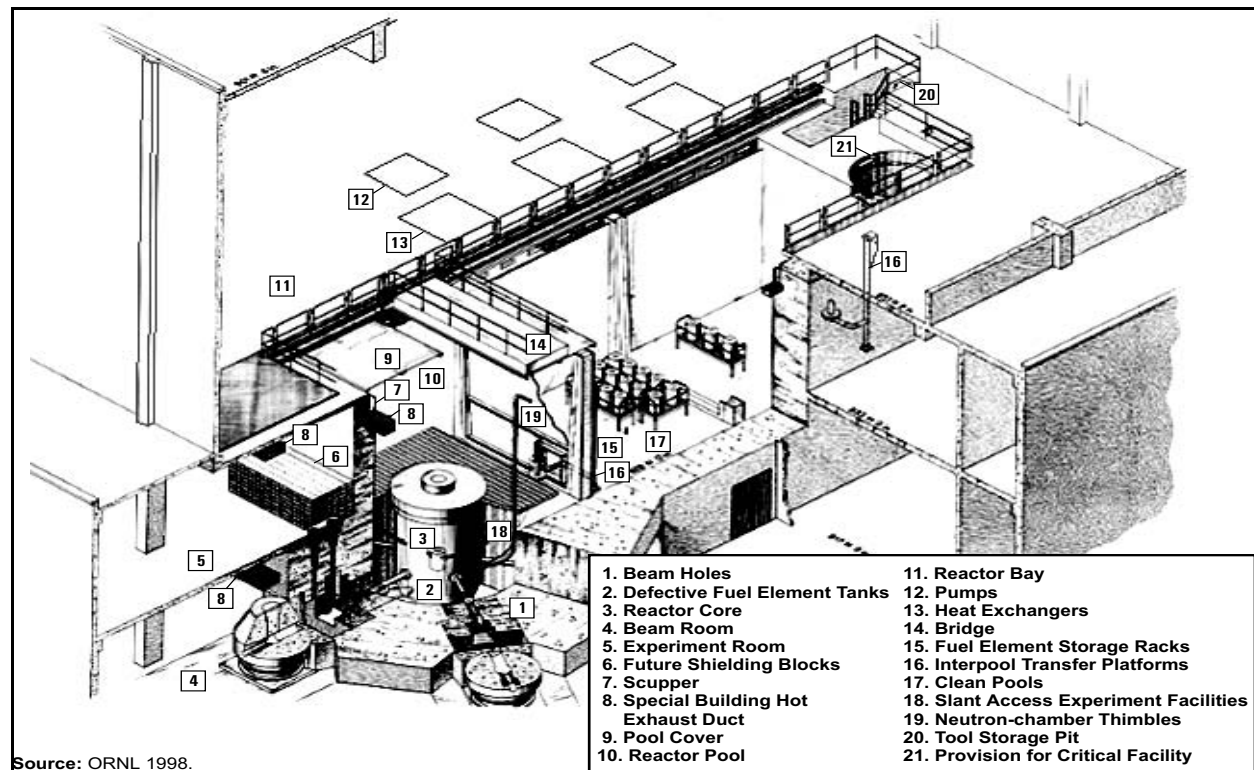

### B.2.1 Facility Description

HFIR is located in Building 7900 of the Melton Valley 7900 Complex at ORR. REDC is also part of this complex. HFIR provides one of the highest steady-state neutron fluxes available in any of the world's reactors. The reactor is operated primarily for Neutron Science Research. It is also used to produce isotopes on a not-to-interfere basis and is the Western World's sole producer of heavy transuranium isotopes. This facility

description is based on information provided in the *High Flux Isotope Reactor Safety Analysis Report* (LMER 1998) and the *High Flux Isotope Reactor Facility Description* (ORNL 1998).

HFIR is used for the production of californium-252 and other transuranic isotopes for research, industrial, and medical applications, as well as for a variety of irradiation tests and experiments on a not-to-interfere basis with its primary mission of neutron science research. Each year, approximately 150 to 200 researchers use the experimental facilities at HFIR.

HFIR is a beryllium-reflected, light-water-moderated and -cooled reactor. Originally designed to operate at 100 megawatts, the currently authorized power level is 85 megawatts. The reactor core is 0.61 meter (2 feet) high, and is contained in a 2.44-meter-diameter (8-foot-diameter) pressure vessel located in a pool of water. The top of the pressure vessel is 5.18 meters (17 feet) below the pool surface, and the reactor horizontal midplane is 8.38 meters (27.5 feet) below the pool surface. The pools and experiment facilities are illustrated in **Figure B-5**.

**Figure B-5 Pools and Experiment Facilities**

HFIR fuel contains enriched uranium-235. The reactor core consists of concentric annular regions. A sectional plan view of the core is shown in **Figure B-6**. The flux trap forms a hole at the center of the core and is 12.70 centimeters (5 inches) in diameter. The fuel region surrounding the flux trap is composed of two concentric fuel elements. The inner element contains 171 fuel plates and the outer element contains 369 fuel plates. The aluminum-clad fuel plates are curved in the shape of an involute (curled spirally), thus providing a constant coolant channel width. A fuel element is illustrated in **Figure B-7**.

The fuel region is surrounded by a concentric ring of beryllium reflector approximately 0.3 meter (1 foot) thick. The beryllium is surrounded by a water reflector of effectively infinite thickness. In the axial direction, the reactor is reflected by water.

Source: ORNL 1998.

Figure B-6 Plan View (Cross Section) of HFIR

In the flux trap in the center of the HFIR fuel element, a thermal neutron flux of  $2 \times 10^{15}$  neutrons per square centimeter per second is available to irradiate target material. Target rods or experiments are loaded into the target holder assembly and positioned in the flux trap. There are 31 target positions in the flux trap. There are 6 peripheral target positions located at the outer edge of the flux trap, and these positions have the highest fast neutron fluxes. In addition, numerous vertical irradiation facilities of various sizes are located throughout the beryllium reflector. These are the circles of various diameters shown in the “Permanent Reflector” and “Removable Reflector” in Figure B-6. These facilities would be used for the irradiation of the neptunium-237 targets to produce the plutonium-238.

The control plates, in the form of two thin, europium-bearing concentric cylinders, are located in the region between the outer fuel element and the beryllium reflector. These plates are driven in opposite directions. Reactivity is increased by downward motion of the inner cylinder, which is used only for shimmiing (fine adjusting) and regulation; it has no fast safety function. Reactivity is increased as the outer plates are raised. Any single control element is capable of shutting the reactor down.

Figure B-7 HFIR Fuel Element

There are a variety of experimental facilities at HFIR. These are described below.

**Hydraulic Tube Facility.** The HFIR hydraulic tube facility consists of the necessary piping, valving, and instrumentation to move aluminum capsules containing materials to be irradiated into and from the flux trap and the capsule loading station during reactor operation. The capsule loading station is located in one of the storage pools adjacent to the pool containing the reactor vessel.

**Flux Trap Target Positions.** Thirty target positions are provided in the flux trap. These positions are usually occupied by target rods used for the production of transuranium elements; however, experiments can, in principle, be irradiated in any of these positions.

**Peripheral Target Positions.** Six peripheral target positions are provided for experiments located at the outer radial edge of the flux trap. Fast-neutron fluxes in these positions are the highest accessible in the reactor, although a steep radial gradient in the thermal-neutron flux exists at this location.

**Large Removable Beryllium Facilities.** There are eight large removable beryllium facilities. In generic terms, these are referred to as the removable beryllium positions. They are located in the removable beryllium near the control region. Either instrumented or noninstrumented experiments can be irradiated in these facilities. Instrument leads and access tubes are accommodated through penetrations in the upper shroud flange and through special penetrations in the pressure vessel upper cover. These positions can accommodate spectral-tailored (i.e., shielded) experiments, making them well suited for fusion material irradiation. When not in use, these facilities contain beryllium or aluminum plugs.

To date, these particular facilities have been used primarily for three types of irradiations: (1) high-temperature gas-cooled reactor fuel irradiations, (2) production of radioisotopes, and (3) fusion materials irradiation program.

**Small Removable Beryllium Facilities.** Four small removable beryllium facilities are located in the removable beryllium near the control region. These unlined facilities have an inside diameter of 1.27 centimeters (0.5 inch). When not in use, these facilities contain beryllium plugs. These facilities have been used primarily for the production of radioisotopes.

**Control Rod Access Plug Facilities.** The semipermanent beryllium contains four control rod access plugs, the removal of which provides access to the coupling between the safety rods and their associated drive mechanisms. Each standard control rod access plug contains two 1.27-centimeter (0.5-inch) inside diameter unlined irradiation facilities, making a total of eight in the reactor. Normally, these facilities accommodate standard target rods of the type and configuration usually irradiated in the small removable beryllium facilities, although, in principle, experiments having other configurations can be accommodated. Only noninstrumented experiments can be irradiated in these facilities, because no provision is made for accommodating instrument leads and/or access tubes. When not in use, these facilities contain beryllium plugs.

**Small Vertical Experiment Facilities.** The permanent reflector is penetrated by 16 vertical holes, referred to as the small vertical experiment facilities, which extend completely through the beryllium. Each of these facilities has a permanent aluminum liner having an inside diameter of 4.01 centimeters (1.584 inches). Those located on the outer circle (five in all) are referred to as the outer small vertical experiment facilities. Vertical Experiment Facility-7 contains one of the pneumatic irradiation facilities and is unavailable for other use. Normally, noninstrumented experiments are irradiated in these facilities.

**Large Vertical Experiment Facilities.** The permanent reflector is penetrated by six vertical holes referred to as the large vertical experiment facilities. These facilities are similar (as to characteristics and capabilities) to the small vertical experiment facilities described in the preceding section except for location, size, and available neutron fluxes. The aluminum liners in the large vertical experiment facilities have an inside diameter of 7.2 centimeters (2.83 inches), and the facilities are located concentric with the core on a circle of radius 46.3 centimeters (18.23 inches). When not in use, these facilities contain beryllium or aluminum plugs.

**Neutron Activation Analysis Laboratory and Pneumatic Tube Facilities.** Two pneumatic tube facilities are available in HFIR. These facilities are designed and built to introduce sample containers (rabbits) into the flight tubes, and irradiation stations to which the rabbits move to be irradiated. The inner diameter of the flight tubes is 15.88 millimeters (0.62 inch), and the outer diameter of the rabbit is 14.48 millimeters (0.56 inch). Capsules are inserted into the reactor and returned to shielded loading stations in the laboratory. The facilities are used to measure the trace element content in a variety of materials by neutron activation analysis. About 65 of the chemical elements can be measured in the range of  $10^{-6}$  to  $10^{-15}$  gram ( $3.5 \times 10^{-6}$  to  $3.5 \times 10^{-17}$  ounce).

The Neutron Activation Analysis systems support Oak Ridge National Laboratory (ORNL) (DOE) programs, are used in work-for-others projects, and are available for use by students and faculty of universities through Oak Ridge Associated Universities and other programs. Several students and faculty members have used the system.

From 1975 to 1985, approximately 100,000 samples were analyzed for uranium by the delayed neutron counter in the ORR system. Most of those samples were generated by the National Uranium Resources Evaluation and the remaining ones from the Formerly Utilized Sites Remedial Action Program.

Neutron Activation Analysis at ORNL was also used to analyze evidence related to the 1961 to 1962 French-connection heroin case and the 1962 assassination of President Kennedy. More recently, it has been used in environmental analysis and in determining levels of uranium in materials used in the semiconductor industry.

**Slant Engineering Facilities.** Provision has been made for installation of up to four engineering facilities to provide additional neutron beams for experiments. These facilities consist of tubes that are inclined upward from horizontal. The inner ends of the tubes terminate at the outer periphery of the beryllium and have lower flux than the main beam tubes. The upper ends of the tubes terminate at the outer face of the pool wall in an experiment room one floor above the main beam room.

**Gamma Irradiation Facility.** Since 1968, a large variety of materials have been irradiated in the HFIR pool with the gamma flux generated from the decay of fission products in the spent HFIR fuel assemblies. In 1972, two 7.6-centimeter (3-inch) diameter stainless steel tubes were fabricated to provide a conduit through which specimens and any associated equipment could be inserted and withdrawn from the gamma fields. Facilities are also available wherein the flux trap sections of depleted fuel elements can be used to irradiate experiments requiring a high gamma flux. To date, such experiments have included studies of the effects of gamma radiation on various salts, insulating materials, paint samples, and a variety of other materials.

**Horizontal Beam Holes.** The reactor has four horizontal beam (HB) tubes with inner diameters of 10 centimeters (3.94 inches) that extend outward from the reactor core at the midplane of the reactor. Beam tube HB-2 extends radially from the reactor centerline, and beam tube HB-3, which extends tangentially from the core, is offset 34 centimeters (13.4 inches) from the reactor center. A third tube is aligned on a tangential line 39 centimeters (15.4 inches) from the reactor centerline with both ends extending outward from the reactor to allow for the installation of two individual facilities. The two ends of this tube are designated HB-1 and HB-4.

The average thermal flux at the end of the beam tubes for a power level of 85 megawatts is above  $1 \times 10^{15}$  neutrons per square centimeters per second.

Many neutron scattering facilities are found on the main experiment floor. All the neutron scattering spectrometers are located on this floor except that of the Center for Small Angle Scattering Research, which is located on the first floor above this area. The main spectrometer at each beam port uses a large monochromator shield that can be rotated under computer control to vary the orientation of the monochromator crystal.

The following paragraphs describe the instrumentation.

**HB-1.** The HB-1 spectrometer is generally operated as a polarized-beam spectrometer for elastic scattering studies, but it has all the capabilities of a three-axis spectrometer.

**HB-1A.** The HB-1A spectrometer is a recently installed triple-axis spectrometer constructed through a collaboration with Ames Laboratory at Iowa State University. The spectrometer has a fixed incident energy of 14.7 million electron volts so that high-order wavelength contamination ( $\lambda n$ ,  $n = 2, 3, \dots$ ) can be removed by a pyrolytic graphite filter. The monochromator is a double-crystal system with vertically focusing and flat pyrolytic graphite crystals. Analyzer crystals include pyrolytic graphite, germanium, or beryllium. The helium-3 detector is mounted vertically so that a large vertical divergence of the scatter beam may be used if desired.

**HB-2.** The HB-2 spectrometer is a very flexible three-axis spectrometer. The incident energy can be continuously varied by changing the monochromator angle. Four vertically focusing monochromator crystals are mounted on an apparatus that provides computer control of the focusing radius and of the selection of the type of crystal used in an experiment. Pyrolytic graphite, beryllium, copper, and silicon crystals are used as monochromators, depending on the desired incident energy and resolution. These same crystals are also used as analyzers. The analyzer angle is continuously variable, allowing experiments to be carried out either with fixed-incident energy or with fixed-scattered energy.

**HB-3.** The HB-3 spectrometer is a three-axis spectrometer that is nearly identical to the HB-2 spectrometer. The incident neutron energy is continuously variable by changing the monochromator angle,  $2\Theta(\text{sub})M$ ; and four vertically focusing monochromator crystals of pyrolytic graphite, beryllium, copper, and silicon are available. A sapphire filter for the HB-3 primary reactor beam is located in the shutter, and the collimator C1 is a separate unit.

**HB-3A.** The HB-3A spectrometer is a small-angle scattering spectrometer that uses perfect silicon crystals to obtain high angular resolution. The angular resolution in the horizontal plane is very high, but the vertical resolution is poor; thus, the spectrometer is most useful for studies of filamentary structures. This is the structure of a fluxoid lattice aligned in the vertical direction by a magnetic field, and a number of interesting studies have been performed on superconductors using this instrument.

**HB-4.** The HB-4 spectrometer is a very flexible time-of-flight spectrometer. The incident neutron energy is continuously variable by changing the angle for a silicon monochromator. The silicon monochromator is also used to pulse the neutron beam by being excited with high-power ultrasonic waves. The ultrasonic frequency is high, about 10 megahertz; therefore, the time resolution is very good. Because the beam is pulsed electronically, a pulse can occur at any time, and the cross-correlation technique can be used to give a high signal-to-noise ratio. Pseudorandom pulse codes are stored in an online computer and can be of various lengths and duty cycles. The neutrons scattered from a sample are timed over a 1.5-meter (4.92-foot) flight path and can be collected simultaneously in 70 helium-3 detectors that can be placed at any position over an

angular range between 10 and 130 degrees. The spectrometer can also be used as a polarized-beam time-of-flight spectrometer in which the beam polarization is varied according to a pseudorandom code. This procedure makes the spectrometer very useful for measuring magnetic excitations in ordered ferromagnetic systems because all phonon and elastic scattering is avoided by use of the polarized beam.

A modification of the HB-4 spectrometer, which will allow it to be operated as a high-resolution powder diffractometer, was constructed recently. The new design involved the addition of a bank of 32 detectors, each with a 1.83-meter (6-foot) Soller collimator, so that a complete diffraction pattern covering a scattering-angle range of 115 degrees can be obtained by step-scanning only 3.6 degrees. Changing from the time-of-flight mode of operation to the powder-diffractometer mode is under computer control.

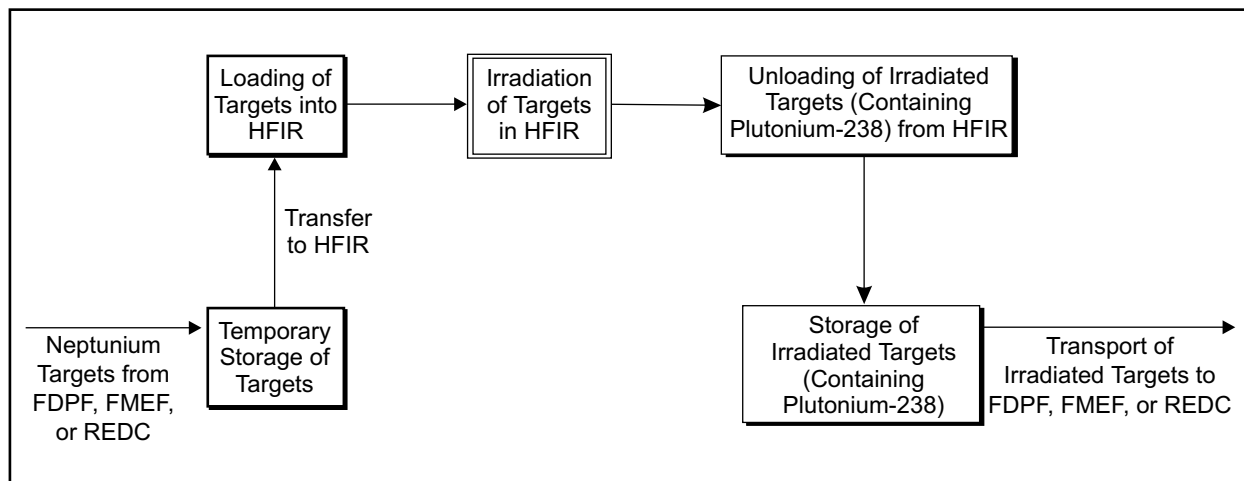

**HB-4A.** The primary spectrometer located at HB-4A is a wide-angle neutron diffractometer that is operated under a United States–Japan Cooperative Program on Neutron Scattering Research. The wide-angle neutron diffractometer uses a curved linear position-sensitive helium-3 detector that subtends a 130-degree scattering angle with a resolution of about 0.6 degree. Between the sample and the detector is a collimator, with radial cadmium-plated steel blades placed at 5-degree intervals, which oscillates back and forth during measurements to reduce background. Data are taken only when the collimator moves so that the collimator shadow is uniformly distributed over the entire detector. A beryllium monochromator provides a beam having a wavelength of 1.537 angstroms ( $1.537 \times 10^{-8}$  centimeter) from the (101) planes. The wide-angle neutron diffractometer was designed to provide two specialized data collection capabilities: (1) time-resolved measurements of powder diffraction patterns, and (2) measurements of diffuse scattering in single crystals using the flat-cone diffraction geometry.

**30-Meter Small-Angle Neutron Scattering Spectrometer.** The 30-meter small-angle scattering spectrometer, constructed with funds supplied by the National Science Foundation, is also located at HB-4. This spectrometer uses pinhole geometry with collimating slits of 0.5 to 3 centimeters (0.2 to 1.18 inches) in diameter separated by a distance of 10 meters (32.8 feet). The detector, with an active area of 64 by 64 centimeters (25.2 by 25.2 inches) and resolution element dimensions of 0.5 by 0.5 centimeter (0.2 by 0.2 inch), can be positioned at any distance from 1.5 to 19 meters (4.92 to 62.32 feet) from the specimen by moving a motor-driven detector carrier along rails in the evacuated flight path. The standard incident wavelength, provided by a bank of pyrolytic graphite crystals, is 4.75 angstroms ( $4.75 \times 10^{-8}$  centimeter). This can be changed to 2.38 angstroms by substituting graphite for the cold beryllium filter normally in position. The changeover time is less than 5 minutes, and the procedure permits experiments to be performed with increased flux over a wider range of scattering angles.

The specimen chamber is designed to accommodate standard samples, or, if necessary, it can be fitted with specialized ancillary equipment (e.g., furnaces, automatic sample changers, a Displex unit, goniometers). The monochromatic beam leaving the upper crystal bank has the approximate dimensions of the projected area of the crystals, 35 by 40 millimeters (1.4 by 1.6 inches). Three horizontal beam guide sections, each 2 meters (6.56 feet) long and with the above cross-sectional area, serve to transport the effective source to distances of 5.5, 3.5, or 1.5 meters (18.0, 11.48, or 4.92 feet) from the sample with overall gain for the appropriate experiment of a factor of about 6. The instrument is interfaced to a personal computer with a 20-megahertz, 80386 microprocessor that acts as a user interface allowing menu-driven spectrometer operations; it also permits users to transfer data on disks directly to their own laboratories after completion of an experiment.

### **B.2.2 Process Description**

The target irradiation operations using HFIR at ORR are illustrated in **Figure B-8**.

**Figure B-8 Target Irradiation Operations Using HFIR at ORR**

Following neptunium-237 target fabrication at FDFP, FMEF, or REDC (Appendix A), the targets would be transported to a shielded location in Building 7930 at ORR for temporary storage. Each target would contain, on average, approximately 750 grams (26 ounces) (approximately 0.5 curie) of neptunium-237 and up to an equivalent curie amount of protactinium-233, depending on the elapsed time following neptunium-237 purification (Wham 1999). The targets then would be transferred in transport casks to the HFIR spent fuel storage pool, where they would be stored for a period of approximately 28 to 30 days. Using a handling and underwater transfer system, the targets then would be transferred from the storage pool and inserted into the beryllium reflector (permanent or removable) area of HFIR. This loading would take approximately 2 to 4 hours to complete.

Targets would be irradiated concurrently in HFIR for a period of approximately 6 months to 2 years. The length of irradiation depends on the positions of the targets in the reactor.

Following irradiation, each target contains, on average, approximately 5 grams (0.18 ounce) of plutonium-238 along with smaller amounts of plutonium isotopes with higher atomic weights (i.e., approximately 0.65 gram [0.023 ounce] of plutonium-239 and approximately 0.06 gram [0.002 ounce] of plutonium-240) and also approximately 35 grams (1.2 ounces) of neptunium-237 (Wham 1999). The irradiated targets would be removed from HFIR using the same handling and underwater transfer system as used during loading and would be stored in the spent fuel storage pool. This unloading would take approximately 2 to 4 hours to complete. The storage of the irradiated targets would be for a period of 4 to 6 months to allow for the decay of short-lived radionuclides generated during irradiation.

After storage, the irradiated targets would be transferred to FDFP, FMEF, or REDC for processing to separate the plutonium-238 product. A discussion of the postirradiation activities at these facilities is given in Appendix A.

### **B.3 COMMERCIAL LIGHT WATER REACTOR**

#### **B.3.1 Facility Description**

The facility description is based on information provided in the *Final Environmental Impact Statement for the Production of Tritium in a Commercial Light Water Reactor* (DOE 1999b) and in the *Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling* (DOE 1995).

The generic pressurized water reactor core holds 177 fuel assemblies, as illustrated in **Figure B-9**, arranged in three regions that are rotated at about 18-month intervals (i.e., the inner region is removed as spent nuclear fuel to the spent fuel pool, the other two regions are moved inward, and fresh fuel is loaded into the outer region). The fuel assemblies each use a 15-by-15 lattice of fuel rods consisting of slightly enriched uranium dioxide pellets clad and sealed in Zircaloy tubing. All fuel assemblies (**Figure B-10**) are identical in mechanical construction and are interchangeable in any core location. The basic fuel assembly is normally composed of 208 fuel rods, 16 control rod guide tubes, and one centrally located position for instrumentation, all within the 15-by-15 lattice. The fuel assembly is approximately 20 centimeters by 20 centimeters (8 inches by 8 inches) in cross section, with an overall length of 420 centimeters (165 inches).

**Figure B-9 Plan View (Cross Section) of a Generic CLWR**

In addition to the nuclear reactor and its surrounding reactor vessel, a nuclear steam supply system contains equipment and components to remove the heat of fission and to convert it into steam to drive a turbine (in test or isotope production reactors such as ATR and HFIR, the heat arising from nuclear fission is merely passed from primary to secondary coolant systems for rejection to the atmosphere through cooling towers). A schematic drawing of a pressurized water reactor nuclear steam supply system is shown in **Figure B-11**. A pressurizer keeps the water reactor coolant under sufficient pressure to prevent it from boiling. The pressurized

Source: TEC 1996.

Figure B-10 CLWR Basic Fuel Assembly

**Figure B–11 Schematic of a Typical Pressurized Water Reactor’s Nuclear Safety Steam Supply System**

water (primary coolant) is pumped by the primary coolant pumps to the reactor, where it is heated by the fissioning of uranium fuel taking place within the core. The secondary coolant pumps send the heated coolant to the tube-side of the steam generators, where heat is transferred to the shell-side, boiling off secondary coolant as steam to drive turbine generators. The turbine generators are outside of the nuclear steam supply system and are major components of the “balance-of-plant” systems. Exhaust steam from the turbines is condensed to lower the back-pressure on the turbines and provide heat recovery.

The particular nuclear steam supply system illustrated in Figure B–11 is arranged as two heat transport loops, each with two primary coolant circulating pumps and one steam generator. In addition to serving as a heat transport medium, the primary coolant also serves as a neutron moderator and reflector, and as a solvent for soluble boron used in chemical “shim” control (fine adjustment of the “reactivity,” or power level of the

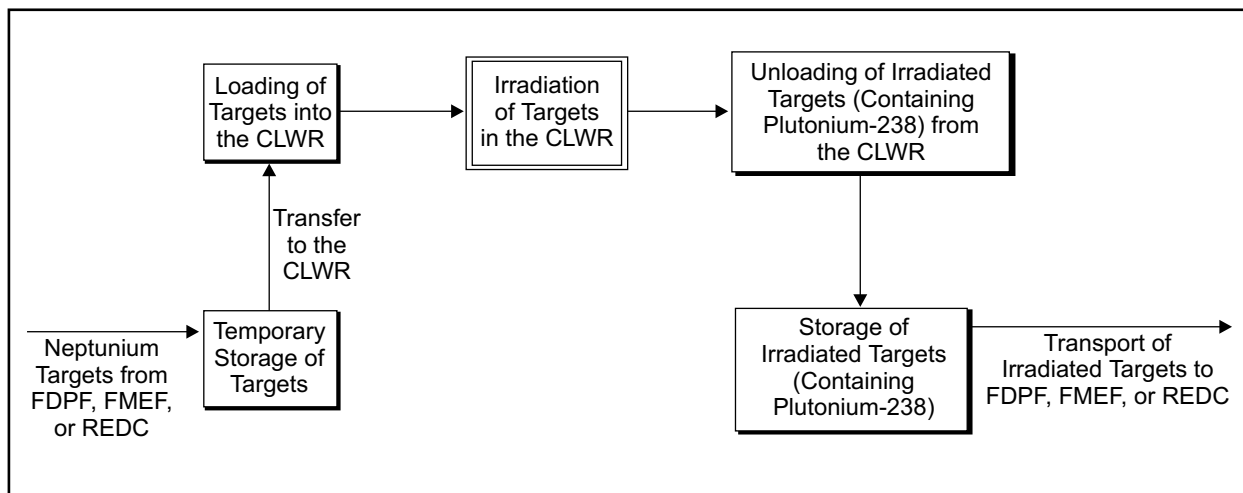

reactor). A domed steel containment vessel envelops many nuclear steam supply system components in addition to the reactor vessel. These include the reactor coolant piping, the pressurizer, the pressurizer quench tank and coolers, reactor primary coolant pumps, steam generators, core flooding tanks, and letdown coolers. Safety systems directly associated with this vessel include the containment spray system, the containment air cooling system, and the containment isolation system.

A second level of containment exists as the reinforced concrete shield building, which surrounds the containment vessel. It is designed to provide biological shielding during normal operation and hypothetical accident conditions. The building provides for the collection and filtration of fission product leakage from the containment vessel following a hypothetical accident by means of its emergency ventilation system. In addition, the building provides environmental protection for the containment vessel from adverse atmospheric conditions and external missiles.

### B.3.2 Process Description

The target irradiation operations using a generic CLWR are illustrated in **Figure B-12**.

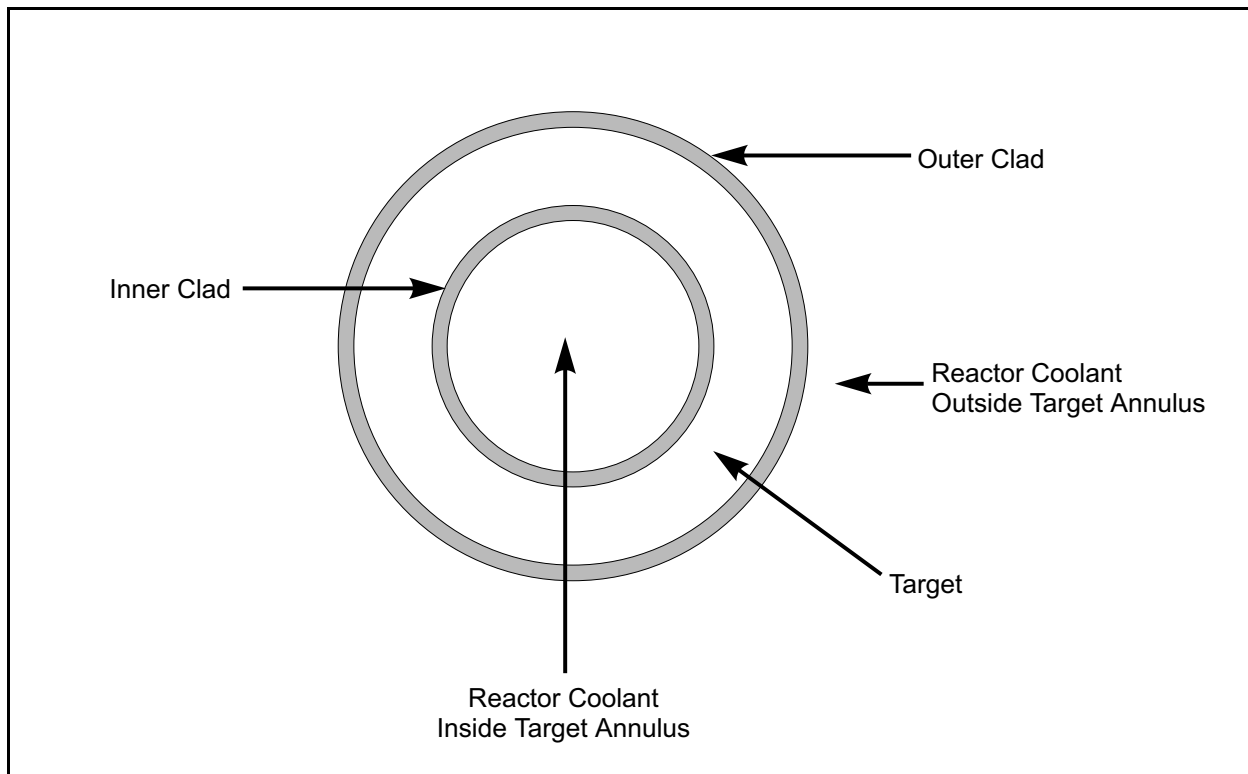

The neptunium-237 targets can be placed in numerous locations within the reactor core (i.e., fuel assembly region) and outside the reactor core region to be irradiated for the production of plutonium-238. Three potential target arrangements were considered for evaluation in this *Final Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility* (NI PEIS): (1) all targets located in the center fuel assembly in the reactor core, (2) all targets distributed in select in-core locations, and (3) all targets distributed in select out-of-core locations. Locating all targets in the center fuel assembly in the reactor core was selected for evaluation in this NI PEIS because it was assumed that this would be the worst-case location during postulated beyond-design-basis accident conditions. The beyond-design-basis accident analysis postulated that the cladding of all targets in the center fuel assembly position would fail during the accident sequence. In the event that the NI PEIS Record of Decision selects the CLWR for the production of plutonium-238, the actual target arrangement in the reactor vessel will be defined during subsequent design and operational tradeoffs, which will consider reactor safety, impact on reactor core design and operation, plutonium-238 purity and generation rates, target handling, worker dose, and target design.

**Figure B-12 Target Irradiation Operations Using a CLWR at a Generic Site**

Following neptunium-237 target fabrication at FDPF, FMEF, or REDC (Appendix A), the targets would be transported to the spent fuel pool at the generic CLWR site for temporary storage. Because design of the neptunium-237 targets for the CLWR is still in the conceptual stage, the amount of neptunium-237 in each target has not yet been determined. During the period of reactor refueling, the neptunium-237 targets would be placed in a fuel assembly that was in the reactor core during the previous operating cycle. The targets would replace fuel rod positions in the fuel assembly. The removal of fuel rods from an irradiated fuel assembly and the substitution of neptunium-237 targets in the fuel rod positions would be performed in the spent fuel pool under approximately 6.1 meters (20 feet) of water to limit radiation doses to the involved workers. The Zircaloy-clad target dimensions are similar to a fuel rod, approximately 1 centimeter (0.4 inch) in diameter by 3.7 meters (12 feet) long. **Figure B–13** presents a cross-sectional view of the CLWR neptunium-237 target. The fuel assembly containing the neptunium-237 targets would be transferred from the spent fuel pool to the reactor using the refueling canal and placed in the center fuel assembly position in the reactor core (refer to Figure B–9). The neptunium-237 targets would remain in the reactor core for a complete operating cycle, nominally 18 months.

**Figure B–13 Radial View (Cross Section) of a CLWR Neptunium-237 Target**

The substitution of neptunium-237 target rods for fuel rod positions in the center fuel assembly would have a minimal impact on reactor operations. The fuel rods located in the center fuel assembly position do not normally contain fresh fuel (i.e., fuel placed in the core for utilization during the first 18-month operating cycle of the reactor), but contain fuel that is in the second or third operating cycle. The normal power distribution within the core and reactor coolant flow and its distribution within the core would remain within existing technical specification limits.

Following irradiation for a complete operating cycle, the targets would be removed from the reactor using the same transfer system used during loading and would be stored in the spent fuel pool. The irradiated targets

would be stored for a period of approximately 4 to 6 months to allow for the decay of short-lived radionuclides generated during irradiation.

After storage, the irradiated targets would be loaded in a spent fuel cask and transported from the reactor site to FDPF, FMEF, or REDC for processing to separate the plutonium-238 product and to recycle the remaining neptunium-237 for fabrication of new targets. A discussion of the postirradiation activities at these facilities is provided in Appendix A.

## Medical and Industrial Isotope Target Fabrication and Processing Operations and Civilian Nuclear Research and Development Targets

This appendix describes the technologies used to fabricate targets, process irradiated targets, recycle unconverted materials, and ship the product medical and industrial isotopes. It uses FFTF specific irradiation systems (vehicles) as examples for clarification and illustrative purposes.

### C.1 TARGET FABRICATION AND PROCESSING FACILITIES

Target fabrication and processing facilities are described in Chapter 2.

### C.2 DESCRIPTION OF THE TARGET FABRICATION PROCESS

The production of medical and industrial isotopes involves fabricating specially designed targets, irradiating the targets in the reactor core or the accelerator target caves to generate specific medical isotopes, and processing the targets to prepare medical isotopes for shipment to customers. At reactors, Long-Term Irradiation Vehicles would be used for irradiating materials to produce long-lived isotopes, and Rapid Radioisotope Retrieval Systems would be used for short-lived isotopes. The Long-Term Irradiation Vehicle would consist of a bundle of target pins installed inside a nozzle, duct, and handling socket assembly similar in appearance to a fuel assembly (Figure C-1). Depending on the isotopes to be produced, the pin bundle could contain moderator pins and neutron shield pins to provide the desired flux in specific core locations for isotope production. A design that would allow reuse of the Long-Term Irradiation Vehicle assembly nozzle, duct, and handling socket hardware would be considered during the design process in an effort to reduce costs and waste generation. Figure C-2 is a picture of the cobalt-60 test vehicle prior to installation of the outer hexagonal duct. While cobalt-60 is not on the list of representative candidate medical isotopes, this assembly configuration is typical of the Long-Term Irradiation Vehicles irradiated in the Fast Flux Test Facility (FFTF).

Figure C-1 An Example of an FFTF 12-Foot Fuel Assembly

The Rapid Radioisotope Retrieval System, which would be developed and used for the production of short-lived isotopes, would allow target materials to be inserted and withdrawn from the reactor core with the reactor operating at power. This system is described in Appendix D. Target material would be contained in individual capsules or interconnected carriers; allowing insertion and retrieval from the reactor as a string of targets. In addition to irradiating solid targets in the rapid retrieval system carrier strings, gas targets also could be irradiated to produce short-lived isotopes, as discussed in Appendix D. The system configuration presented for FFTF in Appendix D is typical of Rapid Radioisotope Retrieval System installations in other reactors engaged in medical and industrial isotope production.

The remainder of this section focuses on the first step in the isotope production process: the fabrication of the medical and industrial isotope targets.

**Table C-1** presents a representative listing of 30 medical isotopes that are evaluated in this programmatic environmental impact statement. These isotopes were selected as being representative considering the current and future domestic and international demand for individual isotopes and current and future production capabilities for these products. The specific mix of isotopes produced by any irradiation facility will vary depending on the operating characteristics and authorized operating limits of the facility and the changing demands for specific isotopes during the production mission.

### **C.2.1 Target Materials**

Each type of medical isotope would be produced using a target enriched in the appropriate isotope target material for neutron irradiation. With the exception of the radium-226 target and those using recycled materials, all of the targets use nonradioactive materials. Table C-1 presents the type and form of the target material to be used to produce each medical isotope. In cases where the target material and the product isotope are the same element, the target and the product cannot be chemically separated and the target material is shipped with the product. In cases where the target material and the isotope product are different elements, the target and isotope product can be chemically separated. After irradiation of the original target material (which in some cases may not be completely pure), there may be radioactive impurities that remain with the target material after the removal of the medical isotope product. Because of these impurities, the reuse of the material can, in some cases, create targets that are radioactive. As a result, the fabrication of targets using recycled target materials would require special handling. Shielding and special handling also would be required for the radium-226 target material (used to produce actinium-227, thorium-238, and thorium-239); it would be the only target material that would be radioactive before irradiation.

**Table C-1 Representative Candidate Medical Isotopes**

Product Isotope	Half-Life	Primary Target Isotope <sup>a</sup>	Target Vehicle	Irradiation Time (days)	Primary Target Isotope Mass (grams)	Irradiation Product Specific Activity (curies per gram)	Product Isotope Activity Produced (curies)	Product Isotope Activity Delivered (curies per assembly)

a. One hundred percent enriched.

b. Actinium-227 will decay to radium-223, which is the isotope that has medical applications.

c. Target form would be either basic element, carbonate, or chloride.

d. Target form would be either the basic metallic element or a metallic oxide or other compound, dependent on availability and on engineering considerations such as material melting point, degradation characteristics, and processing methods.

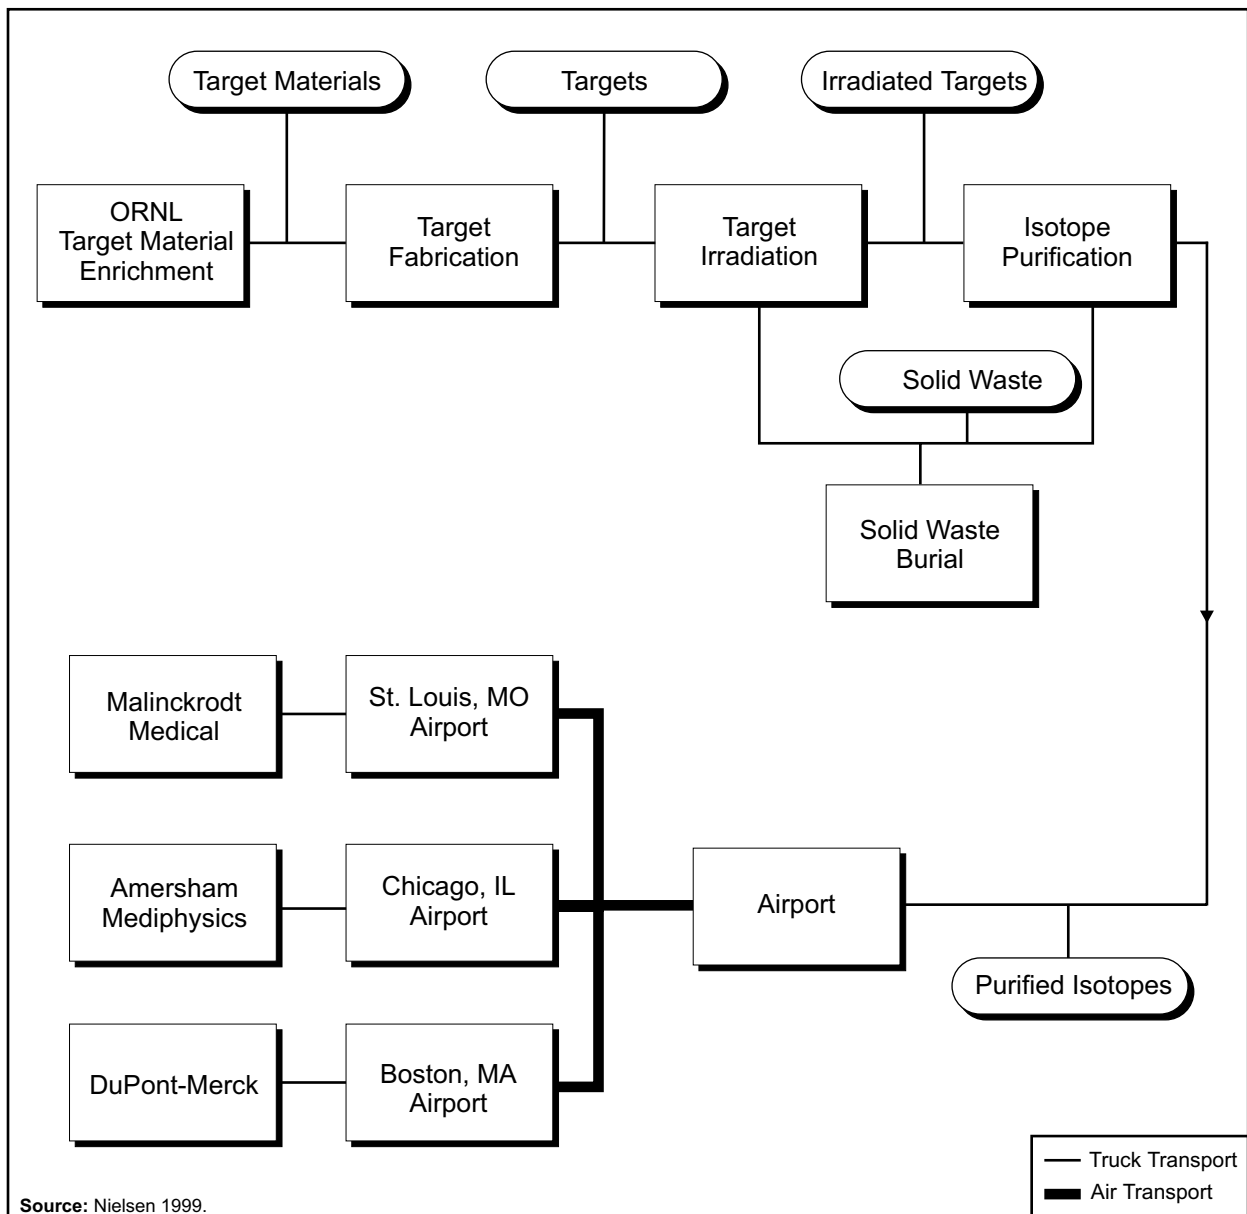

e. Thorium-228 will decay to radium-224, which is the isotope that has medical applications.

f. Thorium-229 will decay to bismuth-213, which is the isotope that has medical applications.

**Key:** LTIV, Long-Term Irradiation Vehicle; LTIV-H, Long-Term Irradiation Vehicle-hydrided; R3, Rapid Radioisotope Retrieval System; R3-H, Rapid Radioisotope Retrieval System-hydrided.

**Source:** Nielsen 1999.

For the nonradioactive targets, the target material typically would be acquired from Oak Ridge National Laboratory (ORNL), where enrichment processes are conducted to produce target material (isotopes) of sufficient purity to support the generation of medical isotopes. The target form may be a metal, metallic oxide, or other chemical compound suitable for irradiation, depending on engineering considerations such as material heat transfer characteristics, melting points, and metallurgical properties. The nonradioactive target material would be transported by truck from ORNL to the Hanford Site (Hanford) or to the U.S. Department of Energy (DOE) site having the new DOE low-energy accelerator or new research reactor and support facilities. The transportation mode, the shipment origin and destination, and transportation requirements for medical isotopes to be produced at Hanford are illustrated in **Figure C-3**. With the exception of the transportation of radium-226 to the medical isotope processing facility for target fabrication, the same transportation scenario would be applicable to each isotope.

**Figure C-3 Isotope Transportation**

The radioactive target material, radium-226, would not be supplied by ORNL. However, radium-226 could be supplied by a variety of sources. Once materials for the targets arrive on the site, the materials would be stored in the medical isotope processing facility until needed for fabrication into medical isotope targets. Nonradioactive target materials do not have special storage requirements and most likely would be stored at the fabrication site. Special storage conditions are required because radium-226 generates radon gas. Recycled target materials would be stored in the processing facility.

For most types of targets, a cladding or encapsulation material would be needed to contain the target material during handling and irradiation. The Long-Term Irradiation Vehicle would be submerged in the reactor coolant, and it is anticipated that the target pins would be similar in construction and cladding to fuel pins. In this case, the cladding material must be fully compatible with the reactor coolant and should have low neutron-induced swelling characteristics.

For the Rapid Radioisotope Retrieval System, the targets would be inserted into and be irradiated in one or more fixed thimbles that extend into the reactor core. The individual targets, each composed of different target material, would be encapsulated or clad as necessary to (1) facilitate target handling, (2) contain the target materials and products during irradiation, (3) avoid interactions between the various target and structural materials at the irradiation temperature, and (4) maintain target purity. Dependent on the method finally selected for target insertion and retrieval (pneumatic or mechanical and cable system), the individual targets may be contained in cylindrical target carriers. These carriers would be interconnected to form a target string. To reduce the volume and weight of shielding required on the retrieval and irradiated target handling equipment, consideration would be given to using low-activation material for the target carriers. Studies also would be done to define the impacts on irradiation conversion efficiency, worker dose, processing efficiency, and waste streams of using higher-activation material for the target carriers or cladding (Nielsen 1999).

### **C.2.2 Target Fabrication Operations**

Solid targets for either the Long-Term Irradiation Vehicles or the Rapid Radioisotope Retrieval System would be fabricated in gloveboxes using a series of mechanical and thermal processes. For the solid targets based on a powder, it is unknown at this time if the powder would be loose or if the powder would be pressed and sintered into pellets in some cases, depending on the material. If it is preferable to have pressed and sintered pellets, this option would require separate dies and boats to press and sinter each type of solid target material to reduce the risk of cross-contamination from other target materials. For solid metallic target material, depending on the purchased form, it may only be necessary to machine or cut the material to the required size.

If pellets are used, the first major step in their preparation would be powder conditioning and pressing. This would include weighing, blending, and pressing the powder and binder into slugs. The slugs would be granulated, blended with binder addition, and pressed into pellets. The pellets would be transferred to the sintering and debind station, weighed, and subjected to a series of thermal processes to debind and sinter the pellets. The sintered pellets would be subject to characterization to ensure that specifications were met.

Acceptable pellets would be transferred to the loading and welding station to be visually inspected before inclusion into a capsule or pin. For both powder or pellet target materials, capsules and pins would be cleaned before final closure. The capsules would be leak-tested and inspected before being cleared for use (Nielsen 1999). Normally, the required characteristics and physical configuration of a target for production of a specific isotope define if the powder should be loose in the target or pressed and sintered into pellets. In the event that there is a choice between powder or pellet, all other irradiation considerations and irradiated target processing considerations being equal, the loose powder target would normally be preferred. The target fabrication process for loose powder targets is much simpler, more cost effective, and generates less waste and

emissions due to the fact that there is less material processing. In addition, less equipment would require general housekeeping and cleanup, test, calibration, and maintenance.

### **C.2.3 Nuclear Research and Development Targets**

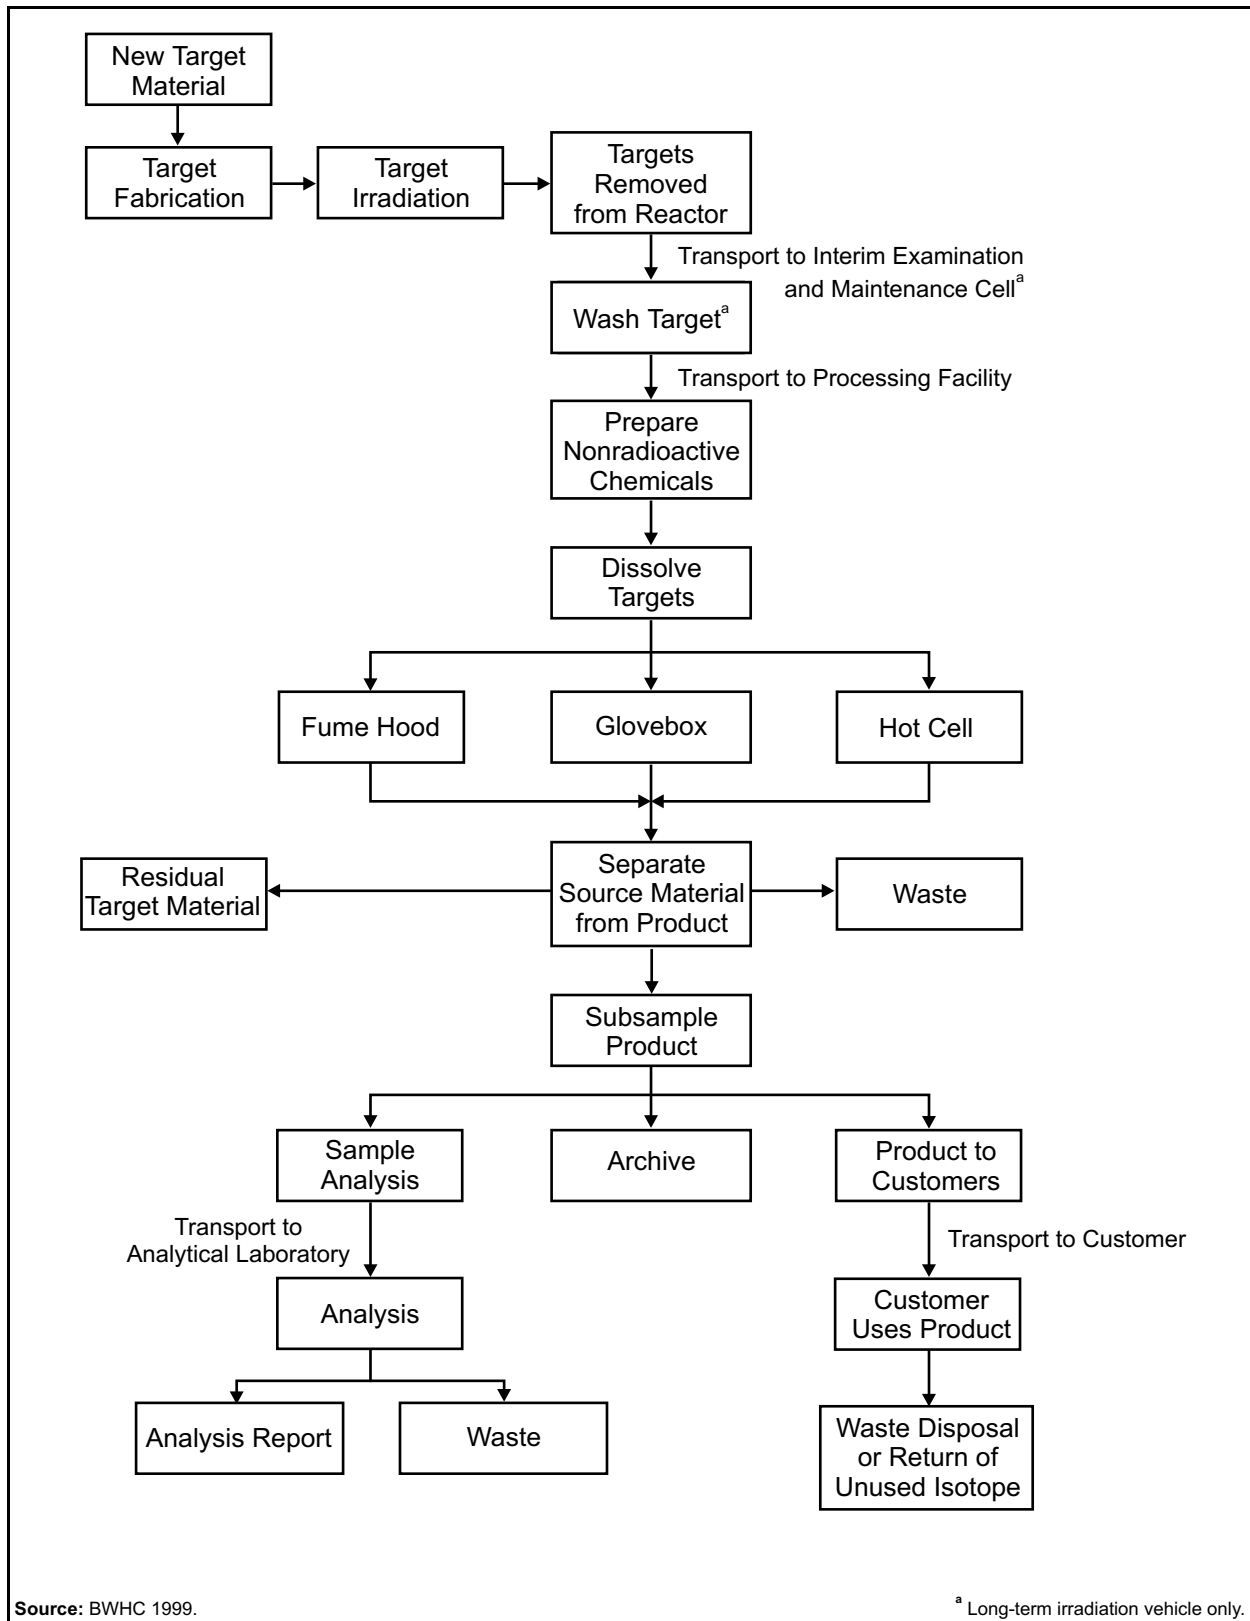

There is particular interest in materials testing associated with commercial nuclear power plant license renewals, cooperative international fusion energy research, space power technology, and transmutation of waste as a means to destroy long-lived isotopes from commercial spent nuclear fuel. Another area of interest is developing nuclear technologies that advance global nonproliferation. Target assemblies to be irradiated in support of these mission areas could be fuel or other materials configured similar to a standard driver fuel assembly (i.e., target material encased in sealed pins, and the pins placed in a ducted assembly). In the FFTF reactor, material specimens also could be installed in an existing open test assembly position within a Material Open Test Assembly. Test target assemblies or materials (e.g., for a Material Open Test Assembly) could be fabricated on site or at the customer's facility and then transported to an accelerator or reactor for irradiation.

One of these proposed testing activities consists of fuel testing for the Accelerator Transmutation of Waste (ATW) program. A fuel development activity for this program could use a reactor for irradiation testing. The tests could be fabricated by the ATW program and transported to the reactor site for irradiation. Specific test compositions and irradiation parameters for these test fuel assemblies have not been defined. It is anticipated that initial tests would involve a few pins in an assembly, while later tests could involve entire assemblies. The target pins are described as containing a matrix of zirconium and transuranic waste with a composition of 25 percent transuranic waste and 75 percent zirconium by weight. The transuranic waste likely would be light water reactor discharge fuel at a typical burnup of 33,000 megawatt days per metric ton of uranium that is stripped of essentially all uranium and fission products. Another potential testing activity could be performed at FFTF for the ATW program is irradiation testing using lead-bismuth alloy as a coolant. Lead-bismuth alloy has been proposed as the target material for production of spallation neutrons in the ATW accelerator and as the coolant for the transuranic target assemblies undergoing irradiation at the ATW facility. FFTF has the capabilities for high-temperature irradiation closed-loop testing involving liquid metal coolant isolated from the reactor coolant system and test positions in the reactor that could be adapted for this test activity (Nielsen 1999).

## **C.3 DESCRIPTION OF THE POSTIRRADIATION TARGET PROCESSING**

Processing of irradiated targets to recover medical- and industrial-grade isotopes can be broken down into distinct steps: receipt of irradiated targets into a chemical separation facility; chemical processing of the targets (using hot cells, shielded gloveboxes, and appropriate open-faced hoods); waste handling; analysis of the products; recycling of some of the target materials; and shipment of the isotope products to customers. A representation of this process for preparation of isotopes is shown in **Figure C-4**.

The 30 representative medical isotope products shown in Table C-1 may be grouped in three categories. Thirteen of the targets would produce an isotope of the same element and would not require separation. Five of the targets would produce different isotopes of the same element but would require some processing to remove impurities. Twelve target materials would produce different elements and would require chemical separation, both for separation of the target material and unwanted impurities. These categories are discussed in more detail in Sections C.3.1, C.3.2, and C.3.3, respectively (BWHC 1999).

**Figure C-4 Production and Radiochemical Processing Steps in the Preparation of Medical and Industrial Isotope Products**

### C.3.1 Same Target/Products Requiring No Separation

Thirteen of the same target element/products would not require extensive chemical separation (**Table C-2**). However, with experience, target purity and customer requirements might change, requiring additional separation and purification.

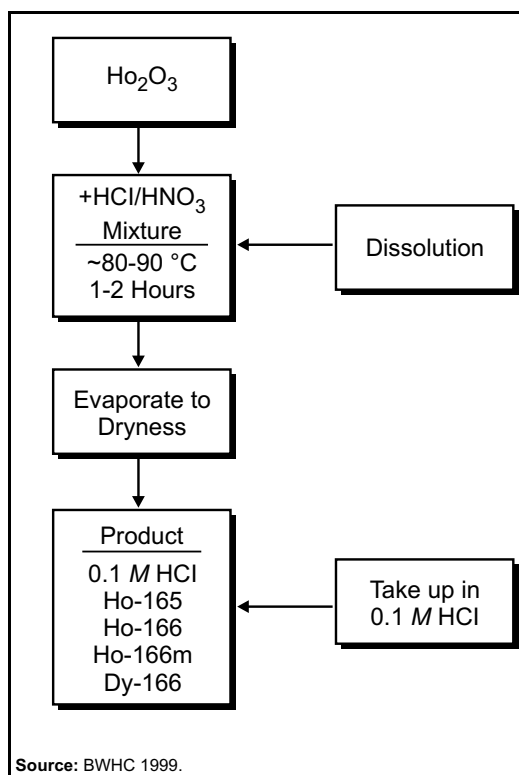

**Table C-2 Products Requiring No Separation**

Product	Curies per Target Campaign	Irradiation		Campaigns per Year
		Material	Time (days)	
Molybdenum-99	21,000	Molybdenum-98	10	25
Palladium-103	14,000	Palladium-102	25	10
Platinum-195m	200	Platinum-195	25	25

Source: BWHC 1999.

A typical example of a product that would require no postirradiation separation is holmium-165/holmium-166 (**Figure C-5**). Medical isotope target carriers would be unloaded from the cask into A-Cell, where they would be separated and prepared for transport from A-Cell to isotope processing stations. The target material would be removed from the carrier and dissolved using nitric acid, hydrochloric acid, or a combination of acids. The dissolved material would be evaporated to near dryness to remove the acid. The resulting salt would be redissolved in dilute acid. The product solution would be analyzed for chemical and radionuclide purity, and aliquots of the analyzed product would be placed in appropriate containers and shipped to customers. Analytical techniques that might be used include (1) inductively coupled plasma/atomic emission spectroscopy, (2) gamma energy analysis, (3) alpha energy analysis, and (4) counting equipment.

All liquid waste would be neutralized and captured on a solid absorbent as solid waste. Solid compacted waste for each product (excluding cladding hardware) would range from 0.28 to 0.14 cubic meters (1 to 5 cubic feet) per year per product (BWHC 1999).

**Figure C-5 Processing of Target Material Where the Isotope Product (Holmium-166) is Chemically Identical to the Target Isotope (Holmium-165)**

### C.3.2 Same Target/Product Requiring Separation

Five target materials producing other isotopes of the same element would require further processing: cadmium-109, lutetium-177, osmium-194, strontium-89, and xenon-127. A typical example of a product requiring separation would be cadmium-109 from cadmium-108. The cadmium-109 produced from enriched cadmium-108 would contain small amounts of cobalt-60, zinc-65, and silver-110m, along with cadmium-109 and cadmium-115m. Medical isotope target carriers would be unloaded from the cask into a hot cell, where they would be prepared for transport from the hot cell to the appropriate isotope processing stations. The cadmium oxide would be removed from the target carrier, dissolved in hydrochloric acid, and diluted with water to 0.1 molar (*M*) hydrochloric acid. The impurities and cadmium would be adsorbed on a Dowex 50-X8 cation exchange column. The cadmium then would be selectively eluted with 0.2 *M* hydrochloric acid. The eluate would be analyzed using inductively coupled plasma/atomic emission spectroscopy and aliquots of the product solution placed in appropriate containers and shipped to the customers.

All liquid waste would be neutralized and captured on a solid absorbent as solid waste. Solid compacted waste (excluding cladding hardware for each same target/product would be about 0.28 to 0.14 cubic meters (1 to 5 cubic feet) per year per product.

### C.3.3 Processing Target Materials Containing New Elements

Twelve target materials would produce different product elements and each would require unique chemical separation. The processing steps would include separation and purification of the product isotope, retrieval of the original target material for possible reuse, and disposal of the residual waste. Four examples of process separation are discussed to show the diversity of the separation methods.

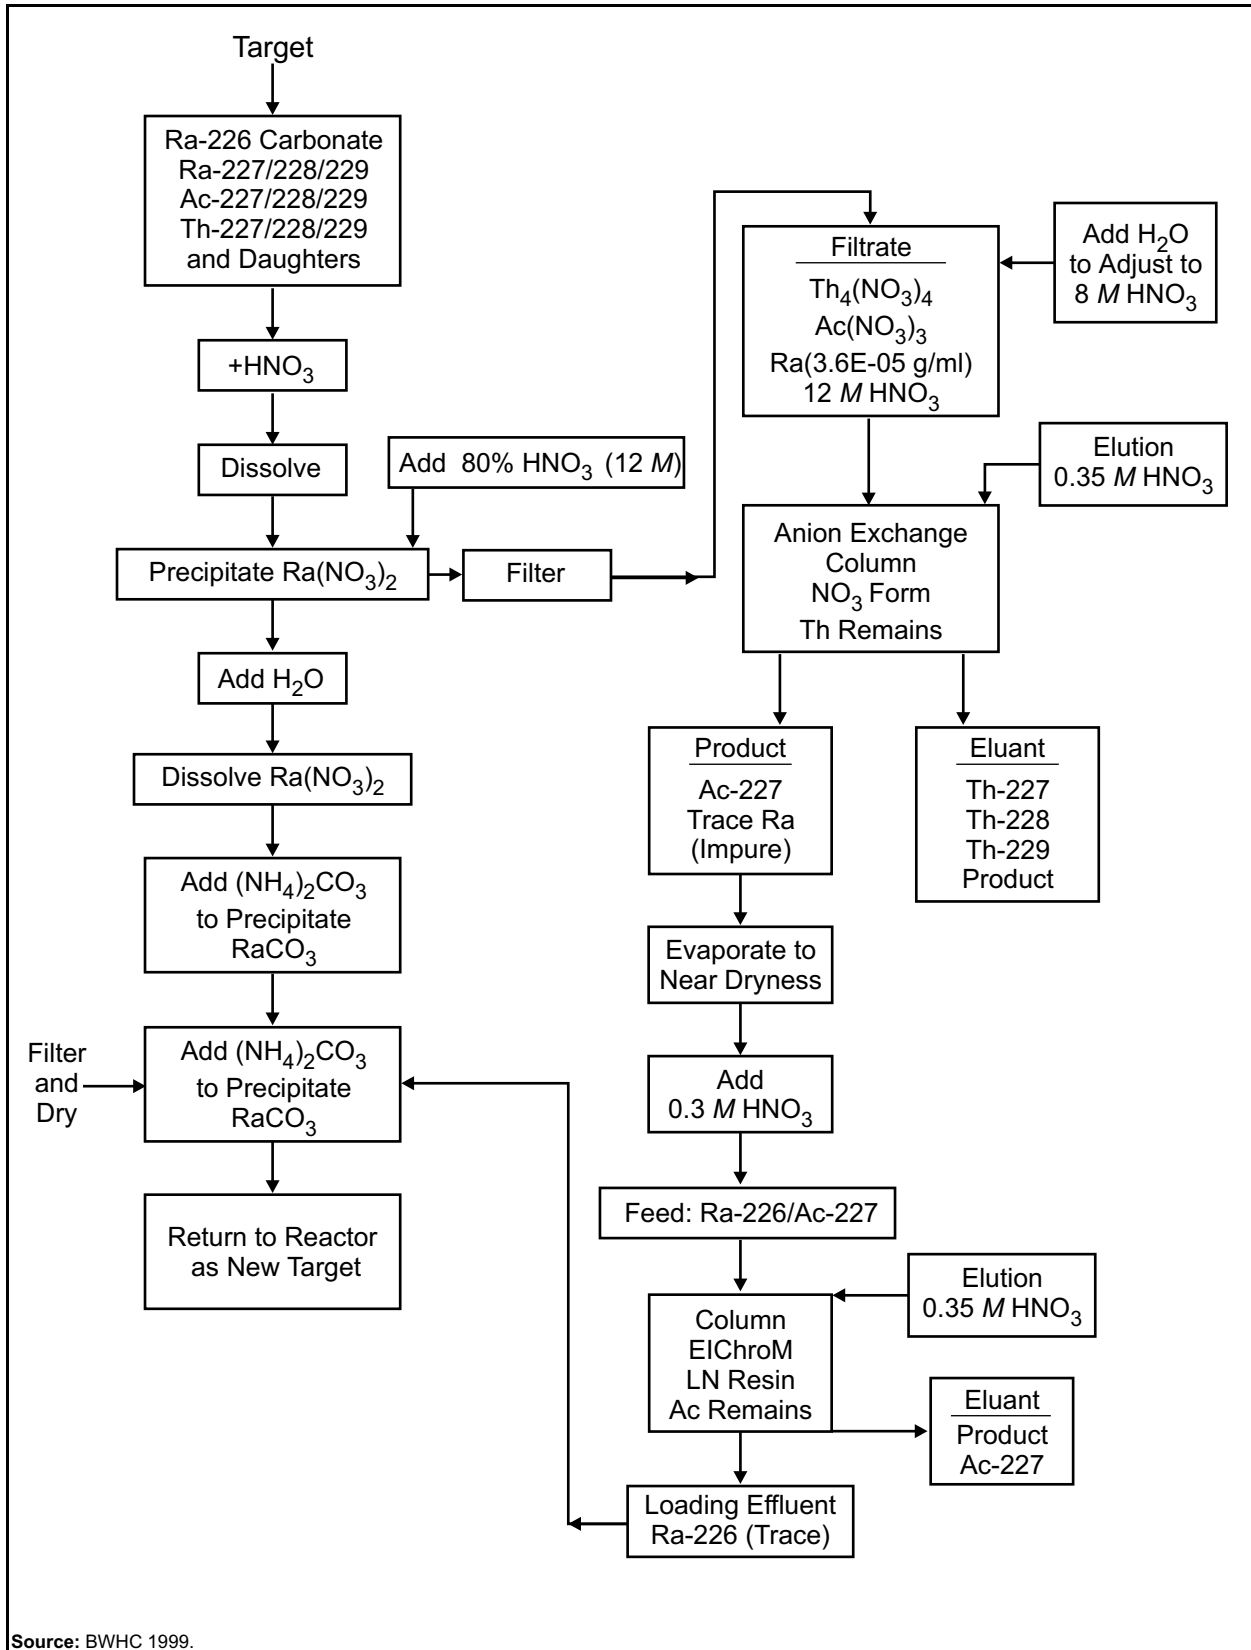

#### ACTINIUM-227 AND THORIUM-228/229 FROM RADIUM-226

Radium-226 would be the only target that would be radioactive before being irradiated. It would be used to produce three products: actinium-227, thorium-228, and thorium-229. The processing room would contain a high-level radiochemical cell, a leaded glovebox, and an open-face hood, all connected to a radon capture facility. The radon capture facility (temperature-controlled charcoal filter) is required to prevent release of radon gas from the facility while storing the original target material and processing the irradiated targets.

The capsule containing the irradiated target (radium carbonate) material would be transported to the hot cell in a shielded container and opened for removal of the target material by cutting the cladding. The carbonate salt would be dissolved with acid (**Figure C–6**). The radium then would be separated by nitrate precipitation and filtration. The remaining thorium, actinium, and radium in the filtrate solution would be purified using ion exchange separation.

Detailed steps in processing the radium-226 would include removal of the radium carbonate solid from the metal capsule for dissolution in dilute nitric acid. An addition of 80 percent nitric acid to the mixture then would be performed to precipitate the radium as radium nitrate, followed by filtration. The precipitated radium would be retrieved by the addition of water to redissolve the radium nitrate precipitate. Ammonium carbonate then would be added to the dissolved radium nitrate solution to precipitate radium carbonate. The carbonate precipitate would be filtered, dried, and could be reused as target material.

The 12 *M* nitric acid filtrate from the radium nitrate precipitation, containing thorium, actinium, and traces of radium, would be adjusted with water to 8 *M* acid and loaded on to an anion exchange column. The thorium

Source: BWHC 1999.

Figure C-6 Processing Procedures for Removal of Actinium-227, Thorium-228, and Thorium-229 Products from Irradiated Radium-226 Targets

would be held on the column, allowing the actinium, radium, and other impurities to be captured in the effluent. The purified thorium would be eluted from the anion exchange column with 0.35 *M* nitric acid. The thorium-228/229 product solution would be analyzed to ensure purity, and aliquots of the analyzed product would be placed in appropriate containers and shipped to customers.

The actinium-227 and traces of radium, found in the effluent solution from the anion exchange purification of thorium, would be evaporated to dryness and redissolved in 0.03 *M* nitric acid. This solution would be loaded onto an EiChroM resin column and the effluent containing the radium retrieved via carbonate precipitation. The resin column containing purified actinium-227 would be eluted with 0.35 *M* nitric acid. The actinium-227 product solution would be analyzed to ensure purity, and aliquots of the analyzed product would be placed in appropriate containers and shipped. The actinium-227 also can be used on site for recovery and shipment of radium-223.

All liquid waste would be neutralized and captured on a solid absorbent. Solid compacted waste (excluding cladding hardware and radon holdup charcoal) is estimated at 0.28 cubic meters (10 cubic feet) per year (BWHC 1999).

#### **COPPER-64 AND COPPER-67 FROM ZINC-64 AND ZINC-67**

The capsule containing the irradiated zinc oxide target would be transported to the receiving hot cell. Irradiated targets and carriers would be transported in shielded containers from the hot cell to an isotope processing station containing a hot cell, a lead-shielded glovebox, a fume hood, and a laminar flow hood. The target material would be removed from the carrier by cutting the capsule containing the zinc oxide. The oxide would be dissolved with sulfuric acid. The sulfuric acid solution would be placed in an electrochemical cell and the copper deposited on a platinum electrode (**Figure C-7**). The platinum electrode would be removed from the electrochemical cell and copper-64 or copper-67 dissolved from the surface by immersing the platinum electrode in nitric acid. The zinc could be retrieved by converting it to the oxide form to be used as target material.

Detailed steps in processing the copper isotopes would include removal of the zinc oxide from the metal capsule for dissolution in 1 *M* sulfuric acid and transfer to the electrochemical cell. After 30 minutes, the copper would have been completely deposited on the platinum electrode. The target solution still containing the zinc would be removed and replaced with fresh acid and the copper deposition would be continued for an additional 30 minutes. This step would be repeated for a second time to assure purification. The deposited copper on the platinum electrode then would be removed from the cell and dissolved by immersing the electrode in concentrated nitric acid for 1 to 2 minutes. This solution would be evaporated to near dryness to remove the strong acid. The dried product then would be redissolved in an appropriate acid. The solution would be analyzed for chemical and radionuclide purity, and aliquots of the final product placed in containers and shipped to customers.

The zinc ion contained in the spent electrochemical solution could be retrieved, converted back to zinc oxide, and returned to the reactor for re-irradiation. If other unwanted metal ions are found in this solution, the zinc ion would be purified by ion exchange prior to oxalate precipitation and calcination to the oxide.

All liquid waste would be neutralized and captured on a solid absorbent as solid waste. Solid compacted waste (excluding cladding hardware and radon holdup charcoal) is estimated at 0.28 cubic meters (10 cubic feet) per year (BWHC 1999).

**Figure C-7 Electrochemical Separation of Copper-67 Product from Zinc-67 Target Material**

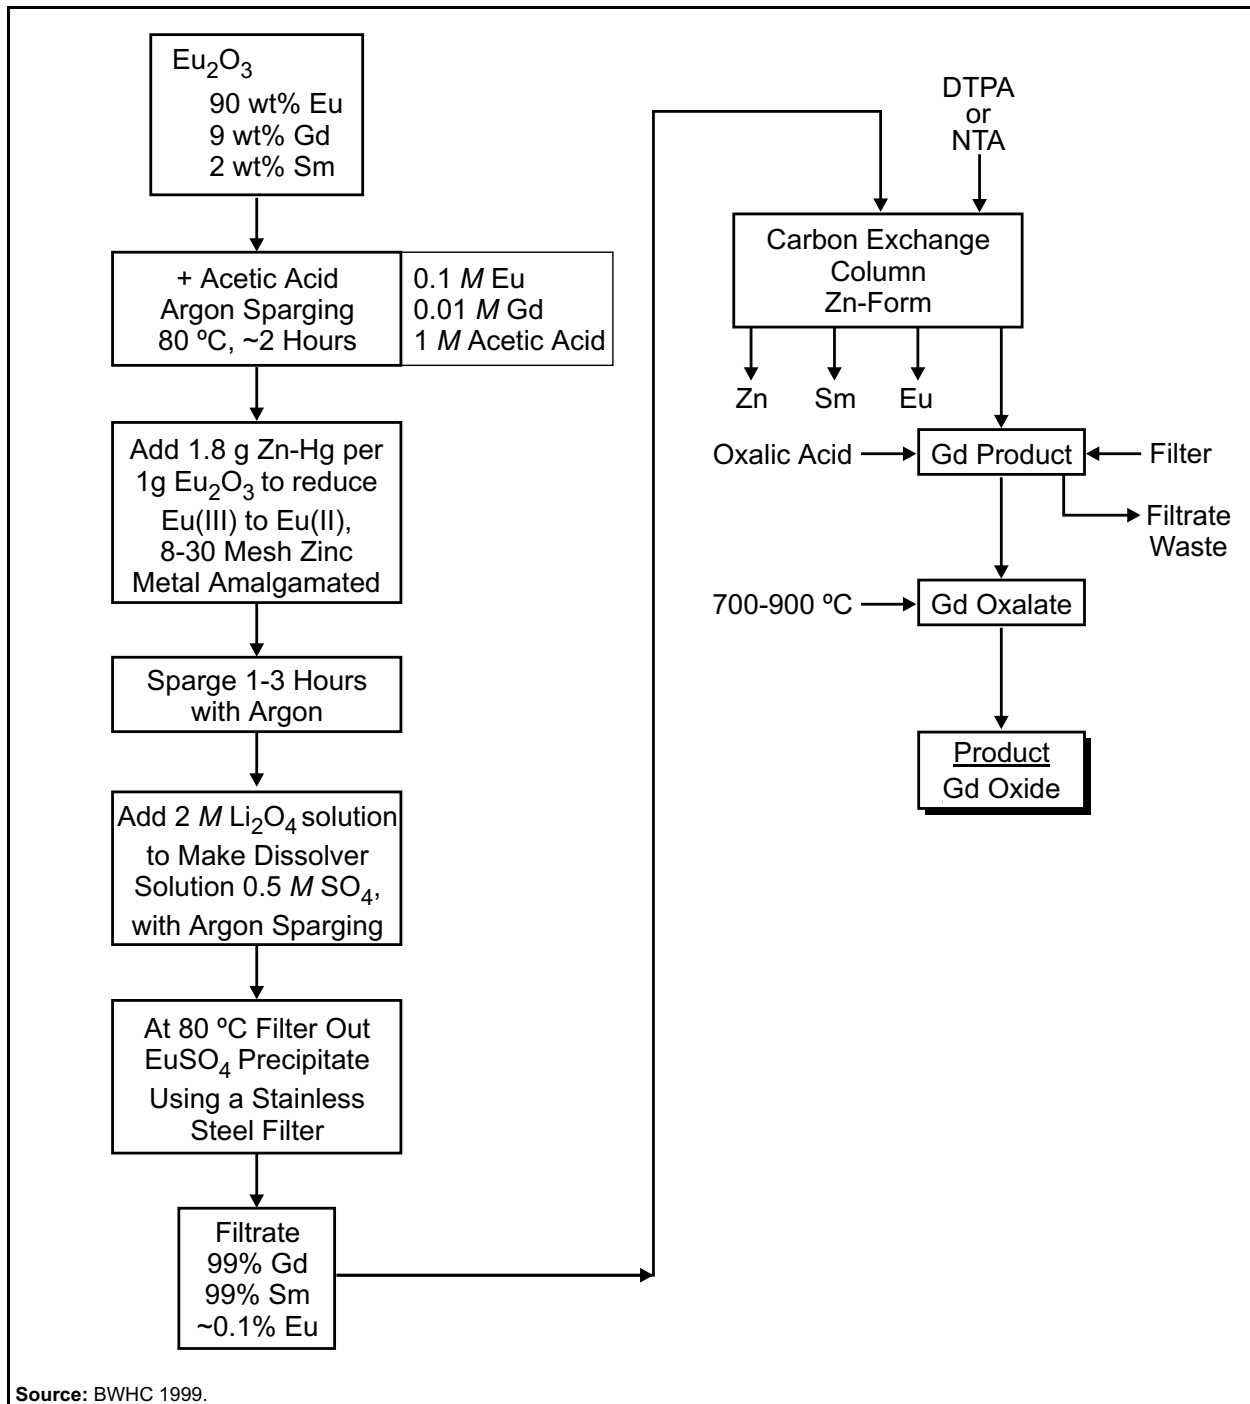

#### GADOLINIUM-153 FROM EUROPIUM AND SAMARIUM

The capsule containing the irradiated europium oxide target pellets would be transferred to a hot cell for dissolution and europium removal, followed by ion exchange band displacement in a heavily shielded glovebox. The pellets would be removed by cutting open the capsule containing the irradiated europium oxide. The europium oxide pellets would be dissolved with acid, greater than 99.9 percent of the europium isotopes would be removed by sulfate precipitation of europium (II), and ion exchange band displacement would be used to separate 0.1 percent of the remaining europium, along with the samarium and gadolinium, into fractional purified bands (**Figure C-8**). The final gadolinium-153 product would be precipitated, dried, and heated to a high temperature to form gadolinium oxide.

Detailed steps in processing the gadolinium-153 include removal of the oxide pellets from the metal capsule for dissolution in acetic acid. With argon sparging to prevent air oxidation, the solution would be contacted with amalgamated zinc (Jones reductor) to reduce the europium (III) to europium (II). A sulfate salt would be added to precipitate the europium (II), separating it from samarium (III) and gadolinium (III).

The resulting filtrate solution would contain gadolinium, samarium, and less than 0.1 percent of the europium. This solution would be transferred to a shielded glovebox to separate and purify the gadolinium-153 using band-displacement cation exchange chromatography. Ammonium-buffered chelating agents such as nitrilotriacetic acid or diethylenetriamine-pentaacetic acid would be used to fractionate gadolinium/samarium/europium using a zinc-loaded cation exchange column.

The purified gadolinium-153 product solution would be transferred into a second shielded glovebox for oxalate precipitation, filtration, and calcination to the oxide, and then pressed into pellets for shipment to customers. Mixed liquid waste would contain zinc, acetic acid, 45 curies of europium per curie of gadolinium product separated, and ammonium diethylenetriamine-pentaacetic acid organic complexant (0.05 to 0.5 liters [0.013 to 0.13 gallons] of liquid waste per curie of gadolinium recovered). Solid compacted waste (excluding cladding

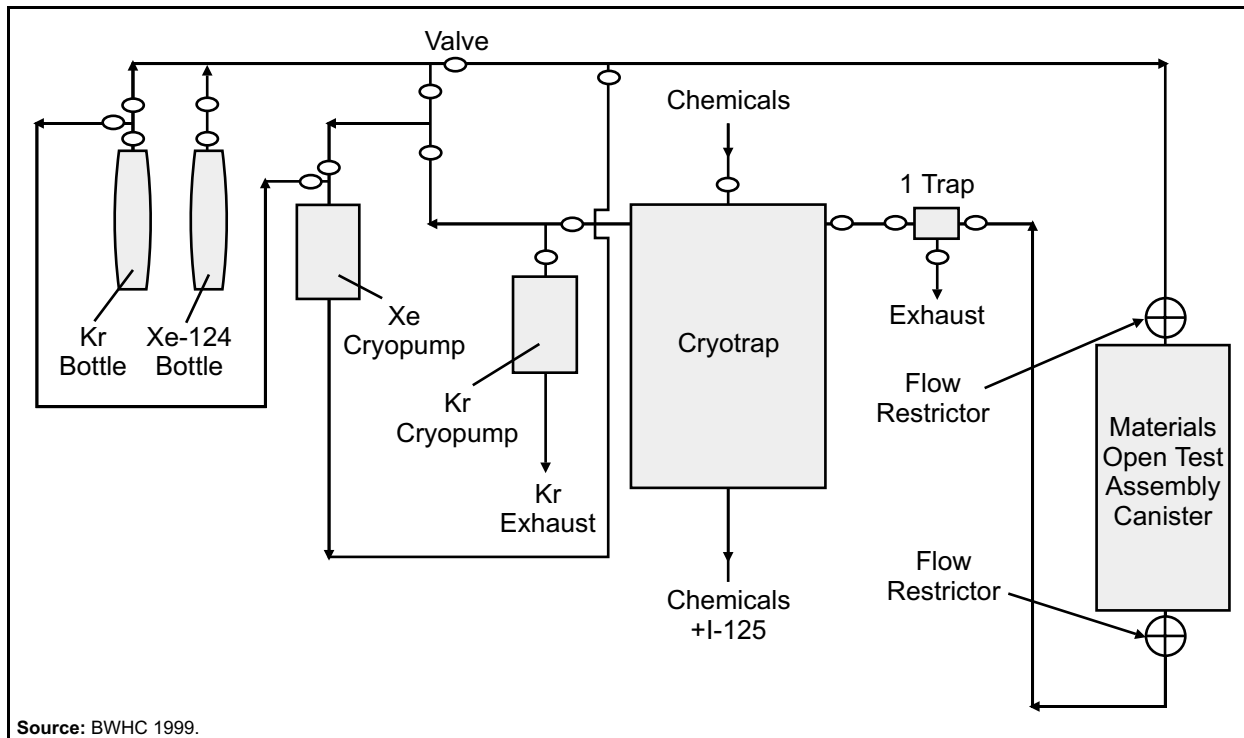

**Figure C-8 Procedure for Separation of Gadolinium-153 Product from Europium Target Isotopes**

and hardware) is estimated at 0.28 cubic meters (10 cubic feet) per year, including a Jones reductor. Ion exchange columns, sulfate precipitation equipment, and the pellet press would be reused and only become waste at the termination of the project. This waste would be about 0.28 to 2.8 cubic meters (10 to 100 cubic feet) (BWHC 1999).

## IODINE-125 FROM XENON-124 GAS TARGET

The method of production and separation would be based on the irradiation of 5 liters (1.3 gallons) of enriched xenon-124 for approximately 2.5 hours, trapping the irradiated gas, letting the xenon-125 gas decay to iodine-125 for approximately 2 days, distilling off the inert gases, chemically reacting to remove iodine-125 from the wall of the cryotrap, followed by final processing, packaging, and shipping of the product. The conceptual system is shown in **Figure C-9**. The system would consist of several cold traps (cryotrap), flow restrictors, a gas canister, and a processing system (glovebox and cryopump).

**Figure C-9 Gas-Trapping Procedure for Separation of Iodine-125 Product from Xenon-124 Gas Target**

Detailed procedures for producing iodine-125 are at the conceptual stage. Once the system is ready, the xenon-124 gas bottle valve would be opened. The rate of flow would be controlled by the flow restrictors located downstream and upstream of the canister. Once the xenon-124 bottle becomes empty, krypton gas would be valved in and used to push the xenon-124 first through the gas line and next through the canister. Once the gas has been pushed through the downstream flow restrictor, the gas would flow through the iodine trap to the cryotrap, which would be maintained at a low temperature and result in a low pressure (less than  $10^{-6}$  torr). The xenon-124, transmuted xenon-125, and some krypton “pusher” gas would be absorbed on the cryotrap cold surface. The cryotrap inlet valve then would be closed and the krypton in the gas lines would be evacuated to the krypton cryopump.

After about 2 days with the xenon-125 (17-hour half-life) decaying to iodine-125 (60-day half-life), the cryotrap downstream valve would be opened and the cryotrap warmed to first distill the xenon-124 to the xenon cryopump, and then any krypton to the krypton cryopump. The product iodine-125 remaining in the cryotrap then would be chemically reacted (caustic) and the product analyzed, processed, packaged, and shipped.

## Appendix D

### Fast Flux Test Facility Operations

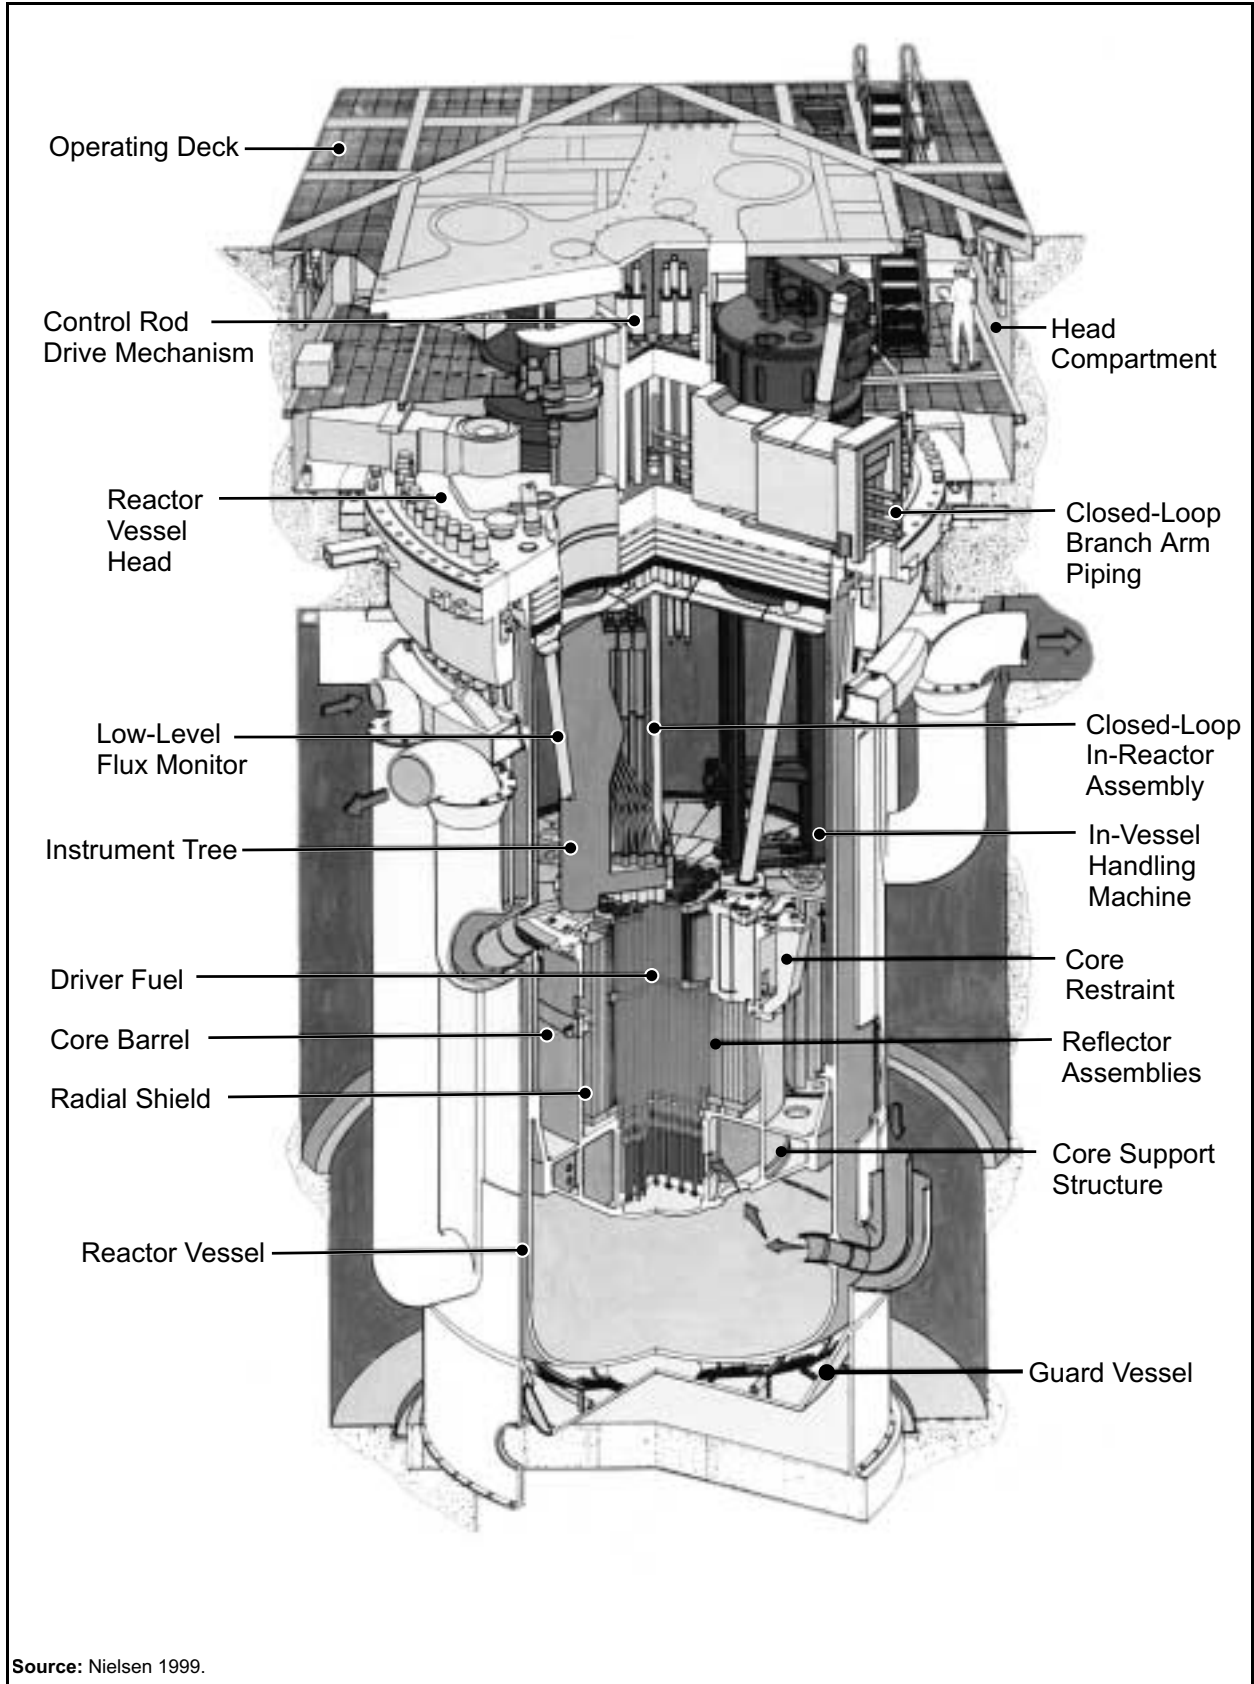

#### D.1 FAST FLUX TEST FACILITY DESCRIPTION

The Fast Flux Test Facility (FFTF) is an advanced liquid-metal-cooled research reactor located in the 400 Area of the Hanford Site. This appendix provides a description of FFTF operations that is based on the *Fast Flux Test Facility Data Request in Response to Data Call from Nuclear Infrastructure Programmatic Environmental Impact Statement* (Nielsen 1999). The reactor (**Figure D-1**) is located in a shielded cell in the center of the containment building. Heat is removed from the reactor by liquid sodium circulated under low pressure through three separate closed primary piping systems, referred to as loops, which include pumps, piping, and intermediate heat exchangers. These loops are located within inerted cells in containment. **Figure D-2** is a cutaway view of the containment building showing the location of the reactor, primary pumps, and intermediate heat exchangers. Three secondary sodium loops transport the reactor heat from the intermediate heat exchangers to the air-cooled tubes of the dump heat exchangers for dissipation to the atmosphere (FFTF does not generate electricity). **Figure D-3** depicts one of the three cooling loops.

FFTF is a versatile fast flux reactor capable of producing plutonium-238 and a variety of medical and industrial isotopes, as well as supporting materials testing and nuclear research and development activities. Due to the reactor size, the number of available test locations, and the instrumentation capabilities for monitoring individual irradiation and test locations in the core, a wide variety of irradiations and tests can be carried out concurrently.

The term “fast flux” is indicative of the high energy (speed) of the neutrons within the reactor core. The total flux density of FFTF (fast plus thermal neutrons) is significantly higher than in a light water reactor. A supply of fast or high-energy neutrons allows FFTF to test a variety of materials and carry out research in an environment where fast neutrons are needed. For producing many isotopes, a thermal neutron environment may be more desirable. In this case, FFTF can slow down, or thermalize, fast neutrons by placing appropriate materials around the irradiation targets. **Figure D-4** shows a possible multitest core configuration for the various missions under consideration. These various reactor locations are discussed in the following paragraphs.

There are eight locations available in the reactor that are called open test assembly positions. These eight locations are distinct from the rest of the reactor in that they allow direct-contact instrumentation for remote monitoring during reactor operations. They are called “open” because they are directly cooled and exposed to the sodium environment within the reactor, as are most of the in-vessel components. What makes these locations distinct are the instrument stalks attached to them that communicate with and extend above the reactor head for routing of various instrumentation packages (**Figure D-5**). They also are positioned so that they allow for inner (core row 2), middle (row 4), and outer (row 6) reactor fluence environments. As many as eight Rapid Radioisotope Retrieval systems could be installed in these positions for the production of short-lived isotopes. However, it is expected that initially only one of these rapid retrieval systems would be installed in open test assembly positions in the reactor core.

Figure D-5 Reactor Core with Various Test Packages Installed

Within the 82 active core locations, there are up to 20 or more additional locations that could contain a standard length (12-foot) irradiation assembly within the active core region. These locations also have specific on-line outlet temperature and flow measurements from installed plant instrumentation in the reactor core Instrument Trees, which are shown in **Figure D-6**. In addition to these test locations within the active fueled region of the core, there are 108 locations available in the surrounding reflector region where other irradiation assemblies could be inserted (e.g., plutonium-238 and cobalt-60 targets). These three basic irradiation configurations enable large-quantity and very diverse testing capabilities. Target designs vary according to the test requirements and the location of the test within the reactor.

**Figure D-6 Instrument Trees Over the Initial (Unfueled) Core**

## **D.2 LONG-TERM IRRADIATION VEHICLES**

The Long-Term Irradiation Vehicles described in Appendix C (e.g., plutonium-238 targets and Long-Term Irradiation Vehicles for isotope production) would be installed in the reactor during normal refueling operations and would be handled using the standard FFTF component handling equipment. FFTF includes areas for receiving, conditioning, storing, installing, and removing from the reactor core all routinely removable core components. There are also areas for washing and storing irradiated fuel and nonfuel reactor components. Test and component examination and packaging capabilities also are provided.

FFTF uses state-of-the-art computer-controlled shielded transfer machines to perform reactor refueling operations as well as component and experiment transfers into and out of the reactor, the Interim Examination and Maintenance Cell, and into shipping/transfer casks. **Figure D-7** is a schematic of the equipment and transfer locations. The transfer machines are designed and operated with safety features and redundant systems to ensure safe transfer of irradiated materials. They are maintained reactor-grade clean; all internal surfaces are made of stainless steel and are maintained inert with argon gas.

Figure D-7 FFTF Equipment and Transfer Locations

The Closed Loop Ex-Vessel Machine, **Figure D-8**, is used to handle both standard-length reactor components (i.e., 12 feet long) and longer test assemblies such as the open test assemblies described in Section D.3. The Closed Loop Ex-Vessel Machine is used for inserting all components into the reactor vessel. Open test assemblies are inserted directly into the reactor core and standard-length components are placed into In-Vessel Storage inside the reactor vessel before transfer into the reactor core. In-Vessel Storage modules are provided in three sections of the annular region between the core barrel and the reactor vessel thermal liner. Each storage module provides 19 natural-convection sodium-cooled receptacles for core components.

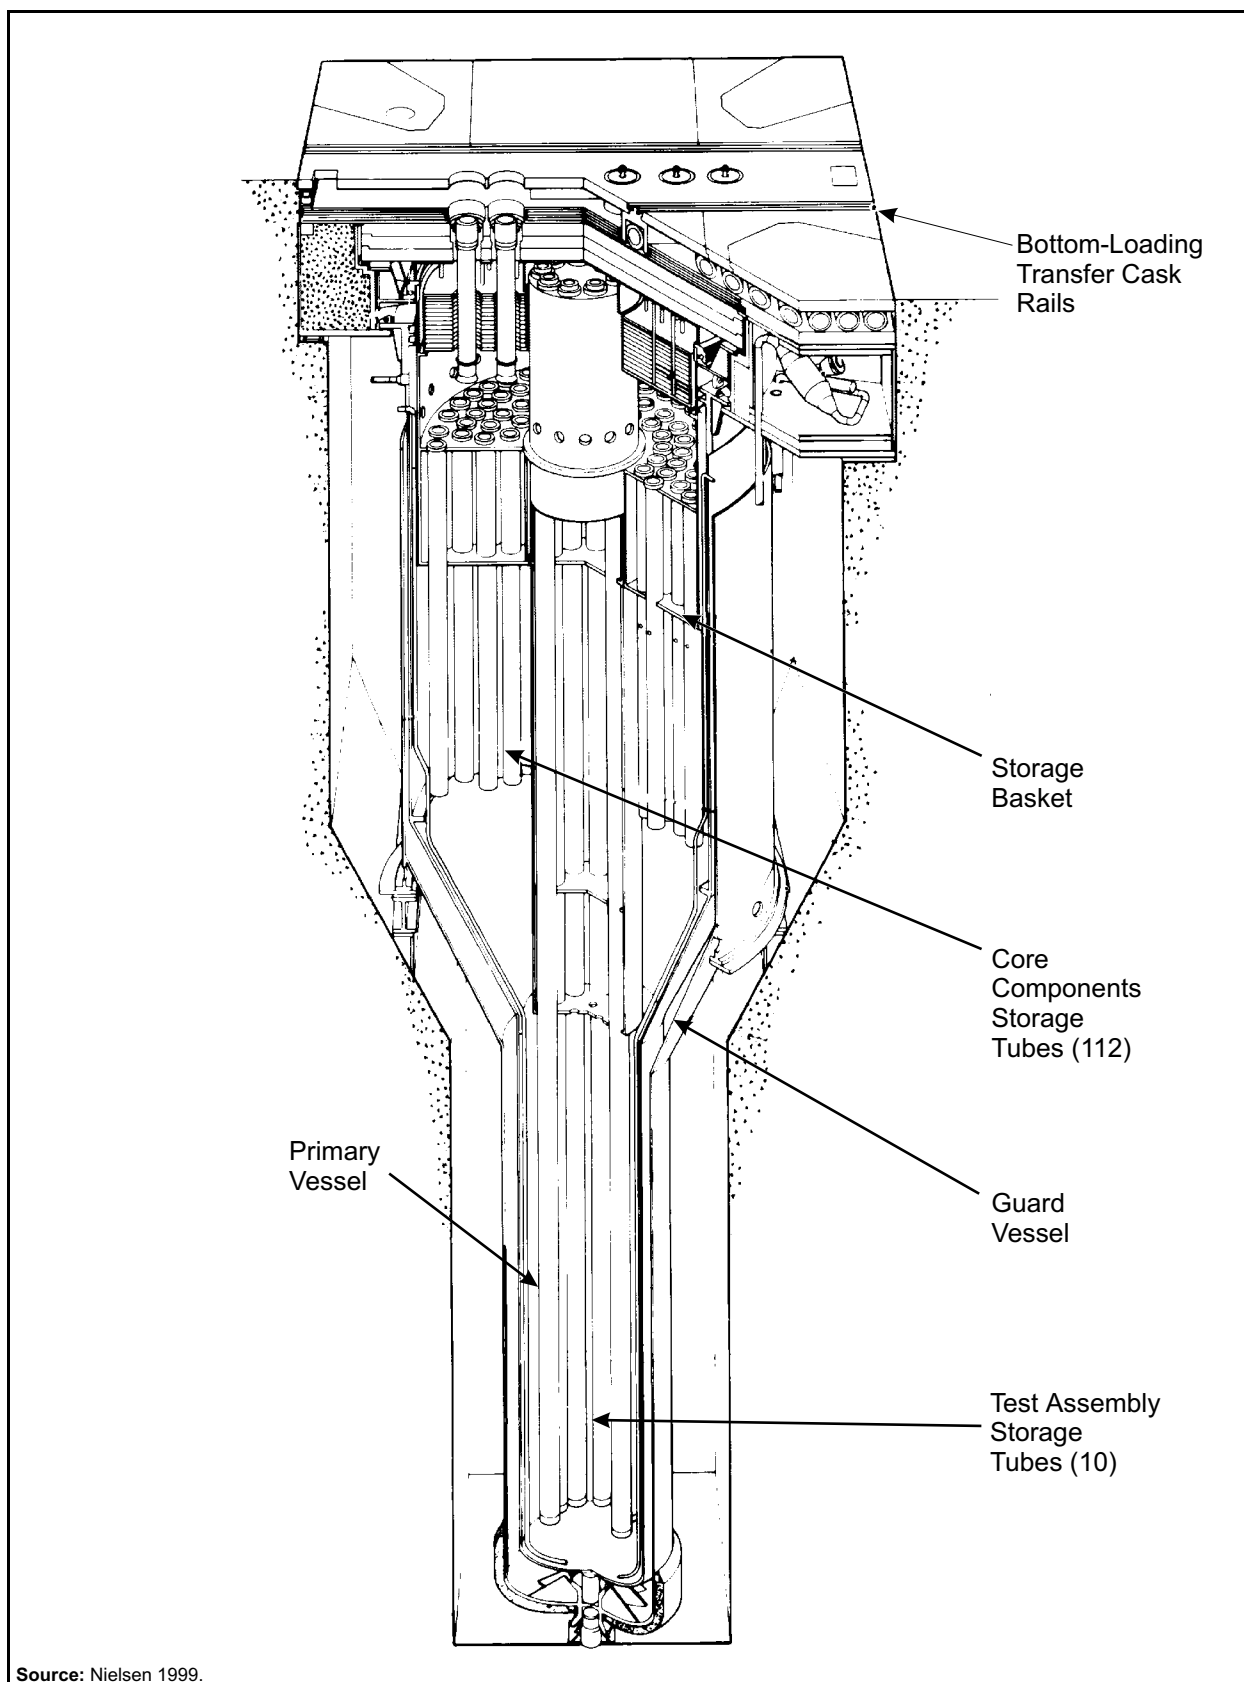

Source: Nielsen 1999.

**Figure D-8 Closed Loop Ex-Vessel Machine**

Assemblies for material surveillance samples can be installed in the In-Vessel Storage modules. During reactor operations, these samples are exposed to the sodium, thermal, and radiation environment typical of the reactor vessel.

The Closed Loop Ex-Vessel Machine is also used for the transfer of sodium-wetted irradiated components from the reactor vessel to either Interim Decay Storage (a sodium-cooled storage vessel inside containment shown in **Figure D-9**) or to the Interim Examination and Maintenance Cell, depending on whether it will be stored for later disposition or undergo examination. The standard-length assemblies are handled by one of the three In-Vessel Handling Machines for installation into or removal from the core. After irradiation, the Long-Term Irradiation Vehicles would be transferred to the Interim Examination and Maintenance Cell for washing and disassembly prior to shipment of the pins to the processing facility for isotope extraction and purification.

The Interim Examination and Maintenance Cell (**Figure D-10**) is a large, shielded, hot cell complex located inside containment that provides a reliable means of conducting nondestructive examination of test assemblies and core components under controlled argon-atmosphere conditions. Four levels of operating galleries provide visual access for remotely operating the hot cell equipment. This highly shielded hot cell has a

Source: Nielsen 1999.

Figure D-9 Interim Decay Storage Vessel

significant number of remote tools and equipment for diverse examination and disassembly needs. The hot cell, which is over 50 feet deep, contains two cranes and two very large electromechanical manipulators as well as multiple pairs of smaller master-slave-type manipulators at various operating levels for component and equipment handling. A sodium-cleaning station is available to wash irradiated components of all external sodium residues after removal from the reactor's sodium environment. This sodium-removal system has been used extensively to wash all fuel and experimental test assemblies processed in the Interim Examination and Maintenance Cell, as well as many of the FFTF spent fuel assemblies as they were offloaded to interim dry storage. The demineralized water used for washing is recycled through ion beds. The ion beds are periodically changed out and buried as low-level radioactive waste.

Source: Nielsen 1999.

**Figure D-10 Interim Examination and Maintenance Cell**

Following sodium removal and drying, irradiated components can be remotely disassembled using the manipulators, fixtures, and special tooling located within the Interim Examination and Maintenance Cell. For example, disassembly of plutonium-238 or cobalt-60 targets

may be required to accommodate shipments of shorter target pin sections, depending on handling limitations of the selected processing facility. Various equipment is available for postirradiation examinations (e.g., weight, visual exam/photography, disassembly, and packaging for shipment). The hot cell also has been used for interim examination of tests and complex reassembly and qualification to allow a test to be returned to the reactor for further irradiation.

The Bottom-Loading Transfer Cask (**Figure D-11**) is used to transfer test articles, standard-length components, and specimen containers from the Interim Examination and Maintenance Cell to the cask-loading station for transfer to offsite facilities for further examination, or to the Fuel Storage Facility (a sodium-cooled storage vessel located outside of containment) for subsequent storage.

Irradiation assemblies can be transferred from the Interim Examination and Maintenance Cell to the cask-loading station for placement into shipping casks for transport to the processing facility or to offsite locations

for destructive examination, other testing, or processing. The cask-loading facility has the capability to handle large spent fuel casks weighing up to 75 tons for vertical loading and unloading.

### D.3 OPEN TEST ASSEMBLIES

During its 10 years of operation, FFTF supported a large and varied test program for industry, nuclear energy (domestic and international), nuclear defense, and medical research and treatment. The testing focused primarily on reactor fuel and different fuel assembly material evaluations, but also provided significant testing for many other programs. Following is a brief description of the major types of tests that were performed at FFTF using the open test assemblies. Similar test vehicles could be used to support the new missions:

- **Material Open Test Assembly.** The 38-foot-long Material Open Test Assembly (**Figure D-12**) provided multiple containers capable of irradiating many different material specimens. Each container was individually temperature-controlled by the online mixing of argon and helium gases in the container annulus. This provided varying heat transfer from the container to the reactor sodium coolant. The support system for this test vehicle includes multiple gas lines, temperature control loops, and an online control and monitoring system.

Source: Nielsen 1999.

**Figure D-11 Bottom-Loading Transfer Cask**

- **Fusion Material Open Test Assembly.** The reactor portion of this test vehicle was essentially identical to the Material Open Test Assembly and included many material test specimens as well as the two canisters that were part of the fusion testing program. This test series was a joint venture for the United States, Canada, and Japan to evaluate tritium production by the irradiation of lithium oxide. The purpose of the experiment was to measure tritium release characteristics and thermal stability of lithium oxide as a function of neutron exposure, temperature, gas composition, and sweep gas flow rates. This equipment also included the instrumentation and controls for tritium measurement, analysis, and recovery.
- **Absorber Open Test Assembly.** The Absorber Open Test Assembly provided for online instrumentation (temperature and pressure) of standard boron carbide absorber pins used in reactor control and safety rods.

Figure D-12 Material Open Test Assembly

- **Fuel Open Test Assembly.** The Fuel Open Test Assembly provided direct measurement during reactor operation of temperatures and pressures of individual fuel pins allowing monitoring of fuel assembly performance during the entire irradiation phase.

#### D.4 RAPID RADIOISOTOPE RETRIEVAL SYSTEMS

Rapid retrieval systems would be installed in selected open irradiation assembly positions for the production of short-lived isotopes. These systems would allow target materials to be inserted and withdrawn from the reactor core region with the reactor operating at power. Systems for routinely inserting and removing irradiation targets, nuclear instrumentation, and research hardware at an operating reactor have been in use at various research reactors throughout the world for years. Most of these systems use either a pneumatic rabbit-type system or a mechanical cable-type system for insertion and retrieval. **Figure D–13** is a conceptual layout of an FFTF rapid retrieval system, which consists of three major components: a 40-foot-long in-reactor thimble assembly, a replaceable string or chain of isotope target carriers, and a target carrier insertion and retrieval system.

The target carrier insertion and retrieval system(s) would be installed external to the reactor to shuttle a target carrier chain into and out of the core region. This system could use some form of mechanical cable insertion and retrieval mechanism or could be based on a pneumatically operated system. Ideally, the insertion and retrieval system would load irradiated target chains directly into the transportation cask for shipment to the hot cell laboratory facilities for isotope separation and purification.

In addition to irradiating solid targets in the rapid retrieval system carrier chains, gas targets also could be irradiated to produce short-lived isotopes. Two options would be evaluated for producing the gas-based isotopes. One option would involve one or more small-diameter, thin-wall tubes routed down through the in-reactor thimble assembly into the active core region. These tubes would be connected via shielded and preheated tubes to a shielded ex-reactor gaseous isotope recovery system. The practice of routing external gas lines into the active core region is not new at FFTF and has been used in several irradiation test assembly designs installed in the reactor (e.g., the Material Open Test Assembly used externally supplied gas mixtures to control material sample temperatures, and the Fusion Material Open Test Assembly had gas lines routed to a glovebox for tritium sampling and gas analysis).

A second option for producing gas-based isotopes would involve irradiating capsules filled with a high-pressure target gas. The gas-filled capsules would be installed in a target carrier and could become part of a target chain.

#### D.5 REACTOR CORE CONFIGURATION PLANNING

Typical operating cycles for FFTF were approximately 100 days at power followed by shutdown periods that ranged from approximately 20 to 30 days for short outages to 60 to 90 days for extended outages, depending on the extent of maintenance and refueling to be performed. These same operating cycles were assumed for evaluating restart activities. There may be benefits to longer operating cycles (e.g., increased capacity factor, reduced equipment use); therefore, future consideration may be given to such intervals.

Reactor core configuration planning would be completed prior to the start of reactor servicing in preparation for the next operating cycle. This planning would accommodate the user-defined irradiation requirements for each target. Those requirements typically would be defined in terms of neutron energy and flux level, duration of the irradiation (or cumulative exposure), and temperature. Given these requirements, the in-core location for each target assembly would be analyzed and decided based on the neutron energy and flux level at that location; the neutronic characteristics of adjacent assemblies; coolant flow and temperature at that location;

Source: Nielsen 1999.

Figure D-13 Conceptual Layout of the Rapid Radioisotope Retrieval System

reactor power level; target gamma heating and the resultant target temperature; and planned operating cycle duration. The resultant core configuration would have to meet the nuclear safety requirements and limitations defined in the Final Safety Analysis Report and the Technical Specifications.

During prior FFTF operations, the reactor physics and nuclear safety aspects of the planned core configuration were analyzed prior to the start of each operating cycle. If FFTF is directed to restart, the reactor initially would be refueled similar to the configuration in place at shutdown. The data from that operating cycle would be included in analysis of the reloaded core to predict safety margins and control rod positions for initial criticality. Following completion of physics testing of that initial core configuration, it would be used as the “reference core configuration,” from which each subsequent core configuration change made to accommodate fuel burnup and irradiation service requirements would be analyzed for control and safety purposes.

## D.6 TARGET TEST AND DEVELOPMENT

Testing programs would be conducted for new materials and target designs to be irradiated in the reactor. Brief descriptions of the types of testing that would be associated with the plutonium-238 and medical isotope production missions are given below.

**Plutonium-238 Production**—As discussed previously, it is expected that the targets used for plutonium-238 production in FFTF would be similar to the concepts developed during the plutonium-238 production core study that was done between 1992 and 1993. Target design would be based on alternating thin pellets or wafers of neptunium dioxide and yttrium hydride. To support the final design of the initial plutonium-238 production target assemblies, at least one lead test assembly would be designed and fabricated to be available after the initial low-power physics testing. Confirmatory irradiation tests would be done in the lead test assembly(ies) at the core periphery prior to the start of fabrication of the plutonium-238 production assemblies. These tests, which would require small amounts of neptunium dioxide, would be done to demonstrate items such as target wafer integrity and dimensional stability, and to confirm target isotopic content from irradiation. Additionally, exploratory materials tests would be irradiated in parallel to investigate any material compatibility or performance issues, and to evaluate options to improve plutonium-238 production rates or optimize/reduce target fabrication costs. These tests, which could be done under accelerated irradiation conditions in a variety of assemblies such as the Long-Term Irradiation Vehicle, could include tests of other hydride materials such as zirconium hydride or calcium hydride as well as various foil wrapper and cladding materials.

**Medical and Industrial Isotope Production**—A testing program would be performed to support the development and detailed design of the Rapid Radioisotope Retrieval system and the associated initial targets. Feature tests would be conducted as necessary to support development of key portions of target insertion, retrieval, and handling equipment. High-temperature furnace tests would be performed as required to ensure materials compatibility for those materials or material combinations for which high-temperature data do not exist. This would be done both for the Rapid Radioisotope Retrieval system and for the Long-Term Irradiation Vehicle assemblies. A full-scale, heated mockup of the key portions of the Rapid Radioisotope Retrieval system would be built, and insertion and retrieval tests performed using simulated targets and target strings. Ex-reactor modifications needed to support insertion, production, and retrieval of targets in Rapid Radioisotope Retrieval assemblies would be completed, and acceptance tests conducted to the extent possible before initial criticality upon a decision to restart.

Following initial criticality and low-power physics testing, the reactor would be shut down and the lead Long-Term Irradiation Vehicle assemblies and at least one 38-foot-long Rapid Radioisotope Retrieval assembly would be inserted into the reactor. Following additional acceptance testing and low-power physics testing, including Rapid Radioisotope Retrieval characterization, the lead targets would be installed in the Rapid Radioisotope Retrieval assembly. These could consist of relatively small quantities of key target

materials plus dosimeter sets for neutron environment characterization. On removal from the reactor, the initial targets irradiated in the Rapid Radioisotope Retrieval assembly would undergo a variety of special inspections, tests, and radioassays as part of a characterization and target qualification program. Over a period of months, the quantity of target material incorporated into the Rapid Radioisotope Retrieval targets would be increased as feasible to provide beneficial quantities of product isotopes. As the demand for short-lived isotopes grows, additional Rapid Radioisotope Retrieval assemblies and associated support systems would be installed in the reactor as needed to support production.

## **D.7 NUCLEAR RESEARCH AND DEVELOPMENT**

FFTF has demonstrated the capability to produce high-energy, high-fluence neutrons for multiple nuclear science and irradiation services applications. High-energy neutrons are fast neutrons that can be used for the transmutation of elements into useful isotopes (e.g., medical and industrial) and for the investigation and development of materials and components that can be used in harsh, radioactive environments (e.g., fusion reactors). High fluence refers to FFTF's capability to produce a lot of neutrons in a given test volume within the reactor.

The large test volume in FFTF allows the production of larger quantities of isotopes and the ability to test more materials and components when compared to other neutron sources. While other neutron sources may have similar neutron high energies or fluences, FFTF is unique in simultaneously providing all three attributes in a single test facility. FFTF can also produce large quantities of epithermal neutrons by the use of moderating materials that slow down the neutrons in specific areas of the core. These distinctive flux tailoring features, coupled with its large core volume, the ability to vary power from a nominal 100 megawatts up to 400 megawatts, and highly instrumented testing capabilities, enable the reactor to function successfully as a multiple-mission nuclear science and irradiation services facility. Researchers from many different countries have used FFTF for nuclear materials testing and fuel research.

There is particular interest in materials testing associated with extension of commercial nuclear power plant license renewals, cooperative international fusion energy research, space power technology, and transmutation of wastes as a means to destroy long-lived isotopes from commercial spent nuclear fuel. Another area of interest is developing nuclear technologies that advance global nonproliferation. FFTF is ideally suited for the study, research, testing, development, and demonstration of technologies necessary to safely convert plutonium-based materials for disposition and use as proliferation-resistant fuel. Target assemblies to be irradiated in support of these mission areas could be fuel or other materials configured similar to a standard driver fuel assembly (i.e., target material encased in sealed pins and the pins placed in a ducted assembly). Material specimens could also be installed in an open test assembly position within a Material Open Test Assembly, which is described in more detail in Section D.3.

One of the proposed testing activities consists of fuel testing for the Accelerator Transmutation of Waste Program. A fuel development activity for this program could use FFTF for irradiation testing. The tests would be fabricated by the Accelerator Transmutation of Waste program and transported to FFTF for irradiation. Specific test compositions and irradiation parameters for these test fuel assemblies have not been defined. It is anticipated that initial tests would involve a few pins in an assembly, while later tests could involve entire assemblies. The target pins are described as containing a matrix of zirconium and transuranic elements; a composition of 75 percent zirconium and 25 percent transuranic elements, by weight. The transuranic elements would likely be light water reactor discharge fuel at a typical burnup of 33,000 megawatt-days per metric tons of uranium that is stripped of essentially all uranium and fission products. Comparisons of this fuel to the standard FFTF fuel indicate comparable plutonium compositions. Therefore, for purposes of this environmental impact statement evaluation, the Accelerator Transmutation of Waste fuel assemblies were modeled as standard FFTF driver fuel assemblies.

## New Research Reactor Operations

### E.1 INTRODUCTION

A preconceptual design of a new research reactor was developed to meet the U.S. Department of Energy's (DOE) missions of (1) producing medical and industrial radioisotopes, (2) producing plutonium-238 (minimum net annual production of 5 kilograms [11 pounds]), and (3) supporting nuclear energy research and development. In accordance with U.S. nuclear nonproliferation policy, a design limitation of this new research reactor is that it can use only low-enriched uranium with an enrichment of less than 20 percent uranium-235. This preconceptual design includes the basic elements of the research reactor facility, which are sufficient to support this programmatic environmental impact statement, but does not include design details (i.e., system and layout drawings, bill of materials, electrical and piping routing, etc.) commensurate with a complete preliminary reactor design. The reactor design uses proven and licensed low-enrichment fuel type in conjunction with a reactor system that features numerous inherent safety features, such as:

- A large low-pressure, low-temperature coolant inventory around the core to keep the core covered under all accident conditions, absorb heat, and filter any released radioisotopes
- A large prompt negative fuel temperature coefficient of reactivity to mitigate any accidental reactivity insertion event
- Extensive research, development, and operational experience in conjunction with a robust nuclear fuel design
- Minimal reliance on the operation of any active system or component for safe shutdown and accident response

Although significant additional work would be required to develop a detailed preliminary design of this research reactor, the preconceptual design provides the basis for evaluating the environmental impacts and cost of this alternative.

### E.2 NEW RESEARCH REACTOR GENERAL DESCRIPTION

The design of the new research reactor is based on current research reactor designs, which have been approved by both the U.S. Nuclear Regulatory Commission (NRC) and the International Atomic Energy Agency (IAEA), as well as nuclear regulatory authorities of many nations. Most low-enriched uranium operating research reactors use one of two types of nuclear fuel: (1) uranium-aluminum matrix, or (2) uranium-zirconium-hydride (UZrH) with either a light or heavy water neutron moderator. In addition, most research reactors are based on either a pool or tank enclosure for the reactor core. Research reactor designs are based on several key factors including, but not limited to: (1) mission, (2) enrichment limits, (3) required neutron flux, (4) thermal limits, (5) irradiation volume, (6) safety, (7) operations, and (8) cost. All these factors were considered in the preconceptual design of this new research reactor.

Reactor core physics scoping calculations were performed using the SCALE-4.4 (ORNL 1998) computer code package to evaluate three different low-enriched uranium nuclear fuel designs: (1) ternary uranium-zirconia-calcium oxide clad in stainless steel 304 similar to that used in the Power Burst Facility reactor at the Idaho National Engineering and Environmental Laboratory (INEEL) (ANC 1971), (2) uranium-aluminum-silicide alloy clad in aluminum (NRC 1988), used in many research reactors, and (3) UZrH alloy clad in Incoloy-800 (a nickel-iron-chromium alloy similar to stainless steel), known as TRIGA (training, research, isotopes General

Atomics) fuel (GA 2000). All core physics analyses assumed a light water moderator instead of the alternative heavy water moderator because of the significant additional cost related to the use of heavy water. Based on this scoping analysis, coupled with the desired mission of this reactor, current nuclear fuel manufacturing capability, and safety considerations, a TRIGA fuel design was selected for the new research reactor. The principal distinguishing features of the TRIGA fuel are its proven safety performance during power pulsing and its demonstrated long-term irradiation integrity. The TRIGA fuel core provided the largest irradiation volume and highest thermal neutron flux for low-enriched uranium-235 in a research reactor. The high thermal neutron flux is desirable for plutonium-238 production and for producing most of the medical and industrial radioisotopes. Although the 50-megawatt power level of the new TRIGA research reactor is larger than the largest currently operating TRIGA reactor power of 16 megawatts, the fuel design is almost identical to the current TRIGA 10-megawatt high power design, and the system thermal-hydraulic performance represents a linear extrapolation of existing designs. The power density of the 50-megawatt design is less than or equal to that for existing TRIGA reactor designs.

To produce the desired quantity of plutonium-238 along with medical and industrial radioisotopes concurrently with nuclear research and development support, it was determined that a reactor core power of 50 megawatts-thermal would be adequate. Although not evaluated for environmental impacts, the core and reactor systems were designed to accommodate a power level of up to 100 megawatts. At the 50-megawatts-thermal power level, the core requires an active cooling system with forced coolant flow to maintain the fuel below its material thermal limits. The new research reactor cooling system design uses a tank within a pool, which is connected to primary coolant circulating pumps, heat exchangers, and an ultimate heat sink consisting of two cooling towers. The pool is housed in a reactor building which also encloses the pumps, heat exchangers, secondary systems, and spent nuclear fuel storage pool. The spent nuclear fuel storage pool, sized to store the reactor core's discharged spent nuclear fuel for its entire 35-year lifetime, can be hydraulically connected to the reactor core pool for refueling and emergency reflooding. The ultimate heat sink cooling towers, air exhaust stack, and emergency diesel generators are located outside the reactor building.

### **E.3 NEW RESEARCH REACTOR FUEL AND CORE DESIGN**

As discussed in Section E.2, TRIGA fuel was selected for the new research reactor core. TRIGA fuel has been used in research reactors since 1958 with over 50 TRIGA reactors currently operating worldwide, including 19 operating U.S. TRIGA reactors that are licensed by the NRC (NRC 1999), at licensed steady-state power levels of 0.02 to 16 megawatts-thermal and power pulsing capabilities of up to 22,000 megawatts-thermal (GA 2000; RRSAS 1999; Simnad 1980). This fuel design has demonstrated ability to provide high burnup cladding integrity as well as reliable performance up to actual burnups of 75 percent uranium-235 (Simnad 1980). The TRIGA fuel, because of its unique composition of hydrogen moderator intimately mixed into the fuel itself, has a large negative fuel temperature reactivity coefficient, which shuts the reactor down during any power excursions or reactivity-induced transients.

#### **E.3.1 Nuclear Fuel Design**

The new research reactor nuclear fuel design is based on an extension of current licensed low-enriched uranium TRIGA fuel designs for 10- to 16-megawatts-thermal reactors. A comparison of the current high-power low-enriched uranium TRIGA fuel design and the new research reactor low-enriched TRIGA fuel design (IAEA 1992) is presented in **Table E-1**.

As presented in Table E-1, the new research reactor fuel design is identical to current low-enriched TRIGA fuel for higher power cores except that the new reactor fuel has a larger assembly configuration array (i.e., 8 by 8 versus 4 by 4) and a longer active fuel length (153.7 centimeters [60.5 inches] versus 55.88 centimeters

**Table E–1 Comparison of New Research Reactor Fuel Design to Current Low-Enriched Uranium TRIGA Fuel Design**

Nuclear Fuel Design Parameter	Current Low-Enriched Uranium TRIGA Fuel Value	New Research Reactor TRIGA Fuel Value
Fuel assembly rod configuration	Square 4 rods by 4 rods	Square 8 rods by 8 rods
Fuel assembly shroud outside dimension	7.572 centimeters (2.981 inches) by 7.963 centimeters (3.135 inches)	16.52 centimeters (6.5 inches) by 16.52 centimeters (6.5 inches)
Fuel rod center-to-center pitch	1.634 centimeters (0.643 inch)	2 centimeters (0.787 inch)
Fuel rod cladding outside diameter	1.377 centimeters (0.542 inch)	1.377 centimeters (0.542 inch)
Cladding material	Incoloy-800	Incoloy-800
Cladding thickness	0.041 centimeter (0.016 inch)	0.036 centimeter (0.014 inch)
Fuel-to-cladding radial gap	0.0022 centimeter (0.0009 inch)	0.0025 centimeter (0.001 inch)
Fuel rod gap and gas plenum backfill gas and fill gas pressure	Helium 0.0103 megapascal (1.5 pounds per square inch absolute)	Helium 0.0103 megapascal (1.5 pounds per square inch absolute)
Fuel pellet outer diameter	1.295 centimeters (0.510 inch)	1.295 centimeters (0.510 inch)
Fuel pellet height	13.97 centimeters (5.5 inches)	13.97 centimeters (5.5 inches)
Fuel pellet composition	UZrH <sub>1.6</sub> -Er	UZrH <sub>1.6</sub> -Er
Fuel pellet uranium weight fraction	45 percent	45 percent
Uranium-235 enrichment	19.95 percent	19.7 percent
Hydrogen-to-zirconium ratio	1.6	1.6
Fuel pellet erbium weight fraction	0.8 percent	0.8 percent
Fuel rod active fuel length	55.88 centimeters (22.0 inches)	153.7 centimeters (60.5 inches)
Mass of uranium per fuel rod	274 grams (0.604 pound)	754 grams (1.660 pounds)
Mass of uranium-235 per fuel rod	54.8 grams (0.121 pound)	148.4 grams (0.327 pound)
Mass of uranium per “all fuel rod” fuel assembly	4.38 kilograms (9.64 pounds)	48.3 kilograms (106.2 pounds)
Total fuel rod length	76.2 centimeters (30 inches)	176 centimeters (69.3 inches)

**Key:** UZrH<sub>1.6</sub>-Er, uranium-zirconium-hydride with erbium.

[22.0 inches]). The larger array and longer length were selected to meet the plutonium-238 production requirements and maintain high safety factors with respect to fuel thermal performance.

### E.3.2 Nuclear Core Design

Along with fuel rods, the core is designed to contain a number of plutonium-238, medical radioisotope, and industrial radioisotope production target rods. These target rods would occupy positions in a fuel assembly where a fuel rod would otherwise exist. Each of these positions would have an Incoloy-800 alloy guide tube with the same dimensions as the fuel rod cladding. The target rods, clad in Incoloy-800, would be inserted into these guide tubes for their design irradiation time period. In addition, some fuel rod positions in core fuel assemblies would be replaced with similar guide tubes to accommodate Incoloy-800-clad boron carbide control rods. Boron carbide is a proven, accepted, and widely used neutron absorber for control rods. **Figure E–1** presents a representative illustration of the fuel rod, neptunium-237 target rod, medical and industrial radioisotope target rod, and control rod. **Figure E–2** shows a cross section of each type of fuel assembly in the core.

The new research reactor core design consists of 68 fuel assemblies, each of which is enclosed in a square aluminum shroud for structural support and coolant flow control. Key design features of the core are presented in **Table E–2**.

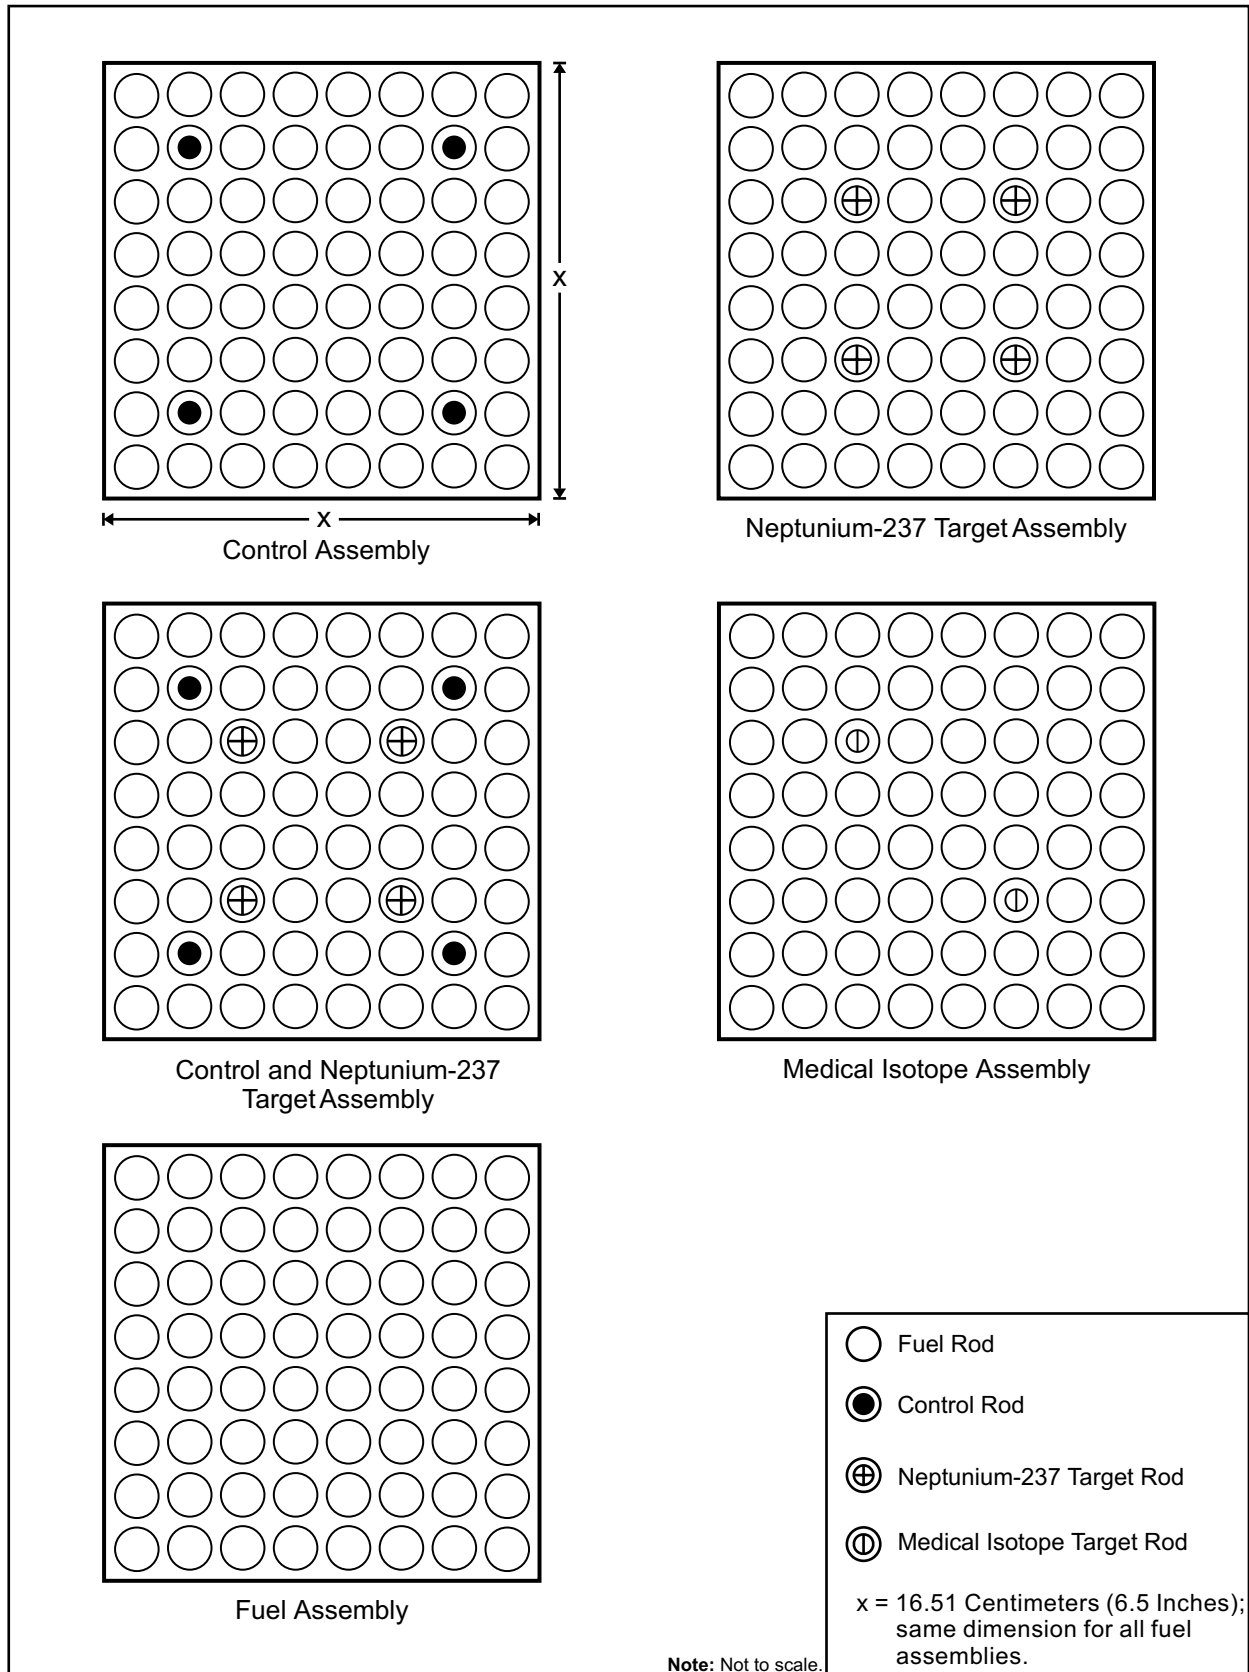

Figure E-1 Representative Illustration of Fuel Rod; Neptunium-237, Medical, or Industrial Radioisotope Target Rod; and Control Rod

**Figure E-2 Cross Section of Fuel Assemblies in the Core**

**Table E-2 Key Design Features of the New Research Reactor Core**

Core Design Parameter	Value
Number of fuel assemblies	68
Core thermal power	50 megawatts
Average fuel assembly power	0.74 megawatt
Number of neptunium-237 target rod assemblies	48
Number of neptunium-237 target rods per assembly and in core	4 per assembly, 192 in core
Number of medical and industrial radioisotope target rod assemblies	8
Number of medical and industrial radioisotope target rods per assembly and in core	2 per assembly, 16 in core
Available radioisotope production volume	42.1 liters (1.5 cubic feet)
Number of control rod assemblies	16
Number of control rods per assembly and in core	4 per assembly, 64 in core
Total number of fuel rods in core	4,080
Core active height	153.7 centimeters (60.5 inches)
Core diameter	166.5 centimeters (65.5 inches)
Core radial reflector material and minimum thickness	Beryllium, 3.0 centimeters (1.18 inches)
Core uranium mass	3.1 metric tons of uranium (6,820 pounds)
Core uranium-235 mass	611 kilograms (1,344 pounds)
Minimum core life at 80 percent capacity factor	10 years

The core design described in Table E-2 also includes eight rabbit tubes for short irradiation-time production of medical or industrial radioisotopes and nuclear research and development. These rabbit tubes are located outside the fuel region of the core, but still within an area with a relatively high neutron flux. A cross-sectional view of the new research reactor core showing the layout of fuel assemblies, target rod assemblies, control rod assemblies, reflector, and rabbit tubes is presented in **Figure E-3**.

#### **E.4 NUCLEAR FUEL THERMAL PERFORMANCE**

The nuclear fuel design, based on core physics analyses, also was evaluated to determine if its thermal performance would meet the relevant thermal limits for TRIGA fuel. The steady-state thermal performance of the new research reactor nuclear fuel was analyzed to evaluate three indicators: (1) peak fuel pellet centerline temperature, (2) critical heat flux ratio (sometimes denoted as departure from nucleate boiling ratio), and (3) fuel rod internal volume gas pressure and associated cladding hoop stresses.

Peak fuel pellet temperature is an important variable for TRIGA fuel because, at elevated temperatures, hydrogen within the UZrH fuel matrix is released as a gas and can cause excessive pressure that may result in cladding rupture. A fuel temperature limit of 650 °C (1,202 °F) precludes excessive hydrogen gas release and pressure (Simnad 1980).

The critical heat flux ratio is a measure of the nature of the heat transfer from the fuel rod cladding surface to the coolant water flowing past it. As the cladding surface heat flux increases, heat transfer to the coolant increases until critical heat flux is reached. Beyond this critical heat flux, further increases in surface heat flux will not result in greater heat transfer to the coolant, thus causing the cladding and fuel temperature to rise rapidly. By maintaining the fuel cladding surface conditions below critical heat flux, a safe heat transfer regime exists between the fuel and the coolant. The critical heat flux ratio is the calculated critical heat flux, for a given set of peak core thermal-hydraulic conditions, to the actual cladding maximum surface heat flux.

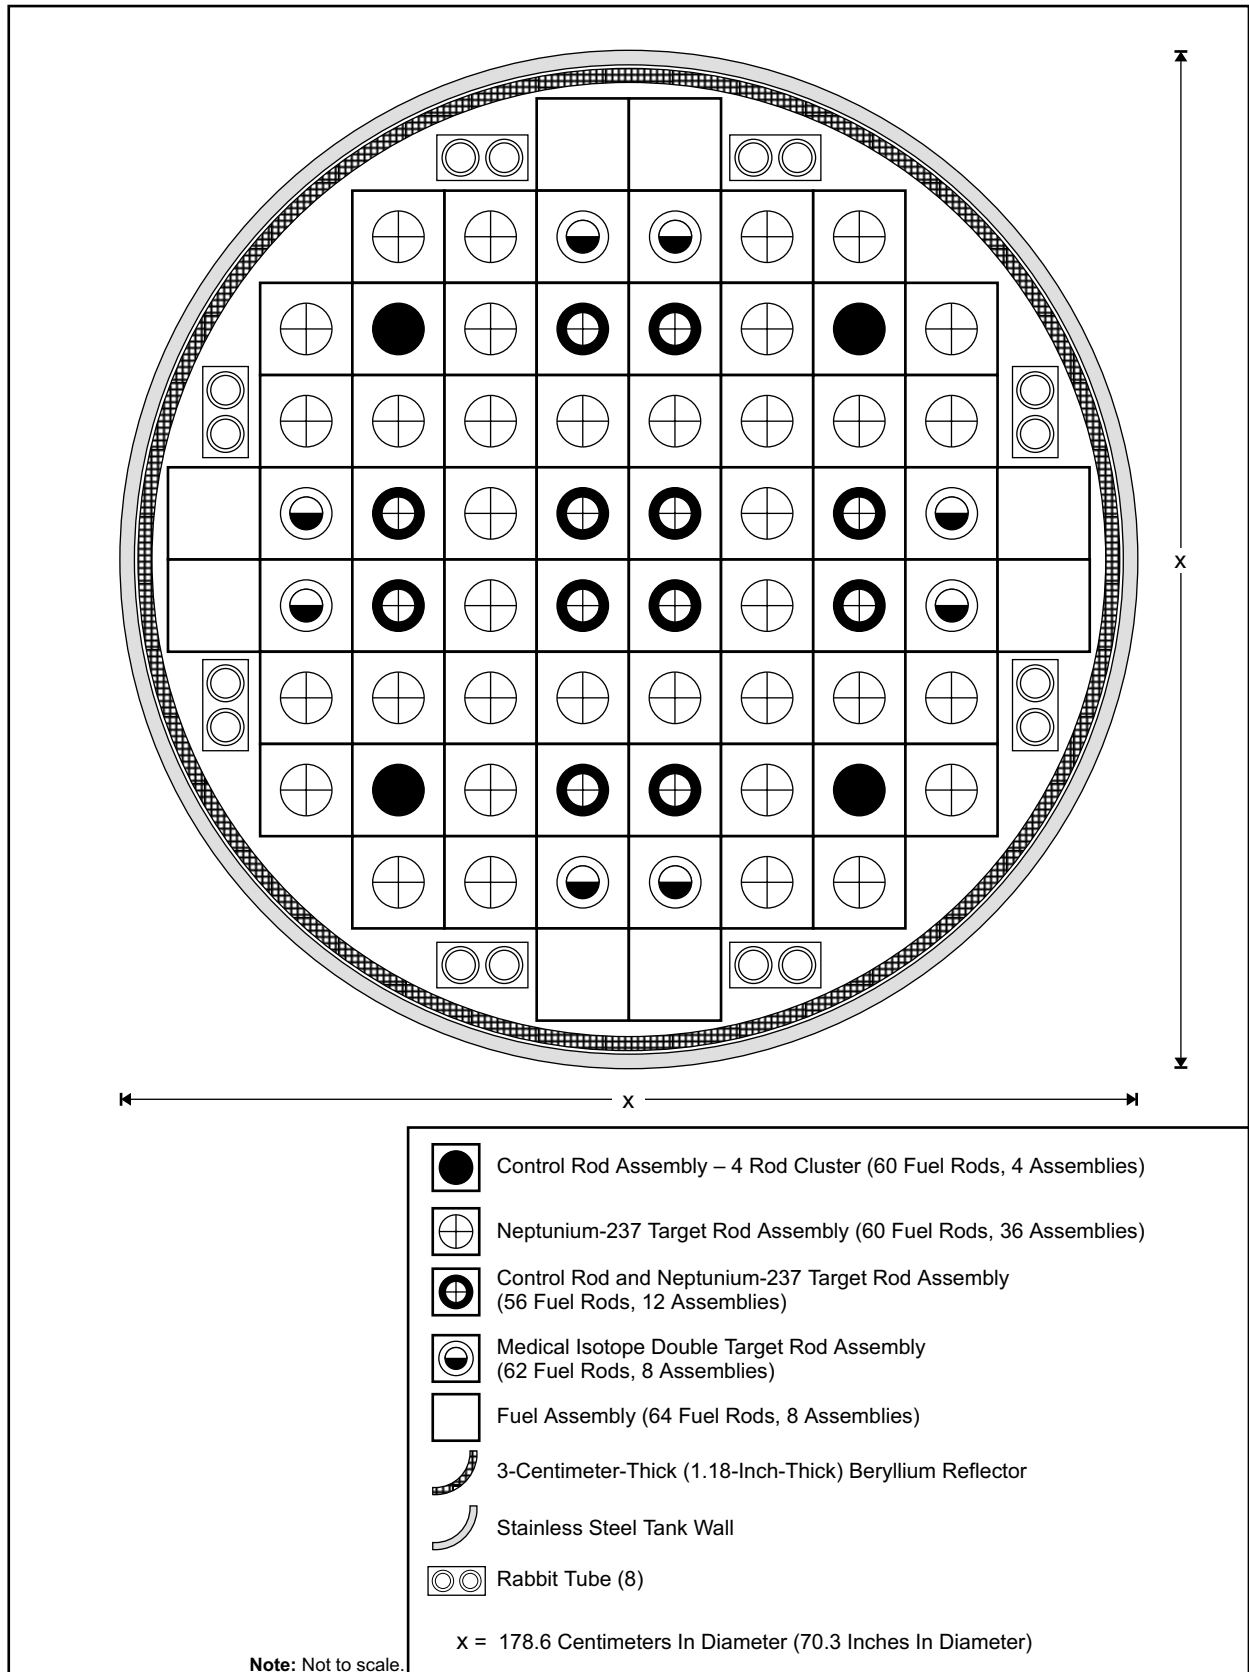

Figure E-3 Cross-Sectional View of Research Reactor Core

A critical heat flux ratio greater than 1 is an indicator of an acceptable thermal design. Typically, due to the statistical uncertainty and experimental conditions associated with maximum core heat flux and critical heat flux correlations, a ratio of greater than 1.2 is desirable.

The calculated peak fuel rod internal gas pressure and associated cladding hoop stress are an indication of the structural integrity of the cladding, which constitutes an important fission product confinement barrier. As the fuel is irradiated in the reactor core, gaseous fission products are produced. Some of these fission products can escape from the fuel pellets and collect in the gap between the fuel and cladding as well as the plenum volume above the fuel pellet stack inside the fuel rod. An increase in the presence of gaseous fission products inside the fuel rod volume results in a higher rod internal pressure and concomitant higher cladding hoop stress over the lifetime of the fuel. It should be noted that the UZrH fuel pellet material has been shown to retain most of its fission products at operating temperatures (Simnad 1980).

The radial temperature distribution of an axial segment in the average and peak fuel rod was calculated using the one-dimensional solution to the conservation of energy equation for a cylindrical geometry. Appropriate values for coolant and fuel rod material thermal-physical properties were used in this analysis. Bounding assumptions were made for boundary conditions and fuel rod peaking factor. **Table E-3** presents the thermal parameters and important results relevant to the analysis of fuel rod temperatures.

**Table E-3 Fuel Rod Temperature Distribution  
Analysis Parameters for Steady-State Operation**

Fuel Rod Temperature Parameter	Value
Core power density	14.9 kilowatts per liter
Average fuel rod linear heat generation rate	79.7 watts per centimeter (8,291 Btu/hr/ft)
Average fuel rod surface heat flux	18.43 watts/cm <sup>2</sup> (58,418 Btu/hr/ft <sup>2</sup> )
Maximum fuel rod peaking factor	2.25
Average core coolant flow rate	1.1 meters per second (3.6 feet per second)
Core hottest channel inlet coolant temperature	46.1 °C (115 °F)
Average fuel channel axial coolant temperature rise	10.9 °C (19.7 °F)
Hottest fuel channel axial coolant temperature rise	24.4 °C (44 °F)
Cladding surface temperature	
Average fuel rod	78.9 °C (174 °F)
Peak fuel rod	113.1 °C (235.6 °F)
Fuel pellet centerline temperature	
Average fuel rod	160 °C (320 °F)
Peak fuel rod	285.7 °C (546.3 °F)
Fuel pellet normal operation temperature limit	650 °C (1,202 °F)
Minimum critical heat flux ratio	
Average fuel rod	2.91
Peak fuel rod	1.30
End-of-core-life fuel rod internal volume pressure	
Average fuel rod	0.146 MPa (21.2 psia)
Peak fuel rod	0.170 MPa (24.6 psia)
End-of-core-life fuel rod cladding hoop stress (external pressure = 0.101 Mpa [14.7 psia])	
Average fuel rod	0.855 MPa (124 psi)
Peak fuel rod	1.303 MPa (189 psi)
Cladding yield strength	251.5 MPa (36,500 psi)
Cladding ultimate strength	900 MPa (130,500 psi)

**Key:** Btu/hr/ft<sup>2</sup>, British thermal units per hour per square foot; MPa, megapascal; psi, pounds per square inch; psia, pounds per square inch absolute; watts/cm<sup>2</sup>, watts per square centimeter.

Table E-3 shows that the maximum calculated fuel pellet centerline temperature, minimum critical heat flux ratio, and maximum fuel rod cladding stress are well within their relevant limits. This analysis demonstrates that the new research reactor fuel and core designs meet basic thermal design criteria with ample safety margins for steady-state operation at a 50 megawatt-thermal core power level.

### E.5 NUCLEAR CORE PHYSICS PERFORMANCE

Nuclear core physics calculations were performed with three state-of-the-art digital computer codes and/or code packages: SCALE-4.4 (ORNL 1998), WIMSDB5 (ORNL 1999), and MCNP4B2 (Briesmeister 1998).

SCALE-4.4 uses discrete ordinate deterministic methods, one-dimensional unit cell geometry, transport theory, and point depletion to calculate neutron flux, k-infinity, and fission product inventory. K-infinity is a measure of neutron multiplication factor for a system of infinite size, which is an indication of reactivity to meet the mission during a core cycle of operation. A minimum value of about 1.1 for k-infinity is required to attain a critical state and produce neutrons for radioisotope production. SCALE-4.4 was used with a 44-energy-group cross-section database to calculate fission products and as an independent validation of k-infinity and neutron flux. WIMSD Version 5B uses a one-dimensional transport theory deterministic method with a lattice representation of the fuel assembly that accounts for fuel rod and assembly geometry and a 69-energy-group cross-section database to calculate neutron flux, k-infinity, and plutonium-238 production rate. WIMSD Version 5B was used to calculate plutonium-238 production rate and neutron flux and as an independent validation of the values of k-infinity. MCNP4B2 uses a three-dimensional monte carlo stochastic transport particle simulation of the full core geometry with continuous, point-wise neutron cross-section data to calculate the k-infinity, spatial neutron flux distribution in the core, and the neutron flux energy spectrum. MCNP4B2 was used to calculate peak and average core neutron flux, in terms of both energy and spatial distribution, and k-infinity.

The three computer codes predicted beginning of core life values of k-infinity to within about 1 percent of each other. Comparisons of calculated core neutron flux were also close among the different computer codes. In addition, a review of maximum thermal neutron flux for operating TRIGA research reactors with a core power from 1 to 14 megawatts showed values of  $1 \times 10^{13}$  to  $3 \times 10^{14}$  neutrons per square centimeter per second (IAEA 1989; ANL 2000). This range of neutron flux compares well with the calculated maximum value of  $6 \times 10^{13}$  neutrons per square centimeter per second for this new 50-megawatt TRIGA-based research reactor. Key core physics results are presented in **Table E-4**.

**Table E-4 Key Core Physics Performance Parameters**

Core Physics Parameter	Value
Beginning-of-life k-infinity	1.5
End-of-life k-infinity	1.1
Plutonium-238 production after 300-day operation	5.3 kilograms (11.7 pounds)
Average core thermal (less than 0.625 electron volt) neutron flux	$2.5 \times 10^{13}$ neutrons/cm <sup>2</sup> /sec
Peak core thermal neutron flux	$6 \times 10^{13}$ neutrons/cm <sup>2</sup> /sec
End-of-life fuel assembly	
Average burnup	2,292 megawatt-days
Maximum burnup	5,157 megawatt-days
Core average end-of-life uranium-235 atom burnup	34 percent

**Key:** neutrons/cm<sup>2</sup>/sec, neutrons per square centimeter per second.

Table E-4 shows that the core is designed for a minimum useful life of approximately 10 years and would produce greater than 5 kilograms (11 pounds) of plutonium-238 during a 300-day operating period. It should be noted that limited core physics calculations were performed as part of this new research reactor preconceptual design. Detailed spatial full core depletion calculations were not performed for this reactor. The numerical core physics performance and plutonium-238 production values presented in Table E-4 are based on conservative calculations. The neptunium-237 target design was based on a limitless supply of neptunium-237. A significant reduction (by a factor of four to eight) in the required neptunium-237 target mass for the same annual plutonium-238 production rate can be achieved by: (1) optimizing target design with annular pellets, (2) inclusion of moderator materials mixed in the target, (3) optimizing fuel geometry, and (4) increasing core power.

## **E.6 PRIMARY COOLANT SYSTEM DESIGN**

The major components of the primary coolant system design for the new research reactor are (1) a reactor core pool, (2) two primary coolant pumps, (3) two primary coolant heat exchangers, (4) shutdown pumps, and (5) piping between the pool, pumps, and heat exchangers. This system is designed to remove core thermal power during normal operation and core decay heat after reactor shutdown while maintaining the fuel below its thermal limits. A schematic of the primary coolant system is presented in **Figure E-4**.

Coolant flow would be drawn down through the core by the primary coolant pump suction pipelines, which would be connected to the bottom of the tank enclosing the core inside the pool. The side and bottom of the cylindrical tank would be sealed, but the top of the tank would be open to the pool. The forced coolant downflow through the core, as opposed to upflow, is designed to mitigate radiological consequences from the production of nitrogen-16, which is created from fast neutron reaction with the oxygen in the water molecule. Nitrogen-16 is a radioisotope which emits high-energy gamma (6 million electron volts per disintegration) radiation, but has a decay half-life of approximately 7 seconds. Therefore, the core coolant downflow allows this nitrogen-16, produced in the core coolant region, to decay before it returns to the reactor core pool. The primary coolant system loop (i.e., core to pump to heat exchanger to pool) is designed to delay the coolant removed from the core by at least 21 seconds (i.e., three half-lives) prior to its return to the pool. Appropriate shielding would be designed for all primary coolant system components to protect workers from nitrogen-16 gamma radiation to allow access during power operation.

Another design feature of the primary coolant system intended to reduce nitrogen-16 radiation at the top of the reactor core pool is the submerged location of the return flow from the heat exchanger. This submerged location allows shielding of the water depth above it and further nitrogen-16 decay before it can diffuse to the top of the pool.

The primary coolant system design has several inherently safe design elements that preclude or mitigate postulated accidents. As illustrated in Figure E-4, the suction piping from the bottom of the core tank would be routed, within the pool, to an elevation of 3 meters (10 feet) above the top of the core before it exits the pool through the pool wall and down to the pump in an adjacent compartment. A vacuum breaker (antisiphon device) would be attached to the high point of this suction piping inside the pool to prevent draining the reactor pool during any postulated pipe break accident. The balance of the primary coolant system (i.e., pump discharge piping, heat exchanger, and heat exchanger outlet piping) all would be elevated above the top of the core so that any leak or rupture could not uncover the core. This primary coolant system configuration precludes any leak from draining the pool below the top of the core.

The reactor core pool would be fully lined with 304 stainless steel, which would be attached to reinforced concrete. The reinforced concrete walls and floor of the pool are designed to meet all design-basis earthquake loads in the United States outside of coastal California.

Note: Not to scale.

Figure E-4 Schematic of Primary Coolant System

All primary coolant system components would be type 304 stainless steel and would be manufactured to meet current nuclear safety and quality assurance standards. The use of two 100 percent capacity pumps and heat exchangers would allow for normal core power operation in the event of the loss of one component. A low flow-rate shutdown pump would be included in the system to provide sufficient flow for core decay heat removal. Key primary coolant system design parameters are presented in **Table E-5**.

**Table E-5 Key Primary Coolant System Design Parameters**

<b>Design Parameter</b>	<b>Value</b>
Reactor core pool water dimensions	7.9 meters (26 feet) long 6.7 meters (22 feet) wide 9.1 meters (30 feet) deep
Reactor core pool materials	304 stainless steel, 1.27-centimeter-thick (0.5-inch-thick) liner over reinforced concrete
Primary coolant system pump flow rate (100 percent capacity each)	1.262 cubic meters per second (20,000 gallons per minute)
Primary coolant system pump design head	61 meters (200 feet)
Primary coolant system heat exchanger design heat removal rate (100 percent capacity each)	50 megawatts (170×10 <sup>6</sup> British thermal units per hour)
Primary coolant system heat exchanger design inlet temperature	51.7 °C (125 °F)
Primary coolant system heat exchanger design outlet temperature	40.6 °C (105 °F)
Primary coolant system shutdown pump flow rate	0.063 cubic meters per second (1,000 gallons per minute)
Primary coolant system shutdown pump design head	61 meters (200 feet)

The design of the primary coolant system employs accepted and widely used nuclear power plant safety principles such as redundancy, single-failure-proof, nuclear quality assurance, and inherent natural phenomena (e.g., elevated piping).

## **E.7 BALANCE OF REACTOR PLANT SYSTEMS**

Due to the preconceptual design nature of the new research reactor, limited details have been developed for the balance of the reactor plant systems. Details were established where they were judged to significantly affect the determination of environmental impacts or cost.

The secondary cooling system design transfers the heat removed from the core by the primary coolant system to the environment. This system would consist of two 100-percent-capacity pumps and two 50-percent-capacity cooling towers with piping connecting them to each other and to the secondary side of the primary coolant system heat exchangers. Unlike the primary coolant system, the secondary coolant system is not designed or considered to be a nuclear-safety-related system because its failure would not challenge the safety of the reactor. Piping and cooling tower tubes would be constructed of carbon steel. To avoid causing fogging at the reactor building area, the cooling towers would be located about 122 meters (400 feet) from the reactor building.

The spent fuel pool is designed to the same standards and with the same materials as the reactor core pool. The spent fuel pool would be sized to store all the fuel expected to be discharged over the 35-year lifetime of the reactor. The spent fuel pool also is designed to accommodate shipping casks for transport of radioisotope target rods and the spent nuclear fuel after this reactor is shut down, decontaminated, and decommissioned. The reactor core pool can be hydraulically connected to the spent fuel pool using an isolable transfer canal for moving spent nuclear fuel from and reloading the core, as well as transferring isotope target rods from the core

to the spent fuel pool. An important safety feature of this canal is its ability to flood the reactor core pool in the unlikely event of a coolant leak from the reactor core pool. The size of the spent fuel pool allows it to completely reflood the entire volume of the reactor core pool, using the transfer canal, while maintaining a sufficiently high level of water above the stored spent fuel to preclude high dose rates in the spent fuel pool area. Another unique safety feature of the spent fuel pool is the design of its fuel storage racks. These racks are designed to separate each fuel assembly from other fuel assemblies by approximately 23 centimeters (9 inches), which neutronically isolates each assembly, thereby assuring criticality safety without the use of soluble or fixed neutron absorbers. The space between fuel assemblies in the rack is covered with steel bars that prevent any accidental insertion of a fuel assembly. In addition, each storage position is recessed more than 23 centimeters (9 inches) below the top of the rack to avoid a dropped assembly neutronically interacting with another assembly. This simple storage rack design provides inherent criticality safety in a cost-effective design.

A spent fuel pool cooling system is incorporated into the facility design. This nuclear-safety-released system would be capable of maintaining the spent fuel pool temperature within acceptable limits under all modes of plant operation. This system would consist of two redundant small pumps, heat exchangers, and appropriate instrumentation. Spent nuclear fuel decay heat removed from the spent fuel pool would be transferred to the secondary cooling system.

A water makeup and purification system would be included in the reactor design for maintaining the water level in both the reactor core and spent fuel pools and removing any contamination. This system, consisting of a small pump, piping, and appropriate filters, resin beds, and makeup water tank, would also be used to maintain the chemistry of the water to within technical specification limits. Periodic monitoring of pool water quality would be used as an indicator of fuel failure or heat exchanger tube leakage.

The reactor instrumentation and control systems are expected to be similar to other higher-power TRIGA reactors and are nuclear safety related. Instrumentation would monitor important nuclear and thermal-hydraulic parameters with digital displays in the control room. Although TRIGA fuel has an inherently large negative temperature reactivity coefficient, a reactor trip system would scram (loss of power would cause the control rods to drop in the reactor core) the reactor on a number of redundant signals such as high power, low pool level, low coolant flow rate, and high core exit coolant temperature.

In the unlikely event of a loss of all offsite alternating current power, a nuclear safety-related emergency power system consisting of two redundant 1,506-kilowatt emergency diesel generators was included in the design. These emergency diesel generators would be nuclear safety grade and subject to periodic testing to ensure their reliability.

The reactor building heating, ventilating, and air conditioning system is designed to maintain the air temperature within the building within specified limits while removing contaminants and certain radioisotopes that may be present in the building air. This system would consist of an interconnected network of ducts, fans, chillers, heating coils, filters, and a 36.6-meter-high (120-foot-high) exhaust stack. High-efficiency particulate air (HEPA) and charcoal filters would remove a minimum of 99.9 percent of airborne particulates and 99 percent of airborne iodine. The exhaust portion of the heating, ventilating, and air conditioning system, which would perform the contaminant and radioisotope removal function, would be safety-related.

The reactor building complex and associated structures are schematically presented in **Figures E-5 and E-6**. The reactor building would consist of three sections, separated by a radiation shield wall: (1) reactor room, (2) system room, and (3) spent fuel pool. The reactor room would house the reactor core pool and provide confinement. The reactor system section would include: (1) primary coolant system pumps and a shutdown pump; (2) primary coolant system heat exchangers; (3) secondary coolant system pumps; (4) a water makeup

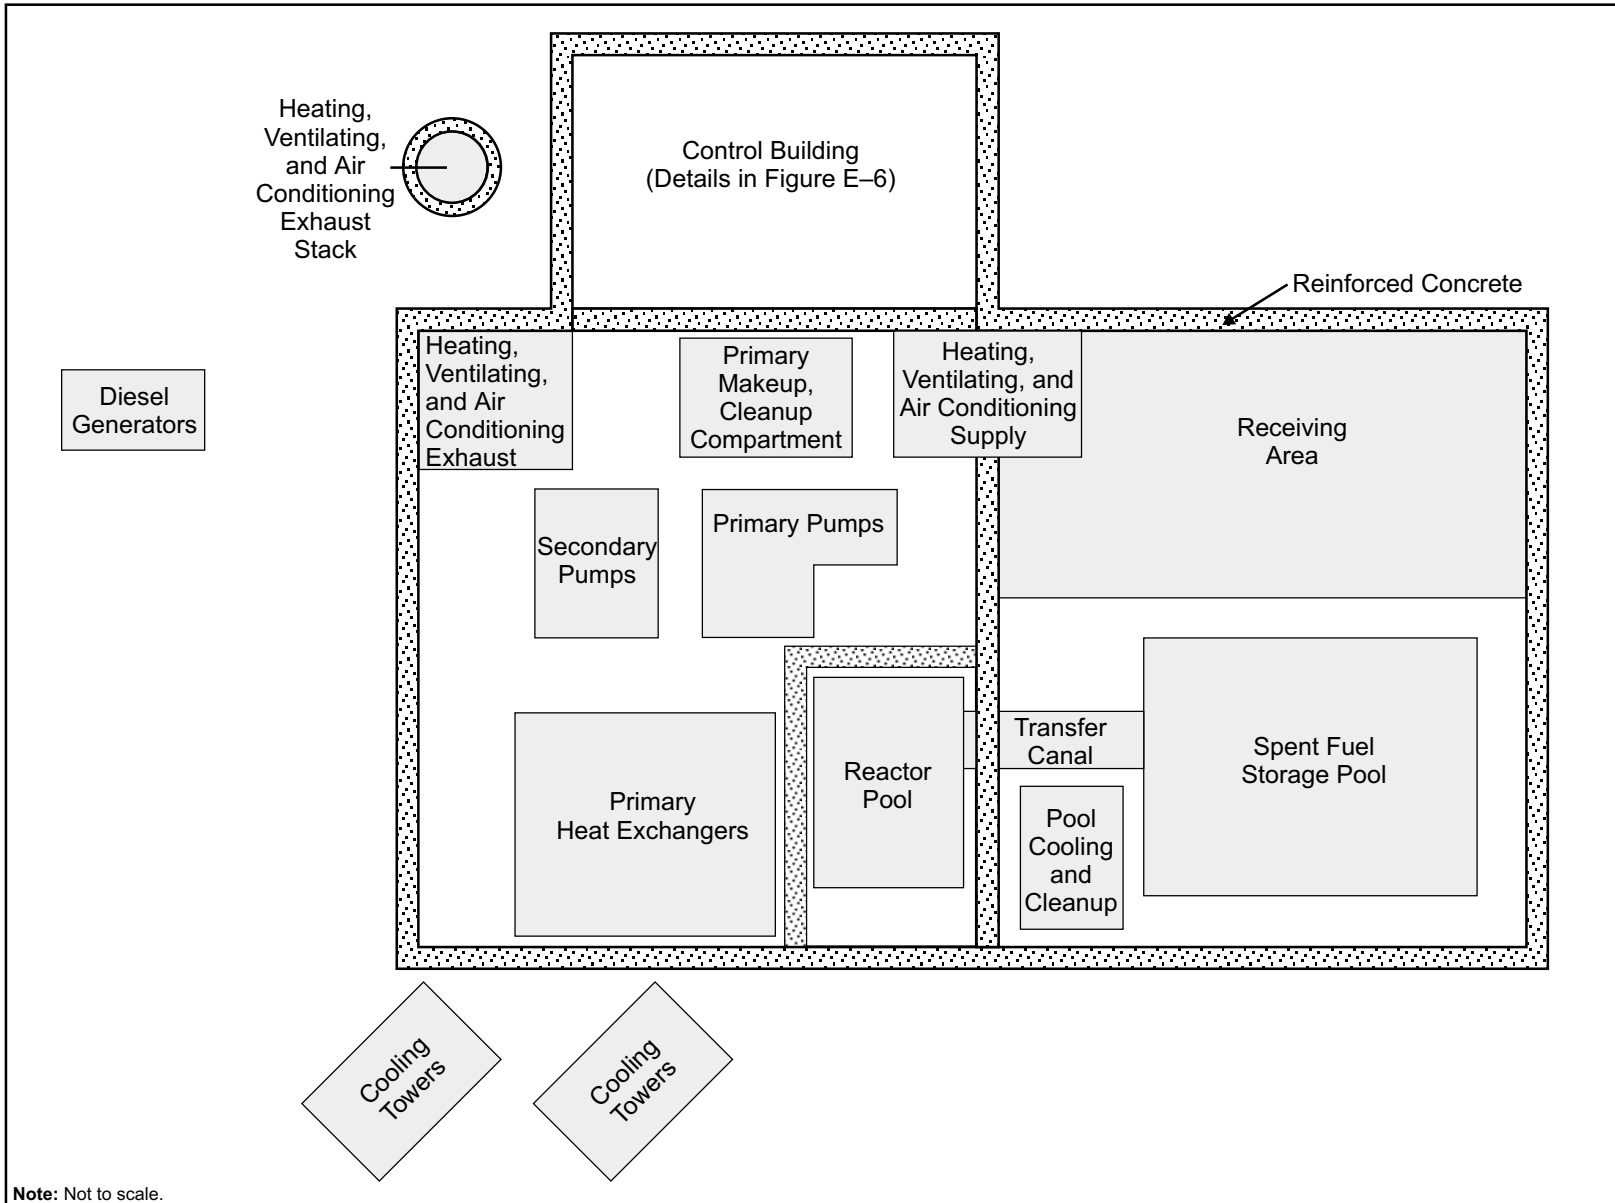

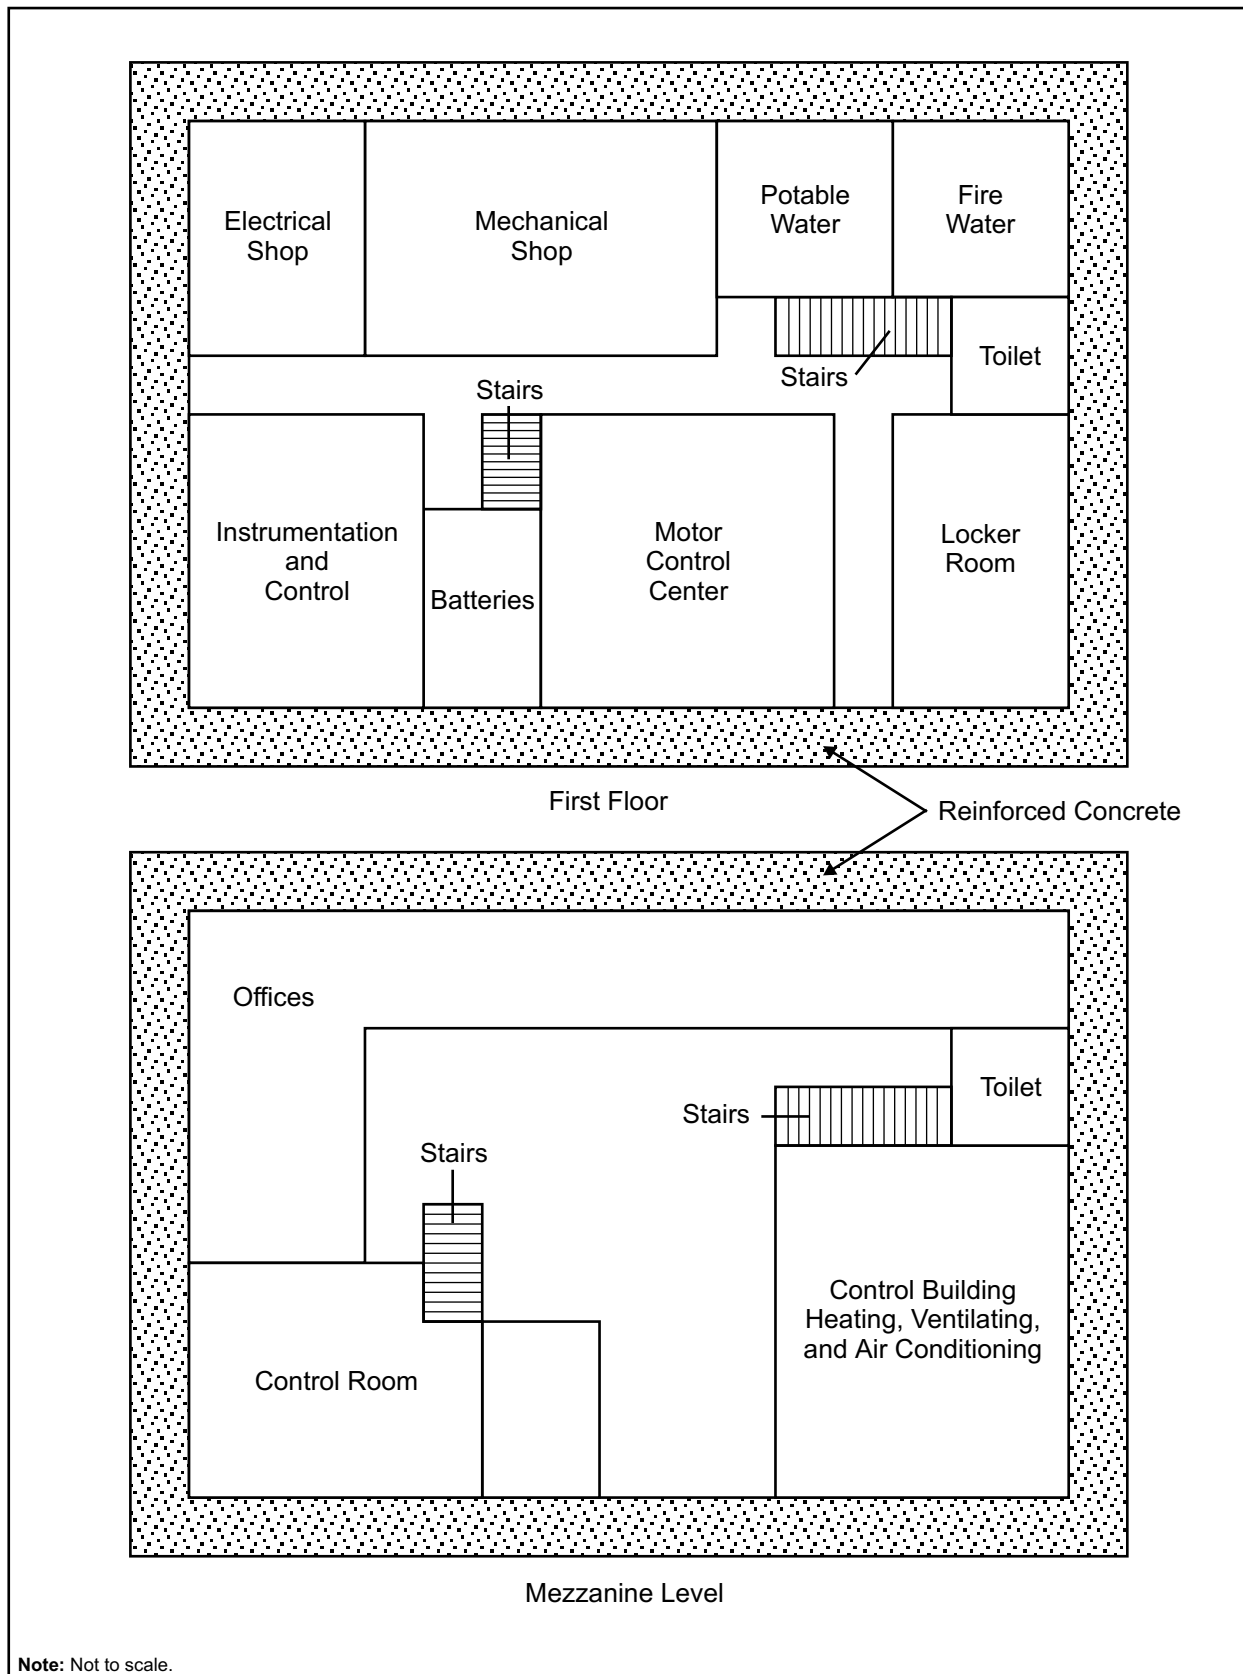

Figure E-5 Schematic of Reactor Building Complex

Note: Not to scale.

Figure E-6 Schematic of Control Building

and purification system; and (5) a nuclear-safety-related, single-failure-proof overhead crane. The spent fuel pool section would include: (1) a spent fuel pool; (2) a spent fuel pool makeup and purification system; (3) a pool transfer canal; (4) a loading dock; and (5) a nuclear-safety-related, single-failure-proof overhead crane capable of lifting a truck-sized spent nuclear fuel cask. The exterior walls and roof of the reactor building, consisting of reinforced concrete, are designed to withstand design-basis tornado missiles and seismic events for the entire United States outside of coastal California in accordance with current DOE and NRC regulations. The total footprint of the facility, including the reactor and control buildings, cooling towers, emergency diesel generators, exhaust stack, and ancillary structures, is estimated to be approximately 3,623 square meters (39,000 square feet, or about 1 acre). The total land area encompassing the facility is estimated to be approximately 4 acres.

## **E.8 REACTOR DESIGN SAFETY FEATURES**

The new research reactor was designed with numerous inherent and passive safety features which prevent or mitigate the consequences of abnormal operational occurrences, off-normal events, and postulated accidents. The basic design constitutes an extrapolation of existing higher-power TRIGA reactors in the United States and in foreign nations. Over 6,000 TRIGA fuel elements have been fabricated and irradiated in research reactors, some with over 20 years of operation. Low-enriched uranium TRIGA fuel has been subjected to over 25,000 power pulses by the vendor with peak fuel temperatures of up to 1,150 °C (2,102 °F) without fuel damage (Simnad 1980).

The primary radiological source for this reactor is the fission products which are produced in the nuclear fuel pellets. The reactor's unique UZrH TRIGA fuel alloy has been experimentally shown to retain approximately 99.995 percent of all fission products at or below an operating temperature of 400 °C (752 °F). As presented in Table E-3, the peak and average fuel pellet centerline temperatures are less than 300 °C. The TRIGA fuel pellet also has been shown to exhibit no significant corrosion or chemical reactivity if exposed to water, steam, or air at temperatures up to 600 °C (1,112 °F). In addition, TRIGA fuel has been successfully irradiated up to a burnup of 75 percent of the available uranium-235 with no fuel damage (Simnad 1980).

The second confinement barrier for fission products is the fuel rod cladding, Incoloy-800, which can operate at much higher temperatures than aluminum and zircaloy cladding, does not oxidize at higher temperatures like zircaloy, and has a higher tensile and ultimate strength than aluminum, zircaloy, and stainless steel. Thus, the Incoloy-800 cladding provides a high degree of confinement integrity.

A third important fuel safety design feature is the inherently large negative temperature coefficient of reactivity for this fuel because it contains the hydrogen moderator intimately mixed within the solid fuel pellets. An increase in fuel temperature causes the fuel to expand, releases some of its hydrogen into the rod inner gas volume, and reduces the fuel hydrogen density. This reduction in hydrogen density shuts down the fission process and reduces power. As the fuel cools down, most of the hydrogen is reabsorbed into the fuel matrix. TRIGA fuel has always been designed to withstand sudden large power pulses and shut itself down. This pulsing feature is integral in the operation of many TRIGA research reactors worldwide.

The submerged configuration (i.e., under more than 6.1 meters [20 feet] of water) of fuel in both the reactor core and spent fuel storage pool provides another radioisotope removal mechanism if a fuel rod leak should occur. Such large depths of water absorb or retain 100 percent of all released solid fission products and over 99 percent of released halogen fission products.

The primary coolant system is designed with the following safety aspects: (1) a low system pressure (i.e., maximum less than 0.345 megapascal [50 pounds per square inch]); (2) low coolant operating temperatures (i.e., maximum hot leg temperature less than 65.6 °C [150 °F]); (3) 304 stainless steel primary

coolant piping routed inside the pool to an elevation about 3 meters (10 feet) above the core before exiting the pool to the pumps; (4) a 304 stainless-steel-lined, seismically qualified reactor core pool structure; (5) primary coolant downflow through the core; (6) a long (i.e., minimum of 21 seconds) primary loop coolant transit time; and (7) a large reactor pool coolant inventory.

The low pressures and temperatures indicate that a primary coolant system pipe break would not release significant quantities of energy into the reactor building. The expected low pressures in the reactor building, coupled with the tornado missile and seismic design of this reinforced concrete structure, provide a high degree of assurance that it would maintain solid, liquid, and removable non-noble gas radioisotope confinement for all postulated accidents.

The likelihood of a primary coolant system pipe leak or break would be extremely small based on the low pressure and temperature coolant conditions and the use of 304 stainless steel that would be designed, procured, supported, and installed in accordance with all current nuclear safety standards. In addition, the elevated pipe routing above the core inside the reactor pool, in conjunction with high point vacuum breakers, would ensure that any pipe leak or break would not drain the pool below about 3 meters (10 feet) above the core. At this pool level, the remaining water would not reach saturation, with core decay heat, for at least 4 days and the water level would not boil down to the top of the core for more than 40 days. This long period for recovery of a coolant source is indicative of the large thermal heat capacity and safety margins inherent in the pool design.

As discussed earlier, the core coolant downflow direction, along with a minimum transit time of 21 seconds for the coolant to return to the pool, was selected to reduce the nitrogen-16, which is produced by neutron absorption in the oxygen component of water molecules as it passes through the core. Nitrogen-16 is a high-energy gamma-emitting radioisotope, but it has a short half-life of approximately 7 seconds. Therefore, the downflow direction and three-half-life decay delay would reduce the activity of nitrogen-16 before it returns to the pool by about a factor of 10, thereby reducing the dose rates to workers during reactor operation.

Use of the spent fuel storage pool as a source of reactor pool water is another safety enhancement of this design. The spent fuel storage pool can be hydraulically connected to the reactor pool through a transfer canal by automatically or manually opening a valve. In the extremely unlikely event that the reactor pool would lose coolant, the spent fuel storage pool is sized so that it can completely reflood the entire reactor pool volume without compromising the decay heat removal and shielding design of the spent fuel pool. Also, the higher relative elevation of the spent fuel storage pool would allow it to reflood the reactor pool by gravity-driven flow requiring no pumps. The spent fuel storage pool can be used to reflood the reactor pool without any electrical power.

The reactor core and spent fuel storage pool coolant purification system, designed to nuclear safety standards, would remove radioisotopes present in the water. In addition, the nuclear safety reactor building heating, ventilating, and air conditioning exhaust system is designed to remove 99.9 percent of airborne radioisotope particulates and 99 percent of airborne radioisotope halogens. A 36.6-meter-tall (120-foot-tall) heating, ventilating, and air conditioning exhaust stack would provide optimum atmospheric dispersion to reduce the environmental impacts of any released materials after filtration.

Along with the many natural and passive aforementioned safety features, the reactor would be equipped with a reactor instrumentation and protection system that would trip the core under specific monitored conditions including, but not limited to (1) high core power, (2) low primary coolant flow rate, (3) loss of offsite power, (4) high core exit or hot leg temperature, (5) low reactor pool level, and (6) core power distribution beyond technical specification limits. A reactor primary coolant shutdown pump is designed to circulate sufficient coolant through the heat exchanger to remove decay heat. Two 100-percent-capacity redundant emergency

power diesel generators would provide adequate electrical power for all emergency systems in the event of a loss of offsite power.

The new research reactor design provides multiple layers of inherent passive and redundant nuclear-safety-related active systems to preclude, mitigate, and control any radioisotope releases to the environment and to minimize doses to both the public and workers.

## **E.9 REACTOR OPERATION**

Operation of the new research reactor would be similar to other research reactors except that the core would be maintained at full power for a minimum of 80 percent of the year. At the beginning of a cycle of operation, neptunium-237 and long irradiation-time medical radioisotope target rod assemblies would be inserted into their appropriate fuel assembly sleeve locations. The target rods would be mechanically attached to a cluster spider assembly similar to that used for the control rod assembly. The neptunium-237 target rod assemblies would remain in the core for the entire annual fuel cycle. These target rod assemblies would be removed from the host fuel assembly without removing the fuel assembly from the core and then transferred to the spent fuel storage pool using the transfer canal.

Medical and/or industrial radioisotope target rods that require a 100-day irradiation cycle would be removed and replaced with new target rod assemblies during brief reactor shutdown periods. These target rod assemblies would be removed and transferred in a manner similar to that of the neptunium-237 target rod assemblies. Short irradiation-time radioisotopes would be inserted into rabbit tubes for the 10- to 25-day required time period. The eight rabbit tubes would be located outside the core, but inside the reflector region. The insertion and removal of irradiation targets in the rabbit tubes would have no significant effect on core reactivity and would not affect power operation.

After a radioisotope-specific cooling time in the spent fuel pool, neptunium-237, medical, and industrial radioisotope target assemblies would be transferred to a shipping cask in the spent fuel storage pool. Using the overhead crane in the spent fuel pool area, shipping casks would be placed onto a truck in the reactor building bay area adjacent to the fuel storage pool for shipment to the processing facility. New targets would be shipped from the target preparation facility into the reactor building bay by truck, transferred into the spent fuel storage pool, and subsequently moved to the reactor core pool or rabbit tube area for insertion into the core.

The plutonium-238 net annual production mission of 5 kilograms (11 pounds) was calculated to be achieved with a 300-day annual irradiation time, which corresponds to a capacity factor of approximately 80 percent. The redundant heat removal systems, low pressure and temperature conditions, and proven reactor design are expected to ensure this capacity factor. An annual shutdown for maintenance would occur during the remaining time of the year. The 10-year core refueling is not expected to affect the 80 percent annual capacity factor. Key reactor annual resource requirements are delineated in **Table E-6**.

The annual water consumption shown in Table E-6 would be due primarily to water losses from the cooling towers which would constitute over 99 percent of the total water use. Diesel fuel consumption would be due to the monthly and annual testing of the two emergency power diesel generators. Sewer water disposal would be due to the potable and sanitary water use by the research reactor facility staff.

**Table E-6 Research Reactor Annual Resource Requirements**

Resource Parameter	Value
Staff	120
Electricity	25,000 megawatt-hours
Reactor operating process water	$7.95 \times 10^8$ liters ( $2.10 \times 10^8$ gallons)
Total water	$8.07 \times 10^8$ liters ( $2.13 \times 10^8$ gallons)
Nonhazardous waste	250 cubic meters (327 cubic yards)
Hazardous waste	4 cubic meters (5.2 cubic yards) <sup>a</sup>
Diesel fuel	28,972 liters (7,655 gallons)
Potable and sanitary water	$1.16 \times 10^7$ liters ( $3.06 \times 10^6$ gallons)

a. DOE 2000.

### E.9.1 Nonradiological Emissions

During normal operations, the nonradiological emissions from the new research reactor facility would consist primarily of exhaust from testing, assumed to be a total of 72 hours per year, of the two emergency power diesel generators. These emission data were based on the estimated annual consumption of diesel fuel associated with this testing and U.S. Environmental Protection Agency (EPA) guidance on diesel engine emissions (EPA 1996). The estimated annual diesel emissions for the new research reactor are presented in **Tables E-7, E-8, E-9, and E-10**.

**Table E-7 Gaseous Emission Factors and Predicted Emissions**

Criteria Pollutant	Emission Factor (pounds per million British thermal units) <sup>a</sup>	Predicted Emissions from Subject Diesels (kilograms [pounds] per year)
Nitrogen oxides		
Uncontrolled	3.2	1,493 (3,290)
Controlled	1.9 <sup>b</sup>	885 (1,950)
Carbon monoxide	0.85	395 (870)
Carbon dioxide	165	77,163 (170,000)
Sulfur dioxide	$1.01 \times S^c$	472 (1,040)

a. EPA 1996.

b. Controlled by timing ignition retard.

c. S is the percent of sulfur in the fuel, which is assumed to be 1 percent (No. 2 Diesel Fuel Oil) (Avalone and Baumeister 1987).

**Table E-8 Emissions Factors and Predicted Emissions for Particulate Matter**

Description of Particulates	Emission Factor (pounds per million British thermal units) <sup>a</sup>	Predicted Emissions from Subject Diesels (kilograms [pounds] per year)
Filterable particulates <sup>b</sup>		
Less than 1 micron	0.0478	22.3 (49.1)
Less than 3 microns	0.0479	22.3 (49.2)
Less than 10 microns	0.0496	23.1 (51.0)
Total filterable particulates	0.0620	28.9 (63.7)
Condensable particulates	0.0077	3.6 (7.9)
Total PM <sub>10</sub> <sup>c</sup>	0.0573	26.7 (58.9)
Total particulates <sup>d</sup>	0.0697	32.5 (71.6)

- a. EPA 1996.
- b. Particle size is expressed as aerodynamic diameter.
- c. Total PM<sub>10</sub> is the sum of the filterable particulate matter with an aerodynamic diameter less than or equal to 10 microns and the condensable particulate.
- d. Total particulates are the sum of the total filterable particulates and the condensable particulates.

**Table E-9 Emission Factors and Predicted Emissions  
for Speciated Organic Compounds**

Pollutant	Emission Factor (pounds per million British thermal units) <sup>a</sup>	Predicted Emissions from Subject Diesels (kilograms [pounds] per year)
Benzene	$7.76 \times 10^{-4}$	0.36 (0.80)
Toluene	$2.81 \times 10^{-4}$	0.13 (0.29)
Xylenes	$1.93 \times 10^{-4}$	0.09 (0.20)
Propylene	$2.79 \times 10^{-3}$	1.30 (2.87)
Formaldehyde	$7.89 \times 10^{-5}$	0.04 (0.08)
Acetaldehyde	$2.52 \times 10^{-5}$	0.01 (0.03)
Acrolein	$7.88 \times 10^{-6}$	0.004 (0.008)

- a. EPA 1996.

**Table E–10 Emission Factors and Predicted Emissions for Polyaromatic Hydrocarbons**

Pollutant	Emission Factor (pounds per million British thermal units) <sup>a</sup>	Predicted Emissions from Subject Diesels (kilograms [pounds] per year)
Naphthalene	$1.30 \times 10^{-4}$	0.060 (0.133)
Acenaphthylene	$9.23 \times 10^{-6}$	0.0043 (0.0095)
Acenaphthene	$4.68 \times 10^{-6}$	0.0022 (0.0048)
Fluorene	$1.28 \times 10^{-5}$	0.0059 (0.013)
Phenanthrene	$4.08 \times 10^{-5}$	0.019 (0.042)
Anthracene	$1.23 \times 10^{-6}$	0.0006 (0.0013)
Fluoranthrene	$4.03 \times 10^{-6}$	0.0019 (0.0041)
Pyrene	$3.71 \times 10^{-6}$	0.0017 (0.0038)
Benz(a)anthracene	$6.22 \times 10^{-7}$	0.00029 (0.00063)
Chrysene	$1.53 \times 10^{-6}$	0.00073 (0.0016)
Benzo(b)fluoranthene	$1.11 \times 10^{-6}$	0.00050 (0.0011)
Benzo(k)fluoranthene	Less than $2.18 \times 10^{-7}$	Less than 0.00010 (less than 0.00022)
Benzo(a)pyrene	Less than $2.57 \times 10^{-7}$	Less than 0.00012 (less than 0.00026)
Indeno (1, 2, 3-cd) pyrene	Less than $4.14 \times 10^{-7}$	Less than 0.00020 (less than 0.00043)
Dibenz (a, h) anthracene	Less than $3.46 \times 10^{-7}$	Less than 0.00016 (less than 0.00036)
Benzo (g, h, l) perylene	Less than $5.56 \times 10^{-7}$	Less than 0.00026 (less than 0.00057)
Total polyaromatic hydrocarbons	$2.12 \times 10^{-4}$	0.100 (0.220)

a. EPA 1996.

## E.9.2 Radiological Emissions

Radiological emissions from the new research reactor during normal operations would be due to the neutron activation of argon gas, which would be dissolved in the reactor pool water, creating argon-41 and neutron capture by oxygen atoms in water molecules, creating tritium. **Table E–11** presents the calculated annual emissions of radioisotopes from the reactor due to normal operations and the estimated maximum annual radioactive waste generation (DOE 2000; AECL 1996).

**Table E–11 Normal Operations Annual Radiological Emissions and Waste Generation**

Radioisotope	Annual Release
Argon-41	2.8 curies
Tritium (hydrogen-3)	0.1 curies
Low-level liquid radioactive waste volume	<6 cubic meters (212 cubic feet) <sup>a</sup>
Low-level solid radioactive waste volume	50 cubic meters (1,766 cubic feet) <sup>b</sup>
Transuranic waste	0
Mixed low-level radioactive waste	<0.5 cubic meter <sup>a</sup> (17.7 cubic feet)

a. DOE 2000.

b. AECL 1996.

**Key:** <, less than.

The maximum dose rate to workers at all locations within the reactor building, due to released argon-41, tritium, and direct radiation from the submerged reactor core at power or the spent fuel in the storage pool is estimated to be less than 1 millirem per hour.

## E.10 REACTOR CONSTRUCTION

Construction of the new research reactor facility was determined to require 4 years after design and licensing activities have been completed (ANSTO 1999; AECL 1996). Based on the dimensions of the reactor and control buildings, cooling towers, cooling tower separation distance from the reactor and control buildings, and ancillary structures (i.e., emergency power diesel generators, heating, ventilating, and air conditioning exhaust stack, etc.), the total surface area of structures and of the facility restricted area were calculated and are presented in **Table E-12**. This table also presents the total construction workforce; quantities of earth moved; and quantities of concrete, structural, and stainless steel estimated for the facility. It was assumed that the new research reactor would be located at an existing DOE site. Another underlying assumption is that the workforce would be present for 2,080 hours per year at the construction site.

**Table E-12 Research Reactor Construction Resources**

Construction Parameter	Value
Time period	4 years
Workforce	160 <sup>a</sup>
Total reactor facility area	3,623 square meters, or 0.9 acre (39,000 square feet)
Reactor restricted area	15,942 square meters, or 3.9 acres (171,600 square feet)
Volume of earth moved	5,199 cubic meters (6,800 cubic yards) <sup>b</sup>
Concrete volume	5,237 cubic meters (6,850 cubic yards) <sup>b</sup>
Mass of structural steel	50,122 kilograms (110,500 pounds) <sup>b</sup>
Mass of stainless steel	3,468 kilograms (7,645 pounds) <sup>b</sup>
Volume of potable and sanitary water used	4.4×10 <sup>7</sup> liters (1.2×10 <sup>7</sup> gallons)
Total volume of water used	4.7×10 <sup>7</sup> liters (1.24×10 <sup>7</sup> gallons)

a. AECL 1996.

b. Tripathi 2000a, 2000b, 2000c.

During construction, pollutant emissions would be generated by vehicle operation, onsite concrete batch plant operation, wind erosion, material handling, bulldozing, scraping, and grading operations. The annual emissions and waste generation for the 4-year construction period were estimated based on the workforce size, concrete production requirements, and facility areas (PFS 1997), and are presented in **Table E-13**.

**Table E-13 Annual Reactor Facility Construction Emissions and Waste Generation**

Criteria Pollutant	Annual Emissions
PM <sub>10</sub> <sup>a</sup>	14,279 kilograms (31,414 pounds)
Nitrogen oxides	5,370 kilograms (11,815 pounds)
Carbon monoxide	6,713 kilograms (14,769 pounds)
Volatile organic compounds	1,343 kilograms (2,954 pounds)
Structural steel scrap waste	1,253 kilograms (2,757 pounds) <sup>b</sup>
Stainless steel scrap waste	87 kilograms (191 pounds) <sup>b</sup>
Concrete waste	131 cubic meters (171 cubic yards) <sup>b</sup>
Hazardous liquid waste	0.25 cubic meter (0.3 cubic yard)
Hazardous solid waste	0.75 cubic meter (1.0 cubic yards)
Nonhazardous liquid waste	11,400 cubic meters (14,387 cubic yards)
Nonhazardous solid waste	307,500 kilograms (676,500 pounds)

a. Total PM<sub>10</sub> is the sum of the filterable particulate matter with an aerodynamic diameter less than or equal to 10 microns and the condensable particulate.

b. Tripathi 2000a, 2000b, 2000c.

## **E.11 DECONTAMINATION AND DECOMMISSIONING**

When the new research reactor ceases its operation, it would be subject to the process of decommissioning. The reactor and its facility would be decontaminated to acceptable levels approved by the regulatory authority such that the land and buildings can be released for unrestricted uses. The research reactor and its facility then would be delicensed. For the decommissioning of a research reactor, decontamination and release for unrestricted use is generally the option chosen, although other options, such as safe storage or entombment are available for consideration.

A conceptual decommissioning plan for the proposed new research reactor emphasizes the major decontamination activities and process for the cleanup of the reactor and its facility, resulting in the final delicensing of the reactor and its facility. Part of the decommissioning plan normally includes the financial assurance requirements for the total cost of decommissioning. This requirement is expected to be exempt from the regulatory agency, since it is a DOE-owned research reactor. If DOE were to select this alternative (i.e., the construction and operation of a new research reactor at an existing DOE site), the formal site-specific decommissioning plan would be submitted for review and approval at the time of decommissioning. The decommissioning action at that time would be under a separate and appropriate National Environmental Policy Act (NEPA) review process.

## **Appendix F**

### **New Accelerator(s)**

The U.S. Department of Energy (DOE) has determined that accelerators could be used for the production of medical and industrial isotopes, the conversion of neptunium-237 to plutonium-238, and to support nuclear energy research and development initiatives. The production of medical and industrial isotopes that are neutron poor could be effectively accomplished using a low-energy accelerator with energies in the range of 30 million to 70 million electron volts. Isotopes that are neutron rich are made in either reactors or high-energy accelerator spallation neutron sources. The irradiation of neptunium-237 targets for plutonium-238 production can be effectively accomplished using a high-energy accelerator with energies much greater than 100 million electron volts. Both low- and high-energy accelerators can be used to support nuclear energy research and development initiatives.

The accelerator(s) would be constructed and operated at one or two DOE sites where security measures would be in place, including access control and procedures, to ensure the adequate protection of all materials processed and stored. Although each accelerator would be independent of the other for the performance of its mission and can therefore be separately located, there may be important efficiencies to be gained by their collocation at the same DOE site.

#### **F.1 LOW-ENERGY ACCELERATOR**

A new 70-million-electron-volt cyclotron can be used for the production of medical and industrial isotopes and to support nuclear energy research and development initiatives. Important uses of the cyclotron would be to:

- Serve as a user facility for radioisotope production research, including excitation function measurements, high-power-density targetry required for isotope production at high beam currents, radiochemical separations, and purification
- Provide research capability for the development and evaluation of next-generation radioisotopes and radiopharmaceuticals for applications to imaging and therapy
- Provide a state-of-the-art, dedicated, multipurpose isotope production facility with simultaneous multiuser capability
- Respond to the national need for a continuous and reliable supply of present and future radioisotopes for biomedical research and other applications
- Provide a training facility for the next generation of nuclear and radiochemists in the areas of: nuclear and radiochemical techniques for radionuclide production, separation, and purification; radiotracer syntheses; radiopharmaceuticals development and evaluation; radiation protection and safety; and application of radiotracer methodology for biomedical investigations

Three low-energy accelerator options would be available for the production of medical and industrial isotopes and to support nuclear energy research and development: (1) a high-current proton linear accelerator (linac), (2) a multiparticle cyclotron, or (3) a proton-only cyclotron. The proton-only cyclotron would have distinct technical advantages over the other two options and is described further in the sections that follow.

### **F.1.1 Overview**

The proton-only cyclotron can be either positive proton or negative ion and is referred to as a proton cyclotron  $H^+$  or proton cyclotron  $H^-$ . The positive proton cyclotron alternative would offer lower vacuum requirements and, with the latest technology, high-extraction efficiency can be achieved. But, obtaining variable energy output would be complicated, extraction can be into only a single port, and splitting the beam would require a complicated septum magnet. In comparison, the negative ion cyclotron would offer a continuous beam with a high-current capacity using very simple high-efficiency extraction, a simple method to vary the particle energy, and the possibility of simultaneous irradiation of two different target arrays at different energies. The high-extraction efficiency would be achieved simply by passing the negatively charged beam through a thin foil that strips the electrons from the ion, creating a positive proton. The proton would be ejected directly from the machine by the existing magnetic field with high efficiency (greater than 98 percent). This feature would be important to minimize the activation of the cyclotron structure and thus reduce radiation exposure to the operational staff.

A high-beam current would be advantageous because more products can be prepared in a shorter time. In addition, a much higher specific-activity radioisotope can be prepared at the higher-beam current of the cyclotron. Specific activity is the ratio of radioactive atoms to total atoms of the same atomic number in the sample and is expressed in units of curies per gram. A stable element can enter the process in many ways, most commonly from the target, the reagents, or from the environment during handling of the irradiated target and subsequent processing. These quantities tend to be fairly constant from run to run, and would be independent of irradiation time or beam current. Therefore, a higher-intensity beam generally makes more radioactivity without adding to the amount of stable element in the final product. Specific activity is often a critical parameter in many nuclear medicine applications, including research and clinical use.

The cyclotron can also continuously tune the beam energy, which would be an advantage for research. The ability to tune the energy with precision can also help achieve high-purity isotope production by avoiding energies where impurity isotopes would be readily co-produced. It would be desirable to precisely tune to a low energy to achieve optimal production of certain radioisotopes. Energy variability from 40 million to 70 million electron volts would be easy, 30 million to 70 million electron volts would be possible, and 20 million to 70 million electron volts would need some design effort. It also would be possible to strip only part of the beam in an orbit and have another stripper at 180 degrees to simultaneously extract a second beam. This beam can have the same or different energy and intensity as the first. These are important advantages for flexibility in research isotope production and are within the capabilities of commercially proven technology.

### **F.1.2 Isotope Production Systems Design**

A new building would be constructed to house the cyclotron and the four beam lines. The walls of the facility would be 4.6 meters (15 feet) thick behind the target stations to minimize the neutron flux outside the building. The walls surrounding the cyclotron itself would be 3 meters (10 feet) thick. The mazes throughout the building in general would have walls 1.5 meters (5 feet) thick, so that the total thickness surrounding the cyclotron area would be 3 meters (10 feet). The beam would be diverted to the four target stations by switching magnets located in the cyclotron vault. The beam would be directed through focusing and steering magnets to the target. In the isotope production beam line (northwest cave), the targets would be installed and removed vertically from a hot cell, which would be located on the second floor directly above the target station. The power supplies for the magnets would be housed with the power supplies for the cyclotron. The mechanical equipment for cooling water would be housed in a shielded mechanical room adjacent to the cyclotron vault. Recirculating water for cooling the targets and systems that could contain potentially radioactive material would be separated to prevent cross contamination. These systems would be contained in mechanical equipment rooms near the respective target station. Piping would be contained in waterproof

trenches with leak detection. Isometric views of the new cyclotron and beam lines are shown in **Figures F-1** and **F-2**.

**Figure F-1 Isometric View of the New Cyclotron**

The isotope production system would be divided into several sections. These are the beam lines out of the cyclotron, the beam lines into each of the target caves, and the target holders and handling system in each of the target caves.

#### **F.1.2.1 Beam Line Design**

The beam would be extracted from the cyclotron by means of a thin carbon foil that strips two electrons off the hydrogen minus-one ion ( $H^-$ ) and would convert the negatively charged hydrogen ions to positively charged ions. These would be bent in the opposite direction in the magnetic field of the cyclotron. Once the beam has been extracted from the cyclotron, it would pass through a beam shutter and into a quadrupole-focusing magnet. After the beam passes through the focusing magnet, it would pass into the switching magnet that would bend the beam into either of the two beam lines located on each end of the facility. After passing through the switching magnet, the beam would pass through another set of focusing and steering magnets inside the cyclotron vault and through the wall into the target cave. The direct current quadrupole and dipole

Source: TechSource 2000.

Figure F-2 Cyclotron and Beam Lines

magnets would be of conventional design and would have pole tip fields that are easily achievable with standard designs. In addition, the beam line for the northwest target cave would have a raster scan system consisting of variable-field horizontal and vertical steering magnets. This would allow rapid sweeping of the beam spot across the target face. Magnet cooling would require high-resistivity deionized water for voltage standoff purposes.

The vacuum system consists of beam pipes, bellows and flanges, vacuum valves and actuators, vacuum pumps, and vacuum instrumentation. The valves for the facility would include gate valves for isolating sections of lines, a fast valve for isolating the cyclotron vacuum volumes from the beam lines in the event of a target window failure, and roughing valves at the cryopumps.

The beam diagnostics system would provide the information needed to monitor and control the beam position throughout the beam lines and on the targets, and the final spot size on the target. Adjusting the fields of the direct current bending magnets would control the coarse beam position. Varying the steering magnet fields would make fine adjustments in the beam position. Adjusting the final quadrupole magnets in the line would control the beam spot size on the target. Each beam line would be equipped with a beam scanner that would give a distribution profile of the beam in both horizontal and vertical directions.

### **F.1.2.2 Isotope Production Equipment**

There would be three separate target systems set up in the low-energy accelerator facility. The first would be the radioisotope production system housed in the northwest target cave. The second would be the positron emission tomography radioisotope production system housed in the southwest target cave. The third would be the research target system housed in the southeast target cave.

#### **F.1.2.2.1 High-Level Radioisotope Production—Northwest Target Cave**

##### **SYSTEM FUNCTION**

The isotope production equipment would include several components: the target housing (with targets), target transfer mechanisms, a hot cell, and a target radiation shield. All these components, except for the hot cell and portions of the target transfer mechanisms, would be in the lower level of the facility. Collectively, these systems must provide for target irradiation in a safe, cost-effective, and environmentally conscious manner.

##### **SYSTEM DESIGN BASIS**

The system would be designed to accept a proton beam with nominal energies of 30 million to 70 million electron volts and a maximum average beam current of 1 milliamperere. Normal operations would be expected to use 250 to 500 microamperes of beam current. Target shielding would be sized to accommodate up to 1 milliamperere of beam current, since the cyclotron would be capable of delivering currents of up to 2 milliampereres.

Targets would be designed with a circular cross section. Calculations of power deposition would assume a flat beam profile over the entire target surface. A rastering system would be in place on this beam line to ensure an optimum distribution of the beam. More than one target would be irradiated at a time, but the targets would be inserted and retrieved as a single assembly. The thickness of this assembly must be at least 10 centimeters (3.9 inches), not including water gaps between the target faces. This ensures that there would always be enough target material or water to stop 70 million electron-volt protons.

The target housing would become very highly activated during the irradiation process. Therefore, personnel would not have access to the target housing after the initial irradiation. In addition, a concrete radiation shield would be installed downstream of the target assembly inside the cave to provide extra shielding from forward-going prompt neutrons and from residual gamma radiation.

## **SYSTEM DESIGN DESCRIPTION**

The isotope production target facility would be housed in a stainless steel cylinder, which would form a 5.5-meter (18-foot) column of water. The top of the tank would open to a hot cell. The bottom of the tank would connect to the beam vacuum chamber. A beam of protons ranging from 30 million to 70 million electron volts would enter the water column through a thin vacuum window at the end of the beam vacuum chamber. The targets would be transported by a trolley holder, which would use a rectangular tube as a track. The rectangular track would be housed within the 5.5-meter (18-foot) water column. The trolley would transport and locate the targets at the beam centerline just downstream of the beam vacuum chamber exit window. The trolley drive system would be a semiautomatic motor-driven chain and cable assembly. The target would be water-cooled by forced water traveling vertically over the face of the target.

The water column would house the target transport system and contain the cooling water. The diameter of the water column would be sufficient to stop protons with energies up to 70 million electron volts. The 5.5-meter (18-foot) height also would provide neutron shielding in the vertical direction. The target water column would be constructed from nuclear-grade, corrosion-resistant material. The column would have inlet and outlet connections for cooling water and a connection for the beam pipe. All the connections would be as-low-as-is-reasonably-achievable-designed to reduce radiation exposure during maintenance or removal of the system. The bottom of the column would form a plenum where the cooling water inlet would be. On the top of the plenum, there would be alignment holes to align the target drive track system. Above the beam line vacuum chamber connection would be the cooling water outlet. The top of the column would penetrate the hot cell to approximately tabletop height. There would be a lid at the top of the column to prevent objects from falling down the column and to reduce radioactive airborne emissions. All water line connections and seals would be made of nuclear-grade material.

At the downstream end of the beam line vacuum chamber would be a thin window. The window would be designed to permit the beam to irradiate the production targets with minimal beam loss. The window would be made of high-strength, nuclear-grade, corrosion-resistant material. The exit window would be designed for quick replacement in the event of a failure.

The targets would be transported vertically to and from the hot cell to the beam line within the water column. The targets would be transported using a motor-driven chain and cable assembly. The chain and cable assembly would be a continuous loop attached to a trolley. The top half of the loop would be a chain for a slip-free connection to the drive motor via the sprocket. The bottom half of the loop would be a cable. The track system for the target transport would be a rectangular tube that would guide and align the trolley. The track system would be removable from the hot cell for replacement or repair. The track would be aligned to the beam centerline by engagement of alignment holes located at the bottom of the water column. A trolley target holder would be attached to the chain and cable assembly and used to transport the targets in the rectangular track. The target holder would be capable of holding targets of various thicknesses in a horizontal array. The targets would be separated in the array by flowing water coolant to allow cooling of both the front and back faces of the target. To insert and remove the targets one at a time from the target trolley holder, a target extraction system would be needed. The extraction system would be installed in the hot cell and would be motorized to simplify the manipulation of the targets from within the hot cell.

The target assembly would consist of the target material housed in a sealed container. The container would be constructed from material designed to withstand corrosion by either the water coolant or the target material. The sealed container would be a circular disk, fabricated in a variety of thicknesses. The targets would be water-cooled. The water coolant would enter the water column at the bottom into the plenum, pass through a fixed orifice into the target track system, flow vertically across the targets, and then exit the water column above the beam centerline. The targets would be placed in the beam line tilted at 30 degrees. This would reduce the heat flux at the target front and back faces, allow for a larger cooling channel across the target, hence more water flow, and would reduce the thickness of the target, thus reducing the heat path to the water coolant.

#### **F.1.2.2.2 Positron Emission Tomography Radioisotope Production—Southwest Target Cave**

##### **SYSTEM FUNCTION**

The isotope production equipment would include several components: the automatic target changer (with targets), the water cooling system, the helium cooling system for the front foil of the targets, and the radioisotope removal system and transport line. Collectively, these systems must provide for target irradiation in a safe, cost-effective, and environmentally conscious manner.

##### **SYSTEM DESIGN BASIS**

The system would be designed to accept a proton beam with a nominal energy of 30 million to 70 million electron volts and a maximum average beam current of 250 microamperes. Targets would be designed with a circular cross section with a minimum diameter of 2.5 centimeters (1 inch). Calculations of power deposition would assume a Gaussian beam energy density profile, with a minimum full-peak width at half of the maximum of 1 centimeter (0.34 inch). One target would be irradiated at a time, but several targets would be present in the vault at a single time in an automatic target changer. The targets would be inserted and retrieved remotely. The target housing would become activated during the irradiation process.

##### **SYSTEM DESIGN DESCRIPTION**

The holders would be cylindrical-shaped with outside diameters of 7.6 centimeters (3 inches) and would occupy the centers of the target holders. The targets themselves would reside inside each of these cylinders. The targets would be solid plates that contain target powder and a small volume of liquid or a larger volume that contains a compressed gas. The beam line would have vacuum isolation foil, which would separate the helium cooling chamber from the cyclotron beam line. The vacuum isolation foil would be 0.0038-centimeter-thick (0.0015-inch-thick) aluminum alloy. The helium chamber would provide the reservoir for the chilled helium that would be passed over the front surface of the target foil. Should a window failure occur, the design of the window and its mounting structures must provide for effective operation and ease of replacement. Capturing the window in a foil holder that would be inserted between the beam line and the helium cooling assembly would satisfy these requirements. The front foil of the target must be thick enough to withstand the pressure generated inside the target during irradiation, which can be more than 600 pounds per square inch. In back of the target chamber would be a water cooling assembly that would help remove heat from the target body.

Radioisotopes can be removed from this target cave in two different ways. The first of these would be used for the solid targets. The target plate containing the irradiated powder would be remotely removed from the target body and placed into a shielded container. This container would be rolled out of the facility and transported to a hot laboratory. Once at a hot laboratory, the target would be processed to extract the desired radioisotope.

The second method of target extraction would be through a processing station in the target vault. In this method, the fluid target contents would be pushed out of the target with a stream of helium and onto a resin or absorbent column that would retain the desired radioisotope. This column then would be transported to a hot laboratory.

### **F.1.2.2.3 Research Radioisotope Production—Southeast Target Cave**

#### **SYSTEM FUNCTION**

The isotope production equipment would include several components: the target holder (with target), the water cooling system, and the helium cooling system for the front foil of the targets. Collectively, these systems must provide for target irradiation in a safe, cost-effective, and environmentally conscious manner.

#### **SYSTEM DESIGN BASIS**

The system would be designed to accept a proton beam with a nominal energy of 70 million electron volts and a maximum average beam current of 1 milliamperere. Cross-section-type experiments would be expected to use only 1 to 10 microamperes of beam current, but target research may use up to 1 milliamperere. Target shielding would be sized to accommodate up to 1 milliamperere of beam current, since the cyclotron would be capable of delivering currents of up to 2 milliampereres.

The operations sequence breaks down into four major operations: (1) load targets, (2) irradiate targets, (3) extract targets, and (4) transport irradiated targets.

#### **Load Targets**

Target irradiation would occur in the southwest target cave in an automated target-changer assembly. Access to the target chamber would be through the maze originating on the west side of the facility. The fluid targets would be loaded remotely from gas or liquid reservoirs residing in the target cave. The solid targets would be prepared outside the facility and brought in and placed in the target holder.

#### **Irradiate Targets**

The first step in preparing to start an irradiation run after the target stack has been loaded would be to establish coolant flow. This would be done by starting flow in the water system, then evacuating and pressurizing the helium system, followed by circulation initiation. The beam can be delivered to the target when the cooling system is functioning properly and all interlocks are satisfied. Irradiation would be continuous as long as the systems performance indicators, such as flow indicators and temperature monitors, remain within specified limits. The beam current striking the target would be integrated to determine when the proper number of protons has struck the target and the irradiation is complete.

#### **Extract Targets**

A transfer rabbit would be in place inside the target cave, which would hold the resin column or absorbent used to extract the desired radioisotope from the target material. The first step in preparing to extract the irradiated target material would be to stop the coolant flows. The target material would be forced out of the target and onto the resin column with a flow of helium. Once the radioactive isotopes have been transferred to the column, the flow of helium would be stopped and the transfer rabbit dropped into the transfer tube.

## **Transport Irradiated Targets**

The transfer rabbit would be dropped into a transfer tube and pneumatically sent to a hot laboratory.

### **F.1.3 Facility Systems Design**

The physical layout of the new cyclotron building would consist of two levels. The first floor (**Figure F-3**) would contain the vault room that would house the 70-million-electron-volt cyclotron, beam transport systems, cyclotron mechanical room, four target rooms, and storage room. The cyclotron vault room would be centrally located with a high bay equipped with a 15-ton bridge crane. There would be concrete trenches in the floor between the target rooms and the cyclotron vault room and a cross-shaped floor trench beneath the cyclotron. These trenches would be lined with an epoxy coating, which acts as secondary containment for any liquid that may be spilled, and have leak-detection sensors to comply with local environmental regulations. The cyclotron vault room would have a concrete ceiling with a removable roof plug for overhead installation of the cyclotron. The second floor would consist of a transfer room, staging area, and electrical and mechanical room. The transfer room would contain a concrete hot cell connected to the target room located directly below. Materials would be transferred from the hot cell to a shielded cask and transported to the hot side of the building for processing.

#### **F.1.3.1 Architectural and Structural Design**

##### **F.1.3.1.1 First-Floor Cyclotron Facility**

The interior spaces on the first floor would include the cyclotron vault, the cyclotron mechanical room, four target rooms with individual mechanical and electrical rooms, and a power supply room.

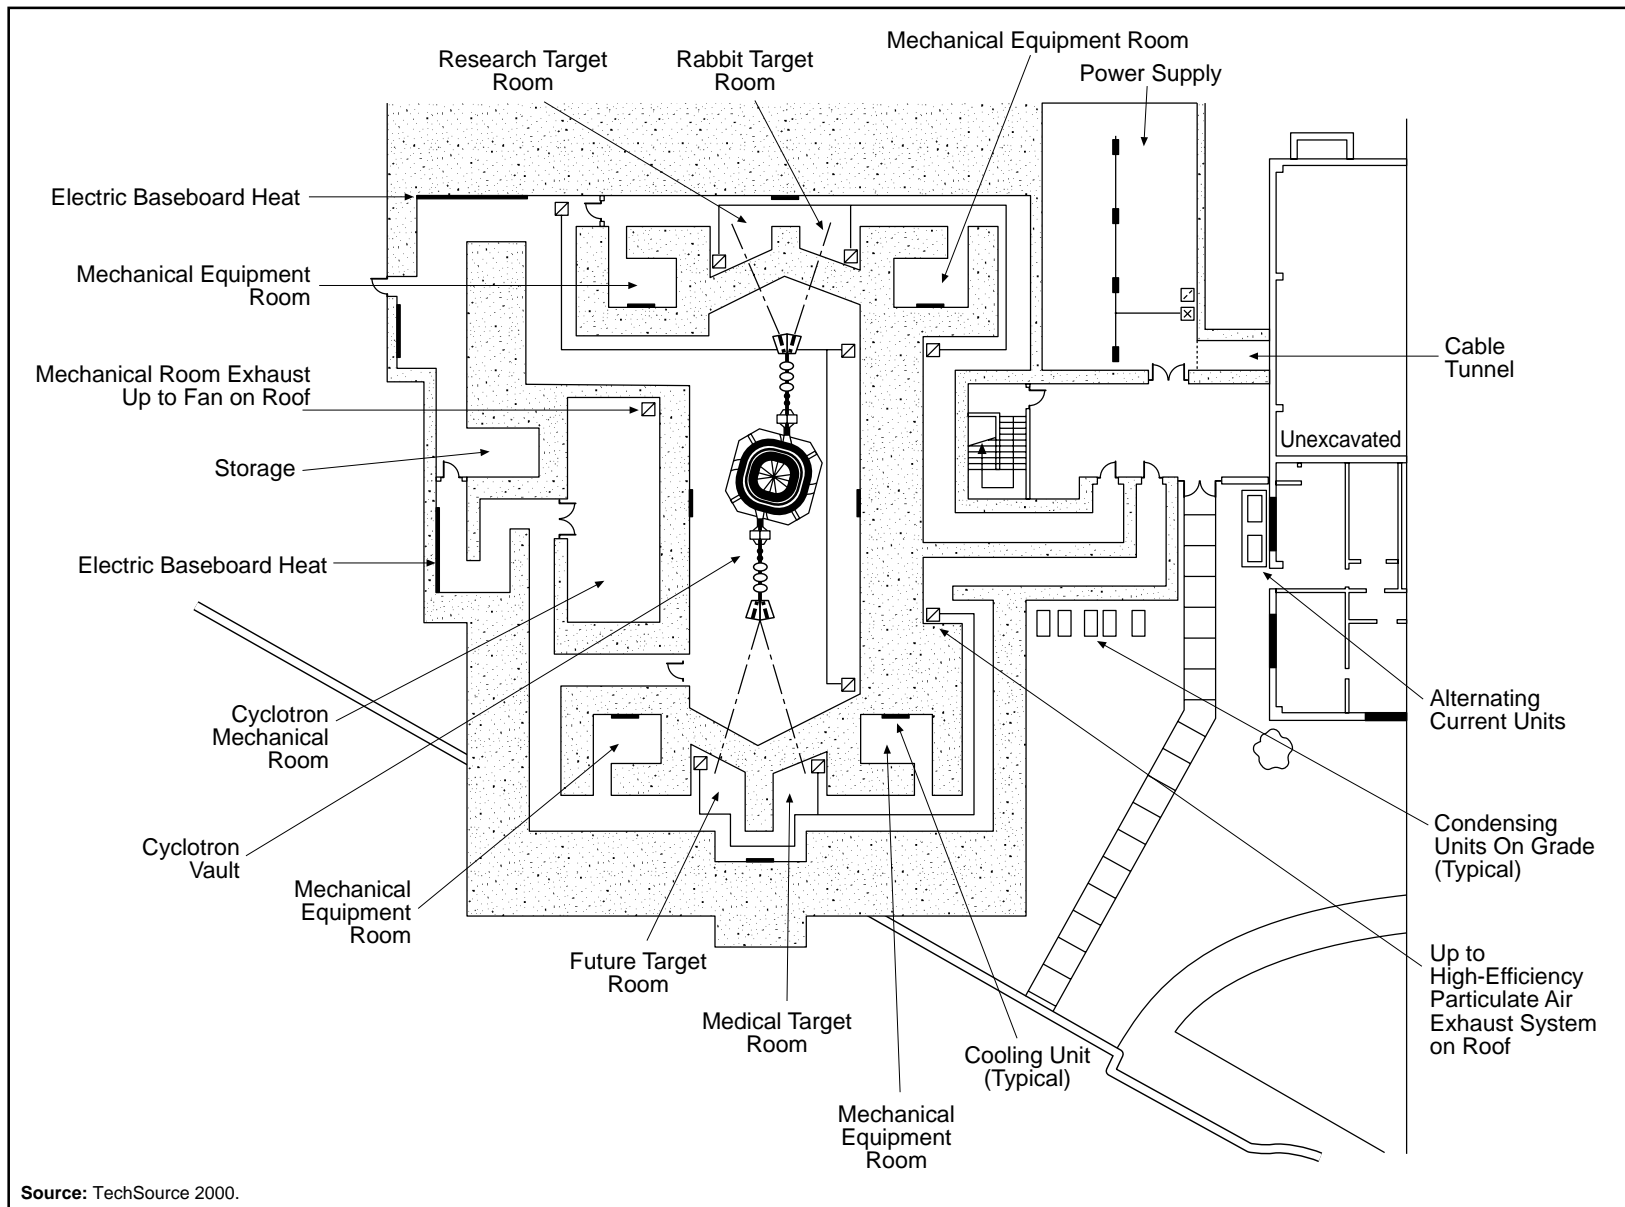

#### **SYSTEM FUNCTION**

The cyclotron vault would be surrounded by perimeter shielding walls that are 4.6 meters (15 feet) thick with a 0.91-meter-thick (3-foot-thick) ceiling constructed of reinforced-concrete. All other interior spaces would have a minimum shielding of 1.5 meters (5 feet) of concrete. The 15-ton bridge crane would be used for handling shield components in the cyclotron vault. The lower floor would be approximately 42.7 by 41.1 meters, or 1,755 square meters (140 by 135 feet, or 18,900 square feet), partially below grade. The first floor would house the cyclotron, target rooms, and cyclotron power supply room. The interior ceiling heights would be 5.8 meters (19 feet) for the cyclotron vault, and a minimum of 2.7 meters (9 feet) for all other spaces. The entire first floor facility would be constructed of reinforced cast-in-place concrete faced with brick veneer. The function of the structural systems would be to resist all anticipated loads from the soil, the second-floor facility, and the mechanical and electrical utilities within the facility. Floors would be constructed of epoxy-coated concrete.

#### **SYSTEM DESIGN BASIS**

The following is a generalized list of anticipated loads imposed on the first-floor cyclotron facility:

- Roof load: soil pressure, second-floor facility, and construction equipment load
- Floor load: live load of 250 pounds per square foot, 1,000-pound point load, target shield cube of 240 tons
- Wall load: lateral soils pressure of 55 pounds per square foot per foot of depth
- Wind load: not applicable
- Seismic load: design-basis-earthquake peak horizontal ground acceleration of 0.2 g

Source: TechSource 2000.

Figure F-3 Cyclotron Facility Floor Plan

## SYSTEM DESIGN DESCRIPTION

The following is a generalized list of descriptions of systems on the first-floor cyclotron facility:

- Roof system: 0.91-meter-thick (3-foot-thick) reinforced cast-in-place concrete
- Wall system: 4.6-meter-thick (15-foot-thick) reinforced cast-in-place concrete
- Foundation system: 0.91-meter-thick (3-foot-thick) reinforced-concrete mat footing
- Lateral resisting system: reinforced-concrete shear walls with a concrete roof diaphragm
- Crane: the cyclotron high-bay facility would include a 15-ton bridge crane for loading and unloading the magnets; the concrete walls would support this crane

### F.1.3.1.2 Second-Floor Cyclotron Facility

The interior spaces for this floor include the transfer room containing a concrete hot cell, the electrical mechanical room for the building, and a staging area. This partial second-floor structure would be constructed of a steel frame with concrete block and brick veneer walls and partitions, with a built-up roof system on a metal roof deck. The mechanical and electrical room would contain the main electrical service switchboards, panel boards, and mechanical equipment used for cooling the magnets, the target below, and the building itself. There would be a 5-ton bridge crane located on the second floor of the cyclotron facility to service the hot cell and target components.

## SYSTEM FUNCTION

The second floor would consist of one structural area, approximately 30.5 by 40 meters, or 1,220 square meters (100 by 130 feet, or 13,000 square feet), and would house the transfer room, staging area, and major utility space. The entire second-floor facility would be constructed of reinforced cast-in-place concrete floors and a steel frame with masonry walls faced with brick veneer. The function of the structural systems would be to resist all anticipated loads from the roof, wind, and the mechanical and electrical utilities within the facility. Floors would be constructed of epoxy-coated concrete.

## SYSTEM DESIGN BASIS

The following is a generalized list of anticipated loads imposed on the second-floor cyclotron facility:

- Roof load: live load of 30 pounds per square foot
- Floor load: live load of 250 pounds per square foot; hot cell live load of 83 tons
- Wind load: the design-basis wind would be a straight wind at 90 miles per hour
- Seismic load: design-basis-earthquake peak horizontal ground acceleration of 0.20 g

## SYSTEM DESIGN DESCRIPTION

The following is a generalized list of descriptions of systems on the second-floor cyclotron facility:

- Roof system: a built-up roofing system on a metal roof deck screwed to steel purlins that are welded to steel channel roof purlins
- Wall system: steel columns and girders with masonry in-fill walls running horizontally at the perimeter of the building
- Floor system: reinforced-concrete under the steel columns; a mat footing approximately 30.5 centimeters (12 inches) thick would be incorporated under the hot cell, and 15.2-centimeter-thick

(6-inch-thick) reinforced-concrete slabs on grade would be incorporated throughout the rest of the facility

- Lateral resisting system: a steel-braced frame with a metal roof diaphragm
- Crane: a 5-ton bridge crane installed over the hot cell

#### **F.1.3.1.3 Hot Cell**

There would be a hot cell on the second floor of the facility located above the northwest target cave that would contain the top of the target after-shaft and the target drive assembly. The hot cell would provide radiation shielding to safely handle the highly activated targets during target insertion and removal operations. It would also provide prompt neutron shielding above the target cave. Although the hot cell area would be an exclusion zone with the beam on, the presence of the hot cell would help reduce “sky shine” outside the target transfer room to acceptable levels for uncontrolled access.

The hot cell would be made from cast concrete and steel components. The concrete thickness would be determined based on criteria that the maximum personnel exposure rate from the highest likely radiation source term in the interior not exceed 5 millirem per hour. The interior dimensions would be adequate to perform operations such as target insertion and removal, simple repair of the target holder, and installation of an interior lead storage cave. The hot cell would have a viewing window made of sheets of lead glass using standard construction techniques. The effective shielding thickness would be equal to that of the walls. The size would be sufficient to allow operators to see most of the interior and perform all required functions. Two master-slave remote manipulators would be provided for remote target-handling operations. They would be sized to reach the entire working area of the hot cell.

The hot cell would have a shielded port hole mounted in a side wall to enable the removal of radioactive targets and radioactive waste. A shutter plug of lead and steel would be constructed. The location and arrangement of this hot cell opening would prevent direct radiation shine from hot cell contents into the target transfer room. The port hole design would be compatible with an existing target transport cask. The transport cask would be moved from this hot cell to the hot cell in the Target Processing Laboratory of the building by an electrical pallet truck. The port hole also would allow the introduction of small materials and equipment into the hot cell. In order to allow larger equipment to be introduced or removed for repair, a larger lead and steel shielded door also would be provided in a side wall. This door would be large enough for personnel entry for major maintenance or decontamination operations. Suitable locks would be provided to restrict such access unless entry would be permitted.

Other small penetrations would be provided for typical services in a serpentine manner to minimize straight-line radiation paths. The hot cell would be connected to a high-efficiency particulate air-filtered ventilation system that would keep the interior pressure slightly negative with respect to the room. This would assure that no radioactive contamination would spread outward. The hot cell would be equipped with high-intensity lighting to ensure adequate vision through the thick lead-glass window. Standard 120-volt alternating current electrical receptacles, water, and air would be supplied into the hot cell interior.

## **F.2 HIGH-ENERGY ACCELERATOR**

### **F.2.1 Overview**

#### **F.2.1.1 System Description**

In accelerator production of plutonium-238, an energetic beam of protons generated by a linac would be transported to a heavy metal target where spallation neutrons would be produced. The beam of protons would

be moderated in a surrounding blanket containing neptunium-237, which would capture the slowed neutrons to produce plutonium-238 through the same nuclear sequence as occurs in a reactor. The accelerator would be housed in a concrete tunnel, buried below ground to provide radiation shielding for operating personnel. A building housing radio frequency power systems and other equipment used to drive, monitor, and control the accelerator would be located above ground close to the accelerator tunnel. The target/blanket assembly would be housed inside a steel and concrete shield located within a multistory building that would contain appropriate service equipment. At the target, the small-diameter proton beam transported magnetically from the accelerator would be converted to a much larger cross section by a beam expander to reduce the power density to acceptable levels for the target cooling systems.

**Figure F-4** shows the accelerator production of plutonium plant layout.

### F.2.1.2 Plutonium-238 Production Process

An accelerator-driven spallation neutron source can be used to produce plutonium-238 from neptunium-237 feedstock through the capture and decay nuclear processes. A 1,000-million-electron-volt proton beam produced by a radio frequency linac would bombard a heavy metal (uranium-238) target, with each proton producing about 40 neutrons. Surrounding the spallation target would be a blanket containing a mixture of neptunium-237 and water coolant in an aluminum structure, all inside a beryllium reflector. The combination of materials in the target/blanket assembly would moderate the neutron spectrum down to thermal energies, where the capture cross section in neptunium-237 would be about 200 barns. As in a reactor, the nuclear reactions would be:

Plutonium-238 nuclei, once formed, would have a significant cross section for destruction through neutron capture, which must be taken into account when optimizing the blanket neutron spectrum, the neutron flux at the neptunium-237 locations, and determining the optimum length of the irradiation periods.

The use of medium-energy proton beams for nuclear material production or conversion is a well-established concept of several decades. The technology basis for high-energy proton accelerators and spallation neutron sources has been developing, over the past 10 years, through two U.S. projects, as well as in Europe and Japan. One U.S. project is the DOE Defense Programs' development of a backup tritium production method (the Accelerator Production of Tritium program) and the other is the design of high-power pulsed spallation sources in the United States (the Oak Ridge Spallation Neutron Source facility).

In the spallation process, the high-energy protons smash into nuclei of the target material, initiating an intranuclear cascade followed by an evaporation process in which many neutrons are emitted. The spallation neutron spectrum would be similar to a fission spectrum, peaking at 1.2 million electron volts, but it has a high-energy tail.

An important factor in the selection of proton beam energy and current is that the number of spallation neutrons produced depends on the beam energy. While there is a nearly linear relationship over a large energy range (up to 2 giga electron volts), there is also a finite energy threshold (about 200 million electron volts) below which neutron production is effectively zero. The existence of this threshold energy means that neutron production as a function of beam power rises steeply for the first few hundred million electron volts, but asymptotically reaches a constant at high energies.

**Figure F-4 Plant Layout for the Accelerator Production of Plutonium**

Several high-Z materials are potential target material contenders, but depleted uranium would be the obvious choice for plutonium-238 production, since it produces more neutrons (by a factor of two) per incident proton than tungsten (the target material used in the Accelerator Production of Tritium), tantalum, or lead. The additional neutrons are produced by fast fission of uranium-238 nuclei induced by a fraction of the spallation neutrons.

### F.2.1.3 Production Requirements

A preliminary target and blanket design has been developed for scoping purposes, based on the architecture employed in the Accelerator Production of Tritium target and blanket design. It would use uranium-238 (cooled by deuterium) as the neutron-production target. The target would be surrounded by a blanket of neptunium-237 in a dilute mixture of aluminum and water coolant. Enclosing the blanket would be a beryllium reflector. Initial code calculations show that, with 72 kilograms (158.7 pounds) of neptunium-237 in the blanket, about 40 neutrons would be produced by each proton, of which about 60 percent would be captured in neptunium-237 to produce plutonium-238. Further optimization may increase both the number of neutrons per proton and the fraction useful for making plutonium-238 nuclei, but improvements greater than a factor of 1.3 in the number of plutonium-238 nuclei made by each proton are unlikely.

Once produced, the plutonium-238 nuclei are subject to destruction processes as long as they remain in the neutron flux. The dominant process is  $\text{plutonium-238} + n \rightarrow \text{plutonium-239} + \gamma$ , which has a 540-barn thermal cross section, significantly greater than the 200-barn cross section for plutonium-238 production. Calculations show that there is an optimum neutron flux and irradiation campaign period that minimizes plutonium-238 destruction without invoking an excessive frequency of blanket reloading cycles. For example, at a flux of  $4 \times 10^{13}$  per square centimeter, the fractional plutonium-238 destruction in 90 days would be 6.7 percent.

The annual production requirement for plutonium-238 for this *Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility* has been given as 5 kilograms (11 pounds). Assuming 20 percent losses in chemical processing, 6 kilograms (13.2 pounds) per year would be needed in the material extracted from the production blanket. The year would be divided into three 4-month production campaigns, with a net amount of 2 kilograms (4.4 pounds) of plutonium-238 produced in each, allowing for the fraction destroyed. Each campaign would be divided into 100 days of production and 21 days for recycling the production blanket. A 90 percent plant availability during the scheduled operating periods is assumed, which should be achievable based on operating experience at the Los Alamos National Laboratory linac. Then the average proton current required as a function of beam energy is determined by the production relationship:

$$M/(1 - 0.067) = 6.24 \times 10^{18} \times I(E) \times Y(E) \times 238 \times 1.67 \times 10^{-27} \times 0.90 \times 0.854 \times 10^7$$

$$M = 17.75 I(E)Y(E)$$

where M is the mass of plutonium-238 required per campaign in kilograms, I(E) is the average proton current in amperes, and Y(E) is the yield of plutonium-238 nuclei per incident proton. With M = 2 kilograms, this becomes

$$I(E) = 0.113 / Y(E)$$

At a beam energy of 1,000 million electron volts, the preliminary target/blanket neutronics show that about 24 plutonium-238 nuclei are produced by each proton, setting 4.7 milliamperes as the nominal average current requirement.

#### **F.2.1.4 Accelerator**

As a stand-alone machine, a reasonable design basis for a plutonium-238 production accelerator would be a pulsed normal-conducting linac having an architecture similar to that of the January 2000 (baseline) normal-conducting linac design for the Oak Ridge Spallation Neutron Source facility. The normal-conducting version of the Spallation Neutron Source linac has a 1,000-million-electron-volt beam energy, and an average output current of 2 milliamperes, about one-third the requirement for plutonium-238 production. The peak current would be 36 milliamperes, corresponding to a beam duty factor of 0.056. However, the Spallation Neutron Source linac design was intended to be directly upgradeable to a 4-milliamper average current by doubling the peak current to 72 milliamperes. For the plutonium-238 production linac scoping design, this step also would be taken and the duty factor would be stretched to 0.066 to provide the required average current. Since the radio frequency power systems in the Spallation Neutron Source machine are designed for up to 0.09 duty factor, the same kind of power stations could be used for the plutonium-238 production linac. This modified version of the Spallation Neutron Source linac would satisfy the beam power requirement for plutonium-238 production and seems a reasonable model for carrying out the estimates needed for the mission.

The plutonium-238 linac concept would begin with an H<sup>+</sup> injector supplying beam to a 6-million-electron-volt radio frequency quadrupole operating at 400 megahertz. The Spallation Neutron Source machine uses an H<sup>-</sup> beam instead of protons, and has complex chopping arrangements at the front end. However, both of these features pertain to injection into a storage ring following the linac and can be eliminated in the plutonium-238 production application, allowing considerable simplification. The radio frequency quadrupole would be followed by a 400-megahertz drift-tube linac to 80 million electron volts, and an 800-megahertz coupled-cavity linac to full energy of 1,000 million electron volts. Accelerating structure lengths, gradients, focusing periods, and aperture sizes would be nominally the same as in the Spallation Neutron Source design. Beam dynamic simulations for the Spallation Neutron Source linac provide assurance of beam losses low enough (less than 0.1 nanoampere at 1,000 million electron volts) to permit unrestricted hands-on maintenance. The Spallation Neutron Source linac radio frequency power system employs high-peak-power klystrons (2.5 megawatts in the drift-tube linac, 5 megawatts in the coupled-cavity linac). Because the radio frequency efficiency (beam loading) of the Spallation Neutron Source linac would be relatively low (0.25), doubling the peak current as proposed above would increase the number of required radio frequency stations by a factor of only 1.25. However, because of the duty factor increase, each station would operate at a factor 1.18 higher average power. Key parameters for the reference accelerator are given in **Table F-1**.

Other accelerator options are possible, and might result in somewhat lower costs, coupled with superior performance. A reduced operating cost can be obtained by using super conducting accelerating cavities in the high-energy part of the pulsed linac, as in the Spallation Neutron Source final design. However, this introduces extra complications and results in somewhat higher capital costs. Using a linac with a lower beam-output beam energy (500 million electron volts) and higher current (14 milliamperes) would be another choice. Such a machine would employ super conducting cavities above 100 million electron volts, and could be somewhat more compact than the nominal Spallation Neutron Source linac. However, scoping cost estimates suggest that its capital costs would likely be not very different than for the reference 1,000-million-electron-volt pulsed linac.

Optimization of target and blanket performance as a function of beam energy, choice of materials and geometry, etc., has not been done. In concert with an analysis of accelerator costs as a function of proton

**Table F-1 Linac Parameters**

Parameter	Radio Frequency Quadrupole	Drift-Tube Linac	Coupled-Cavity Linac	Total
Radio frequency (megahertz)	400	400	800	
Output beam energy (million electron volts)	6	80	1,000	1,000
Accelerating gradient (average) (megavolts per meter)	–	–	2.63	–
Average current (milliamperes)	4.7	4.7	4.7	4.7
Peak current (milliamperes)	72	72	72	72
Beam duty factor (milliamperes)	0.066	0.066	0.066	0.066
Radio frequency duty factor (milliamperes)	0.081	0.081	0.081	0.081
Output beam power (average) (megawatts)	0.03	0.38	4.7	4.7
Output beam power (peak) (megawatts)	0.45	5.76	71.2	71.2
Average cavity power loss (megawatts)	0.17	0.45	6.58	7.20
Radio frequency station peak power (megawatts)	2.5	2.5	5.0	–
Number of radio frequency stations (megawatts)	1	9	37	47
Radio frequency power delivered (peak) (megawatts)	2.0	12.9	165.2	180.3
Radio frequency power delivered (average) (megawatts)	0.15	0.95	12.2	13.3
Alternating current power for radio frequency (megawatts)	0.3	2.1	26.5	28.9
Alternating current for linac and high-energy beam transport (megawatts)	–	–	–	34.4
Section length (meters)	7	59	404	470

**Key:** Linac, linear accelerator.

**Source:** TechSource 2000.

energy (using models developed for the Accelerator for Production of Tritium and other high-power linac projects), such an optimization might well lead to a plutonium-238 production system design with significantly improved performance and lower costs. In this connection, it should be noted that a multipurpose higher-power accelerator-driven system, in which the costs of producing the protons are shared between several nuclear missions, would result in much lower capital costs for plutonium-238 production, as well as lower operating costs. Such a system almost certainly would involve an accelerator with a beam current of 30 to 50 milliamperes, using a super conducting high-energy section, and suitable beam-sharing arrangements for the different missions.

## F.2.2 Isotope Production Systems Design

### F.2.2.1 Target Blanket Assembly

The spallation target portion of the reference target blanket assembly would be 28.4 centimeters (11.2 inches) wide by 28.4 centimeters (11.2 inches) high, and 100 centimeters (39.4 inches) long in the beam direction. It would consist of 504 kilograms (1,111 pounds) of depleted uranium packaged in 11 kilograms (24.3 pounds) of aluminum and contain 10 kilograms (22 pounds) of heavy water in its cooling channels. The target would require the removal of 4,360 kilowatts of heat due to fissions and 956 kilowatts due to gamma heating.

The blanket portion of the target blanket assembly would contain 72 kilograms (158.7 pounds) of neptunium-237 packaged in 1 kilogram of aluminum structure and would be cooled with 93 kilograms of light

water. It would occupy a 5-centimeter-thick (2-inch-thick) layer wrapped around the four long sides and the down-beam end of the target. The side layers would extend 30 centimeters (11.8 inches) beyond the uncovered end of the target. The purpose of this extension would be to capture some of the neutrons that would emanate from the beam entrance face of the target. That face would be exposed because placement of feedstock in the proton beam would cause its demise by spallation. The blanket region would require the removal of 361 kilowatts of heat due to fissions and 966 kilowatts due to gamma heating.

Cooling water manifolds 2 centimeters (0.8 inch) thick and containing 25 kilograms of light water would cover the top and bottom surfaces of the target assembly. The total weight of the target assembly would be 716 kilograms (1,578 pounds). The weight of the dry assembly would be 588 kilograms (1,296 pounds).

#### **F.2.2.2 Reflector Assembly**

The reflector would consist of 30-centimeter-thick (11.8-inch-thick) beryllium slabs that would cover all but the beam-entrance face of the target. It would weigh 2.5 metric tons. The outer dimensions of the reflector would be 99 centimeters (39 inches) wide by 103 centimeters (40.6 inches) high, and 165 centimeters (65 inches) long in the beam direction.

#### **F.2.2.3 Vacuum Tank and Internal Shielding**

The target assembly would be positioned near the center of a vacuum tank that would be 6.1 meters (20 feet) in diameter and 5.5 meters (18 feet) high. The target and reflector assemblies would be hung from the bottom of a shield plug that would be 1 meter (3.3 feet) wide, 1.7 meters (5.6 feet) long, and 2.4 meters (7.9 feet) tall. The top of the plug seals, and would be supported by, a penetration in the top lid of the tank. Cooling water and instrumentation lines would be routed from the target reflector assemblies, up through the plug, to the top of the tank.

The purpose of the large tank would be to allow space to install sufficient steel shielding so that the tank would not become activated. This would allow personnel to work on the plug at the top of the tank when the beam is off. It also would make it possible to use elastomers as seals for the plug and tank lid. It would greatly simplify tank removal when the facility is decommissioned.

The shielding within the tank would be 2.4 meters (7.9 feet) thick above and downstream of the target assembly, 2.0 meters (6.6 feet) below and upstream, and 2 meters (6.6 feet) to the sides.

The shielding to the sides of the plug and surrounding the target and reflector assembly would be movable to allow extraction of the plug and the assemblies hung from it.

#### **F.2.2.4 External Shielding**

An additional 3 meters (9.8 feet) of steel shielding, plus 1 meter (3.3 feet) of concrete, are wrapped around and over the tank to permit unlimited personnel access when the beam is on. Access to this region would be required to prepare for target blanket assembly change out and to prepare irradiated target blanket assemblies for disassembly in the hot cells. A portion of the shielding directly above the tank would be mounted on rollers that would allow it to be rolled aside to provide easy access to the plug and its associated piping.

### **F.2.2.5 Beam Transport**

The beam transport system would direct the proton beam from the accelerator onto a straight-ahead beam stop or bend it toward the target. The straight-ahead beam stop would be required for the commissioning and tune-up of the accelerator.

The beam transport system would consist of quadrupole magnets that would maintain the focus of the beam and dipole magnets that would bend the beam. The beam would travel inside a vacuum pipe that would be located within the magnets. Instruments that would diagnose the location of the beam would be positioned at strategic points within the beam transport line. A few very thick plugs would be located within the transport line, but would be held above the beam position. These plugs would be lowered to block passage of the beam as protection to workers in the very unlikely situation that a beam would be directed into the wrong area.

The beam line that would be bent toward the target would contain additional diagnostic and beam-steering components. This equipment would raster the proton beam back and forth across the front face of the target to provide uniform heating of the target. A large-capacity vacuum pumping system would maintain the beam transport line and the target assembly at pressures in the microtor region.

### **F.2.2.6 Target Building**

The building that houses the target would be a massive concrete structure with a 23- by 62-meter (75.5- by 203.6-foot) footprint. The beam stop and the target assembly tank occupy about one-half of the building. The roof height at that location would be 27 meters (23 feet). The beam centerline has a 100-meter (328.4-foot) reference elevation. The roof would be at 121 meters (397.4 feet) and the floor would be at 94 meters (308.7 feet).

The building would be oriented so that the long side would be at right angles to the accelerator. The straight-ahead beam line runs parallel to the short side and would be 6 meters into the building from the end wall. The tune-up beam stop would be located on that line. The target assembly tank would be located 15 meters (49.3 feet) from the short wall (9 meters [29.6 feet] from the beam stop). The beam transport system bends the beam about 30 degrees to enter the tank. The tank rests on 3 meters (9.9 feet) of steel that would be stacked on the floor. Additional steel and concrete shielding surrounds the beam stop and tank. The top of the shielding would be 13 meters (42.7 feet) above the floor (elevation of 107 meters [351.4 feet]).

A remotely operable crane covers the large area of the deck. The crane hook rises 9 meters (29.6 feet) above the deck floor.

Three hot cells with 1-meter-thick (3.3-foot-thick) walls would be lined up in a row down the centerline of the first floor. The space on either side of the row of hot cells forms operating galleys for the remote-handling operations within the cells. The exterior wall of the galley floor would be indented under the operating deck. The indentation forms a truck unloading station. Large hatches over the station allow the crane hook to lift heavy loads from trucks into the operating deck.

The hot cell closest to the tank houses the purification systems for the target assembly and beam stop water systems. The middle cell would be used for demounting the target assembly from its shield plug and for disassembling the irradiated target and packaging it for shipment.

The third cell would be used for general maintenance and repair. It would also be used for preparing a new target for installation, especially if old components were reused.

Hatches in the operating deck provide crane and remote-handling equipment access to several locations below the deck. Access would be provided to each hot cell and to several storage wells located within the massive beam stop and tank shielding. The primary cooling systems, heavy water (deuterium oxide) for the target and light water (hydrogen oxide) for the blanket, would also be located under hatches in pits within the shielding.

The floor, exterior walls, and roof of the operating deck would be at least 1-meter-thick concrete, which would provide both structural strength to the building and shielding from the radiation sources within the room during target transfers. All exterior penetrations for services would be sealed, and all pipes and ducts contain valves, which permit the building to be sealed airtight if necessary in an accident situation.

#### **F.2.2.7 Cooling Systems**

The proton beam passes through thin layers of heavy water used to cool the uranium in the target. The neutrons and other particles that would be created in the uranium also pass through the heavy water and scatter outward and interact with the light water cooling the neptunium in the blanket. Particle interactions with the oxygen atoms of water create every isotope lighter than oxygen, and several that would be heavier. Of all the isotopes created, beryllium-7 would be particularly bad because of its energetic 500-kiloelectron-volt gamma ray and relatively long half-life of 53 days. Calculations show that the proton beam alone creates  $4.4 \times 10^{13}$  beryllium-7 nuclei per second. Minute failures of the cladding would allow uranium and neptunium, and their fission fragments, to enter the cooling water.

This water would be a potential source of radioactive emissions; therefore, an intermediate water-cooling loop would be inserted between the water that cools the target and the water that flows through the air in the cooling towers. The three loops are known as primary, secondary, and tower.

The roles of the three cooling loops are:

- There would be two primary loops, one filled with heavy water to cool the target and the other filled with light water to cool the blanket and reflector. The components used in these loops would be shielded and provided with leak detectors. Ion exchange resin tanks used to remove impurities, including beryllium-7, would be located in shields. These two loops reject their heat to two primary heat exchangers. All the components of these two loops would be located in pits beneath the operating deck and would be designed to be remotely maintained and removed.
- The two primary heat exchangers would be cooled by the secondary cooling loop. All the components of this loop (except the primary heat exchangers) would be in a mechanical equipment room outside the shielded target building.
- The secondary loop heat exchanger would be cooled by water that flows through wet heat exchangers that reject the heat in the water to air.

The heat removal requirements for the two primary cooling systems would be heavy water cooling the target (5.1 megawatts) and light water cooling the blanket and reflector (1.3 megawatts). The heat removal requirement for the secondary and tower cooling systems would be 6.4 megawatts.

### **F.3 REFERENCES**

TechSource (TechSource, Inc.), 2000, *Nuclear Infrastructure PEIS Data Submittal for Accelerators*, Santa Fe, NM, July 24.

## **Appendix G**

### **Methods for Assessing Environmental Impacts**

This appendix briefly describes the methods used to assess the potential direct, indirect, and cumulative effects of the alternatives in this *Final Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS])*. Included are impact assessment methods for land resources, noise, air quality, water resources, geology and soils, ecological resources, cultural and paleontological resources, socioeconomics, waste management, and cumulative impacts. Each section includes a description of the affected resource and the impact assessment method. Impact assessment methods are described separately, as appropriate, for alternatives involving existing facilities and for those involving the new accelerator(s) or a new research reactor at a generic U.S. Department of Energy (DOE) site. Descriptions of the methods for the evaluation of human health effects from normal operations, facility accidents, and transportation, and for environmental justice are presented in Appendixes H, I, J, and K, respectively.

Impact analyses vary for each resource area. For air quality, for example, estimated pollutant emissions from the candidate facilities were compared with appropriate regulatory standards or guidelines. Comparison with regulatory standards is a commonly used method for benchmarking environmental impacts and is done here to provide perspective on the magnitude of identified impacts. For waste management, waste generation ratios were compared with the capacities of waste management facilities. Impacts within each resource area were analyzed consistently; that is, the impact values were estimated using a consistent set of input variables and computations. Moreover, efforts were made to ensure that calculations in all areas used accepted protocols and up-to-date models.

Baseline conditions at the three DOE sites (Oak Ridge Reservation [ORR], Idaho National Engineering and Environment Laboratory [INEEL], and the Hanford Site [Hanford]) assessed in this NI PEIS include present actions at each site. Option 1 of the No Action Alternative was used as the basis for the comparison of impacts that would occur under implementation of the other options and alternatives.

#### **G.1 LAND RESOURCES**

##### **G.1.1 Land Use**

###### **G.1.1.1 Description of Affected Resources**

Land use includes the land on and adjacent to each candidate site, the physical features that influence current or proposed uses, pertinent land use plans and regulations, and land ownership and availability. The region of influence for land use varies due to the extent of land ownership, adjacent land use patterns and trends, and other geographic or safety considerations.

###### **G.1.1.2 Description of Impact Assessment**

The amount of land disturbed and conformity with existing land use were considered in order to evaluate impacts (**Table G-1**). Conformity with existing land use was evaluated for each alternative. However, land disturbance was considered only for those alternatives involving new construction. These alternatives include the Fuels and Materials Examination Facility (FMEF) at Hanford, which requires a new stack, and the new accelerator(s) or a research reactor at a generic DOE site. For the new stack at FMEF, the general location and amount of land to be disturbed is known; thus, impacts to land use may be determined. However, the location of the new accelerator(s) or research reactor is unknown, and the acreage required is only an approximation.

**Table G–1 Impact Assessment Protocol for Land Resources**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Land area used	Site acreage	Facility acreage requirement	Acreage converted to project use
Compatibility with existing or future facility land use	Existing facility land use configurations	Location of facility on the site; expected modifications of facility activities and missions to accommodate the alternatives	Incompatibility with existing or future facility land use
Visual resources	Current Visual Resource Management classification	Location of facility on the site; facility dimensions and appearance	Change in Visual Resource Management classification

Thus, the evaluation of impacts for these new facilities are addressed in general terms. In order to determine the range of potential effects from new facilities, the analysis considered potential impacts from construction and operation at both a disturbed and an undisturbed location at a generic DOE site.

## **G.1.2 Visual Resources**

### **G.1.2.1 Description of Affected Resources**

Visual resources are the natural and human-created features that give a particular landscape its character and aesthetic quality. Landscape character is determined by the visual elements of form, line, color, and texture. All four elements are present in every landscape; however, they exert varying degrees of influence. The stronger the influence exerted by these elements in a landscape, the more interesting the landscape. The region of influence for visual resources includes the geographic area from which the candidate facilities may be seen.

### **G.1.2.2 Description of Impact Assessment**

Impacts to visual resources may be determined by evaluating whether or not the Bureau of Land Management Visual Resource Management classifications of the candidate sites would change as a result of the proposed action (DOI 1986) (Table G–1). Existing classifications were derived from an inventory of scenic qualities, sensitivity levels, and distance zones for particular areas. For those alternatives involving existing facilities at candidate DOE sites, alterations to visual features may be readily evaluated and the impact on the current Visual Resource Management classification determined. For those alternatives involving construction and operation of the new accelerator(s) or research reactor at a generic DOE site, the visual characteristics of the site are unknown. Thus, impacts are addressed in a general manner. In order to determine the range of potential visual effects from new facilities at a generic DOE site, the analysis considered potential impacts from construction and operation at both a disturbed and an undisturbed location at the generic site. Impacts associated with the use of an existing CLWR are also described in a general manner because its location is not known.

## **G.2 NOISE**

### **G.2.1 Description of Affected Resources**

Sound results from the compression and expansion of air or some other medium when an impulse is transmitted through it. Sound requires a source of energy and a medium for transmitting the sound wave. Propagation of sound is affected by various factors, including meteorology, topography, and barriers. Noise

is undesirable sound that interferes or interacts negatively with the human or natural environment. Noise may disrupt normal activities (e.g., hearing, sleep), damage hearing, or diminish the quality of the environment.

Sound-level measurements used to evaluate the effects of nonimpulsive sound on humans are compensated by an A-weighting scale that accounts for the hearing response characteristics (i.e., frequency) of the human ear. Sound levels are expressed in decibels, or in the case of A-weighted measurements, decibels A-weighted. The U.S. Environmental Protection Agency (EPA) has developed noise-level guidelines for different land use classifications. Some states and localities have established noise control regulations or zoning ordinances that specify acceptable noise levels by land use category.

Noise from facility operations and associated traffic could affect human and animal populations. The region of influence for each candidate site includes the site and surrounding area, including transportation corridors, where proposed activities might increase noise levels. Transportation corridors most likely to experience increased noise levels are those roads within a few miles of the site boundary that carry most of the site’s employee and shipping traffic.

Sound-level data representative of site environs were obtained from existing reports. The acoustic environment was further described in terms of existing noise sources for each candidate site. Generic sites are described in terms of existing noise characteristics at existing DOE and nuclear power plant sites.

### G.2.2 Description of Impact Assessment

Noise impacts associated with the alternatives may result from modification (including construction of a new stack at FMEF) and operation of existing facilities, as well as increased traffic (**Table G–2**). Impacts from facility modification and operation were assessed according to the types of noise sources and the locations of the candidate facilities relative to the site boundary. Potential noise impacts from traffic were based on the likely increase in traffic volume. Possible impacts to wildlife were evaluated based on the possibility of sudden loud noises occurring during facility modification and operation.

**Table G–2 Impact Assessment Protocol for Noise**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Noise	Identification of sensitive offsite receptors (e.g., nearby residences); description of sound levels in the vicinity of the site	Description of major construction, modification, and operational noise sources; shipment and workforce traffic estimates	Increase in day/night average sound level at sensitive receptors

Acoustic impacts from facility construction, modification, and operation at generic sites were assessed according to the types of new noise sources and characteristics identified for a generic site. The potential for traffic noise impacts is discussed, but the change in traffic noise levels at a generic site could not be assessed without site-specific data.

## G.3 AIR QUALITY

### G.3.1 Description of Affected Resources

Air pollution refers to the introduction, directly or indirectly, of any substance into the air that could endanger human health and harm living resources and ecosystems, as well as material property and impair or interfere with the comfortable enjoyment of life and other legitimate uses of the environment. For the purpose of this

NI PEIS, only outdoor air pollutants were addressed. They may be in the form of solid particles, liquid droplets, gases, or a combination of these forms. Generally, they can be categorized as primary pollutants (those emitted directly from identifiable sources) and secondary pollutants (those produced in the air by interaction between two or more primary pollutants, or by reaction with normal atmospheric constituents that may be influenced by sunlight). Air pollutants are transported, dispersed, or concentrated by meteorological and topographical conditions. Thus, air quality is affected by air pollutant emission characteristics, meteorology, and topography.

Ambient air quality in a given location can be described by comparing the concentrations of various pollutants in the atmosphere with the appropriate standards. Ambient air quality standards have been established by Federal and state agencies, allowing an adequate margin of safety for the protection of public health and welfare from the adverse effects of pollutants in the ambient air. Pollutant concentrations higher than the corresponding standards are considered unhealthy; those below such standards, acceptable.

The pollutants of concern are primarily those for which Federal and state ambient air quality standards have been established, including criteria air pollutants, hazardous air pollutants, and other toxic air compounds. Criteria air pollutants are those listed in 40 CFR Part 50, "National Primary and Secondary Ambient Air Quality Standards." Hazardous air pollutants and other toxic compounds are those listed in Title I of the Clean Air Act as amended, those regulated by the National Emissions Standards for Hazardous Air Pollutants (NESHAPs), and those that have been proposed or adopted for regulation by the respective state, or are listed in state guidelines. NESHAPs (40 CFR Part 61) is also discussed in Section H.2.1.1. States may set ambient standards that are more stringent than the national ambient air quality standards. The more stringent of the state or Federal standards for each site is shown in this document. Also of concern are air pollutant emissions that may contribute to the depletion of stratospheric ozone or global warming.

Areas with air quality better than the National Ambient Air Quality Standards (NAAQS) for criteria air pollutants are designated as being in attainment, while areas with air quality worse than the NAAQS for such pollutants are designated as nonattainment. Areas may be designated as unclassified when sufficient data for attainment status designation are lacking. Attainment status designations are assigned by county, metropolitan statistical area, consolidated metropolitan statistical area, or portions thereof, or air quality control regions. Air Quality Control Regions designated by EPA are listed in 40 CFR Part 81, "Designation of Areas for Air Quality Planning Purposes." ORR, INEEL, and Hanford are all located in attainment areas (40 CFR Sections 81.313, 81.343, and 81.348).

For locations that are in an attainment area for criteria air pollutants, Prevention of Significant Deterioration regulations limit pollutant emissions from new or modified sources and establish allowable increments of pollutant concentrations. Three Prevention of Significant Deterioration classifications are specified with the criteria established in the Clean Air Act. Class I areas include national wilderness areas, memorial parks larger than 2,020 hectares (5,000 acres), national parks larger than 2,430 hectares (6,000 acres), and areas that have been redesignated as Class I. Class II areas are all areas not designated as Class I. No Class III areas have been designated (42 U.S.C. 7472, Title I, Section 162).

ORR, INEEL, and Hanford are all in Class II areas. In addition, ORR is 48.3 kilometers (30 miles) from the Great Smoky Mountains Class I area, and INEEL is 53 kilometers (33 miles) from the Craters of the Moon Wilderness Area Class I area. There are no Prevention of Significant Deterioration Class I areas within 100 kilometers (62 miles) of Hanford (DOE 1996; DOE 1999a). The recent designation of the Hanford Reach as a national monument may eventually lead to the redesignation of this area, which includes part of Hanford and adjoining areas, as a Prevention of Significant Deterioration Class I area.

The region of influence for air quality encompasses an area surrounding a candidate site that is potentially affected by air pollutant emissions caused by the alternatives. The air quality impact area normally evaluated is the area in which concentrations of criteria pollutants would increase more than a significant amount in a Class II area (i.e., on the basis of averaging period: 1 microgram per cubic meter for annual, 5 micrograms per cubic meter for 24 hours, 500 micrograms per cubic meters for 8 hours, 25 micrograms per cubic meters for 3 hours, and 2,000 micrograms for 1 hour [40 CFR Section 51.165]). Generally, this covers a few kilometers downwind from the source. Further, for sources within 100 kilometers (60 miles) of a Class I area, the air quality impact area evaluated would include the Class I area if the increase in concentration were greater than 1 microgram per cubic meter (24-hour average). The area of the region of influence depends on emission source characteristics, pollutant types, emission rates, and meteorological and topographical conditions. For the purpose of this analysis, where most of the candidate sites are large, impacts were evaluated at the site boundary and roads within the sites to which the public has access, plus any additional area in which contributions to pollutant concentrations are expected to exceed significance levels.

Baseline air quality is typically described in terms of pollutant concentrations modeled for existing sources at each candidate site and background air pollutant concentrations measured near the sites. For this analysis, concentrations for existing sources were obtained from existing source documents such as the *Idaho High-Level Waste and Facilities Disposition Draft Environmental Impact Statement* (DOE 1999c) and *Final Environmental Impact Statement for the Treatment and Management of Sodium-Bonded Spent Nuclear Fuel* (DOE 2000) and from modeling of concentrations using recent emissions inventories and the Industrial Source Complex (ISCST3) model (EPA 1995a, 2000). These concentrations were compared with Federal and state standards or guidelines (**Table G-3**). To determine human health risk, modeling outputs on chemical concentrations in air were weighed against chemical-specific toxicity values.

**Table G-3 Impact Assessment Protocol for Air Quality**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Criteria air pollutants and other regulated pollutants <sup>a</sup>	Measured and modeled ambient concentrations (micrograms per cubic meter) from existing sources at site	Emission (kilograms per year) of air pollutants from facility; source characteristics (e.g., stack height and diameter, exit temperature and velocity)	Concentration of alternative and total site concentration of each pollutant at or beyond site boundary, or within boundary on public road compared to applicable standard
Toxic and hazardous air pollutants <sup>b</sup>	Measured and modeled ambient concentrations (micrograms per cubic meter) from existing sources at site	Emission rate (kilograms per year) of pollutants from facility; source characteristics (e.g., stack height and diameter, exit temperature and velocity)	Concentration of alternative and total site concentration of each pollutant at or beyond site boundary, or within boundary on public road compared to applicable standard

a. Carbon monoxide; hydrogen fluoride; lead; nitrogen oxides; ozone; particulate matter with an aerodynamic diameter less than or equal to 10 microns; particulate matter with an aerodynamic diameter less than 2.5 microns; sulfur dioxide; total suspended particulates.

b. Clean Air Act, Section 112, hazardous air pollutant; pollutants regulated under the National Emissions Standard for Hazardous Air Pollutants; and other state-regulated pollutants.

### G.3.2 Description of Impact Assessment

Potential air quality impacts of pollutant emissions from facility modification and normal operations were evaluated for those alternatives associated with the Fast Flux Test Facility (FFTF) restart and the use of existing facilities. This assessment included a comparison of pollutant concentrations from each alternative with applicable Federal and state ambient air quality standards. If both Federal and state standards exist for

a given pollutant and averaging period, compliance was evaluated using the more stringent standard. Operational air pollutant emissions data for each alternative were based on conservative engineering analyses.

For each alternative, contributions to offsite air pollutant concentrations were modeled on the basis of guidance presented in EPA's "Guidelines on Air Quality Models" (40 CFR Part 51, Appendix W). The EPA-recommended screening model SCREEN3 (EPA 1995b), was selected as an appropriate model to perform the air dispersion modeling because it is designed to support the EPA regulatory modeling program and predicts conservative worst-case impacts. The SCREEN3 model was used to estimate maximum 1-hour concentrations. Appropriate regulatory scaling factors were used to estimate concentrations for other averaging periods based on the maximum 1-hour concentration (3 hours, 0.9; 8 hours, 0.7; 24 hours, 0.4; annual, 0.05) (Brode 1988).

The modeling analysis incorporated conservative assumptions, which tend to overestimate pollutant concentrations. The maximum modeled concentration for each pollutant and averaging time was selected for comparison with the applicable standard. The concentrations evaluated were the maximum occurring at or beyond the site boundary and a public access road, or other publicly accessible area within the site. Available monitoring data, which reflect both onsite and offsite sources, were also taken into consideration. Concentrations of the criteria air pollutants, hazardous air pollutants, and toxic air compounds were presented for each alternative. A set of worst-case meteorological conditions were used in the air quality modeling.

Ozone is typically formed as a secondary pollutant in the ambient air (troposphere). It is formed in the presence of sunlight from the mixing of primary pollutants, such as nitrogen oxides, and volatile organic compounds that emanate from vehicular (mobile), natural, and other stationary sources. Ozone is not emitted directly as a pollutant from the candidate sites. Although ozone may be regarded as a regional issue, specific ozone precursors, notably nitrogen dioxide and volatile organic compounds, were analyzed as applicable to the alternatives under consideration.

The Clean Air Act, as amended, required that Federal actions conform to the host state's "state implementation plan." A state implementation plan provides for the implementation, maintenance, and enforcement of NAAQS for the six criteria pollutants: sulfur dioxide, particulate matter with an aerodynamic diameter less than or equal to 10 microns, carbon monoxide, ozone, nitrogen dioxide, and lead. Its purpose is to eliminate or reduce the severity and number of violations of NAAQS and to expedite the attainment of these standards. No department, agency, or instrumentality of the Federal Government shall engage in or support in any way (i.e., provide financial assistance for, license or permit, or approve) any activity that does not conform to an applicable implementation plan. The final rule for "Determining Conformity of General Federal Actions to State or Federal Implementation Plans" (58 FR 63214) took effect on January 31, 1994. ORR, INEEL, and Hanford are within areas currently designated as attainment for criteria air pollutants. Therefore, the alternatives being considered at these sites are not affected by the provisions of the conformity rule.

Continued operation of a CLWR at an unknown site would result in a small amount of nonradiological air pollutants being released to the atmosphere, mainly due to the requirement of periodical testing of the emergency diesel generators. Air quality impacts associated with a CLWR were addressed as a contribution from the facility operation.

Air quality impacts from the new accelerator(s) or a research reactor are discussed for construction and operation at a generic DOE site. The potential for an increase in nonradiological air emissions is attributed to the supporting facility equipment and construction activities, such as increased employee vehicles, truck traffic, and diesel generator use.

Emissions of potential stratospheric ozone-depleting compounds such as chlorofluorocarbons were not evaluated, as no emissions of these pollutants were identified in the conceptual engineering design reports.

## G.4 WATER RESOURCES

### G.4.1 Description of Affected Resources

Water resources are the surface and subsurface waters that are suitable for human consumption, aquatic or wildlife propagation, agricultural purposes, irrigation or industrial/commercial purposes. The region of influence used for water resources encompasses those surface water and groundwater systems which could be impacted by water withdrawals, effluent discharges, and spills or stormwater runoff associated with construction and operation of the candidate facilities.

### G.4.2 Description of Impact Assessment

#### G.4.2.1 Water Use

This analysis involved the review of engineering estimates of expected water use and effluent discharges associated with each alternative, and the impacts on local water availability and quality, including surface water and groundwater. Impacts on water use were assessed by determining changes in the volume of current water usage and effluent discharges as a result of the proposed activities. The determination of the impacts on water usage and effluent discharge are summarized in **Table G–4**.

**Table G–4 Impact Assessment Protocol for Water Use and Effluent Discharge**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Surface water availability	Surface waters near the facilities, including average flow and current usage	Volume of withdrawals from, and discharges to, surface waters	Changes in availability to downstream users of water for drinking, irrigation, or animal feeding
Groundwater availability	Groundwater near the facilities, including existing water rights for major water users and current usage	Volume of withdrawals from, and discharges to, groundwater	Changes in availability of groundwater for human consumption, irrigation, or animal feeding

If the determination reflected an increase in water use or effluent discharge, then an evaluation of the design capacity of the water and effluent treatment facilities was made to determine whether the design capacity would be exceeded by the additional flow. If the combined flow (i.e., the existing flow plus those from the proposed activities), was less than the design capacity of the water supply systems and effluent treatment plants, then it was assumed that there would be no impact on water availability for local users, nor on the receiving stream from effluent discharges. Because flows from the candidate facilities were generally found not to exceed the design capacity of existing water supply systems or effluent treatment facilities, no additional analyses were performed.

#### G.4.2.2 Water Quality

The water quality impact assessment for this NI PEIS analyzed how effluent discharges to surface water, as well as discharges reaching groundwater, from the candidate facilities would affect current water quality. The determination of the impacts of the alternatives is summarized in **Table G–5** and consisted of a comparison of the projected water quality with relevant regulatory standards such as the Clean Water Act, Safe Drinking

Water Act, state regulations, and existing permit conditions. Separate analyses were conducted for surface water and groundwater impacts.

**Table G-5 Impact Assessment Protocol for Water Quality**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Surface water quality	Surface waters near the facilities in terms of stream classifications and changes in water quality	Expected contaminants and contaminant concentrations in discharges to surface water	Compliance of discharge to surface water with relevant standards of Clean Water Act or with state regulations and existing National Pollutant Discharge Elimination System permits
Groundwater quality	Groundwater near the facilities in terms of classification, presence of designated sole source aquifers, and changes in quality of groundwater	Expected contaminants and contaminant concentrations in discharges that could reach groundwater	Concentrations of contaminants in groundwater exceeding standards established in accordance with Safe Drinking Water Act or state regulations

**Surface Water Quality.** The evaluation of the surface water quality impacts focused on the quality and quantity of the effluent to be discharged and the quality of the receiving stream upstream and downstream from the discharge. The evaluation of effluent quality featured review of the expected parameters, such as the design average and maximum flows, as well as the effluent parameters reflected in the existing or expected National Pollutant Discharge Elimination System (NPDES) permit. Those parameters include total suspended solids, metals, organic and inorganic chemicals, radionuclides, and any other parameters that affect the local environment. Water quality management practices were reviewed to ensure that NPDES permit limitations would be met. Factors that currently degrade water quality were also identified.

**Groundwater Quality.** Potential groundwater quality impacts associated with effluent discharges were examined. Engineering estimates of contaminant concentrations were weighed against Federal and state groundwater quality standards, effluent limitations, and drinking water standards to determine the impacts of each alternative. Also evaluated were the consequences for groundwater use in the area.

The water resources impact assessment for activities involving generic DOE or CLWR sites was generally conducted in the same manner as described above. However, as the exact nature of the sites is not known, it was necessary to make bounding assumptions regarding the range of potential resource conditions that could be present and potentially affected (e.g., surface or groundwater) coupled with using highly conservative estimates of expected impacts (e.g., water withdrawals). This was done to better ensure that the resulting analysis would be applicable to any site and to provide a comparative basis for the impacts assessment.

## **G.5 GEOLOGY AND SOILS**

### **G.5.1 Description of Affected Resources**

Geologic resources include consolidated and unconsolidated earth materials, including mineral assets such as ore and aggregate materials, and fossil fuels such as coal, oil, and natural gas. Geologic conditions include hazards such as earthquakes, faults, volcanoes, landslides, and land subsidence. Soil resources include the loose surface materials of the earth in which plants grow, usually consisting of mineral particles from disintegrating rock, organic matter, and soluble salts. Prime farmland, as defined in 7 CFR Part 657, is land

that contains the best combination of physical and chemical characteristics for producing crops. It includes cropland, pasture land, rangeland, and forest land.

The region of influence for geology and soils includes all areas subject to disturbance by construction and operation or decontamination and decommissioning of the candidate facilities, as applicable, and those areas beneath existing or new facilities that would remain inaccessible for the life of the facilities.

Geology and soil conditions that could affect the integrity and safety of the candidate facilities include large-scale geologic hazards (e.g., earthquakes) and attributes of the soil and bedrock beneath the new facilities. The area within which these conditions exist, and which could impact existing or new facilities, constitute the region of influence for this resource area.

### G.5.2 Description of Impact Assessment

The geology and soils impact analysis (**Table G–6**) considered the risks to the existing and new facilities of large-scale geologic hazards such as faulting and earthquakes, lava extrusions and other volcanic activity, landslides, and sinkholes, (i.e., conditions that tend to affect broad expanses of land). While evidence of impacts in facility-specific areas was developed, as appropriate, there was no attempt to revisit the basic conclusions of the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement (Storage and Disposition PEIS)* (DOE 1996) as reviewed in the *Surplus Plutonium Disposition Final Environmental Impact Statement (Surplus Plutonium Disposition EIS)* (DOE 1999a) for INEEL and Hanford in this regard: that the risks of such hazards to storage and disposition facilities at the candidate sites are acceptable. The findings of those analyses, which focused on the presence of the hazard and the distance of the facilities from it, were accepted as generally applicable to the candidate facilities. Because no major construction is associated with any of the alternatives (which involve only existing facilities), geologic resources and soils (including prime farmland) would not be affected.

**Table G–6 Impact Assessment Protocol for Geology and Soils**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Geologic hazards	Presence of geologic hazards within the region of influence	Location of facility on the site	Potential for damage to facilities
Prime farmland soils	Presence of prime farmland within the region of influence	Location of facility on the site	Loss of prime farmland

The geology and soils impact assessment for activities involving generic DOE or CLWR sites was generally conducted in the same manner as described above. However, as the exact nature of the sites is not known, it was necessary to make bounding assumptions regarding the range of potential geologic and soils conditions that could be present (e.g., subsurface composition, proximity of faults) coupled with using highly conservative estimates of expected impacts (e.g., land disturbance). This was done to better ensure that the resulting analysis would be applicable to any site and to provide a more comparative basis for the impacts assessment. If a DOE or CLWR site were selected, subsequent National Environmental Policy Act (NEPA) actions would be required.

## **G.6 ECOLOGICAL RESOURCES**

### **G.6.1 Description of Affected Resources**

Ecological resources include terrestrial and aquatic resources (plants and animals), wetlands, and threatened and endangered species. The region of influence used for the ecological resource analysis encompassed the area potentially disturbed by construction and operation of the candidate facilities.

Terrestrial resources are defined as those plant and animal species and communities that are most closely associated with the land; for aquatic resources, a water environment. Wetlands are defined by the U.S. Army Corps of Engineers and EPA as “. . . those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas” (33 CFR Section 328.3).

Endangered species are defined under the Endangered Species Act of 1973 as those in danger of extinction throughout all or a large portion of their range. Threatened species are defined as those species likely to become endangered within the foreseeable future. The U.S. Fish and Wildlife Service and the National Marine Fisheries Service propose species to be added to the lists of threatened and endangered species. They also maintain a list of “candidate” species for which they have evidence that listing may be warranted but for which listing is currently precluded by the need to list species more in need of Endangered Species Act protection. Candidate species do not receive legal protection under the Endangered Species Act, but should be considered in project planning in case they are listed in the future. Critical habitat for threatened and endangered species is designated by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service. Critical habitat is defined as specific areas that contain physical and biological features essential to the conservation of species and that may require special management consideration or protection. States may also designate species as endangered, threatened, sensitive protected, in need of management, of concern, monitored, or species of special concern.

### **G.6.2 Description of Impact Assessment**

Impacts to ecological resources may occur as a result of land disturbance, water use, air and water emissions, human activity, and noise associated with project implementation (**Table G-7**). Each of these factors was considered when evaluating potential impacts from the proposed action. All alternatives, except those involving construction and operation of the new accelerator(s) or research reactor, involve only internal facility modification or limited new construction (a new stack for FMEF). Thus, direct impacts to ecological resources from land disturbance and human activity would be minimal. For alternatives involving construction and operation of the new accelerator(s) or research reactor at a generic DOE site, potential impacts to terrestrial resources were determined based on the approximate acreage of land disturbed. Because a specific facility location is not known, the analysis generally considered impacts at both a disturbed and an undisturbed location at a generic DOE site. Impacts to terrestrial and aquatic ecosystems and wetlands from water use and air and water emissions were evaluated based on the results of the analysis conducted for air quality and water resources. Consultations were conducted with the U.S. Fish and Wildlife Service and National Marine Fisheries Service to comply with Section 7 of the Endangered Species Act. Consultations were also conducted with appropriate state agencies (see Table 5-3). The determination of impacts to threatened and endangered species was based on similar factors as noted above for terrestrial resources, wetlands, and aquatic resources.

**Table G–7 Impact Assessment Protocol for Ecological Resources**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Terrestrial resources	Vegetation and wildlife within vicinity of facilities	Facility location, air and water emissions, and noise	Loss or disturbance to terrestrial habitat; emissions and noise values above levels shown to cause impacts to terrestrial resources
Aquatic resources	Aquatic resources within vicinity of facilities	Facility air and water emissions, water source and quantity, and wastewater discharge location and quantity	Discharges above levels shown to cause impacts to aquatic resources; changes in water withdrawals and discharges
Wetlands	Wetlands within vicinity of facilities	Facility location, air and water emissions, and wastewater discharge quantity and location	Loss or disturbance to wetlands; discharge to wetlands
Threatened and endangered species	Threatened and endangered species within vicinity of facilities	Facility location, air and water emissions, noise, water source and quantity, and wastewater discharge location and quantity	Measures similar to those noted above for terrestrial and aquatic resources

## G.7 CULTURAL AND PALEONTOLOGICAL RESOURCES

### G.7.1 Description of Affected Resources

Cultural resources are the indications of human occupation and use of the landscape as defined and protected by a series of Federal laws, regulations, and guidelines. For this NI PEIS, potential impacts were assessed separately for each of the three general categories of cultural resources: prehistoric, historic, and Native American. Paleontological resources are the physical remains, impressions, or traces of plants or animals from a former geological age, and may be sources of information on paleoenvironments and the evolutionary development of plants and animals. Although not governed by the same historic preservation laws as cultural resources, they could be affected by the proposed action in much the same manner.

Prehistoric resources are physical remains of human activities that predate written records; they generally consist of artifacts that may alone or collectively yield otherwise inaccessible information about the past. Historic resources consist of physical remains that postdate the emergence of written records; in the United States, they are architectural structures or districts, archaeological objects, and archaeological features dating from 1492 and later. Ordinarily, sites less than 50 years old are not considered historic, but exceptions can be made for such properties if they are of particular importance, such as structures associated with Cold War themes. Native American resources are sites, areas, and materials important to Native Americans for religious or heritage reasons. Such resources may include geographical features, plants, animals, cemeteries, battlefields, trails, and environmental features. The region of influence for the cultural and paleontological resource analysis encompassed the area potentially disturbed by construction and operation of the candidate facilities.

### G.7.2 Description of Impact Assessment

The analysis of impacts to cultural and paleontological resources addressed potential direct and indirect impacts at each candidate site, including an unspecified CLWR site and a generic DOE site (**Table G-8**).

**Table G-8 Impact Assessment Protocol for Cultural and Paleontological**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Prehistoric resources	Prehistoric resources within the vicinity of facilities	Location of facility on the site	Potential for loss, isolation, or alteration of the character of prehistoric resources; introduction of visual, audible, or atmospheric elements out of character; neglect of resources listed or eligible for listing on the National Register of Historic Places
Historic resources	Historic resources within the vicinity of facilities	Location of facility on the site	Potential for loss, isolation, or alteration of the character of historic resources; introduction of visual, audible, or atmospheric elements out of character; neglect of resources listed or eligible for listing on the National Register of Historic Places
Native American resources	Native American resources within the vicinity of facilities	Location of facility on the site	Potential for loss, isolation, or alteration of the character of Native American resources; introduction of visual, audible or atmospheric elements out of character
Paleontological resources	Paleontological resources within the vicinity of facilities	Location of facility on the site	Potential for loss, isolation or alteration of paleontological resources

Potential indirect impacts include those associated with reduced access to a resource site, as well as impacts associated with increased traffic and visitation to sensitive areas. Direct impacts include those resulting from groundbreaking activities associated with new construction. Direct impacts would be associated with construction of the new accelerator(s) or research reactor at a generic DOE site. Because the specific location is unknown, however, impacts from new construction were addressed in a general manner. In order to determine the range of potential impacts, the analysis considered potential effects at both a disturbed and an undisturbed location at a generic DOE site. Impacts associated with the use of an existing CLWR at an unknown location were also addressed in a general manner. Consultations to comply with Section 106 of the National Historic Preservation Act were conducted with the various State Historic Preservation Officers. Consultations were also conducted with interested Native American tribes (see Table 5-3).

## **G.8 SOCIOECONOMICS**

### **G.8.1 Description of Affected Resources**

Socioeconomic impacts are defined in terms of changes to the demographic and economic characteristics of a region. The number of jobs created by the proposed action would affect regional employment, income, and expenditures. Job creation is characterized by two types: (1) construction-related jobs, transient in nature and short in duration, and thus less likely to impact public services; and (2) jobs related to plant operations, required for a decade or more, and thus possibly creating additional service requirements in the region of influence.

The socioeconomic environment is made up of two geographic regions, the regional economic area and region of influence. Regional economic areas are made up of regional economies and include descriptions of industrial and service sector characteristics and their linkages to the communities within a region. These linkages determine the nature and magnitude of any effect associated with a change in regional economic activity. For example, as work expands within a region, the money spent on accomplishing this work flows into the local economy; it is spent on additional jobs, goods, and services within the regional economic area.

Similarly, potential demographic impacts were assessed for the region of influence. The region of influence could represent a smaller geographic area, one in which only the housing market and local community services would be significantly affected by a given alternative. Site-specific regions of influence were identified as those counties in which approximately 90 percent or more of the site's workforce reside. This distribution reflects an existing residential preference for people currently employed at the sites and was used to estimate the distribution of new workers supporting the alternatives.

### **G.8.2 Description of Impact Assessment**

For each regional economic area, data were compiled on the current socioeconomic conditions, including unemployment rates, economic industrial and service sector activities, and the civilian labor force. The workforce and cost requirements of each alternative were determined in order to measure their possible effect on these socioeconomic conditions. Although workforce requirements may be able to be filled by employees already working at DOE sites, it was assumed these requirements would be filled by new employees to ensure that the maximum impact was assessed. For each region of influence, census statistics were also compiled on population, housing demand, and community services. U.S. Bureau of the Census population forecasts for the regions of influence were combined with overall projected workforce requirements for each of the alternatives being considered at each candidate site to determine the extent of impacts on housing demand and levels of community services (**Table G-9**).

For those alternatives involving construction and operation of the new accelerator(s) or research reactor at a generic DOE site, the socioeconomic characteristics of the site are unknown. Impacts cannot be measured until candidate sites are identified. Therefore, if one of these alternatives were selected, additional NEPA documentation would be required, which would address the socioeconomic impacts.

Impacts associated with the use of an existing CLWR were addressed in a general manner as the location is unknown.

**Table G-9 Impact Assessment Protocol for Socioeconomics**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
<b>Regional Economic Characteristics</b>			
Workforce requirements	Site workforce projections from DOE sites	Estimated construction and operating staff requirements and timeframes	Workforce requirements added to sites' workforce projections
Regional economic area civilian labor force	Labor force projections based on state population projections	Estimated construction and operating staff requirements and timeframes	Workforce requirements as a percentage of the civilian labor force
Unemployment rate	1996 unemployment rates in counties surrounding sites and in host states	Estimated construction and operating staff requirements	Projected change in unemployment rates
<b>Population and Housing</b>			
Population	Latest available population projection estimates from the U.S. Bureau of the Census	Estimated contribution to projected population	Projected change in population projection
Housing—Percent of occupied housing units	Latest available rates from the U.S. Bureau of the Census	Assess potential need for new housing units to meet workforce requirements	Projected change in workforce
<b>Community Services</b>			
Education Percent operating capacity for school districts in the region of influence	Latest available rates from the U.S. Bureau of the Census	Assess potential need for new schools	Projected change in student population
Teacher-to-student ratio	Latest available rates from the U.S. Bureau of the Census	Assess potential need for additional teachers	Projected change to maintain current teacher-to-student ratio
Public safety—Ratio of police and firefighters to 100,000 residents	Latest available rates from the U.S. Bureau of the Census	Assess potential need for additional officers and firefighters	Projected change to maintain the current police officer/firefighter to population ratio
Health care—Number of hospital beds and physicians per 100,000 residents	Latest available rates from the U.S. Bureau of the Census	Assess potential need for additional hospitals and physicians	Projected change in the availability of hospital beds/physicians to population ratio

## G.9 WASTE MANAGEMENT

### G.9.1 Description of Affected Resources

Depending on the alternative, construction and operation of the candidate facilities, as well as the permanent deactivation of FFTF and decontamination and decommissioning of the new accelerator(s), research reactor, and support facility, would generate several types of waste. Such wastes may include the following:

- **High-level radioactive:** The highly radioactive waste resulting from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing and any solid material derived from the liquid waste that contains fission products in sufficient concentrations; and other highly radioactive material that is determined, consistent with existing law, to require permanent isolation.

- **Transuranic:** Waste containing more than 100 nanocuries per gram of alpha-emitting transuranic isotopes, with half-lives greater than 20 years, except for (1) high-level radioactive waste; (2) waste that DOE has determined, with the concurrence of EPA, does not need the degree of isolation required by 40 CFR Part 191; and (3) waste that the U.S. Nuclear Regulatory Commission has approved for disposal, case-by-case in accordance with 10 CFR Part 61. Contact-handled transuranic waste is packaged transuranic waste whose external surface dose rate does not exceed 200 millirem per hour. Remote-handled transuranic waste is packaged transuranic waste whose external surface dose rate exceeds 200 millirem per hour. Mixed transuranic waste contains hazardous components regulated under the Resource Conservation and Recovery Act (RCRA).
- **Low-level radioactive:** Waste that contains radioactivity and is not classified as high-level radioactive waste, transuranic waste, or spent nuclear fuel, or the tailings or wastes produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level radioactive waste, provided the transuranic concentration is less than 100 nanocuries per gram of waste.
- **Mixed low-level radioactive:** Low-level radioactive waste that also contains hazardous components regulated under RCRA.
- **Hazardous:** Under RCRA, a waste that, because of its characteristics, may (1) cause or significantly contribute to an increase in mortality or an increase in serious irreversible, or incapacitating reversible illness, or (2) pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed. Hazardous wastes appear on special EPA lists or possess at least one of the following characteristics: ignitability, corrosivity, reactivity, or toxicity. This category does not include source, special nuclear, or byproduct material as defined by the Atomic Energy Act.
- **Nonhazardous:** Discarded material including solid, liquid, semisolid, or contained gaseous material resulting from industrial, commercial, mining, and agricultural operations, and from community activities. This category does not include source, special nuclear, or byproduct material as defined by the Atomic Energy Act.

The alternatives could have an impact on existing site facilities devoted to the treatment, storage, and disposal of these categories of waste. Waste management activities in support of the proposed action would be contingent on Records of Decision issued for the *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste (Waste Management PEIS)* (DOE 1997). The high-level radioactive waste Record of Decision, issued on August 12, 1999 (64 FR 46661), states that immobilized high-level radioactive waste will be stored at the site of generation until transfer to a geologic repository. The Record of Decision for transuranic waste, issued on January 20, 1998 (63 FR 3629), states that transuranic and transuranic mixed waste would be certified on site and shipped to a suitable geologic repository. According to the Record of Decision for hazardous waste, released on August 5, 1998 (63 FR 41810), DOE sites evaluated in this NI PEIS will continue to use offsite facilities for the treatment and disposal of major portions of their nonwastewater hazardous waste, with ORR continuing to treat some of its nonwastewater hazardous waste in existing facilities where economically feasible. Based on the Record of Decision for low-level radioactive waste and mixed low-level radioactive waste issued on February 18, 2000 (65 FR 10061), minimal treatment of low-level radioactive waste will be performed at all sites, and to the extent practical, onsite disposal of low-level radioactive waste will continue. Hanford and the Nevada Test Site will be made available to all DOE sites for the disposal of low-level radioactive waste. Mixed low-level radioactive waste analyzed in the *Waste Management PEIS* (DOE 1997)

will be treated at Hanford, INEEL, ORR, and the Savannah River Site and will be disposed of at Hanford and the Nevada Test Site.

### G.9.2 Description of Impact Assessment

As shown in **Table G–10**, impacts were assessed by comparing the projected waste stream volumes generated from the proposed activities at each candidate site with that site’s waste management capacities and generation rates. Only the impacts relative to the capacities of waste management facilities were considered; other environmental impacts of waste management facility operations (e.g., human health effects) are evaluated in other sections of this NI PEIS, or in other facility-specific or sitewide NEPA documents. Projected waste generation rates for the proposed activities were compared with site processing rates and capacities of those treatment, storage, and disposal facilities likely to be involved in managing the additional waste. The waste generation rates were provided by the sites’ technical personnel.

**Table G–10 Impact Assessment Protocol for Waste Management**

Resource	Required Data		Measure of Impact
	Affected Environment	Alternative	
Waste management capacity High-level radioactive waste Transuranic waste Low-level radioactive waste Mixed low-level radioactive waste Hazardous waste Nonhazardous waste	Site generation rates (cubic meters per year) for each waste type  Site management capacities (cubic meters) or rates (cubic meters per year) for potentially affected treatment, storage, and disposal facilities for each waste type	Generation rates (cubic meters per year) from facility operations for each waste type	Combination of facility waste generation volumes and other site generation volumes in comparison to the capacities of applicable waste management facilities

For the generic DOE site or CLWR site, projected waste stream volumes could not be compared to site waste management capacities and generation rates because a specific location was not identified.

### G.10 CUMULATIVE IMPACTS

Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR Section 1508.7). The cumulative impact analysis for this NI PEIS involved combining the impacts of the alternatives (including No Action) with the impacts of other present and reasonably foreseeable activities in the region of influence. The regions of influence for different resources can vary widely in extent. For example, the regions of influence for waste management would generally be confined to the areal extent of each site, whereas the region of influence for human health would include the areas extending out to 80 kilometers (50 miles) from each site.

In general, cumulative impacts were calculated by adding the values for the baseline affected environment (i.e., conditions attributable to present actions by DOE and other public and private entities), the proposed action (or no action), and other future actions. This cumulative value was then weighed against the appropriate impact indicators (e.g., standards or number of fatalities) to determine the potential for impact. For this cumulative impact assessment, it was conservatively assumed that all facilities would operate concurrently at the candidate DOE sites. The selected indicators of cumulative impacts evaluated in this NI PEIS are shown in **Table G–11**.

**Table G–11 Selected Indicators of Cumulative Impact**

Category	Indicator
Resource use	Electricity use compared with site capacity Water use compared with site capacity Workers required compared with existing workforce
Air quality	Criteria pollutant concentrations and comparisons with standards or guidelines
Human health	Public Offsite population dose Maximally exposed individual dose Fatalities Comparison with DOE dose limits Workers Total dose Average worker dose Fatalities Comparison with DOE dose limits
Waste	Transuranic waste/high-level radioactive waste generation rate compared with existing management capacities and generation rate Low-level radioactive generation rate compared with existing management capacities and generation rate Mixed low-level radioactive generation rate compared with existing management capacities and generation rate Hazardous waste generation rate compared with existing management capacities and generation rate Nonhazardous generation rate compared with existing management capacities and generation rate
Spent nuclear fuel	Spent nuclear fuel generation rate and storage capacity
Transportation	Radiation exposures Public Transportation workers Fatalities Traffic fatalities

Public documents prepared by agencies of Federal, state, and local governments were the primary sources of information for non-DOE actions.

The analysis focused on the potential for cumulative impacts at each candidate site from DOE actions under detailed consideration at the time of this NI PEIS, as well as cumulative impacts associated with transportation between the sites, between Savannah River Site and other sites, and between the processing sites and Los Alamos National Laboratory (**Table G–12**). Non-DOE actions were also considered where information was readily available.

It is assumed that construction impacts would not be cumulative because construction is typically short in duration, and construction impacts are generally temporary. Further, except for a stack required for FMEF, construction is limited to internal modifications to existing DOE facilities. Decontamination and decommissioning of the candidate facilities was not addressed in the cumulative impact estimates. Given the uncertainty regarding the timing of decontamination and decommissioning, any impact estimate at this time would be highly speculative. A detailed evaluation of decontamination and decommissioning would be provided in follow-on NEPA documentation closer to the actual time of those actions.

**Table G–12 Other Present and Reasonably Foreseeable Actions  
Considered in the Cumulative Impact Assessment**

Activities	ORR	INEEL	Hanford
Disposition of Surplus Plutonium	X

## Evaluation of Human Health Effects from Normal Facility Operations

### H.1 INTRODUCTION

This appendix presents detailed information on the methodology employed for calculating potential impacts and risks to humans associated with releases of radioactivity and hazardous chemicals from the proposed facilities during normal operations and certain accident scenarios. This information is intended to support the public and occupational health and safety assessments described in Chapter 4 of this *Final Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS])*. Section H.2.1 provides general background information on ionizing radiation and associated health effects, Section H.2.2 discusses the methodology used in the assessment of normal radiological impacts, and Section H.2.3 provides a brief overview of data used in the radiological assessments. Hazardous chemical impacts are presented in Section H.3. Further detailed information regarding potential radiological impacts resulting from facility accidents is discussed in Appendix I of this NI PEIS.

This appendix presents numerical information using engineering and/or scientific notation. For example, the number 100,000 can also be expressed as  $1 \times 10^5$ . The fraction 0.00001 can also be expressed as  $1 \times 10^{-5}$ . The following chart defines the equivalent numerical notations that may be used in this appendix.

<b>Fractions and Multiples of Units</b>			
Multiple	Decimal Equivalent	Prefix	Symbol
$1 \times 10^6$	1,000,000	mega-	M
$1 \times 10^3$	1,000	kilo-	k
$1 \times 10^2$	100	hecto-	h
$1 \times 10$	10	deka-	da
$1 \times 10^{-1}$	0.1	deci-	d
$1 \times 10^{-2}$	0.01	centi-	c
$1 \times 10^{-3}$	0.001	milli-	m
$1 \times 10^{-6}$	0.000001	micro-	$\mu$
$1 \times 10^{-9}$	0.000000001	nano-	n
$1 \times 10^{-12}$	0.000000000001	pico-	p
$1 \times 10^{-15}$	0.000000000000001	femto-	f
$1 \times 10^{-18}$	0.000000000000000001	atto-	a

### H.2 RADIOLOGICAL IMPACTS ON HUMAN HEALTH

#### H.2.1 Background Information

##### H.2.1.1 Nature of Ionizing Radiation and Its Effects on Humans

**What Is Ionizing Radiation?** Ionizing radiation (hereafter referred to as “radiation”) is energy transferred in the form of particles or waves. Humans are exposed constantly to cosmic radiation and radiation from the earth’s rocks and soil. (The term “radiation” encompasses several phenomena, including light, heat waves,

microwaves, radio waves, and ionizing radiation. The discussion of radiation in this section addresses ionizing radiation, and the term “radiation” is used to mean ionizing radiation.) This radiation contributes to the natural background radiation that has always surrounded us. Manmade sources of radiation also exist, including medical and dental x-rays, household smoke detectors, and materials released from nuclear and coal-fired power plants.

Radiation comes from the activity of atoms, which form the substance of all matter in the universe. Atoms are composed of even smaller particles (protons, neutrons, electrons), whose number and arrangement distinguish atoms of one element from another. Elements consist of atoms having the same number of protons. Atoms of the same element with varying numbers of neutrons are known as isotopes of that element. There are more than 100 natural and manmade elements. Some of these isotopes (including isotopes of elements, such as uranium, radium, plutonium, and thorium) share a very important quality: they are unstable (i.e., they decay). As they change into more stable forms, invisible waves of energy or particles, known as ionizing radiation, are released. Radioactivity is the emitting of this radiation.

Ionizing radiation refers to the fact that this energy emitted from unstable atoms can ionize, or electrically charge, atoms by stripping off electrons, leaving them with a positive charge. Ionizing radiation can cause a change in the chemical composition of many materials, including living tissue (organs), which can affect the way they function.

- Alpha particles are one type of ionizing radiation and the heaviest of the types discussed here; despite a speed of approximately 16,000 kilometers per second (9,940 miles per second), they can travel only several centimeters in air. Alpha particles lose their energy almost as soon as they collide with anything. They can be stopped easily by a sheet of paper or by the skin’s surface.

Radiation Type	Typical Speed (km/sec)	Typical Travel Distance in Air (meters)	Barrier
Alpha	16,000	Less than 1	Sheet of paper or skin’s surface
Beta	160,000	3	Thin sheet of aluminum foil or glass
Gamma	300,000	Very large <sup>a</sup>	Thick wall of concrete, lead, or steel
Neutron	39,000	Very large	Water, paraffin, graphite

a. Would be infinite in a vacuum.

- Beta particles are much lighter than alpha particles. They can travel at a speed of up to 160,000 kilometers per second (99,400 miles per second) and can travel in the air for a distance of approximately 3 meters (9.8 feet). Beta particles can pass through a sheet of paper but may be stopped by a thin sheet of aluminum foil or glass.
- Gamma rays and x-rays, unlike alpha or beta particles, are waves of pure energy. Gamma rays travel at the speed of light (300,000 kilometers per second [186,000 miles per second]). Gamma radiation is very penetrating and requires a thick wall of concrete, lead, or steel to stop it.
- The neutron is another particle that contributes to radiation exposure, both directly and indirectly. The latter is associated with the gamma rays and alpha particles that are emitted following neutron capture in matter. A neutron has about one quarter the weight of an alpha particle and can travel at speeds of up to 39,000 kilometers per second (24,200 miles per second). Neutrons are more penetrating than beta particles but typically less penetrating than gamma rays.

The effects on people of radiation emitted during the disintegration (decay) of a radioactive substance depend on the type of radiation (alpha and beta particles and gamma and x-rays) and the total amount of radiation energy absorbed by the body. The total energy absorbed per unit quantity of tissue is referred to as absorbed dose. The absorbed dose, when multiplied by certain quality factors and factors that take into account different sensitivities of various tissues, is referred to as effective dose equivalent or, where the context is clear, simply dose. The common unit of effective dose equivalent is the roentgen equivalent man (rem); 1 rem equals 1,000 millirem.

The radioactivity of a material decreases with time. The time it takes a material to lose half of its original radioactivity is designated its half-life. For example, a quantity of iodine-131, a material that has a half-life of eight days, will lose one-half of its radioactivity in that amount of time. In eight more days, one-half of the remaining radioactivity will be lost, and so on. Eventually, the radioactivity will essentially disappear. Each radioactive element has a characteristic half-life. The half-lives of various radioactive elements may vary from millionths of a second to millions of years.

When a radioactive element emits a particle or gamma-ray, it often changes to an entirely different element, one that may or may not be radioactive. Eventually, a stable element is formed. This transformation, which may take several steps, is known as a decay chain. Radium, for example, is a naturally occurring radioactive element with a half-life of 1,622 years. It emits an alpha particle and becomes radon, a radioactive gas with a half-life of only 3.8 days. Radon decays first to polonium, then through a series of steps to bismuth, and ultimately to lead.

**Units of Radiation Measure.** Scientists and engineers use a variety of units to measure radiation. These different units can be used to determine the amount, type, and intensity of radiation. Just as heat can be measured in terms of its intensity or effects using units of calories or degrees, amounts of radiation can be measured in curies, radiation absorbed dose (rad), or rem.

- **Curie.** The curie, named after the French scientists Marie and Pierre Curie, describes the “intensity” of a sample of radioactive material. The rate of decay of 1 gram of radium is the basis of this unit of measure. It is equal to  $3.7 \times 10^{10}$  disintegrations (decays) per second.
- **Rad.** The total energy absorbed per unit quantity of tissue is referred to as absorbed dose. The rad is the unit of measurement for the physical absorption of radiation. As sunlight heats pavement by giving up an amount of energy to it, radiation gives up rads of energy to objects in its path. One rad is equal to the amount of radiation that leads to the deposition of 0.01 joule of energy per kilogram of absorbing material.
- **Rem.** A rem is a measurement of the dose from radiation based on its biological effects. The rem is used in measuring the effects of radiation on the body. Thus, 1 rem of one type of radiation is presumed to have the same biological effects as 1 rem of any other kind of radiation. This allows comparison of the biological effects of radionuclides that emit different types of radiation.

**Radiation Units and Conversions**

1 Ci =  $3.7 \times 10^{10}$  sec<sup>-1</sup> =  $3.7 \times 10^{10}$  becquerel  
 1 rad = 100 erg/g = 0.01 gray  
 1 erg =  $10^{-7}$  joule  
 1 gray = 1 joule/kg = 100 rad  
 1 rem = 0.01 sievert

An individual may be exposed to ionizing radiation externally (from a radioactive source outside the body) or internally (from ingesting or inhaling radioactive material). The external dose is different from the internal dose because an external dose is delivered only during the actual time of exposure to the external radiation

source, but an internal dose continues to be delivered as long as the radioactive source is in the body. For the analyses conducted in this NI PEIS, the dose from internal exposure is calculated over 50 years following the initial exposure; both radioactive decay and elimination of the radionuclide by ordinary metabolic processes decrease the dose rate with the passage of time.

The three types of doses calculated in this NI PEIS are external dose, internal dose, and combined external and internal dose. Each type of dose is discussed separately in the following paragraphs.

- **External dose.** The external dose can result from several different pathways, all having in common the fact that the radiation causing the exposure is external to the body. In this NI PEIS, these pathways include exposure to a cloud of radiation passing over the receptor or standing on ground that is contaminated with radioactivity. The appropriate measure of dose is called the effective dose equivalent. If the receptor departs from the source of radiation exposure, the dose rate will be reduced. It is assumed that external exposure occurs uniformly during the year.
- **Internal dose.** The internal dose results from a radiation source entering the human body via any means, such as through ingestion of contaminated food or water or inhalation of contaminated air. In this NI PEIS, pathways for internal exposure include: (1) ingestion of crops contaminated by airborne radiation deposits, (2) ingestion of animal products from animals that ingested contaminated food, and (3) inhalation of contaminated air. In contrast to external exposure, once radioactive material enters the body, it remains there for a period of time that depends on the rate of radiological decay and biological elimination rates. The unit of measure for internal doses is the committed dose equivalent. It is the internal dose that each body organ receives from the ingestion and inhalation of radioactive material. In this analysis of health impacts from normal operations, the committed dose equivalent is calculated for an annual intake period. Normally, a 50-year dose-commitment period is used (i.e., the 1-year intake period plus 49 years). The dose rate increases during the 1-year intake. The dose rate after the first year intake declines slowly as the radioactivity in the body continues to produce a dose. The integral of the dose rate over the 50 years gives the committed dose equivalent.

The various organs of the body have different susceptibilities to harm from radiation. The quantity that takes these different susceptibilities into account to provide a broad indicator of the risk to the health of an individual from radiation is called the committed effective dose equivalent. It is obtained by multiplying the committed dose equivalent in each major organ or tissue by a weighting factor associated with the risk susceptibility of the tissue or organ, then summing the totals. It is possible for the committed dose equivalent to an organ to be larger than the committed effective dose equivalent if that organ has a small weighting factor. The concept of committed effective dose equivalent applies only to internal pathways.

- **Combined external and internal dose.** The sum of the committed effective dose equivalent from internal pathways and the effective dose equivalent from external pathways is called the “total effective dose equivalent.” The U.S. Department of Energy (DOE), in DOE Order 5400.5, calls this quantity the “effective dose equivalent.”

The units used in this NI PEIS for committed dose equivalent, effective dose equivalent, and committed effective dose equivalent to an individual are the rem and millirem (1/1000 of 1 rem). The corresponding unit for the collective dose to a population (the sum of the doses to members of the population, or the product of the number of exposed individuals and their average dose) is the person-rem.

**Sources of Background Radiation.** The average American receives a total of approximately 360 millirem per year from all sources of radiation, both natural and manmade. The sources of radiation can be divided into six different categories: (1) cosmic radiation, (2) external terrestrial radiation, (3) internal radiation,

(4) consumer products, (5) medical diagnosis and therapy, and (6) other sources (NCRP 1987). These categories are discussed in the following paragraphs:

- **Cosmic radiation.** Cosmic radiation is ionizing radiation resulting from energetic charged particles from space continuously hitting the earth's atmosphere. These particles, and the secondary particles and photons they create, are cosmic radiation. Because the atmosphere provides some shielding against cosmic radiation, the intensity of this radiation increases with altitude above sea level. The average dose to the people in the United States from this source is approximately 27 millirem per year.
- **External terrestrial radiation.** External terrestrial radiation is the radiation emitted from the radioactive materials in the earth's rocks and soils. The average dose from external terrestrial radiation is approximately 28 millirem per year.
- **Internal radiation.** Internal radiation results from the human body metabolizing natural radioactive material that has entered the body by inhalation or ingestion. Natural radionuclides in the body include isotopes of uranium, thorium, radium, radon, polonium, bismuth, potassium, rubidium, and carbon. The major contributor to the annual dose equivalent for internal radioactivity are the short-lived decay products of radon, which contribute approximately 200 millirem per year. The average dose from other internal radionuclides is approximately 39 millirem per year.
- **Consumer products.** Consumer products also contain sources of ionizing radiation. In some products such as smoke detectors and airport x-ray machines, the radiation source is essential to product operation. In other products, such as televisions and tobacco, the radiation occurs incidentally to the product function. The average dose from consumer products is approximately 10 millirem per year.
- **Medical diagnosis and therapy.** Radiation is an important diagnostic medical tool and cancer treatment. Diagnostic x-rays result in an average exposure of 39 millirem per year. Nuclear medical procedures result in an average exposure of 14 millirem per year.
- **Other sources.** There are a few additional sources of radiation that contribute minor doses to individuals in the United States. The dose from nuclear fuel-cycle facilities (e.g., uranium mines, mills, and fuel processing plants), nuclear power plants, and transportation routes has been estimated to be less than 1 millirem per year. Radioactive fallout from atmospheric atomic bomb tests, emissions of radioactive material from DOE facilities and facilities licensed by the U.S. Nuclear Regulatory Commission (NRC), emissions from certain mineral extraction facilities, and transportation of radioactive materials contribute less than 1 millirem per year to the average dose to an individual. Air travel contributes approximately 1 millirem per year to the average dose.

The collective (or population) dose to an exposed population is calculated by summing the estimated doses received by each member of the exposed population. This total dose received by the exposed population is measured in person-rem. For example, if 1,000 people each receive a dose of 1 millirem (0.001 rem), the collective dose is 1,000 persons  $\times$  0.001 rem = 1.0 person-rem. Alternatively, the same collective dose (1.0 person-rem) results if 500 people each receive a dose of 2 millirem (500 persons  $\times$  2 millirem = 1 person-rem).

**Limits of Radiation Exposure.** The amount of manmade radiation that the public may be exposed to is limited by Federal regulations. Although most scientists believe that radiation absorbed in small doses over several years is not harmful, U.S. Government regulations assume that the effects of all radiation exposures are cumulative.

Under the Clean Air Act, releases of materials to the atmosphere from DOE facilities are limited by the U.S. Environmental Protection Agency (EPA) to quantities that would produce a dose of less than 10 millirem per year to a member of the general public (40 CFR Part 61). DOE also limits to 10 millirem the dose annually received from material released to the atmosphere (DOE Order 5400.5). EPA and DOE also limit the annual dose to a member of the general public from radioactive releases in drinking water to 4 millirem, as required under the Safe Drinking Water Act (40 CFR Part 141, DOE Order 5400.5). The annual dose from all radiation sources from a nuclear-fuel-cycle facility site is limited by EPA to 25 millirem (40 CFR Part 190). The DOE annual limit of radiation dose from all pathways to a member of the general public is 100 millirem (DOE Order 5400.5).

Each of the three sites covered by this NI PEIS operates below all of these limits. The average individual in the United States receives a dose of approximately 0.3 rem (300 millirem) per year from natural sources of radiation. For perspective, a modern chest x-ray results in an approximate dose of 0.006 rem (6 millirem) and a diagnostic pelvis and hip x-ray results in an approximate dose of 0.065 rem (65 millirem) (NCRP 1987). An acute dose (i.e., a dose over a short period of time) of about 450 rem (450,000 millirem) would result in a 50 percent chance of death.

For people working in an occupation that involves radiation, NRC and DOE limit doses to 5 rem per year (5,000 millirem per year) (10 CFR Part 20, 10 CFR Part 835). The Administrative Control Level of 2 rem (2,000 millirem) per year is typically imposed at DOE sites to comply with “as low as is reasonably achievable” initiatives (10 CFR Part 835).

### **H.2.1.2 Health Effects**

Radiation exposure and its consequences are topics of interest to the general public. For this reason, this NI PEIS places much emphasis on the consequences of exposure to radiation, even though the effects of radiation exposure under most circumstances evaluated in this NI PEIS are small. To provide the background for discussions of impacts, this section explains the basic concepts used in the evaluation of radiation effects.

Radiation can cause a variety of adverse health effects in people. The most significant adverse health effect that depicts the consequences of environmental and occupational radiation exposure is induction of cancer fatalities. This effect is referred to as “latent” cancer fatalities because the cancer may take many years to develop. In the discussions that follow, all fatal cancers are considered latent, and therefore the term “latent” is not used.

Health impacts from radiation exposure, whether from sources external or internal to the body, generally are identified as “somatic” (affecting the individual exposed) or “genetic” (affecting descendants of the exposed individual). Radiation is more likely to produce somatic effects than to produce genetic effects. For this NI PEIS, therefore, only the somatic risks are presented. The somatic risks of most importance are the induction of cancers. With the exception of leukemia, which can have an induction period (time between exposure to carcinogen and cancer diagnosis) of as little as 2 to 7 years, most cancers have an induction period of more than 20 years.

For a uniform irradiation of the body, the incidence of cancer varies among organs and tissues; the thyroid and skin demonstrate a greater sensitivity than other organs. Such cancers, however, also produce relatively low mortality rates because they are relatively amenable to medical treatment. Because of the readily available data for cancer mortality rates and the relative scarcity of prospective epidemiologic studies, somatic effects leading to cancer fatalities rather than cancer incidence are presented in this NI PEIS. The numbers of cancer fatalities can be used to compare the risks among the various alternatives.

The National Research Council's Committee on the Biological Effects of Ionizing Radiation (BEIR) has prepared a series of reports to advise the U.S. Government on the health consequences of radiation exposures. The latest of these reports, *Health Effects of Exposure to Low Levels of Ionizing Radiation BEIR V* (NAS 1990), provides the most current estimates for excess mortality from leukemia, and cancers other than leukemia, expected to result from exposure to ionizing radiation. This report updates the models and risk estimates provided in an earlier report of the Committee, *The Effects on Populations of Exposure to Low Levels of Ionizing Radiation*. The BEIR V models were developed for application to the U.S. population.

BEIR V provides estimates that are consistently higher than those in its predecessor BEIR III. This increase is attributed to several factors, including the use of a linear dose response model for cancers other than leukemia, revised dosimetry for the Japanese atomic bomb survivors, and additional follow-up studies of the atomic bomb survivors and other cohorts. BEIR III employs constant relative and absolute risk models, with separate coefficients for each of several sex and age-at-exposure groups; BEIR V develops models in which the excess relative risk is expressed as a function of age at exposure, time after exposure, and sex for each of several cancer categories. The BEIR III models were based on the assumption that absolute risks are comparable between the atomic bomb survivors and the U.S. population; BEIR V models were based on the assumption that the relative risks are comparable. For a disease such as lung cancer, where baseline risks in the United States are much larger than those in Japan, the BEIR V approach leads to larger risk estimates than the BEIR III approach.

The models and risk coefficients in BEIR V were derived through analyses of relevant epidemiologic data that included the Japanese atomic bomb survivors, ankylosis spondylitis patients, Canadian and Massachusetts fluoroscopy patients (breast cancer), New York postpartum mastitis patients (breast cancer), Israel Tinea Capitis patients (thyroid cancer), and Rochester thymus patients (thyroid cancer). Models for leukemia, respiratory cancer, digestive cancer, and other cancers used only the atomic bomb survivor data, although results of analyses of the ankylosis spondylitis patients were considered. Atomic bomb survivor analyses were based on revised dosimetry with an assumed relative biological effectiveness<sup>1</sup> of 20 for neutrons and were restricted to doses less than 400 rads. Estimates of risks of fatal cancers other than leukemia were obtained by totaling the estimates for breast cancer, respiratory cancer, digestive cancer, and other cancers.

**Risk Estimates for Doses Equal To or Greater Than 20 Rem (Accident Scenarios).** BEIR V includes risk estimates for a single exposure to a high level of radiation to all people in a large population group. The estimates are given in terms of lifetime risks per  $1.0 \times 10^6$  person-rem. Fatality estimates for leukemia, breast cancer, respiratory cancer, digestive cancer, and other cancers are given for both sexes and nine age-at-exposure groups. These estimates, based on the linear model, are summarized in **Table H-1**. The average risk estimate from all ages and both sexes is 885 excess latent cancer fatalities per million person-rem. This value has been conservatively rounded up to 1,000 excess latent cancer fatalities per million person-rem.

Although values for other health effects are not presented in this NI PEIS, the risk estimators for nonfatal cancers and for genetic disorders to future generations are estimated to be approximately 200 and 260 per million person-rem, respectively. These values are based on information presented in the *1990 Recommendations of the International Commission on Radiological Protection* (ICRP 1991) and are seen to be 20 percent and 26 percent, respectively, of the fatal cancer estimator. Thus, if the number of excess latent fatal cancers is projected to be "X," the number of excess genetic disorders would be 0.26 times "X."

---

<sup>1</sup> A relative biological effectiveness factor is essentially used to represent a given radiation type's (neutron, gamma, alpha, etc.) ability to transfer energy to a given biological receptor.

**Table H-1 Lifetime Risks per Million Person-Rem for Individual Exposures Greater Than 20 Rem**

Gender	Type of Fatal Cancer		
	Leukemia <sup>a</sup>	Cancers Other Than Leukemia	Total Cancers
Male	220	660	880
Female	160	730	890
Average	190	695	885 <sup>b</sup>

a. These are the linear estimates, which are double the linear-quadratic estimates provided in BEIR V for leukemia at low doses and dose rates.

b. This value has been rounded up to 1,000 excess cancer fatalities per million person-rem.

Source: NAS 1990.

**Risk Estimates for Doses Less Than 20 Rem (Normal Operational Scenarios).** For doses lower than 20 rem, a linear-quadratic model provides a significantly better fit to the data for leukemia than a linear model, and leukemia risks were based on a linear-quadratic function, which reduces the effects by a factor of two over estimates that are obtained from a linear model. For other cancers, linear models were found to provide an adequate fit to the data and were used for extrapolation to low doses. The BEIR V Committee, however, recommended reducing these linear estimates by a factor between 2 and 10 for doses received at low dose rates. For this NI PEIS, a risk reduction factor of two was adopted for conservatism.

Based on the preceding discussion, the resulting risk estimator would be equal to half the value observed for high-dose situations or approximately 500 excess latent cancer fatalities per million person-rem (0.0005 excess cancer fatality per person-rem). This is the risk value used in this NI PEIS to calculate cancer fatalities to the general public during normal operations and also for accidents in which individual doses are less than 20 rem. For workers, a value of 400 excess latent cancer fatalities per million person-rem (0.0004 excess latent cancer fatality per person-rem) is used in this NI PEIS. This lower value reflects the absence of children (who are more radiosensitive than adults) in the workforce. Again, based on information provided in the *1990 Recommendations of the International Commission on Radiological Protection (ICRP 1991)*, the health risk estimators for nonfatal cancer and genetic disorders among the public are 20 percent and 26 percent, respectively, of the fatal cancer risk estimator. For workers, the health risk estimators are both 20 percent of the fatal cancer risk estimator. For this NI PEIS, only fatal cancers are presented.

The risk estimates may be applied to calculate the effects of exposing a population to radiation. For example, in a population of 100,000 people exposed only to natural background radiation (0.3 rem per year), 15 latent cancer fatalities per year would result from this radiation (100,000 persons  $\times$  0.3 rem per year  $\times$  0.0005 latent cancer fatality per person-rem = 15 latent cancer fatalities per year).

Calculations of the number of excess cancer fatalities associated with radiation exposure do not always yield whole numbers; calculations may yield numbers less than 1.0, especially in environmental applications. For example, if a population of 100,000 were exposed as described in the previous paragraph, but to a total dose of only 0.001 rem, the collective dose would be 100 person-rem, and the corresponding estimated number of latent cancer fatalities would be 0.05 (100,000 persons  $\times$  0.001 rem  $\times$  0.0005 latent cancer fatality per person-rem = 0.05 latent cancer fatality).

For latent cancer fatalities less than 1.0, the estimated latent cancer fatality is a statistical estimate. The latent cancer fatality of 0.05 associated with a 100 person-rem dose is the average number of deaths that would result if the same exposure situation were applied to many different groups of 100,000 people. In most groups, no person (zero people) would incur a latent cancer fatality from the 0.001 rem dose each member would have received. In a small fraction of the groups, one latent cancer fatality would result; in exceptionally few groups, two or more latent cancer fatalities would occur. The average number of deaths over all the groups would be

0.05 latent cancer fatality (just as the average of 0, 0, 0, and 1 is 1/4, or 0.25). The most likely outcome is 0 latent cancer fatality.

These same concepts apply to estimating the effects of radiation exposure on a single individual. Consider the effects, for example, of exposure to background radiation over a lifetime. The “number of latent cancer fatalities” corresponding to a single individual’s exposure over a (presumed) 72-year lifetime to 0.3 rem per year is the following:

$1 \text{ person} \times 0.3 \text{ rem per year} \times 72 \text{ years} \times 0.0005 \text{ latent cancer fatality/person-rem} = 0.011 \text{ latent cancer fatality.}$

Again, this is a statistical estimate; that is, the estimated effect of background radiation exposure on the exposed individual would produce a 1.1 percent chance that the individual might incur a latent cancer fatality caused by the exposure over his full lifetime. Presented another way, this method estimates that approximately 1.1 percent of the population might die of cancers induced by background radiation.

## **H.2.2 Methodology for Estimating Radiological Impacts**

The potential radiological impacts associated with normal operating conditions and accidents at the processing facilities were calculated using Version 1.485 of the GENII computer code. Site-specific and technology-specific input data were used, including location, meteorology, population, food production and consumption, and source terms. Section H.2.2.1 briefly describes GENII and outlines the approach used for modeling normal operations and facility accidents.

### **H.2.2.1 GENII Computer Code**

The GENII computer model, developed by DOE at the Pacific Northwest National Laboratory, is an integrated system of various computer modules that analyze environmental contamination resulting from acute or chronic releases to, or initial contamination in, air, water, or soil. The model calculates radiation doses to individuals and populations. The GENII computer model is well documented for assumptions, technical approach, methodology, and quality assurance issues (Napier et al. 1988). The GENII computer model has gone through extensive quality assurance and quality control steps, including comparing results from model computations with those from hand calculations and performing internal and external peer reviews. Recommendations given in these reports were incorporated into the final GENII computer model, as deemed appropriate.

For this NI PEIS, only the ENVIN, ENV, and DOSE computer modules were used. The codes are connected through data transfer files. The output of one code is stored in a file that can be used by the next code in the system.

- **ENVIN.** The ENVIN module of the GENII code controls the reading of input files and organizes the input for optimal use in the environmental transport and exposure module, ENV. The ENVIN code interprets the basic input, reads the basic GENII data libraries and other optional input files, and organizes the input into sequential segments based on radionuclide decay chains.

A standardized file that contains scenario, control, and inventory parameters is used as input to ENVIN. Radionuclide inventories can be entered as functions of releases to air or water, concentrations in basic environmental media (air, soil, or water), or concentrations in foods. If certain atmospheric dispersion options have been selected, this module can generate tables of atmospheric dispersion parameters that will be used in later calculations. If the finite plume air submersion option is requested in addition to the atmospheric dispersion calculations, preliminary energy-dependent finite plume dose factors are prepared. The ENVIN module prepares the data transfer files that are used as

input by the ENV module; ENVIN generates the first portion of the calculation documentation—the run input parameters report.

- **ENV.** The ENV module calculates the environmental transfer, uptake, and human exposure to radionuclides that result from the chosen scenario for the user-specified source term. The code reads the input files from ENVIN and then, for each radionuclide chain, sequentially performs the precalculations to establish the conditions at the start of the exposure scenario. Environmental concentrations of radionuclides are established at the beginning of the scenario by assuming decay of preexisting sources, considering biotic transport of existing subsurface contamination, and defining soil contamination from continuing atmospheric or irrigation depositions. For each year of postulated exposure, the code then estimates the air, surface soil, deep soil, groundwater, and surface water concentrations of each radionuclide in the chain. Human exposures and intakes of each radionuclide are calculated for (1) pathways of external exposure from finite atmospheric plumes; (2) inhalation; (3) external exposure from contaminated soil, sediments, and water; (4) external exposure from special geometries; and (5) internal exposures from consumption of terrestrial foods, aquatic foods, drinking water, animal products, and inadvertent intake of soil. The intermediate information on annual media concentrations and intake rates are written to data transfer files. Although these may be accessed directly, they are usually used as input to the DOSE module of GENII.
- **DOSE.** The DOSE module reads the intake and exposure rates defined by the ENV module and converts the data to radiation dose.

#### **H.2.2.2 Data and General Assumptions**

To perform the dose assessments for this NI PEIS using the GENII code, different types of data were collected and/or generated. In addition, calculational assumptions were made. This section discusses both the data collected and/or generated for use in performing the dose assessments and the assumptions made for this NI PEIS.

- **Meteorological data.** The meteorological data used for all normal operational and accident assessments were in the form of Oak Ridge Reservation (ORR), Idaho National Environmental and Engineering Laboratory (INEEL), and Hanford Site (Hanford) joint frequency data files. A joint frequency data file is a table listing the fractions of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The joint frequency data files were based on measurements taken over a period of several years at different locations and heights. Average annual meteorological conditions (averaged over the measurement period) were used for normal operation and the 50th percentile atmospheric conditions were used for accident scenarios. (Accident analysis results and additional analysis detail are presented in Appendix I.)
- **Population data.** Population distributions were based on the *1990 Census of Population and Housing* data (DOC 1992). Projections were determined for the year 2020 (approximate midlife of operations) for areas within 80 kilometers (50 miles) of ORR, INEEL, and Hanford release locations. The site populations in 2020, assumed to be representative of the populations over the operational period evaluated, were used in the impact assessments. The populations were spatially distributed on circular grids with 16 directions and 10 radial distances up to 80 kilometers (50 miles). The grids were centered at the precise locations from which the radionuclides were assumed to be released.
- **Source term data.** Source term(s) (i.e., quantities of radioactive material released to the environment over a given period) were estimated based on characteristic releases associated with historical data.

The source term used to estimate the incremental impacts of normal operations addresses releases of radioactive material during normal operations and from anticipated events (e.g., powder spills).

- **Food production and consumption data.** Agricultural data from *Health Risk Data for Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (HNUS 1996) were used as a source for food production quantities. Food production was spatially distributed on the same circular grid used for the population distributions. The consumption rates used in GENII were those for the maximum individual and average individual. People living within the 80-kilometer (50-mile) assessment area were assumed to consume only food grown in that area.
- **Calculational assumptions.** For normal operations, impact assessments were performed for both members of the general public and workers associated with processing facility activities. These assessments were made to determine the incremental impacts that would be associated with the action alternatives addressed in this NI PEIS. Incremental doses for members of the public were calculated (via GENII) for two different types of receptors: the maximally exposed offsite individual and the general population living within 80 kilometers (50 miles) of a given facility. The maximally exposed individual associated with the alternatives addressed in this NI PEIS was assumed to be located at a position on the site boundary that would yield the highest impacts during normal operations of a given alternative. For facility workers, incremental doses were cited directly from facility-specific data reports. For doses associated with storage actions (i.e., “No Action” neptunium-237 storage), it was conservatively assumed that 10 percent of the total fabrication and processing doses are attributable to storage impacts exclusively.

To estimate radiological impacts from normal operations, the following additional assumptions and factors were considered in using GENII.

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year (16.8 hours per day) for the maximally exposed offsite individual (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year (12 hours per day) for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1.0 year for the maximally exposed individual and general population (NRC 1977).
- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.
- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops and animal products contaminated by either deposition of radioactivity from the air or irrigation. No liquid pathways were analyzed because expected releases will only be to the air.
- Reported release heights were used for atmospheric releases and were assumed to be the effective stack heights.
- The calculated doses were 50-year committed doses from 1 year of intake.

The exposure, uptake, and usage parameters used in the GENII model for normal operations are provided in Tables H-2 through H-4.

**Table H-2 GENII Exposure Parameters to Plumes and Soil Contamination (Normal Operations)**

Maximum Individual				General Population			
External Exposure		Inhalation of Plume		External Exposure		Inhalation of Plume	
Plume (hours)	Soil Contamination (hours)	Exposure Time (hours)	Breathing Rate (cm <sup>3</sup> /sec)	Plume (hours)	Soil Contamination (hours)	Exposure Time (hours)	Breathing Rate (cm <sup>3</sup> /sec)
6,136	6,136	8,766	270	4,383	4,383	8,766	270

**Key:** cm<sup>3</sup>/sec, cubic centimeters per second.

### H.2.2.3 Health Effects Calculations

In this NI PEIS, the collective combined effective dose equivalent is the sum of the collective committed effective dose equivalent (internal dose) and the collective effective dose equivalent (external dose). Doses calculated by GENII were used to estimate health effects using the risk estimators presented in Section H.2.1.2.

The incremental cancer fatalities in the general population and in groups of workers were, therefore, estimated by multiplying the collective combined effective dose equivalent by 0.0005 and 0.0004 cancer fatality per person-rem, respectively. Although health risk factors are statistical factors and not strictly applicable to individuals, they have been used in the past to estimate the incremental risk to an individual from exposure to radiation. Therefore, the factor of 0.0005 and 0.0004 per rem of individual committed effective dose equivalent for a member of the public and for a worker, respectively, have also been used in this NI PEIS to calculate the individual's incremental fatal cancer risk from exposure to radiation. As stated previously, for doses greater than 20 rem to an individual, these factors are doubled.

Under the realm of normal operations, for the public, the health effects expressed in this NI PEIS are the risk of fatal cancer to the maximally exposed individual and the number of fatal cancers to the 80-kilometer (50-mile) population from exposure to radioactivity released from any of the candidate sites over the full period of operations. For workers, the health effects expressed are the risk of fatal cancer to the average worker at a facility and the number of fatal cancers to all workers at that facility from the full period of operations.

#### **H.2.2.4 Uncertainties**

The sequence of analyses performed to generate the radiological impact estimates from normal operation include: (1) selection of normal operational modes, (2) estimation of source terms, (3) estimation of environmental transport and uptake of radionuclides, (4) calculation of radiation doses to exposed individuals, and (5) estimation of health effects. There are uncertainties associated with each of these steps. Uncertainties exist in the way the physical systems being analyzed are represented by the computational models and in the data required to exercise the models (due to measurement, sampling, or natural variability).

In principle, one can estimate the uncertainty associated with each source and predict the remaining uncertainty in the results of each set of calculations. Thus, one can propagate the uncertainties from one set of calculations to the next and estimate the uncertainty in the final results. However, conducting such a full-scale quantitative uncertainty analysis is neither practical nor a standard practice for a study of this type. Instead, the analysis is designed to ensure through judicious selection of release scenarios, models, and parameters, that the results represent the potential risks. This is accomplished by making conservative assumptions in the calculations at each step. The models, parameters, and release scenarios used in the calculations are selected in such a way that most intermediate results and, consequently, the final estimates of impacts are greater than what would be expected. As a result, even though the range of uncertainty in a quantity might be large, the value calculated for the quantity is close to one of the extremes in the range of possible values, so that the chance of the actual quantity being greater than the calculated value is low (or the chance of the quantity being less than the calculated value if the criteria are such that the quantity has to be maximized). This has been the goal of the radiological assessment for normal operation in this study (i.e., to produce results that are conservative).

The degree of conservatism in the calculated results is closely related to the range of possible values the quantity can have. This range is determined by what can be expected to realistically occur. Thus, the only processes considered are those credible for the conditions under which the physical system being modeled operates. This consideration has been employed for normal operation analyses.

Although the radionuclide composition of source terms are reasonable estimates, there are uncertainties in the radionuclide inventory and release reactions that affect estimated impacts.

### H.2.3 Radiological Impact Assessment Data and Releases to the Environment

This section discusses the various site-dependent GENII input data required for quantifying the potential radiological impacts associated with the action alternatives in this NI PEIS. Agricultural data, population data, meteorological data, and release quantity data are discussed for the candidate sites.

- **Agricultural data.** Agricultural food production data (wheels) were cited from *Health Risk Data for Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS* (HNUS 1996). The wheels were generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII (leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs). Each county's food production (in kilograms) was assumed to be distributed uniformly over a given county's land area. These categorized food wheels were fed into GENII as an input file and were used in the assessment of doses to a given general population from the ingestion pathway.
- **Population data.** Population data (wheels) were generated based on the 1990 *U.S. Census of Population and Housing* (DOC 1992). For each block in the 1990 census, the population was assigned a distance and direction from the release point; then the block's population was projected based on estimates of county growth in the year 2020. The population in each segment (e.g., south, southwest, north-northeast) was cumulated over all the blocks in the census. These population wheels were fed into GENII as an input file and were used in the assessment of a total dose incurred to a given general population.
- **Meteorological data.** Meteorological data (i.e., joint frequency distributions) were based on measurements of the fractions (given as percentages) of time the wind blows in a certain direction, at a certain speed, and within a certain stability class for ORR, INEEL, and Hanford, as cited in *Health Risk Data for Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS* (HNUS 1996). The joint frequency distribution data is derived from 1 year of data (from X-10 Plant Tower 4 at ORR [1990 data] and the Grid 3 meteorological tower [1986 data] at INEEL), 9 years of data (1983–1991 from Hanford's 400 Area tower), or 13 years of data (1983–1996 from Hanford's 300 Area Tower 11). Data for facilities to be located at a generic site (the new accelerator(s), research reactor, and support facility) are derived from the hourly meteorological data developed for the health impacts from facility accidents presented in Appendix I. These data were fed into GENII as an input file and were used in the evaluation of  $\chi/Q$  or  $E/Q$  values (these values represent radioisotope concentrations divided by the rates at which they are emitted to the environment); these were then used to determine the total dose incurred to a given general population, or an offsite maximally exposed individual.
- **Radiological releases to the environment.** Normal operational radiological releases to the environment ( $1.7 \times 10^{-7}$  curies per year plutonium-238) were determined based on the conservative assumption that a 5 kilograms (11 pounds) inventory of plutonium-238 is processed on an annual basis at ORR, INEEL, or Hanford. Employing a processing facility emission factor of  $1.98 \times 10^{-12}$  (Wham 1999), and a specific activity of 17 curies per gram, a resulting annual release quantity of  $1.7 \times 10^{-7}$  curies is calculated as shown below:

$$(5,000 \text{ grams per year of plutonium-238}) \times (17 \text{ curies of plutonium-238 per gram of plutonium-238}) \times (1.98 \times 10^{-12}) = 1.7 \times 10^{-7} \text{ curies per year of plutonium-238}$$

Normal operational releases associated with the fabrication and processing of medical target material are based on an estimate of the releases that might occur during the normal handling and processing of target materials,

including anticipated off-normal conditions such as powder spills. Ventilation systems in all facilities used for processing of the target material would consist of at least two sets of high-efficiency particulate air filters, providing an emission removal efficiency of  $2.4 \times 10^{-6}$  and a total facility emission factor of  $1.5 \times 10^{-9}$ . (The emission factor for the elements radon and krypton, both gases, is 1.0.) (BWHC 1999). This results in the normal operational releases that are shown in **Table H-5**. These are the normal operational releases used for the facilities that process only the medical targets; the source term for facilities that process both medical targets and the plutonium-238 would be a combination of the plutonium operational release defined above and the medical releases shown in Table H-5.

**Table H-5 Annual Normal Operational Releases Associated with Medical Target Processing**

Isotope	Quantity Released (curies per year)	Isotope	Quantity Released (curies per year)
Copper-64	$4.9 \times 10^{-5}$	Xenon-131m	$2.0 \times 10^1$
Zinc-65	$5.2 \times 10^{-6}$	Europium-152	$2.1 \times 10^{-5}$
Strontium-85	$9.7 \times 10^{-6}$	Europium-152m	$2.9 \times 10^{-4}$
Krypton-85	$2.9 \times 10^{-3}$	Gadolinium-153	$5.0 \times 10^{-6}$
Krypton-85m	$4.5 \times 10^{-4}$	Samarium-153	$1.4 \times 10^{-4}$
Molybdenum-99	$6.3 \times 10^{-5}$	Europium-154	$7.0 \times 10^{-5}$
Palladium-103	$2.0 \times 10^{-5}$	Europium-155	$1.6 \times 10^{-5}$
Rhodium-103m	$2.0 \times 10^{-5}$	Europium-156	$1.5 \times 10^{-3}$
Technetium-99m	$6.9 \times 10^{-5}$	Holmium-166	$2.2 \times 10^{-6}$
Cadmium-109	$2.9 \times 10^{-6}$	Tungston-187	$3.3 \times 10^{-3}$
Iodine-125	$1.1 \times 10^{-5}$	Iridium-192	$1.6 \times 10^{-5}$
Iodine-131	$4.6 \times 10^{-6}$	Radon-222	$4.3 \times 10^1$

The Radiochemical Processing Laboratory (RPL) at Hanford would require modification prior to its use in medical isotope target fabrication and processing. Preoperational activities were assumed to result in the same emissions as those associated with operation of the facility in 1998; modification activities are not expected to result in significant quantities of airborne particulate of gaseous materials in excess of those generated during facility operation in prior years (BWHC 1999). These normal operational emissions are provided in **Table H-6**.

**Table H-6 Annual Normal Operational Releases from RPL During Preoperational Activities**

Isotope	Quantity Released (curies per year)
Tritium	$1.6 \times 10^2$
Strontium-90 <sup>a</sup>	$1.5 \times 10^{-7}$
Plutonium-239 <sup>a</sup>	$4.4 \times 10^{-8}$

a. Strontium and plutonium releases have been increased to include all alpha and beta emissions detected during facility operation but not attributed to any single isotope.

Source: BWHC 1999.

The normal operational releases associated with operation (for target irradiation), preoperational startup, and standby operation of the Fast Flux Test Facility (FFTF) are based on measured releases for the facility in 1990 when the facility was operating at 300 megawatts and in 1998 when the facility was maintained in standby. These measured releases are provided in **Table H-7**. Normal operational releases have been scaled from those associated with 300-megawatt operations in 1990 to 400-megawatt operations. Operation at 400 megawatts was assumed for the analysis of normal operational impacts. Although operation at a lower power level should meet production goals for most of the mission time, operation at this higher level may be required and impacts

**Table H-7 Annual Normal Operational Releases from FFTF**

FFTF Normal Operations			
Isotope	Quantity Released (curies per year)

from operations at the 400-megawatt power level will bound the normal operational impacts. The standby normal releases are used for both standby and preoperational startup.

The normal operational releases from target irradiation at one or two new accelerators (a low-energy accelerator and a high-energy accelerator) at a generic DOE site used in the analysis of public health impacts are derived from information in Appendix F. The release terms for that accelerator were modified to reflect differences in energy levels to produce the releases provided in **Table H-8**.

**Table H-8 Annual Normal Operational Releases from the Low- and High-Energy Accelerators**

Accelerator Startup Operations				
Isotope	Low-Energy Accelerator		High-Energy Accelerator	
	Airborne Release (curies per year)	Liquid Release (curies per year)	Airborne Release (curies per year)	Liquid Release (curies per year)
Nitrogen-13	0.0027	0.33	0.039	4.7
Carbon-14	$8.0 \times 10^{-5}$	–	0.0011	–
Beryllium-7	$2.7 \times 10^{-5}$	0.0014	$3.9 \times 10^{-4}$	0.020
Fluorine-18	–	$6.5 \times 10^{-4}$	–	0.0096
Argon-41	$9.7 \times 10^{-4}$	–	0.014	–
Hydrogen-3	$3.6 \times 10^{-5}$	–	$5.1 \times 10^{-4}$	–
Accelerator Normal Operations				
Nitrogen-13	0.052	0.33	0.74	4.7
Carbon-14	$8.0 \times 10^{-5}$	–	0.0011	–
Beryllium-7	$2.4 \times 10^{-4}$	0.0014	0.0034	0.020
Fluorine-18	$1.0 \times 10^{-4}$	$6.5 \times 10^{-4}$	0.0014	0.0096
Argon-41	1	–	22	–
Hydrogen-3	$3.6 \times 10^{-5}$	–	$5.1 \times 10^{-4}$	–

The normal operational releases from target irradiation at a new research reactor at a generic DOE site used in the analysis of public health impacts are taken from the analysis in Appendix E. The isotopes and release quantities are provided in **Table H-9**.

**Table H–9 Annual Normal Operational Releases from the Research Reactor**

Isotope	Quantity Released (curies per year)
Tritium	0.1
Argon-41	2.8

A site has not been selected for either the accelerator(s) or the research reactor. The analysis of public health impacts was performed by assuming a population distribution consisting of a uniform population density of 100 people per square mile within 10 miles of the facility (excluding the area within 2 miles of the facility that was assumed to be within the DOE property) and a density of 200 people per square mile for the area 10 to 50 miles from the facility. Also, a representative “generic” meteorological profile was selected. This weather profile was determined to be representative of the average normal weather conditions for the continental United States. Additional information supporting the selection of this population and weather profile is provided in Appendix I, as the same information has been used for the analyses of both normal operations and accident-related public health impacts.

In the event that DOE selects an alternative that incorporates the use of either the new reactor or the accelerator(s), a specific DOE site would have to be selected for the location of these generic facilities. Selection of a specific site would require additional site- and facility-specific National Environmental Policy Act analysis and documentation, which would address the potential human health impacts associated with operation of the facility at the selected site.

Chapter 3 provides information on the current environmental impacts associated with the operation of reactors at the three candidate DOE sites. Included in these current impacts is an assessment of the radiological impact of operation of HFIR at ORR and ATR at INEEL. **Tables H–10** and **H–11** list the isotopes used in the evaluation of the population doses resulting from normal operations of these two reactors. Population doses calculated for HFIR are based on monitored operational releases during the years 1997 through 1999 (Boyd 2000). For HFIR, the largest annual release for each isotope released through the facility stack during one of these three years was selected. Table H–11 is based on ATR emission data for the year 1999 (Perry 2000).

**Table H–10 Maximum HFIR Annual Releases for 1997 Through 1999**

Isotope <sup>a</sup>	Quantities Released (curies per year)	Isotope <sup>a</sup>	Quantities Released (curies per year)
Argon-41	13,000	Krypton-87	56
Barium-139	0.27	Krypton-88	66
Barium-140	4.8x10 <sup>-4</sup>	Krypton-89	44
Cesium-137	0.83	Lanthanum-140	1.6x10 <sup>-4</sup>

Iodine-132	0.0015	Xenon-135	15
Iodine-133	0.0029	Gross $\alpha$ (plutonium-239)	$6.0 \times 10^{-6}$
Iodine-134	0.0022	Gross $\beta$ (strontium-90)	$5.0 \times 10^{-4}$

a. Only isotopes with release quantities of  $10^{-4}$  curies or greater were included in the analysis.

**Table H-12** provides the results of the human health impacts—population dose and maximally exposed individual dose—for each of the scenarios evaluated using GENII. Some of these results are combined to produce the human health effects from normal operations presented in Chapter 4. For example, the impacts associated with the operation of FFTF are the combined impacts of the releases from the three identified release points (the combined exhaust system, the heat transfer system, and the reactor service building). Other health impacts that are reported in Chapter 4 are the result of multiple activities being performed in the same facility. For example, target processing (fabrication and irradiated target processing) and storage may both be done at the Radiochemical Engineering Development Center (REDC), the Fluorinel Dissolution Process Facility (FDPF), and the Fuels and Materials Examination Facility (FMEF). The health impacts from these combined activities are also presented in Table H-12.

Storage of the neptunium-237 is considered for each of the alternatives. (In the No Action Alternative, storage is the only activity assessed.) Releases associated with storage of the neptunium-237 would be expected to be essentially zero. Neptunium-237 would remain in its containment vessels and would be stored in a shielded area (see Section A.1.2). However, it has been assumed that the doses due to storage would be 10 percent of the doses due to processing activities. The analysis of health impacts that could result from processing irradiated targets is based on information that accounts for normal handling of the targets during operation as well as accidents that could occur during handling, such as spills. The determining factor used for annual releases is the amount of material that would be released from an operational spill. During storage, the neptunium-237 would not be subject to activities that could result in a material spill. Therefore, this assumption ensures that the doses associated with neptunium-237 storage have been conservatively addressed.

### Occupational (Worker) Health Impacts

Health impacts from radiological exposure due to normal facility operation were determined for the facility worker directly involved in the fabrication, irradiation, processing, and storage of the medical isotope and plutonium-238 targets. Health risks to individual workers and to the total workforce were assessed.

The dose to facility workers was derived from recorded occupational exposures at the candidate facilities, or from recorded exposures at facilities that perform similar operations as those being considered in each of the alternatives.

Typically, either the average annual worker dose or the total workforce dose has been provided. The number of workers has been estimated based on prior experience with similar activities at the facility or on activities at similar facilities with the same type of operations.

**Table H–12 Radiological Impacts on Populations from Normal Operations**

Facility	Process	Population Dose (person-rem)	Maximally Exposed Individual Dose (millirem)
REDC	Neptunium target processing	$8.0 \times 10^{-5}$	$1.7 \times 10^{-6}$
FDPF	Neptunium target processing	$3.5 \times 10^{-6}$	$1.4 \times 10^{-7}$
FMEF	Neptunium target processing	$4.0 \times 10^{-5}$	$4.3 \times 10^{-7}$
	Target processing - all targets <sup>a</sup>	0.085	$3.0 \times 10^{-4}$
RPL	Preoperational activities	1	0.043
	Medical and research and development target processing	0.21	0.005
FFTF	Standby	0.028	$1.3 \times 10^{-4}$
	Standby: gross alpha and beta emissions	$4.8 \times 10^{-4}$	$6.6 \times 10^{-6}$
	Normal operations: combined exhaust system release	0.044	$4.1 \times 10^{-4}$
	Normal operations: heat transfer system release	$3.7 \times 10^{-5}$	$3.3 \times 10^{-7}$
	Normal operations: reactor service building release	$4.3 \times 10^{-5}$	$3.9 \times 10^{-7}$
Low-energy accelerator	Preoperation/startup	0.0024	$1.4 \times 10^{-5}$
	Normal operations: target irradiation	0.0043	$1.1 \times 10^{-4}$
High-energy accelerator	Preoperation/startup	0.035	$1.8 \times 10^{-4}$
	Normal operations: target irradiation	0.055	$8.8 \times 10^{-4}$
Generic research reactor	Normal operations: target irradiation	0.0023	$6.8 \times 10^{-5}$
Generic support facility	Normal operations: medical and research and development target processing	0.01	0.0025
ATR	Current operations <sup>b</sup>	0.013	0.0013
HFIR	Current operations <sup>b</sup>	8.4	0.46
<b>Human Health Impacts Derived from the Above GENII Computer Analysis Results</b>			
REDC	Neptunium-237 storage	$8.0 \times 10^{-6}$	$1.7 \times 10^{-7}$
	Target processing and storage	$8.8 \times 10^{-5}$	$1.9 \times 10^{-6}$
FDPF	Neptunium-237 storage	$3.5 \times 10^{-7}$	$2.4 \times 10^{-8}$
	Target processing and storage	$3.9 \times 10^{-6}$	$2.6 \times 10^{-7}$
FMEF	Neptunium-237 storage	$4.0 \times 10^{-6}$	$4.3 \times 10^{-8}$
	Neptunium target processing and storage	$4.4 \times 10^{-5}$	$4.7 \times 10^{-7}$
	Target processing and storage: all targets	0.085	$3.0 \times 10^{-4}$
FFTF	Preoperations and standby	0.028	$1.4 \times 10^{-4}$
	Normal operations: target irradiation	0.044	$4.1 \times 10^{-4}$
	Deactivation <sup>c</sup>	0.036	0.00026

a. All targets include medical isotope, civilian nuclear energy research and development, and neptunium targets.

b. Impacts are from existing operations at this reactor. Incremental impacts are 0.

c. FFTF deactivation health impacts are derived from the normal and standby calculations and information provided in the *Environmental Assessment, Shutdown of the Fast Flux Test Facility* (DOE 1995).

**Note:** Target processing includes target fabrication and irradiated target processing.

**Table H–13** provides the source data used for the calculation of worker health impacts from radiological exposure associated with normal operations. Additional health impacts (latent cancer fatalities) are derived from these dose parameters, and this information is presented in Chapter 4 for each of the alternatives. Worker doses were converted into the number of projected latent cancer fatalities using the risk estimator of 400 fatal cancers per million person-rem given in the *1990 Recommendation of the International Commission on Radiological Protection* (ICRP 1991). This risk estimator, compared with the estimator of 500 fatal cancers per million person-rem for members of the public, reflects the absence of infants and children (the most radiosensitive age groups) from the workforce.

**Table H-13 Radiological Impacts on Workers from Normal Operations**

Activity	Number of Workers	Average Annual Individual Dose (millirem)	Total Annual Workforce Dose (person-rem)	Source
FFTF in standby	200	3.5 <sup>a</sup>	0.69	Nielsen 1999

Low-energy accelerator startup	150	150	23 <sup>a</sup>	TechSource 2000 <sup>d</sup>
Low-energy accelerator operations	100	150	15 <sup>a</sup>	TechSource 2000
High-energy accelerator startup	300	150	45 <sup>a</sup>	TechSource 2000 <sup>d</sup>
High-energy accelerator operations	200	150	30 <sup>a</sup>	TechSource 2000
Research reactor operations	120	100	12 <sup>a</sup>	Appendix E
Accelerator and reactor support facility operations	100	102	10 <sup>a</sup>	BWHC 1999
Low-energy accelerator decontamination and decommissioning	35	160	5.6 <sup>a</sup>	Gallagher 2000
High-energy accelerator decontamination and decommissioning	70	160	11 <sup>a</sup>	Gallagher 2000
Research support facility	40	25	1	NRC 1988
Research reactor decontamination and decommissioning	40	275	11	NRC 1988

- This value is derived from the other two parameters for this facility.
- These values are the sum of medical isotope target and plutonium target processing at this facility.
- There are no incremental worker impacts from the use of these currently operating facilities.
- Number of workers for startup increased by 50 percent from normal operation staff levels.

Support facility worker dose estimations are derived from the dose estimates for the operation of RPL at Hanford for the fabrication, processing, and storage of medical isotope targets. The support facility would meet the same DOE requirements and similar administrative requirements for the radiological protection of workers as at existing facilities. Because similar processes would be performed at the support facility as at RPL, it was assumed that radiological and nonradiological worker doses would be similar.

### H.3 IMPACTS OF EXPOSURES TO HAZARDOUS CHEMICALS ON HUMAN HEALTH

The potential impacts of exposure to hazardous chemicals released to the atmosphere were evaluated for routine operations associated with the alternatives analyzed in this NI PEIS.

The receptors considered in these evaluations are the public. Impacts of exposures to hazardous chemicals for workers directly involved in the treatment process were not quantitatively evaluated because workers use

personal protective equipment and engineering process controls which limits their exposure to levels within applicable Occupational Safety and Health Administration Permissible Exposure Limits or American Conference of Governmental Industrial Hygienists Threshold Limit Values.

As a result of releases from routine operations, receptors are expected to be potentially exposed to concentrations of hazardous chemicals that are below those that could cause acutely toxic health effects. Acutely toxic health effects generally result from short-term exposure to relatively high concentrations of contaminants, such as those that may be encountered during facility accidents. Long-term exposure to relatively lower concentrations of hazardous chemicals can produce adverse chronic health effects that include both carcinogenic and noncarcinogenic effects. The health effect endpoints evaluated in this analysis include excess incidences of latent cancers for carcinogenic chemicals, and a spectrum of chemical-specific noncancer health effects such as headache, membrane irritation, neurotoxicity, immunotoxicity, liver toxicity, kidney toxicity, developmental toxicity, reproductive toxicity, and genetic toxicity for noncarcinogens.

## METHODOLOGY

Annual airborne concentrations of hazardous chemicals were estimated from the expected chemical usage provided by the sites and a conservative screening dispersion model described in Chapter 4.

This NI PEIS estimates the noncancer health risks by comparing annual air concentrations of contaminants to the EPA Reference Concentrations published in the Integrated Risk Information System. For each noncarcinogenic chemical, potential health risks are estimated by dividing the estimated airborne concentration by the chemical-specific Reference Concentration value to obtain a noncancer hazard quotient:

$$\text{Noncancer Hazard Quotient} = \text{air concentration/Reference Concentrations}$$

Reference Concentrations are estimates (with an uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of harmful effects during a lifetime. Hazard Quotients are calculated for each hazardous chemical to which receptors may be exposed. Hazard Quotients for each chemical are summed to generate a Hazard Index. The Hazard Index is an estimate of the total noncancer toxicity potential from exposure to hazardous chemicals. According to EPA risk assessment guidelines, if the Hazard Index value is less than or equal to 1.0, the exposure is unlikely to produce adverse toxic effects. If the Hazard Index exceeds 1.0, adverse noncancer health effects may result from the exposure.

For carcinogenic chemicals, risk is estimated by the following equation:

$$\text{Risk} = \text{CA} \times \text{URF}$$

where:

- Risk = a unitless probability of cancer incidence
- CA = contaminant concentration in air (in micrograms per cubic meters)
- URF = cancer inhalation unit risk factor (in units of cancers per micrograms per cubic meters)

Cancer unit risk factors are used in risk assessments to estimate an upper-bound lifetime probability of an individual developing cancer as a result of exposure to a particular level of a potential carcinogen.

## **ASSUMPTIONS**

The airborne pathway is assumed to be the principal exposure route by which the offsite population maximally exposed individual is exposed to hazardous chemicals released from processing facilities. No synergistic or antagonistic effects are assumed to occur from exposure to the hazardous chemicals. Synergistic effects among released contaminants may result in adverse health effects that are greater than those estimated, whereas antagonistic effects among released chemicals may result in less severe health effects than those estimated.

Because released contaminants may have either synergistic or antagonistic effects, chemical risk factors are not combined into a single chemical risk factor, either carcinogenic or noncarcinogenic. A risk factor, either a cancer unit risk factor or a noncancer hazard quotient, is derived for each released contaminant. (The analyses presented in Chapter 4 provide the risk factors for all chemical contaminants considered. In providing the overview of the chemical hazards in Chapter 2, only the highest chemical risk factor is presented.) These chemical cancer unit risk factors are a measure of the likelihood of an individual developing cancer given an exposure to a particular concentration of a known carcinogen for a specified duration. Population risk factors are not developed for chemical contaminants. Concentrations and exposure periods used in this analysis are the maximum that a member of the public could be expected to encounter. (In contrast, the population risk factors developed for the radiological impacts of normal operation do take into consideration the population distribution and varying isotope concentrations, and resulting dose, depending on an individual's location.) Not all of the population could experience this level of exposure. It would be inaccurate to apply the chemical risk factor to the entire population—an application that would overestimate the impact on the total population.

## **ANALYSIS**

The potential impacts of exposure to hazardous chemicals released to the atmosphere during routine operations of the processing facilities are presented in Chapter 4 for each alternative.

# **Appendix I**

## **Evaluation of Human Health Effects from Facility Accidents**

This appendix presents the method and assumptions used for estimating potential impacts on, and risks to, individuals and the general public from exposure to releases of radioactive and hazardous chemical materials during hypothetical accidents at irradiation and processing facilities cited under the production alternatives described in this *Final Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS])*. The impacts of accidental radioactive material releases are given in Section I.1; the impacts of releases of hazardous chemicals, in Section I.2; and industrial accident impacts in Section I.3.

### **I.1 RADIOLOGICAL ACCIDENT IMPACTS ON HUMAN HEALTH**

The accidents considered in this NI PEIS for both the irradiation facilities and the processing facilities were based on a complete spectrum of accidents ranging from high-probability low-consequence events to extremely unlikely and incredible events. For this NI PEIS, a design-basis accident and a beyond-design-basis accident were specifically evaluated for each facility. More frequent events were specifically evaluated at the processing facilities because of the contribution to risk. These higher frequency events were not specifically evaluated for the irradiation facilities because they do not contribute to the risk (i.e., the risks of the design-basis accident and beyond-design-basis accidents are orders of magnitude higher than any more frequent event).

An extensive review of facility safety documentation (safety analysis reports, process hazard reviews, hazard analysis documents, and probabilistic risk analyses) was conducted. The review identified several accidents and their causes (initiating events). The initiating events reviewed included external events (e.g., airplane crashes, nearby explosions, fires), internal events (e.g., equipment failures, human error), natural phenomena (e.g., floods, tornadoes, earthquakes), and sabotage and terrorist activities. The review also determined that the only significant common-cause initiating event would be a catastrophic earthquake. In a common-cause event, the consequences from colocated facilities are summed. However, because of the low frequency of a catastrophic earthquake, the accidents evaluated in this NI PEIS bound the risks of a common-cause summation.

The accidents were grouped into one of four categories—anticipated occurrences, unlikely events, extremely unlikely events, or incredible events—based on the estimated frequency of occurrence. The accidents within each frequency category were examined to determine which accident(s) would result in the highest consequences (i.e., dose) and the highest risks (frequency  $\times$  consequence). As a result, all other accident scenarios were screened from further consideration in this NI PEIS because the consequences and risks associated with those accidents would be lower than—or bounded by—the consequences and risks of the selected accidents.

The accident evaluation methodology ensures that all the facilities are treated on an equal basis. The analysis also considered facility-specific differences in design and mitigation features (e.g., filtration systems). Filtration efficiencies were obtained from facility safety reports, facility descriptions, and appropriate U.S. Department of Energy (DOE) and U.S. Nuclear Regulatory Commission (NRC) guidance.

#### **I.1.1 Irradiation Facility Accident Scenario Selection and Description**

A spectrum of potential accident scenarios was considered in this accident analysis assessment for the High Flux Isotope Reactor (HFIR) at the Oak Ridge National Laboratory (ORNL) in Oak Ridge, Tennessee; the

Advanced Test Reactor (ATR) at the Idaho National Engineering and Environmental Laboratory (INEEL) near Idaho Falls, Idaho; a generic commercial light water reactor (CLWR); the Fast Flux Test Facility (FFTF) at the Hanford Site near Richland, Washington; low-energy and high-energy accelerators at a generic site; and a new research reactor at a generic site.

For each irradiation facility, a spectrum of accidents encompassing the full range of probabilities and consequences was considered for evaluation and inclusion in this NI PEIS. From the reactor final safety analysis reports, it was determined that only a few low-probability design-basis accidents or very low probability beyond-design-basis accidents contributed significantly to risk. Hence, only these events were specifically evaluated in this NI PEIS. In addition, handling accidents involving irradiated targets were also analyzed for HFIR, ATR, and FFTF. For the generic CLWR and the new research reactor, NRC guidance and published studies were used to determine appropriate design-basis and beyond-design-basis accidents. The specific guidance and studies used are presented in each of the following reactor analysis sections. The irradiation facilities analyses include the development of accident scenarios, transport of radioisotopes, and evaluation of health consequences, in addition to discussions of the methodologies used in these evaluations.

<b>Accident</b>	<b>Frequency Range</b>
Anticipated occurrences	1.0 – 0.01
Unlikely events	$1 \times 10^{-2}$ – $1 \times 10^{-4}$
Extremely unlikely events	$1 \times 10^{-4}$ – $1 \times 10^{-6}$
Incredible events	$< 1 \times 10^{-6}$

Irradiation facility accident source terms include postulated neptunium-237 targets with a common spectrum of isotopes at the end of the plutonium-238 production cycle. The accident consequences were analyzed with end-of-cycle irradiated targets. Because of the radioisotope content, the end-of-cycle irradiated targets contribute most significantly to offsite consequences. **Table I-1** presents the inventory of target radioisotopes per gram of plutonium-238 produced.

**Table I-1 Neptunium-237 Irradiated Target End-of-Cycle Nuclide Inventory

The FFTF reactor, low-energy accelerator, and new research reactor accident source terms include medical, industrial, and research and development isotope targets. Projected radioisotope inventories for the target systems most likely to be considered for medical, industrial, and research and development isotope production are presented in **Table I-2**. These are maximum irradiated target inventories. The radium-226 target for actinium-227 production is the only target with a significantly radioactive target material. However, the dose due to the radium-226 target is insignificant compared with the dose due to the product isotopes. Therefore, the accident consequences were analyzed with the irradiated target products. Several of the isotope production targets generate substantial amounts of radioactive byproduct isotope in addition to the desired product. In these cases (gadolinium-153, actinium-227, and plutonium-238 production targets), the additional target inventory was included when calculating consequences.

**Table I-2 Medical, Industrial, and Research and Development Isotope Irradiated Target Product Inventories**

### I.1.1.1 Advanced Test Reactor

ATR would generate 5 kilograms (11 pounds) per year of plutonium-238 in support of Alternative 2, Options 1 through 3, and 3 kilograms (6.6 pounds) per year of plutonium-238 in support of Alternative 2, Options 7 through 9. On average, ATR has seven refueling outages per year. ATR accident analyses assumed that one-seventh of the annual plutonium-238 production would be harvested at each refueling outage and an equal amount of plutonium-238 would remain in the core in targets that were not ready to be harvested. The accident analyses postulated that the plutonium-238 at risk in targets during ATR accidents is 857 grams (1.89 pounds) for the annual production rate of 3 kilograms (6.6 pounds) per year and 1,429 grams (3.144 pounds) for the annual production rate of 5 kilograms (11 pounds) per year.

### I.1.1.1.1 Design-Basis Accident

The *ATR Upgraded Final Safety Analysis Report* (LMIT 1998) stated that seven design-basis accidents would provide the greatest challenge to the engineered safety features of ATR. These accidents and the affected engineered safety systems are summarized in **Table I-3**.

**Table I-3 ATR Engineered Safety Feature Design-Basis Accidents**

Accident Sequence	Engineered Safety System
3-inch diameter opening in the primary coolant system due to an opening of a drain valve, relief valve, or vent valve	Emergency firewater injection system
Experiment loop piping failure	Radiation monitoring and seal system
Long-term complete loss of flow or complete loss of heat sink	Primary coolant overpressure relief and vent systems and emergency firewater injection system
Opening of flow control butterfly valve to full open	Primary pump shutoff system
Loss of primary coolant system pressure control (loss of instrument air)	Pressurizing pumps and gland seal pumps shutoff system
Loss of pressure control of primary coolant system and failure of the pressurizing pumps and gland seal pumps shutoff system	Primary coolant overpressure relief system
Loss of primary coolant system inventory during depressurized and outage operations when irradiated fuel elements are in the reactor vessel	Vessel level alarm system

**Source:** LMIT 1998.

The accident sequences listed in the table do not lead to core damage and do not have the potential to damage appropriately designed neptunium-237 targets being irradiated in the core.

### I.1.1.1.2 Severe Reactor Accident

The large-break loss-of-coolant accident postulated for ATR is a severe reactor accident. This event would result in a decrease in the primary coolant inventory of ATR. As treated in the *ATR Upgraded Final Safety Analysis Report*, the large-break loss-of-coolant accident is a limiting accident compared with other initiating events because 100 percent core damage is estimated to occur. The probability for the occurrence of an ATR large-break loss-of-coolant accident is on the order of  $1 \times 10^{-4}$  per year.

The radiological analysis of the large-break loss-of-coolant accident shows that an ATR core inventory of 1.11 gigacuries at reactor scram conditions releases an available source term of 175 megacuries (LMIT 1998). The emergency firewater injection system is assumed to pump water through the break into confinement, until shutoff level is reached, about 33 hours after the break. Within that period, about 65 percent of the available source term, or 113 megacuries, will have been released as the early release source term. Following the termination of emergency firewater injection system flow at 33 hours, the confinement leak rate is assumed to drop to the design value of 10 percent per day, resulting in a release of the remaining 62 megacuries as the late-release source term, ending about 85 hours after the loss-of-coolant accident. Consequently, the total release duration for the large-break loss-of-coolant accident is 118.5 hours, or the sum of 33.3 hours for the early-release source term and 85.2 hours for the late-release source term.

The core inventories and environmental releases for the three possible plutonium-238 production rates (0, 3, or 5 kilograms per year) are presented in **Table I-4**. The core inventory was based on a maximum design power level of 250 megawatts.

**Table I-4 ATR Large-Break Loss-of-Coolant Accident Source Terms**

Source: LMIT 1998 and Schnitzler 1999.

The ATR core inventory and release fractions were obtained from the *ATR Upgraded Final Safety Analysis Report* which provides the end-of-cycle core inventory for several hundred isotopes (LMIT 1998). These isotopes were screened and reduced to those that contribute to human health effects.

#### I.1.1.1.3 Neptunium-237 Target-Handling Accident

The neptunium-237 target-handling accident scenario postulates the maximum amount of targets in the storage pool. A drop sufficient to damage the entire neptunium-237 target inventory is assumed. This accident is assumed to have a likelihood of occurrence of 0.001 per year.

For the purposes of this analysis, the following assumptions are made for the target-handling accident. The fuel-clad gap contains 10 percent of the fission product gases and iodine (NRC 1978). One-hundred percent of the noble gases and tritium gas in the fuel-clad gap is released to the environment through the reactor building exhaust system. This results in an overall release fraction of 0.1 for the noble gases and tritium. Twenty-five percent of the iodine in the fuel-clad gap is released from the fuel assembly, and 90 percent of the released iodine is absorbed in the reactor pool. The remaining iodine is released to the environment through the reactor building exhaust system. The exhaust system charcoal filter is assumed to remove 99 percent of the iodine (NRC 1978). This results in an overall release fraction of  $2.5 \times 10^{-5}$  ( $0.1 \times 0.25 \times 0.1 \times 0.01 = 2.5 \times 10^{-5}$ ) for the iodine. These assumptions result in the source terms shown in **Table I-5** for the 3- and 5-kilogram-per-year (6.6- and 11-pounds-per-year) production rates.

**Table I-5 ATR Neptunium-237 Target-Handling Accident Source Terms**

Isotope	Environmental Release (curies) Versus Plutonium-238 Production Rate	
	3 kilograms per year	5 kilograms per year
Hydrogen-3	0.207	0.344
Krypton-85	1.73	2.89

#### I.1.1.1.4 Meteorological Data

Meteorological characteristics of the ATR site are described by 1 year of hourly windspeed, atmospheric stability, and rainfall recorded at INEEL.

#### I.1.1.1.5 Population Data

The population distribution surrounding ATR is based on the 1990 Census of Population and Housing (DOC 1992). State and county population estimates were examined to extrapolate the 1990 data to the year 2020.

#### I.1.1.1.6 Evacuation Information

In the event of an accident, DOE would implement site emergency plans and procedures that include restricting site access, patrolling onsite roads, and relocating members of the public. These actions would significantly reduce the consequences to onsite individuals. DOE sites also coordinate with offsite agencies in the event of an emergency. However, no relocation or evacuation of the offsite population was assumed for ATR accident analyses. It was assumed that interdiction and condemnation of contaminated crops and foods were implemented based on U.S. Environmental Protection Agency (EPA) Protective Action Guides.

#### I.1.1.2 High Flux Isotope Reactor Accident Analyses

HFIR would generate 2 kilograms (4.4 pounds) per year of plutonium-238 in support of Alternative 2, Options 7 through 9. On average, HFIR has 11 refueling outages per year. HFIR accident analyses assumed that one-eleventh of the annual plutonium-238 production would be harvested at each refueling outage and an equal amount of plutonium-238 would remain in the core in targets that were not ready to be harvested. The accident analyses postulated that the plutonium-238 at risk in targets during HFIR accidents is 364 grams (0.80 pound).

#### **I.1.1.2.1 Design-Basis Accident**

The *HFIR Safety Analysis Report* (LMER 1998) detailed numerous small-break loss-of-coolant accidents. The worst-case scenario is a 2-inch (5-centimeter) break at the reactor vessel. The primary flow drops sharply in the first few seconds after the break before recovering at about one-fourth of its normal value. However, the primary coolant system fluid remains subcooled throughout the event, and there is considerable margin to critical heat flux. This is the maximum tolerable break short of fuel damage and nonrecoverable flow. It also represents the largest break size that still has a frequency of occurrence greater than  $1 \times 10^{-4}$  per year.

No reactor fuel or target rods fail as a result of the worst-case small-break loss-of-coolant accident.

#### **I.1.1.2.2 Severe Reactor Accident**

The large-break loss-of-coolant accident is the limiting severe reactor accident at HFIR. Two large-break loss-of-coolant accidents were evaluated in the *HFIR Safety Analysis Report* (LMER 1998). Both accidents involve breaks in the primary coolant system piping. The first is a double-ended guillotine break of the cold leg in the reactor pool, in which the reactor coolant is retained inside confinement. The second is a double-ended guillotine break of a primary coolant pump discharge line in a heat exchanger cell. The consequences of a large-break loss-of-coolant accident in the heat exchanger cell are bounded by those resulting from a large-break loss-of-coolant accident in the reactor pool. Therefore, the large-break loss-of-coolant accident in the reactor pool was chosen for analysis in this NI PEIS.

The large-break loss-of-coolant accident in the reactor pool assumes that 100 percent of the core melts. Equipment in service at the beginning of the accident is assumed to operate for the duration of the accident. This equipment includes the special building or confinement hot-exhaust system, which is designed to filter out airborne particulate activity from the HFIR building.

The *HFIR Safety Analysis Report* (LMER 1998) states that 100 percent of noble gases and 1 percent of iodines are released to the environment. The accident scenario presented in the facility safety analysis report assumes that the primary coolant piping breaks in the reactor pool. Therefore, even though the primary coolant piping inventory is lost, the core remains covered with water. Because of this assumption, only noble gases and iodine are assumed to be released to the environment. This differs from other reactors in the assumption that no other radioisotopes are released. For most reactors, a severe loss-of-coolant accident results in an uncovered core, leading to a fractional release of all isotopes.

The accident source term is presented in **Table I-6** for the two possible HFIR core configurations.

Table I-6 HFIR Large-Break Loss-of-Coolant Accident Source Term

### I.1.1.2.3 Neptunium-237 Target-Handling Accident

The neptunium-237 target-handling accident scenario postulates the maximum number of targets in the storage pool. A drop sufficient to damage the entire neptunium-237 target inventory is assumed. This accident is assumed to have a likelihood of occurrence of 0.001 per year. The accident assumptions are described in Section I.1.1.1.3. These assumptions result in the source terms, shown in **Table I-7**, for a 2-kilograms-per-year (4.4-pounds-per-year) production rate.

**Table I-7 HFIR Neptunium-237 Target-Handling Accident Source Term**

Isotope	Environmental Release <sup>a</sup> (curies)
Hydrogen-3	0.0877
Krypton-85	0.735
Krypton-85m	193
Krypton-87	321
Krypton-88	451
Iodine-131	0.295
Iodine-132	0.443
Iodine-133	0.593
Iodine-134	0.628
Iodine-135	0.553
Xenon-133	2,230
Xenon-135	280

a. Based on a 2-kilogram-per-year plutonium-238 production rate.

### I.1.1.2.4 Meteorological Data

Meteorological characteristics of the HFIR site are described by 1 year of hourly windspeed, atmospheric stability, and rainfall recorded at ORNL.

### I.1.1.2.5 Population Data

The population distribution surrounding HFIR is based on the 1990 census (DOC 1992). State and county population estimates were examined to extrapolate the 1990 data to the year 2020.

#### **I.1.1.2.6 Evacuation Information**

In the event of an accident, DOE would implement site emergency plans and procedures that include restricting site access, patrolling onsite roads, and relocating members of the public. These actions would significantly reduce the consequences to onsite individuals. DOE sites also coordinate with offsite agencies in the event of an emergency. However, no relocation or evacuation of the offsite population was assumed for HFIR accident analyses. It was assumed that interdiction and condemnation of contaminated crops and foods were implemented based on EPA Protective Action Guides.

#### **I.1.1.3 Commercial Light Water Reactor**

The CLWR would generate 5 kilograms (11 pounds) per year of plutonium-238 in support of Option 4, 5, or 6 of Alternative 2. On average, CLWR has one refueling outage every 18 months. The accident analysis assumes that 100 percent of the targets in the reactor core would be harvested at each refueling outage. The analysis postulates that the plutonium-238 at risk in targets during CLWR operation is 7.5 kilograms (16.5 pounds).

The analysis is based primarily on NUREG/CR-6295 (Davis 1997). NUREG/CR-6295 provides simplified design-basis and severe-accident source terms and generic site parameters based on the risk insights of NUREG-1150 (NRC 1990). These simplified source terms and generic parameters are used to analyze accidents for the current core for a baseline impact and with the proposed neptunium-237 targets to determine the incremental impact of plutonium-238 production. Core damage and containment failure frequencies were updated using more recent risk insights from the Individual Plant Examination (IPE) database (NRC 1997).

##### **I.1.1.3.1 Core Inventories**

After a review of NUREG/CR-6295, the 3,800 megawatts-thermal pressurized-water-reactor accident release fractions were chosen for this analysis. This reactor has the highest energy level and the consequences result in the highest risk of the reactors analyzed in NUREG/CR-6295. The MELCOR Accident Consequence Code System (MACCS2) documentation provides a typical end-of-cycle core inventory for a 3,412 megawatts-thermal pressurized-water-reactor. This power level was selected for the analysis because only 5 of the 73 currently operating pressurized water reactors have higher power levels, and 19 have a power level of 3,411 megawatts-thermal.

**Table I-8** provides inventories for the current core configuration, the target inventory, and the core-containing targets. The end-of-cycle inventories provide bounding source terms which lead to maximum consequences. The calculation conservatively assumes that the targets are additions to the core and not replacements for some fuel rods. Replacing some burned fuel rods with targets would lower the core activity, perhaps below that without targets. As noted in the total activities line of the table, there is very little difference (approximately 0.16 percent) between the current core at  $6.37 \times 10^9$  curies versus  $6.38 \times 10^9$  curies for the current core plus the targets.

**Table I-8 Core Inventories Based on a Target Maximum Core Loading of 7.5 Kilograms**

### I.1.1.3.2 Meteorological Data

According to NUREG/CR-6295 (Davis 1997), the Sandia Siting Study evaluated data from 29 National Weather Service sites representing the nation's meteorological conditions. The 29 sites were compared to determine which site best represents the nation's meteorological conditions. It was determined that the site with the least deviation from the mean is the one at Omaha, Nebraska. Another comparison of the 29 sites indicated that the mean mixing height is 1.5 kilometers (0.93 mile). The mean meteorological data used in the NI PEIS analysis are a composite of the Omaha meteorological conditions and the mean mixing height.

### I.1.1.3.3 Population Data

To be as generic as possible, the population around the plant was assumed to be uniformly distributed. The analysis was performed for a population density of 100 persons per square mile (38.6 persons per square kilometer) from 0 to 10 miles (representing the median population density for all pressurized water reactors) and 200 persons per square mile (77.2 persons per square kilometer) from 10 to 50 miles (representing an average population density beyond 10 miles). The exclusion area boundary was assumed to be 640 meters (0.4 mile) from the reactor.

### I.1.1.3.4 Evacuation Information

Consistent with NUREG-1150, this analysis assumes that 99.5 percent of the population within the 16.1-kilometer (10-mile) emergency planning zone participates in an evacuation. It was also assumed that the 0.5 percent of the population that did not participate in the initial evacuation was relocated within 12 to 24 hours after plume passage, based on the measured concentrations of radioactivity in the surrounding area and the comparison of projected doses with EPA guidelines. Mean evacuation time and speed were based on the average of the five NUREG-1150 plants. This results in an evacuation delay time of 1.9 hours and an evacuation speed of 9.3 kilometers (5.8 miles) per hour.

### I.1.1.3.5 Design-Basis Accident

Design-basis events are defined by the American Nuclear Society as Condition IV occurrences or limiting faults. Condition IV occurrences are faults which are not expected to take place, but are postulated because their consequences would include the potential for the release of substantial radioactive material. These are the most serious events which must be designed against and represent limiting design cases.

A realistic design-basis large-break loss-of-coolant accident was chosen for evaluation because it is the limiting design-basis accident at pressurized water reactor plants. The large-break loss-of-coolant accident is defined as a break equivalent in size to a double-ended rupture of the largest pipe of the reactor coolant system. Following a postulated double-ended rupture of a reactor coolant pipe, the emergency core cooling system keeps cladding temperatures well below melting, ensuring that the core remains intact and in a coolable geometry. As a result of the increase in cladding temperature and rapid depressurization of the core, however, some cladding failure may occur in the hottest regions of the core. Thus, a fraction of the fission products accumulated in the pellet-cladding gap may be released to the reactor coolant system and thereby to the containment. Although no core melting would occur for the design-basis loss-of-coolant accident, a postulated gross release of fission products is evaluated in accordance with NRC accident analysis guidelines (AEC 1974). The only postulated mechanism for such a release would be a number of simultaneous and extended failures in the engineered safety feature systems, producing severe physical degradation of core geometry and partial melting of the fuel.

The realistic large-break loss-of-coolant accident release characteristics, obtained from NUREG/CR-6295, are described by the release height, timing, duration, and heat content of the plume; the fraction of each isotope group released; and the warning time (time when offsite officials are warned that an emergency response should be initiated.) **Tables I-9 and I-10** provide the release parameters for the realistic large-break loss-of-coolant accident.

**Table I-9 Design-Basis Accident Release Characteristics**

Accident Scenario	Scenario Frequency	Elevation of Release (m)	Energy of Release (W)	Warning Time (hr)	Time of Release (hr)	Duration of Release (hr)

**Source:** Davis 1997.

NUREG/CR-6295 (Davis 1997) provides frequencies for each accident category. However, these frequencies are based solely on the NUREG-1150 (NRC 1990) plant data. To apply more recent accident frequencies, data from commercial pressurized water reactor IPEs were reviewed. For each of the accident categories (loss-of-coolant accident, early containment failure, late containment failure, and containment bypass) the failure probability medians were calculated. These data represent significant additional risk studies more recent than NUREG-1150.

The frequency of occurrence for the design-basis large-break loss-of-coolant accident is  $4.65 \times 10^{-5}$  per year. This frequency is based on internal initiators (i.e., plant upsets) and does not include external initiators (e.g., earthquakes). External initiators were not included because the frequencies depend solely on site location.

#### **I.1.1.3.6 Beyond-Design-Basis Events**

Beyond-design-basis accidents (severe reactor accidents) are less likely to occur than reactor design-basis accidents. In reactor design-basis accidents, the mitigating systems are assumed to be available. In severe reactor accidents, even though the initiating event could be a design-basis event (e.g., large-break loss-of-coolant accident), additional failures of mitigating systems would cause some degree of physical deterioration of the fuel in the reactor core and a possible breach of the containment structure leading to the direct release of radioactive materials to the environment.

In NUREG/CR-6295, representative source terms were developed which represent the full spectrum of severe accidents. A small set of source terms was developed by considering release categories which account for a spectrum of possible times and modes of containment failure. For each containment failure mode the source terms were selected based on the dominant accident progression characteristics leading to the containment failure. The magnitudes of releases for each release category were obtained by using the mean values of the probability distributions of source term parameters used in NUREG-1150.

In NUREG/CR-6295, a total of four release categories was selected to represent the spectrum of containment failure modes of the 3,800 megawatts-thermal pressurized water reactor: a containment bypass event, an early containment failure coincident with reactor core vessel breach, a late containment failure, and a no-containment-failure event. The no-containment-failure event is initiated by a large-break loss-of-coolant accident and was used to represent a realistic design-basis large-break loss-of-coolant accident. The containment bypass and failure scenarios are considered beyond-design-basis events and are evaluated in this section.

**Containment Bypass.** A containment bypass involves failure of the pressure boundary between the high-pressure reactor coolant and low-pressure auxiliary system. For pressurized water reactors, steam generator tube rupture, either as an initiating event or as a result of severe accident conditions, will lead to containment bypass. In these scenarios, if core damage occurs, a direct path to the environment can exist.

**Early Containment Failure.** This accident is defined as the failure of containment prior to, or very soon (within a few hours) after, breach of the reactor vessel. A variety of mechanisms (e.g., direct contact of core debris with the containment, rapid pressure and temperature loads, hydrogen combustion, fuel-coolant interactions) can cause structural failure of the containment. Failure to isolate the containment and early containment venting after core damage are also classified as early containment failures.

**Late Containment Failure.** A late containment failure involves structural failure of the containment several hours after breach of the reactor vessel. A variety of mechanisms (e.g., gradual pressure and temperature increase, hydrogen combustion, basemat melt-through by core debris) can cause late containment failure. Venting the containment late in the accident is also classified as a late containment failure.

The release characteristics for each accident, obtained from NUREG/CR-6295, are described by the release height, timing, duration, and heat content of the plume, the fraction of each isotope group released, and the warning time (time when offsite officials are warned that an emergency response should be initiated). **Tables I-11 and I-12** provide the release parameters for the beyond-design-basis accidents.

**Table I-11 Beyond-Design-Basis Accident Release Characteristics**

Accident Scenario	Scenario Frequency	Elevation of Release (m)	Energy of Release (W)	Warning Time	Time of Release (hr)	Duration of Release
Containment bypass <sup>a</sup>	1.53×10 <sup>-6</sup>	10	5.5×10 <sup>6</sup>	20 min	1.0	30 min
			9.9×10 <sup>5</sup>		1.5	2 hr
Early containment failure <sup>a</sup>	7.92×10 <sup>-8</sup>	10	8.6×10 <sup>5</sup>	5.0 hr	6.0	10 min

As in the design-basis-accident analysis, the frequency of occurrence is based on internal initiators and does not include external initiators.

#### I.1.1.4 Fast Flux Test Facility (FFTF)

A spectrum of postulated accidents was evaluated for three separate FFTF conditions: operation, standby, and deactivation. Conservative assumptions were made on core configuration and isotopic inventory in order to provide conservative estimates of impacts.

##### I.1.1.4.1 FFTF Operation

For operation, the FFTF core would be modified to include an array of target assemblies and Rapid Radioisotope Retrieval systems to produce cobalt-60, a number of long- and short-lived isotopes for medical applications, and 5 kilograms (11 pounds) per year of plutonium-238 for space power applications. In addition, space is to be provided for research and development test articles such as Accelerator Transmutation of Waste test assemblies.

It is expected that the characteristics of the new mission core will be similar to previous cores, and that the existing facility safety analysis report analyses will be comparable to the new core accidents. A wide range of postulated reactor accidents was analyzed in the existing *FFTF Final Safety Analysis Report* (Dautel 2000).

These include design-basis and beyond-design-basis accidents. A spectrum of postulated accidents was evaluated to provide bounding scenarios for determining potential environmental and health impacts of the new missions. The accident scenarios were selected from the existing *FFTF Final Safety Analysis Report* and represent design-basis and beyond-design-basis events, including reactor, target-handling, and fuel storage accidents. Source terms and frequencies were selected to provide conservative estimates of the potential impacts.

The accident analysis included a review of external events (e.g., nearby explosions, fires), internal events (e.g., equipment failures, human errors), natural phenomena (e.g., floods, earthquakes), as well as sabotage and terrorist acts. A recent external event of concern is the threat of wildfires. Several features of FFTF make it well equipped to deal with an event like a large range fire. First, the layout and construction of the facility make it very unlikely that an external fire would spread to the plant structures (e.g., there is a large clear gravel and asphalt buffer zone, and much of the facility is constructed of fire-resistant materials). Furthermore, most of the critical plant systems, including the reactor and its heat transport system, are housed inside of the steel and concrete containment building, which is completely closed during reactor operation. As appropriate, the balance of the facility is protected by automatic fire detection/suppression systems. Although FFTF has several sources of both offsite and onsite electrical power, another significant safety factor is that, except for a few batteries, FFTF requires no electricity to accomplish any required safety function (i.e., reactor shutdown, isolation of the containment building, and emergency core cooling). Finally, the FFTF control building includes systems such as a filtered air supply for ensuring habitability during a variety of offnormal conditions, and emergency respirators are available to the operators. A wildfire-initiated accident would be bounded by the accidents evaluated and therefore not considered further.

Two large range fires at Hanford burned very close to FFTF. In 1984, a very large fire occurred while the reactor was in operation at 100 percent power. The plant continued to operate normally and safely throughout this event, although a reduction in power was initiated as a precautionary measure. The second fire occurred in June 2000 while the reactor was in standby. In neither case, did the range fire cause any damage or operational difficulties at FFTF. Both fires reached the gravel and asphalt buffer zone around FFTF, but never posed any significant threat to plant structures. Precautionary measures were taken by essential plant personnel to perform continuous monitoring and to reduce or eliminate the intake of smoke passing over the facility.

The reactor power will be 100 megawatts, which is one-fourth of the design power, for most of the mission operation. However, periodic increases in power level between 100 and 400 megawatts may be required to support civilian nuclear energy research and development activities. The accident analyses provided are based on the FFTF design power level of 400 megawatts and will provide conservative estimates of operation at 400 megawatts-thermal and lower power levels.

## **CORE INVENTORIES**

### **Mixed Oxide Driver Fuel**

The current FFTF fuel contains mixed oxide driver fuel assemblies. The plutonium fuel enrichment is assumed to be the same as during previous reactor operations and as currently authorized by the facility safety analysis report. A total of 76 driver fuel assemblies were assumed in the facility safety analysis report. Although it is expected that some of the driver fuel positions will be taken up by test articles and isotope production targets, the same number of driver fuel assemblies are to be assumed for conservatism for purposes of this analysis. A total of six fueled test articles were included in the assumed core loading for this analysis, but were treated as part of the complement of 76 driver fuel assemblies.

An ORIGEN2 (Wootan 1999) calculation for a reference driver fuel assembly was used to generate the radioisotope inventories used in the accident analyses. Evaluation focused on a typical end-of-irradiation inner-row driver fuel assembly with a plutonium enrichment of about 22 percent—specifically, assembly 16439 irradiated to 445.8 effective full-power days through cycle four in core location 1201. Previous studies have determined that 60 isotopes are important for offsite impact analysis. These 60 isotopes are provided in NUREG/CR-4691, *MELCOR Accident Consequence Code System*, Volume 1, Table B.4-2 (Chanin et al. 1990). The resulting driver fuel inventory is shown in **Table I-13**.

### **Highly Enriched Uranium Driver Fuel**

A future core loading may require use of highly enriched uranium. The highly enriched uranium fuel would be in an oxide form. Radioisotope inventories were calculated for a highly enriched uranium fuel assembly that is directly comparable to the reference mixed oxide fuel assembly. To generate comparable values for a highly enriched uranium fueled core, a highly enriched uranium fuel assembly with a uranium-235 enrichment of 25 percent was used to replace the reference mixed oxide assembly in the ORIGEN2 calculation of radioisotope inventories. This enrichment provides about 25 percent more uranium-235 in the highly enriched uranium assembly than plutonium-239 in the mixed oxide assembly, so that the highly enriched uranium assembly would have comparable power and burnup at a lower flux level than the reference mixed oxide assembly. This enrichment is lower than the enrichments expected in a full highly enriched uranium core (likely in the range of 35 percent), but the dose rates for this assembly should bound the higher enrichments, since the fission products would be nearly identical and the plutonium contribution would be less with higher enrichments. The resulting highly enriched uranium driver fuel inventory is shown in **Table I-14**.

Although accidents were evaluated for both the mixed oxide and highly enriched uranium core configurations, it is important to point out that the radiological consequences of the mixed oxide fueled core assumed in this analysis will bound those of the highly enriched uranium core.

Table I-13 FFTF Core Inventory with Mixed Oxide Driver Fuel

Core Isotope	Driver Assemblies		Pu-238 Production		Medical	Co-60	Core Activity (Ci)
	Driver Activity (Ci)	76 Drivers (6 ATWs) <sup>a</sup> Activity (Ci)	Per Gram Pu-238 Activity (Ci)	Max. Core Activity <sup>b</sup> (Ci)	12 Ac-227 <sup>c</sup> 7 Re-186 I-125 Activity (Ci)	48 Co-60 Assemblies Activity (Ci)

a. Six Accelerator Transmutation of Waste test assemblies included as driver fuel assemblies.

b. Based on a 5-kilogram-per-year plutonium-238 production rate.

c. For the actinium-227 target, over 99.9 percent of the consequences are attributable to six isotopes (actinium-227; radium-223, 224, 226; thorium-227, 228). Therefore, the other actinium-227 target byproducts are not included.

**Key:** Ac-227, actinium-227; ATW, Accelerator Transmutation of Waste; Ci, curies; Co-60, cobalt-60; I-125, iodine-125; Pu-238, plutonium-238; Re-186, rhenium-186.

**Source:** BWHC 1999; Schnitzler 1999; Wootan 1999.

a. Based on a 5-kilogram-per-year plutonium-238 production rate.

b. For the actinium-227 target, over 99.9 percent of the consequences are attributable to six isotopes (actinium-227; radium-223, 224, 226; thorium-227, 228). Therefore, the other actinium-227 target byproducts are not included.

c. Six Accelerator Transmutation of Waste test assemblies included as mixed oxide driver fuel assemblies.

**Key:** Ac-227, actinium-227; ATW, Accelerator Transmutation of Waste; Ci, curies; Co-60, cobalt-60; HEU, highly enriched uranium; I-125, iodine-125; Pu-238, plutonium-238; Re-186, rhenium-186.

**Source:** BWHC 1999; Schnitzler 1999; Wootan 1999.

## **Targets**

The proposed core modifications include an array of target assemblies and Rapid Radioisotope Retrieval systems to produce plutonium-238 for space power applications, cobalt-60, and a number of long- and short-lived isotopes for medical applications. In addition, space is to be provided for research and development test articles such as Accelerator Transmutation of Waste test assemblies. As stated previously, a total of six Accelerator Transmutation of Waste test assemblies were conservatively modeled as mixed oxide driver fuel assemblies and included as part of the complement of 76 driver fuel assemblies.

To determine which Rapid Radioisotope Retrieval system and Long-Term Irradiation Vehicle irradiated targets would result in the maximum consequences, the radioisotope inventories for each of the irradiated targets were multiplied by the same release fractions as were assumed for the fuel and fission products (1 percent for solids and 100 percent for noble gases). The resulting inventories were then multiplied by dose conversion factors resulting in a dose for each isotope. The isotope doses within each target were totaled for a target dose, and the target doses were compared to determine which target would result in the maximum consequence for each target type.

### **Rapid Radioisotope Retrieval Systems**

There is to be a maximum of eight Rapid Radioisotope Retrieval systems in the core. One of the Rapid Radioisotope Retrieval systems is to be configured as a gas target to produce iodine-125 from xenon-124. The other seven will be used for production of solid, short-lived medical isotopes. These seven targets are all modeled as the worst-case type (other than gas) to maximize the resulting dose contribution of an accident. The worst-case target planned for insertion in a Rapid Radioisotope Retrieval system is the xenon-124 gas tube, which is assumed to release 100 percent of its iodine-125 inventory along with the xenon-124 gas into containment in the event of any break in the system. As the next worst is the rhenium-186 production target, the other seven Rapid Radioisotope Retrieval systems were assumed to be rhenium-186 production targets. The Rapid Radioisotope Retrieval system inventory is shown in Tables I-13 and I-14.

### **Long-Term Irradiation Vehicle**

Twelve Long-Term Irradiation Vehicle assemblies for production of long-lived medical isotopes are assumed. These assemblies are all modeled as the worst-case type to maximize the dose contribution of an accident. The worst-case Long-Term Irradiation Vehicle target is the actinium-227 production target. All 12 Long-Term Irradiation Vehicle targets are therefore assumed to be actinium-227 production targets. The Long-Term Irradiation Vehicle inventory is shown in Tables I-13 and I-14.

### **Cobalt-60 Production Target Assemblies**

Forty-eight cobalt-60 production targets are to be included in row 9 (outside the reflector assemblies) with a currently assumed annual production rate of  $2.016 \times 10^7$  curies. The residence time for these targets is to be three 100-day cycles with 16 assemblies being harvested at the end of each cycle. Assuming 2.73 cycles per year for FFTF, this leads to a maximum end-of-cycle core inventory of  $(1/3 + 2/3 + 1) (2.016 \times 10^7 \text{ curies}) / 2.73 = 1.48 \times 10^7$  curies. This inventory is included in Tables I-13 and I-14.

### **Plutonium-238 Production Target Assemblies**

Fifteen plutonium-238 production targets are to be included in the reflector region with a currently assumed annual production rate of 5 kilograms (11 pounds). The residence time for these targets is to be three 100-day cycles with five assemblies being harvested at the end of each cycle. Assuming 2.73 cycles per year for FFTF,

this leads to a maximum end-of-cycle core inventory of  $(1/3 + 2/3 + 1)$  (5 kilograms)/ $2.73 = 3.66$  kilograms (8.07 pounds). The end-of-cycle target inventory per gram of plutonium-238 and the associated maximum end-of-cycle inventory (3.66 kilograms [8.07 pounds]) are shown in Tables I-13 and I-14.

## DESIGN-BASIS ACCIDENT

A wide range of design-basis accidents is analyzed in Chapter 15 of the *FFTF Final Safety Analysis Report* (Dautel 2000). The reactor accidents include various reactivity increase and heat removal reduction transients as well as local fuel failure and natural phenomena (e.g., seismic) events. It should be noted that the *FFTF Final Safety Analysis Report* does not specifically identify a probability of occurrence for each event, but does classify each as being in the anticipated, unlikely, or extremely unlikely category.

For the design-basis transients, the reactor shutdown system was shown to initiate automatic reactor shutdown (scram) in sufficient time to maintain calculated cladding temperatures/strains within limits that ensured that the integrity of the fuel cladding was maintained. Postulated local fuel failure events were shown to remain local (not propagate) and thus have minimal radiological consequences. The core characteristics (physical, nuclear, and thermal) used in the accident analyses of the final safety analysis report were selected to bound those for any anticipated core design. Also, the characteristics of the new-missions core are expected to be similar to those of previous cores (at the same power level). Therefore, the design-basis transients for the new missions core are expected to be essentially the same as those documented in the final safety analysis report. However, the isotopic inventory of the new-missions core will be different from that is used in the final safety analysis report.

The accidental release of primary sodium from the main heat transport system resulted in a larger radiological release than any other reactor related design-basis event (radiological releases can also occur due to non-reactor-related events, such as fuel-handling accidents). The analyses given in the final safety analysis report include some large spills of primary sodium but the spills involving primary sodium are in cells which are inerted and located within containment. The amount of radioactivity released to the environment is bounded by the main heat transport system spill. Secondary-loop sodium does not contain significant radioactive materials, so the radiological consequences of secondary sodium spills are negligible.

Primary sodium is radioactive and may also contain small amounts of fission products. Sodium temperatures are maintained at less than  $566\text{ }^{\circ}\text{C}$  ( $1,050\text{ }^{\circ}\text{F}$ ), much below the sodium boiling point ( $881\text{ }^{\circ}\text{C}$  [ $1,618\text{ }^{\circ}\text{F}$ ] at atmospheric pressure). Sodium at this temperature will retain practically all of the fission products dissolved in it (except the noble gases). Therefore, sodium itself provides the first barrier to the release of any radioactive species.

Primary sodium is contained in high-integrity stainless steel piping and vessels, which provide the second barrier to release. An additional safety margin is provided by the low system operating pressure (less than 200 pounds per square inch gage). The primary sodium systems are located in inert-gas-filled cells (nitrogen plus 0.8–1.2 volume-percent oxygen) to preclude sustained burning in the event of a spill. Therefore, the cell temperature and pressure rise due to primary sodium spills are minimized. An additional protective feature is the sensitive primary sodium leak detection system, including detectors which annunciate on low oxygen level in the cell atmosphere. These cells are constructed of reinforced concrete several feet thick and completely lined with welded steel plate. They provide the third barrier to radioactivity release in case of a primary sodium spill. These subgrade primary cells are located within the Containment Building, the fourth barrier to the release of radioactivity. Some low-pressure, low inventory auxiliary sodium systems, which are connected to the main primary sodium coolant system, are located in similar concrete, steel-lined subgrade cells in a building adjacent to the Containment Building.

The limiting accident is a spill of primary sodium in the inerted sodium and argon sampling pipeway located outside of containment in the Heat Transport System Building–South. The spill is assumed to occur with the reactor at full power (400 megawatts) and very conservatively assumed to be operating with 1 percent failed fuel. In other words, it is assumed that 1 percent of the radioactive inventory (fission products and actinides plus daughters) of 76 fuel assemblies is dispersed uniformly in the primary sodium. Radioactive gases would not be dispersed in the sodium and therefore would not be available for release in this accident. However, for conservatism, 1 percent of the radioactive gas inventory was included in the analysis.

The mass of primary sodium in the main heat transport system is 421,940 kilograms (930,220 pounds). In addition to fission products and fuel, sodium activation products (sodium-22 and sodium-24) will be created during irradiation. The equilibrium sodium activity is assumed to be  $4.1 \times 10^{-4}$  curie per pound for sodium-22 and 5.38 curies per pound for sodium-24. The final safety analysis report assumes that 393 kilograms (867 pounds) of primary sodium is spilled in the inerted sodium and argon sampling pipeway and that 24.4 kilograms (53.7 pounds) of the total spill burns to form an airborne oxide. The fraction of radioactive inventory (sodium activation, fission products and actinides plus daughters) available for release from the sodium and argon sampling pipeway is  $(0.01 \times 53.7)/930,220 = 5.77 \times 10^{-7}$ . The leak rate of the sodium and argon sampling pipeway is assumed to be 25 percent per day. The probability of this event is judged to be extremely unlikely ( $1 \times 10^{-4}$  to  $1 \times 10^{-6}$  per year). For this NI PEIS, the probability is conservatively chosen to be  $1 \times 10^{-4}$  per year.

The source terms for the design-basis sodium spill with mixed oxide fuel and highly enriched uranium fuel are presented in **Tables I–15 and I–16**, respectively.

It should be noted that the reactor power will be 100 megawatts or one-fourth of the design power, for most of the new-missions operation. The fission production rate will be less for this lower-power operation. Therefore, the actual inventory of radioisotopes will likely be less than the conservative bounding inventory assumed for this analysis.

## SEVERE REACTOR ACCIDENT

In addition to the design-basis accidents analyzed in Chapter 15 of the *FFTF Final Safety Analysis Report* (Dautel 2000), Appendix A of the facility safety analysis report documents the analysis of two beyond-design-basis events: unprotected transient overpower and unprotected loss of primary sodium flow (unprotected refers to the assumption that the reactor shutdown system fails to shut down the reactor). These two unprotected events are considered to bound the consequences of other potential beyond-design-basis events such as loss of decay heat removal capability.

The unprotected transient overpower event was found to be relatively benign (i.e., no substantial release of radioactive material is expected). The final safety analysis report results indicated that the event would be terminated by fuel melting and sweepout from a few fuel assemblies and in-place cooling of the remainder of the core. There was no identified source of substantial energetics that would challenge the integrity of the reactor vessel, primary heat transport system, or containment boundaries.

In the case of the unprotected loss-of-flow event, meltdown of the entire core could not be precluded, and release of the entire core contents to the primary heat transport system could occur. Extensive analysis showed, however, that a core meltdown does not threaten the integrity of the reactor vessel or primary heat transport system. The core contents are released and severely contaminate the primary system, but are not expected to leak from the primary boundary. Although a relatively benign scenario of fuel melting/boilout was predicted, the possibility of energetics from either large-reactivity insertion events or hot-core interaction with outlet plenum sodium (rapid generation/expansion of sodium vapor) could not be precluded. Conservative estimates of the energy releases from these scenarios were made, and it was shown that the reactor vessel, primary heat

transport system, and containment boundaries would remain intact (although some primary sodium was calculated to be expelled through reactor head seals into the Containment Building due to sodium slug impact on the underside of the reactor head).

Since the neutronic and thermal-hydraulic conditions for the proposed new-missions core are expected to be similar to those for the previous FFTF cores (at 400 megawatts), the severe-accident scenarios are also expected to be similar. It should be noted that lower-power (100-megawatt) operation would reduce the severity of severe accidents. It is assumed that all the core fuel assemblies and reflector target assemblies eventually melt during the unprotected loss-of-flow accident. It is further assumed that no mitigating actions are taken to restore core cooling during the event, and that, as a bounding case, all fuel assemblies melt immediately after reactor shutdown with no decay time prior to release from containment, and that an energetic sodium release into containment occurs consistent with the final safety analysis report—stipulated unprotected loss-of-flow accident.

In the final safety analysis report analysis, 136 kilograms (300 pounds) of sodium was assumed to spray into the containment and burn, thereby heating and pressurizing the containment atmosphere. This provides the driving force for leakage from the containment into the environment. The inclusion of up to eight Rapid Radioisotope Retrieval systems provides additional potential leakage paths for sodium ejection into the Containment Building during sodium slug impact on the bottom of the reactor head. An increase in the quantity of sodium ejected from the primary system would cause increased leakage into the environment.

According to the current conceptual design for the Rapid Radioisotope Retrieval system, each system uses a target tube with an inside diameter of 1.89 centimeters (0.745 inch). This leads to a leakage area for eight systems (including the gas target) of 22.5 square centimeters (3.49 square inches). Assuming that the leak rate is proportional to the leakage area leads to an estimated total leakage of approximately 336 kilograms (740 pounds) of sodium from the eight Rapid Radioisotope Retrieval positions during a postulated unprotected loss-of-flow accident. To account for uncertainty in the calculation and to add conservatism to the evaluation, a leakage of 363 kilograms (800 pounds) of sodium was specified as the contribution from the Rapid Radioisotope Retrieval systems. This increases the total sodium leakage into containment from 136 kilograms (300 pounds) to 499 kilograms (1,100 pounds). In addition to the sodium, 100 percent of the noble gases and one percent of the core fuel and fission product inventory were assumed to be released to the containment.

One of the effects of an additional amount of sodium being sprayed into the containment and burned is to increase the pressurization of the containment and hence the amount and rate of release from the containment. Heating of the containment atmosphere due to the 136-kilograms (300-pound) sodium spill resulted in a peak containment pressure of 1.84 pounds per square inch gage. The revised analysis assumes that 499 kilograms (1,100 pounds) of sodium is ejected into the containment, increasing the peak containment pressure to 4.99 pounds per square inch gage.

The sodium is assumed to mix uniformly with the air in the containment and burn completely. In addition, all the heat conducted from the sodium due to its elevated temperature and all of the heat of combustion are used to heat the air in the containment, with no transmission to the walls or structure. The resulting peak containment pressure of 4.99 pounds per square inch gage is well below the containment design pressure of 10 pounds per square inch gage. The release from the containment building is based on the design release rate of 0.5 percent per day for the duration of the pressure buildup (approximately 225 hours).

Assuming 100 percent of the noble gases and tritium in the core is released to the containment, and the containment leaks at 0.5 percent per day for 24 hours, the release fraction for noble gases and tritium is 0.05 ( $.005/24 \times 225 = 0.047 \approx 0.05$ ). Assuming 1 percent of the fission products, fuel, and target inventory is released to the containment, the release fraction for these isotopes is  $5 \times 10^{-4}$  ( $0.05 \times 0.01$ ). Assuming

499 kilograms (1,100 pounds) of the 421,940 kilograms (930,220 pounds) of primary sodium is released to the containment, the release fraction for sodium is  $5.92 \times 10^{-5}$  ( $0.05 \times 1,100/930,220$ ).

The unprotected loss-of-flow event, resulting in a complete core melt, represents the most severe accident analyzed for FFTF. The frequency of this event was estimated to be  $1 \times 10^{-9}$  per year, based on internally initiated events (Dautel 2000). For this analysis, the frequency was increased to  $1 \times 10^{-6}$  to incorporate the spectrum of externally initiated events that could contribute to the severe core melt scenario. The main contributor to the increased frequency is a catastrophic earthquake. The magnitude of potential earthquakes with return periods greater than 10,000 years is highly uncertain. For the purposes of this NI PEIS, it was assumed that an earthquake with a return period of 1 million years would result in sufficient ground motion to cause major damage to FFTF resulting in a core melt scenario. An earthquake of this magnitude could result in severe effects to the entire region, including building collapses, power outages, and road hazards.

The source terms for the beyond-design-basis core melt accident with mixed oxide fuel and highly enriched uranium fuel are presented in **Tables I-17** and **I-18**, respectively.

**Table I-17 Beyond-Design-Basis Accident Source Term—Mixed Oxide Fuel**

## FUEL- AND TARGET-HANDLING ACCIDENTS

A range of accidents related to ex-reactor irradiated fuel- and target-handling were postulated to occur outside of the reactor vessel (i.e., nonreactor accidents). The accident scenarios were selected from the *FFTF Final Safety Analysis Report* (Dautel 2000) and evaluated using the existing FFTF irradiated-fuel source term and new source terms for the neptunium-237 and medical isotope targets. The consequences of ex-reactor accidents involving industrial and civilian nuclear energy research and development targets are expected to be bounded by the accident selected in this NI PEIS.

The accident that would lead to the maximum radiological consequences is a seismic event during fuel assembly transfer. The bottom-loading transfer cask is used to transfer single core components from the containment building to the sodium storage vessel located in the Fuel Storage Facility or to a cask at the cask-loading station in the Reactor Service Building. The bottom-loading transfer cask is qualified to protect a fuel element from breach of cladding during a design-basis earthquake. However, if an element is being transferred into or out of another vessel when a design-basis earthquake occurs, a potential for damage to the component exists. This event is much less likely than the design-basis earthquake because of the small fraction of process time spent in the transfer of an assembly from one vessel to another.

Although the bottom-loading transfer cask is designed to remain upright during a design-basis earthquake at all transfer locations, it could move along the supporting rails during such an event. The probability of a design-basis earthquake is about  $1 \times 10^{-4}$  per year. If an assembly were being transferred through the interface between the bottom-loading transfer cask and the top of the other vessel or a floor valve at the exact moment of a design-basis earthquake, then the movement of the bottom-loading transfer cask could produce bending stresses on the assembly. The likelihood of such an occurrence is on the order of 0.001 per year for the proposed mission, resulting in a combined frequency of  $1 \times 10^{-7}$  for this scenario. Failure of fuel pin cladding as a result of assembly bending is not predicted by analysis. However, for the purpose of showing the depth of protection provided by FFTF against any undue risk to the public health and safety, the conservative assumptions listed below for an extreme beyond-design-basis fuel-handling accident were made in the final safety analysis report and are specified for this reevaluation of a fuel assembly.

- The fuel region of the assembly is in the transfer interface, such that the fuel could be damaged.
- Five percent of the fuel pins are assumed to lose cladding integrity.
- Release fractions are 1.0 for tritium and noble gases, 0.5 for halogens, and 0.05 for volatile solids.
- The release fraction for transuranics and nonvolatile solids is determined as follows: 5 percent of the fuel in the column is crushed and 5 percent of the crushed fuel is of respirable size (equal to or less than 10 microns). A suspension and release fraction of 1 percent is assumed for the respirable particles, i.e., 1 percent is released from the bottom-loading transfer cask and from containment or the Reactor Service Building.
- A 50 percent plateout fraction is assumed for halogens.
- No containment isolation is assumed, and the release is assumed to occur at ground level.

In addition to the mixed oxide and highly enriched uranium fuel assemblies, this accident was analyzed for maximum releases from the neptunium-237 and worst-case medical, industrial, and research and development isotope targets. Because the medical, industrial, and research and development isotope target assemblies have not been structurally analyzed for this type of impact event, all the target assembly rods are assumed to breach. No credible scenario has been identified that could produce temperatures high enough to vaporize target material. Because only one assembly can be accommodated by the bottom-loading transfer cask, the maximum release for this accident is from one fuel or target assembly only.

The radioisotope inventory, release fractions, and resulting environmental release for the mixed oxide and highly enriched uranium assemblies are provided in **Tables I-19 and I-20**.

The bottom-loading transfer cask would be used to transfer the Long-Term Irradiation Vehicle medical isotope targets. Except for the xenon-127 product target, which has a gaseous target material (xenon-126), the chemical and physical forms of the target material have not been decided upon. The release mechanism is assumed to be a breaking or tearing of the cladding tube due to the impact of a heavy object. The recommended bounding airborne release fraction for powder in a can which is broken or torn open due to the impact of a heavy object is 0.001; the respirable fraction, 0.1 (DOE 1994a). This gives a net release fraction of  $1.0 \times 10^{-4}$  for nongases. The release fraction of gases is assumed to be 1.0. The Long-Term Irradiation Vehicle targets were screened using these release fractions, and it was determined that the actinium-227 product target would result in the maximum consequences. The complete radioisotope inventory, release fraction, and resulting environmental release are presented in **Table I-22**. Although the entire radioisotope content of the actinium-227 product target is presented, 98.6 percent of the consequences are attributable to actinium-227 and thorium-228. Over 99.9 percent of the consequences are attributable to six radioisotopes (actinium-227, radium-223, radium-224, radium-226, thorium-227, and thorium-228).

#### I.1.1.4.2 FFTF Standby

The limiting accident for FFTF in its current standby condition is a primary heat transport system sodium spill. This accident has a frequency of about  $1 \times 10^{-4}$  per year. In its standby condition, the FFTF primary sodium is far less radioactive than under the proposed operating conditions. This is mainly because the fuel has been previously removed, but also because the radioactive sodium has had time to decay.

The current radioactive inventory in the primary heat transport sodium is provided **Table I-23**.

**Table I-23 Current FFTF Primary Sodium Activity**

Isotope	Activity (curies)
Hydrogen-3	54.9
Sodium-22	76.0
Cesium-137	0.0384
Plutonium-239	$5.07 \times 10^{-4}$

Source: Nielsen 2000.

The size of the sodium spill is equivalent to that of the design-basis accident (393 kilograms [867 pounds], of which 24.4 kilograms [53.7 pounds] burn). Since the reactor is in a standby condition, no credit is taken for containment holdup of releases. Therefore, the release fraction is simply the ratio of the sodium burned to the total sodium inventory (i.e.,  $53.7/930,220 = 5.77 \times 10^{-5}$ ). The FFTF standby accident source term is provided in **Table I-24**.

**Table I-24 FFTF Standby Accident Source Term**

Isotope	Environmental Release (curies)
Hydrogen-3	0.00317
Sodium-22	0.00439
Cesium-137	$2.22 \times 10^{-6}$
Plutonium-239	$2.93 \times 10^{-8}$

Source: Calculated results.

It should be noted that the radioactive isotopes are continuously reduced by radioactive decay. Examination of the current inventories and dose conversion factors for these isotopes reveals that almost the entire dose would be attributable to plutonium-239 and sodium-22. Plutonium-239 has an extremely long half-life (24,000 years) and therefore its rather small decay would have little effect on consequences for quite some time. Sodium-22, however, has a fairly short half-life (2.6 years), and its decay would have a significant effect on the dose. For instance, after 35 years, only 21 percent of the original dose level would remain.

#### I.1.1.4.3 FFTF Deactivation

The limiting deactivation accident was determined from a review of the *Environmental Assessment, Shutdown of the Fast Flux Test Facility, Hanford Site, Richland, Washington* (DOE 1995). The bounding accident is a sodium spill during the transfer of the primary sodium to a treatment tank. A 9.1-kilogram (20-pound) spill of primary sodium outside the containment is assumed. The release fractions are 100 percent for noble gases and 1 percent for nongases.

The resulting source term, based on current primary sodium radioactivity is presented in **Table I-25**. As noted in the standby accident, the primary sodium radioactivity is continuously being reduced by radioactive decay.

**Table I–25 FFTF Deactivation Accident Source Term**

<b>Isotope</b>	<b>Environmental Release (curies)</b>
Hydrogen-3	0.00118
Sodium-22	$1.63 \times 10^{-5}$
Cesium-137	$8.26 \times 10^{-9}$
Plutonium-239	$1.09 \times 10^{-10}$

**Source:** Calculated results.

The environmental analysis states that the accident frequency is greater than 0.01. For this NI PEIS, the accident frequency is conservatively chosen to be 0.10. This frequency is the probability of a sodium spill during the sodium transfer process. It is a frequency per event rather than per year.

#### **I.1.1.4.4 Meteorological Data**

Meteorological characteristics of the FFTF site are described by 1 year of hourly windspeed, atmospheric stability, and rainfall recorded at the Hanford 400 Area.

#### **I.1.1.4.5 Population Data**

The population distribution surrounding FFTF is based on the 1990 census (DOC 1992). State and county population estimates were examined to extrapolate the 1990 data to the year 2020.

#### **I.1.1.4.6 Evacuation Information**

In the event of an accident, DOE would implement site emergency plans and procedures that include restricting site access, patrolling onsite roads, and relocating members of the public. These actions would significantly reduce the consequences to onsite individuals. DOE sites also coordinate with offsite agencies in the event of an emergency. However, no relocation or evacuation of the offsite population was assumed for FFTF accident analyses. It was assumed that interdiction and condemnation of contaminated crops and foods were implemented based on EPA Protective Action Guides.

#### **I.1.1.5 Low-Energy Accelerator**

A spectrum of potential accidents at a low-energy accelerator used for the production of medical, industrial, and research and development isotopes was investigated. The accidents with the greatest potential for onsite and offsite consequences were evaluated in detail.

##### **I.1.1.5.1 Design-Basis Accident**

The limiting design-basis accident at the low-energy accelerator was determined to be a target assembly handling accident with an estimated probability of  $1.0 \times 10^{-4}$  per year (TechSource 2000).

The accident is assumed to occur one day after the beam is shut off. The medical, industrial, or research and development target is assumed to be damaged from mishandling. One hundred percent of the volatile fission products is assumed to be released from the target into the building. One percent of all the nonvolatile radioisotopes are released into the building. Fifty percent of the released radioisotopes, except noble gases, are assumed to plateout in the building. The radioisotopes which do not plateout are released to the environment through two stages of high-efficiency particulate air (HEPA) filters with a 99.95 percent efficiency for each stage and an activated charcoal filter with an assumed 99 percent iodine removal efficiency.

These assumptions result in a release fraction of  $1.25 \times 10^{-9}$  ( $0.01 \times 0.5 \times 0.0005 \times 0.0005$ ) for the nonvolatile radioisotopes, 0.005 ( $1 \times 0.5 \times 0.01$ ) for iodine, and 1.0 for noble gases. The likely medical, industrial, and research and development targets were screened with these release fractions to determine which target would result in the highest consequences from the target-handling accident. The target with the highest consequence is the iodine-125 product target with an environmental release of 12.7 curies. The likely medical, industrial, and research and development target product inventories are provided in Section I.1.4.2.

#### I.1.1.5.2 Beyond-Design-Basis Accident

The beyond-design-basis accident for the low-energy accelerator is a severe earthquake with an estimated frequency of  $1.0 \times 10^{-5}$  per year (TechSource 2000).

The medical, industrial, or research and development target is assumed to be crushed. One hundred percent of the volatile fission products are assumed to be released from the target into the building. One percent of the nonvolatile radioisotopes are assumed to be released into the building. None of the noble gases, 50 percent of the iodine, and 90 percent of the other radioisotopes are assumed to plateout in the building. The HEPA and charcoal filters are assumed to be destroyed and ineffective.

These assumptions result in a release fraction of 0.001 ( $0.01 \times 0.1$ ) for the nonvolatile radioisotopes, 0.5 ( $1 \times 0.5$ ) for iodine, and 1.0 for noble gases. The likely medical, industrial, and research and development targets were screened with these release fractions to determine which target would result in the highest consequences from the severe earthquake accident. The target with the highest consequence is the actinium-227 product target with the source term presented in **Table I-26**.

**Table I-26 Low-Energy Accelerator Beyond-Design-Basis Accident Source Term**

Isotope	Target Product Inventory <sup>a</sup> (curies)	Release Fraction	Environmental Release (curies)
Actinium-227	$3.40 \times 10^1$	$1.0 \times 10^{-3}$	$3.40 \times 10^{-2}$
Radium-223	$1.96 \times 10^1$	$1.0 \times 10^{-3}$	$1.96 \times 10^{-2}$
Radium-224	$3.88 \times 10^1$	$1.0 \times 10^{-3}$	$3.88 \times 10^{-2}$
Radium-226	$1.43 \times 10^1$	$1.0 \times 10^{-3}$	$1.43 \times 10^{-2}$
Thorium-227	$2.48 \times 10^1$	$1.0 \times 10^{-3}$	$2.48 \times 10^{-2}$
Thorium-228	$4.21 \times 10^1$	$1.0 \times 10^{-3}$	$4.21 \times 10^{-2}$

a. Although the product target contains several other radioisotopes, these six radioisotopes contribute over 99.9 percent of the dose consequences.

#### I.1.1.5.3 Meteorological Data

The meteorological characteristics of the generic accelerator site are assumed to be the same as those for the generic CLWR site and are described in Section I.1.1.3.2.

#### I.1.1.5.4 Population Data

The population distribution surrounding the generic accelerator site is assumed to be the same as that for the generic CLWR site and is described in Section I.1.1.3.3.

#### I.1.1.5.5 Evacuation Information

In the event of an accident, DOE would implement site emergency plans and procedures that include restricting site access, patrolling onsite roads, and relocating members of the public. These actions would significantly reduce the consequences to onsite individuals. DOE sites also coordinate with offsite agencies in the event

of an emergency. However, no relocation or evacuation of the offsite population was assumed for FFTF accident analyses. It was assumed that interdiction and condemnation of contaminated crops and foods were implemented based on EPA Protective Action Guides.

### **I.1.1.6 High-Energy Accelerator**

A spectrum of potential accidents at a high-energy accelerator used for the production of plutonium-238 was investigated. The accidents with the greatest potential for onsite and offsite consequences were evaluated in detail. The meteorological data, population data, and evacuation information for the high-energy accelerator analysis are the same as those used for the low-energy accelerator analysis.

#### **I.1.1.6.1 Design-Basis Accident**

The limiting design-basis accident for the high-energy proton accelerator was determined to be a target assembly handling accident with an estimated probability of  $1.0 \times 10^{-4}$  per year (TechSource 2000).

The target is exposed to the beam for an estimated 99 days. The accident is assumed to occur after the target has been exposed to the beam for the full 99 days and 1 day after the beam is shut off. The target assembly is postulated to be dropped and partially crushed as it is being moved from the beam location to a cooled storage well. Without cooling, the assembly is estimated to begin to melt in 70 minutes. It would take about 1 to 4 hours to retrieve a target assembly and place it in a cooled storage well. It is assumed that 2 hours pass before retrieving the assembly and that the target has begun to melt.

Secondary neutrons produce a number of fissions within the uranium-238 target and the neptunium-237 blanket. The target and blanket generate 2.464 and 0.164 megawatts, respectively, from fission. The quantity of fission products produced in the target and blanket assembly is equivalent to that of a low-power reactor operating at a power level of 2.63 megawatts for 99 days.

In addition to fission products, high-energy protons striking the target also produce spallation products that results in isotopes from several to many mass units lower than the original target nucleus. The heat generated by spallation products is estimated to be 3.32 megawatts (2.604 and 0.719 megawatts in the target and blanket, respectively). The resulting spallation product isotopes were not directly calculated. An estimate was made by noting that approximately one isotope chain results per spall, whereas two result per fission. Therefore, it was assumed that there are one-half as many isotopic chains for the spallation process and that these chains are also comparable to those found in nuclear reactors. Hence, the radionuclides generated by spallation were characterized as having the same composition and quantities as fission products from a reactor operating at a power level of one-half of 3.32, or 1.66 megawatts, for a period of 99 days. This is considered to be conservative since the fraction of spallation products having masses comparable to the more volatile and hazardous fission products such as iodine are estimated to be smaller than the fission product yield of these same isotopes.

The total activity in the target and blanket assembly consists of the target and blanket materials, plutonium-238 and other isotopes produced (e.g., beryllium-7), fission products, and spallation products.

As a result of the accident, 1 percent of all the radioisotopes is assumed to be released into the building. Fifty percent of the released radioisotopes, except noble gases, is assumed to plate out or deposit within the building. The radioisotopes that do not plate out are released to the environment after passing through two stages of HEPA filters with a 99.95 percent efficiency for each stage, and a charcoal filter with an iodine removal efficiency of 99 percent. This results in release fractions of 0.01 for the noble gases,  $5 \times 10^{-5}$  ( $0.01 \times 0.5 \times 0.01$ ) for the iodines, and  $1.25 \times 10^{-9}$  ( $0.01 \times 0.5 \times 0.0005 \times 0.0005$ ) for the nonvolatile radioisotopes. The release

is elevated from a 30-meter-high (98-foot-high) stack. The source term for the design-basis accident is presented in **Table I-27**.

**Table I-27 Accelerator Design-Basis Accident Source Term**

#### I.1.1.6.2 Beyond-Design-Basis Accident

The beyond-design-basis accident for the high-energy accelerator is a severe earthquake with an estimated frequency of  $1.0 \times 10^{-5}$  per year (TechSource 2000). The earthquake is postulated to occur on the 99th day of beam irradiation, rupturing all cooling pipes serving the target assembly. Without cooling, the target assembly is estimated to begin to melt within about 30 minutes.

Five percent of the radioisotopes are assumed to be released into the building. The ventilation systems fail, resulting in a slow radioisotope transport from the building. Because of the slow transport, 90 percent of the radioisotopes (except for the noble gases) are assumed to plate out in the building. It is assumed that the earthquake has also destroyed the HEPA and charcoal filters as well as the stack. These assumptions result in a ground level release with release fractions of 0.05 ( $0.05 \times 1$ ) for the noble gases, and 0.005 ( $0.05 \times 0.1$ ) for the others. The source term for the beyond-design-basis accident is presented in **Table I-28**.

**Table I-28 Accelerator Beyond-Design-Basis Accident Source Term**

Isotope	Activity in Target and Blanket (curies)	Activity from Fission Products (curies)	Activity from Spallation Products (curies)	Total Activity (curies)	Release Fraction	Environmental Release (curies)

### I.1.1.7 New Research Reactor

The new research reactor would produce a number of long- and short-lived isotopes for medical and industrial applications and 5 kilograms (11 pounds) of plutonium-238 per year for space power applications. The new research reactor would contain 48 neptunium-237 target assemblies, each assembly consisting of four neptunium-237 target rods. The maximum plutonium-238 produced in each target rod is 27.6 grams (0.97 ounce). The reactor would also contain eight medical and industrial target assemblies, each assembly consisting of two medical and industrial target rods. The reactor would also contain eight rabbit tubes for short-irradiation-time production of medical or industrial isotopes and civilian nuclear energy research and development. The rabbit tubes are outside the fuel region of the core, but still within an area with a rather high flux. Detailed descriptions of the new research reactor are provided in Appendix E. The meteorological data, population data, and evacuation information for the new research reactor analysis are the same as those used for the low-energy accelerator analysis.

#### I.1.1.7.1 Design-Basis Accident

A spectrum of accidents was reviewed according to the guidance provided in NUREG-1537 (NRC 1996). It was concluded that the maximum hypothetical accident is an accident whose potential consequences would exceed and bound all credible accidents. The accident scenario was assumed to represent the design-basis accident for the new research reactor.

Operational incidents leading to loss of coolant, loss of flow, loss of normal electrical power, and reactivity insertion would not result in any fuel damage. The built-in safety features of the new research reactor, such as elevation of the spent fuel pool system above the core, elevation of primary piping above the core, and antisiphon devices, would preclude loss of core cooling capability. The inherent large prompt negative fuel temperature coefficient of reactivity, would minimize the effect of accidental reactivity insertion. The reactivity insertion would cause a sudden increase in reactor power, leading to a higher fuel temperature which,

in turn, because of its large negative temperature coefficient of reactivity, would shut down the reactor. The design of the control rods would limit reactivity insertion below that which could cause any fuel failure.

The design-basis accident for the reactor is cladding failure of a single irradiated element (NRC 1996). The single fuel element could fail due to material deficiencies at any time during normal operation or while the reactor is shut down. Judging from experience with TRIGA (training, research, isotopes General Atomics) fuels, this type of failure is considered infrequent (a likelihood of 1 in 100 years) (UC-Davis 1999). For the new research reactor, it was assumed that the cladding of all fuel rods in an assembly (a maximum of 64 rods) would fail at any time during normal reactor operation. Further, it was assumed that this event would occur in an irradiated fuel assembly with high burnup. This accident was assumed without any consideration of mechanisms that could cause the failure of all cladding. The accident would cause the gaseous fission products and halogens collected in the fuel-clad gap to be released to the reactor pool. The likelihood of such an event was assumed to be 1 in 10,000 years.

The failed fuel assembly was assumed to have been operated at a power density 2.25 times that of the average. It was assumed that the assembly had a burnup of 5,157 megawatt days, which would occur at the end of a 10-year fuel cycle.

The fraction of fission gases released to the fuel-clad gap depends on the operating temperature of the fuel. Based on the calculated fuel temperature for the peak rod of less than 300 °C (572 °F), the fraction of volatile fission products that would escape the fuel material would be  $1.5 \times 10^{-5}$  (Simnad 1980; West, Simnad, and Copeland 1986). For this analysis, the fractional release was conservatively assumed to be  $1 \times 10^{-4}$ , which corresponds to an average operating fuel material temperature of 490 °C (914 °F).

One hundred percent of the noble gases and tritium gas collected in the fuel-clad gap would be released from the fuel assembly and subsequently enter the reactor room. Twenty-five percent of the halogens in the fuel-clad gap would be released from the fuel assembly, and 90 percent of the released halogens would be absorbed in the 9.1-meter-deep (30-foot deep) reactor pool before entering the reactor room. All the radioactive noble gases and halogens that were released to the reactor room are assumed to enter the environment through the reactor building exhaust stack after passing through an activated charcoal filter. The charcoal filter is assumed to remove 99 percent of the halogens (NRC 1978). These assumptions result in an overall release fraction of  $1 \times 10^{-4}$  for the noble gases and tritium gas and  $2.5 \times 10^{-8}$  ( $10^{-4} \times 0.25 \times 0.1 \times 0.01$ ) for the halogens.

A neptunium-237 target assembly is assumed to be damaged along with the fuel assembly. The same release fractions are assumed for the neptunium-237 target as the fuel.

The release to the environment is assumed to occur over 1 hour without decay. This assumption is conservative, because the concentration of the fission products in the reactor room would activate the emergency ventilation system, thereby reducing the room air exchange rate and extending release duration, thus resulting in further decay of the short-lived isotopes.

The radioactive noble, tritium, and halogen gases that would be released to the environment from the design-basis accident scenario are provided in **Table I-29**.

#### **I.1.1.7.2 Fuel- and Target-Handling Accidents**

Fuel movements would occur once every 10 years when the whole core (68 fuel assemblies) would be replaced with fresh fuel assemblies. Neptunium-237 target movements would occur once a year. Each year, the irradiated target rods would be removed from the fuel assemblies, packaged in cans, and transferred to the

spent fuel pool for temporary cooling and storage. The medical and industrial isotope movements would occur more frequently depending on the isotope. The likelihood of a fuel assembly or target drop is estimated to be in the range of 0.01 to 0.0001 per year, or an unlikely event. For this analysis, the likelihood is estimated to be 0.01 per year.

The drop of a fuel assembly could lead to releases of radioactive fission gases. Since the fuel rods are protected by the assembly shroud, fuel damage would be minimal. It is assumed that the drop would damage one fuel rod, releasing the gaseous fission products and halogens to the reactor pool. It is also assumed that the earliest fuel movement would start about 24 hours after the reactor was shut down. Since handling activities would be performed under 3 meters (10 feet) of water, the halogens and gaseous fission products release fractions are assumed to be the same as those for the design-basis accident. The estimated radioactive material release from this accident is provided in **Table I-30**.

A neptunium-237 target assembly consists of four target rods, each containing approximately 27.6 grams (0.97 ounces) of plutonium-238. As these rods are not protected, a drop could lead to a breach of all four.

The target rods are made from neptunium oxides. The fission gas release fraction from the target material to the gap would be similar to that from uranium oxides. Fractional fission gas release was estimated using American National Standards Institute 5.4 (ANSI 1982) and the low-temperature release calculation method. Target rod temperature is not expected to be greater than that of the cladding temperature of an average-power-density fuel rod (approximately 80 °C [176 °F]). For an estimated target rod burnup of

Iodine-135	109	$2.73 \times 10^{-6}$

706 megawatt days per metric ton of heavy metal, about 0.01 percent of both the long- and short-lived noble gases and halogen gases would be available for release.

As in the fuel-handling accident, 100 percent of the noble and tritium gases in the fuel-clad gap would be released to the environment through the reactor building exhaust system. This results in an overall release fraction of  $1 \times 10^{-4}$  for the noble gases and tritium. Twenty-five percent of the iodine in the fuel-clad gap would be released from the fuel assembly, and 90 percent of the released iodine would be absorbed in the reactor pool. The remaining iodine would be released to the environment through the Reactor Building exhaust system. The exhaust system charcoal filter is assumed to remove 99 percent of the iodine (NRC 1978). This results in an overall release fraction of  $2.5 \times 10^{-8}$  ( $10^{-4} \times 0.25 \times 0.1 \times 0.01$ ) for the iodine.

These assumptions result in the source term shown in **Table I-31**.

Medical, industrial, and research and development isotope targets could also be damaged from a drop accident. Only targets which produce noble gases and halogens either as products or byproducts (including decay) need be considered for analysis. Since the fuel-handling activities are performed under 3 meters (10 feet) of water, these will be the isotopes that have releases to the environment. The iodine-125 product target consequences bound those of the other possible medical and industrial isotope targets.

The iodine-125 product target is assumed to release 100 percent of its inventory to the water. Interaction with the water removes 90 percent of the iodine. The building exhaust system charcoal filters then removes 99 percent of the iodine released from the water. This results in a release fraction of 0.001. The iodine-125 product target would contain approximately 2,530 curies of iodine-125. The estimated radioactive material release from this accident is 2.53 curies of iodine-125.

**Table I-31 Neptunium-237 Target-Handling Accident Source Term**

a. Contains 110.4 grams of plutonium-238 (four target rods of 27.6 grams of plutonium-238).

### I.1.1.7.3 Beyond-Design-Basis Accident

The beyond-design-basis accident assumes an earthquake with sufficient energy to cause structural and equipment failure. The likelihood of such an event was assumed to be the equal to the Reactor Building performance goal for a Performance Category 4 structure. The performance goal for the Reactor Building is  $1 \times 10^{-5}$ , a safety factor of 10 over the return period of 1 in 10,000 years for a Performance Category 4 structure (DOE 1994b). Performance Category 4 is the highest deterministic seismic design criteria for structures, systems, and components in accordance with DOE standards (DOE 1993, 1994b). A performance goal of  $1 \times 10^{-5}$  refers to the annual probability that a seismic event would cause damage to a component so that it could not perform its function. Therefore, an earthquake level with a return period of 1 in 100,000 years was assumed to initiate the beyond-design-basis accident. Since both the reactor pool and the spent fuel pool would be designed to withstand a higher-level earthquake than that for Performance Category 4, no failure of these pools was assumed. However, it was assumed that the equipment and systems that support these pools would fail. Further, it is assumed that the earthquake would initiate reactor scram (loss of power would cause the control rods to drop in the reactor core), damage the cooling pipe outside of the reactor pool, and possibly breach the reactor room confinement.

Since the accident would not result in a loss of reactor pool coolant below the level at which primary piping leaves the pool and the reactor shuts down, sufficient coolant would be available to keep the core covered for

at least 40 days after the accident. For this analysis, it was assumed that the fuel-handling crane above the pool would fall into the pool and damage the core tank and fuel rods inside the core. This assumption is conservative since the top of the core tank would be 0.61 meters (2 feet) above the top of the fuel assemblies acting as a chimney to enhance natural-convection core cooling during reactor shutdowns. In addition, the top of the active fuel is another foot below the top of the fuel assembly. Therefore, the crane would have to damage both the upper core barrel and the top of the fuel assemblies before it could damage the fuel. Nevertheless, it was assumed that the drop would cause fuel damage.

The drop was assumed to cause releases of all gaseous fission products and halogens through the pool water directly to the environment, bypassing the charcoal filter and the building exhaust stack. For the fuel and neptunium-237 targets, the release fractions are  $1 \times 10^{-4}$  for the noble gases and tritium and  $2.5 \times 10^{-6}$  for the halogens. For the medical isotope targets, the release fractions are 1.0 for noble gases and 0.1 for halogens.

The new research reactor core consists of 68 fuel assemblies with a total of 4,080 fuel rods; 48 neptunium-237 assemblies with 4 target rods each; 8 medical, industrial, and research and development target assemblies with 2 target rods each; and 8 rabbit tubes. For this analysis, the 8 medical, industrial, and research and development target assemblies are assumed to contain the xenon-127 product target. The rabbit tubes would contain 7 iodine-131 product targets and 1 iodine-125 product target. This core configuration results in the highest consequences from accidental releases.

This core configuration and these release fraction assumptions result in the source term presented in **Table I-32**.

- a. Fuel inventory lists only those isotopes with an environmental release.
- b. Medical, industrial, and research and development inventory lists only the isotopes with the highest environmental release.
- c. Neptunium-237 inventory lists only those isotopes with an environmental release.
- d. Based on a 5-kilogram-per-year plutonium-238 production rate.

#### **I.1.1.7.4 Decontamination and Decommissioning Accidents**

The decontamination and decommissioning activities would be performed according to a preestablished plan, known as the decommissioning plan. Activities would include decontamination and dismantling of reactor components, removal of spent nuclear fuel, cleaning and removal of the reactor pool and spent fuel pool water, decontamination and dismantling of equipment and structures, and preparation of the site for unrestricted use. These activities could potentially result in an accidental release of radioactive material. Radioactive releases could occur from improper cutting of activated components and equipment, dropping of a radioactively contaminated component, and from spills of contaminated liquids. The potential on- and offsite impacts of accidents would be expected to be less than, or within, the values estimated for occurrences during normal operations.

At this preconceptual research reactor design stage, the major areas with the greatest inventory of radioactivity would be the spent fuel pool and the components within the reactor pool and primary coolant system. The spent fuel pool would contain about 272 spent fuel assemblies, that is, four full core loads. The minimum decay times for each assembly would range between 5 and 30 years. The assumption is that spent fuel removal would begin 5 years after the last core was removed from the reactor. Once the fuel assemblies were removed from the core, the beryllium reflector and the reactor core tank would contain the highest radioactive inventory of tritium and cobalt-60 in the reactor pool area.

A spectrum of accidents was evaluated considering activities that would occur during decontamination and decommissioning of the research reactor and support facility. It was determined that two accidents had the greatest potential for onsite and offsite impacts: a drop of a spent nuclear fuel cask during fuel removal and an accidental vaporization of a small segment of the reactor core tank during dismantlement.

##### **SPENT FUEL CASK DROP ACCIDENT**

The lifting capability of the spent fuel pool crane would be limited to truck-sized spent nuclear fuel transportation casks that would be used to move the spent fuel to a central storage location. The cask would be loaded under water, the cask cover would be installed but not tightly sealed, and the cask raised above the water where it would be sprayed with demineralized water before it was put on the ground for decontamination and draining of pool water. The cask then would be sealed, backfilled with inert gas, and moved to be loaded onto the truck trailer bed. The maximum lift would be less than 9.1 meters (30 feet) above the pool floor, or less than 30 centimeters (1 foot) above the spent fuel pool building floor level.

A spent nuclear fuel cask was assumed to drop while it was stopped to be rinsed. The drop would not damage the cask or the spent fuel pool liner. The cask is designed to withstand a drop from 9.1 meters (30 feet) onto an unyielding surface without failure. The cask would not be lifted above 9.1 meters (30 feet) above the ground, and the drop over the spent fuel pool would hit the pool surface which provides 7.62 meters (25 feet) of water acting as a damper, reducing the impact velocity. Therefore, no damage to the spent fuel pool liner would be expected.

The fuel rods in the cask would be protected from damage not only by the cask, but also by the assembly shroud. However, for this analysis, it was assumed that one row of fuel in one assembly would fail and release the gaseous fission products from the fuel-clad gap. The fraction of fission gases released to the fuel-clad gap was conservatively assumed to be  $1 \times 10^{-4}$ . One hundred percent of the noble gases and tritium gas in the fuel-clad gap would be released through the pool to the reactor room. Twenty-five percent of the halogens in the fuel-clad gap would be released and 90 percent of the released halogens would be absorbed in the reactor pool before entering the reactor room. All the noble gases, tritium, and halogens that enter the reactor room would be released to the environment through the reactor building exhaust system after passing through an

activated charcoal filter. The charcoal filter was assumed to remove 99 percent of the halogens (NRC 1978). These assumptions result in a release fraction of  $1 \times 10^{-4}$  for noble gases and tritium and  $2.5 \times 10^{-8}$  for halogens.

The likelihood of such an accident was estimated to be less than 5 in 1 million, or  $5 \times 10^{-6}$  per year. This estimate was derived from a recent NRC technical study of spent fuel accident risk at decommissioning nuclear power plants (NRC 2000). Based on an assumption of 100 heavy-load cask lifts per year, the NRC estimated a cask drop mean frequency of  $9.6 \times 10^{-6}$  per year. Considering that the total number of spent fuel cask lifts at this facility would be less than 40, assuming that all the fuel would be shipped offsite in a year, the cask drop frequency would be less than  $5 \times 10^{-6}$  per year for that year.

For analysis, the frequency of this accident was assumed to be  $5.0 \times 10^{-6}$  per year. The source term for the spent fuel cask drop accident is presented in **Table I-33**.

**Table I-33 Spent Fuel Cask Drop Accident Source Term**

Isotopes	Fuel Assembly - Fission Gas and Halogen Inventory (curies)	Eight Fuel Rods - Fission Gas and Halogen Inventory (curies)	Release Fraction	Environmental Release (curies)
Hydrogen-3 (tritium)	$2.12 \times 10^1$	2.65	$1.00 \times 10^{-4}$	$2.65 \times 10^{-4}$
Krypton-85	$1.44 \times 10^3$	$1.80 \times 10^2$	$1.00 \times 10^{-4}$	$1.80 \times 10^{-2}$
Iodine-129	$1.86 \times 10^3$	$2.33 \times 10^4$	$2.50 \times 10^{-8}$	$5.81 \times 10^{-12}$

## REACTOR CORE TANK VAPORIZATION ACCIDENT

An accidental vaporization of a small segment of the reactor core tank during size reduction was assumed. The stainless steel reactor core tank would need to be cut into pieces in order to be transported offsite. The major activation product in the tank would be cobalt-60, with an inventory of 359 curies after a 5-year decay time. Plasma torches would most likely be used for the process. The cutting process would occur with strict radiological controls under a tent with proper ventilation to collect any vaporized particulates. The vaporized particulates would be passed through HEPA filters before exhausting to the environment.

For this analysis, it was assumed that the exhaust system would fail and that the torch would not shut down and would vaporize a small segment of the tank. It was assumed that the torch would burn through the wall of the tank creating a 6.25-square centimeter (1-square inch) hole in the wall. The frequency of this accident was assumed to be  $1 \times 10^{-4}$ . The source term for the reactor core tank vaporization accident is estimated to be 0.026 curies of cobalt-60 released directly to the environment.

### I.1.2 Methodology for Estimating Irradiation Facility Accident Radiological Impacts

The MACCS2 computer code (Version 1.12) was used to estimate the consequences of the postulated accidents. A detailed description of the MACCS model is provided in NUREG/CR-4691 (Chanin et al. 1990). The enhancements incorporated in MACCS2 are described in the MACCS2 User's Guide (Chanin and Young 1997). Originally developed to model the radiological consequences of nuclear reactor accidents, this code has been used for the analysis of accidents for many EISs and other safety documentation, and is considered applicable to the analysis of accidents associated with the production of plutonium-238 and other proposed isotopes.

MACCS2 models the offsite consequences of an accident that releases a plume of radioactive materials to the atmosphere. Should such an accidental release occur, the radioactive gases and aerosols in the plume would be transported by the prevailing wind and dispersed into the atmosphere, and the population would be exposed

to radiation. The atmospheric dispersion is modeled on a polar-coordinate spatial grid centered on the facility and extending out to 80 kilometers (50 miles). The user specifies the number of radial divisions and their endpoint distances. The angular divisions used to define the spatial grid correspond to the 16 directions of the compass. MACCS2 generates the distribution of downwind doses at specified distances, as well as the distribution of population doses.

Radiological consequences may vary somewhat as a result of variations in the duration of release. For longer releases, there is a greater chance of plume meander (i.e., changes in flow attributable to variations in wind direction over the duration of release). MACCS2 models plume meander by increasing the lateral dispersion coefficient of the plume for longer release durations, thus lowering the dose. The other effect of longer release durations is involvement of a greater variety of meteorological conditions in a given release, which reduces the variance of the resulting dose distributions. This would tend to lower high-percentile doses, raise low-percentile doses, and have no effect on the mean dose.

The MACCS2 code was applied in a probabilistic manner using a weather bin–sampling technique. The weather bin–sampling method sorts weather sequences into categories and assigns a probability to each category according to the initial conditions (wind speed and stability class) and the occurrence of rain. Each of the sampled meteorological sequences was applied to each of the 16 sectors accounting for the frequency of occurrence of the wind blowing in that direction (i.e., site compass sector wind rose frequencies). Individual doses, as a function of distance and direction, were calculated for each of the meteorological sequence samples. The mean dose values of the sequences were generated for each of the 16 sectors. The highest of these dose values was used as the dose delivered to the maximally exposed offsite individual and the noninvolved worker. Population doses within 80 kilometers (50 miles) of each facility were also calculated.

In addition to short-term health effects of exposure to the plume passage, long-term effects were also modeled. The long-term health effects include direct exposure to contaminated ground and inhalation of resuspended materials, as well as indirect health effects of the consumption of contaminated food and water. Long-term protective measures such as decontamination, temporary relocation, contaminated crops, milk condemnation, and prohibition of farmland production are based on EPA Protection Action Guides.

For each potential accident, information is provided on accident consequences and frequencies to three types of receptors: (1) a noninvolved worker, (2) the maximally exposed individual, and (3) the offsite population. The first receptor, a noninvolved worker, is a hypothetical individual working on site but not involved in the proposed activity. The worker is assumed to be downwind at a point 640 meters (0.4 miles) from the accident. Although other distances closer to the accident could have been assumed, the calculations break down at distances of about 200 meters (656 feet) or less due to limitations in modeling of the effects of building wake and local terrain on dispersion of the released radioactive substances. A worker closer than 640 meters (2,100 feet) to the accident would generally receive a higher dose; a worker farther away, a lower dose. The second receptor, the maximally exposed individual, is a hypothetical individual assumed to be downwind at the site boundary or on a highway within the site boundary, whichever results in a higher dose. Exposures received by this individual are intended to represent the highest doses to a member of the public. The third receptor, the offsite population, is all members of the public within 80 kilometers (50 miles) of the accident location.

It is possible that an individual member of the public could be closer to a facility than either the site boundary or the nearest onsite highway. However, such individuals would be present only occasionally and for brief periods (a few hours or more). Hence, the annual probability that an individual would be close is relatively low, and the associated risk to that individual would be bounded by the site boundary or onsite highway maximally exposed individual risk.

For the CLWR analysis, a noninvolved worker was not evaluated for two reasons. First, the noninvolved worker was originally developed for large DOE sites, where several different facilities are under facility-specific control. The noninvolved worker is an individual not under specific facility control, but also not outside the site boundary. At a CLWR, however, the entire site is within the exclusion area and under the same control.

Second, each accident scenario has a warning time and a subsequent release time. The warning time is the time at which notification is given to offsite emergency response officials to initiate protective measures for the surrounding population. The release time is the time when the release to the environment begins. The minimum time between the warning time and the release time for this analysis is 20 minutes. Twenty minutes is enough time to evacuate onsite personnel. It is also conservatively assumed that an onsite emergency has not been declared prior to initiating offsite notification.

Consequences to involved workers are addressed in Section I.1.7.

All radiological impacts are calculated in terms of committed dose and associated health effects for an individual or exposed population. The radiation dose calculated is the total effective dose equivalent, which is the sum of the effective dose equivalent from the external radiation exposure and the 50-year committed effective dose equivalent from internal radiation exposure. Radiation doses are presented in units of rem for individuals and person-rem for a population. The impacts are further expressed as health risks, specifically in terms of latent cancer fatalities.

The health risks for a noninvolved worker and the maximally exposed offsite individual are expressed as the additional potential or likelihood of a latent cancer fatality. The health risk to the population is expressed as the increased number of latent cancer fatalities.

The probability coefficients for determining the likelihood of latent cancer fatality, given a dose, are taken from the *1990 Recommendations of the International Commission on Radiological Protection* (ICRP 1991). For low doses or dose rates, respective probability coefficients of 0.0004 and 0.0005 fatal cancer per rem are applied for workers and the general public. For high doses received at a high rate, respective probability coefficients of 0.0008 and 0.001 fatal cancer per rem are applied for noninvolved workers and the public. These higher probability coefficients apply where doses are above 20 rad or dose rates are above 10 rad per hour.

Tritium releases were modeled as tritiated water vapor rather than elemental tritium. Tritiated water is more effectively absorbed by humans and therefore results in a much greater health hazard.

### **I.1.2.1 Uncertainties**

The analyses of accidents are based on calculations relevant to hypothetical sequences of events and models of their effects. The models provide estimates of the frequencies, source terms, pathways for dispersion, exposures, and the effects on human health and the environment that are as realistic as possible within the scope of the analysis. In many cases, the scarcity of experience with the accidents postulated leads to uncertainty in the calculation of their consequences and frequencies. This fact has prompted the use of models or input values that yield conservative estimates of consequence and frequency. All alternatives have been evaluated using uniform methods and data, allowing for a fair comparison of all alternatives.

Of particular interest are the uncertainties in the estimate of cancer deaths from exposure to radioactive materials. The numerical values of the health risk estimates used in this NI PEIS were obtained by the practice of linear extrapolation from the nominal risk estimate for lifetime total cancer mortality resulting from

exposures at 10 rad. Other methods of extrapolation to the low-dose region could yield higher or lower estimates of cancer deaths. Studies of human populations exposed at low doses are inadequate to demonstrate the actual level of risk. There is scientific uncertainty about cancer risk in the low-dose region below the range of epidemiological observation, and the possibility of no risk or even health benefits (hormesis effects) cannot be excluded. Because the health risk estimators are multiplied by conservatively calculated radiological doses to predict fatal cancer risks, the fatal cancer values presented in this NI PEIS are expected to be overestimates.

For the purposes of presentation in this NI PEIS, the impacts calculated from the linear model are treated as an upper-bound case, consistent with the widely used methodologies for quantifying radiogenic health impacts. This does not imply that health effects are expected. Moreover, in cases where the upper-bound estimators predict a number of latent cancer deaths that is greater than 1, this does not imply that the latent cancer death can be determined for a specific individual.

### **I.1.3 Irradiation Facility Accident Consequences and Risks**

The irradiation facility accident source term data presented in Sections I.1.1.2–I.1.1.7 were evaluated using the MACCS2 accident analysis computer code. **Tables I–34** through **I–41** summarize the consequences and risks of the accidents, with mean meteorological conditions, for the maximally exposed individual, the offsite population within an 80-kilometer (50-mile) radius of the facility, and a noninvolved worker 640 meters (2,100 feet) from the release point. As explained in Section I.1.2, noninvolved worker consequences were not evaluated for the CLWR accidents.

**Table I–34** presents ATR accident consequences and risks for three possible plutonium-238 production rates: 0, 3, and 5 kilograms (0, 6.6, and 11 pounds) per year.

**Table I–35** presents HFIR accident consequences and risks for two possible plutonium-238 production rates: 0 and 2 kilograms (0 and 4.4 pounds) per year.

**Table I–36** presents CLWR accident consequences and risks for two possible plutonium-238 production rates: 0 and 5 kilograms (0 and 11 pounds) per year.

Severe-accident scenarios that postulate large, abrupt releases could result in early fatalities if the radiation dose were sufficiently high. For the irradiation facilities analyzed, early fatalities are postulated only for the early containment failure and containment bypass event at the generic CLWR.

**Table I–37** presents CLWR-estimated early fatalities and associated risks for two possible plutonium-238 production rates: 0 and 5 kilograms (0 and 11 pounds) per year.

**Table I–38** presents FFTF accident consequences and risks for simultaneous medical, industrial, research and development, and plutonium-238 production for both mixed oxide and highly enriched uranium fuels.

**Table I–39** presents accelerator accident consequences and risks for medical, industrial, research and development, and plutonium-238 isotope production.

**Table I–40** presents new research reactor accident consequences and risks for the simultaneous medical, industrial, research and development, and plutonium-238 isotope production.

**Table I–41** presents new research reactor decontamination and decommissioning accident consequences and risks.

Containment early failure ( $7.92 \times 10^{-8}$ )	0	3350	1.00 <sup>e</sup>	$7.92 \times 10^{-8(f)}$	$1.80 \times 10^6$	1,250	$9.89 \times 10^{-5}$
	5	3670	1.00 <sup>e</sup>	$7.92 \times 10^{-8(f)}$	$1.90 \times 10^6$	1,340	$1.06 \times 10^{-4}$
Containment late failure ( $1.07 \times 10^{-5}$ )	0	1.11	$5.55 \times 10^{-4}$	$5.94 \times 10^{-9}$	$1.06 \times 10^5$	53.6	$5.74 \times 10^{-4}$
	5	1.12	$5.60 \times 10^{-4}$	$5.99 \times 10^{-9}$	$1.06 \times 10^5$	53.6	$5.74 \times 10^{-4}$
LOCA ( $4.65 \times 10^{-5}$ )	0	0.0312	$1.56 \times 10^{-5}$	$7.25 \times 10^{-10}$	186	0.0931	$4.33 \times 10^{-6}$
	5	0.0313	$1.57 \times 10^{-5}$	$7.30 \times 10^{-10}$	187	0.0935	$4.35 \times 10^{-6}$
Containment bypass ( $1.53 \times 10^{-6}$ )	0	1540	1.00 <sup>e</sup>	$1.53 \times 10^{-6(f)}$	$1.45 \times 10^6$	922	$1.41 \times 10^{-3}$
	5	1680	1.00 <sup>e</sup>	$1.53 \times 10^{-6(f)}$	$1.52 \times 10^6$	978	$1.49 \times 10^{-3}$

- a. Likelihood of a latent cancer fatality assuming the accident occurred.
- b. Increased likelihood of a latent cancer fatality per year.
- c. Number of latent cancer fatalities assuming the accident occurred. MACCS2 calculates the dose to each exposed individual in the population, applies the appropriate cancer risk factor, and then sums the individual probabilities to determine the number of latent cancer fatalities.
- d. Increased number of latent cancer fatalities per year.
- e. Early fatality due to radiation dose assuming the accident occurred. A radiation dose of 450 to 500 rem causes fatalities in 50 percent of those exposed. Early fatalities are expected for exposures greater than 600 rem.
- f. Increased likelihood of an early fatality per year.

## **I.1.4 Processing Facility Accident Scenario Selection and Description**

### **I.1.4.1 Plutonium-238 Processing**

For the processing facilities, a spectrum of accidents was developed that considered a full range of accidents associated with such facilities. The scenarios evaluated, however, represent bounding cases that are considered to envelop the risk profile.

The processing facility accidents presented in the ORNL Radiochemical Engineering Development Center (REDC) Safety Analysis Report for Building 7920 (ORNL 1999) were reviewed for evaluation in this NI PEIS. Process and facility details were based on the preconceptual design study to support plutonium-238 production (Wham et al. 1998). Since process details at the Fluorine Dissolution Processing Facility (FDPF) and the Fuel and Materials Examination Facility (FMEF) are essentially the same as those at REDC, the same spectrum of accidents was evaluated for all the processing facilities. However, facility differences were accounted for in evaluating the consequences of these accidents.

Several design-basis accidents were selected for inclusion in this NI PEIS. These include:

1. A postulated explosion in a glovebox during neptunium-237 target fabrication, representing the glovebox-handling accident having the largest potential consequences
2. A postulated failure of the target dissolver tank containing both neptunium-237 and plutonium-238, representing the accidental spill having the greatest consequences
3. A postulated explosion of an ion exchange column during plutonium-238 purification, which has the potential to release more plutonium-238 than any other processing facility design-basis accident.

A fire in a hot cell was judged to have lower consequences than an explosion, and was not included in this NI PEIS. This is based on an extensive experimental investigation (Hasegawa et al. 1992), which concluded that a fire in a hot cell would not represent a threat to the effectiveness of the facility roughing or HEPA filters and would be self-extinguishing within a short time from lack of oxygen.

Criticality accidents were not evaluated in this NI PEIS because the risk of accidental criticality, given appropriate administrative and process controls, is considered to be very low. Both neptunium-237 and plutonium-238 would be stored in shielded containers in quantities and configurations that preclude criticality. Target preparation and postirradiation processing will be carried out in batches involving quantities well below those at which criticality could occur. As a result, a criticality accident could occur only as a result of a series of gross, deliberate violations of established controls.

The postulated beyond-design-basis processing facility accident selected for use in this NI PEIS is a catastrophic earthquake resulting in a collapse of the nearby stack and failure of the HEPA filter system intended to mitigate the consequences of releases. Two cases of this accident were evaluated. Case 1 assumed that the facility was only being used to store neptunium-237. Case 2 assumed that the facility was an integrated storage, target fabrication, and irradiated-target-processing facility.

| The waste stream from the irradiated targets would be processed in the same facilities as the irradiated targets.  
| Accidents occurring during the processing of the waste stream were not evaluated in this NI PEIS because their  
| consequences are bounded by the irradiated target accidents that have been evaluated.

#### I.1.4.1.1 Design-Basis Accidents

##### ION EXCHANGE EXPLOSION DURING NEPTUNIUM-237 TARGET FABRICATION

An accident can occur during fabrication of the neptunium-237 targets. As part of the target preparation, 1-kilogram (2.2-pound) quantities of neptunium-237 solution are processed (Wham et al. 1998) to yield neptunium in an oxide form for use as a target material. This operation takes place in a shielded glovebox and involves use of an ion exchange column. This accident scenario postulates an explosion of the ion exchange column in the glovebox. Judging from historical occurrences of this type of accident at radiochemical laboratories and processing facilities, the frequency of this event is “unlikely” (between  $1 \times 10^{-2}$  and  $1 \times 10^{-4}$  per year) (ORNL 1999). For the purpose of this NI PEIS, the accident frequency is assumed to be  $1 \times 10^{-2}$  per year.

The glovebox is maintained at a slight negative pressure with respect to that portion of the building outside the hot cells, and is continually exhausted to the atmosphere through roughing filters and HEPA filters, and via a stack.

An explosion is estimated to release essentially all of the neptunium-237 into the glovebox. Additional data to calculate releases were taken from relevant facility data (ORNL 1999; Green 1998, 1999) and other accepted sources (DOE 1994a). Since an explosion involves small quantities of materials, any increase in pressure is expected to be small and is not expected to result in transitory leakage of radioactive material from the glovebox into the operating area.

The glovebox is exhausted through roughing filters and then through two banks of HEPA filters arranged in series outside the building and then to the environs via a stack. Each bank of the HEPA filters is assumed to remove 99.95 percent of all particulates at or above a size of 0.3 micron (Burchsted et al. 1976). (Note: This assumes two HEPA filters are in series and each is 99.95 percent efficient, yielding a  $2.5 \times 10^{-7}$  reduction factor.)

Airborne releases can be divided into respirable (smaller than about 10 microns) and nonrespirable fractions. Nonrespirable airborne particles can cause localized onsite contamination, but they do not contribute significantly to offsite doses for several reasons. For design-basis accidents, the filter efficiency for the larger, nonrespirable particles is greater than that for all particles of the respirable fractions, and significantly greater than the minimum value of 99.95 percent for 0.3-micron particles. For the beyond-design-basis earthquake, where filters are postulated to be ineffective, leakage from the hot cells is at a low rate, allowing for increased deposition and settling of the larger particles prior to release. Even where large, nonrespirable particles are released to the environment, their atmospheric transport is limited and they will “fall out” within a short distance from the release point.

**Table I-42** shows the release fractions and source terms for this accident.

**Table I-42 Neptunium-237 Target Preparation Accident Source Terms**

Analysis Parameters	Units
Neptunium-237 inventory in glovebox	1,000 grams
Neptunium-237 released into glovebox from explosion	1,000 grams
Airborne release fraction times respirable particle fraction	$7 \times 10^{-2}$
Leak path factor	0.50
Neptunium-237 reaching HEPA filters	35.0 grams
Neptunium-237 released from stack to environs	$8.75 \times 10^{-6}$ grams

Source: Calculated results.

### TARGET DISSOLVER TANK FAILURE DURING PLUTONIUM-238 SEPARATION

A hypothetical accident considered was the failure of a tank in which irradiated neptunium-237 targets are to be dissolved. The irradiated neptunium-237 target processing is planned to be carried out in approximately five batches per year. Each batch of irradiated targets is expected to contain approximately 1 kilogram (2.2 pounds) of plutonium-238 and 8 to 10 kilograms (17.6 to 22 pounds) of neptunium-237. A complete failure of the dissolver tank envelops a spectrum of accidental spills involving plutonium-238 in the hot cells. The complete failure of this tank is judged to be unlikely (between  $1 \times 10^{-2}$  and  $1 \times 10^{-4}$  per year) (ORNL 1999). For the purpose of this NI PEIS, the accident frequency is assumed to be  $1 \times 10^{-2}$  per year.

This scenario postulates the sudden, complete failure of the dissolver tank and the spilling of its contents onto the floor of the hot cell. The product of the airborne release fraction and the respirable fraction is the sum of that for a free-fall spill, plus evaporation of a shallow pool and are estimated (DOE 1994a) to be 0.00013. A leak path factor of 0.75, applicable for a hot cell (Green 1998), was used.

The cell is exhausted first to roughing filters, then through two stages of HEPA filters in series, and then to the environs via a stack. (Note: This assumes two HEPA filters are in series, and each is 99.95 percent efficient, yielding a  $2.5 \times 10^{-7}$  reduction factor.)

Table I-43 shows the release fractions and source terms for this accident.

**Table I-43 Target Dissolver Tank Failure Source Terms**

Analysis Parameters	Neptunium-237	Plutonium-238
Inventory in dissolver tank	9,000 grams	1,000 grams
Spilled onto hot cell floor	9,000 grams	1,000 grams
Airborne release fraction times respirable fraction	0.00013	0.00013
Leak path factor	0.75	0.75
Amount entering HEPA filters	0.88 gram	0.098 gram
Amount released from stack to environs	$2.19 \times 10^{-7}$ gram	$2.44 \times 10^{-8}$ gram

Source: Calculated results.

### ION EXCHANGE EXPLOSION DURING PLUTONIUM-238 SEPARATION

A hypothetical accident considered is the postulated explosion of an ion exchange column during plutonium-238 purification in a hot cell. Although plans for plutonium purification call for a solvent extraction process, an alternative method involves the use of an ion exchange process (Wham et al. 1998). In this alternative procedure, 495 grams (1.1 pounds) of plutonium-238 are loaded onto an ion exchange column. This postulated accident scenario involves an explosion of this ion exchange column. Judging from historical occurrences of this type of accident at radiochemical laboratories and processing facilities, the frequency of

this event is unlikely (between  $1 \times 10^{-2}$  and  $1 \times 10^{-4}$  per year) (ORNL 1999). For the purpose of this NI PEIS, the accident frequency is assumed to be  $1 \times 10^{-2}$  per year.

Most of the plutonium will be deposited on the cell walls and floor along with other explosion debris. The fraction of plutonium estimated to be released in airborne form and respirable size particles is 0.07 (DOE 1994a).

The hot cell is maintained at a slight negative pressure with respect to the rest of the building. After effluents are exhausted from the hot cell, they pass first through roughing filters, then through two banks of HEPA filters outside the building. On exiting the HEPA filters, effluents are released to the environs through a stack. At the REDC, the explosion could also result in the generation of a weak shock wave and a momentary pressure increase of up to several pounds per square inch gage in the hot cell (ORNL 1999). This accident would not be expected to generate dynamic pressures sufficient to damage the hot cell confinement structure, but could result in some leakage of radioactive materials into the operating areas of the building due to the brief pressurization of the hot cell cubicle (ORNL 1999). Because of the larger volume of the FDPF and FMEF facilities, the magnitude of a shock wave would be much lower.

For REDC, the shock wave may impact the HEPA filters, possibly degrading their performance. Although the HEPA filters are tested to retain 99.97 percent efficiency, tornado conditions are estimated (DOE 1994a) to reduce their efficiency to approximately 99 percent. This scenario assumes that the efficiency of the first-stage HEPA filters at REDC is partially degraded to 99.5 percent while the second-stage efficiency is 99.95 percent. This yields a reduction factor of  $2.5 \times 10^{-6}$  at REDC. Both HEPA stages are 99.95 percent efficient, yielding a reduction factor of  $2.5 \times 10^{-7}$  at FDPF and FMEF. For FDPF and FMEF, the HEPA filters were assumed not to be degraded, because the magnitude of any shock wave generated would be much less. The release to the environment was conservatively assumed to consist of a single “puff” associated with the immediate explosion.

**Table I-44** shows the release fractions and source terms for this accident.

**Table I-44 Plutonium-238 Ion Exchange Explosion Accident Source Terms**

Analysis Parameters	Units
Plutonium-238 material at risk	495 grams
Plutonium-238 released into Hot Cell E from explosion	495 grams
Airborne release fraction times respirable particle fraction	$7 \times 10^{-2}$
Leak path factor	0.75
Plutonium-238 reaching HEPA filters	26.0 grams
Plutonium-238 released to environs	$6.50 \times 10^{-5}$ gram REDC
	$6.50 \times 10^{-6}$ gram FDPF, FMEF

**Source:** Calculated results.

#### I.1.4.1.2 Beyond-Design-Basis Accident

The postulated beyond-design-basis processing facility accident selected for use in this NI PEIS is a catastrophic earthquake. Such an event is less likely than the design-basis processing facility accidents, although its consequences could be severe. Its frequency is assumed to be  $1 \times 10^{-5}$  per year.

## **CASE 1—STORAGE FACILITY**

The earthquake is postulated to collapse the stack, severely damaging the HEPA filter system located nearby. Although the building is expected to collapse, the hot cells are expected to remain intact, but with cracked walls. In addition, one or more of the shielded viewing windows may be cracked or broken. The ventilation systems exhausting from the hot cells are expected to fail. Neptunium-237 is stored in double steel cans, with both the inner and outer cans sealed. The double cans are stacked in an array of robust, seismically supported steel storage tubes inside the hot cell. The analysis postulated the storage tube array would maintain geometry and not be damaged by equipment dislodged within the hot cell during the event. It was postulated that none of the storage cans in the storage tubes would be damaged. The storage cans would not be stressed to a level that would breach the double containment of the can design. No neptunium was postulated to be released from the storage cans during the event.

At INEEL, neptunium-237 may be stored in the CPP-651 vault, which is within 91 meters (100 yards) of FDPF. The CPP-651 vault has 100 in-ground concrete storage silo positions sealed with 5-centimeter (2-inch) stainless steel shielding plugs. The neptunium-237 storage cans would be placed in a rack inside the silo. While the postulated beyond-design-basis earthquake could cause portions of the facility to collapse, none of the storage cans in the in-ground storage silos would be breached. The storage cans would not be stressed to a level that would breach the double containment of the can design.

## **CASE 2—PROCESSING FACILITY**

The earthquake is postulated to collapse the stack, severely damaging the HEPA filter system located nearby. Although the building is expected to collapse, the hot cells are expected to remain intact, but with cracked walls. In addition, one or more of the shielded viewing windows may be cracked or broken. The ventilation systems exhausting from the hot cells are expected to fail. Radioactive materials in the hot cells will be released as a result of cracks in cell walls and shielded windows, but the rate of leakage is expected to be low, since the hot cells are not pressurized and there is no forced ventilation. The leak path factor (i.e., the mass fraction of airborne particulates in an enclosure that is released to the environment) under these conditions has been conservatively estimated to be 0.1 (Green 1997).

The plutonium-238 inventory in the facility will be in several different chemical and physical forms. Since processing is carried on in batches that overlap one another (Wham et al. 1998), the total quantity of plutonium-238 considered available for release from the facility is the sum of the amounts in the dissolver tank, in the ion exchange column during purification, and in powder form and not yet been placed into a sealed canister. Any plutonium-238 in irradiated targets awaiting processing is unlikely to be mechanically damaged by the earthquake because of their rather small size and thus resistance to mechanical breakage. Even if some targets were broken, the plutonium-238 is intimately mixed with the neptunium-237 oxide and an aluminum matrix, rendering it essentially immobile. The earthquake is postulated to result in a massive spill and/or failure of the dissolver tank, an explosion in an ion exchange column, and a spill of any plutonium-238 powder not in a sealed container.

| **Table I-45** shows the release fractions and the ground-level release source terms for this accident.

**Table I-45 Beyond-Design-Basis Earthquake Accident Source Terms**

Analysis Parameters	Plutonium-238 Form and Location			
	Solution—Dissolver Tank	Solution—Ion Exchange Column	Powder—Hot Cell Cubicle	Total
Material at risk	1,000 grams	495 grams	186 grams	1,681 grams
Released into hot cell	1,000 grams	495 grams	186 grams	1,681 grams
Airborne release fraction times respirable fraction	0.00013	0.07	0.0033	—
Leak path factor	0.1	0.1	0.1	—
Released to environs	0.013 gram	3.47 grams	0.061 gram	3.54 grams

#### I.1.4.2 Medical, Industrial, and Research and Development Isotope Processing

The accident analyses included identification of a set of potential accidents that could occur during medical, industrial, and research and development isotope processing at the Radiochemical Processing Laboratory (RPL) (Building 325), FMEF, and the support facility. The analyses are based on scenarios evaluated in the *Building 325 Safety Analysis Report* (the safety analysis report for RPL) for similar types of processes (Battelle 2000). Since process details at the FMEF and the support facility are essentially the same as those at RPL, the same spectrum of accidents was evaluated for all the processing facilities.

The set of accidents evaluated for the Safety Analysis Report was selected using a standard Preliminary Hazards Assessment to identify the potential hazardous conditions in facility operations and to determine the significance of potential accidents. The types of events considered in the Safety Analysis Report included operator errors and handling accidents, fires and explosions, natural phenomena such as seismic events, criticality, and external events such as loss of support services.

For this analysis one bounding event was identified in each of the frequency categories evaluated in the Safety Analysis Report (anticipated, unlikely, or extremely unlikely) in order to identify the events that result in both maximum consequence and maximum risk to onsite and offsite individuals. All types of events that could apply to medical isotope processing were evaluated to determine which scenarios could result in the maximum radionuclide release fraction for each frequency category. The analysis is intended to provide a conservative estimate for the potential consequences of the proposed activities.

Potential accidental releases of radioactive materials during medical, industrial, and research and development isotope processing were estimated using projected radionuclide inventories for the target systems most likely to be considered for production of medical, industrial, and research and development isotopes. **Table I-46** presents the radioactive inventories for the most likely target products. The irradiated targets have a much greater radioactive inventory than the unirradiated targets. Only the radium-226 target is initially radioactive, and its products, actinium and thorium, have greater health consequences than the initial radium-226. Therefore, the accident consequences were analyzed for the irradiated target products.

Processing was assumed to occur 1 day after removal of the targets from the reactor, and only the isotopes associated with a single product target are assumed to be at risk for release in any given event. Release fractions for the radionuclides associated with each product were calculated using the same assumptions as those used for similar types of materials in the Safety Analysis Report scenarios.

#### I.1.4.2.1 Localized Solvent Fire

The safety analysis report for RPL identified a number of accident scenarios with an anticipated frequency greater than 0.01 per year. The types of accidents that fell into this category included the following:

1. Localized solvent fire
2. Localized solid fire
3. Spill in a hot cell
4. Spill in a laboratory

Of these events, the scenario with the highest radionuclide release was the solvent fire. A localized fire of sufficient severity to produce radionuclide releases was estimated to occur no more than once in 10 years. The upper-bound frequency of such an event was supported by the fire loss history at Hanford over a 45-year period. During that time, the site experienced 10 fires that resulted in significant property loss. Of those fires, 6 potentially involved radioactive materials, and 2 of the 6 occurred in laboratory facilities. No fires of that magnitude have occurred in RPL since it was occupied in 1953 and would not be expected to occur routinely in that facility because of the facility design, administrative controls on conduct of operations, and the fire protection program. Since only 2 events potentially involving radioactive materials occurred in laboratory facilities over a 45-year period, a frequency of  $4.44 \times 10^{-2}$  per year was assumed for this accident.

The heating, ventilating, and air conditioning system was assumed to be operating during and after the fire. Combustibles (e.g., solvent-soaked rags) were assumed to be present in sufficient quantity to support combustion. The source terms used for this accident scenario were based on radioactive materials representative of anticipated medical-isotope-processing activities in the hot cells and other laboratories in the facility. Manual fire suppression was assumed not to occur or to be ineffective.

The final HEPA filters were assumed to be unaffected by the fire because they are located in a facility separate from RPL. This assumption was based on the observations that the primary filters would stop most smoke particles and that air dilution would cool the hot gases leaving the laboratory or hot cell so the final HEPA filter bank would not be subjected to extreme temperatures. Therefore, the final stage of HEPA filters was assumed to remain intact. For conservatism, particle deposition along the release path was assumed not to occur. The radon holdup system was assumed to be ineffective, and it was also assumed that no deposition or filtration of noble gases would occur.

It was assumed that charcoal filters will be included in the emergency ventilation system. The activated-charcoal filters will comply with current industry standards. Filter efficiency was conservatively assumed to be 99 percent, consistent with NRC Regulatory Guide 1.52 (NRC 1978). For conservatism, iodine deposition prior to filtration was assumed not to occur.

The radionuclide releases for this event, as estimated in the safety analysis report, were assumed to be the same as those for a solvent fire involving radioactive solutions. Although many of the processes for preparing medical and industrial isotopes would involve only dissolution in aqueous acid solution, some of the chemical

separations could require solvent extraction or ion exchange apparatus. Therefore, the solvent fire was assumed to be a bounding case for this scenario. Separate release fractions were calculated for nonvolatile materials, volatile materials (iodine, sulfur), and noble gases.

The release fractions were calculated by the following generic formula: Airborne Release Fraction  $\times$  Respirable Fraction  $\times$  Leak Path Factor  $\times$  Filter Removal Factor. Calculations for the three releases fractions are:

$$\text{Nonvolatiles: } 0.01 \times 1.0 \times 1.0 \times 0.0005 = 5 \times 10^{-6}$$

$$\text{Volatiles: } 1.0 \times 1.0 \times 1.0 \times 0.01 = 0.01$$

$$\text{Gases: } 1.0 \times 1.0 \times 1.0 \times 1.0 = 1.0$$

To determine which irradiated target would result in the maximum consequences, the radionuclide inventories for each of the irradiated targets were multiplied by the appropriate release fractions. The resulting inventories were then multiplied by dose conversion factors. This final multiplication resulted in a dose for each isotope. The isotope doses within each target were totaled for a target dose. The target doses were compared to determine the target with the maximum dose consequences. The iodine-125 gas line product target resulted in the highest target dose. Therefore, the iodine-125 product target was used to determine the bounding consequences for the localized fire event.

The resulting source term for the localized fire accident is an elevated release of 25.3 curies of iodine-125.

#### **I.1.4.2.2 Unlikely Seismic Event**

Events in the unlikely frequency category (between  $1 \times 10^{-4}$  and  $1 \times 10^{-2}$  per year) in the RPL safety analysis report included:

1. Liquid waste cask failure and spill
2. Unlikely seismic event

Of these scenarios, the unlikely seismic event resulted in a higher radionuclide release fraction. This event was assigned to the unlikely frequency category due to the return period of the initiating earthquake. Earthquake hazard curves have been developed for the 300 Area that define ground acceleration at RPL for a given frequency. The seismic event analyzed in this section has a peak horizontal ground acceleration of 0.139 g for a frequency range of  $1 \times 10^{-4}$  to  $1 \times 10^{-2}$  per year. For earthquakes in the unlikely category, a single potential process upset was assumed, but it was estimated that multiple major upsets would not occur. The facility's superstructure was assumed to remain intact, but the heating, ventilating, and air conditioning system was assumed to fail because it has not been seismically qualified. For the purpose of this NI PEIS, the accident frequency is assumed to be  $1 \times 10^{-2}$  per year.

Spilling of the powdered contents of one in-process medical, industrial, or research and development isotope target was conservatively assumed to occur (i.e., the probability of the spill given that the seismic event occurs was assumed to be 1.0). The release from the spill and holdup release were reduced by 50 percent to account for deposition of the powder within the facility. This 50 percent building removal factor could be applied to this scenario because of essentially static conditions that result from failure of the ventilation system. Because this event does not involve a heat source to mobilize volatile materials, the release fraction was assumed to be the same for all materials except noble gases. The radon holdup system was assumed to be ineffective for this scenario.

Releases from this event were estimated as follows: Airborne Release Fraction  $\times$  Respirable Fraction  $\times$  Leak Path Factor  $\times$  Filter Removal Factor. The specific release fractions are:

$$\text{Nongases: } 0.002 \times 0.3 \times 0.5 \times 1.0 = 3 \times 10^{-4}$$

$$\text{Gases: } 1.0 \times 1.0 \times 1.0 \times 1.0 = 1.0$$

As in the anticipated category source term analysis, the radionuclide inventories for each of the irradiated targets were multiplied by the appropriate release fractions and dose conversion factors. A comparison of the target doses indicated that the actinium-227 product target results in maximum dose consequences for this accident. In addition to the actinium-227 product, the irradiated target contains 9 impurity isotopes and 32 decay products. The dose screening, however, determined that at least 99.9 percent of the total dose is attributable to six isotopes (actinium-227, radium-223, radium-224, radium-226, thorium-227, thorium-228).

| The ground-level release source term for the unlikely seismic event is as follows (releases in curies):

Isotope	Release
Actinium-227	0.0102
Radium-223	0.00588
Radium-224	0.0116
Radium-226	0.00429
Thorium-227	0.00744
Thorium-228	0.0126

#### **I.1.4.2.3 Loss of Electric Power and Explosion**

The safety analysis report for RPL identified the following events in the extremely unlikely category (between  $1 \times 10^{-6}$  and  $1 \times 10^{-4}$  per year):

1. Loss of electric power and explosion
2. Large uncontrolled fire
3. Extremely unlikely seismic event

Of the extremely unlikely events identified in the safety analysis report for RPL, the highest radionuclide release was associated with the loss of electrical services followed by an explosion. This scenario assumes loss of power to RPL, which inactivates the ventilation system. On failure of the ventilation systems, airflow through the hot cells, gloveboxes, hoods, and tanks would also cease. Without ventilation, the potential exists for a buildup of flammable or combustible vapors in those areas with volatile chemicals. A deflagration in a glovebox from the buildup of a flammable solvent or volatile chemical is assumed to occur, potentially breaching the primary confinement barriers. The walls and ceilings of the glovebox or fume hood would mitigate the impact of an explosion. Most of the airborne material within a glovebox or hood would be carried out through the exhaust system, even if the explosion were to cause material to be released from the glovebox to an adjoining area. Judging from actual glovebox explosions, the front panel of a glovebox could fail. In most cases, these events have not resulted in offsite releases because the explosions did not cause malfunctions of ventilation systems or the failure of other barriers, including room walls and ceilings. However, for the extremely unlikely scenario in this analysis, the explosion is assumed to be sufficiently forceful to breach the building or ventilation system barriers, rendering the HEPA filters and radon holdup system ineffective.

Releases from this event were estimated as follows: Airborne Release Fraction × Respirable Fraction × Leak Path Factor × Filter Removal Factor. The specific release fractions are:

Nonvolatiles:  $0.05 \times 0.4 \times 0.5 \times 1.0 = 0.01$

Volatiles and gases:  $1.0 \times 1.0 \times 1.0 \times 1.0 = 1.0$

As in the previous source term analyses, the radionuclide inventories for each of the irradiated targets were multiplied by the appropriate release fractions and dose conversion factors. A comparison of the target doses indicated that the actinium-227 product target results in maximum dose consequences for this accident.

The ground-level release source term for the extremely unlikely loss of electrical services followed by an explosion is:

Isotope	Release
Actinium-227	0.340
Radium-223	0.196
Radium-224	0.388
Radium-226	0.143
Thorium-227	0.248
Thorium-228	0.421

### I.1.5 Methodology for Estimating Processing Facility Accident Radiological Impacts

The exposure, uptake, and usage parameters used in the GENII model for assessing processing facility accident impacts are provided in **Tables I-47 through I-49**. The GENII computer code was used to estimate the radiological consequences of the postulated accidents at the processing facilities. A discussion of the GENII computer code is presented in Appendix H. Doses to a noninvolved worker, the maximally exposed individual, and the population within 80 kilometers (50 miles) of each plant were calculated. To determine the consequences for the maximally exposed individual, doses were calculated at the site boundary and at the nearest highway within the site boundary. The population and boundary maximally exposed individual doses included doses via ingestion. The nearest highway maximally exposed individual is assumed to be exposed for a period of 2 hours. The consequences (doses) were then multiplied by the frequencies of the accidents to determine the risk.

**Table I-47 GENII Exposure Parameters to Plumes and Soil Contamination (Accidents)**

Maximum Individual				General Population			
External Exposure		Inhalation of Plume		External Exposure		Inhalation of Plume	
Plume (hours)	Soil Contamination (hours)	Exposure Time (hours)	Breathing Rate (cubic centimeters per second)	Plume (hours)	Soil Contamination (hours)	Exposure Time (hours)	Breathing Rate (cubic centimeters per second)
0.00	6,136	100% of release time	330	0.00	4,383	100% of release time	330

Key: kg/yr, kilograms per year; kgs/m<sup>2</sup>, kilograms per square meter.

Source: Napier et al. 1988.

It is possible that an individual member of the public could be closer to a facility than either the site boundary or the nearest onsite highway. However, such individuals would be present only occasionally and for brief periods (a few hours or more). Hence, the annual probability that an individual would be close is relatively low, and the associated risk to that individual would be bounded by the site boundary or onsite highway maximally exposed individual risk.

For all of the processing facilities, accidents were evaluated using 50 percent meteorology. The meteorological data used were in the form of joint frequency data files at each site location. The joint frequency data files were based on measurements taken over a period of several years at different locations and heights. Population distributions were based on the 1990 Census of Population and Housing (DOC 1992). Projections were determined for the year 2020 (approximate midlife of operations) for areas within 80 kilometers (50 miles) of each facility.

Consequences to involved workers are addressed in Section I.1.7.

In addition to the GENII computer code, the MACCS2 computer code was used for the localized solvent fire accident analysis. GENII does not permit interdiction or the disposal of food and therefore is inappropriate for the ingestion pathway analysis for the solvent fire accident. The iodine release postulated during the fire accident is sufficient to prompt interdiction. Therefore, GENII was used for the inhalation and external exposure pathways, and MACCS2 was used for the ingestion pathway. The doses via the two pathways were then summed for the total dose.

### **I.1.6 Processing Facility Accident Consequences and Risks**

The processing facility accident source term data presented in Sections I.1.4.1 and I.1.4.2 were evaluated using the GENII accident analysis computer code. The MACCS2 computer code was used in addition to GENII for the medical, industrial, and research and development isotope localized solvent fire accident. **Tables I-50** through **I-54** summarize the consequences and risks of the accidents, with mean meteorological conditions, for the maximally exposed individual, the offsite population within an 80-kilometer (50-mile) radius of the facility, and a noninvolved worker 640 meters (2,100 feet) from the release point.

**Table I-50** presents REDC accident consequences and risks for plutonium-238 fabrication and processing.

**Table I-51** presents FDPF accident consequences and risks for plutonium-238 fabrication and processing.

**Table I-52** presents FMEF accident consequences and risks for plutonium-238 fabrication and processing and for simultaneous plutonium-238, medical, industrial, and research and development isotope fabrication and processing.

**Table I-53** presents RPL accident consequences and risks for medical, industrial, and research and development isotope fabrication and processing.

**Table I-54** presents generic support facility accident consequences and risks for medical, industrial, and research and development isotope fabrication and processing.

## I.1.7 Involved Worker Accident Consequences and Risks

The estimated number of involved workers at each of the proposed irradiation and processing facilities is shown in **Table I-55**.

**Table I-55 Estimated Number of Involved Workers at Each Facility**

Facility	Type	Involved Workers
FFTF	Irradiation	242
ATR	Irradiation	100
HFIR	Irradiation	100
CLWR	Irradiation	300
New research reactor	Irradiation	120
High-energy accelerator	Irradiation	225
Low-energy accelerator	Irradiation	13
REDC	Processing	116
FDPF	Processing	75
FMEF	Processing	105
RPL/306-E	Processing	30
New support facility	Processing	100

### I.1.7.1 Irradiation Facility Consequences and Risks

#### I.1.7.1.1 Design-Basis Accident

Each of the proposed irradiation facilities would have an approved onsite emergency plan. The likelihood of a design-basis accident is estimated to be once in 10,000 years. Since an accident could occur at any given time, the number of workers on site at the time of an accident would be unlikely to exceed one-third the total number of involved workers shown above (assuming a three-shift operation). The workers at the facility at the time of a design-basis accident can be grouped into three major categories, as follows:

1. Those workers not having duties associated with accident management or recovery. These would be promptly notified and evacuated from the site. Individuals in this group would be expected to receive low doses significantly below the EPA Protective Action Guides (PAGs) (EPA 1992) of 1-5 rem. Most involved workers would be in this group.
2. Those workers located in shielded areas such as the control room or other designated plant emergency operation areas having duties associated with accident management and recovery. These workers, because of the radiation protection afforded by their locations, would be unlikely to receive doses in excess of the EPA PAGs. For the irradiation facilities, this group is estimated to range from about 6 to 20 individuals.
3. Those few workers in areas of the plant who may be directly affected or impacted by the accident, (e.g., performing maintenance in the immediate area where an accident initiating event occurs). This very small group of involved workers could receive significant doses in excess of the EPA PAGs. With appropriate radiation instrumentation, alarms and administrative controls, it is unlikely that individuals in this group would receive doses high enough to result in acute radiation effects (doses greater than about 100 rem).

### **I.1.7.1.2 Beyond-Design-Basis Accident**

The likelihood of a beyond-design-basis accident is estimated to be once in 100,000 years. A beyond-design-basis accident may begin as a design-basis accident, but would involve additional equipment failures that lead to more serious reactor or facility damage than in a design basis event. For this reason, the previous discussion on design-basis events is largely applicable. Most involved workers would likely be evacuated prior to receiving any significant dose. A small group of workers, including operators and personnel directly involved in accident management and recovery could receive significant doses, however. One or two individuals could conceivably receive high doses if emergency actions were to be taken (e.g., entering a high radiation area for a short time to actuate a valve or pump).

### **I.1.7.2 Processing Facility Consequences and Risks**

#### **I.1.7.2.1 Design-Basis Accident**

##### **GLOVEBOX EXPLOSION DURING NEPTUNIUM-237 TARGET FABRICATION**

For the purposes of this NI PEIS, this accident frequency is estimated to be  $1 \times 10^{-2}$  per year. Assuming this accident occurs, the involved worker at the affected glovebox may be seriously injured as a result of the explosion as well as likely to be contaminated with the explosion debris. This worker could receive a significant radiation dose. The extent of the contamination and the radiation doses are likely to be highly localized, however. Neighboring workers in nearby gloveboxes will be exposed to significantly lower doses and effects from the explosion, while workers in other locations in the processing facility will be only minimally affected.

##### **TARGET DISSOLVER TANK FAILURE DURING PLUTONIUM-238 SEPARATION**

For the purposes of this NI PEIS, this accident frequency is estimated to be  $1 \times 10^{-2}$  per year. This accident is postulated to occur in a shielded hot cell, whose integrity is not challenged by this accident. Consequently, those workers outside the hot cell carrying out this operation will not be affected. Some plutonium-238 and neptunium-237 will be released from an elevated stack after passing through two stages of HEPA filters, which removes all but a very small fraction of the spilled tank contents. Workers at the processing facility will be exposed to very low concentrations of plutonium-238 and neptunium-237 as a result of this release. It is estimated that since an elevated release results in very low concentrations at ground level close to the release point, that worker doses will be generally similar to those received by the maximally exposed offsite individual for this accident.

##### **ION EXCHANGE EXPLOSION DURING PLUTONIUM-238 SEPARATION**

For the purposes of this NI PEIS, this accident frequency is estimated to be  $1 \times 10^{-2}$  per year. As for the postulated dissolver tank failure discussed above, this accident is postulated to occur in a shielded hot cell, whose integrity is unlikely to be challenged by this accident. Consequently, those workers outside the hot cell carrying out this operation will not be affected. Some plutonium-238 will be released from an elevated stack after passing through two stages of HEPA filters, which removes all but a very small fraction of the explosion debris. Workers at the processing facility will be exposed to very low concentrations of plutonium-238 as a result of this release. It is estimated that since an elevated release results in very low concentrations at ground level close to the release point, that worker doses will be generally similar to those received by the maximally exposed offsite individual for this accident.

### **I.1.7.2.2 Beyond-Design-Basis Accident**

The beyond-design-basis accident postulated for the processing facilities is a catastrophic earthquake whose likelihood is taken to be once in 100,000 years for this NI PEIS. The earthquake is postulated to collapse the stack, severely damaging the HEPA filters. Although the building is expected to collapse, the hot cells are expected to remain intact, but with cracked walls. In addition, one or more of the shielded viewing windows may be cracked and broken. The ventilation systems exhausting from the hot cells are expected to fail. Radioactive materials in the hot cells will be released as a result of cracks in cell walls and shielded windows, but the rate of leakage is expected to be low, since the hot cells are not pressurized and there is no forced ventilation.

Many of the workers in the processing facility are expected to be injured as a direct result of the earthquake. Those workers who are mobile are expected to leave the facility, and this group is not likely to receive any significant radiation dose. Workers who are trapped in the rubble and debris of the earthquake and unable to leave the immediate vicinity could receive significant additional radiation doses, however.

### **I.1.7.3 Medical and Industrial Isotopes Processing Facility Consequences and Risks**

#### **I.1.7.3.1 Localized Solvent Fire**

This event postulates a localized solvent fire in a hot cell. Because only two events potentially involving radioactive materials have occurred in laboratory facilities over a 45-year period, a frequency of  $4.44 \times 10^{-2}$  per year was assumed for this accident. The integrity of the hot cell would not be challenged by the localized nature of the fire, and the final HEPA and iodine-removing charcoal filters were assumed to be unaffected by the fire because they are located away from the hot cells. Some radioactive materials would be released after passing through the filters, which would remove all but a small fraction of the materials reaching them. Workers at the processing facility would be unaffected by the fire, but would be exposed to low concentrations of released radioactive isotopes. It is estimated that worker doses would generally be similar to those received by the maximally exposed individual (0.0135 rem for RPL and 0.0194 rem for the generic support facility) for this accident.

#### **I.1.7.3.2 Unlikely Seismic Event**

For the purposes of this NI PEIS, this accident frequency is assumed to be  $1 \times 10^{-2}$  per year. The facility's superstructure was assumed to remain intact, but the heating, ventilating, and air-conditioning system was assumed to fail because it has not been seismically qualified. Some injuries may occur because of the seismic event itself. Releases of radioactive materials would be at ground level. It is estimated that worker doses would generally be somewhat greater than those received by the maximally exposed individual (1.52 rem for RPL and 0.075 rem for the generic support facility) for this accident.

#### **I.1.7.3.3 Loss of Electrical Power and Explosion**

For the purposes of this NI PEIS, this accident frequency is assumed to be  $1 \times 10^{-4}$  per year. This scenario assumes a loss of electrical power that inactivates the ventilation system. This is postulated to lead to an explosion in a glovebox as a result of a buildup of flammable vapors. Most of the airborne material within a glovebox would be carried out through the exhaust system. For this scenario, the explosion is assumed to be sufficiently forceful to render the HEPA filters and radon holdup system ineffective. Assuming this accident occurs, the involved worker at the affected glovebox may be seriously injured as a result of the explosion and may be contaminated with explosion debris. This worker could receive a significant radiation dose. The extent of the contamination and the radiation dose is likely to be highly localized, however. Neighboring

workers in nearby gloveboxes, if any, would be exposed to significantly lower doses and effects from the explosion. Releases of radioactive materials would be at ground level. It is estimated that worker doses at the facility (except for the worker directly affected by the explosion) would generally be somewhat greater than those received by the maximally exposed individual (50.0 rem for RPL and 2.5 rem for the generic support facility) for this accident.

### **I.1.8 Risk Summation**

To provide a better indication of risks of the postulated accidents, the risks are summed for each facility and also for each option. The summed risks for each alternative and option are presented in **Tables I-56 through I-76**. Although the summation provides the combined risk for the spectrum of accidents analyzed, it does not indicate total risk. To determine total risk of accidents, a full-scope (Level 3) probabilistic risk analysis is required for each facility. However, since full-scope probabilistic risk analyses are not available to incorporate into this NI PEIS, summation of the spectrum of accident risks was considered appropriate.

As explained previously, a full spectrum of accidents was considered at the irradiation and fabrication and processing facilities. The accidents evaluated represent bounding cases that are considered to envelop the risk profile.

For each option, the highest risks are presented for the maximally exposed individual and the noninvolved worker. The highest risk to an individual may result from either a single facility or a combination of facilities. A combination of facilities can occur only if the facilities are colocated. In this case, the individual risks are summed. For each option, all facility population risks are summed.

For the currently operating reactors (ATR, HFIR, and CLWR), the incremental risk of target irradiation is determined by subtracting the risk without target irradiation from the risk with target irradiation. For example, in Alternative 2, Option 1, there is an incremental risk to the maximally exposed individual from a large-break loss-of-coolant accident. The incremental risk is determined by subtracting the maximally exposed individual risk from a large-break loss-of-coolant accident without target irradiation (i.e., 0 kilograms per year plutonium-238 production) from the maximally exposed individual risk with target irradiation (i.e., 5 kilograms per year plutonium-238 production). The incremental risk is therefore  $3.02 \times 10^{-8} - 2.33 \times 10^{-8} = 6.09 \times 10^{-9}$  as presented in the table. The incremental risks are used to determine the summed risks. Therefore, summing every risk presented in the tables will not directly produce the summed risk.

**Table I-56 Risk Summation for Alternative 1—Option 1**

Accident	Maximally Exposed Individual	Population to 80 Kilometers (50 Miles)	Noninvolved Worker (640 Meters)
<b>FFTF</b>			
Design-basis primary sodium spill (MOX)	$5.65 \times 10^{-11}$	$3.93 \times 10^{-6}$	$1.25 \times 10^{-10}$

## **I.2 HAZARDOUS CHEMICAL ACCIDENT IMPACTS ON HUMAN HEALTH**

### **I.2.1 Irradiation Facility**

#### **I.2.1.1 Advanced Test Reactor**

Irradiation of neptunium-237 targets to produce plutonium-238 at ATR would not introduce any additional operations that require the use of hazardous chemicals. No hazardous chemical accidents attributable to the irradiation of neptunium-237 targets for plutonium-238 production are postulated at ATR.

#### **I.2.1.2 High Flux Isotope Reactor**

Irradiation of neptunium-237 targets to produce plutonium-238 at HFIR would not introduce any additional operations that require the use of hazardous chemicals. No hazardous chemical accidents attributable to the irradiation of neptunium-237 targets for plutonium-238 production are postulated at HFIR.

#### **I.2.1.3 Commercial Light Water Reactor**

Irradiation of neptunium-237 targets to produce plutonium-238 at the generic CLWR would not introduce any additional operations that require the use of hazardous chemicals. No hazardous chemical accidents attributable to the irradiation of neptunium-237 for plutonium-238 production are postulated at the generic CLWR.

#### **I.2.1.4 Fast Flux Test Facility**

The FFTF primary heat transport system contains a substantial quantity of liquid sodium. In the event of an accident, sodium could be released from the primary system. Sodium mainly forms sodium oxide upon burning; however, in the presence of moisture, it can form the more hazardous sodium hydroxide. The beyond-design-basis core melt accident would result in the greatest sodium release to the environment. Previous analyses have shown that the concentration of sodium hydroxide released in this accident scenario would be below the Emergency Response Planning Guidelines-1 (ERPG-1) limit of 2 milligrams per cubic meter at 100 meters (DOE 1997). Since this is the bounding sodium release and all the sodium released was assumed to be in the form of sodium hydroxide, no further analysis was performed for this NI PEIS.

### **I.2.2 Processing Facility**

Processing associated with the plutonium-238 production program at REDC, including storage of neptunium-237 and plutonium-238, neptunium-237 target fabrication, and postirradiation processing to extract plutonium-238 and to recycle the unconverted neptunium-237 into new targets, does not require the introduction of hazardous chemicals that are not in current use in the facility. The quantities of in-process hazardous chemicals for the plutonium-238 production program are bounded by the quantities of the material currently stored in the facility. The impacts of in-process hazardous chemical accidents associated with plutonium-238 production are bounded by the impacts of hazardous chemical accidents for existing storage facilities at REDC.

No chemical processing activities are currently performed at FDPF and FMEF, and no chemicals are stored in these facilities. If either of these facilities is selected to support the plutonium-238 production program, a hazardous chemical accident analysis will be required. The analysis for FDPF and FMEF assumes that the chemical inventory required for 1 year of operation is stored in the facility and that each chemical is stored in a single tank or container with no mitigating design features (e.g., dikes to limit the spill area).

### I.2.2.1 Accident Scenario Selection

This section describes the process used to identify the chemicals for the accident analysis, the methodology used in analyzing potential accidents involving hazardous chemicals, the baseline accident scenarios, and the potential health risks associated with a release from identified scenarios. The anticipated chemical inventory for 1 year of plutonium-238 processing at FMEF and FDPF is given in **Table I-77**.

**Table I-77 Anticipated Annual Inventory for Plutonium-238 Processing**

Chemical	Inventory (pounds)	TPQ (pounds)	Chemical	Inventory (pounds)	TPQ (pounds)
Aluminum nitrate	5.2	Not in list	Acetone	69	–
Aluminum powder	303	–	Acetylene	16	–
Aluminum stearate	0.6	Not in list	Adogen 364	459	Not in list
Anion exchange resin	97	Not in list	Argon	1,333	Not in list
Ascorbic acid	157	Not in list	Compressed air	135	Not in list
Diethyl benzene	485	Not in list	Devcon 5-minute epoxy resin	7.4	Not in list
Dodecanol	93	Not in list	Helium	62	Not in list
Ferrous sulfamate	7	Not in list	Hydrochloric acid	321	–
Hydrazine nitrate	28	Not in list	Hydrogen (2-5 percent) in argon	24	Not in list
Hydroxylamine nitrate	60	Not in list	Hydrogen peroxide solution (< 52 percent)	8.8	1,000 lb for >52 percent
Methanol	17	Not in list	Nitric oxide	156	100
Nitric acid	2,170	1,000	Nitrogen	833	Not in list
Normal paraffin hydrocarbons	157	Not in list	Oxygen	29	Not in list
Oxalic acid	56	Not in list	P-10 nuclear counter mixture	1,184	Not in list
Polystyrene resin	783	Not in list	Potassium carbonate	5.5	Not in list
Sodium fluoride	0.6	–	Propane	450	–
Sodium hydroxide	1,078	–	Sodium carbonate	8.8	Not in list
Sodium nitrate	1,146	Not in list	Sodium hydroxide (40-50 percent)	7,422	–
Sodium nitrite	1.7	–	Sodium hydroxide (>10 percent solution)	1,068	–
Tributyl phosphate	849	Not in list	Sodium hypochlorite solution	27	–

**Key:** TPQ, Extremely Hazardous Substances List Threshold Planning Quantity Value; <, less than; >, greater than; –, no value in the list.

**Source:** EPA 1998.

Only the anticipated annual usage of nitric acid and nitric oxide for plutonium-238 processing exceeds the Threshold Planning Quantities for these substances as stipulated on the Extremely Hazardous Substances List provided in Section 3.02 of the Emergency Planning and Community Right-to-Know Act (EPA 1998). The respective Threshold Planning Quantities for nitric acid and nitric oxide are 454 kilograms (1,000 pounds) and 45.4 kilograms (100 pounds). Since inventories of these chemicals exceed the Threshold Planning Quantities, an evaluation of potential accident scenarios is presented in this NI PEIS.

### I.2.2.2 Accident Scenario Descriptions

Two accidental chemical scenarios are postulated for this NI PEIS: the accidental uncontrolled release of nitric acid, and the accidental uncontrolled release of nitric oxide.

### **I.2.2.2.1 Nitric Acid Release**

The nitric acid release scenario was developed on the basis of the following assumptions: the nitric acid released from the tank is red fuming nitric acid (100 percent). A catastrophic tank failure is the initiating event. There are no engineered safety features for the tank. The tank is in an unsheltered building in an open rural area. The release fraction is 100 percent. However, the actual amount of nitric acid that volatilizes to the atmosphere was determined by the method described in the *Technical Guidance for Hazards Analysis* (EPA 1987).

The consequences of the postulated nitric acid release scenario are overstated because of the conservatism of two assumptions: 100 percent red fuming nitric acid and a lack of engineered safety features to restrict releases from spills. Facilities under consideration for this program do not permit storage of red fuming nitric acid, which has a high vapor pressure, and they have engineered safety features (e.g., sloped floors and dikes) to restrict releases from spills.

### **I.2.2.2.2 Nitric Oxide Release**

The analysis postulated a storage cylinder failure. A release fraction (percentage of material released) of 100 percent was used. An aggregated release of 71.8 kilograms (158 pounds) for nitric oxide gas was postulated. The rate of release of nitric oxide was calculated by the method described in the *Technical Guidance for Hazards Analysis* (EPA 1987).

### **I.2.2.3 Hazardous Chemical Accident Analysis Methodology**

The potential health impacts of accidental releases of hazardous chemicals were assessed by comparing estimated airborne concentrations of the chemicals with the ERPG developed by the American Industrial Hygiene Association. The ERPG values are not regulatory exposure guidelines and do not incorporate the safety factors normally included in healthy worker exposure guidelines. ERPG-1 values are maximum airborne concentrations below which nearly all individuals could be exposed for up to 1 hour, resulting in only mild, transient, and reversible adverse health impacts. ERPG-2 values are indicative of irreversible or serious health effects or impairment of an individual’s ability to take protective action. ERPG-3 values are indicative of potentially life-threatening health effects.

No approved ERPG levels are available for nitrous oxide (Kelly 1999). The ERPG values for nitric acid are presented in **Table I-78**. The ERPG values referenced by Kelly (1999) were used in this NI PEIS.

**Table I-78 Emergency Response Planning Guideline Values for Nitric Acid**

ERPG Level	DOE 1997	Kelly 1999
ERPG-1	2 parts per million	0.5 parts per million
ERPG-2	15 parts per million	10 parts per million
ERPG-3	30 parts per million	25 parts per million

**Key:** ERPG, Emergency Response Planning Guideline.

There are also no ERPG values for nitric oxide. For these cases, the “level of concern” has been estimated by using one-tenth of the “immediately dangerous to life and health” level for that substance—i.e., 100 parts per million—as published by the National Institute for Occupational Safety and Health (NIOSH 1997). For this NI PEIS, therefore, the level of concern for nitric oxide is 10 parts per million. Level of concern is defined as the concentration of an extremely hazardous substance in air above which there may be serious irreversible health effects or death as a result of a single exposure for a rather short period of time (EPA 1987).

### **I.2.2.3.1 Receptor Description**

The potential health impacts of the accidental release of nitric acid and nitric oxide were assessed for three types of receptors:

1. A noninvolved worker—a worker assumed to be 640 meters (0.4 mile) from the point of release.
2. Site boundary maximally exposed individual—a hypothetical member of the public off site at the nearest point of access (7,210 meters [4.5 miles] for FMEF and 13,952 meters [8.7 miles] for FDFP) to the point of release.
3. Nearest highway maximally exposed individual—a hypothetical member of the public at the nearest point on an onsite highway (7,100 meters [4.4 miles] for FMEF and 5,800 meters [3.6 miles] for FDFP) to the point of release.

Facility workers (i.e., those individuals in the building at the time of the accident) are assumed to be killed by the release.

### **I.2.2.3.2 Analysis Computer Code**

The computer code used for estimation of airborne concentrations was the Computer Aided Management of Emergency Operations Areal Locations of Hazardous Atmospheres (ALOHA), developed by the National Safety Council, EPA, and the National Oceanic and Atmospheric Administration.

#### **DESCRIPTION OF THE MODEL**

The atmospheric dispersion modeling for the above scenarios was conducted using the ALOHA 5.05 computer code (NSC 1990). The ALOHA code was designed for use by first responders. The model is most useful for estimating plume extent and concentration downwind from the release source for short-duration chemical accidents. It uses a Gaussian dispersion model to describe the movement and spreading of a gas that is neutrally buoyant. For heavier-than-air vapor releases, the model uses the same calculations as those used in EPA's Dense Gas Dispersion Model DEGADIS 2.1 (EPA-450/4-89-019). There are a number of limitations to the model:

1. ALOHA is not intended for modeling accidents involving radioactive chemicals.
2. It is not intended for use in modeling the permitting of stack gas or chronic, low-level (fugitive) emissions.
3. The ALOHA-DEGADIS heavy-gas module is more conservative than the DEGADIS model, which could result in a larger footprint than would actually be expected.
4. ALOHA does not consider the effects of thermal energy from fire scenarios or the byproducts of chemical reactions.
5. ALOHA does not include the process needed to model particulate dispersion.
6. ALOHA does not consider the shape of the ground under the spill or in the area affected by the plume.

7. ALOHA does not estimate concentrations under very low wind speeds (less than 1 meter [3.3 feet] per second), as the wind direction may become inconsistent under these conditions.
8. For very stable atmospheric conditions (usually late night or early morning), there will be uncertainties in the model estimates due to shifting wind directions and virtually no mixing of the plume into the surrounding air. The estimates may in fact, reflect to high airborne concentrations for long periods of time or at great distances from the release source.
9. ALOHA does not accurately represent variations associated with near-field (close to the release source) patchiness. In the case of a neutrally buoyant gas, the plume will move downwind; very near the source, however, it can be oriented in a different direction (e.g., going backward) due to the effect of drifting eddies in the wind.

#### WEATHER CONDITION ASSUMPTIONS

The model results are presented for atmospheric Stability Classes D and F, with wind speeds of 5.3 meters (17 feet) per second and 1.5 meters (4.9 feet) per second, respectively. Atmospheric Stability Class D is considered to be representative of average weather conditions; Stability Class F is considered to be representative of worst-case weather conditions. These weather conditions were selected because they are recommended in *Technical Guidance for Hazards Analysis* (EPA 1987). **Table I-79** presents the model parameter values for these weather conditions.

**Table I-79 Analysis Weather Conditions**

Parameter	Average Condition Stability Class D	Worst-Case Condition Stability Class F
Ambient air temperature	75 °F	60 °F
Relative humidity	50 percent	25 percent
Cloud cover	50 percent	20 percent
Average wind speed	5.3 meters per second	1.5 meters per second

Source: EPA 1987.

#### I.2.3 Human Health Impacts

The potential health impacts of the accidental releases were assessed by comparing the modeled ambient concentrations of nitric acid and nitrous oxide at each of the previously identified receptor locations with the ERPGs. The estimated airborne concentrations of nitric acid and nitric oxide are presented in **Table I-80** and **Table I-81**, respectively. **Table I-82** and **Table I-83** present of the impacts data for nitric acid and nitric oxide.

**Table I-80 Airborne Concentration Estimates for Nitric Acid Release Scenarios**

Downwind Distance from Source (meters)	Nitric Acid Concentration Under Stability Class D (parts per million)		Nitric Acid Concentration Under Stability Class F (parts per million)		
	Facility	FMEF	FDPF	FMEF	FDPF
30		1,200	1,130	1,070	1,040
640		3.3	3.3	8.6	8.4
1,000		1.4	1.4	3.9	3.9
3,000		0.17	0.17	0.5	0.5
5,000		0.06	0.06	0.2	0.2
Nearest highway <sup>a</sup>		0.03	0.05	0.1	0.15
Site boundary <sup>b</sup>		0.03	(c)	0.1	(c)

- a. FMEF = 7,100 meters (4.4 miles); FDPF = 5,800 meters (3.6 miles).  
 b. FMEF = 7,210 meters (4.5 miles); FDPF = 13,952 meters (8.7 miles).  
 c. Not calculated; the distance to the site boundary exceeds the analysis code 10-kilometer maximum distance limit for calculations.  
**Source:** Calculated results.

**Table I-81 Airborne Concentration Estimates for Nitric Oxide Scenarios**

Downwind Distance from Source (meters)	Nitric Oxide Concentration Under Stability Class D (parts per million)		Nitric Oxide Concentration Under Stability Class F (parts per million)		
	Facility	FMEF	FDPF	FMEF	FDPF
30		1,370	1,370	9,990	9,480
640		4.2	4.2	66	67.5
1,000		2	2	29.2	29.6
3,000		0.36	0.36	3.6	3.6

Site boundary maximally exposed individual	Parts per million (ppm) Level of concern Potential health effects	0.09 < LOC None	(a) < LOC None	0.53 < LOC None	(a) < LOC None

a. Not calculated; the distance to the site boundary exceeds the analysis code 10-kilometer maximum distance limit for calculations.  
**Key:** <, less than; >, greater than.

### I.2.3.1 Impacts to Noninvolved Workers

**Nitric Acid.** A noninvolved worker is assumed to be located 640 meters (0.4 mile) from the point of release. The concentrations of nitric at that distance range from 3.3 to 8.6 parts per million for FMEF and 3.3 to 8.4 parts per million for FDPF, given assumed meteorological conditions. The maximum estimated airborne concentration at 640 meters (0.4 mile) Stability Class F exceeds the ERPG-1 value of 0.5 part per million for nitric acid, which suggests the potential for only mild, transient, and reversible health impacts on a noninvolved workers at that distance from the release.

**Nitric Oxide.** For the nitric oxide release scenarios, the concentrations at 640 meters (0.4 miles) range from 4.2 to 66 parts per million for FMEF and 4.2 to 67.5 parts per million for FDPF, given assumed meteorological conditions. As a result, the maximum estimated airborne concentration at 640 meters (0.4 miles) exceeds the level-of-concern value of 10 parts per million for nitric oxide, which suggests that a noninvolved worker may experience irreversible or serious, but not life-threatening, health impacts if the exposures are not mitigated.

### I.2.3.2 Impacts on Access Roads

**Nitric Acid.** The receptor at the nearest highway is assumed to be located 7,100 meters (4.4 miles) and 5,800 meters (3.6 miles) for FDPF from the points of release at FMEF and FDPF respectively. For the nitric acid release scenarios, the receptor on the nearest highway could be exposed to a nitric acid concentration of 0.03 to 0.05 part per million under Stability Class D conditions, which is below the ERPG-1 value for nitric acid of 0.5 part per million. Exposures to concentrations below the ERPG-1 value are not expected to have any adverse health impacts on the receptor. Under Stability Class F conditions, the offsite receptor may be exposed to a nitric acid concentration of about 0.1 to 0.15 part per million, which is below the ERPG-1 value for nitric acid of 10 parts per million. Exposure of the receptor to concentrations greater than the ERPG-1 value may have only mild, transient and reversible health impacts.

**Nitric Oxide.** For the nitric oxide release scenarios, the receptor on the nearest highway could be exposed to concentrations of 0.09 part per million under Stability Class D conditions, which is below the level-of-concern value for nitric oxide of 10 parts per million. Exposures to concentrations below the level-of-concern value are not expected to produce any adverse health effects for the receptor. Under Stability Class F conditions, the offsite receptor may be exposed to a nitric oxide concentration of about 0.55 to 0.87 parts per million, which is below the level-of-concern value for nitric oxide of 10 parts per million.

### I.2.3.3 Offsite Impacts

The site boundary receptor is assumed to be located at a distance of 7,210 meters (4.5 miles) and 13,952 meters (8.7 miles) from the points of release at FMEF and FDPF, respectively. ALOHA does not draw any plume larger than 10 kilometers (6.2 miles) (NSC 1990). The FDPF site boundary is 13.3 kilometers (8.3 miles) from the point of release. Therefore, no impacts to site boundary receptor at FDPF were performed. Health impacts on the nearest highway at a distance of 5.8 kilometers (3.6 miles) from the point of release were only mild, transient, and reversible. Exposure of the receptor at concentrations below the level-of-concern value may have only mild, transient, and reversible health impacts. At a distance of 14.0 kilometers (8.7 miles) from the point of release, adverse health effects are not expected.

**Nitric Acid.** For the nitric acid release scenarios, the site boundary receptor at Hanford could be exposed to a nitric acid concentration of 0.03 part per million under Stability Class D conditions, which is below the ERPG-1 value for nitric acid of 0.5 part per million. Exposures to concentrations below the ERPG-1 value are not expected to have any adverse health impacts on the receptor. Under Stability Class F conditions, the site boundary receptor may be exposed to a nitric acid concentration of about 0.1 part per million, which is below the ERPG-1 value for nitric acid of 10 parts per million. Exposure of the receptor at concentrations greater than the ERPG-1 value may have only mild, transient, and reversible health impacts.

**Nitric Oxide.** For the nitric oxide release scenarios, the site boundary receptor exposures were 0.09 part per million under Stability Class D conditions, which is below the level-of-concern value for nitric oxide of 10 parts per million. Exposures to concentrations below the level of concern value are not expected to have any adverse health impacts on the receptor. Under Stability Class F conditions, the site boundary receptor may be exposed to a nitric oxide concentration of about 0.53 part per million, which is below the level-of-concern value for nitric oxide of 10 parts per million. Exposure of the receptor at concentrations below the level-of-concern value may produce only mild, transient, and reversible health impacts.

### I.2.3.4 Uncertainties

This screening-level analysis is subject to a number of uncertainties relative to the atmospheric dispersion modeling. Among those uncertainties are the following:

1. On the day of an accident, it will undoubtedly be very difficult to establish exactly the rate or magnitude of the release.
2. The weather conditions and wind speed may well be different from those used in the analysis.
3. The dispersion modeling does not take into account the deposition of highly reactive vapors onto surfaces, including equipment, groundwater, and vegetation. This means that the model overestimates airborne concentrations at longer distances.
4. Overall, the uncertainties in predicted airborne concentrations may be as large as a factor of plus or minus two times the estimated concentration.
5. In view of these uncertainties, the results of this analysis should be considered only as screening-level estimations.

### I.3 INDUSTRIAL SAFETY

Estimates of potential industrial impacts to workers during construction, irradiation, fabrication, and processing were evaluated based on DOE and Bureau of Labor Statistics data. Impacts are classified into two groups: total recordable cases and fatalities. A recordable case includes work-related death, illness, or injury that resulted in loss of consciousness, restriction of work or motion, transfer to another job, or required medical treatment beyond first aid.

DOE and contractor total recordable cases and fatality incidence rates were obtained from the CAIRS database (DOE 2000a, 2000b). The CAIRS database is used to collect and analyze DOE and DOE contractor reports of injuries, illnesses, and other accidents that occur during DOE operations. The 5-year average (1995–1999) rates were determined for average construction total recordable cases, average operation total recordable cases, and average operation fatalities. The average construction fatality rate was obtained from the Bureau of Labor Statistics (Toscano and Windau 1998).

**Table I–84** presents the average occupational total recordable cases and fatality rates for construction and operation activities.

**Table I–84 Average Occupational Total Recordable Cases and Fatality Rates (per worker-year)**

Labor Category	Total Recordable Cases	Fatalities
Construction	0.053	0.000139
Operation	0.033	0.000013

Expected impacts (both annual and for the duration of the activity) to workers at each facility for construction and operation are presented in **Table I–85**.

**Table I–85 Industrial Safety Impacts from Construction and Operation**

Facility	Estimated Number of Workers	Construction or Operation Duration (years)	Annual Total Recordable Cases	Activity Duration Total Recordable Cases	Annual Fatalities	Activity Duration Fatalities
<b>Construction</b>						
Low-energy accelerator	75	3	4.0	12	0.010	0.03
High-energy accelerator	410	5	22	110	0.057	0.285
New research reactor	160	7	8.5	59.5	0.022	0.154
<b>Operation</b>						
ATR <sup>a</sup>	0	35	NA	NA	NA	NA
HFIR <sup>a</sup>	0	35	NA	NA	NA	NA
CLWR <sup>a</sup>	0	35	NA	NA	NA	NA
FFTF	242	35	8.0	280	0.0031	0.109
Low-energy accelerator	13	35	0.4	14	0.00017	0.00595
High-energy accelerator	225	35	7.4	259	0.0029	0.102
New research reactor	120	35	4.0	140	0.0016	0.056
REDC	116	35	3.8	133	0.0015	0.0525
FDPF	75	35	2.5	87.5	0.00098	0.0343
FMEF	105	35	3.5	123	0.0014	0.049
RPL/306–E	30	35	1.0	35	0.00039	0.0137
New support facility	100	35	3.3	116	0.0013	0.0455

a. Not applicable. No additional workers would be required for the proposed activities evaluated in this NI PEIS.

Computation of total recordable cases and fatalities expected during construction or modification of target fabrication and processing facilities, prior to operation, have been neglected because of the relatively short duration of these activities.

As expected, the incidence of impacts, above and beyond those requiring first aid, do indeed exceed impacts from radiation and hazardous chemical accidents evaluated in this NI PEIS. No fatalities would be expected from either construction or operation of any facility.

# **Appendix J**

## **Evaluation of Human Health Effects of Transportation**

### **J.1 INTRODUCTION**

The overland transportation of any commodity involve risk to both transportation crew members and members of the public. This risk can result directly from transportation-related accidents and indirectly from the increased levels of pollution from vehicle emissions, regardless of the cargo. The transportation of certain materials, such as hazardous or radioactive substances, can pose an additional risk because of the unique nature of the material itself. To permit a complete appraisal of the environmental impacts of the proposed action and alternatives, the human health risks associated with the transportation of radiological material are analyzed in this appendix.

This appendix provides an overview of the approach used to assess the human health risks that may result from overland transportation. The appendix includes discussion of the scope of the assessment, analytical methods used for the risk assessment (i.e., computer models), assessment assumptions, potential transportation routes, and presents the results of the assessment. In addition, to assist in understanding and interpreting the results, specific areas of uncertainty are described with an emphasis on how the uncertainties may affect comparisons of the alternatives.

The risk assessment results are presented in this appendix in terms of “per-shipment” risk factors, as well as for the total risks for a given alternative. Per-shipment risk factors provide an estimate of the risk from a single shipment. The total risks for a given alternative are found by multiplying the expected number of shipments by the appropriate per-shipment risk factors.

### **J.2 SCOPE OF ASSESSMENT**

The scope of the transportation human health risk assessment, including the alternatives and options, transportation activities, potential radiological and nonradiological impacts, and transportation modes considered, is described below. Additional details of the assessment are provided in the remaining sections of the appendix.

#### **PROPOSED ACTION AND ALTERNATIVES**

The transportation risk assessment conducted for this *Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS])* estimates the human health risks associated with the transportation of radioactive materials for a number of alternatives.

#### **TRANSPORTATION-RELATED ACTIVITIES**

The transportation risk assessment is limited to estimating the human health risks incurred during transportation and handling when away from U.S. Department of Energy (DOE) facilities (i.e., at a port) for each alternative. The transportation risk assessment does not address possible impacts from increased transportation levels on local traffic flow, noise levels, or infrastructure.

## **RADIOLOGICAL IMPACTS**

For each alternative, radiological risks (those risks that result from the radioactive nature of the materials) are assessed for both incident-free (normal) and accident transportation conditions. The radiological risk associated with incident-free transportation conditions would result from the potential exposure of people to external radiation in the vicinity of a loaded shipment. The radiological risk from transportation accidents would come from the potential release and dispersal of radioactive material into the environment during an accident and the subsequent exposure to people.

All radiological impacts are calculated in terms of committed dose and associated health effects in the exposed populations. The radiation dose calculated is the total effective dose equivalent (10 CFR Part 20), which is the sum of the effective dose equivalent from external radiation exposure and the 50-year committed effective dose equivalent from internal radiation exposure. Radiation doses are presented in units of roentgen equivalent man (rem) for individuals and person-rem for collective populations. The impacts are further expressed as health risks in terms of latent cancer fatalities and cancer incidence in exposed populations, using the dose-to-risk conversion factors published by the National Council on Radiation Protection and Measurement (NCRP 1993), and by the International Council on Radiation Protection (ICRP 1991).

## **NONRADIOLOGICAL IMPACTS**

In addition to the radiological risks posed by overland transportation activities, vehicle-related risks are also assessed for nonradiological causes (i.e., causes related to the transport vehicles and not the radioactive cargo) for the same transportation routes. The nonradiological transportation risks, which would be incurred for similar shipments of any commodity, are assessed for both incident-free and accident conditions. The nonradiological risks during incident-free transportation conditions would be caused by potential exposure to increased vehicle exhaust emissions. The nonradiological accident risk refers to the potential occurrence of transportation accidents that directly result in fatalities unrelated to the shipment of cargo. National transportation fatality rates are used in the assessment. Nonradiological risks are presented in terms of estimated fatalities.

## **TRANSPORTATION MODES**

All overland shipments are assumed to use trucks, those requiring secure shipment will use safe, secure trailer/SafeGuards Transport (SST/SGT). Transatlantic shipments of mixed oxide fuel would use purpose-built vessels<sup>1</sup>. Medical isotopes would be shipped via aircraft as well as trucks.

## **RECEPTORS**

Transportation-related risks are calculated and presented separately for workers and members of the general public. The workers considered are truck, ship, and aircraft crew members involved in the actual transportation. The general public includes all persons who could be exposed to a shipment while it is moving or stopped during transit. Potential risks are estimated for the collective populations of exposed people and for the hypothetical maximally exposed individual. The collective population risk is a measure of the radiological risk posed to society as a whole by the alternative being considered. As such, the collective population risk is used as the primary means of comparing various alternatives. Persons handling casks at DOE facilities are included in site dose assessments. Workers handling packages at military ports are included in this appendix.

---

<sup>1</sup> Purpose-built vessels are specifically designed to transport casks containing radioactive material.

### **J.3 PACKAGING AND REPRESENTATIVE SHIPMENT CONFIGURATIONS**

Shipment Configurations Regulations that govern the transportation of radioactive materials are designed to protect the public from the potential loss or dispersal of radioactive materials, as well as from routine radiation doses during transit. The primary regulatory approach to promote safety is through the specification of standards for the packaging of radioactive materials. Because packaging represents the primary barrier between the radioactive material being transported and radiation exposure to the public and the environment, packaging requirements are an important consideration for transportation risk assessment. Regulatory packaging requirements are discussed briefly below. The representative packaging and shipment configurations assumed for this NI PEIS also are described below.

#### **J.3.1 Packaging Overview**

Although several Federal and state organizations are involved in the regulation of radioactive material transportation, primary regulatory responsibility resides with the U.S. Department of Transportation (DOT) and the U.S. Nuclear Regulatory Commission (NRC). All transportation activities must take place in accordance with the applicable regulations of these agencies as specified in 49 CFR and 10 CFR Part 71. Packaging for radioactive materials may be either DOE-specification packagings, Type A packagings designed and tested commercially, Type B certified (DOE or NRC) packagings, or DOE-designed and -tested Type A packagings. Transatlantic shipments would also be in accordance with the International Atomic Energy Agency (IAEA) regulations. DOT and NRC work to ensure that U.S. regulations are consistent with IAEA regulations.

Transportation packaging for small quantities of radioactive materials must be designed, constructed, and maintained to contain and shield their contents during normal transport conditions. For large quantities and for more highly radioactive material, such as spent nuclear fuel, packaging must contain and shield their contents in the event of severe accident conditions. The type of packaging used is determined by the total radioactive hazard presented by the material within the packaging. Four basic types of packaging are used. Excepted, Industrial, Type A, and Type B. Another packaging option, “Strong, Tight,” is available for some domestic shipments.

Excepted packages are limited to transporting materials with extremely low-levels of radioactivity. Industrial packages are used to transport materials that, because of their low concentration of radioactive materials, present a limited hazard to the public and the environment. Type A packages are designed to protect and retain their contents under normal transport conditions and must maintain sufficient shielding to limit radiation exposure to handling personnel. These packages are used to transport radioactive materials with higher concentrations or amounts of radioactivity than Excepted, or Industrial packages. Strong, Tight packages are used in the United States for shipment of certain materials with low-levels of radioactivity, such as natural uranium and rubble from the decommissioning of nuclear reactors. Type B packages used to transport material with the highest radioactivity levels, are designed to protect and retain their contents under transportation accident conditions and are described in more detail in the following sections.

#### **J.3.2 Regulations Applicable to Type B Casks**

Regulations for the transport of radioactive materials in the United States are issued by DOT and are codified in 49 CFR Part 173. The regulation authority for radioactive materials transport is jointly shared by DOT and NRC. As outlined in a 1979 Memorandum of Understanding with the NRC, DOT specifically regulates the carriers of spent nuclear fuel and the conditions of transport, such as routing, handling and storage, and vehicle and driver requirements (44 FR 38690). DOT also regulates the labeling, classification, and marking of all packages. NRC regulates the packaging and transport of spent nuclear fuel for its licensees, which include

commercial shippers of spent nuclear fuel. In addition, NRC sets the standards for packages containing fissile materials and spent nuclear fuel.

DOE policy requires compliance with applicable Federal regulations regarding domestic shipments of spent nuclear fuel. Accordingly, DOE has adopted the requirements of 10 CFR Part 71, “Packaging and Transportation of Radioactive Materials,” and 49 CFR Part 173, “Shippers—General Requirements for Shipments and Packagings.” DOE Headquarters can issue a certificate of compliance for a package to be used only by DOE and its contractors.

### **J.3.2.1 Cask Design Regulations**

Neptunium-237, neptunium-237 targets, mixed oxide fuel, plutonium-238 and many isotopes are transported in robust “Type B” transportation casks that are certified for transporting radioactive materials. Casks designed and certified for spent nuclear fuel transportation within the United States must meet the applicable requirements promulgated by the NRC for design, fabrication, operation, and maintenance, as contained in 10 CFR Part 71.

Cask design and fabrication can only be done by approved vendors with established quality assurance programs (10 CFR Section 71.101). Cask and component suppliers or vendors are required to obtain and maintain documents that prove the materials, processes, tests, instrumentation, measurements, final dimensions, and cask operating characteristics meet the design-basis established in the Safety Analysis Report for Packaging for the cask and that the cask will function as designed.

Regardless of where a transportation cask is designed, fabricated, or certified for use, it must meet certain minimum performance requirements (10 CFR Sections 71.71, 71.73–71.75, 71.77). The primary function of a transportation cask is to provide containment and shielding. Casks similar to the designs being considered for targets have been used to transport spent nuclear fuel for many years. Regulations require that casks must be operated, inspected, and maintained to high standards to ensure their ability to contain their contents in the event of a transportation accident (10 CFR Section 71.87). There are no cases of a major release of radioactive materials from a Type B package, even though thousands of shipments have been made by road, rail, and water transport. Further, a number of obsolete casks have been tested under severe accident conditions to demonstrate their adherence to design criteria without failure. Such tests have demonstrated that transportation casks are not only fabricated to a very high factor of safety, they are even sturdier than required.

Transportation casks are built out of heavy, durable structural materials such as stainless steel. These materials must ensure cask performance under a wide range of temperatures (10 CFR Section 71.43). In addition to the structural materials, shielding is provided to limit radiation levels at the surface and at prescribed distances from the surface of transportation casks (10 CFR Section 71.47). Shielding typically consists of dense material such as lead or depleted uranium. However, heavily shielded casks are needed for targets because irradiated targets have gamma radiation levels similar to those of spent fuel. The cask cavity can be configured to hold various contents, including irradiated or unirradiated targets. The assemblies are supported by internal structures, called baskets, that provide shock and vibration resistance and establish minimum spacing and heat transfer to maintain the temperature of the contents within the limits specified in the Safety Analysis Report for Packaging.

Finally, to limit impact forces and minimize damage to the structural components of a cask in the event of a transportation accident, impact-absorbing structures may be attached to the exterior of the cask. These are usually composed of foam, or aluminum honeycomb that is designed to readily deform upon impact to absorb impact energy. All of these components are designed to work together in order to satisfy the regulatory

requirements for a cask to operate under normal conditions of transportation and maintain its integrity in an accident.

### J.3.2.2 Design Certification

For certification, Type B transportation casks must be shown by analysis and/or testing to withstand a series of hypothetical accident conditions. These conditions have been internationally accepted as simulating damage to transportation casks that could occur in most reasonably foreseeable accidents. The impact, puncture, fire, and water-immersion tests are considered in sequence to determine their cumulative effects on one package. These accident conditions are described in **Figure J–1**. NRC issues regulations, 10 CFR Part 71, governing the transportation of radioactive materials. In addition to the tests shown in Figure J–1, the regulations affecting Type B casks require that a transportation cask with activity greater than  $10^6$  curies (which is applicable to irradiated targets) be designed and constructed so that its undamaged containment system would withstand an external water pressure of 20 kilograms per square centimeter (290 pounds per square inch) or immersion in 200 meters (656 feet) of water, for a period of not less than 1 hour without collapsing, buckling, or allowing water to leak into the cask.

Under the Federal certification program, a Type B packaging design must be supported by a Safety Analysis Report for Packaging, which demonstrates that the design meets Federal packaging standards. The Safety Analysis Report for Packaging must include a description of the proposed packaging in sufficient detail to identify the packaging accurately and provide the basis for evaluating its design. The Safety Analysis Report for Packaging must provide the evaluation of the structural design, materials properties, containment boundary, shielding capabilities, and criticality control, and present the operating procedures, acceptance testing, maintenance program, and the quality assurance program to be used for design and fabrication. Upon completion of a satisfactory review of the Safety Analysis Report for Packaging to verify compliance to the regulations, a Certificate of Compliance is issued. DOE is permitted to certify Type B and fissile material packages for its own use by 49 CFR Section 173.7, and guidance for that certification is provided by DOE Order 461.1.

### J.3.2.3 Transportation Regulations

To ensure that the transportation cask is properly prepared for transportation, trained technicians perform numerous inspections and tests (10 CFR Section 71.87). These tests are designed to ensure that the cask components are properly assembled and meet leak-tightness, thermal, radiation, and contamination limits before shipping radioactive material. The tests and inspections are clearly identified in the Safety Analysis Report for Packaging and/or the Certificate of Compliance for each cask. Casks can only be operated by registered users who conduct operations in accordance with documented and approved quality assurance programs meeting the requirements of the regulatory authorities. Records must be maintained that document proper cask operations in accordance with the quality requirements of 10 CFR Section 71.91. Reports of defects or accidental mishandling must be submitted to the NRC. DOE would be the Shipper-of-Record for the shipments.

External radiation from a package must be below specified limits that minimize the exposure of handling personnel and the general public. For an exclusive-use shipment (i.e., carrying no other cargo) in a closed transport vehicle, the external radiation dose rate during normal transportation conditions must be maintained below the following limits of 49 CFR Part 173:

- 10 millirems per hour at any point 2 meters (6.6 feet) from the vertical planes projected by the outer lateral surfaces of the transport vehicle (referred to as the regulatory limit throughout this document)

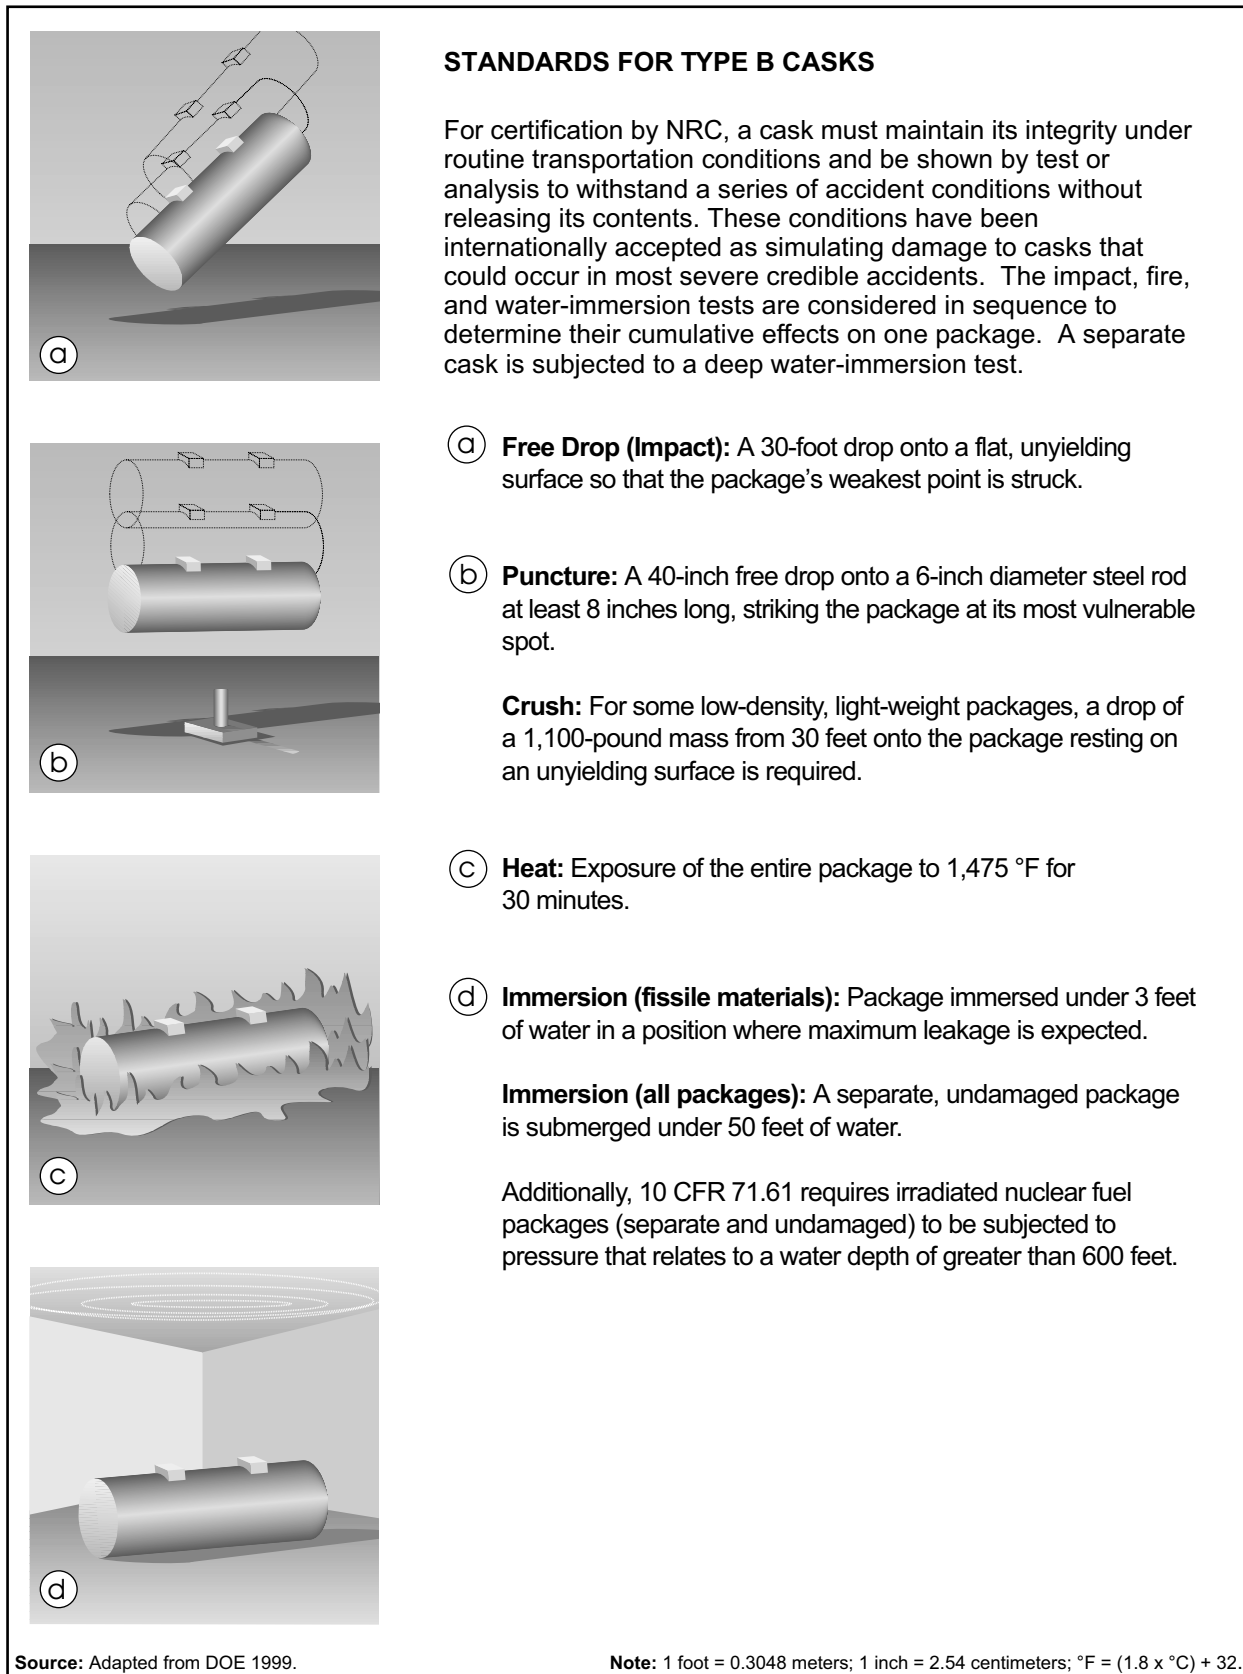

Figure J-1 Standards for Transportation Casks

- 2 millirems per hour in any normally occupied position in the transport vehicle

Additional restrictions apply to package surface contamination levels, but these restrictions are not important for the transportation radiological risk assessment. For risk assessment purposes, it is important to note that all packaging of a given type is designed to meet the same performance criteria. Therefore, two different Type B designs would be expected to perform similarly during incident-free and accident transportation conditions. The specific containers selected or designed, however, will determine the total number of shipments necessary to transport a given quantity of material.

#### **J.3.2.4 Communications**

Proper communication assists in ensuring safe preparation and handling of transportation casks. Communication is provided by labels, markings, placarding, shipping papers, or other documents. Labels applied to the cask, document the contents and the amount of radiation emanating from the cask exterior, known as the transport index (49 CFR Section 172.403). The transport index lists the ionizing radiation level in millirems per year at a distance of 1 meter (3.3 feet) from the cask surface.

In addition to the label requirements, markings (49 CFR Section 173.471) should be placed on the exterior of the cask to show the proper shipping name and the consignor and consignee in case the cask is separated from its original shipping documents (49 CFR Section 172.203). Transportation casks are required to be permanently marked with the designation “Type B,” name and address of the owner or fabricator, Certificate of Compliance number, and the gross weight (10 CFR Section 71.83).

Placards are applied to the transport vehicle or freight container holding the transportation cask (49 CFR Section 172.500). The placards indicate the radioactive nature of the contents. Neptunium-237, neptunium-237 targets, and plutonium-238 shipments which constitute a highway route-controlled quantity or “HRCQ,” must be placarded according to 49 CFR Section 172.507. Placards provide first responders to a traffic or transportation accident with initial information about the nature of the contents.

Shipping papers should contain the notation “HRCQ” and have entries identifying the following: name of the shipper, emergency response telephone number, description of contents, and the shipper's certificate, as described in 49 CFR Part 172, Subpart C.

In addition, drivers of motor vehicles transporting radioactive material must have training in accordance with the requirements of 49 CFR Section 172.700. The training requirements include familiarization with the regulations, emergency response information, and the hazard communication programs required by the Occupational Health and Safety Administration in 29 CFR Section 1910.1200. Drivers are also required to have training on the procedures necessary for safe operation of the vehicle.

#### **J.3.3 Packages Used in the Nuclear Infrastructure Program**

This section describes currently available packaging systems that have been used for similar materials and could be used to implement the activities described in this NI PEIS. DOE could choose to design new or procure similar packaging. This similar packaging would be designed to the same level of safety and would be expected to have similar features. These packages have been used for the purpose of estimating input parameters, such as number of shipments and mass of contents, for the purpose of impact analysis.

### **J.3.3.1 Neptunium-237 Packaging**

The Type B 9975 container could be used to transport neptunium-237 from the Savannah River Site (SRS) to the storage or processing facility the Radiochemical Engineering Development Center (REDC), Fluorinel Dissolution Process Facility (FDPF), or Fuels and Materials Examination Facility (FMEF). The 9975 package includes a 132-liter (35-gallon) drum, insulation, bearing plates, primary containment vessel, secondary containment vessel, lead shielding and aluminum honeycomb spacers (**Figure J-2**). The weight of the package is 163 kilograms (360 pounds), the overall height is 0.9 meter (35 inches) and the diameter is 0.5 meter (20 inches) (WSRC 1996).

In the spring of 2000, the 9975 packaging failed the recertification test and the Certificate of Compliance has been canceled. During the sequential 30-foot drop and puncture bar test, which are part of the hypothetical accident condition testing, the package lid buckled and partially opened. DOE could either redesign the 9975 package, design a new package or modify an existing package. In any case, the new design would be evaluated for compliance with current regulatory requirements by the Package Approval and Safety Program. DOE needs a package of similar size and capability to the 9975 for several programs, including the Rocky Flats cleanup (Scott 2000). The size and general characteristics of the replacement package (i.e., 132-liter [35-gallon] or 206-liter [55-gallon] drum, can-in-can construction, insulation, approximately 5-kilogram [11-pound] capacity) would be similar to the 9975. Therefore, for the purpose of risk analysis, the capacity and general characteristics of the 9975 package will be used.

The neptunium-237 would be sealed into a convenience can and placed on a honeycomb spacer inside the stainless steel primary containment vessel. The primary containment vessel would be bolted closed, and placed into the similarly constructed, but larger, secondary containment vessel. The secondary containment vessel would be bolted closed and loaded into the drum. The drum is equipped with lead shielding that reduces radiation levels, and fiberboard insulation that protects the containment vessels in the unlikely event of a severe impact. The drum and cover are made of 18-gage carbon steel and are galvanized and coated with zinc chromate. A locking ring with drop-forged lugs secures the cover to the drum.

### **J.3.3.2 Neptunium Targets**

After targets are fabricated at the processing facility, located at the REDC at ORR, FDPF at the Idaho National Engineering and Environmental Laboratory (INEEL), or FMEF at the Hanford Site (Hanford), they will be transported to either the High Flux Isotope Reactor (HFIR) at ORR, Advanced Test Reactor (ATR) at INEEL, Fast Flux Test Facility (FFTF) at Hanford, a new reactor or a new accelerator, or a commercial light water reactor (CLWR) for irradiation. After they are irradiated, they will be returned to the processing facility for extraction of the plutonium-238. The same casks and number of shipments will apply to both the unirradiated and irradiated targets.

#### **INTRASITE SHIPMENT—REDC TO HFIR OR FDPF TO ATR**

If HFIR is selected to irradiate and REDC to process the targets, targets would be transported the short distance between REDC and HFIR in a cask that was formerly certified to Type B standards. These formerly certified packages are verified to be equivalent to Type B packages by site procedures. Since the move is only about 90 meters (100 yards), on closed roads, and entirely at ORR, DOE procedures and NRC regulations do not require the use of a certified Type B cask. Similar procedures and equipment would be used at INEEL for transfers between FDPF and ATR.

Figure J-2 Typical Assembly of Type 9975 Package

## **INTERSITE SHIPMENT**

The transportation of irradiated targets would involve shipments of Type B quantities (based on activation levels) using NRC- or DOE-certified shipping casks. The amount of material that can be loaded in a shipping cask is controlled by the thermal load, the fission product inventory, the neutron dose rate, and the physical size. Although a new cask could be designed for this application, the most likely approach would be to design a new basket to fit inside an existing cask. Since this design effort is not yet underway, the exact number of shipments cannot be determined. As an example case, if the GE-2000 container (**Figure J-3**) is used, the thermal load limit would determine the total number of shipments. Transportation of the irradiated targets is likely to require updating the Certificate of Compliance for the casks. Preliminary calculations to determine the decay heat were done for several irradiation positions and cycles to estimate the thermal load of the irradiated targets. The preliminary analysis indicates that irradiated targets that have cooled for at least 100 days will generate about 0.58 watt (0.033 British thermal unit per minute) of heat for each gram (0.035 ounce) of plutonium-238. If the targets are classified as spent nuclear fuel, then the thermal load limit for the GE-2000 cask is 600 watts (34 British thermal units per minute) per shipment. In this case, a total of nine shipments would be required to move the targets. If the targets are classified as a by-product or special nuclear material, then the thermal load limit is 2,000 watts (114 British thermal units per minute) per shipment for a total of three shipments. Thus, the range is roughly three to nine shipments per year, and the risk analysis is based on nine shipments per year. This range is representative of other commercially available casks. Note that the GE-2000 is too large and heavy to transport on an SST/SGT.

DOE realizes that a CLWR, new reactor, accelerator, or FFTF would use larger targets than HFIR or ATR. A GE-2000 container would not be long enough for these targets. However, about the same thermal parameters would apply for all but the accelerator targets, so the same shipping estimates are used. Based on the preconceptual design, accelerator targets would be much larger, but would require fewer shipments.

### **J.3.3.3 Plutonium-238**

The 5320 cask, designed for shipment of americium or plutonium by surface transportation modes could be used to carry plutonium-238 oxide that would be produced at the processing facility. Several versions of the 5320 (the 5320 B(U) and the 5320 B(M)) comply with the regulatory safety requirements of 10 CFR Part 71, as well as DOE and IAEA requirements. The 5320 package was evaluated for transport of plutonium-238 oxide in any solid form, in excess of Type A quantities as Fissile Class I. The radioactive content is limited to 357 grams (12.6 ounces) of plutonium-238. When the only plutonium isotope is plutonium-238, the 5320 packages may be shipped Fissile Exempt, subject to the provisions of 49 CFR Section 173.453(f). The plutonium-238 oxide may be any density up to 11 grams per cubic centimeter (6.4 ounces per cubic inch), contain a maximum of 1 gram of volatile constituents, and not exceed a decay heat load of 203 watts (11.6 British thermal unit per minute). The time that the plutonium-238 can be sealed within the primary containment vessel prior to and including shipment is limited to 2 years.

The 5320 packaging is a dome topped, upright circular cylinder mounted on a baseplate supported by casters, as shown in **Figure J-4**. The weight of the packaging is about 148 kilograms (327 pounds), the overall height is 81 centimeters (32 inches) and the diameter is 42.5 centimeters (16.75 inches).

The plutonium-238 would be loaded into an EP-60 product canister. The EP-60 is not credited in the safety analysis as part of the packaging. It is a stainless steel shell confinement vessel which is used to load the product into the package safely and conveniently. The EP-60 would be seal welded into the removable stainless shell primary containment vessel, the EP-61. The EP-61 is placed into the secondary containment vessel, the EP-62. The stainless steel EP-62 has a removable bolted closure lid. The gasketed flange of the EP-62 satisfies the containment requirements of normal conditions of transport and hypothetical accident

Figure J-3 GE-2000 Container

Source: Adapted from DOE 2000.

Figure J-4 Cross Section of 5320 Packaging Assembly

conditions. Shipments must be completed within 2 years of sealing the EP-61 because of the possibility of undetected gas buildup.

The nested EP-61 and EP-62 are surrounded by a tinned aluminum-shield tank filled with water-extend polyester neutron shielding material. The EP-62 is retained with the inner shell of the shield tank by a bolt which fastens the bottom of the vessel to the baseplate. Heat from the package contents is conducted to the outer shell of the shield tank by radial aluminum webs that connect the inner shell to the outer shell. Axial fins on the outer shell dissipate the heat to the environment.

DOE estimates that one shipment per year would support the operational requirements for 5 kilograms (11 pounds) of plutonium per year. Based on the heat limit of the cask, 203 watts (11.6 British thermal units per minute), the casks would be loaded with up to 350 grams (12 ounces) of plutonium-238. Therefore, each SST/SGT shipment would carry about fifteen 5320 casks.

The *Environmental Assessment of the Import of Russian Plutonium-238* (DOE 1993) analyzed the smaller Mound 1-kilowatt packages. These packages were actually used for two successful shipments. The risk analysis results from that environmental assessment have been used in this NI PEIS.

#### **J.3.3.4 Irradiated Target Assembly Packages for Medical and Industrial Isotopes**

Although there are two different target vehicles, the long irradiated target vehicle (up to 1 meter [3 feet] in length) and the rapid retrieval target vehicle (up to 20 centimeters [8 inches] in length), both irradiation vehicles would be shipped from FFTF at Hanford to the Radiochemical Processing Laboratory (RPL) at Hanford using the T-2 shipping cask. The elements or pins from the long irradiation target vehicles would be inserted directly into the shipping cask, whereas the rapid retrieval targets would be inserted into a smaller package, which would be inserted into the shipping cask. For the purposes of this analysis, it is assumed that the elements or pins from one assembly (i.e., carrying a single target isotope and its associated impurities), would be shipped at a time. Similar packages would be used at the new reactor or accelerator facility.

##### **J.3.3.4.1 Long-Length Irradiated Target Vehicle Shipping Cask**

The long-length irradiated target shipping cask would be used for transporting irradiated targets. A typical example for this type of casks is the T-2 shipping cask (**Figure J-5**). This cask has been used at Hanford in the past and is certified to carry sodium-bonded metal fuel pins. The T-2 meets the requirements for a Type B shipping package.

The T-2 cask is 295 centimeters (116 inches) long with a 254-centimeter (100-inch) long by 15-centimeter (6-inch) inner diameter liner made of schedule 40 stainless steel pipe. The outside shell of the cask is made in three sections. The center section is a 61-centimeter (24-inch) outer diameter schedule 40 carbon steel pipe. Each end section is made of 41 centimeter (16 inch) outer diameter schedule 40 carbon steel pipe. The space between the liner and shell is filled with lead for shielding. At the top, there is a 19-centimeter (7-5/8-inch) inner diameter opening which is closed by a 20-centimeter (8-inch) thick stainless steel shield plug. Figure J-5 shows the cross section of a T-2 cask and its dimensions. The cask is enclosed in a steel shipping case during transport (Lavender and Nielsen 1997).

##### **J.3.3.4.2 Rapid Retrieval Target Vehicle Package**

The rapid retrieval targets would be packaged in a container and inserted in the T-2 shipping cask for transport to RPL from FFTF. A “shielded pig” or sample pig would be used for packaging the rapid retrieval targets. For the purposes of this analysis, the proposed “shielded pig” is assumed to be 122 centimeters (48 inches)

Figure J-5 T-2 Shipping Cask: Long-Length Irradiated Target

tall by 15 centimeters (6 inches) in diameter. Based on existing sample pig design information, the “shielding pig” inner and outer walls will be constructed with schedule 40 carbon steel pipe. Lead shielding would be provided between the inner and outer carbon steel pipes in a “sandwich” configuration. The T-2 would be equipped with spacers to prevent the movement of the sample pig within the T-2 cask cavity. Smaller (i.e., shorter) shielded pigs have been approved for use at Hanford in the past. It is anticipated that the longer shielded pig proposed for the transport of the rapid retrieval targets would also be approved for use at Hanford (Lavender and Nielsen 1997).

### **J.3.3.5 Packages for Separated Medical Isotopes**

DOE has been producing and shipping medical and industrial isotopes for several decades. This NI PEIS proposes alternatives that expand the amount and number of isotopes that DOE can supply for its customers (ultimately to hospitals, research laboratories, and other private and government users of isotopes). Alternatives proposed in this NI PEIS pose no new shipping issues or requirements for package development. Various Type A and Type B containers could be used for shipping the separated isotopes from Pacific Northwest National Laboratory (PNNL) to the pharmaceutical distributor. Following target processing, the separated isotopes, either as liquids, gases or solids, would be placed in glass vials and inserted into the protective container. For this analysis, it is assumed the CI-20WC-2A would be used for the separated isotope shipments. The CI-20WC-2A is a specification package, constructed and used in accordance with 49 CFR Section 178.362.

The CI-20WC-2A container, shown in **Figure J-6**, consists of an outer steel jacket, 62 centimeters (24.25 inches) high by 46 centimeters (18 inches) in diameter and an inner depleted uranium shipping cask, 22.9 centimeters (9 inches) high by 11.4 centimeters (4.5 inches) in diameter and 4.6 centimeters (1.8 inches) thick. Between the outer steel jack and the depleted uranium cask is a wooden impact limiter 14.0 centimeters (5.5 inches) thick on the sides, top, and bottom. The inner and outer walls of the depleted uranium cask are constructed of schedule 40 carbon steel pipe with a gasketed and bolted flange closure. The inner cavity of the depleted uranium cask, which is designed to accept a 2R shipping container, is 15.2 centimeters (6 inches) high and 7.9 centimeters (3.1 inches) in diameter.

The 2R shipping container is a 6.9-centimeter (2.7-inch) outer diameter by 14.1-centimeter (5.6-inch) long stainless steel, gasketed and threaded container. Spacers would be placed within the 2R shipping container to limit the movement of the glass vial containing the separated isotope (Lavender and Nielsen 1997).

### **J.3.3.6 Mixed Oxide Fuel Package**

Two European casks could be considered for shipping the SNR-300 mixed oxide fuel to FFTF. The major characteristics are:

1. The British cask GB/136 (owned by AEA Technologies)
  - Capacity is four assemblies per cask
  - 16 casks are available
  - Activity is less than 400 kilocuries
  - Heat load is less than 400 watts
  - Head load/assembly is less than 150 watts
  - Heat load may limit to only two to three assemblies in some casks
  - Quantity of casks makes this cask system desirable

**Figure J-6 CI-20WC-2A Shipping Casks: Separated Isotopes**

2. The SNR-300 fuel assembly cask
  - Capacity is nine assemblies per cask
  - Two casks are available
  - Activity is less than 57 kilocuries
  - Heat load/assembly is less than 115 watts
  - Capacity, and with this cask being built for this fuel, makes this cask system desirable

Neither of the casks is currently certified by DOE, NRC, or DOT for use in the United States. SBK of Germany, owner of the SNR-300 fuel, could obtain a DOT Certificate of Competent Authority for either cask (Hiller 2000). Alternatively, SBK could select an existing cask for modification or design a new cask. For the purpose of conservative analysis, DOE assumes that two assemblies are shipped in each Type B package.

The shielding and accident performance parameters used in the impact analysis are typical for Type B packages.

### **J.3.3.7 Highly Enriched Uranium Package**

DOE has several Type B packages that could be used to ship highly enriched uranium oxide to the fuel fabricator. The two identified packages are DT-22 and DC-1. Several other packages are used in normal commercial shipment of highly enriched uranium and could be used in this application.

### **J.3.3.8 Highly Enriched Uranium Fuel Packages**

Alternatives 1 (Restart FFTF) and Alternative 4 (Construct New Research Reactor) would require packages for delivering fresh uranium fuel to the sites. Package selection cannot be made at this time, so this section will describe the general characteristics of packages that would be used. The driving requirement comes from 10 CFR Section 71.55 (e), stating “A package used for the shipment of fissile material must be so designed and constructed and its contents so limited that under the tests specified in 10 CFR Section 71.73 (“Hypothetical accident conditions”), the package would be subcritical.” A criticality analysis would have to be performed to design the packages.

### **Highly Enriched Uranium Fuel for FFTF**

FFTF can use highly enriched uranium or mixed oxide fuel. For all options in Alternative 1, FFTF would require highly enriched uranium fuel for part of its mission. DOE estimates that FFTF would use 12 to 15 fuel assemblies per year containing about 26.5 kilograms (16.5 pounds) of 35 percent enriched uranium. These quantities of uranium would require Type B packages to withstand the hypothetical accident conditions defined in 10 CFR Part 71. A reasonably large Type B package would hold four assemblies, and would be carried alone on a truck. Alternatively, two smaller Type B packages, each holding two assemblies, could be used. In either case, the same number of shipments would be required.

### **J.3.3.9 Nuclear Research and Development Materials Test Transport**

The T-3, an existing licensed DOT irradiated fuel shipping cask is available for offsite transportation (e.g., shipment of fueled tests to other DOE facilities for diagnostic examinations). This cask can accommodate shipments of pins or a single FFTF fuel assembly, as well as non-fuel experiments and materials. There are three of these casks available for shipping material within the fuel descriptions of approved packages shown in the T-3 Certificate of Compliance, or for anyone willing to pay for the addition of new packages through an addendum to the NRC Certificate of Compliance. Equipment is available to use the T-3 cask in either the horizontal or the vertical position. Following are some facts about the T-3 cask:

- NRC License, docket no. 71-9132
- DOT Certificate (IAEA Certificate of Compliance)
- DOE License from 1998-1999
- Designed to meet all licensing requirements of 10 CFR Part 71 for a Fissile Class III, Type B shipping container
- 17,300 kilograms (38,200 pounds) gross weight for a loaded container; overall package weight, 19,296 kilograms (42,595 pounds)
- Overall cask dimensions: 67 centimeters (26 inches) in diameter by 450 centimeters (177 inches) long
- Internal cavity dimensions: 20 centimeters (8 inches) in diameter by 373 centimeters (147 inches) long
- Cavity volume: 0.1 cubic meters (4.3 cubic feet)
- Decay heat for contents: 1,400 watts (80 British thermal units per minute) maximum

- Weight of contents: 320 kilograms (700 pounds) maximum
- Designed and fabricated to meet ASME Section III (1977 ed.)
- Design allows shipping intact FFTF standard core components (control rods, reflector, experiments, etc.)
- Design envelope includes use of fuel pin containers (irradiated fuel pins)
- Design allows for handling of hardware shipping containers (irradiated hardware)

No specific shipments or mission has been identified for this cask, however it is included as a general purpose package available on Hanford.

### **J.3.4 Safeguarded Transportation**

DOE anticipates that any transportation of neptunium, plutonium dioxide, mixed oxide fuel, or highly enriched uranium would be required to be made through use of the Transportation Safeguards System and shipped using SST/SGTs. Transportation safeguards are required for (1) nuclear explosives; (2) components moved in a single shipment that could comprise a complete nuclear explosive; (3) any form of uranium-235 enriched 20 percent or greater in quantities of 5 kilograms or more, or uranium-233 or plutonium in quantities of 2 kilograms or more; (4) classified forms of plutonium and uranium-235 regardless of quantity as requested by Heads of Field Elements; (5) DOE-owned plutonium in any quantity to be transported by air; or (6) any form of plutonium-238 in excess of 5 grams (DOE Order Supplemental Directive AL 5610.14). The SST/SGT is a fundamental component of the Transportation Safeguards System. The Transportation Safeguards System is operated by the DOE Transportation Safeguards Division of the Albuquerque Operations Office for the DOE Headquarters Office of Defense Programs. Based on operational experience between fiscal year 1984 and fiscal year 1998, the mean probability of an accident requiring the tow-away of the SST/SGT was 0.058 accident per million kilometers (0.096 accident per million miles) (Claus and Shyr 1999). By contrast, the rate for commercial trucking in 1989 was about 0.3 accident per million kilometers (0.5 accident per million miles) (Saricks and Tompkins 1999). Commercial trucking accident rates and SST/SGTs were used in the human health effects analysis. Since its establishment in 1975, the Transportation Safeguards Division has accumulated more than 151 million kilometers (94 million miles) of over-the-road experience transporting DOE-owned cargo with no accidents resulting in a fatality or release of radioactive material.

Neptunium must be handled under the safeguards applicable to special nuclear materials, in accordance with DOE Office of Safeguards and Security guidance (McCallum 1999). Pure neptunium is a form of neptunium that would be desirable as a potential weapons material, so this NI PEIS assumes that the neptunium shipped from SRS to the storage locations would need to be shipped under the Transportation Safeguards System. The unirradiated and irradiated targets would carry much less neptunium per shipment, and the form of the neptunium would be less desirable for diversion, so this NI PEIS assumes that the neptunium shipped from SRS to the storage locations might be shipped under the Transportation Safeguards System program. The unirradiated and irradiated targets carry much less neptunium per shipment, and the neptunium is in a less desirable form, so the safeguards requirements would be lower. DOE's policy is to ship DOE-owned Safeguard Categories I and II quantities of special nuclear material and other forms and quantities of strategic materials under the safeguards protection of the Transportation Safeguards System program (DOE Order 5610.14). DOE Order 474.1, *Control and Accountability of Nuclear Materials* contains the methodology for determining the Safeguards Categories of the various nuclear materials that DOE handles. The highly enriched uranium, the highly enriched uranium fuel and mixed oxide fuel required for operation of FFTF will be transported under safeguards protection.

Although DOE may choose to use the Transportation Safeguards System program for unirradiated and irradiated target shipments, for the purposes of conservative safety analysis and flexibility in package selection, this NI PEIS assumes that commercial vehicles are used for target shipments. Under DOE Order 474.1,

plutonium-238 would be in a safeguard category less than Categories I and II, which require the use of a safe, secure trailer. However, DOE Order Supplemental Directive AL 5610.14 directs the use of the Transportation Safeguards System for shipments of plutonium-238.

The SST/SGT is a specially designed component of an 18-wheel tractor-trailer vehicle. While 49 CFR Section 173.7(b) exempts SST/SGT shipments from DOT regulations, DOE operates and maintains these vehicles in a way that exceeds DOT requirements. Although details of vehicle enhancements and some operational aspects are classified, key characteristics of the SST/SGT system include the following:

- Enhanced structural characteristics and a highly-reliable tie-down system to protect cargo from impact
- Heightened thermal resistance to protect the cargo in case of fire (newer SST/SGT models)
- Established operational and emergency plans and procedures governing the shipment of nuclear materials
- Various deterrents to prevent unauthorized removal of cargo
- An armored tractor component that provides courier protection against attack and contains advanced communications equipment
- Specially designed escort vehicles containing advanced communications and additional couriers
- 24-hour-a-day real-time communications to monitor the location and status of all SST/SGT shipments via DOE's Security Communication system
- Couriers, who are armed Federal officers, receive rigorous specialized training and are closely monitored through DOE's Personnel Assurance Program
- Significantly more stringent maintenance standards than those for commercial transport equipment
- Conduct of periodic appraisals of the Transportation Safeguards System operations by the DOE Office of Defense Programs to ensure compliance with DOE orders and management directives, and continuous improvement in transportation and emergency management programs

Loading and unloading of SST/SGTs at DOE sites is routinely done in accordance with site facility and Transportation Safeguards Division procedures. However, special attention is required at commercial facilities and military ports. The DOE SST/SGT operations team will direct and approve loading and securing of packages within SST/SGT vehicles and will be solely responsible for closing and securing SST/SGT vehicles and cargo areas prior to transport. DOE will take custody of packaged mixed oxide nuclear reactor fuel loaded on SST/SGT vehicles for transport at the military port and of the packaged highly enriched uranium or highly enriched uranium nuclear fuel at the commercial site. DOE will require that the commercial German and/or Scottish entities involved in shipping the material fully comply with the Certificate of Compliance for the package and applicable NRC and DOT regulations in preparing and offering packaged mixed oxide fuel for transportation, including proper shipping papers and nuclear material transfer forms. DOE anticipates that, if applicable, approved IAEA safeguard seals will be placed on packages in accordance with established protocols and procedures by the shippers, DOE, and other cognizant authorities prior to release of loaded packages for transport. IAEA safeguard seals may also be applied to transport vehicles.

Task interactions between Transportation Safeguards Division operations teams, the SST/SGT operations center, the shipping company, and military port operations and security personnel involved in loading, securing, and dispatching SST/SGT shipments will be conducted in accordance with the requirements of DOE Orders 461.1, 5632.1C, and 474.1 and SST/SGT operations procedures. The military port and ship will provide necessary labor, loading areas and docks, and package-handling equipment that is necessary for loading mixed oxide transportation packages into SST/SGTs. Personnel involved in fuel-handling operations will be required to have a “need to know” and possess either appropriate NRC [10 CFR 73.50(c)(1)] or DOE Level 3 (DOE M 474.1) access authorization. In dispatching shipments of mixed oxide fuel to FFTF, DOE’s SST operations team and operations center will also coordinate with the security operations center at a DOE site. Estimated time of arrival, shipment, and material accountability information will be transmitted to designated persons at the FFTF in accordance with prearranged protocols. DOE anticipates the time necessary to prepare, load, secure, and dispatch SST/SGTs to be on the order of less than 1 day (per convoy).

DOE realizes that the use of SST/SGT vehicles complicates package handling. ORNL/TM-13427 (Ludwig 1997) provides the following general dimensions for an SST:

Gross vehicle weight rating	36,288 kilograms (80,000 pounds)
Maximum payload	6,169 kilograms (13,600 pounds)
Trailer overall length	18.3 meters (60 feet)
Trailer overall width	259 centimeters (102 inches)
Trailer overall height	410 centimeters (13 feet)
Trailer rear door width	179.1 to 215.9 centimeters (70.5 to 85 inches)
Trailer rear door height	229 centimeters (90 inches)
Trailer floor height above roadway	144 centimeters (56.5 inches)
Tractor trailer minimum turning radius	11.4 meters (37.5 feet)

SGT dimensions are similar. The payload and physical dimensions of the trailer will constrain the selection of a cask for the mixed oxide fuel and for plutonium-238 targets. Additionally, a gurney or similar device will be necessary to place the cask into the SST/SGT. The ship, port, or facility crane would place the cask on the gurney, and the gurney would load the cask into the SST/SGT. The cask would be tied down in accordance with normal SST/SGT operational procedures.

### **J.3.5 Ground Transportation Route Selection Process**

According to DOE guidelines, radioactive material shipments must comply with both NRC and DOT regulatory requirements. NRC regulations cover the packaging and transport of neptunium, plutonium and waste, whereas DOT specifically regulates the carriers and the conditions of transport, such as routing, handling and storage, and vehicle and driver requirements. The highway routing of nuclear material is systematically determined according to DOT regulation 49 CFR Part 397 for commercial shipments. Specific routes cannot be publicly identified in advance for DOE’s Transportation Safeguards Division’s shipments because they are classified to protect national security interests.

DOT routing regulations require that shipment of a highway route controlled quantity of radioactive material be transported over a preferred highway network, including interstate highways, with preference toward interstate system bypasses and beltways around cities and state-designated preferred routes. A state may designate a preferred route to replace or supplement the interstate highway system in accordance with DOT requirements (49 CFR Section 397.103).

Carriers of highway route-controlled quantities are required to use the preferred network unless they are moving from their origin to the nearest interstate highway or from the interstate highway to their destination,

they are making necessary repair or rest stops, or emergency conditions render the interstate highway unsafe or impassable. The primary criterion for selecting the preferred route for a shipment is travel time. Preferred routing takes into consideration accident rate, transit time population density, activities, time of day, and day of the week.

The HIGHWAY computer code (Johnson et al. 1993) is used for selecting highway routes in the United States. The HIGHWAY database is a computerized road atlas that describes about 386,400 kilometers (240,000 miles) of roads. The Interstate System and all U.S. (U.S.-designated) highways are completely described in the database. Most of the principal state highways and many local and community roads are also identified. The code is updated periodically to reflect current road conditions and has been benchmarked against reported mileages and observations of commercial truck firms. Features in the HIGHWAY code allow the user to select routes that conform to DOT regulations. Additionally, the HIGHWAY code contains data on population densities along the routes. The distances and populations from the HIGHWAY code are part of the information used for the transportation impact analysis in this NI PEIS.

### **J.3.6 Shipment of SNR-300 Fuel**

The SNR-300 reactor, located at Kalkar in the northwest of Germany, was designed and constructed as a 327 megawatt (electric) fast breeder power reactor. However, in the 1980s, startup and operation fell into disfavor and the German government decided not to operate the SNR-300 reactor.

In parallel with the construction of the SNR-300 reactor, and in anticipation of its ultimate operation, approximately 205 mixed oxide fuel assemblies were fabricated in Europe. This unused inventory of reactor fuel is now stored at Dounreay, Scotland, and has raised international concerns over its possible proliferation as weapons-usable nuclear material. Currently, there is interest in having these surplus fuel assemblies transferred to the United States for disposition to reduce and eventually eliminate the proliferation potential of this material.

The SNR-300 fuel is very similar in both composition and construction to the fuel used in the FFTF at Hanford. The SNR-300 fuel assemblies, if reconfigured for the FFTF, could make about 150 to 160 FFTF assemblies. This could supply two FFTF core loads for approximately 15 years of FFTF operation at 100 megawatts.

Conversion of SNR-300 fuel into FFTF fuel has been previously studied. Reconfiguration to FFTF fuel would include disassembly of SNR-300 fuel assemblies, removal of fuel pin end caps in a glovebox, addition of tag gas and retainer, re-closing fuel pins (weld) and leak testing, addition of wire wrap to fuel pins, inverting the pins and reinsertion into an FFTF fuel assembly duct, completion of FFTF bundle assembly, and quality assurance verification. This would be done in Europe prior to packaging the fuel for shipment to the United States.

The risk of possible use of nuclear material for non-peaceful purposes underlines the need for its special protection. Therefore, effective systems are required to protect this material from theft, sabotage or other malicious acts. The elaborate measures to be taken to ensure the safety and security of transatlantic mixed oxide shipments are provided in:

- *Convention on the Physical Protection of Nuclear Material*, IAEA publication INFCIRC 274
- *Recommendations on the Physical Protection of Nuclear Material*, IAEA publication INFCIRC 225

- *Code for the Safe Carriage of Irradiated Nuclear Fuel, Plutonium and High-Level Radioactive Wastes in Flasks on Board Ships* (IMO 1993)
- DOE orders and 10 CFR Part 73

### **J.3.6.1 Port Selection**

Physically, any seaport could receive mixed oxide fuel. Legally, the mixed oxide fuel could be brought into many commercial and military ports. In the *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel (Foreign Research Reactor Spent Nuclear Fuel EIS)* (DOE 1996), DOE developed and implemented a systematic process for selecting ports of entry for spent nuclear fuel. Information needed to evaluate ports and port activities, and the potential environmental impacts (incident-free and accidents) associated with the receipt of foreign research reactor spent nuclear fuel from vessels were collected and evaluated. In the *Foreign Research Reactor Spent Nuclear Fuel EIS*, 153 commercial ports and 13 military ports were evaluated (DOE 1996).

The criteria used for screening ports in the *Foreign Research Reactor Spent Nuclear Fuel EIS* were 1) appropriate port experience, 2) safe port transit to open ocean; 3) appropriate port facilities for safe receipt, handling and transshipment; 4) ready intermodal access; and 5) low human population of the ports and along transportation routes (DOE 1996). These same criteria can be used to identify ports for receiving mixed oxide fuel from Europe. **Table J-1** shows the military ports (the analysis of Hampton Roads, Virginia, covers several military and commercial facilities in that area) considered in the *Foreign Research Reactor Spent Nuclear Fuel EIS*, the distance to Hanford and the number of persons along the route. The following discusses the application of these criteria for mixed oxide fuel.

**Table J-1 Overland Distances from Military Ports to Hanford and Affected Persons Along the Routes**

Port	Distance (kilometers [miles])	Number of Affected Persons
<b>Eastern ports</b>		
Charleston Naval Weapons Station, South Carolina	4,677 (2,894)	609,000
Military Ocean Terminal Sunny Point, North Carolina	5,157 (3,194)	679,000
Mayport, Florida	4,754 (2,964)	624,000
Kings Bay, Georgia	4,685 (2,926)	555,000
Pensacola, Florida	4,430 (2,767)	549,000
Yorktown, Virginia	4,717 (2,946)	569,000
Hampton Roads, Virginia	4,748 (2,949)	694,000
<b>Western ports</b>		
Military Ocean Terminal Bay Area, California	1,531 (951)	263,000
Bremerton, Washington	451 (282)	143,000
Everett, Washington	397 (248)	135,000
Port Hueneme, California	2,030 (1268)	386,000
Port Townsend, Washington	666 (416)	159,000

**Note:** All except the Charleston Naval Weapons Station are from DOE 1996. Charleston Naval Weapons Station is from Table J-2.

In addition to the military ports listed in Table J-1, Naval facilities at the following locations could be used: San Diego, California; Seal Beach, California; Ingleside, Texas; Pascagoula, Mississippi; Pensacola, Florida; Earle, New Jersey; and Groton, Connecticut. The distances and affected persons fall within the range of those

listed in Table J–1. If DOE decides to import mixed oxide fuel, additional analysis will be required to select the appropriate port(s).

**Criterion 1, Appropriate Port Experience.** DOE believes that all military ports could establish a secure area for loading mixed oxide fuel packages into SST/SGTs. Therefore, any of the named ports could safely and securely handle these packages. Charleston Naval Weapons Station has been the primary port for receipt of foreign research reactor spent nuclear fuel for the last 5 years. Dozens of casks have been safely and securely received and transported to DOE facilities. Therefore, it is clearly the most experienced port. Military Ocean Terminal Sunny Point received two foreign research reactor spent nuclear fuel casks in 1994, so it has some experience. Military Ocean Terminal Bay Area has received several packages of foreign research reactor spent nuclear fuel from training, research, and isotope reactors (TRIGA reactors built by General Atomics) and shipped these packages to INEEL. The port at Hampton Roads, Virginia, has experience handling spent fuel casks and has recent experience handling Russian plutonium-238 for DOE (DOE 1993).

**Criterion 2, Safe Port Transit.** All of the ports listed have demonstrated safe port transit based on their continuous and routine usage by seagoing military vessels. DOE could choose to provide enhanced safety and security in the immediate vicinity of ports using necessary harbor patrol, Coast Guard and Naval assets. However, western ports require transit through the Panama Canal. While traveling through the Panama Canal, the ship would be in Panamanian waters, where DOE could not directly request assistance from other assets.

**Criterion 3, Appropriate Port Facilities.** The *Foreign Research Reactor Spent Nuclear Fuel EIS* evaluated Charleston Naval Weapons Station, Military Ocean Terminal Sunny Point and Military Ocean Terminal Bay Area in detail and determined that they had appropriate facilities. Essentially all working seaports have port cranes capable of lifting mixed oxide casks from the ships. At least a 30-metric ton (33-ton) capacity crane would be adequate. For seaports without a port crane, portable cranes are available in most areas. Purpose-built ships are moderate sized oceangoing vessels, and all of the identified ports have berthing facilities with adequate water depth and length to allow safe access. While Charleston Naval Weapons Station, Military Ocean Terminal Sunny Point and Military Ocean Terminal Bay Area have actually used their facilities and procedures to unload Type B casks for DOE, DOE considers the other military ports to have appropriate facilities and could establish procedures for the security necessary around the ship carrying the mixed oxide fuel.

**Criterion 4, Ready Intermodal Access.** Access to other modes of transportation, such as rail and barge routes, was relevant for the *Foreign Research Reactor Spent Nuclear Fuel EIS* but are not relevant to this NI PEIS since the mixed oxide fuel will travel over roads in SST/SGTs.

**Criterion 5, Low Human Population.** The distance to Hanford and the population along the routes are similar for each of the eastern ports. All are within 15 percent of the average distance and number of affected persons. The western ports vary significantly, but are all lower than the eastern ports. The *Foreign Research Reactor Spent Nuclear Fuel EIS* did not calculate the populations around all of the military ports listed in Table J–1. However, it conducted detailed risk analyses for delivery of foreign research reactor spent nuclear fuel to ports located near heavily populated metropolitan areas such as New York, New York (port of Elizabeth, New Jersey) and Los Angeles, California (port of Long Beach, California). The accident risk for direct shipment to these ports is less than  $1 \times 10^{-5}$  latent cancer fatality per shipment. The risk of foreign research reactor spent nuclear fuel material bounds the risk of fresh mixed oxide fuel because of the fission products in spent nuclear fuel. The population of the New York and Los Angeles metropolitan areas bounds the population in the area of any military ports. Therefore, all of the ports listed meet the low human population criteria for the area around the port, and the populations along the routes are as shown in Table J–1.

The voyage distance from Europe to the eastern United States is about 4,000 nautical miles, and the distance to the western United States is about 8,000 nautical miles, through the Panama Canal. There are no known restrictions for passing mixed oxide fuel through the Panama Canal. Using the *Foreign Research Reactor Spent Nuclear Fuel EIS* methodology, the voyage duration for the east coast is about 12 days, about 24 days for the west coast. Traveling to the west coast along a route south of South America or Africa is more than double the distance of the route through the Panama Canal and considered to be prohibitive for practical reasons.

DOE is currently in negotiation with Germany on the details for receiving this fuel. The Germans would be responsible for the fuel until it is delivered to DOE at a U.S. port. The Germans may not be willing to ship the fuel to a western port because of the cost associated with the longer voyage, and possible safety and security issues associated with using the Panama Canal. On the open seas, purpose-built ships are considered to be safe and secure based on their design, the distance from threats, and their constant communication with authorities. However, they are more vulnerable in the constrained waters of the Panama Canal, since these waters are not controlled by German or American authorities.

In the *Foreign Research Reactor Spent Nuclear Fuel EIS* Record of Decision, DOE decided to use military ports to take advantage of their characteristics to increase the safety and security of the spent fuel transportation process. DOE concluded that the use of military ports provides additional confidence in the safety of shipments due to the increased security. This could also require much of the spent nuclear fuel to be shipped by chartered ships because commercial ships do not schedule stops at military ports. Since the security issues are far greater for fresh mixed oxide fuel than for spent nuclear fuel because of the potential for proliferation, DOE would use a military port to bring the SNR-300 into the country. This conclusion is consistent with Criterion 3, Appropriate Port Facilities. The impact analysis is described in Section J.6.2. The Charleston Naval Weapons Station is used for the purpose of impact analysis.

### **J.3.6.2 Purpose-Built Vessels**

As used here, purpose-built vessels are those vessels specifically designed to transport spent nuclear fuel casks (**Figure J-7**). These vessels are not used for the transport of any other cargo and they operate as dedicated vessels. Casks are loaded directly into the holds of the vessel because the cargo compartments contain the hardware needed to mate with the tiedown fixtures of the cask. If the vessel has no crane, dockside cranes are used for loading and unloading. The cargo compartments are typically intended to handle a specific cask; other casks cannot be used without modification to the tiedown mechanisms.

At present, purpose-built vessels are operated by Pacific Nuclear Transport Services of Japan, by the Swedish Nuclear Fuel and Waste Management Company, and by British Nuclear Fuels, Limited. They are used to move spent nuclear fuel from operating nuclear power plants to spent nuclear fuel processing facilities operated by COGEMA and British Nuclear Fuels, Limited; or, in the case of Sweden, to the repository in Forsmark. Since 1998, they have been used to transport spent nuclear fuel from foreign research reactors to the Charleston Naval Weapons Station. There are no U.S.-owned purpose-built vessels for spent nuclear fuel transport.

Pacific Nuclear Transport Services operates a fleet of purpose-built vessels that carried mixed oxide fuel from Europe to Japan in the summer of 1999 (COGEMA, BNFL, ORC 2000). Pacific Nuclear Transport Services' vessels are representative of, but not identical to the other fleets. All vessels in the fleet are certified to INF3—the highest safety category of the International Maritime Organization for nuclear voyages. The vessels have been designed and built specifically to carry these nuclear materials. They employ a range of safety features far in excess of those found on conventional cargo vessels. The vessels are constructed with double hulls, effectively making them able to withstand a severe collision with a much larger vessel without penetrating the inner hull. Each vessel has two sets of navigation, communications, cargo monitoring,

**Figure J-7 Purpose-Built Vessel**

electrical and cooling systems, so there is always a back-up in the event of failure or damage. The navigation system includes automatic radar plotting and collision avoidance equipment. This redundancy extends to the vessel's propulsion system. Every part of the Pacific Nuclear Transport Services' vessels are covered by a fire detection system. And every vessel has sophisticated firefighting equipment on board. In the highly unlikely event of fire, a vessel's hold, engine room, or any other on-board space, may be flooded with fire-suppressant gases. Individual holds can even be deliberately flooded, and if all the holds were flooded in this way, the vessel would still remain afloat. The vessels carry the most modern satellite and navigation, weather routing, and tracking equipment, enabling them to automatically transmit their position. While at sea, each vessel's crew can maintain permanent communication with a report center that is operated 24 hours a day (COGEMA, BNFL, and ORC 2000).

#### **J.4 METHODS FOR CALCULATING TRANSPORTATION RISKS**

The overland transportation risk assessment method is summarized in **Figure J-8**. After this NI PEIS alternatives were identified and the goals of the shipping campaign were understood, data were collected on material characteristics and accident parameters. Accident parameters were largely based on NRC studies of transportation accidents undertaken for NUREG-0170, the *Final Environmental Statement on the Transportation of Radioactive Material by Air and Other Modes* (NRC 1977) and the Modal Study (NUREG/CR-4829) (Fischer et al. 1987).

Representative routes that may be used for the shipments were selected for risk assessment purposes using the HIGHWAY code. They do not necessarily represent the actual routes that would be used to transport nuclear materials. Specific routes cannot be identified in advance because the routes cannot be finalized until they have been reviewed and approved by the NRC. The selection of the actual route would be responsive to

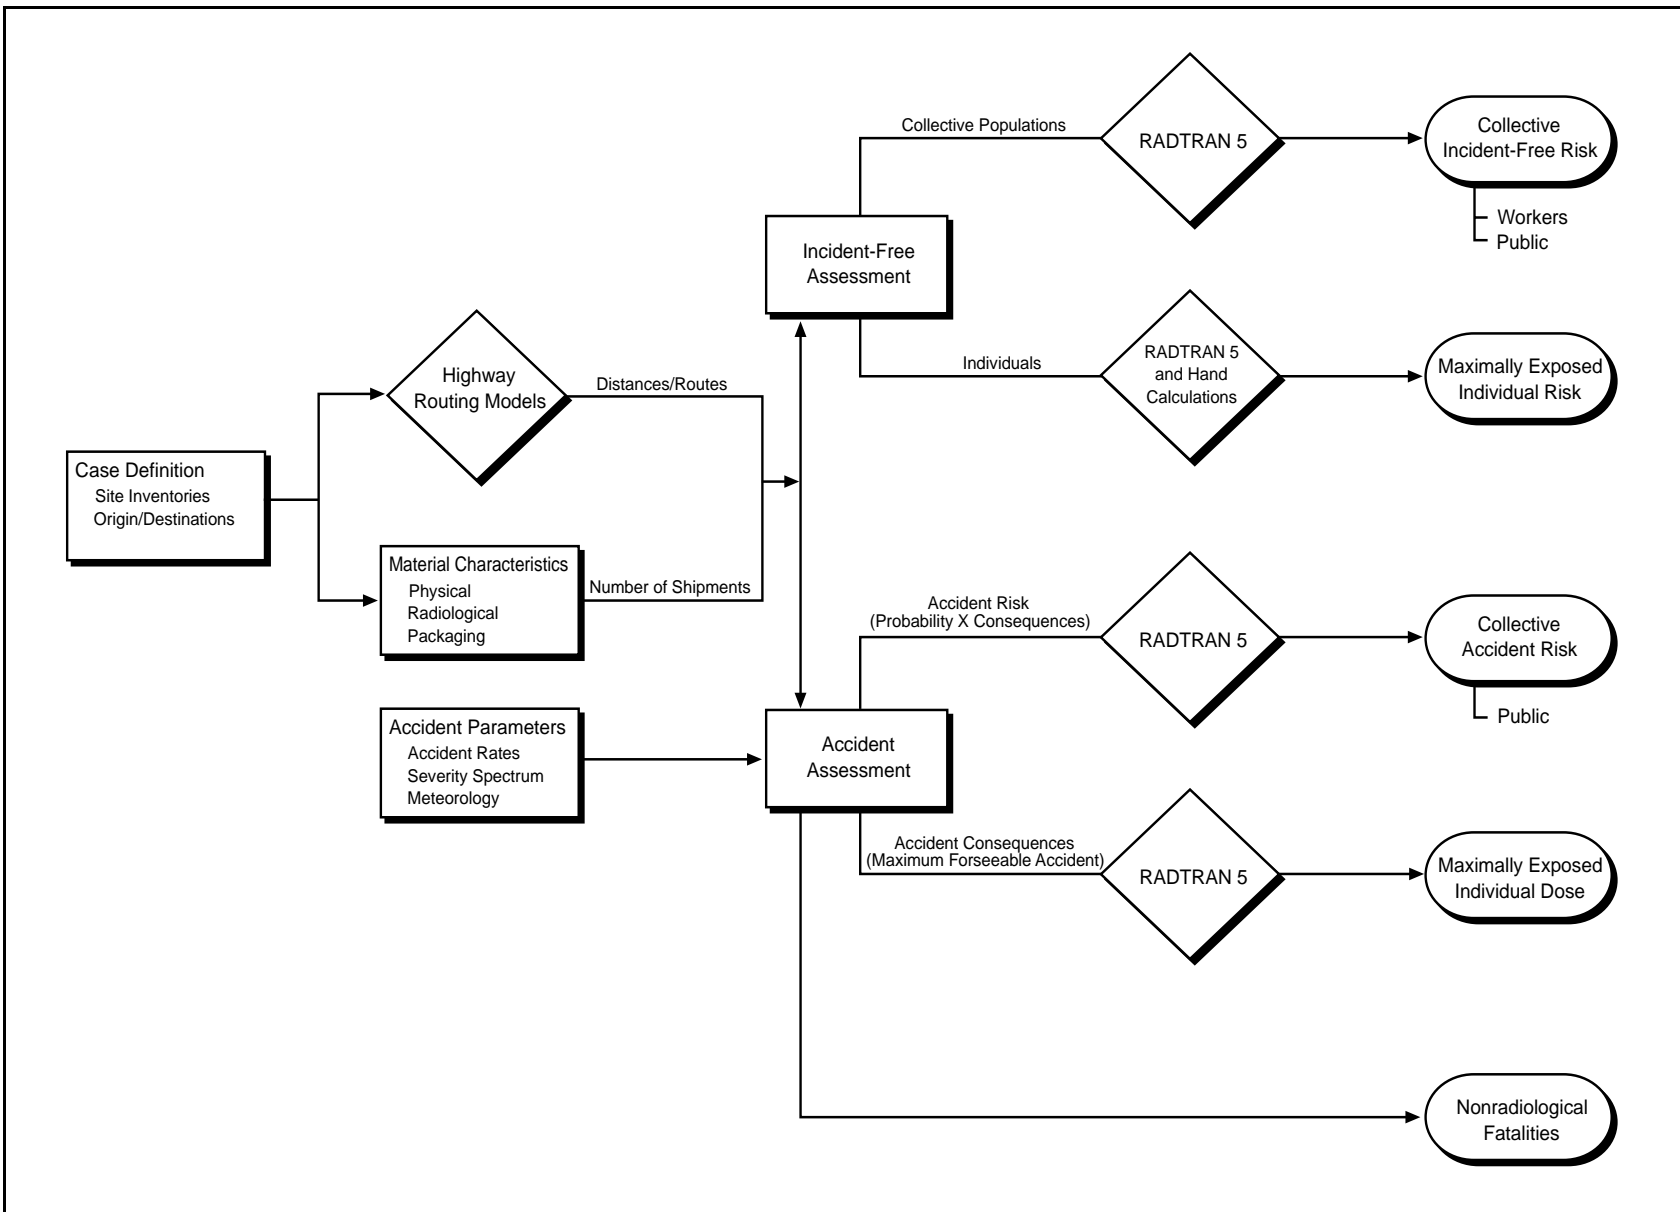

Figure J-8 Overland Transportation Risk Assessment

environmental and other conditions that would be in effect or could be predicted at the time of shipment. Such conditions could include adverse weather conditions, road conditions, bridge closures, and local traffic problems. For security reasons, details about a route would not be publicized before the shipment. Air transport of shipping casks was modeled on procedures for radiopharmaceutical suppliers using commercial air transport at the Tri-Cities Airport in Pasco, Washington. As a bounding assumption, air transport of shipping casks is assumed to be on commercial passenger flights. The shipping cask would be unloaded from their truck shipments and shipped to the destination airport with a stopover and plane change, for the purpose of impact analysis, in Salt Lake City, Utah.

The first analytic step in the transportation analysis was to determine the incident-free and accident risk factors on a per-shipment basis. Risk factors, as with any risk estimate, are the product of the probability of exposure and the magnitude of the exposure. Accident risk factors were calculated for radiological and nonradiological traffic accidents. The probabilities, which are much lower than one, and the magnitudes of exposure were multiplied, yielding very low risk numbers. Incident-free risk factors were calculated for crew and public exposure to radiation emanating from the shipping container (cask) and public exposure to the chemical toxicity of the truck exhaust. The probability of incident-free exposure is unity (one).

For each alternative, risks were assessed for both incident-free transportation and accident conditions. For the incident-free assessment, risks are calculated for both collective populations of potentially exposed individuals and for maximally exposed individuals. Handling doses are included in the transportation risk for airport and seaport handling. Truck unloading at DOE sites is included in facility dose estimates. The accident assessment consists of two components: (1) a probabilistic accident risk assessment that considers the probabilities and consequences of a range of possible transportation accident environments, including low-probability accidents that have high consequences, and (2) an accident consequence assessment that considers only the consequences of maximum foreseeable transportation accidents.

As a practical matter, the maximum foreseeable transportation accident is defined as an accident with a frequency of greater than  $1 \times 10^{-7}$  per year (once in 10 million years). This hypothetical accident is well beyond the “design basis” of a transportation cask. The “design basis” of a transportation cask is to survive the tests shown in Figure J-1 without releasing its contents. The risk of accidents that are less likely than the maximum foreseeable accident are included in the analysis, but specific accident sequences and consequences are not analyzed. The RADTRAN 5 computer code (Neuhauser and Kanipe 2000) uses a probability and consequence binning approach to include the impacts of these extremely rare and severe accidents. It would not be practical to analyze all potential accident forces that could affect a transportation cask because there are such a large number of potential scenarios and locations.

The RADTRAN 5 computer code (Neuhauser and Kanipe 2000) is used for incident-free and accident risk assessments to estimate the impacts on population. RADTRAN 5 was developed by Sandia National Laboratories to calculate population risks associated with the transportation of radioactive materials by a variety of modes, including truck, rail, air, ship, and barge. RADTRAN 5 was used to calculate the doses to the maximally exposed individuals.

The RADTRAN 5 population risk calculations take into account both the consequences and probabilities of potential exposure events. The RADTRAN 5 code consequence analyses include cloud shine, ground shine, inhalation, and resuspension exposures. The collective population risk is a measure of the total radiological risk posed to society as a whole by the alternative being considered. As such, the collective population risk is used as the primary means of comparing the various alternatives.

## **J.5 ALTERNATIVES, PARAMETERS, AND ASSUMPTIONS**

### **J.5.1 Description of Alternatives**

Five alternatives with numerous options and a No Action Alternative with options have been identified for this NI PEIS. **Table J-2** depicts these alternatives and the following describes them from a transportation perspective.

#### **J.5.1.1 No Action Alternative**

**Option 1.** Plutonium-238, needed in power systems for future space missions, would continue to be purchased from Russia. The transportation analysis performed in the *Environmental Assessment of the Import of Russian Plutonium-238* (DOE 1993) would be expanded to cover the transportation from Russia, through the ports of entry, and to the Los Alamos National Laboratory (LANL) site for the time period covered by this NI PEIS, as described in Chapter 4. Medical, industrial, and research and development isotope production would continue as per the current conditions. Neptunium-237 would not be converted to oxide or shipped.

**Options 2, 3, and 4.** These options are like the No Action Alternative, Option 1 in all respects except for the disposition of the neptunium-237. The neptunium-237 would be converted to oxide and transported from SRS to a storage site at ORR, INEEL, or Hanford. The neptunium transportation would be the only transportation leg quantitatively analyzed in this NI PEIS.

#### **J.5.1.2 Alternative 1—Restart FFTF**

**FFTF Production (Options 1 through 3).** FFTF at Hanford would be used to produce up to 5 kilograms (11 pounds) per year of plutonium-238 and medical, industrial, and research and development isotopes. When the mixed oxide fuel already at Hanford is depleted, FFTF would use SNR-300 mixed oxide fuel imported from Europe, and after 21 years of operation, would switch to highly enriched uranium fuel. For the purpose of analysis, it is assumed that the mixed oxide fuel enters the United States at the Charleston Naval Weapons Station and is shipped in SST/SGTs to FFTF. The analysis includes shipment of a single mixed oxide fuel assembly for testing in the FFTF reactor and the shipping campaign during mixed oxide fuel operations. The highly enriched uranium fuel would be fabricated at a commercial fuel fabrication facility located in the eastern United States. Medical and industrial isotope target fabrication and processing would occur at Hanford, using purified materials from ORR, and the products would be shipped to commercial vendors as described in Section J.5.3. Plutonium-238 production would require the transportation of neptunium-237 from SRS to a target fabrication facility at ORR, INEEL, or Hanford; transportation of unirradiated targets from the fabrication facility to Hanford; transportation of irradiated targets from Hanford to a target processing facility at the same locations as the fabrication facility; and transportation of plutonium-238 from the fabrication facility to LANL.

**FFTF Production (Options 4 through 6).** Options 4 through 6 are similar to Options 1 through 3, with differences in timing and fuel source for FFTF. When the mixed oxide fuel already at Hanford is depleted, FFTF would immediately switch to highly enriched uranium fuel as described for Options 1 through 3.

#### **J.5.1.3 Alternative 2—Use Only Existing Operational Facilities**

**One-Reactor Production (Options 1 through 6).** The ATR at INEEL or a CLWR would be used to produce up to 5 kilograms (11 pounds) per year of plutonium-238. Therefore, production would require the transportation of neptunium-237 from SRS to a target fabrication facility at ORR, INEEL, or Hanford;

**Table J-2 NI PEIS Alternatives and Options**

Alternative Option Number	Irradiation Options						Storage, Target Fabrication, and Processing Options for Plutonium-238 Production

<b>Alternative 5—Permanently Deactivate FFTF (with No New Missions)</b>									

a. FMEF is being considered along with several other facilities. See Chapter 2 for details.

**Key:** ATR, Advanced Test Reactor; CLWR, commercial light water reactor, no defined location; FDPF, Fluorinel Dissolution Process Facility; FFTF, Fast Flux Test Facility; FMEF, Fuels and Materials Examination Facility; HFIR, High Flux Isotope Reactor; INEEL, Idaho National Engineering and Environmental Laboratory; ORR, Oak Ridge Reservation; REDC, Radiochemical Engineering Development Center.

transportation of unirradiated targets from the fabrication facility to INEEL or a CLWR; transportation of irradiated targets from INEEL or a CLWR to a target processing facility at the same location as the fabrication facility; and transportation of plutonium-238 from the fabrication facility to LANL. Medical, industrial, and research and development isotope production would continue per current conditions.

**Two-Reactor Production (Options 7, 8, and 9).** The ATR at INEEL and HFIR at ORR would be used to produce plutonium-238. HFIR could only produce between 1 and 2 kilograms (2.2 and 4.4 pounds) of plutonium-238 per year. Therefore, between 3 and 4 kilograms (6.6 and 8.8 pounds) per year would be produced at ATR. Production would require the transportation of neptunium-237 from SRS to a target fabrication facility at ORR, INEEL, or Hanford; transportation of unirradiated targets from the fabrication facility to ORR and INEEL; transportation of irradiated targets from ORR and INEEL to a target processing facility at the same location as the fabrication facility; and transportation of plutonium-238 from the fabrication facility to LANL. It is assumed that production rates at ATR and HFIR would require the maximum amount of transportation. For example, in Option 7 (target fabrication and processing at ORR), it is assumed that HFIR produces its minimum rate of 1 kilogram (2.2 pounds) per year of plutonium-238, which maximizes the transportation to INEEL. Medical, industrial, and research and development isotope production would continue per the current conditions.

#### **J.5.1.4 Alternative 3—Construct New Accelerator(s)**

One or two new accelerators at a generic DOE site would be used to produce up to 5 kilograms (11 pounds) per year of plutonium-238 and medical and industrial isotopes, as well as conducting nuclear research and development. The accelerator(s) would be on a DOE site to be identified later. Shipping distances, route characteristics, and material inventories are assumed to be the same as those modeled in HNF-1844 (Lavender and Nielsen 1997). Medical and industrial isotope target fabrication and processing would occur on the accelerator site, and the products would be shipped to commercial vendors. Plutonium-238 production would require the transportation of neptunium-237 from SRS to a target fabrication facility at ORR, INEEL, or Hanford; transportation of unirradiated targets from the fabrication facility to the accelerator(s); transportation of irradiated targets from the accelerator(s) to a target processing facility at the same locations as the fabrication facility; and transportation of plutonium-238 from the fabrication facility to LANL.

#### **J.5.1.5 Alternative 4—Construct New Research Reactor**

A new research reactor at a generic DOE site would be used to produce up to 5 kilograms (11 pounds) per year of plutonium-238 and medical and industrial isotopes, as well as conducting nuclear research and development. The reactor would be on a DOE site to be identified later. Shipping distances, route characteristics, and material inventories are assumed to be the same as those modeled in HNF-1844 (Lavender and Nielsen 1997). Medical and industrial isotope target fabrication and processing would occur on the reactor site, and the products would be shipped to commercial vendors. Plutonium-238 production would require the transportation of neptunium-237 from SRS to a target fabrication facility at ORR, INEEL, or Hanford; transportation of unirradiated targets from the fabrication facility to the reactor; transportation of irradiated targets from the reactor to a target processing facility at the same location as the fabrication facility; and transportation of plutonium-238 from the fabrication facility to LANL.

#### **J.5.1.6 Permanently Deactivate FFTF (with No New Missions)**

No offsite transportation of radioactive material would occur as a result of selecting this alternative. The sodium coolant would be removed from FFTF and processed at Hanford. Any transportation impacts would be negligible compared with the impacts of other alternatives. Medical, industrial, and research and development isotope production would continue per the current conditions.

### **J.5.2 Material Inventory**

| The amount of neptunium-237 that must be shipped is determined from the basic mission requirement to  
| remove all the 466 kilograms (1,025 pounds) of neptunium-237 (Gibson 1999) from SRS to a new storage

facility. The stated mission is to produce 5 kilograms (11 pounds) of plutonium-238 per year for 35 years. **Table J-3** summarizes the masses of material and the number of shipments required to implement the various alternatives, and can be used in conjunction with Table J-1 to determine the origins and destinations of the shipments for the various alternatives. The material masses listed are those of heavy metal. The word “shipment” means a transportation leg. For example, a package that is loaded onto a truck, driven to an airport, loaded onto an aircraft, flown to another airport, loaded onto a truck, and driven to a final destination would count as three shipments (two by truck and one by air). Neptunium and plutonium shipments also contain small amounts of radioactive decay products, and irradiated targets contain fission products.

DOE estimates that about 50 kilograms (110 pounds) of neptunium-237 will have to be exposed to reactor flux to make 5 kilograms of plutonium-238. This neptunium-237 would be shipped in about 9 shipments per year, each carrying about 6 kilograms (13.2 pounds) of neptunium in the unirradiated targets. The targets would be returned to the fabrication and processing facility with about 5 kilograms (11 pounds) of neptunium-237 and less than a kilogram of plutonium. Again, about 9 shipments per year would be needed to return the irradiated targets. For options in which some or all of the irradiation is done at the same DOE site as the fabrication and processing, less transportation is required. These transportation assumptions are used for irradiation at FFTF (Alternative 1) existing reactors (Alternative 2), the new accelerators (Alternative 3), and the new research reactor (Alternative 4).

The highly enriched uranium transportation assumptions are based on the assumption of 16 fuel assemblies per year made from 35 percent enriched uranium (Nielsen 1999). The fuel assemblies would contain about 27 kilograms of heavy metal. The SNR-300 mixed oxide fuel transportation requirements come from information provided by SBK of Germany (Hiller 2000).

These assumptions are considered preliminary. Since they provide for conservative amounts of material shipped and numbers of shipments, they are considered to be adequate for impact analysis. No specific estimates of transportation requirements for other research and development isotopes have been included. However, DOE believes that they are small compared to the transportation requirements assumed for medical isotopes. If large research and development projects are scheduled in the future, they would displace some of the medical isotope or plutonium-238 production and their transportation impacts would be similar or less.

### **J.5.3 Transportation of Medical Isotopes**

DOE isotope program sales projections are made in the context of a worldwide market for radioactive isotopes. Isotope programs market share is a small fraction of the total, but is very significant for some products, and is particularly important for a large number of isotopes that are used in relatively small quantities for research. There is uncertainty in future growth trends, and recent studies have indicated a large potential for growth if promising research developments in the medical use of radioisotopes can be brought to commercialization. DOE's production rate could increase significantly as world demand changes.

Through the duration of the period covered by this NI PEIS, the transportation impacts of the current DOE isotope programs are and would remain very low compared to the proposed new missions analyzed in this NI PEIS. These isotopes are being produced at reactor and accelerator facilities throughout the country. Selection of Alternative 1, 3, or 4 would significantly increase the production capabilities with a corresponding increase in transportation impacts. Selection of the No Action Alternative or Alternative 2 would not increase production capabilities, nor would their selection significantly affect the baseline production rate. The transportation impacts from isotopes currently produced by DOE are small compared with the impacts of NI PEIS alternatives and are neglected for the purpose of transportation risk analysis. The following describes

**Table J-3 Summary of Material Shipments**

Hazardous Material	Container	Applicable Alternatives	SST/SGT <sup>a</sup>	Number of Shipments	Amount of Heavy Metal per Package	Packages per Shipment	Total Heavy Metal Shipped
Neptunium-237	9975 <sup>b</sup>	NA-2 through NA-4, 2, 3, and 4	Yes	24	3 kilograms of neptunium	14	446 kilograms
Unirradiated targets (neptunium-237)	To be determined; similar to GE-2000	1, 2-1 through 2-6, and 4	No	315	6 kilograms of neptunium	1	1,750 kilograms of neptunium
		2-7		252			1,400 kilograms of neptunium
		2-8 and 2-9		126			700 kilograms of neptunium
	To be determined	3		105	500 kilograms of uranium 72 kilograms of neptunium	1	52,500 kilograms of uranium 7,560 kilograms of neptunium
Irradiated targets (plutonium-238)	To be determined; similar to GE-2000	1, 2-1 through 2-6, and 4	No	315	0.6 kilograms of plutonium 5 kilograms of neptunium	1	175 kilograms of plutonium 1,500 kilograms of neptunium <sup>c</sup>
		2-7		252			140 kilograms of plutonium 1,200 kilograms of neptunium <sup>c</sup>
		2-8 and 2-9		126			70 kilograms of plutonium 600 kilograms of neptunium <sup>c</sup>
	To be determined	3		105	500 kilograms of uranium 70 kilograms of neptunium 2 kilograms of plutonium	1	52,500 kilograms of uranium 7,350 kilograms of neptunium 210 kilograms of plutonium
Plutonium-238	5320	1, 2, 3, and 4	Yes	35	0.35 kilograms of plutonium	15	175 kilograms of plutonium
Highly enriched uranium	DT-22 or DC-1	1-1 through 1-3	Yes	5	10 kilograms of highly enriched uranium	12	520 kilograms of highly enriched uranium
		1-4 through 1-6		9			1,080 kilograms of highly enriched uranium
Highly enriched uranium fuel	To be determined	1-1 through 1-3	Yes	56	26.5 kilograms of uranium	4	1,500 kilograms of uranium
		1-4 through 1-6		116			3,100 kilograms of uranium
Fresh SNR-300 mixed oxide fuel	GB/1356 or SNR-300	1-1 through 1-3	Yes	79	70 kilograms of plutonium, uranium, and americium	1	5,500 kilograms of plutonium, uranium, and americium
Irradiated targets (medical isotopes)	T-2	1, 3, and 4	No	8,610	Various	1	NA
Separated isotopes	To be determined	1,3, and 4	No	8,610	Various	1	NA

a. For purposes of analysis.

b. Either a redesigned 9975 or suitable replacement.

c. Much of the neptunium-237 is recycled into new targets during fabrication.

**Note:** 1 kilogram = 2.2 pounds.

**Key:** NA, not applicable; SST/SGT, safe, secure trailer/SafeGuards Transport.

the transportation analyzed in this NI PEIS. The isotopes produced and transported are listed in Appendix C. Over 8,000 shipments, each with two truck and one aircraft leg, would be required to deliver these isotopes to commercial vendors. The transportation impacts of these representative isotopes are expected to bound the impacts of transportation associated with unspecified future research and development activities.

The transportation evaluation addressed the shipment of enriched target materials from Oak Ridge National Laboratory (ORNL) to Hanford for target fabrication, shipping the fabricated targets to FFTF, shipping the irradiated targets from FFTF to RPL for target processing, and shipping isotope products to commercial pharmaceutical distributors. HNF-1844 (Lavender and Nielsen 1997) analyzed distributors in Boston, Massachusetts; Chicago, Illinois; and St. Louis, Missouri. Only the results of shipping the isotopes to Boston are shown in this document to ensure that the risk analysis is bounding. The transportation impacts of medical isotopes were analyzed for FFTF and are considered to be the best estimate for FFTF or the hypothetical accelerator(s) or research reactor. The impact analysis is bounding for the accelerator(s) or reactor because either would be located on a major DOE site. The following paragraphs describe the material transportation for production at FFTF, with onsite target fabrication and processing, as analyzed in HNF-1844.

With the exception of the production of actinium-227, thorium-228, and thorium-229, this evaluation assumes that the same transportation scenario, from the target material supplier to the pharmaceutical distributor, is applicable to each isotope. That is, target materials are shipped from ORNL to PNNL, fabrication targets are shipped from PNNL to FFTF, irradiated targets are shipped from FFTF to PNNL, and the separated isotopes are shipped from PNNL to the three isotope distributors. Actinium-227, thorium-228, and thorium-229 are produced by irradiating a radium-226 target. Sufficient quantities of radium-226 would be stored at the target fabrication facility; therefore radium-226 target material is not shipped from ORNL to PNNL. The rest of the transport scenario from the target fabrication facility to the pharmaceutical distributor is the same as for other isotopes.

The target materials (with the exception of radium-226) required to produce the medical isotopes are assumed to be obtained from ORNL. The target materials would be shipped on an as-needed basis from ORNL to PNNL for target fabrication. Target fabrication is assumed to occur in the 300 Area at Hanford. For this analysis, it is assumed that target material would be shipped by truck one at a time from ORNL to PNNL. This is a bounding assumption that maximizes the number of shipments, because the trucks are capable of transporting loads containing multiple types of target materials. All of the target materials receive from ORNL are nonradioactive.

The target materials would be fabricated into specially-designed targets for irradiation at FFTF. The fabricated targets would be shipped by truck from RPL/306-E to FFTF. As with the target materials shipments, it was assumed that only one unirradiated target would be shipped at a time to FFTF. Following irradiation in FFTF, the irradiated targets would be shipped to RPL for required processing. Irradiated targets were assumed to be shipped by truck one at a time from FFTF.

Following required processing and packaging, an isotope product would be shipped by truck from RPL to the Tri-Cities Airport located in Pasco, Washington. From the Tri-Cities Airport, the isotopes are transported by air, using commercial passenger flights, to an intermediate airport or hub (i.e., Salt Lake City, Utah). At Salt Lake City, the isotopes are transferred to another airplane for transport to the airport nearest the pharmaceutical distributor in Chicago, Illinois (Amersham Mediphsysics), Boston, Massachusetts (Dupont-Merck), and St. Louis, Missouri (Mallinckrodt). The isotope product is transported from the destination airport to the pharmaceutical distributor by truck, using public roadways. Shipments of waste (i.e., liquid processing waste and solid waste, including spent target hulls and miscellaneous wastes), would go to the 200 East and West Areas for subsequent storage and disposal (Lavender and Nielsen 1997).

#### **J.5.4 Representative Routes**

Representative overland truck routes were selected for the shipments to ORR, INEEL, Hanford, and SRS. The routes were selected consistent with current routing practices and all applicable routing regulations and guidelines (40 CFR Section 397.103). However, the routes were determined for risk assessment purposes. They do not necessarily represent the actual routes that would be used to transport materials in the future. Specific routes cannot be identified in advance. The planning process for actual shipments may identify similar routes, which would have similar public risks, but could be determined to be preferable. The representative truck routes are shown in **Figure J-9**.

Route characteristics that are important to the radiological risk assessment include the total shipment distance and the population distribution along the route. The specific route selected determines both the total potentially exposed population and the expected frequency of transportation-related accidents. Route characteristics are summarized in **Table J-4**. The population densities along each route are derived from 1990 data from the U.S. Bureau of the Census (DOC 1992). Rural, suburban, and urban areas are characterized according to the following breakdown: rural population densities range from 0 to 54 persons per square kilometer (0 to 139 person per square mile); the suburban range is from 55 to 1,284 persons per square kilometer (140 to 3,326 persons per square mile); and the urban range includes all population densities greater than 1,284 persons per square kilometer (3,326 persons per square mile). The exposed population, for the purpose of route characterization and incident-free dose calculation, includes all persons living within 800 meters (0.5 mile) of each side of the road.

Alternative 2, Options 4, 5, and 6 include irradiation of the neptunium targets at a CLWR. Determining which CLWR will actually provide the irradiation services is beyond the scope of this NI PEIS. For the purpose of impact analysis, a distance and population distribution that bounds all CLWRs is given for each DOE site evaluated in this NI PEIS in Table J-3. This distance and population would also bound shipments to and from Canada, if DOE should consider the use of a CANDU reactor in the future. Alternatives 3 and 4 include irradiation at a hypothetical facility located on an unspecified DOE site. For shipments originating at or destined for the unspecified reactor or accelerator site, a distance that bounds the furthest major DOE site is used.

#### **J.5.5 External Dose Rates**

In absence of analytical information, all shipments of neptunium-237, irradiated targets and plutonium-238 are conservatively assumed to be at the regulatory limit of 10 millirems per hour at a distance of 2 meters (6.6 feet) from the outer surface of the vehicle. The unirradiated targets, shipped in the same shielded cask as the irradiated targets, are assumed to be at one-tenth the regulatory limit. Other dose rates are estimated from cask contents.

#### **J.5.6 Health Risk Conversion Factors**

The health risk conversion factors used to estimate expected latent cancer fatalities were 0.0005 and 0.0004 fatal cancer cases per person-rem for members of the public and workers, respectively (ICRP 1991).

- a. CLWR site is assumed to be the furthest operating pressurized water reactor from the processing facility.
- b. Bounding distance for a new reactor or accelerator constructed on an existing DOE site.
- c. Using routes other than those designated for a vehicle carrying a Highway Route Controlled Quantity of a hazardous material; used by a vehicle carrying unirradiated medical isotope targets.

All other routes selected are for Highway Route Controlled Quantities (49 CFR Part 397, Subpart D).

**Note:** 1 kilometer = 0.62 mile; 1 square kilometer = 0.39 square mile.

**Key:** km, kilometer.

### **J.5.7 Truck Accident Rates**

For the calculation of accident risks, vehicle accident and fatality rates are taken from data provided in ANL-ESD/TM-150 (Saricks and Tompkins 1999). Accident rates are generically defined as the number of accident involvements (or fatalities) in a given year per unit of travel in that same year. Therefore, the rate is a fractional value, with accident-involvement count as the numerator of the fraction and vehicular activity (total travel distance in truck-kilometers) as its denominator. Accident rates are generally determined for a multiyear period. For assessment purposes, the total number of expected accidents or fatalities is calculated by multiplying the total shipment distance for a specific case by the appropriate accident or fatality rate.

For truck transportation, the rates presented are specifically for heavy combination trucks involved in interstate commerce (Saricks and Tompkins 1999). Heavy combination trucks are rigs composed of a separable tractor unit containing the engine and one to three freight trailers connected to each other. Heavy combination trucks are typically used for radioactive waste shipments. The truck accident rates are computed for each state based on statistics compiled by the Federal Highway Administration, Office of Motor Carriers from 1994 to 1996. A fatality caused by an accident is the death of a member of the public who is killed instantly or dies within 30 days due to the injuries sustained in the accident.

The HIGHWAY code classifies highways as rural, suburban or urban, and provides the distance and population information for use in RADTRAN. These codes require accident frequency data calculated for rural, urban and suburban zones. An older report, TM-68 (Saricks and Kvitck 1994), reports accident rates for Federally Aided Interstates in urban and rural areas, and a composite accident rate for all Federally Aided Interstates. TM-150 does not provide data that can be directly used to estimate frequencies for rural, urban and suburban zones. The ratio's of accident frequencies for the zones was calculated from TM-68 data, and used with the newer TM-150 data to establish up-to-date accident frequency estimates. Since the distance traveled on non-interstate highways was very small compared to the distance traveled on interstates, and the accident rates are similar, interstate accident rates were used for all roads. TM-68 and TM-150 information is used for both the accident rate estimate for the radiological risk, and the fatal accident rate estimate for the nonradiological risk.

For SST/SGT transportation, the rates presented are specifically adjusted for the experience of the DOE Transportation Safeguards Division. Between fiscal year 1984 and fiscal year 1998, the Transportation Safeguards Division reports 0.058 accident per million kilometers (0.096 accident per million miles) (Clauss and Shyr 1999). Using influence factors from SAND93-0111 (Phillips, Clauss, and Blower 1994), accident frequencies for rural, urban, and suburban driving can be estimated.

### **J.5.8 Container Accident Response Characteristics and Release Fractions**

NUREG-0170 (NRC 1977) was used to estimate the conditional probabilities and release fractions associated with the neptunium-237, plutonium-238, and highly enriched uranium shipments. The Modal Study, an initiative taken by NRC (Fischer et al. 1987) to refine more precisely the analysis presented in NUREG-0170 (NRC 1977) for spent nuclear fuel shipping casks, was used to estimate the conditional probabilities and release fractions for target and nuclear fuel shipments. The release fractions used for the analysis of medical and industrial isotopes are based on the severity of the accident, the shipping container, and the material being shipped (Lavender and Nielsen 1997).

Whereas the NUREG-0170 analysis was primarily performed using best engineering judgments and presumptions concerning cask response, the Modal Study relies on sophisticated structural and thermal engineering analysis and a probabilistic assessment of the conditions that could be experienced in severe transportation accidents. The Modal Study results are based on representative spent nuclear fuel casks that

were assumed to have been designed, manufactured, operated, and maintained in accordance with national codes and standards. Design parameters of the representative casks were chosen to meet the minimum test criteria specified in 10 CFR Part 71. The study is believed to provide realistic, yet conservative, results for radiological releases under transport accident conditions.

In both NUREG-0170 and the Modal Study, potential accident damage to a cask is categorized according to the magnitude of the mechanical forces (impact) and thermal forces (fire) to which a cask may be subjected during an accident. Because all accidents can be described in these terms, severity is independent of the specific accident sequence. In other words, any sequence of events that results in an accident in which a cask is subjected to forces within a certain range of values, it is assigned to the accident severity region associated with that range. The accident severity scheme is designed to take into account all potential foreseeable transportation accidents, including accidents with low probability but high consequences and those with high probability but low consequences.

As discussed above, the accident consequence assessment only considers the potential impacts from the most severe transportation accidents. In terms of risk, the severity of an accident must be viewed in terms of potential radiological consequences, which are directly proportional to the fraction of the radioactive material within a cask that is released to the environment during the accident. Although regions span the entire range of mechanical and thermal accident loads, they are grouped into accident categories that can be characterized by a single set of release fractions and are, therefore, considered together in the accident consequence assessment. The accident category severity fraction is the sum of all conditional probabilities in that accident category. NUREG-0170 (NRC 1977) provides eight accident severity categories for the neptunium-237 and plutonium-238. The Modal Study (Fischer et al. 1987) provides six accident severity categories for the targets.

#### **J.5.9 Nonradiological Risk (Vehicle-Related)**

Vehicle-related health risks resulting from incident-free transport may be associated with the generation of air pollutants by transport vehicles during shipment and are independent of the radioactive nature of the shipment. The health end-point assessed under incident-free transport conditions is the excess latent mortality due to inhalation of vehicle exhaust emissions. Risk factors for pollutant inhalation in terms of latent mortality have been generated (Neuhauser and Kanipe 2000). These risks are  $1 \times 10^{-7}$  mortality per kilometer ( $1.6 \times 10^{-7}$  per mile) of truck travel in urban areas. The risk factors are based on regression analyses of the effects of sulfur dioxide and particulate releases from diesel exhaust on mortality rates. Excess latent mortalities are assumed to be equivalent to latent cancer fatalities. Vehicle-related risks from incident-free transportation are calculated for each case by multiplying the total distance traveled in urban areas by the appropriate risk factor. Similar data are not available for rural and suburban areas.

Risks are summed over the entire route and over all shipments for each case. This method has been used in several environmental impact statements to calculate risks from incident-free transport. Lack of information for rural and suburban areas is an apparent data gap, although the risk factor would be much lower than for urban areas because of lower total emissions from all sources and lower population densities in rural and suburban areas.

#### **J.5.10 Intrasite Shipment**

If HFIR were selected to irradiate and REDC to process the targets, targets would be transported the short distance between REDC and HFIR in a cask that was formerly certified to Type B standards. Since the move is only about 90 meters (100 yards) on closed roads, and entirely within ORR, DOE procedures and NRC regulations do not require the use of a certified Type B cask. No incident-free risk analysis is necessary because the public would receive no measurable exposure. Similar procedures and equipment would be used

at INEEL for transfers between FDPF and ATR. Worker dose would be included in the handling analysis. No accident analysis is necessary because potential accidents during transportation are bounded in frequency and consequence by handling accidents. Once the cask is closed for the low speed transportation to the nearby building, the likelihood of any foreseeable accident that could expose the cask to conditions severe enough to fail the cask are very small.

At Hanford, the distances between facilities are somewhat larger and the roads could remain open for traffic. Therefore, DOE plans to use certified packaging. Risk analysis for unirradiated and irradiated plutonium-238 and medical and industrial isotope targets have been included. The facility locations for the new accelerator(s) and reactor have not been established, so the risk analysis used the same parameters as for Hanford.

## J.6 RISK ANALYSIS RESULTS

### J.6.1 Transportation Risk Analysis

Per-shipment risk factors have been calculated for the collective populations of exposed persons and for the crew for all anticipated routes and shipment configurations. The radiological doses are presented in doses per shipment for each unique route, material, and container combination. The radiological dose risk factors per shipment for incident-free transportation are presented in **Table J-5**. The per-shipment doses from medical and industrial isotopes come from HNF-1844 (Lavender and Nielsen 1997). The impacts from importing plutonium-238 were scaled from DOE/EA-0841 the *Environmental Assessment of the Impact of Russian Plutonium-238* (DOE 1993) as described in Section 4.2.1.1. Doses are calculated for the crew, off-link public (i.e., people living along the route), on-link public (i.e., pedestrians and drivers along the route), and public at rest and fueling stops (i.e., stopped cars, buses and trucks, workers, and other bystanders).

The radiological dose risk factors for transportation accidents are also presented in Table J-5. The accident risk factors are called “dose risk” because the values incorporate the spectrum of accident severity probabilities and associated consequences. Commercial vehicles have higher nonradiological and radiological accident risks because of the lower accident frequency calculated for SST/SGTs. The SST/SGTs have lower public risk estimates because they only stop in secure locations. The commercial vehicles have lower emission risk estimates because the SST/SGTs travel with escort vehicles. Crew risks are about the same.

The nonradiological risks of transporting each of the hazardous materials on the various routes are given in **Table J-6**. The risks are calculated by multiplying the previously given per-shipment factors by the number of shipments over the 35-year duration of the program. The risk estimates include the highest conceivable impacts of shipping. The total exhaust emission risks are higher if SST/SGTs are used because of the additional emission of escort vehicles. The accident risk of escort vehicles was considered in the analysis of traffic accident risk.

**Table J-7** shows the risks of transportation for each alternative for the production of plutonium-238. The risks are calculated by multiplying the previously given per-shipment factors by the number of shipments over the duration of the program, and for the radiological doses, by the health risk conversion factors. The risks are summed for all material transported under each alternative. The risks shown in Table J-7 conservatively assume that the neptunium-237, mixed oxide fuel, highly enriched uranium fuel, and plutonium-238 would be shipped in an SST/SGT and that all other intersite transportation would be done in commercial vehicles. Use of SST/SGTs for other shipments would lower the radiological risk estimates. They include the risk from overland, sea, and air transportation to the vessel crews and the public. **Table J-8** was created by adding the risk associated with the production and distribution of medical and industrial isotopes (Alternatives 1, 3, and 4) to the values in Table J-7. Table J-8 shows the risks for the missions analyzed in this NI PEIS.

The accident consequence assessment is intended to provide an estimate of the maximum potential impacts posed by the most severe hypothetical transportation accidents involving a shipment of materials covered by this NI PEIS. As a practical matter, the maximum foreseeable transportation accident is defined as an accident with a frequency greater than  $1 \times 10^{-7}$  per year (once in 10 million years). The previously described risk assessment (RADTRAN analysis) takes into account the risk of accidents not considered in the consequence assessment. The risk of accidents with frequencies lower than  $1 \times 10^{-7}$  per year is included in the risk estimates shown in Table J-7.

c. All risks are expressed as number of latent cancer fatalities, except for the Accident-Traffic column, which lists number of accident fatalities.

d. Production means storage, target fabrication, and processing.

**Key:** HEU, highly enriched uranium fuel; km, kilometers; MOX, mixed oxide fuel.

**Source:** Calculated results.

Accidents involving neptunium-237, mixed oxide fuel, irradiated targets, and plutonium-238 were evaluated in the consequence assessment. Accidents involving unirradiated targets were not evaluated because they occur at the same frequency, but clearly have lower consequences than accidents involving irradiated targets. SST/SGT accidents with higher frequencies than  $1 \times 10^{-7}$  per year did not release any neptunium-237 or plutonium-238 to the environment because the temperature and mechanical stresses predicted for accidents in this frequency range are within the design basis of the packages. The maximum foreseeable offsite transportation accident involves a shipment of irradiated plutonium-238 targets under neutral (average) weather conditions. The accident has a probability of occurring about once every 10 million years for the alternatives that involve shipping radioactive targets from one DOE facility to another. The accident could result in a dose of 0.61 person-rem to the public with an associated  $3.1 \times 10^{-4}$  latent cancer fatalities and 2.6 millirem to a hypothetical maximally exposed individual 30 meters (about 100 feet) from the vehicle. This results in a latent fatal cancer risk of  $1.3 \times 10^{-6}$ . No immediate fatalities from radiation would be expected. This accident would fall into Severity Category V (Fischer et al. 1987). In this hypothetical accident, the impact would cause the cask to fail, and the deformation of the cask would be assumed to fail a portion of the target material. In the event of a fire, it would not be hot enough or would not last long enough to damage the targets. To incur this level of damage, the cask would have to collide with an immovable object at a speed of greater than 88.5 kilometers (55 miles) per hour. The probability of an accident with a more energetic collision or fire and higher consequences is lower.

For alternatives and options in which irradiated targets are not shipped offsite, but mixed fuel is received at an east coast port, the maximum foreseeable offsite transportation accident is a shipment of mixed oxide fuel. This Category V accident in a suburban population zone could result in a dose of 0.40 person-rem to the public with an associated  $2.0 \times 10^{-4}$  latent cancer fatality, and 3.3 millirem to the hypothetical maximally exposed individual. No fatalities would be expected as a result of the radiation exposure.

The risks to various exposed individuals under incident-free transportation conditions have been estimated for hypothetical exposure scenarios. The estimated doses to inspectors and the public are presented in **Table J-9** on a per-event basis (person-rem per event). Note that the potential exists for larger individual exposures if multiple exposure events occur. For example, the dose to a person stuck in traffic next to a shipment for 30 minutes is calculated to be 11 millirem. If the exposure duration were longer, the dose would rise proportionally. In addition, a person working at a truck service station could receive a dose if trucks were to use the same stops repeatedly. The dose to a person fueling a truck could be as much as 1 millirem. Administrative controls could be instituted to control the location and duration of truck stops if multiple exposures were to happen routinely.

**Table J-9 Estimated Dose to Exposed Individuals During Incident-Free Transportation Conditions**

	Receptor	Dose to Maximally Exposed Individual <sup>a</sup>
Workers	Crew member (truck driver)	0.1 rem per year <sup>b</sup>
	Inspector	0.0029 rem per event
Public	Resident	$4.0 \times 10^{-7}$ rem per event
	Person in traffic congestion	0.011 rem per event
	Person at service station	0.001 rem per event

a. Doses are calculated assuming that the shipment external dose rate is equal to the maximum expected dose of 10 millirem per hour at 2 meters (6.6 feet) from the package.

b. This is a dose limit for a nonradiation worker (10 CFR Part 20). The dose to the truck driver could exceed this limit in the absence of administrative controls.

The cumulative dose to a resident was calculated assuming all shipments passed the resident's home. The cumulative doses assume that the resident is present for every shipment and there is no shielding between the

package and the receptor at a distance of 30 meters (98 feet) from the route. If all the material were to be shipped via this route, the maximum dose to this resident would be less than 0.1 millirem.

The estimated dose to transportation crew members is presented for a commercial crew who would be limited to 0.1 rem per year by 10 CFR Part 20. Drivers of SST/SGTs and some commercial trucks are trained as radiological workers. Allowed exposure limits vary. The exposure is limited to 2 millirem per hour in a “normally occupied space,” in accordance with 10 CFR Section 71.47.

### **J.6.2 Marine Transport Risk Analysis for Mixed Oxide Fuel**

The potential impacts of marine transport of mixed oxide fuel were considered in two ways, incident-free and accident impacts. Impact analysis includes the impacts on the global commons (i.e., portions of the ocean not within the territorial boundary of any nation) in accordance with Executive Order 12114 (44 FR 1957), the impacts approaching and docking at the port, and the impacts of unloading the mixed oxide package at the port.

The incident-free impacts would be those that occur simply due to the marine shipping of the mixed oxide fuel, assuming there are no accidents. The ships crew and dock crew would be affected in this case. The previously described RADTRAN 5 code was used to analyze the dose to the ships crew for transportation from Europe to the U.S. east coast. The accident impacts for the egress into the Charleston Naval Weapons Station were also modeled using the RADTRAN 5 code and are displayed in Table J-5.

The dose to the ships crew and the dockside personnel that would result from off loading the mixed oxide fuel packages was taken directly from the *Foreign Research Reactor Spent Nuclear Fuel EIS* (DOE 1996). The results are included in Table J-5 and are also in the by-alternative risk calculations shown in Table J-7. Exposure to handlers, inspectors, crane operators, and observers are included.

The *Foreign Research Reactor Spent Nuclear Fuel EIS* (DOE 1996) analyzed the shipment of spent nuclear fuel, and much of the analysis of shipping mixed oxide fuel can be taken from that document. The *Foreign Research Reactor Spent Nuclear Fuel EIS* is useful for both an absolute assessment of impacts and a relative assessment of impacts of using various ports. This NI PEIS analysis will show that the risk of shipping mixed oxide fuel is significantly less than the risk of shipping spent nuclear fuel by comparing the overland risk assessment of the two fuels. These risk assessments were both carried out using the same systematic approach to the analysis and using the RADTRAN series of codes.

**Table J-10** shows the per-shipment risk estimates performed for a mixed oxide fuel shipment from Charleston Naval Weapons Station to Hanford and the comparable estimates for a shipment of spent nuclear fuel from Charleston Naval Weapons Station and 10 other ports to Hanford. The dock and channel accident risk is from Appendix D and Attachment 2 to the *Foreign Research Reactor Spent Nuclear Fuel EIS* (DOE 1996). It is based on direct shipment of BR-2 spent nuclear fuel to the ports and includes hypothetical accidents at a point in the channel near population centers and at the dock. For example, the channel accident for the Charleston, South Carolina, area was performed for an accident at commercial anchorage area D, which is near the city of Charleston. The remaining columns in Table J-10 are from RADTRAN analysis of overland transportation and is the same information provided in Table J-5.

Comparing the overland transportation risks of shipping mixed oxide fuel and spent nuclear fuel along the same route from Charleston, South Carolina, to Hanford indicates the relative risks of the two materials. The crew risk is about a factor of 20 higher for the spent nuclear fuel than for the mixed oxide fuel because the dose rate from the spent fuel package is estimated to be at least 20 times higher. Public risk is about 50 times higher because of this dose rate difference. Also, the mixed oxide fuel would be carried in SST/SGTs, which would

**Note:** All except the Charleston Naval Weapons Station, South Carolina (MOX) are for spent nuclear fuel shipments from DOE 1996. Charleston Naval Weapons Station, South Carolina (MOX) is for a shipment of mixed oxide fuel from the transportation analysis of this NI PEIS, and the dock and channel accident risk for mixed oxide fuel is estimated from DOE 1996 results.

**Key:** <, less than; LCF, latent cancer fatality, MOX, mixed oxide fuel.

not be expected to expose the public to as much radiation as commercial trucks. In the risk analysis, commercial trucks carrying spent nuclear fuel are assumed to stop for food, fuel, and rest in the same manner as typical long distance trucking practices. However, SST/SGTs have specific procedures to ensure fueling is performed in a safe and secure manner, and routine rest and inspection stops are done in secure areas. Truck emissions are estimated to be the same for SST/SGTs and commercial trucks, but the emission risk for the mixed oxide fuel is higher because the SST/SGTs travel with escorts. SST/SGT accident frequencies are about a factor of 20 lower than truck accident frequencies, but the risk estimate for nonradiological accidents is only a factor of 10 lower because of the increased accident risk associated with SST/SGT escort vehicles.

The overland transportation radiological risk is a factor of one million lower for mixed oxide fuel than for spent nuclear fuel. Part of this difference is because the accident frequency is about 20 times lower for SST/SGTs. The risk estimated in Table J–10 were calculated by multiplying frequencies time consequences. Since the risk is about one million times lower and the frequency is about 20 times lower, the consequences of the same spectrum of accidents for the mixed oxide fuel packages is 50,000 times lower than for spent nuclear fuel packages ( $20 \times 50,000 = 1,000,000$ ). Based on the risk estimate of  $1.3 \times 10^{-9}$  latent cancer fatality per-shipment risk estimate for the foreign research reactor spent nuclear fuel package, the risk of shipping a mixed oxide fuel package into the port of Charleston Naval Weapons Station would be about  $2.6 \times 10^{-14}$  ( $1.3 \times 10^{-9}$  divided by  $50,000 = 2.6 \times 10^{-14}$ ).

Table J–10 shows the range of impacts calculated for the use of military ports for spent nuclear fuel, which can be used to bound the range of impacts for mixed oxide fuel. The overland transportation impacts of using

the Charleston Naval Weapons Station are representative (i.e., about the same) as for any of the east coast ports and were used in the presentation of transportation impacts in Tables J-7 and J-8. Based on the estimate for the Charleston Naval Weapons Station, the dock and channel accident risk of bringing a mixed oxide fuel package into any of the east coast military ports listed in Table J-10 would be less than  $10^{-13}$  latent cancer fatality. The incident-free and accident risks would be about the same as Charleston Naval Weapons Station for any eastern port. The dock and channel accident risk for western ports would be higher than those for eastern ports because of the higher local populations, but all would be less than  $10^{-12}$  latent cancer fatality per shipment. The overland transportation incident-free and accident risk for western ports ranges from about one-tenth to about one-half of those for eastern ports. The overland transportation accident risk for any east coast port is estimated to be less than  $2 \times 10^{-11}$  latent cancer fatality per shipment. The lower risk for western ports is caused by the reduced distance to Hanford.

The *Foreign Research Reactor Spent Nuclear Fuel EIS* (DOE 1996) evaluated the risks of damaged and undamaged casks sinking into coastal and deep ocean waters. The analysis included probabilities of recovery, and conservatively assumed failure of the cask in all accidents in greater than 200 meters of water depth. All program risks were less than  $10^{-7}$  rem per year to the peak individual. Since mixed oxide fuel accident consequences are much lower and this NI PEIS is proposing fewer shipments than the *Foreign Research Reactor Spent Nuclear Fuel EIS*, all risks would be less than  $10^{-10}$  rem per year for mixed oxide fuel alternatives to the maximally exposed individual. The *Foreign Research Reactor Spent Nuclear Fuel EIS* concluded that following a hypothetical severe accident, radioactive particles dispersed over the ocean would not be in large enough amounts to have a measurable impact on the environment. The same conclusion would be appropriate for this NI PEIS since the casks would contain considerably fewer curies of radioactive material.

## J.7 CONCLUSIONS

The transportation requirements for the alternatives of this NI PEIS have been analyzed, and the following conclusions have been reached:

- It is unlikely that the transportation of radioactive materials will cause an additional fatality as a result of either incident-free transportation or associated with postulated transportation accidents.
- The highest risk estimate for any transportation activity is for the air transport of medical and industrial isotopes. Since the amount and nature of isotopes to be produced is uncertain, this analysis is necessarily conservative. However, in order for an isotope production facility to be successful, it is likely that large amounts of isotopes would be transported to locations throughout the country. All isotopes were assumed to be transported by air for the purpose of analysis.
- Options in which the processing and fabrication facility and the irradiation facility are colocated, such as Alternative 1, Options 3 and 6 and Alternative 2, Options 2, 7, and 8, have lower transportation risks than other alternatives.
- Options in which the irradiation facility is at an unspecified site, such as Alternative 2, Options 4, 5, and 6, and Alternatives 3 and 4, appear to have higher risks than other options. However, if an actual radiation facility were sited nearby the processing and fabrication facility, the risk estimates would be considerably lower.
- The overland transportation impacts are somewhat higher for mixed oxide fuel acceptance at east coast ports rather than a west coast port. The sea transportation impacts are much lower than overland transportation risks for shipment to either coast. The sea transportation impacts for western ports are

double those for eastern ports. Use of the Panama Canal for shipment to western ports poses safeguards and security concerns.

## **J.8 UNCERTAINTY AND CONSERVATISM IN ESTIMATED IMPACTS**

The sequence of analyses performed to generate the estimates of radiological risk for transportation includes: (1) determining the inventory and characteristics, (2) estimating shipment requirements, (3) determining route characteristics, (4) calculating radiation doses to exposed individuals (including estimation of environmental transport and radionuclides uptake), and (5) estimating health effects. Uncertainties are associated with each of these steps. Uncertainties exist in the way that the physical systems being analyzed are represented by the computational models; in the data required to exercise the models due to measurement errors, sampling errors, natural variability, or unknown simply caused by the future nature of the action being analyzed; and in the calculations themselves (e.g., approximate algorithms used by the computer). In principle, one can estimate the uncertainty associated with each input or computational source and predict the resultant uncertainty in each set of calculations. Thus, one can propagate the uncertainties from one set of calculations to the next and estimate the uncertainty in the final, or absolute, result. However, conducting such a full-scale quantitative uncertainty analysis is often impractical and sometimes impossible, especially for actions to be initiated at an unspecified time in the future. Instead, the risk analysis is designed to ensure, through uniform and judicious selection of scenarios, models, and input parameters, that relative comparisons of risk among the various alternatives are meaningful. In the transportation risk assessment, this design is accomplished by uniformly applying common input parameters and assumptions to each alternative. Although considerable uncertainty is inherent in the absolute magnitude of the transportation risk for each alternative, much less uncertainty is associated with the relative differences among the alternatives in a given measure of risk.

In the following sections, areas of uncertainty are discussed for the assessment steps listed above. Special emphasis is placed on identifying whether the uncertainties affect relative or absolute measures of risk. The degree of reality conservatism of the assumption is addressed. Where practical, the parameters that most significantly affect the risk assessment results are identified.

### **J.8.1 Uncertainties and Conservatism in Neptunium-237 and Plutonium-238 Inventory and Characterization**

The inventories and the physical and radiological characteristics are important input parameters to the transportation risk assessment. The potential amount of transportation for any alternative is determined primarily by the projected dimensions of package contents, strength of the radiation field, heat that must be dissipated, and assumptions concerning shipment capacities. The physical and radiological characteristics are important in determining the amount of material released during accidents and the subsequent doses to exposed individuals through multiple environmental exposure pathways.

Uncertainties in the inventory and characterization will be reflected to some degree in the transportation risk results. If the inventory is overestimated (or underestimated), the resulting transportation risk estimates also will be overestimated (or underestimated) by roughly the same factor. However, the same inventory estimates are used to analyze the transportation impacts of each alternative of this NI PEIS. Therefore, for comparative purposes, the observed differences in transportation risks among the alternatives, as given in Table J-6, are believed to represent unbiased, reasonably accurate estimates from current information in terms of relative risk comparisons.

If DOE should enter into the final design and implementation phase of the project, the amount of neptunium and plutonium in the targets could change. The incident-free risk estimate would not change, unless the number of shipments changes, because the maximum regulatory limit dose rate was used.

### **J.8.2 Uncertainties in Containers, Shipment Capacities, and Number of Shipments**

The amount of transportation required for each alternative is based in part on assumptions concerning the packaging characteristics and shipment capacities for commercial trucks and SST/SGTs. Representative shipment capacities have been defined for assessment purposes based on probable future shipment capacities. In reality, the actual shipment capacities may differ from the predicted capacities such that the projected number of shipments and, consequently, the total transportation risk would change. However, although the predicted transportation risks would increase or decrease accordingly, the relative differences in risks among alternatives would remain about the same.

### **J.8.3 Uncertainties in Route Determination**

Representative routes have been determined between all origin and destination sites considered in this NI PEIS. The routes have been determined consistent with current guidelines, regulations, and practices, but may not be the actual routes that would be used in the future. In reality, the actual routes could differ from the representative ones in terms of distances and total population along the routes. Moreover, since materials could be transported over an extended period of time starting at some time in the future, the highway infrastructures and the demographics along routes could change. These effects have not been accounted for in the transportation assessment; however, it is not anticipated that these changes would significantly affect relative comparisons of risk among the alternatives considered in this NI PEIS. Specific routes cannot be identified in advance because the routes are classified to protect national security interests.

### **J.8.4 Uncertainties and Conservatism in the Calculation of Radiation Doses**

The models used to calculate radiation doses from transportation activities introduce a further uncertainty in the risk assessment process. It is generally difficult to estimate the accuracy or absolute uncertainty of the risk assessment results. The accuracy of the calculated results is closely related to the limitations of the computational models and to the uncertainties in each of the input parameters that the model requires. The single greatest limitation facing users of RADTRAN 5, or any computer code of this type, is the scarcity of data for certain input parameters.

Uncertainties associated with the computational models are minimized by using state-of-the-art computer codes that have undergone extensive review. Because there are numerous uncertainties that are recognized, but difficult to quantify, assumptions are made at each step of the risk assessment process that are intended to produce conservative results (i.e., overestimate the calculated dose and radiological risk). Because parameters and assumptions are applied to all alternatives, this model bias is not expected to affect the meaningfulness of relative comparisons of risk; however, the results may not represent risks in an absolute sense.

To understand the most important uncertainties and conservatism in the transportation risk assessment, the results for all cases were examined to identify the largest contributors to the collective population risk.

Postaccident mitigative actions are not considered for dispersal accidents. For severe accidents involving the release and dispersal of radioactive materials in the environment, no postaccident mitigative actions, such as interdiction of crops or evacuation of the accident vicinity, have been considered in this risk assessment. In reality, mitigative actions would take place following an accident in accordance with EPA radiation protection guides for nuclear incidents (EPA 1992). The effects of mitigative actions on population accident doses are

highly dependent upon the severity, location, and timing of the accident. For this risk assessment, ingestion doses are only calculated for accidents occurring in rural areas (the calculated ingestion doses, however, assume all food grown on contaminated ground is consumed and is not limited to the rural population). Examination of the severe accident consequence assessment results has shown that ingestion of contaminated foodstuffs contributes on the order of 50 percent of the total population dose for rural accidents. Interdiction of foodstuffs would act to reduce, but not eliminate, this contribution.

## Environmental Justice Analysis

### K.1 INTRODUCTION

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations* (59 FR 7629), directs Federal agencies to identify and address, as appropriate, disproportionately high and adverse health or environmental effects of their programs, policies, and activities on minority populations and low-income populations.

The Council on Environmental Quality has oversight responsibility for documentation prepared in compliance with the National Environmental Policy Act (NEPA). In December 1997, the Council released its guidance on environmental justice under NEPA (CEQ 1997). The Council's guidance was adopted as the basis for the analysis of environmental justice contained in this *Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS])*.

This appendix provides an assessment of the potential for disproportionately high and adverse human health or environmental effects on minority and low-income populations from the implementation of each alternative.

### K.2 DEFINITIONS

#### MINORITY INDIVIDUALS AND POPULATION

The following definitions of minority individuals and population were used in this analysis of environmental justice:

- **Minority individuals**—Individuals who are members of the following populations groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic.
- **Minority population**—Minority populations should be identified where either: (a) the minority population of the affected area exceeds 50 percent or (b) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis. In identifying minority communities, agencies may consider as a community either a group of individuals living in geographic proximity to one another, or a geographically dispersed and transient set of individuals (such as migrant workers or Native American), where either type of group experiences common conditions of environmental exposure or effect. The selection of the appropriate unit of geographic analysis may be a governing body's jurisdiction, a neighborhood, census tract, or other similar unit that is to be chosen so as to not artificially dilute or inflate the affected minority population. A minority population also exists if there is more than one minority group present and the minority percentage, as calculated by aggregating all minority persons, meets one of the above-stated thresholds.

In the discussions of environmental justice in this NI PEIS, persons self-designated as Hispanic are included in the Hispanic population, regardless of race. For example, the Asian or Pacific Islander population is composed of persons self-designated as Asian or Pacific Islander and not of Hispanic origin. Asian or Pacific Islanders who designated themselves as having Hispanic origins are included in the Hispanic population. Data for the analysis of minority populations in 1990 were extracted from Table P012 of Summary Tape File 3 (DOC 1992). Data for the analysis of minorities and racial populations were extracted for year 2020 from the Census Bureau's World Wide Web site (DOC 1999).

## **LOW-INCOME INDIVIDUALS AND POPULATION**

Executive Order 12898 specifically addresses “disproportionately high and adverse effects” on “low-income” populations. The Council on Environmental Quality recommends that poverty thresholds be used to identify “low-income” individuals.

The following definition of low-income population was used in this analysis:

- **Low-income population**—Low-income populations in an affected area should be identified with the annual statistical poverty thresholds from the U.S. Bureau of the Census’ Current Population Reports, Series P-60 on Income and Poverty. In identifying low-income populations, agencies may consider as a community either a group of individuals living in geographic proximity to one another, or a set of individuals (such as migrant workers or Native Americans), where either type of group experiences common conditions of environmental exposure or effect.

Data for the analysis of low-income populations were extracted from Table P121 of Summary Tape File 3 (DOC 1992).

## **DISPROPORTIONATELY HIGH AND ADVERSE HUMAN HEALTH EFFECTS**

Adverse health effects are measured in risks and rates that could result in latent cancer fatalities, as well as other fatal or nonfatal adverse impacts to human health. Disproportionately high and adverse human health effects occur when the risk or rate of exposure to an environmental hazard for a minority population or low-income population is significant and exceeds the risk of exposure rate for the general population or, where available, for another appropriate comparison group (CEQ 1997).

## **DISPROPORTIONATELY HIGH AND ADVERSE ENVIRONMENTAL IMPACTS**

A disproportionately high environmental impact refers to an impact (or risk of an impact) in a low-income or minority community that is significant and exceeds the environmental impact on the larger community. An adverse environmental impact is an impact that is determined to be both harmful and significant. In assessing cultural and aesthetic environmental impacts, impacts that uniquely affect geographically dislocated or dispersed or minority low-income populations are considered (CEQ 1997).

Potentially affected areas examined in this NI PEIS include areas defined by an 80-kilometer (50-mile) radius centered on candidate facilities for plutonium-238 production, radioisotope production, or processing activities located at the Idaho National Engineering and Environmental Laboratory (INEEL), the Oak Ridge Reservation (ORR), and the Hanford Site (Hanford). Potentially affected areas used in the analysis of environmental justice are the same as those used in the analysis of radiological health effects described in Chapter 4.

## **K.3 METHODOLOGY**

### **K.3.1 Spatial Resolution**

For the purposes of enumeration and analysis, the Census Bureau has defined a variety of areal units (DOC 1992). Areal units of concern in this document include (in order of increasing spatial resolution) states, counties, census tracts, block groups, and blocks. The “block” is the smallest of these entities and offers the finest spatial resolution. This term refers to a relatively small geographical area bounded on all sides by visible features such as streets and streams or by invisible boundaries such as city limits and property lines. During the 1990 census, the Census Bureau subdivided the United States and its territories into 7,017,425 blocks. For

comparison, the number of counties, census tracts, and block groups used in the 1990 census were 3,248; 62,276; and 229,192; respectively. While blocks offer the finest spatial resolution, economic data required for the identification of low-income populations are not available at the block-level of spatial resolution. In the analysis below, block groups are used throughout as the areal unit. Block groups generally contain between 250 and 500 housing units (DOC 1992).

During the decennial census, the Census Bureau collects data from individuals and aggregates the data according to residence in a geographical area, such as a county or block group. This NI PEIS uses data from the 1990 census as a baseline. The Census Bureau has not yet published results of the year 2000 census. Boundaries of the areal units are selected to coincide with features such as streams and roads or political boundaries such as county and city borders. Boundaries used for aggregation of the census data usually do not coincide with boundaries used in the calculation of health effects. As discussed in Chapter 4, radiological health effects due to an accident at each of the sites considered for the proposed actions are evaluated for persons residing within a distance of 80 kilometers (50 miles) of an accident site. In general, the boundary of the circle with an 80-kilometer (50-mile) radius centered at the accident site will not coincide with boundaries used by the Census Bureau for enumeration of the population in the potentially affected area. Some block groups lie completely inside or outside of the radius for health effects calculation. However, other block groups are only partially included. As a result of these partial inclusions, uncertainties are introduced into the estimate of the population at risk from the accident.

To estimate the populations at risk in partially included block groups, it was assumed that populations are uniformly distributed throughout the area of each block group. For example, if 30 percent of the area of a block group lies within 80 kilometers (50 miles) of the accident site, it was assumed that 30 percent of the population residing in that block group would be at risk.

### **K.3.2 Population Projections**

Health effects were calculated for populations projected to reside in potentially affected areas during the year 2020. Extrapolations of the total population for individual states are available from both the Census Bureau and various state agencies (Campbell 1996). The Census Bureau also projects populations by ethnic and racial classification in 1-year intervals for the years from 1995 to 2025 at the state level. State agencies project total populations for individual counties. No Federal or state agency projects block group or low-income populations. Data used to project minority populations were extracted from the Census Bureau's World Wide Web site (DOC 1999). To project minority populations in potentially affected areas, minority populations determined from the 1990 census data were taken as a baseline for each block group. Then it was assumed that percentage changes in the minority population of each block group for a given year (compared to the 1990 baseline data) will be the same as percentage changes in the state minority population projected for the same year. An advantage to this assumption is that the projected populations are obtained using a consistent method, regardless of the state and associated block group involved in the calculation. A disadvantage is that the method is insensitive to localized demographic changes that could alter the projection in a specific area.

The Census Bureau uses the cohort-component method to estimate future populations for each state (Campbell 1996). The set of cohorts is comprised of: (1) age groups from 1 year or less to 85 years or more, (2) male and female populations in each age group, and (3) the following racial and ethnic groups in each age group: Hispanic, non-Hispanic Asian, non-Hispanic Black, non-Hispanic Native American, and non-Hispanic White. Components of the population change used in the demographic accounting system are births, deaths,

net state-to-state migration, and net international migration. If  $P(t)$  denotes the number of individuals in a given cohort at time “ $t$ ,” then:

$$P(t) = P(t_0) + B - D + DIM - DOM + IIM - IOM$$

where:

- $P(t_0)$  = Cohort population at time  $t_0 \leq t$ . For this analysis,  $t_0$  denotes the year 1990.
- $B$  = Births expected during the period from  $t_0$  to  $t$ .
- $D$  = Deaths expected during the period from  $t_0$  to  $t$ .
- $DIM$  = Domestic migration into the state expected during the period from  $t_0$  to  $t$ .
- $DOM$  = Domestic migration out of the state expected during the period from  $t_0$  to  $t$ .
- $IIM$  = International migration into the state expected during the period from  $t_0$  to  $t$ .
- $IOM$  = International migration out of the state expected during the period from  $t_0$  to  $t$ .

Estimated values for the components shown on the right side of the equation are based on past data and various assumptions regarding changes in the rates for birth, mortality, and migration (Campbell 1996). Persons of Hispanic origin are included in the Hispanic population regardless of race. It should be noted that the Census Bureau does not project populations of individuals who identified themselves as “other race” during the 1990 census. This population group is less than 2 percent of the total population in each of the states. However, to project total populations in the environmental justice analysis, population projections for the “other race” group were made under the assumption that the growth rate for the “other race” population will be identical to the growth rate for the combined minority and white populations.

#### **K.4 ENVIRONMENTAL JUSTICE ASSESSMENT**

The analysis of environmental justice concerns was based on an assessment of the impacts reported in Chapter 4. This analysis was performed to identify any disproportionately high and adverse human health or environmental impacts on minority or low-income populations surrounding the candidate sites. Demographic information obtained from the Census Bureau was used to identify the minority populations and low-income communities in the zone of potential impact surrounding the sites (DOC 1992).

#### **K.5 RESULTS FOR THE SITES FOR THE NO ACTION ALTERNATIVE, ALTERNATIVE 1, ALTERNATIVE 2, AND ALTERNATIVE 5**

As discussed in Chapter 2, the Advanced Test Reactor (ATR) at INEEL, the High Flux Isotope Reactor (HFIR) at ORR, and the Fast Flux Test Facility (FFTF) at Hanford are candidate reactors for DOE’s nuclear infrastructure programs. Candidate processing facilities include the Fluorinel Dissolution Process Facility (FDPF) at INEEL, the Radiochemical Engineering Development Center (REDC) at ORR, and the Fuels and Materials Examination Facility (FMEF) at Hanford. This section describes the analysis of potentially affected minority and low-income populations residing near those facilities. Projections of the total population provided in this appendix differ from the projected total populations used in the health effects calculations described in Chapter 4. This is because the projections used in the analysis of environmental justice are based on projections for the states provided by the Census Bureau (Campbell 1996). Projections used in the analysis of health effects are based on county-wide projections provided by state agencies. As discussed above, the county projections are more sensitive to localized demographic changes. However, the states do not provide projections for minority populations. Therefore, the Census Bureau’s projections were used in the analysis of environmental justice. Population projections obtained with the two approaches differ by 14 percent or less and have essentially no effect on the results of the analyses.

### K.5.1 Results for INEEL

As discussed in Chapter 2, three of the candidate facilities for participation in DOE’s program for the supply of isotope products and services are located at INEEL: ATR, FDPF, and CPP-651. **Figure K-1** shows the racial and Hispanic composition of the minority population residing within 80 kilometers (50 miles) of ATR in 1990 (DOC 1992) and those projected to reside in the potentially affected area in the year 2020. In the interval between 1990 and 2020, the percentage of the total population composed of minorities is projected to increase from 10 percent to 18 percent. ATR and FDPF are within approximately 3 kilometers (1.9 miles) of one another, and the populations in potentially affected areas for the two facilities are similar.

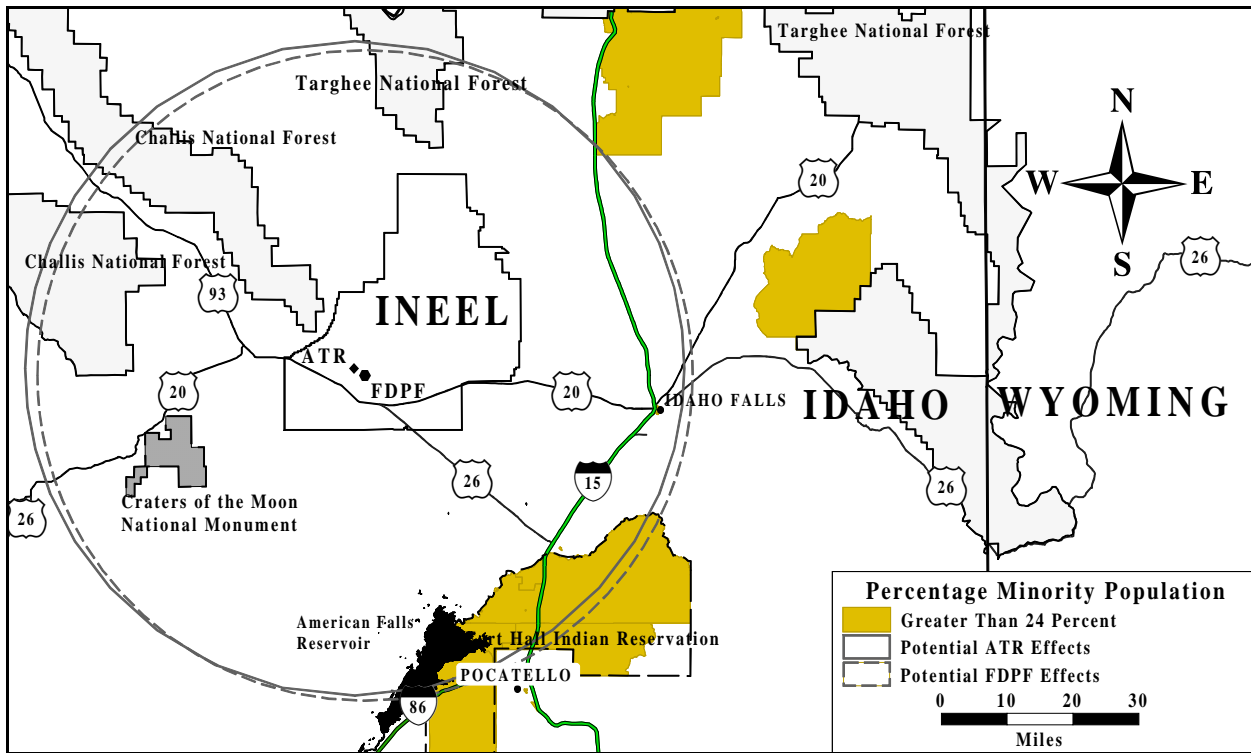

**Figure K-1 Racial and Hispanic Composition of the Population Residing Within 80 Kilometers (50 Miles) of ATR at INEEL**

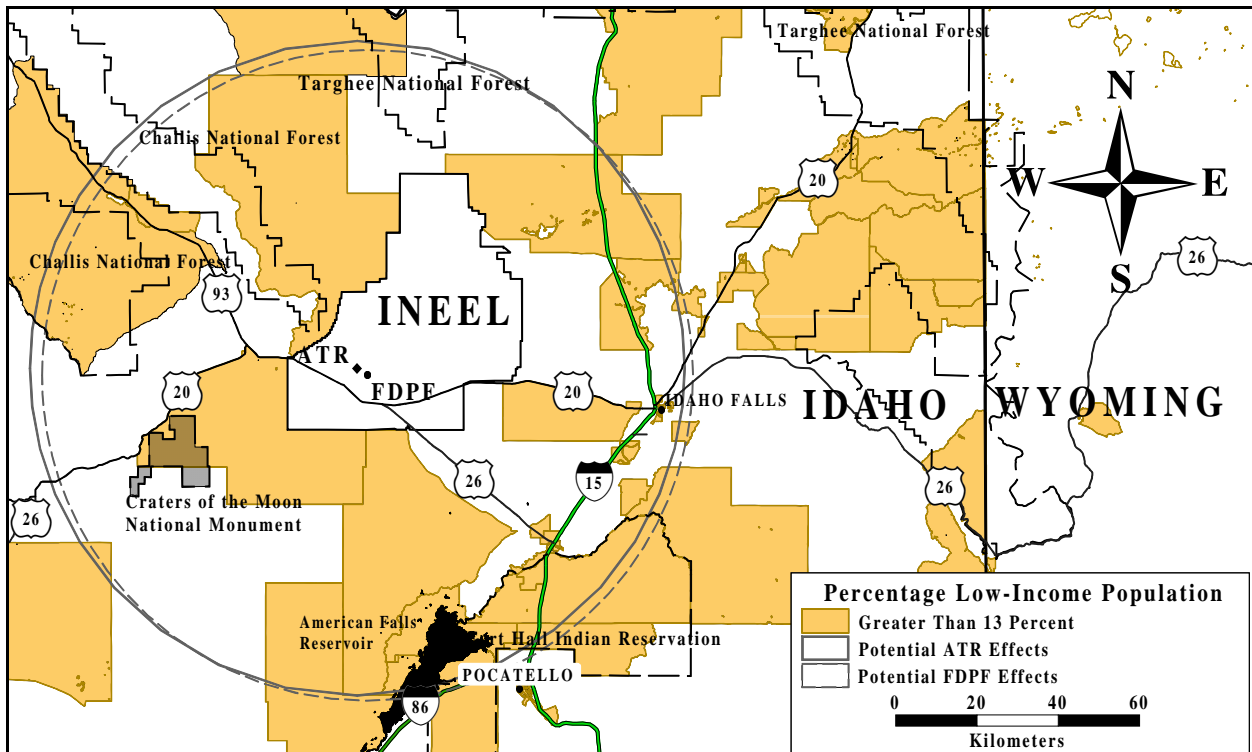

For comparison, during the 1990 census, minorities were found to comprise approximately one-quarter of the total national population. By the year 2020, minorities are projected to comprise approximately one-third of the total national population. The percentage of the minority population residing in the potentially affected areas surrounding the INEEL site was less than the corresponding national percentage in 1990, and is expected to remain so through the year 2020. Hispanics are the largest minority group residing in the potentially affected area, and both Asian and Hispanic populations are projected to show the largest growth rates.

During the 1990 census, approximately 13 percent of the residents within the potentially affected area surrounding the INEEL site reported incomes below the poverty threshold. Slightly over 13 percent of the national population reported incomes below the poverty threshold, and approximately 13 percent of the residents of Idaho reported incomes below the poverty threshold during the same year. Thus, the percentage of low-income population residing within the potentially affected area in 1990 was equal to that for the Nation and the State of Idaho.

**Figures K-2** and **K-3** show the geographical distribution of minority and low-income populations residing near INEEL in 1990. As indicated in Figure K-2, block groups for which the percentage of minority residents exceeds the corresponding national percentage (approximately 24 percent in 1990) are concentrated in the area

**Figure K-2 Geographical Distribution of Minority Populations Residing Within 80 Kilometers (50 Miles) of ATR and FDPF at INEEL**

**Figure K-3 Geographical Distribution of Low-Income Populations Residing Within 80 Kilometers (50 Miles) of ATR and FDPF at INEEL**

of the Fort Hall Reservation. Block groups for which the percentage of the low-income population exceeds the national percentage (approximately 13 percent in 1990) are located throughout the potentially affected area. Thus, estimates of the effects of radiological or chemical releases to the atmosphere on minority populations could be noticeably influenced by assumptions concerning weather conditions existing during a given release. Low-income populations are located more uniformly throughout the potentially affected area, and estimates of the radiological effects on low-income populations would be less sensitive to assumptions concerning prevailing wind direction, wind speed, and atmospheric stability class. Appendix H discussed the radiological and nonradiological release models used in this NI PEIS.

As discussed in Chapter 4, normal operations that would result from implementation of the alternatives at INEEL would pose no significant incremental health or other risks to persons residing within the potentially affected area. Environmental justice concerns in the INEEL area include food consumption patterns of minority communities, such as the Fort Hall Indian Reservation, and low-income communities that are located throughout the potentially affected area. In order to assess potential health risks to minority and low-income populations, the health impacts due to ingestion of contaminated food in the potentially affected area were evaluated with the GENII computer model (see Appendix H). Health risks due to normal operations were evaluated under the assumption that all food consumed by residents in the potentially affected area during the 35-year operational period would be obtained locally and would be subject to radiological contamination that could result from normal operations. The maximum population dose to populations at risk near INEEL due to ingestion of radiologically contaminated food would be approximately  $2.6 \times 10^{-6}$  person-rem. The associated risk of a latent cancer fatality would be essentially zero. Thus, no credible pattern of food consumption by minority or low-income populations would result in a significant health risk attributable to radiological contamination of the food supply that could result from normal operations.

In the event of a radiological accident at one of the INEEL facilities, radiological contamination would be directed toward the Fort Hall Indian Reservation if the prevailing winds at the time of the accident were blowing from the northwest (see Figure K-2). However, accidents that could occur at INEEL under implementation of the alternatives would not be expected to result in a latent cancer fatality among the exposed population or the maximally exposed individual residing within the boundaries of the Fort Hall Reservation.

Implementation of the alternatives would thus pose no significant radiological risks to minority or low-income populations residing within the potentially affected area surrounding INEEL.

### **K.5.2 Results for ORR**

As discussed in Chapter 2, HFIR is a candidate reactor for DOE's isotope supply program, and REDC is a candidate processing facility. These facilities are co-located at latitude 35° 55'7" north and longitude 84° 18'14" west. **Figure K-4** shows the racial and Hispanic composition of the minority population residing within 80 kilometers (50 miles) of HFIR and REDC at ORR in 1990 (DOC 1992) and those projected to reside in the potentially affected area in the year 2020. In the interval between 1990 and 2020, the percentage of the total population composed of minorities is projected to increase from approximately 6 to 8 percent. For comparison, during the 1990 census, minorities were found to comprise approximately one-quarter of the total national population. By the year 2020, minorities are projected to comprise approximately one-third of the total national population. The percentage of the minority population residing in the potentially affected area surrounding ORR was less than the corresponding national percentage in 1990, and is expected to remain so through the year 2020. Blacks are the largest minority group residing in the potentially affected area, while the Asian and Hispanic populations are projected to show the largest growth rates.

**Figure K-4 Racial and Hispanic Composition of Populations Residing Within 80 Kilometers (50 Miles) of HFIR and REDC at ORR**

**Figure K-5** shows the geographical distribution of the minority population residing near ORR. Minority populations within the potentially affected area are concentrated largely in the area of Knoxville, Tennessee. **Figure K-6** provides an expanded view of the areas surrounding Knoxville and ORR. The minority community of Scarboro is adjacent to the northern boundary of ORR. Approximately 60 percent of the minority populations residing in the potentially affected area surrounding ORR also reside within 16 kilometers (10 miles) of Knoxville. Thus, estimates of the effects of radiological or chemical releases could be noticeably influenced by assumptions concerning weather conditions existing during a given release.

During the 1990 census, 16 percent of the residents within the potentially affected area surrounding ORR reported incomes below the poverty threshold. Slightly over 13 percent of the national population reported incomes below the poverty threshold, and nearly 16 percent of the residents of Tennessee reported incomes below the poverty threshold during the same year. Thus, the percentage of low-income population residing within the potentially affected area exceeded that for the Nation, but is equal to the corresponding percentage for Tennessee. **Figures K-7** and **K-8** show the geographical distribution of low-income residents surrounding ORR and the Knoxville-ORR area, respectively. Block groups for which the percentage of low-income residents exceeds the corresponding national percentage are located throughout the potentially affected area. Thus, estimates of the effects of radiological or chemical releases on low-income populations are less sensitive to assumptions concerning existing weather conditions.

As discussed in Chapter 4, normal operations that would result from implementation of the alternatives at ORR would pose no significant incremental health or other risks to persons residing within the potentially affected area. Environmental justice concerns in the ORR area include food consumption patterns of minority communities, such as those in Scarboro and Knoxville, and low-income communities that are located throughout the potentially affected area. In order to assess potential health risks to minority and low-income populations, the health impacts due to ingestion of contaminated food in the potentially affected area were evaluated with the GENII computer model (see Appendix H). Health risks due to normal operations were evaluated under the assumption that all food consumed by residents in the potentially affected area during the

**Figure K-5 Geographical Distribution of Minority Populations Residing Within 80 Kilometers (50 Miles) of HFIR and REDC at ORR**

**Figure K-6 Geographical Distribution of Minority Populations in the Knoxville, Tennessee Area**

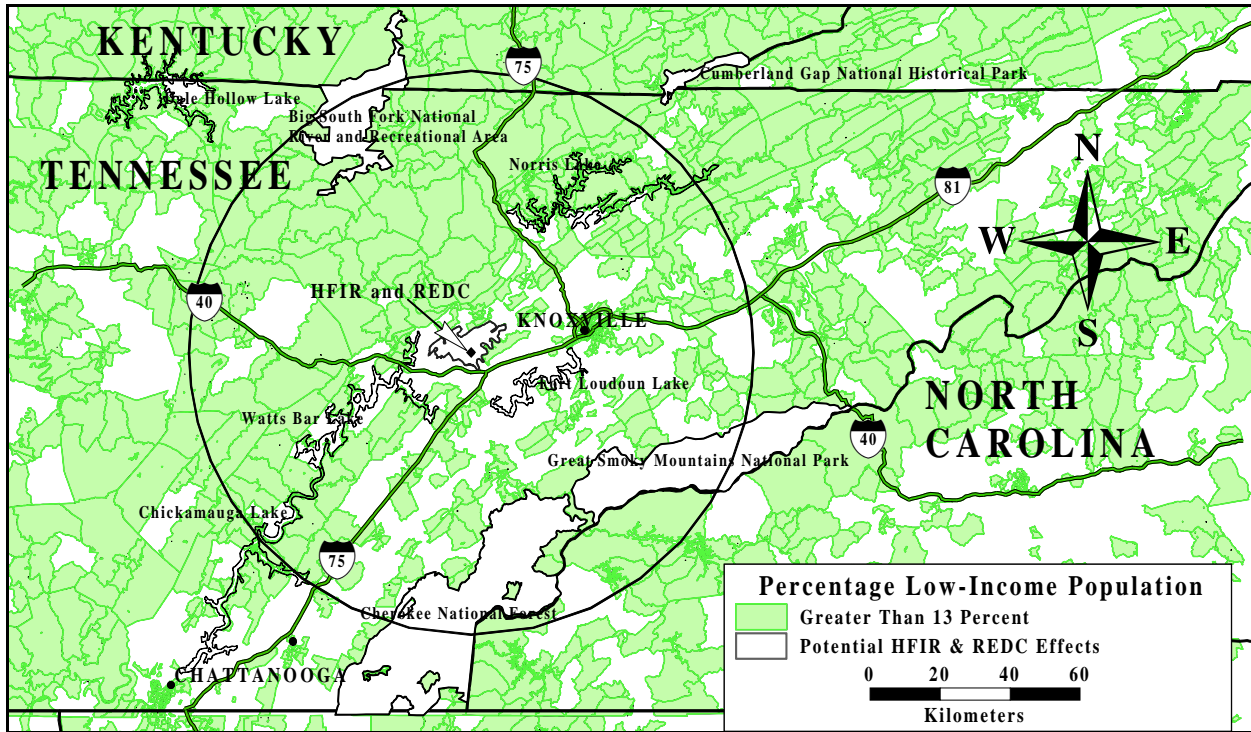

Figure K-7 Geographical Distribution of Low-Income Populations Residing Within 80 Kilometers (50 Miles) of HFIR and REDC at ORR

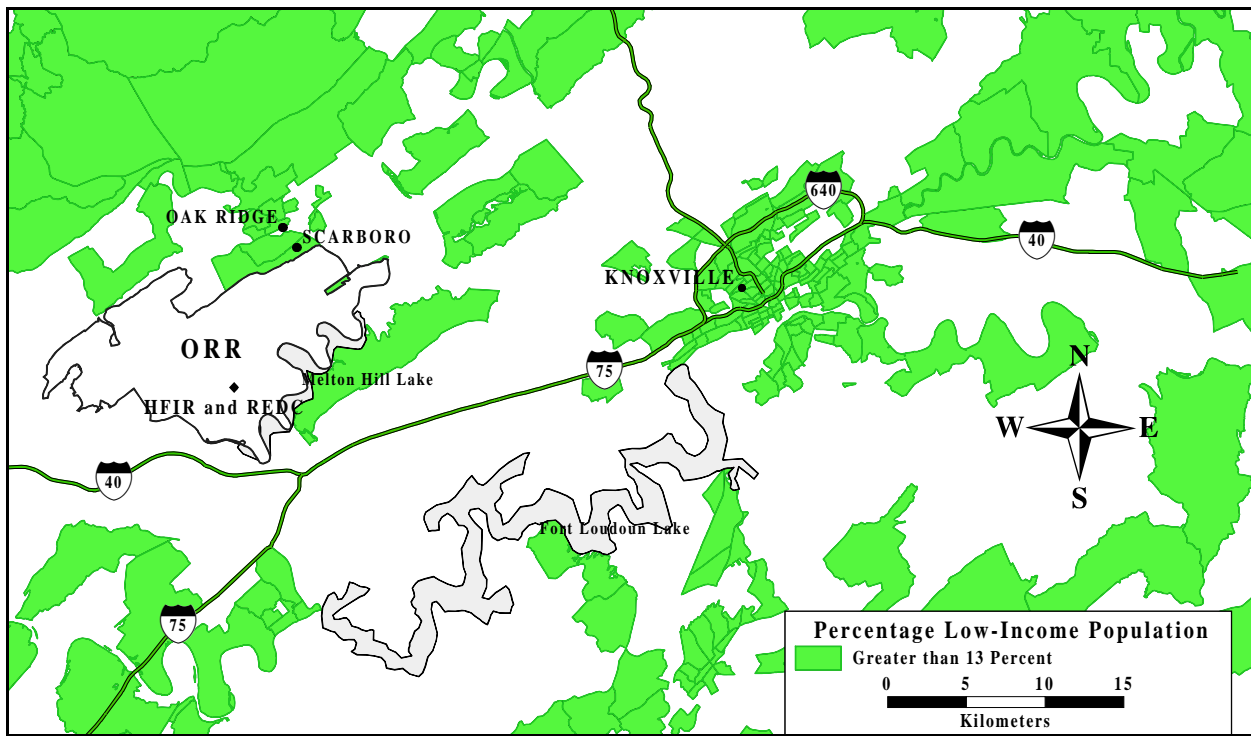

Figure K-8 Geographical Distribution of Low-Income Populations in the Knoxville, Tennessee Area

35-year operational period would be obtained locally and would be subject to radiological contamination that could result from normal operations. The maximum population dose to populations at risk near ORR due to ingestion of radiologically contaminated food would be approximately  $2.6 \times 10^{-7}$  person-rem. The associated risk of a latent cancer fatality would be essentially zero. Thus, no credible pattern of food consumption by minority or low-income populations would result in a significant health risk attributable to radiological contamination of the food supply that could result from normal operations.

As shown in Figure K–6, minorities at risk in the potentially affected area are concentrated in the community of Scarboro adjacent to the northern boundary of ORR and Knoxville, Tennessee. In the event of a radiological accident at one of the ORR facilities, radiological contamination would be directed toward Scarboro if the prevailing winds at the time of the accident were blowing from the south-southwest (see Figure K–6). As discussed in Chapter 4 (e.g., see Section 4.3.1.1.10), the largest radiological risks to the public that could result from implementation of the alternatives are those that could result from accidents at candidate fabrication and processing facilities.

Scarboro is the minority community closest to the boundary of ORR. The residents of Scarboro are among the populations at risk due to radiological accidents that could occur at REDC. Demographic data for Scarboro is contained in the block group designated by Federal Information Processing Standard (FIPS) code 470010201004. Projection of the population of Scarboro to the year 2020 shows that its total population is expected to be approximately 964 in 2020, and the minority population is expected to be approximately 877 in 2020. In order to conservatively estimate the risk of latent cancer fatalities resulting among minority residents of Scarboro from a beyond-design-basis earthquake at REDC, it was assumed that if such an earthquake were to occur, then all minority residents of Scarboro would receive a radiation dose of 26.3 rem. That is the dose that would be received by the maximally exposed individual residing at the ORR boundary in the direction north-northwest from REDC. Under this assumption, the resulting population dose would be approximately 23,065 person-rem. For an accident frequency of  $10^{-5}$  (see Section 4.3.1.1.10), the annual risk to the projected minority population under these conservative assumptions would be  $2.3 \times 10^{-4}$  latent cancer fatality. Over the 35-year program duration, the expected latent cancer fatalities among the minority population would be approximately 0.008. No latent cancer fatalities among the minority population of Scarboro would be expected to result from a beyond-design-basis earthquake at REDC. In addition, if REDC were selected to process plutonium-238 under the nuclear infrastructure alternatives, specific safety analysis documentation would be developed to provide the authorization basis for REDC operations. If DOE site officials deem it necessary, facility and/or operational modification would be used to mitigate the impacts of severe accidents.

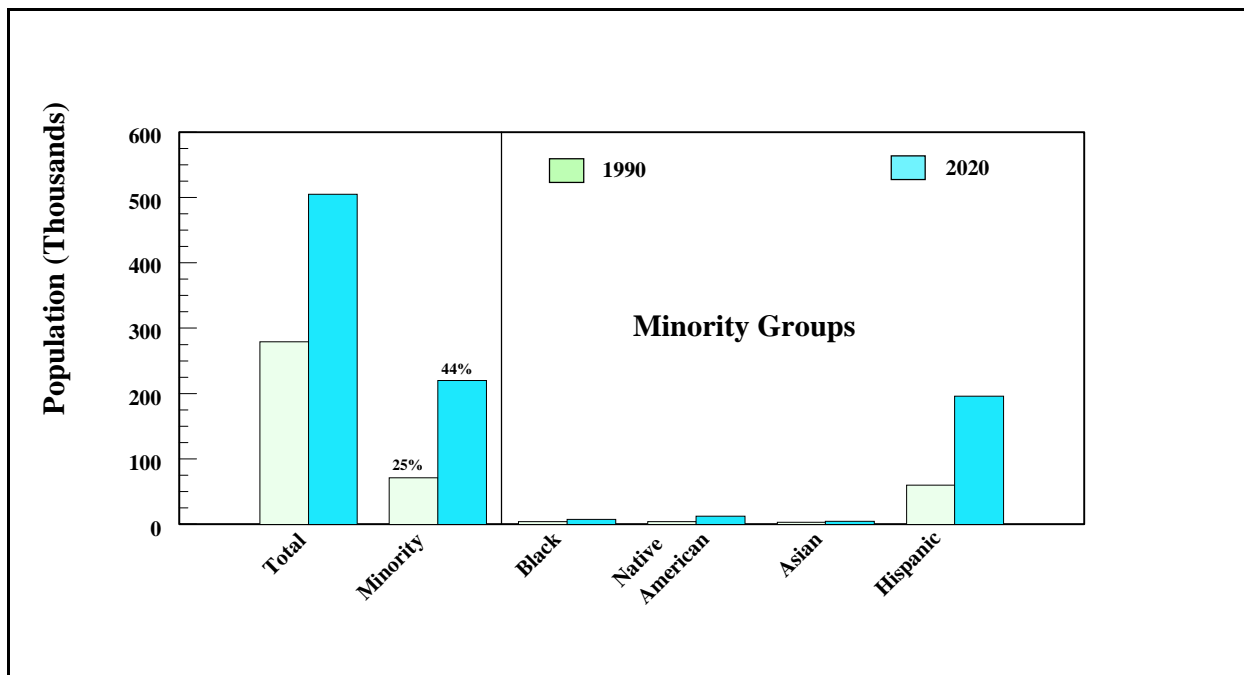

Approximately one-third of the residents of Scarboro reported incomes less than the poverty threshold in 1990. Under the assumption that one-third of the residents of Scarboro in 2020 would report incomes less than the poverty threshold, the dose received by low-income residents due to a beyond-design-basis earthquake at REDC would be approximately 8,450 person-rem. The annual risk to low-income residents of Scarboro would then be approximately  $8.5 \times 10^{-5}$  latent cancer fatality. Over the 35-year program duration, the expected latent cancer fatalities among the projected low-income population would be approximately 0.003. No latent cancer fatalities among the low-income population of Scarboro would be expected to result from a beyond-design-basis earthquake at REDC.

If the prevailing winds were blowing from the west-southwest during an accident at REDC, then radiological contamination resulting from the accident would be directed toward minority and low-income communities residing in the Knoxville area. The closest of these communities is approximately 30 kilometers (18.8 miles) from HFIR and REDC (see Figures K–6 and K–8), and therefore accidents at the reactor or fabrication and processing facilities would not be expected to pose a significant risk to the minority or low-income populations in the Knoxville area.

Implementation of the alternatives would thus pose no significant radiological risks to minority or low-income populations residing within the potentially affected area surrounding ORR.

### K.5.3 Results for Hanford

As discussed in Chapter 2, candidate facilities at Hanford include the FFTF reactor, the FMEF processing and storage facility, and storage facilities in the Radiochemical Processing Laboratory (RPL) and Building 306-E. FFTF is located at latitude 46° 26'8" north and longitude 119° 21'32" west. FMEF is located at latitude 46° 26'7.0" north and longitude 119° 21'55.0" west. RPL is located at latitude 46° 22'7.7" north and longitude 119° 16'43.7" west. **Figure K-9** shows the racial and Hispanic composition of the minority population residing within 80 kilometers (50 miles) of FMEF in 1990 and those projected to reside in the potentially affected area in 2020. In the interval from 1990 to 2020, the percentage of the total population composed of minorities is projected to increase from approximately 25 percent to 44 percent. For comparison, during the 1990 census, minorities were found to comprise nearly one-quarter of the total national population. By the year 2020, minorities are projected to comprise approximately one-third of the total national population. The percentage of the minority population residing in the potentially affected area surrounding Hanford and FMEF was approximately equal to the corresponding national percentage in 1990, but is projected to exceed the corresponding national percentage by the year 2020. As indicated in Figure K-9, Hispanics are the largest minority group residing in the potentially affected area. The population at risk near FMEF is typical of populations at risk surrounding FFTF and RPL/306-E in the 300 Area. Total and minority populations residing in potentially affected areas surrounding FMEF, FFTF, and RPL differ by less than 1 percent.

**Figure K-9 Racial and Hispanic Composition of Populations Residing Within 80 Kilometers (50 Miles) of FFTF and RPL/306-E at Hanford**

During the 1990 census, approximately 17 percent of the residents within the potentially affected area surrounding Hanford reported incomes below the poverty threshold. Slightly over 13 percent of the national population reported incomes below the poverty threshold, and approximately 11 percent of the residents of the State of Washington reported incomes below the poverty threshold during the same year. Thus, the percentage

of low-income population residing within the potentially affected area in 1990 exceeded both the national percentage and that for the State of Washington.

**Figures K–10 and K–11** show the geographical distribution of minority and low-income populations residing near the Hanford site in 1990. As indicated in the figures, block groups for which the percentage of minority residents exceeds the corresponding national percentage (approximately 24 percent in 1990) or for which the percentage low-income population exceeds the corresponding national percentage (approximately 13 percent in 1990) are located throughout the potentially affected area.

As discussed in Chapter 4, normal operations that would result from implementation of the alternatives at Hanford would pose no significant incremental health or other risks to persons residing within the potentially affected area. Environmental justice concerns in the Hanford area include food consumption patterns of minority communities, such the Yakama Indian Reservation, and low-income communities that are located throughout the potentially affected area. In order to assess potential health risks to minority and low-income populations, the health impacts due to ingestion of contaminated food in the potentially affected area were evaluated with the GENII computer model (see Appendix H). Health risks due to normal operations were evaluated under the assumption that all food consumed by residents in the potentially affected area during the 35-year operational period would be obtained locally and would be subject to radiological contamination that could result from normal operations. The maximum population dose to populations at risk near Hanford due to ingestion of radiologically contaminated food would be approximately 2.0 person-rem due to normal operations at FMEF and 4.6 person-rem due to normal operations at RPL. The associated risk would be approximately 0.001 latent cancer fatality due to normal FMEF operations and approximately 0.0023 latent cancer fatality due to normal operations at RPL. Thus, no credible pattern of food consumption by minority or low-income populations would result in a significant health risk attributable to radiological contamination of the food supply that could result from normal operations.

In the event of a radiological accident at one of the Hanford facilities, radiological contamination would be directed toward the Yakama Indian Reservation if the prevailing winds at the time of the accident were blowing from the northeast (see Figure K–11). However, accidents that could occur at Hanford under implementation of the alternatives would not be expected to result in a latent cancer fatality among the exposed population or the maximally exposed individual residing within the boundary of the Yakama Indian Reservation.

Implementation of the alternatives would thus pose no significant radiological risks to minority or low-income populations residing within the potentially affected area surrounding Hanford.

## **K.6 RESULTS FOR REPRESENTATIVE TRANSPORTATION ROUTES**

As discussed in Chapter 4 and Appendix J, selection of the No Action Alternative or Alternative 5 would pose no significant radiological or nonradiological risks to the public. Hence, selection of the No Action Alternative would not be expected to result in disproportionately high and adverse risks for any group within the general population, including minority and low-income groups.

The highest transportation risks to the public would occur if Alternative 1, 3, or 4 were selected for implementation. Due largely to the radiological risks that could result from accidents during the air transportation of isotopes under these alternatives, the number of latent cancer fatalities over the 35-year program would be approximately 0.5. Because air transportation accidents could occur anywhere along the flight path, the associated radiological risks would not disproportionately fall on any particular population regardless of the racial, ethnic, and economic composition of that population.

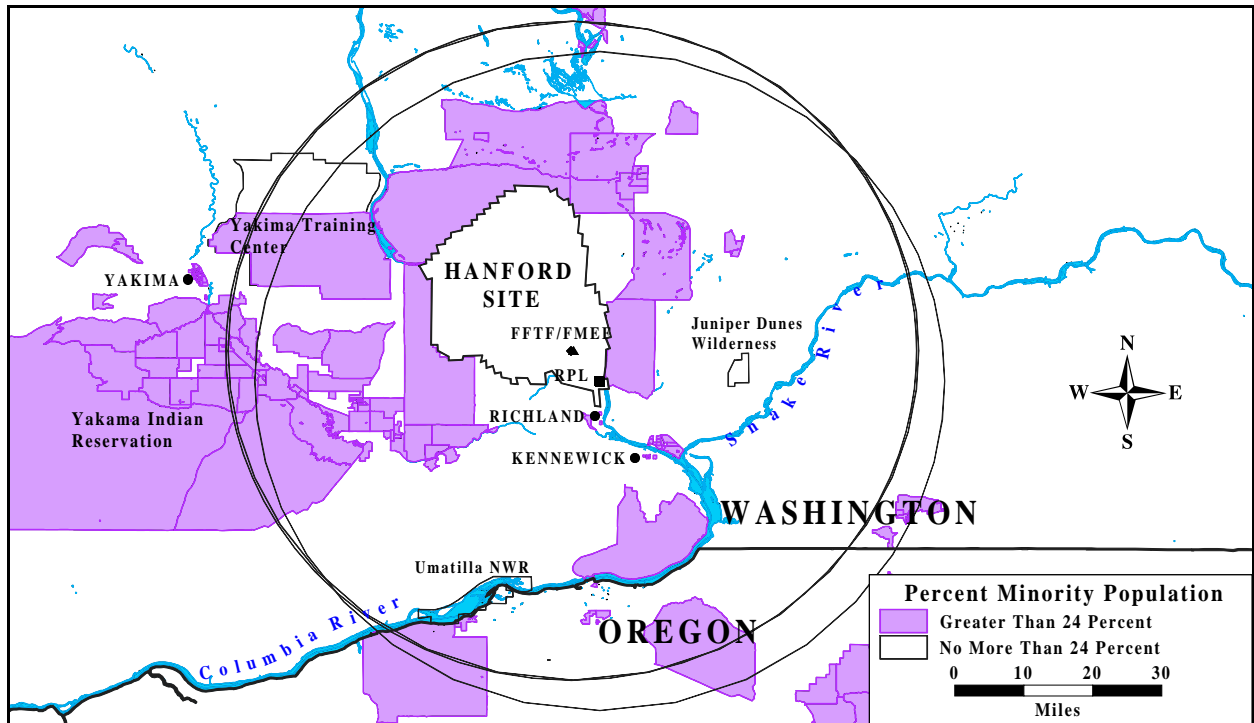

Figure K-10 Geographical Distribution of Minority Populations Residing Within 80 Kilometers (50 Miles) of FFTF and RPL/306-E at Hanford

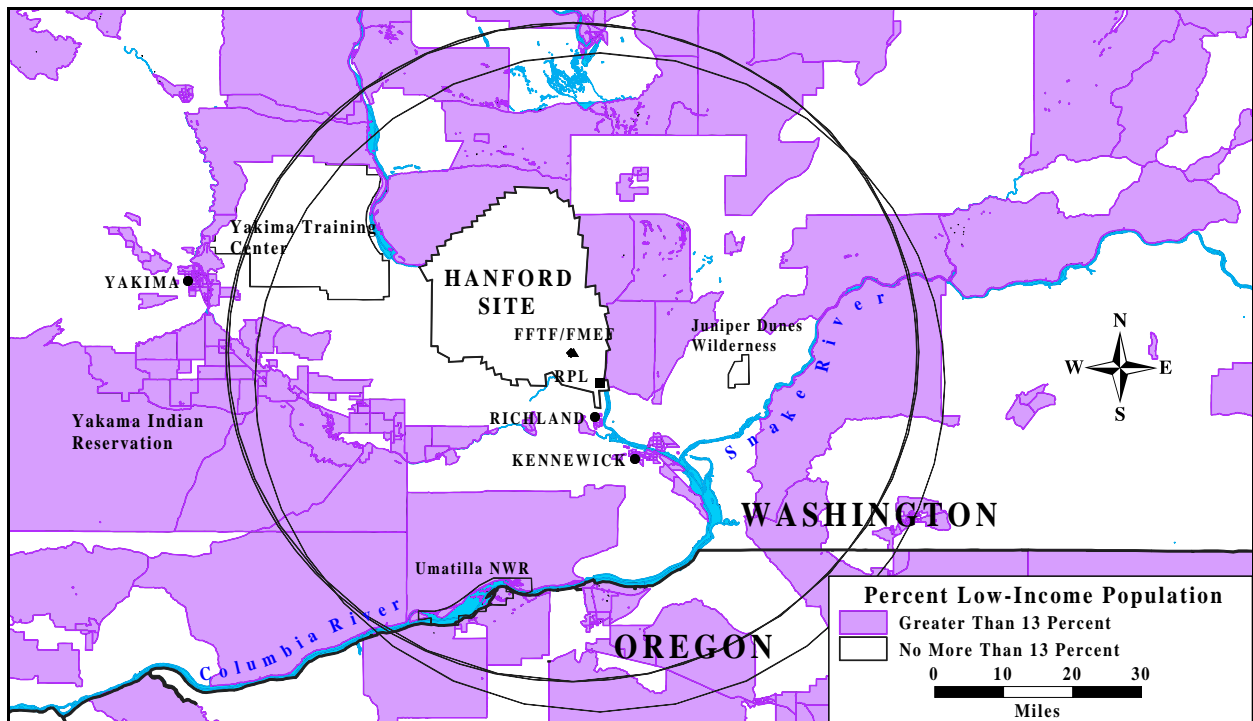

Figure K-11 Geographical Distribution of Low-Income Populations Residing Within 80 Kilometers (50 Miles) of FFTF, FMEF, and RPL/306-E at Hanford

Under Alternative 2, the highest transportation risks to the public result from vehicular collisions (without radiological consequences). No traffic fatalities would be expected. Traffic accidents could occur anywhere along the highway routes, and no identifiable group within the general population would be subject to disproportionate risks.

#### **K.7 ENVIRONMENTAL JUSTICE FOR ALTERNATIVES 3 AND 4**

As discussed in Chapter 2, under Alternatives 3 and 4, DOE would construct one or more new facilities for isotope production at sites yet to be selected. Environmental effects described in Chapter 4 for these alternatives are intended to be representative of the impacts on total populations that could occur for generic populations. However, the characterization of minority and low-income populations is site-specific. If Alternative 3 or Alternative 4 were selected for implementation at a specific site, an additional environmental justice analysis for that site would be conducted prior to implementation.

#### **K.8 CUMULATIVE IMPACTS**

As discussed in Section 4.8, implementation of the alternatives would be expected to have no significant impact on existing environments at INEEL, ORR, and Hanford. Cumulative radiological risks to the maximally exposed individual in the general population are essentially zero. Radiological impacts on the public that could result from implementation of the No Action Alternative, Alternative 1, Alternative 2, or Alternative 5 at these sites are small. No credible pattern in food consumption would result in significant risks to the public residing within potentially affected areas surrounding INEEL, ORR, and Hanford due to implementation of these alternatives.

Evaluations of environmental justice are site specific, and if Alternative 3 or Alternative 4 were selected for implementation, an analysis of the cumulative impacts on minority and low-income populations would be performed prior to implementation.

## Socioeconomics Analysis

### L.1 INTRODUCTION

This appendix includes the supporting data used for assessing the alternatives in the socioeconomics sections of this *Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility*. The socioeconomic analysis involved two major steps: (1) the characterization and projection of existing social, economic, and infrastructure conditions surrounding each of the candidate sites (i.e., the affected environment); and (2) the evaluation of potential changes in the socioeconomic conditions that could result from alternatives in the regions addressed (i.e., the environmental consequences). Data and analyses used to support the assessment made for the socioeconomic sections are presented in **Tables L-1 through L-27**.

The socioeconomic environment is defined for two geographic regions: the regional economic area and the region of influence. Regional economic areas are used to assess potential effects on the regional economy, and regions of influence are used to assess effects that are more localized in political jurisdictions surrounding the sites.

The regional economic areas for each site encompasses a broad market that involves trade among and between regional industrial and service sectors and is characterized by strong economic linkages between the communities in the region. These linkages determine the nature and magnitude of multiplier effects of economic activity (purchases, earnings, and employment) at each site. Regional economic areas are defined by the U.S. Bureau of Economic Analysis and consist of an economic node that serves as the center of economic activity and the surrounding counties that are economically related and include the places of work and residences of the labor force.

Potential demographic impacts were assessed for each region of influence, a smaller geographic area where the housing market and local community services would be most affected. Site-specific regions of influence were identified as those counties where approximately 90 percent of the current U.S. Department of Energy and contractor employees reside. This residential distribution reflects existing commuting patterns and attractiveness of area communities for people employed at each site and is used to estimate the future distribution of in-migrating workers.

## Appendix M Ecological Resources

The scientific names of animal and plant species that exist in the areas of or on the candidate sites are listed in **Table M-1**. Species are grouped by common name and listed in alphabetical order.

**Table M-1 Scientific Names of Animal and Plant Species**

Common Name	Scientific Name
<b>Mammals</b>	
Black-tailed jackrabbit	<i>Lepus californicus</i>
Bobcat	<i>Lynx rufus</i>
Coyote	<i>Canis latrans</i>
Elk	<i>Cervus elaphus</i>
Gray bat	<i>Myotis grisescens</i>
Gray fox	<i>Urocyon cinereoargenteus</i>
Gray wolf	<i>Canis lupus</i>
Great Basin pocket mouse	<i>Perognathus parvus</i>
Indiana bat	<i>Myotis sodalis</i>
Mink	<i>Mustela vison</i>
Mountain lion	<i>Felis concolor</i>
Mule deer	<i>Odocoileus hemionus</i>
Pronghorn	<i>Antilocapra americana</i>
Pygmy rabbit	<i>Brachylagus idahoensis</i>
Raccoon	<i>Procyon lotor</i>
Townsend's ground squirrel	<i>Spermophilus townsendii</i>
Townsend's western big-eared bat	<i>Corynorhinus townsendii</i>
White-footed mouse	<i>Peromyscus leucopus</i>
Whitetail deer	<i>Odocoileus virginianus</i>
<b>Birds</b>	
Aleutian Canada goose	<i>Branta canadensis leucopareia</i>
American kestrel	<i>Falco sparverius</i>
Bald eagle	<i>Haliaeetus leucocephalus</i>
Black tern	<i>Chlidonias niger</i>
Burrowing owl	<i>Athene cunicularia</i>
California gull	<i>Larus californicus</i>
Canada goose	<i>Branta canadensis</i>
Carolina chickadee	<i>Parus carolinensis</i>
Common loon	<i>Gavia immer</i>
Ferruginous hawk	<i>Buteo regalis</i>
Forster's tern	<i>Sterna forsteri</i>
Golden eagle	<i>Aquila chrysaetos</i>
Great blue heron	<i>Ardea herodias</i>
Great horned owl	<i>Bubo virginianus</i>
Horned lark	<i>Eremophila alpestris</i>
Loggerhead shrike	<i>Lanius ludovicianus</i>
Magpie	<i>Pica spp.</i>
Northern cardinal	<i>Cardinalis cardinalis</i>
Northern goshawk	<i>Accipiter gentilis</i>

Common Name	Scientific Name
<b>Birds (Continued)</b>	
Northern harrier	<i>Circus cyaneus</i>
Osprey	<i>Pandion haliaetus</i>
Peregrine falcon	<i>Falco peregrinus</i>
Prairie falcon	<i>Falco mexicanus</i>
Raven	<i>Corvus spp.</i>
Red-tailed hawk	<i>Buteo jamaicensis</i>
Ring-billed gull	<i>Larus delawarensis</i>
Sage grouse	<i>Centrocercus urophasianus</i>
Sage sparrow	<i>Amphispiza belli</i>
Swainson's hawk	<i>Buteo swainsoni</i>
Trumpeter swan	<i>Cygnus buccinator</i>
Western meadowlark	<i>Sturnella neglecta</i>
Wild turkey	<i>Meleagris gallopavo</i>
<b>Reptiles</b>	
Eastern garter snake	<i>Thamnophis sirtalis</i>
Gopher snake	<i>Pituophis melanoleucus</i>
Northern Pacific rattlesnake	<i>Crotalus viridis oregonus</i>
Short-horned lizard	<i>Phrynosoma douglassi</i>
Side-blotched lizard	<i>Uta stansburiana</i>
<b>Amphibians</b>	
American toad	<i>Bufo americanus</i>
<b>Fish</b>	
Blacknose dace	<i>Rhinichthys atratulus</i>
Bluegill	<i>Lepomis macrochirus</i>
Brook trout	<i>Salvelinus fontinalis</i>
Channel catfish	<i>Ictalurus punctatus</i>
Chinook salmon	<i>Oncorhynchus tshawytscha</i>
Coho salmon	<i>Oncorhynchus kisutch</i>
Common carp	<i>Cyprinus carpio</i>
Crappie	<i>Pomoxis spp.</i>
Freshwater drum	<i>Aplodinotus grunniens</i>
Kokanee salmon	<i>Oncorhynchus nerka</i>
Largemouth bass	<i>Micropterus salmoides</i>
Mountain whitefish	<i>Prosopium williamsoni</i>
Rainbow trout	<i>Salmo gaidneri</i>
Sauger	<i>Stizostedion canadense</i>
Shorthead sculpin	<i>Cottus confusus</i>
Smallmouth bass	<i>Micropterus dolomieu</i>
Sockeye salmon	<i>Oncorhynchus nerka</i>
Speckled dace	<i>Rhinichthys osculus</i>
Steelhead trout	<i>Oncorhynchus mykiss</i>
Stoneroller	<i>Campostoma spp.</i>
Sunfish	<i>Lepomis spp.</i>
Walleye	<i>Stizostedion vitreum</i>
White sturgeon	<i>Acipenser transmontanus</i>

Common Name	Scientific Name
<b>Fish (Continued)</b>	
Yellow perch	<i>Perca flavescens</i>
<b>Plants</b>

## The Public Scoping Process

### N.1 SCOPING PROCESS DESCRIPTION

An early step in the development of a programmatic environmental impact statement (PEIS) following the guidance and requirements contained in the Council on Environmental Quality and the Department of Energy (DOE) regulations is to initiate “an early and open process for determining the scope of the issues to be addressed and for identifying the significant issues related to the proposed action.” Major purposes of this scoping process include (1) informing the public about the proposed action; (2) obtaining input from the public and other concerned entities on significant issues that should be evaluated in this *Final Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS])*; (3) identifying and eliminating from detailed study issues that are not significant or have been addressed by other environmental reviews; (4) determining appropriate roles for lead and cooperating agencies, as needed; (5) identifying other environmental review and consultation requirements; and (6) indicating how the preparation of this NI PEIS relates to the agency’s planning and decision-making processes (40 CFR Section 1501.7). As shown in **Figure N–1**, the scoping process is one of the opportunities for public involvement required as part of the National Environmental Policy Act (NEPA) process.

On October 5, 1998, DOE published a Notice of Intent in the Federal Register (63 FR 53398) to prepare an environmental impact statement (EIS) on the proposed production of plutonium-238 for use in advanced radioisotope power systems for future space missions. With that announcement, DOE began preparing the *Environmental Impact Statement for the Proposed Production of Plutonium-238 for Use in Advanced Radioisotope Power Systems for Future Space Missions (Plutonium-238 Production EIS)*. The scope of the *Plutonium-238 Production EIS* was established through a public scoping process conducted from November 4, 1998, through January 4, 1999, as shown in **Table N–1**. As part of the scoping process for that EIS, DOE announced that the Fast Flux Test Facility (FFTF) would not be considered a reasonable alternative for the plutonium-238 production mission unless restart of the facility was proposed for other reasons.

**Figure N–1 NEPA Process**

The Secretary of Energy subsequently announced on August 18, 1999, that DOE would prepare this NI PEIS. Because plutonium-238 production would be among the missions considered in this NI PEIS, the scope of the *Plutonium-238 Production EIS* in its entirety was incorporated within the scope of this NI PEIS, and preparation of the *Plutonium-238 Production EIS* as a separate NEPA review was terminated. As such, DOE reviewed and considered all comments originally received from the public during the *Plutonium-238 Production EIS* scoping period in the preparation of this NI PEIS.

**Table N-1 Schedule of Public Scoping Meetings**

Location	Date	Approximate Number of Attendees
<b>Plutonium-238 Production EIS Scoping Meetings—1998</b>		
Idaho Falls, Idaho	November 12	20
Oak Ridge, Tennessee	November 17	30
Richland, Washington	November 19	200
<b>Total</b>		250
<b>NI PEIS Scoping Meetings—1999</b>		
Oak Ridge, Tennessee	October 13	30
Idaho Falls, Idaho	October 15	20
Seattle, Washington	October 18	200
Portland, Oregon	October 19	300
Hood River, Oregon	October 20	300
Richland, Washington	October 21	200
Washington, D.C.	October 27	60
<b>Total</b>		1,110

On September 15, 1999, DOE published a Notice of Intent in the Federal Register (64 FR 50064) to prepare this NI PEIS. DOE held scoping meetings in October 1999, as shown in Table N-1. This Notice of Intent initiated the 45-day scoping period. Based on comments from participants who attended the *Plutonium-238 Production EIS* scoping meetings, additional scoping meetings were held in the Pacific Northwest related to this NI PEIS. The Pacific Northwest meeting locations included Seattle and Richland, Washington, and Portland and Hood River, Oregon. Meetings were held in Oak Ridge, Tennessee, and Idaho Falls, Idaho, and a meeting was also added in Washington, D.C., to accommodate national interest groups and others.

As a result of previous experience and positive responses from attendees of other DOE/NEPA public meetings and hearings, DOE chose an interactive format for the scoping meetings. Each meeting began with a presentation by the DOE EIS Document Manager, who explained the proposed action and planned scope of the subject PEIS, and answered questions on the presentation. Afterwards, an impartial facilitator opened the floor for comments and concerns from the audience. DOE, national laboratory staff, and contractor personnel were available to respond to the questions and comments, as needed. A verbatim transcript of public comments and DOE responses was prepared by court reporters who attended each of the meetings. The transcripts were made available to the public at DOE reading rooms and on the Internet at [www.nuclear.gov](http://www.nuclear.gov). Reading room locations are shown in **Table N-2**. Written statements or comments from the public were collected at the meetings. In addition, the public was encouraged to submit comments to DOE by U.S. mail, electronic mail, a toll-free fax line, and a toll-free telephone line until the end of the scoping comment period. Comments received after that date were considered to the extent practicable.

The comments received during the *Plutonium-238 Production EIS* and NI PEIS scoping periods are described in the following sections.

**N.1.1 Plutonium-238 Production EIS Scoping Comments**

DOE received approximately 750 comments from about 245 citizens, interested groups, and Federal, state, and local officials during the public scoping period for the *Plutonium-238 Production EIS*. About 220 of these comments were presented orally during the public meetings. Approximately half of all the commentors (117) were supportive of the proposed plutonium-238 production mission, 105 were opposed to plutonium-238 production, and 23 commentors were neither for nor against the proposal.

In general, the people who attended the meetings in Idaho and Tennessee were supportive of DOE's proposed plans to produce plutonium-238 domestically for future space missions. In Richland, Washington, the meeting was attended by representatives of several stakeholder and environmental groups who voiced opposition to DOE's consideration of using FFTF for plutonium-238 production.

Other main concerns of the Richland, Washington, meeting participants were that DOE should not consider restarting FFTF, that DOE has worked hard over the years to change Hanford's mission from "production" to "cleanup," and that DOE should continue to honor its commitment to cleanup. There were concerns about the generation of additional waste streams at the site and the operational safety of FFTF. There was strong opposition to the restart of FFTF for any mission.

Of all the comments submitted during the scoping period, approximately 320 concerned the Hanford Site. Of these Hanford-specific comments, there were roughly equal numbers of comments supporting and opposing the use of FFTF and the Fuels and Materials Examination Facility for plutonium-238 production. The major concern of those in opposition was that DOE should not consider restarting FFTF and should continue to honor DOE's commitment to the cleanup at Hanford, rather than introducing a new production mission. The safety of FFTF, potential for further contamination, and generation of additional waste streams were concerns expressed by commentors.

About 65 of the comments concerned the use of plutonium-238 in space, or the National Aeronautics and Space Administration (NASA) Space Program in general. The majority of the space-related comments were in opposition to the use of plutonium-238 in space because of concerns about the safety of radioisotope power systems.

Approximately 45 of the comments addressed issues related to waste management, including concerns about the amount of waste generated by the program, the processing and final disposition of all generated wastes, and the impact of additional wastes on the ongoing environmental cleanup programs at the sites.

The cost of the plutonium-238 production program was another concern expressed by commentors. About 45 comments included requests for information related to the costs of each alternative. Several commentors also proposed additional alternatives for consideration in the EIS.

The following general issues and concerns are highlights of the comments made.

- It was suggested that additional irradiation service alternatives such as commercial light water reactors and accelerators should be considered.
- It was suggested that additional storage, target fabrication, and target processing alternatives should be considered, such as the Hot Fuel Examination Facility at Argonne National Laboratory–West and the H-Canyon and HB-Line at the Savannah River Site.
- Concerns were voiced about additional waste streams being generated, including what the waste streams would be and how they would be disposed. Concerns were also related to the generation and disposal of any transuranic waste since non-defense-related wastes are not eligible for disposal at the Waste Isolation Pilot Plant.
- It was suggested that the cost of implementing the various alternatives should be analyzed, and a cost breakdown for each alternative should be provided. Costs of concern that were mentioned included equipment and facility modifications, annual operating expenses, transportation, appropriate waste

storage and final disposal. Commentors were concerned about who would bear the costs of plutonium-238 production.

The scope of the proposed *Plutonium-238 Production EIS* was incorporated within the scope of this NI PEIS. DOE has considered all comments originally received from the public during the *Plutonium-238 Production EIS* scoping period in preparing this NI PEIS.

### **N.1.2 NI PEIS Scoping Comments**

The written and oral comments received at the scoping meetings and the additional comments received via U.S. mail, electronic mail, and toll-free faxes and telephone calls during the public comment period were reviewed and considered by DOE in preparing this NI PEIS, along with all comments and input originally received from the public during the *Plutonium-238 Production EIS* scoping period.

In addition to the comments received on the *Plutonium-238 Production EIS*, DOE received approximately 7,000 comments from citizens, interest groups, and other stakeholders during the scoping comment period for this NI PEIS. Campaigns including the same or similar submittals made by multiple people accounted for more than 4,300 comments. Other submittals accounted for more than 2,600 comments. Of the comments received, there were more than 700 unique comments. In some cases, a commentor provided similar or identical comments both orally at the scoping meetings and in writing, so their comments were duplicated.

The comments obtained by DOE throughout the scoping process addressed several key issues. At the scoping meetings on this NI PEIS, the most prevalent concerns are shown below.

- The status of, and commitment to, cleanup at Hanford and the impact of FFTF restart on the existing waste problem.
- There was concern about the lack of justification for the identified missions.
- Commentors requested information about the cost of implementing the various alternatives.
- Commentors repeatedly emphasized the need for an additional alternative calling for the permanent deactivation of FFTF coupled with the No Action Alternative elements, that is, no plutonium-238 production and no additional research and development or medical isotope production beyond existing operating facility capabilities.

As shown in Table N-1, the number of people who commented at the scoping meetings conducted in Oak Ridge, Tennessee; Idaho Falls, Idaho; and Washington, D.C., was smaller in comparison to the meetings held in the Pacific Northwest. At the scoping meeting in Oak Ridge, Tennessee, a commentor was concerned with the relationship of this NI PEIS to other DOE programs and the relative merits of accelerator and reactor performance. The commentor stated the PEIS should include an explanation of mixed oxide fuel disposition. In addition, the commentor supported medical isotope production in Oak Ridge because it is near a transportation hub and some medical isotopes are short-lived; therefore, transportation is key.

At the scoping meetings in Idaho Falls, Idaho, most commentors supported the new missions at the Idaho National Engineering and Environmental Laboratory. The commentors also stated that the socioeconomic impacts of the alternatives need to be considered in the NI PEIS. A commentor stated that decisions in regard to medical isotope production should be based on the needs of the Nation as a whole and not on perceived commercial needs. The commentor also stated that incremental DOE and commercial investments in the

Advanced Test Facility would be sufficient to enhance reactor radioisotope production needs and meet the requirements of the nuclear medicine industry.

At the meetings held in the States of Washington and Oregon, the comments frequently were about FFTF, either supporting or opposing the use of FFTF to accomplish the proposed missions. Many of the commentors who attended the meetings in Seattle, Washington; Portland, Oregon; and Hood River, Oregon, were strongly opposed to the restart of FFTF. As a result of these public comments, DOE added a fifth alternative: the shutdown of FFTF without new production missions. Many commentors stated that the Hanford cleanup mission would be jeopardized, especially when DOE has not met Hanford cleanup milestones.

Most of the comments received at the Richland, Washington, meeting were in support of restarting FFTF. Supporters said restart would not hamper Hanford's cleanup mission, and stated that operation of FFTF could help save the lives of many people by producing isotopes to be used in new ways to treat cancer, heart disease, and other illnesses. Commentors were also concerned about the potential generation of radioactive and hazardous waste as a result of the proposed missions. Commentors stated that DOE should analyze projected waste streams, including health and safety risks and the cumulative impacts to the environment, as well as analyzing impacts from additional spent nuclear fuel storage.

In general, many commentors stated that the PEIS should include a detailed cost analysis of each alternative, including total life-cycle costs. Some commentors stated that DOE has a substantial investment of public resources and money and every effort needs to be made to use FFTF. Others opposed the use of FFTF as a waste of money and stated that keeping FFTF on standby is expensive.

At the scoping meeting in Washington, D.C., the commentors supported the need for medical isotope production. Several commentors were against the restart of FFTF and others stated that DOE needs to consider partnerships with private industry to generate necessary funds for restart. Some commentors thought that a cost study should be prepared and should include avoided future health care costs and cost savings to the national Medicare and Medicaid programs that could be realized by using nuclear isotopes in medical applications. Proliferation concerns were also raised as some commentors stated that: (1) the United States would be sending the wrong message by restarting FFTF; (2) a change in the U.S. nonproliferation policy would be required to import German mixed oxide fuel; and (3) the use of highly enriched uranium would be contrary to existing U.S. nonproliferation policy. Other concerns included waste generation, Hanford cleanup, and safety at FFTF.

## **N.2 HOW COMMENTS WERE HANDLED**

As comments were received during both the *Plutonium-238 Production EIS* and NI PEIS scoping periods, they were logged in, assigned a unique document identification number and placed into the Administrative Record. Comments were identified and assigned to the general categories that are shown in **Table N-3**. By grouping the comments in these categories, DOE representatives were aided in deciding which comments were within or outside the scope of this NI PEIS and which comments needed to be added to the scope of this NI PEIS.

Once the comments were grouped into the categories of comments, they were all reviewed and taken into consideration in the preparation of this Draft NI PEIS. DOE received many comments that were found to be within the scope of this NI PEIS and these comments are addressed in the document. Comments that were added to the scope of this NI PEIS and those that were determined to be outside of the scope of this NI PEIS are summarized in the following sections. All comments were placed in this NI PEIS project Administrative Record.

**Table N-3 Categories of Comments**

Purpose and need, including medical isotopes, plutonium-238 production, research and development, general irradiation needs, and commercial isotopes
Site-specific recommendations and alternative selection, which included the No Action Alternative, Alternatives 1 through 4 that were included in the Notice of Intent, Alternative 5 that was added as a result of the scoping process, and other general alternative issues
EIS process, including the adequacy of the process, public involvement, the availability of information, the need for additional scoping meetings, and the extension of the comment period
Impacts to the environment in the areas of geology and soils, socioeconomics, environmental justice, cumulative impacts, and general environmental contamination from the proposed action
Public and occupational safety and health
Waste and spent nuclear fuel generation, storage, and disposition
Transportation
Decontamination and decommissioning of facilities
Applicable laws, regulations, and other requirements, including general issues, licensing of facilities, and external regulations of facilities
Costs, including FTF investment and the cost of each alternative
Other miscellaneous issues, including the cleanup of Hanford, the suggestion that no new missions would be appropriate for Hanford, and antinuclear and non-proliferation-related comments

### N.3 COMMENTS THAT WERE ADDED TO THE SCOPE OF THIS NI PEIS

Some comments were received during both the *Plutonium-238 Production EIS* and NI PEIS scoping periods that DOE representatives added to the scope of this NI PEIS. These comments are highlighted in the following sections.

#### N.3.1 Plutonium-238 Comments Added

- Commentors were opposed to any new missions or operations at Hanford that would generate additional nuclear waste. Information has been added to this NI PEIS addressing potential waste generation and other environmental impacts associated with the proposed missions.
- Commentors proposed the use of non-DOE facilities for irradiation services. The addition of non-DOE facilities, such as a commercial light water reactor, is an existing radiation source that DOE will consider to meet the requirements of the plutonium-238 production mission. The ability of the commercial light water reactor to meet the requirements of the other proposed isotope production missions is addressed in this NI PEIS.
- Commentors requested additional meetings in Washington and Oregon at the *Plutonium-238 Production EIS* scoping meetings in November 1998. The public meetings for this NI PEIS were expanded to include Seattle, Washington; Portland, Oregon; and Hood River Oregon, in addition to the Richland, Washington, meeting.

### **N.3.2 NI PEIS Comments Added**

- Commentors strongly suggested that DOE shut down FFTF. In response to public comment, DOE has added to the NI PEIS a new alternative (Alternative 5) to permanently deactivate FFTF, with no new missions at Hanford.
- Commentors were concerned about the restart of FFTF and budget constraints. DOE has made a commitment that implementation of the Record of Decision will not divert or reprogram budgeted funds designated for Hanford cleanup, regardless of the alternative(s) selected.
- Commentors stated that DOE should adhere to the Tri-Party Agreement. DOE has completed more than 900 Tri-Party Agreement milestones and targets with more than a 98 percent on-time completion rate. The Tri-Party Agreement is a living document and is routinely modified in accordance with procedures defined by the agreement. DOE alone cannot modify the agreement. Implementation of any of the proposed missions at Hanford would not be in conflict with the land use plan or the Tri-Party Agreement.
- Commentors suggested that this NI PEIS should include information on the stewardship of FFTF. There would be no transfer of FFTF stewardship when it is in the standby, startup, or operating mode. This NI PEIS addresses the transition of FFTF stewardship after it is deactivated.
- Commentors suggested that European regulatory and government issues associated with the export of SNR-300 fuel be addressed in this NI PEIS. It is anticipated that a “Nuclear Infrastructure Nonproliferation Impacts Assessment” report would address the export issue.

### **N.4 OUT OF SCOPE COMMENTS**

Some comments were received by DOE that were determined to be outside the scope of the environmental impact analyses of this NI PEIS. The major comments that fall into this group are summarized below for comments received related to both the *Plutonium-238 Production EIS* and this NI PEIS.

#### **N.4.1 Plutonium-238 Out of Scope**

- Commentors voiced both support and opposition to the NASA space program and the use of radioisotopes for space exploration in particular. This NI PEIS does not address the merits of the space program or the desirability of radioisotope use in space missions. Those questions fall under the purview of NASA. This NI PEIS is concerned only with the question of how to provide for the identified plutonium-238 requirements for space missions.
- Commentors requested additional information and analysis of the costs associated with the different alternatives. This NI PEIS is required by regulation to examine the environmental impacts of the identified alternatives. Cost information to support the Record of Decision is developed separate from this NI PEIS.
- Commentors voiced concern over the continued production of plutonium by the United States. This NI PEIS is limited to the examination of environmental impacts resulting from the production of plutonium-238 only. Plutonium-238 is not weapons-grade material. In fact, plutonium-238 is a contaminant in weapons-grade plutonium (plutonium-239) that degrades weapon performance.

#### N.4.2 NI PEIS Out of Scope

- Commentors requested additional analysis on medical isotope demand and the benefits associated with medical isotope use. This NI PEIS evaluates the environmental impacts of medical isotopes production given a projected production level. However, the demand and associated benefits are described in the report, *Expert Panel: Forecast Future Demand for Medical Isotopes* (Wagner et al. 1998).
- Commentors requested additional analysis of alternative power sources for space vehicles and the production requirements for plutonium-238. This NI PEIS evaluates the environmental impacts of producing plutonium-238 in the quantity required by the space program. NASA is responsible for evaluating alternative energy sources for space vehicles and determining the desirability of plutonium-238 usage for power.
- Commentors expressed both support and opposition to restarting FFTF and requested additional risk/benefit analysis and safeguards associated with the FFTF restart alternative. This NI PEIS evaluates the risks and environmental impacts associated with FFTF restart (and all other alternatives). The evaluation of benefits occurring from the implementation of any alternative is covered in separate documents and will be taken into consideration in developing the Record of Decision. The subject of additional safeguards for FFTF restart, that is, commitment to Nuclear Regulatory Commission oversight, is an operational issue to be considered only if FFTF restart is selected in the Record of Decision.
- Commentors requested additional analysis on the environmental effects of combining radioactive waste from alternative implementation and existing hazardous wastes, such as, pesticides. Some commentors voiced opposition to any additional radioactive waste production. This NI PEIS evaluates the environmental and health impacts of the wastes produced by the alternatives. Wastes produced from other activities, for example, pesticide application, are not required to be evaluated in this document. Additionally, this NI PEIS evaluates the impacts of wastes generated by the alternatives and identifies those alternatives that result in no additional waste produced.
- Commentors requested additional cost analysis for alternatives. This NI PEIS evaluates the environmental impacts associated with the implementation of the alternatives. Cost analysis is not required to be included in an EIS, although it would contribute to a decision made in the Record of Decision.

CEQ Regulations at 40 CFR 1506.5(c), which have been adopted by the DOE (10 CFR 1021), require contractors who will prepare an EIS to execute a disclosure specifying that they have no financial or other interest in the outcome of the project. The term "financial interest or other interest in the outcome of the project" for the purposes of this disclosure is defined in the March 23, 1981 guidance, "Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations," 46 FR 18026-18038 at Question 17a and b.

"Financial or other interest in the outcome of the project 'includes' any financial benefit such as a promise of future construction or design work in the project, as well as indirect benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm's other clients)." 46 FR 18026-18038 at 18031.

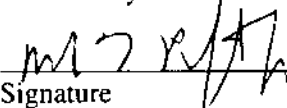

In accordance with these requirements, the offeror and any proposed subcontractors hereby certify as follows: (check either (a) or (b) to assure consideration of your proposal).

- (a)  Offeror/subcontractor have no financial interest in the outcome of the project.
- (b)  Offeror and any proposed subcontractor have the following financial or other interest in the outcome of the project and hereby agree to divest themselves of such interest prior to award of this contract.

**TECHSOURCE, Incorporated**

CEQ Regulations at 40 CFR 1506.5(c), which have been adopted by the DOE (10 CFR 1021), require contractors who will prepare an EIS to execute a disclosure specifying that they have no financial or other interest in the outcome of the project. The term "financial interest or other interest in the outcome of the project" for the purposes of this disclosure is defined in the March 23, 1981 guidance, "Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations," 46 FR 18026-18038 at Question 17a and b.

"Financial or other interest in the outcome of the project 'includes' any financial benefit such as a promise of future construction or design work in the project, as well as indirect benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm's other clients)." 46 FR 18026-18038 at 18031.

In accordance with these requirements, the offeror and any proposed subcontractors hereby certify as follows: (check either (a) or (b) to assure consideration of your proposal).

- (a)  Offeror/subcontractor have no financial interest in the outcome of the project.
- (b)  Offeror and any proposed subcontractor have the following financial or other interest in the outcome of the project and hereby agree to divest themselves of such interest prior to award of this contract.

Financial or Other Interests:

- 1.
- 2.
- 3.

---

## SUMMARY

### S.1 INTRODUCTION AND BACKGROUND

The following is a summary of a report evaluating the costs associated with the U.S. Department of Energy (DOE) proposal to enhance its existing nuclear facility infrastructure to accommodate new and expanding missions in the areas of nuclear research and development and isotope production. DOE currently does not have sufficient steady-state irradiation sources to meet the Nation's projected needs for: (1) isotopes for medical and industrial uses, (2) fuel to power future U.S. National Aeronautics and Space Administration (NASA) spacecraft, and (3) nuclear research and development.

The alternatives for the proposed expanded isotope production missions that were evaluated in this Cost Report are presented in the *Draft Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility* (Nuclear Infrastructure Programmatic Environmental Impact Statement [NI PEIS]) (DOE 2000).

Costs of potential decisions are not typically evaluated in an environmental impact statement (EIS), but DOE recognizes that the financial implications of its future programs are important considerations for decision making and has resolved to inform the public about those costs. The findings of this Cost Report and public input received on the NI PEIS are among the factors that DOE will consider when preparing the Record of Decision.

The programmatic alternatives considered in this Cost Report focus on the use of irradiation facilities that are currently operating, could be brought online, or could be constructed and operated to meet DOE's irradiation needs. Thus, the report considers the following alternatives (presented in more detail in Chapter 2 of the NI PEIS):

- **No Action Alternative**, maintaining the status quo; that is, DOE's existing facilities would continue to meet their current mission requirements within their operating levels, and DOE would not enhance existing U.S. nuclear facility infrastructure or expand its current missions to accommodate new missions.
- **Alternative 1**, which includes resuming operation of the Fast Flux Test Facility (FFTF) at the Hanford Site (Hanford) in Richland, Washington
- **Alternative 2**, using only existing operational facilities (the Advanced Test Reactor [ATR] at Idaho National Engineering and Environmental Laboratory [INEEL], the High Flux Isotope Reactor [HFIR] at Oak Ridge National Laboratory [ORNL], or a generic commercial light water reactor [CLWR]) to accommodate the plutonium-238 production mission
- **Alternative 3**, constructing and operating one or two new accelerator(s) at an existing DOE site
- **Alternative 4**, constructing and operating a new research reactor at an existing DOE site
- **Alternative 5**, permanently deactivate Hanford's FFTF without enhancing U.S. nuclear facility infrastructure to accommodate new or expanded missions. Although Alternatives 2, 3, and 4 include the deactivation of FFTF, Alternative 5 is included as a stand-alone alternative in response to numerous public comments received during the scoping period for the NI PEIS.

The No Action Alternative and Alternatives 1 through 4 each have several options, evaluated in this Cost Report. These options involve primarily DOE facilities that could be used for fabrication, storage, and postirradiation processing of the targets necessary for the program missions. Among the facilities proposed are: (1) the Radiochemical Engineering Development Center (REDC) at ORNL, (2) the Fluorinel Dissolution Process Facility (FDPF) and/or the Chemical Processing Plant (CPP) Building 651 (CPP-651) (storage only) at INEEL, (3) the Fuels and Materials Examination Facility (FMEF) at Hanford, (4) Building 325, the Radiochemical Processing Laboratory (RPL), and Building 306-E at Hanford, and (5) a new facility to be constructed and operated at an existing DOE site to support the one or two new accelerator or new research reactor alternatives. **Table S-1** presents an overview of the alternatives and options evaluated in the NI PEIS.

## S.2 DECISIONS TO BE MADE

In reaching programmatic decisions regarding potential expansion of its existing nuclear facility infrastructure, DOE will factor the analytical environmental results of the NI PEIS together with the findings presented in this Cost Report and the NI Nonproliferation Impacts Assessment<sup>1</sup>, the *Nuclear Science and Technology Infrastructure Roadmap*, recommendations of the Nuclear Energy Research Advisory Committee (NERAC) and its various subcommittees, public input, and other DOE policy and programmatic considerations.

With the benefit of this broad base of information, DOE intends to make the following decisions:

- Whether to expand its current nuclear facility infrastructure to meet projected requirements for future medical and industrial isotope production, plutonium-238 production, and nuclear research and development.
- If a decision is made to expand DOE's existing nuclear facility infrastructure, whether to (1) construct new facilities (one or two accelerators or a research reactor), or (2) restart FFTF at Hanford as part of a nuclear infrastructure expansion program and, if not, whether to remove FFTF from standby mode and permanently deactivate it in preparation for its eventual decontamination and decommissioning.
- If a decision is made not to expand DOE's existing nuclear facility infrastructure, decide whether to (1) select from existing operating facilities those needed to support the proposed plutonium-238 mission, or (2) continue purchasing plutonium-238 from Russia to support future NASA space missions, and (3) whether DOE inventories of neptunium-237 should be relocated and stored for future plutonium-238 production needs. Existing operating facilities performing medical, research, and/or industrial isotope production and/or nuclear research and development missions would continue to support existing missions at current levels.

The programmatic decisions to be made in association with the NI PEIS are the responsibility of the DOE Office of Nuclear Energy, Science and Technology. In addition to the range of reasonable programmatic alternatives evaluated in the NI PEIS, DOE could choose to combine components of several alternatives in selecting the most appropriate strategy. For example, DOE could select a low-energy accelerator to produce medical, research, and industrial isotopes, and an existing operating reactor to produce plutonium-238 and conduct nuclear research and development. If alternatives were selected involving the siting, construction, and operation of one or two new accelerators or a new research reactor, appropriate site- and project-specific National Environmental Policy Act (NEPA) documentation, tiered from the NI PEIS, would be prepared.

---

<sup>1</sup>The DOE Office of Arms Control and Nonproliferation is analyzing the nonproliferation policy impacts of FFTF's restart, and of the other alternatives and their various options, and will be reporting its findings in the *Nonproliferation Impacts Assessment for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility* (Nuclear Infrastructure Nonproliferation Impacts Assessment).

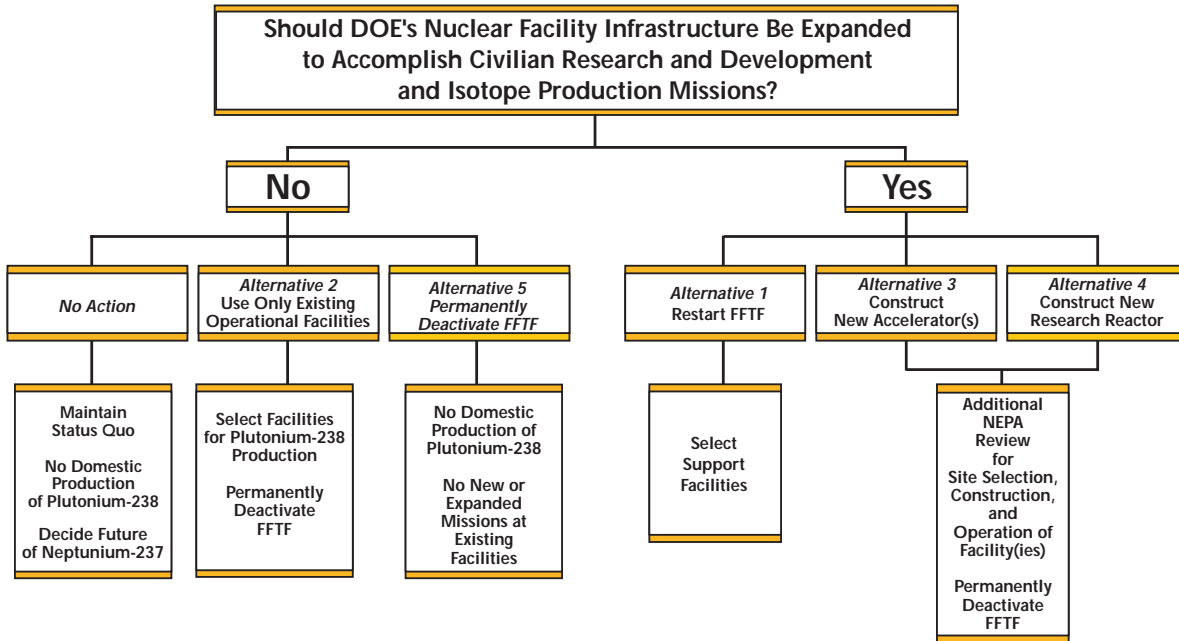

**Table S-1 Alternatives and Options Evaluated in the NI PEIS**

	Option Number	Irradiation Facility	Plutonium-238 Production Mission		Medical and Industrial Isotopes Production and Nuclear Research and Development Mission	
			Storage Facility	Target Fabrication and Processing Facility	Storage Facility	Target Fabrication and Processing Facility
<b>No Action Alternative</b>	1	–	–	–	–	–
	2	–	REDC	–	–	–
	3	–	CPP-651	–	–	–
	4	–	FMEF	–	–	–
<b>Alternative 1: Restart FFTF</b>	1	FFTF <sup>a</sup>	REDC	REDC	RPL/306-E	RPL/306-E
	2	FFTF <sup>a</sup>	FDPF/CPP-651	FDPF	RPL/306-E	RPL/306-E
	3	FFTF <sup>a</sup>	FMEF	FMEF	FMEF	FMEF
	4	FFTF <sup>b</sup>	REDC	REDC	RPL/306-E	RPL/306-E
	5	FFTF <sup>b</sup>	FDPF/CPP-651	FDPF	RPL/306-E	RPL/306-E
	6	FFTF <sup>b</sup>	FMEF	FMEF	FMEF	FMEF
<b>Alternative 2: Use Only Existing Operational Facilities</b>	1	ATR	REDC	REDC	–	–
	2	ATR	FDPF/CPP-651	FDPF	–	–
	3	ATR	FMEF	FMEF	–	–
	4	CLWR	REDC	REDC	–	–
	5	CLWR	FDPF/CPP-651	FDPF	–	–
	6	CLWR	FMEF	FMEF	–	–
	7	HFIR and ATR	REDC	REDC	–	–
	8	HFIR and ATR	FDPF/CPP-651	FDPF	–	–
	9	HFIR and ATR	FMEF	FMEF	–	–
<b>Alternative 3: Construct New Accelerator(s)</b>	1	New	REDC	REDC	New <sup>c</sup>	New <sup>c</sup>
	2	New	FDPF/CPP-651	FDPF	New <sup>c</sup>	New <sup>c</sup>
	3	New	FMEF	FMEF	New <sup>c</sup>	New <sup>c</sup>
<b>Alternative 4: Construct New Research Reactor</b>	1	New	REDC	REDC	New <sup>c</sup>	New <sup>c</sup>
	2	New	FDPF/CPP-651	FDPF	New <sup>c</sup>	New <sup>c</sup>
	3	New	FMEF	FMEF	New <sup>c</sup>	New <sup>c</sup>
<b>Alternative 5: Permanently Deactivate FFTF (with no new missions)</b>	–	–	–	–	–	–

**Key:** RPL/306-E = Radiochemical processing Laboratory and Hanford 300 Area Building 306-E.

- a. Hanford FFTF would start up and operate with onsite and German mixed oxide (MOX) fuel and then highly enriched uranium (HEU) fuel.
- b. Hanford FFTF would start up and operate with only the onsite MOX fuel and then HEU fuel.
- c. The new facility would not be required if a DOE site with available support capability and infrastructure is selected.

The programmatic decisions to be reached in association with the NI PEIS are schematically presented in **Figure S–1**. In accordance with the first-tier “yes or no” decision to be made (as seen in Figure S–1), alternatives analyzed in the NI PEIS were arranged into two groups—nonexpanded infrastructure alternatives, including the No Action Alternative and Alternatives 2 and 5; and expanded infrastructure alternatives, including Alternatives 1, 3, and 4. Cost estimates for the nonexpanded and expanded infrastructure alternatives were also arranged into these groups and are presented in Section S.3, Results and Conclusions.

**Figure S–1 Pending Decisions**

### S.3 RESULTS AND CONCLUSIONS

Summaries of cost estimates for the nonexpanded and expanded infrastructure alternatives identified in Figure S–1 are presented in **Tables S–2** and **S–3**. All figures shown represent millions of FY 2000 dollars. No credit was taken for projected revenues from medical and industrial isotope sales, or from fees paid by domestic or international users of facilities.

#### Nonexpanded Infrastructure Alternatives

A summary of the estimated costs of the nonexpanded infrastructure alternatives (the No Action Alternative and Alternatives 2 and 5 of the NI PEIS) is presented in Table S–2. Capital costs (costs of modifying existing facilities), costs for permanently deactivating FFTF (where appropriate), annual operating costs, and transportation costs are presented for irradiation facilities and neptunium-237 storage and plutonium-238 processing facilities. In addition, costs for the purchase and transport of Russian plutonium-238 are presented. DOE would continue its medical and industrial isotope production and nuclear research and development activities of the current operating levels of existing facilities.

**Table S-2 Summary of Estimated Costs of Nonexpanded Infrastructure Alternatives (Millions of FY 2000 Dollars)**

Cost Elements	Alternatives														
	No Action	Alternative 2: Use Only Existing Operational Facilities											Alternative 5: Deactivate FFTF		
		ATR	CLWR		ATR and HFIR										
<b>Irradiation Facilities</b>															
FFTF in standby mode (annual) (A)	40.8														
FFTF deactivation (B)		281.2	281.2	281.2											281.2

Modification and startup costs (F)		16.9	2.12	19.3	51.2	37.2	72.8	55.1	41.2	72.8	51.2	37.2	72.8		
Operations (annual) (G)		1.5	1.5	2.6	7.8	6.7	15.3	10.8	9.7	18.3	7.8	6.7	15.3		
<b>Medical and Industrial Isotope/Nuclear Research and Development Processing Facilities<sup>b</sup></b>															
Modification or construction and startup costs															
Operations (annual)															
<b>Combined Estimated Costs</b>															
Total Costs (B+C+F)	0	16.9	2.12	19.3	334.4	320.4	356	356.3	342.4	374	335.9	321.9	357.5	281.2	
Annual Costs (A+D+E+G)	49.6	51.1	51.1	52.2	15.9	14.8	23.4	15.9	14.8	23.4	15.9	14.8	23.4	0	
<b>Plutonium-238 Production Transportation</b>															
Neptunium-237 from SRS (total)		1.4	7.1	8.5	1.4	7.1	8.5	1.4	7.1	8.5	1.4	7.1	8.5		
Total annual plutonium-238 production shipping and handling costs						0.39	0.24	0.32	0.41	0.40	0.46	0.34	0.29	0.35	
<b>Medical and Industrial Isotope Transportation (annual)<sup>b</sup></b>															

**Key:** LANL = Los Alamos National Laboratory; SRS = Savannah River Site.

a. Based on FY 2000 contract year eight, \$1.74 million per kilogram × 5 kilograms. Succeeding year purchase price escalated at a contractual 3.5 percent per year for the remaining two years of the contract.

b. DOE would continue its medical and industrial isotope production and nuclear research and development activities at the current operating levels of existing facilities.

**Note:** Shaded areas indicate that no costs would be incurred under that alternative and/or option.

**Table S-3 Summary of Estimated Costs of Expanded Infrastructure Alternatives (Millions of FY 2000 Dollars)**

Cost Elements	Alternatives								
	Alternative 1: Restart FFTF			Alternative 3: Construct New Accelerator(s)			Alternative 4: Construct New Research Reactor		
<b>Irradiation Facilities</b>									
Modification or construction and startup, including target development, testing, and evaluation	314			1,096.0			312		
FFTF deactivation				281.2			281.2		
<b>Total costs (A)</b>	<b>314</b>			<b>1,377.2</b>			<b>593.2</b>		
Operations (annual) <sup>a</sup> (B)	58.9			45.1			25		
Processing Facility Alternative Options	<b>1 and 4 <sup>b</sup></b>	<b>2 and 5 <sup>b</sup></b>	<b>3 and 6 <sup>b</sup></b>	<b>1</b>	<b>2</b>	<b>3</b>	<b>1</b>	<b>2</b>	<b>3</b>
<b>Plutonium-238 Production Facilities</b>	<b>REDC</b>	<b>FDPF</b>	<b>FMEF</b>	<b>REDC</b>	<b>FDPF</b>	<b>FMEF</b>	<b>REDC</b>	<b>FDPF</b>	<b>FMEF</b>

Operations (annual) (D)	10.8	9.7	18.3	7.8	6.7	15.3	7.8	6.7	15.3
<b>Medical and Industrial Isotope/Nuclear Research and Development Processing Facilities</b>	<b>RPL/306-E</b>		<b>FMEF</b>	<b>New Processing Support Facility</b>			<b>New Processing Support Facility</b>		
Modification or construction and startup costs (E)	29.4		36.8	71.1			71.1		
Operations (annual) (F)	12.1		12.9	23.3			23.3		
<b>Combined Estimated Costs</b>									
Total Costs (A+C+E)	398.5	384.6	423.6	1,499.5	1,485.5	1,521.1	715.5	701.5	737.1
Annual Operating Costs <sup>c</sup> (B+D+F)	81.8	80.7	90.1	76.2	75.1	83.7	56.1	55	63.6
<b>Plutonium-238 Production Transportation</b>									
Neptunium-237 from SRS (total)	1.4	7.1	8.5	1.4	7.1	8.5	1.4	7.1	8.5
Total annual plutonium-238 production shipping and handling costs	0.41	0.28	0.28	1.54	1.50	1.54	2.39	2.37	2.42
<b>Medical and Industrial Isotope Transportation (annual)</b>	0.73	0.73	0.73	0.73	0.73	0.73	0.73	0.73	0.73

**Key:** SRS = Savannah River Site; RPL/306-E = Radiochemical Processing Laboratory and Hanford 300 Area Building 306-E.

- a. Annual operating costs are an average of FFTF operating costs using onsite mixed oxide fuel (MOX) = \$56.2 million, German MOX fuel = \$56.7, highly enriched uranium (HEU) fuel = \$63.9 million.
- b. Options 1, 2, and 3 assume FFTF would use onsite MOX, German MOX, and then HEU fuel during operations. Options 4, 5, and 6 assume FFTF would use onsite MOX and then HEU fuel during operations.
- c. Alternative 1 annual operating costs include an average of the FFTF operating costs.

**Note:** Shaded area indicates that no costs would be incurred under that alternative cost element.

- Under the No Action Alternative, FFTF would be maintained in its current standby mode at a cost of \$40.8 million per year. The No Action Alternative would also include the annual purchase of 5 kilograms (11 pounds) of Russian plutonium-238 at an assumed annual cost of \$8.84 million per year. Additional costs would depend on which option is chosen under the No Action Alternative. Option 1 would only incur the cost of maintaining FFTF in standby and the purchase of plutonium-238 from Russia. Options 2, 3, or 4 would involve the transport of neptunium-237 from SRS to REDC, CPP-651, or FMEF for long-term storage (costing \$17 to 19 million for storage modifications and startup at REDC and FMEF and \$2 million at CPP-651, which has existing storage capacity). Annual operating costs at all three storage sites would be approximately \$1.5 to 2.6 million per year. The total costs of transporting neptunium-237 from SRS to storage facilities is a function of distance and would vary from \$1.4 million for transport to REDC to \$7.1 to 8.5 million to CPP-651 or FMEF, respectively.
- Alternative 2 would combine the use of existing irradiation facilities (ATR, ATR in combination with HFIR, or a CLWR) with the choice of three processing facilities (REDC, FDPF, or FMEF) to provide nine different options for producing plutonium-238. FFTF would be deactivated at a cost of \$281 million constituting the major cost element of all options under Alternative 2. In addition, the following costs would be incurred:
  - Processing facility modification costs would be about \$37 million for FDPF; \$51 million for REDC; and \$73 million for FMEF (for the addition of most process flowsheet items of equipment, within existing plant and services) for Options 1, 2, 3, 7, 8, and 9. An additional cost of \$4 million for additional facility modifications was estimated for REDC and FDPF to fabricate stainless steel targets for the CLWR under Options 4, and 5.
  - Processing facility operating costs would be about \$7 to 8 million per year for REDC and FDPF and \$15 million per year for FMEF for Options 1, 2, 3, 7, 8, and 9. An additional cost of \$3 million was estimated for REDC, FDPF, and FMEF for the fabrication of stainless steel targets for the CLWR under Options 4, 5, and 6.
  - Irradiation charges would be \$8 million per year for ATR and ATR in combination with HFIR, and \$5 million per year for the CLWR.
  - Total transportation costs for the shipment of neptunium-237 from SRS to processing facilities would be the same as previously described for the No Action Alternative. Differences in annual plutonium-238 production shipping and handling costs between the options are due to distance, the location of the irradiation facility, and the number of shipments. All shipments to and from irradiation facilities under this alternative would be by commercial truck.
- Alternative 5 would involve the deactivation of FFTF, at a cost of \$281 million.

*The sum of all facility modification costs for the nonexpanded infrastructure alternatives would be \$0 to 19 million for the No Action Alternative; \$320 to 374 million for Alternative 2; and \$281 million for Alternative 5. The sum of all annual facility operating costs (less transportation) for this program would be \$50 to 52 million for the No Action Alternative; \$15 to 23 million for Alternative 2; and \$0 for Alternative 5.*

### **Expanded Infrastructure Alternatives**

A summary of the estimated costs of the expanded infrastructure alternatives (Alternatives 1, 3, and 4 of the NI PEIS) is presented in Table S-3. Capital costs (costs of either modifying existing facilities or constructing

new facilities), costs for permanently deactivating FFTF (where appropriate), annual operating costs, and transportation costs are presented for irradiation and processing facilities.

With respect to irradiation facilities, which constitute the major cost element of these alternatives, it can be seen that:

- Capital costs would be in the order of \$300 million for Alternative 1 (FFTF restart) and Alternative 4 (construction of a new research reactor), and more than \$1 billion for Alternative 3 (construction of new accelerators). An additional burden of \$281 million would be placed on Alternatives 3 and 4 for FFTF deactivation costs because these alternatives involve the construction of new facilities. Alternative 1, FFTF restart, would not incur this cost.
- The estimated annual costs of operating the irradiation facilities would be: \$25 million per year for the new research reactor in Alternative 4; \$45 million per year for the accelerators in Alternative 3; and \$59 to 64 million per year for FFTF in Alternative 1.

It can also be seen that the other types of facilities used in the expanded infrastructure alternatives (isotope processing facilities and support facilities that fabricate targets for irradiation and chemically process irradiated targets to recover, package, and ship isotopes) are specific to the production of either (1) plutonium-238, or (2) medical and industrial isotopes.

- Costs of modifying REDC, FDPF, or FMEF to support plutonium-238 production, together with startup costs, would range from \$37 to 73 million. The lower end of this range of front-end costs represents investments in REDC and FDPF, which have been built. FMEF has not been fully equipped nor operated, and would therefore require the higher modification costs to bring this facility online. Similarly, the annual operating costs for these facilities, would range from about \$7 to 18 million per year, due to the availability of shared resources that can reduce operating costs, compared to a nonoperating facility like FMEF. An additional cost of \$4 million for additional facility modifications at REDC and FDPF and \$3 million operating costs at REDC, FDPF, and FMEF was estimated for the fabrication of stainless steel targets for the FFTF under Alternative 1.
- The mission to produce medical and industrial isotopes and expand nuclear research and development capabilities would be supported by either the modification of existing operational facilities at Hanford under Alternative 1 (RPL/Building 306-E or FMEF) or the construction of a new facility supporting either new accelerators (Alternative 3) or a new research reactor (Alternative 4). The investment for modifications or construction and startup would amount to about \$29 to 37 million for the Hanford facilities and \$71 million for a newly constructed processing support facility. Annual operating costs would be lower for the two existing facilities compared to a new processing support facility (\$12 to 13 million per year for RPL/Building 306-E or FMEF and \$23 million per year for a new processing support facility).

Transportation costs for the expanded infrastructure alternatives would be higher for the plutonium-238 production mission than the medical and industrial isotope mission, due to distances traveled, (e.g., REDC at ORNL to FFTF at Hanford versus shipping to the nearest air freight terminal) the number of shipments, and the cost of secure shipments. Differences in annual plutonium-238 production shipping and handling costs between the three alternatives are due to the cost of secure transport versus commercial truck and the number of shipments. Under Alternative 1, commercial trucks would be used to transport neptunium targets between processing facilities and FFTF. Alternative 3 would have the fewest number of shipments but requires the use of secure transport. Alternative 4 would have the same number of shipments and nearly the same shipping and handling costs as Alternative 1, but would require the use of secure transport to ship fabricated neptunium-237 targets from processing facilities to the new research reactor. The difference in the total costs of shipping

neptunium-237 from the Savannah River Site (SRS) to plutonium-238 processing facilities is a function of distance from SRS. These costs would range from a low of \$1.4 million per year for REDC to about \$7 to 8 million per year for FDPF and FMEF. By comparison, transportation costs in medical and industrial isotope production (involving intrasite transfers of relatively small targets and offsite transfers to the nearest air freight terminal) would amount to \$0.73 million per year for each alternative.

*The sum of all facility modification costs in the expanded infrastructure alternatives would be \$385 to 424 million for Alternative 1; \$1,485 to 1,521 million for Alternative 3; and \$702 to 737 million for Alternative 4. The sum of all annual facility operating costs (less transportation) would be \$82 to 90 million per year for Alternative 1; \$75 to 84 million per year for Alternative 3; and \$55 to 64 million per year for Alternative 4.*

#### **S.4 RISK ANALYSIS OF COST ESTIMATES**

Although several types of contingencies can be defined, in general, a contingency refers to the cost that must be added to a base estimate to account for “unknown” costs. Two broad types of contingencies have been identified by Los Alamos National Laboratory (LANL) in the conceptual design report for a high-energy tritium production linear accelerator (LANL 1997). The most common type of contingency is an allowance for indeterminates, such as uncertainties in time, materials, or equipment items which may have inadvertently been omitted from the estimate. It should also be noted that the quality of the design basis for the development of the cost estimate is often a determinant of the magnitude of this type of contingency (Peters and Timmerhaus 1991). The Contingencies and Uncertainties columns in **Table S-4** reflect these types of uncertainties. A second type of contingency, often termed “risk contingency,” is particularly applicable to projects involving new technologies (e.g., projects which require the preparation of cost estimates while nuclear research and development is still in progress). This contingency covers the cost effects of unforeseen design changes, altered performance requirements, or major schedule delays due to developmental problems. The Technical Risk and Schedule Risk columns in Table S-4 are indicative of risk contingency considerations.

The contingencies listed in Table S-4 that apply to the costs of the alternatives can be considered under these definitions:

**No Action Alternative**—Alternative cost involves little or no contingencies, technical or schedule risk, as no action is being taken other than the purchase and transport of Russian plutonium-238 to LANL and transport of neptunium-237 from SRS to long-term storage facilities at either REDC, CPP-651, or FMEF. There is a high uncertainty regarding the future purchase price for Russian plutonium-238 that could significantly affect the current estimated cost of this alternative. The current estimate for the cost for purchasing Russian plutonium-238 assumed that the contract price would be extended using the negotiated annual escalation rate of 3.5 percent for the duration of the project planning period described in the NI PEIS. The contract for the purchase of Russian plutonium-238 is in year eight, with two years remaining (DOE 1997). Beyond the last two years of the contract, the future price of Russian plutonium-238 is unknown.

**Alternative 1: Restart FFTF**—This alternative uses existing facilities and proven technologies, which implies relatively low contingencies (in the order of 10 to 20 percent), which is customary for this type of operation. The potential exists for schedule delays in the neptunium-237 and medical and industrial isotope stainless steel target development for FFTF. The schedule risk is considered low, because it was assumed that neptunium-237 and medical and industrial isotope target development and testing would be accomplished during FFTF startup. However, some schedule risk would remain if stainless steel targets should fail during testing or not meet performance requirements during target evaluation prior to isotope production.

**Table S-4 Risk Analysis of Cost Estimates**

<i>Alternatives</i>	<i>Contingencies</i>	<i>Uncertainties</i>	<i>Technical Risk</i>	<i>Schedule Risk</i>	<i>Discussion</i>
No Action	Low range	High	None	Low	Uncertainty: cost of Russian plutonium-238
Alternative 1: Restart FFTF	Low range	Low	None	Low	Schedule risk: neptunium-237 and medical and industrial isotope target development
Alternative 2: Use Only Existing Operational Facilities					
ATR and HFIR	Low range	Low	None	Low	Existing technology
CLWR	Moderate range	Moderate	Low	High	Schedule risk: neptunium-237 target development. Uncertainties: proprietary irradiation services costs and unknown target development cost
Alternative 3: Construct New Accelerator(s)					
High-energy linear accelerator	High range	High	High	Very high	Contingency: factor associated with preconceptual design and target/blanket development. Uncertainty: technology in development for this application. Schedule risks: target/blanket shipping cask development and certification
Low-energy cyclotron accelerator	Low range	Low	None	Low	Proven technology
Alternative 4: Construct New Research Reactor	High range	Moderate	Low	Moderate	Contingency: factor associated with preconceptual design, capability risk. Schedule risk: neptunium-237 target development
Alternative 5: Deactivate FFTF	Low range	None	None	Low	None

Alternative 2: Use Only Existing Operational Facilities—This alternative should have a low contingency of 20 percent or less because of existing technology. This alternative presents no technological requirements for modifications to existing operational facilities for the production of isotopes or the use of new technologies.

CLWR use is considered a low technological risk because it is a proven technology and an ongoing operation. However, the schedule risk is considered high because of uncertainties associated with the development of neptunium-237 targets for a CLWR (i.e., neptunium-237 target development, testing, and evaluation would have to fit in with the CLWR refueling cycle). If the neptunium-237 target fails during testing or does not meet performance requirements during target evaluation, additional target testing could not occur until the next refueling cycle (generally, another 18 months). CLWR irradiation services costs are also uncertain due to the proprietary nature of the industry.

Alternative 3: Construct New Accelerator(s)—This alternative involves the use of high-energy linear accelerator technology for the production of neutrons via spallation for isotope production. This technology places Alternative 3 in an area of high technological and schedule risks, and of high contingency factors in several areas of component development for the application of high-energy linear acceleration for plutonium-238 production.

Conversely, low-energy cyclotron accelerator use for the production of medical and industrial isotopes is a low-cost, proven technology, is currently used commercially, and has little or no schedule risk.

Alternative 4: Construct New Research Reactor—This alternative involves the use of proven research reactor technology, which implies low risk; however, the very nature of the preconceptual design requires that a high level of contingency be applied to the construction cost estimate and operating costs. The schedule risk for neptunium-237 target development is considered moderate, because even though the new research reactor design is based on proven research reactor and fuel technologies, it is preconceptual. Like FFTF, it was assumed that neptunium-237 and medical and industrial isotope target development, testing, and evaluation would be accomplished during construction and startup of the new research reactor. Unlike the CLWR, targets can be pulled from the new research reactor core at any time during testing for evaluation.

Alternative 5: Deactivate FFTF—This alternative involves only the deactivation of the FFTF reactor, which is currently in standby mode; except for uncertainties associated with the disposal of the sodium coolant, the deactivation of FFTF poses little or no technological risk and has a low-cost contingency.

**Appendix Q**  
***Nuclear Infrastructure Nonproliferation Impact Assessment***  
**Executive Summary**

---

# NUCLEAR INFRASTRUCTURE NONPROLIFERATION IMPACT ASSESSMENT

*For Accomplishing Expanded Civilian Nuclear Energy Research and  
Development and Isotope Production Missions in the United States,  
Including the Role of the Fast Flux Test Facility*

---

September 2000

United States Department of Energy  
Office of Arms Control and Nonproliferation

## ***EXECUTIVE SUMMARY***

### **ES-1 PURPOSE, SCOPE, AND OBJECTIVE**

This document assesses the potential nonproliferation impacts that might result from U.S. Department of Energy (hereafter referred to as the Department or DOE) nuclear infrastructure improvements as proposed and described in the *Draft Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility* (DOE/EIS 0310D), July, 2000 (hereafter referred to as the Draft NI PEIS). The DOE Office of Arms Control and Nonproliferation has prepared this *Nuclear Infrastructure Nonproliferation Impact Assessment for Accomplishing Expanded Civilian Nuclear Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility* (hereafter referred to as the NI NIA). Together with the Draft NI PEIS and an associated cost report, both being prepared by the DOE Office of Nuclear Energy, this assessment is being made available to the public as part of the Department's decision-making process to evaluate nuclear infrastructure improvement alternatives.

The United States has an annual requirement for the production of radioisotopes needed for medical, industrial, and scientific applications. The Department has an obligation to supply Pu-238 thermal/power supplies to support currently scheduled and future NASA missions. Civil nuclear energy research and development (R&D) is also required to support future U.S. nuclear energy production, civil nuclear waste disposal, and possible nuclear science applications (*e.g.*, space reactors for future NASA missions). These programmatic needs, particularly those emanating from the projected growth rate in the use of medical isotopes and the continued requirement to produce isotopes for other applications (*e.g.*, Pu-238 for NASA missions), have led the Department to consider various infrastructure improvement alternatives, including the utilization of existing and new facilities.

The Department issued a Notice of Intent on September 15, 1999 to prepare a PEIS for specified alternatives to accomplish these nuclear infrastructure missions.<sup>1</sup> The Notice of Intent identified alternatives as follows: 1) resume Fast Flux Test Facility (FFTF) operation; 2) construct and operate a new research reactor at a generic DOE site; 3) construct and operate one or more new neutron-producing accelerators at a generic DOE site; or 4) meet these projected mission needs utilizing existing reactor and accelerator facilities (other than FFTF). The Draft NI PEIS assesses the environmental impact of all these alternatives, though not in precisely this order. Furthermore, the Draft NI PEIS also evaluates a No Action Alternative and a fifth alternative: permanently deactivate FFTF with no new missions at any U.S. facilities. This NI NIA will follow the same delineation of alternatives as the Draft NI PEIS to assess the nonproliferation impact of actions that are proposed in the Draft NI PEIS.

The objective of the NI NIA is to evaluate the relationship between the missions, facilities, alternatives and options as described in the Draft NI PEIS, and the body of U.S. Government nonproliferation policy, U.S. laws and regulations, and international agreements. Based on that evaluation, the NI NIA presents conclusions and recommendations regarding the nonproliferation merits and drawbacks of the various activities proposed in the Draft NI PEIS to assist the Secretary of Energy to render a Record of Decision following publication of the Final NI PEIS.

---

<sup>1</sup>“Notice of Intent To Prepare a Programmatic Environmental Impact Statement for Accomplishing Expanded Civilian Nuclear Energy Research and Development and Isotope Production Missions in the United States, Including the Role of the Fast Flux Test Facility,” 64 *Fed. Reg.* 50064, 1999.

# NONPROLIFERATION IMPACT ASSESSMENT

This assessment is limited to an evaluation of the direct and reasonably implied nonproliferation impact of the activities proposed in the Draft NI PEIS. Mission necessity, safety, environmental impact, effectiveness, costs, and life-cycle economics of activities described in the Draft NI PEIS are not considered to be central to the nonproliferation analysis reported in the NI NIA.

## ES-2 FACILITIES, ALTERNATIVES, AND OPTIONS

The facilities identified by the Department in the Draft NI PEIS are presented in Table ES-1. The irradiation facilities are described and evaluated in Sections 4 and 5 and target fabrication and processing facilities are described and evaluated in Section 6. The facility type, name, location, acronym assigned in the NI NIA, and the operational status of each facility is shown in the table.

**Table ES-1. Facilities Identified in the Draft NI PEIS**

Type	Name	Acronym	Location	Status
<i>Irradiation</i>	Fast Flux Test Facility	FFTF	Hanford, WA	Standby
	Advanced Test Reactor	ATR	Idaho National Energy and Environmental Laboratory (INEEL), ID	Operational
	High Flux Isotope Reactor	HFIR	Oak Ridge National Laboratory (ORNL), TN	Operational
	Commercial Light Water Reactor	CLWR	Existing CLWR site to be determined	Operational
	New High-Energy Accelerator New Low-Energy Accelerator	- -	Existing DOE site to be determined	- -
	New Research Reactor	-	Existing DOE site to be determined	-
<i>Target Fabrication and Processing</i>	Radiochemical Engineering Development Center	REDC	Oak Ridge National Laboratory (ORNL), TN	Operational
	Fluorinel Dissolution Process Facility CPP-651	FDPF CPP-651	Idaho National Energy and Environmental Laboratory (INEEL), ID	FDPF: Non-operational Available CPP-651: Operational
	Fuels and Materials Examination Facility	FMEF	Hanford, WA	Non-operational Available
	Radiochemical Processing Laboratory Building 306-E	RPL 306-E	Hanford, WA	Operational
	New Support Facility	-	Existing DOE site to be determined	-

Using the facilities identified above, the Department has defined five potential alternatives and a No-Action Alternative to accomplish the missions described above. Table ES-2 defines the five alternatives and enumerates the options under each alternative (*i.e.*, the facility variations within each alternative). Each alternative and option is evaluated in Section 8. Under the No Action Alternative (all options) and Alternative 5, Pu-238 is purchased from Russia to meet NASA program requirements. Furthermore, under all options in Alternatives 2, 3, 4 and 5, FFTF is permanently deactivated. FFTF standby/deactivation is covered by a previous NEPA action that is not evaluated in this assessment, but the standby/deactivation activity is covered as a special case under the comprehensive FFTF nonproliferation assessment given in Section 4.<sup>2</sup>

<sup>2</sup> Environmental Assessment – Shutdown of the Fast Flux Test Facility, Hanford Site, Richland, Washington, DOE/EIA-0993, May, 1995.

Table ES-2. Alternatives and Options Defined in the Draft NI PEIS

Alternatives	Options	Irradiation Facility	Pu-238 Production Mission		Medical and Industrial Isotope Production and Nuclear Energy Research and Development Mission	
			Storage Facility	Processing Facility	Storage Facility	Processing Facility
<b>No Action Alternative<sup>d, e</sup></b>	1	-	-	-	-	-
	2	-	REDC	-	-	-
	3	-	CPP-651	-	-	-
	4	-	FMEF	-	-	-
<b>Alternative 1: Restart FFTF<sup>g</sup></b>	1	FFTF <sup>a</sup>	REDC	REDC	RPL/306-E	RPL/306-E
	2	FFTF <sup>a</sup>	FDPF/CPP-651	FDPF	RPL/306-E	RPL/306-E
	3	FFTF <sup>a</sup>	FMEF	FMEF	FMEF	FMEF
	4	FFTF <sup>b</sup>	REDC	REDC	RPL/306-E	RPL/306-E
	5	FFTF <sup>b</sup>	FDPF/CPP-651	FDPF	RPL/306-E	RPL/306-E
	6	FFTF <sup>b</sup>	FMEF	FMEF	FMEF	FMEF
<b>Alternative 2: Use Only Existing Operational Facilities<sup>f</sup></b>	1	ATR	REDC	REDC	-	-

	6	CLWR	FMEF	FMEF	-	-
	7	HFIR/ATR	REDC	REDC	-	-
	8	HFIR/ATR	FDPF/CPP-651	FDPF	-	-
	9	HFIR/ATR	FMEF	FMEF	-	-
<b>Alternative 3: Construct New Accelerators<sup>f, g, h</sup></b>	1	New	REDC	REDC	New <sup>c</sup>	New <sup>c</sup>
	2	New	FDPF/CPP-651	FDPF	New <sup>c</sup>	New <sup>c</sup>
	3	New	FMEF	FMEF	New <sup>c</sup>	New <sup>c</sup>
<b>Alternative 4: Construct New Research Reactor<sup>f</sup></b>	1	New	REDC	REDC	New <sup>c</sup>	New <sup>c</sup>
	2	New	FDPF/CPP-651	FDPF	New <sup>c</sup>	New <sup>c</sup>
	3	New	FMEF	FMEF	New <sup>c</sup>	New <sup>c</sup>
<b>Alternative 5: Permanently Deactivate FFTF (with no new missions)<sup>d</sup></b>	-	-	-	-	-	-

- a) FFTF operates with MOX fuel for 21 years and uranium fuel for 14 years.
- b) FFTF operates with MOX fuel for 6 years and uranium fuel for 29 years.
- c) The New Support Facility would not be required if a DOE site with available support capability and infrastructure is selected.
- d) Under the No Action Alternative (all options) and Alternative 5, Pu-238 is purchased from Russia to supply NASA programs.
- e) Under the No Action Alternative, FFTF is maintained in standby mode indefinitely.
- f) Under Alternatives 2, 3, and 4, the FFTF is permanently deactivated.
- g) The ATW placeholder is not evaluated in this NI NIA. The ATW program will be the topic of a future ATW NIA.
- h) A new low-energy accelerator might also be combined with reactor options under Alternative 2 to fulfill all proposed missions.

### ES-3 NUCLEAR MATERIALS RELEVANT TO THIS ASSESSMENT

**Mixed Oxide Reactor Fuel.** Fresh and spent mixed oxide (MOX) fuel contains plutonium isotopes that are immediately useful as a fissile material in nuclear weapons following chemical separation from the uranium contained in the fuel matrix and metallurgical processing. MOX fuel (PuO<sub>2</sub> mixed with UO<sub>2</sub> in sintered pellet form) is intended as the initial fuel supply for the FFTF in the event that a Record of

## NONPROLIFERATION IMPACT ASSESSMENT

---

Decision directs FFTF to restart. Two sources of fresh MOX fuel for FFTF have been identified in the Draft NI PEIS:

- FFTF MOX fuel currently stored at the Hanford site that was remaining when FFTF went into standby mode. There is enough Hanford MOX fuel to operate the reactor at 100 megawatts thermal (MWt) for about 6 years. This fuel is hereafter referred to as Hanford MOX fuel.
- Partially remanufactured German SNR-300 MOX fuel currently stored at Hanau, Germany and Dounreay, Scotland. This fuel would require some remanufacturing and would be imported to the United States for use in the FFTF. There is enough German SNR-300 MOX fuel to operate the FFTF at 100 MWt for about 15 years following the consumption of the Hanford MOX fuel. This fuel is hereafter referred to as German MOX fuel.

**Highly Enriched Uranium Reactor Fuel.** All uranium enriched in U-235 to or above 20% is called highly enriched uranium (HEU). HEU is special nuclear material (SNM). HEU fuel is required to operate two of the irradiation facilities proposed in the Draft NI PEIS: the High-Flux Isotope Reactor (HFIR) and the Advanced Test Reactor (ATR). Both research reactors use aluminum clad HEU plate fuel. The HEU contained in the HFIR and ATR plate fuel is 93% enriched such that it is immediately useful as a fissile material in nuclear weapons following chemical separation from the fuel matrix and metallurgical processing.

HEU fuel may be required to operate FFTF following the consumption of available MOX fuel supplies. FFTF can use HEU oxide fuel in the form of sintered pellets. The HEU contained in the FFTF oxide fuel is enriched to between 30 and 37%. International and domestic safeguards regulations treat uranium, that is enriched above 20%, as material that is usable as fissile material for nuclear weapons. However, higher assays are more readily usable than lower assays.

**Low Enriched Uranium Reactor Fuel.** Any uranium enriched in U-235 to less than 20% is called low enriched uranium (LEU). LEU is SNM. LEU fuel is required to operate two of the irradiation facilities proposed in the Draft NI PEIS: commercial light water reactor (CLWR) and new research reactor. A CLWR uses sintered LEU oxide fuel pellets enriched to between 3 and 4%. A new research reactor would use aluminum clad LEU oxide plate fuel enriched to slightly below 20%. In both cases, conversion to uranium hexafluoride, further enrichment and metallurgical processing would be required to obtain material that is readily usable for nuclear weapons.

In fiscal year 2001, the Department's RERTR program plans to study conversion of ATR to use LEU fuel. If a Record of Decision directs a restart of FFTF, the RERTR program will study the conversion of FFTF to LEU fuel. In both cases, If LEU fuel is found to be technically feasible, it would probably be enriched to slightly less than 20%. LEU fuel would require conversion to uranium hexafluoride, further enrichment and metallurgical processing to obtain material that is readily usable for nuclear weapons.

**Neptunium.** Neptunium is an alternate nuclear material (ANM). The utility of ANM in nuclear weapons is recognized by the U.S. Government and the international community. The Pu-238 production mission described in the Draft NI PEIS requires the production and irradiation of neptunium targets. Neptunium targets are typically made of purified, concentrated neptunium dioxide with an aluminum binder, canned or clad in aluminum. The production of Pu-238 requires the production of purified neptunium dioxide from neptunium solution followed by target fabrication, irradiation to build in Pu-238, chemical processing to separate and purify neptunium and Pu-238 from fission products and other waste products, and a repeat of the cycle to produce further Pu-238. Each cycle destroys neptunium since neptunium is converted to Pu-238 in the process.

**Plutonium-238.** Pu-238 is special nuclear material (SNM). However, isotopically concentrated Pu-238 (above 80%) is generally recognized to not constitute a nuclear proliferation threat. The IAEA exempts plutonium that contains more than 80% Pu-238 from international safeguards and DOE assigns this material to the lowest DOE safeguards grade. However, this material is rigorously protected against loss, theft and sabotage (through physical protection and accounting) and is strictly contained (to prevent accidental release) as a result of the health and safety risks presented by the material.

**Target and Product Materials Associated with Isotope Production Missions.** A wide variety of materials (radioactive and nonradioactive) are described in the Draft NI PEIS to produce targets for the production of medical and industrial isotopes. None of the materials listed as targets or products are materials of nuclear nonproliferation concern. As such, these materials are not relevant to this NI NIA.

**Civil Nuclear Energy Research and Development Materials.** The nuclear materials that might be involved in civil nuclear energy R&D are not described, or listed in detail in the Draft NI PEIS. However, example missions are described. This NI NIA focuses on the use of materials of nonproliferation concern (nuclear weapons-usable fissile materials: plutonium,<sup>3</sup> HEU and ANM) in facilities, alternatives, and options described in the Draft NI PEIS. Civil nuclear energy R&D studies on materials other than the materials of concern are not germane to this NI NIA.

### ES-4 NONPROLIFERATION POLICY CONTEXT

In broad terms, the analysis performed in this assessment focuses on four major proliferation concerns that may be raised by the nuclear facilities and operations reviewed in the Draft NI PEIS:

- The concern that, pursuant to the Draft NI PEIS, the construction or operation of a facility in the United States that uses weapons-usable nuclear materials might encourage the development of similar facilities abroad, to the detriment of U.S. non-proliferation efforts aimed at discouraging the development of such facilities;
- The risk that weapons-usable nuclear material might be stolen from a U.S. nuclear facility constructed or operated pursuant to the Draft NI PEIS by agents of a country of proliferation concern or by a subnational organization or terrorist group;
- The risk that restrictions on voluntary or legally mandated international monitoring of certain U.S. facilities operated pursuant to the Draft NI PEIS might reduce confidence in U.S. pledges that it will never use for nuclear weapons certain weapons-usable nuclear materials that it has declared to be excess to defense needs; and
- The risk that activities proposed under the Draft NI PEIS might interfere with the implementation of anticipated future treaties, such as the Fissile Material Cutoff Treaty (FMCT).

The three weapons-usable nuclear materials whose use and processing are analyzed in this assessment, and which are discussed below, are HEU, plutonium,<sup>4</sup> and neptunium. Although HEU and plutonium have long been the subject of U.S. and international nonproliferation controls, neptunium, which to date has been separated in significant quantities only in nuclear-weapon states, became the subject of international regulation only in 1999.

The United States has long led global efforts to prevent the proliferation of nuclear weapons and to safeguard weapons-usable fissile materials against the risk of theft or diversion. Because the knowledge needed to make at least a crude nuclear weapon is now widespread, limited access to these essential

---

<sup>3</sup> The term “plutonium” is understood in this context to mean isotopic mixtures of plutonium other than isotopically concentrated Pu-238.

<sup>4</sup> Ibid.

# NONPROLIFERATION IMPACT ASSESSMENT

---

ingredients of nuclear weapons is the principal technical barrier to nuclear proliferation in the world today. Hence, the United States has placed heavy emphasis on efforts to help monitor, protect, control, account for, and, ultimately, dispose of weapons-usable fissile materials worldwide.

Because of its pivotal role in preventing the proliferation of nuclear weapons and its own extensive nuclear programs and activities, the manner in which the United States manages its nuclear activities has a significant influence on other states. U.S. technical and policy choices frequently affect similar choices in other countries both by example and in the way these choices support U.S. diplomatic efforts. Thus, decisions of the type analyzed in the Draft NI PEIS that are taken in the United States can positively or negatively affect efforts to enhance the global nonproliferation regime and bolster the international norm against the acquisition of nuclear weapons. In recent years, the United States has sought to make its nuclear activities increasingly transparent in order to increase international confidence in the global arms control and nonproliferation regime and to encourage similar actions by other countries.

In order to practically evaluate the nonproliferation merits and drawbacks of the activities proposed in the Draft NI PEIS, this NI NIA analyzes the proposed missions, facilities, alternatives, and options within the context of U.S. nonproliferation policy. This body of policy is articulated in President Clinton's 1993 Nonproliferation and Export Control Policy Statement (see Appendix 10.2), other relevant U.S. laws and regulations, and international agreements. Most central to this assessment are policies concerning:

- Plutonium reprocessing;
- Civil use of HEU;
- Monitoring of ANM; and
- Support of anticipated FMCT negotiations.

## ES-5 NONPROLIFERATION ASSESSMENT METHODS

**Technical and Policy Factors.** This NI NIA evaluates the nonproliferation impact of the activities proposed in the Draft NI PEIS by analyzing the various missions, facilities, alternatives, and options against three technical factors and four policy factors. The technical evaluation factors focus on assuring that weapons-usable fissile materials are physically difficult to either steal or divert, and that this material and associated processes are appropriately safeguarded. The three technical factors assess the degree to which an activity would be:

- Assuring against theft or diversion;
- Facilitating cost-effective international monitoring; and
- Resulting in final material forms from which retrieval is more difficult than from original material forms.

The four policy factors used in this assessment focus on the ability of the United States to maintain and strengthen international efforts to stem the spread of nuclear weapons, including the overall approach to limit, restrict, and minimize the use of weapons-usable fissile material in civilian applications. Furthermore, the policy factors also address the continued transparency of the U.S. domestic moratorium on fissile material production for nuclear weapons. The four policy factors include the degree to which an activity would be:

- Maintaining consistency with U.S. nonproliferation policy;
- Avoiding encouragement of plutonium reprocessing;
- Building confidence that the United States is not producing material for nuclear weapons; and

- Supporting negotiation of a verifiable Fissile Material Cutoff Treaty.

**Evaluation Grading Scale.** A qualitative grading scale on three levels is defined to indicate the degree to which particular missions, facilities, alternatives, or options meet U.S. nonproliferation objectives. The three levels in the grading scale are:

● *Fully Meets Nonproliferation Objectives.* A mission, facility, alternative, or option under a factor assessment *fully meets nonproliferation objectives* if: *there are no significant identified concerns* that can be raised demonstrating how the use of the facility or implementation of the alternative is contrary to U.S. nonproliferation objectives as defined by the assessment factor.

⦿ *Might Raise Nonproliferation Concerns.* A mission, facility, alternative, or option under a factor assessment *might raise nonproliferation concerns* if: *there is significant uncertainty* as to whether the use of the facility or implementation of the alternative *might have an adverse effect* on U.S. nonproliferation objectives as defined by the assessment factor.

○ *Raises Nonproliferation Concerns.* A mission, facility, alternative, or option under a factor assessment *raises nonproliferation concerns* if: *there are significant identified concerns* that can be raised demonstrating how the use of the facility or implementation of the alternative is contrary to U.S. nonproliferation objectives as defined by the assessment factor.

## ES-6 SUMMARY OF NONPROLIFERATION ASSESSMENTS

Table ES-3 shows the summary of the detailed facility assessment scores. Facilities and mission cases (e.g., FFTF standby/deactivation, neptunium storage) are shown across rows and nonproliferation assessment technical and policy factors are shown down columns. *There are currently no U.S. nonproliferation policies, laws, regulations or international agreements that preclude the use of any of the facilities in the manner described in the Draft NI PEIS.* However, there are a few instances of nonproliferation concerns and uncertainties.

These concerns and uncertainties are associated with the use of processing facilities to recover Pu-238 and neptunium from irradiated neptunium targets as part of the Pu-238 production mission. In all facility cases (REDC, FDPF, and FMEF), the repeated separation and purification of neptunium (which is an unavoidable part of the process) raises *significant uncertainty* under the third technical factor associated with reduction in material attractiveness. This is always the case and is technically unavoidable (even if Pu-238 is purchased from Russia, this process is required in a Russian nuclear facility).

Other concerns and uncertainties surrounding the use of FDPF stem from concerns about transparency measures that could be required as part of an FMCT verification regime. The extent to which FDPF, as a former defense nuclear material production facility, would be available for international monitoring under an FMCT is currently unknown.

Irradiation facilities and missions, as described in the Draft NI PEIS, do not have any identified nonproliferation concerns or uncertainties. Although the intended fuel supply for FFTF includes two different sources for existing MOX fuel, an analysis of these MOX supply options identified significant mitigating factors that indicated substantial nonproliferation benefits to disposing of that attractive material as highly radioactive spent fuel (see Section 4). If HEU fuel is required for either FFTF (30 to 37% enriched) or ATR (93% enriched) it will be procured in strict accordance with U.S. nonproliferation policy following the principles outlined in the Schumer Amendment (see Appendix 10.3). The Schumer

# NONPROLIFERATION IMPACT ASSESSMENT

amendment places restrictions on the export of HEU, requiring that facilities pursue conversion to LEU fuels and targets.

It should be added that operation of the FFTF does not set a precedent that may encourage other states to build new high-flux test reactors using MOX or HEU fuels. The FFTF case is unique: it involves an existing, previously operated facility and the irradiation of previously fabricated MOX fuel now in storage, conditions that are highly unlikely to arise elsewhere. Possible future use of HEU at the facility will be subject to the same strict scrutiny that the United States would wish to have applied by other states considering the use of such fuel.

**Table ES-3. Assessments of Facilities as Described in the Draft NI PEIS**

		<i>Irradiation Facilities</i>								<i>Target Fabrication and Processing Facilities</i>					<i>Np-237 Storage</i>			
		FFTF Restarted	FFTF Standby/Deactivated	ATR	HFIR	CLWR	New Low-Energy Accelerator	New High-Energy Accelerator	New Research Reactor	REDC	FDPF	FMEF	RPL	306-E	New Support Facility	REDC	CPP-651	FMEF
<b>Technical Factors</b>	Assuring Against Theft or Diversion	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●
	Facilitating Cost-Effective International Monitoring	●	●	●	●	●	●	●	●	●	○	●	●	●	●	●	●	●
	Resulting in Final Material Forms from which Retrieval is More Difficult than from Original Material Forms	●	●	●	●	●	●	●	●	◐	◐	◐	●	●	●	●	●	●
<b>Policy Factors</b>	Maintaining Consistency with U.S. Nonproliferation Policy	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●
	Avoiding Encouragement of Plutonium Reprocessing	●	●	●	●	●	●	●	●	●	◐	●	●	●	●	●	●	●
	Building Confidence that the U.S. is not Producing Material for Nuclear Weapons	●	●	●	●	●	●	●	●	●	◐	●	●	●	●	●	●	●
	Supporting Negotiation of a Verifiable FMCT	●	●	●	●	●	●	●	●	●	○	●	●	●	●	●	●	●

- Fully meets nonproliferation objectives
- ◐ Might raise nonproliferation concerns
- Raises nonproliferation concerns

It should also be noted that although the ATR’s defense program mission precludes it from international monitoring, there are no U.S. nonproliferation policy directives, international agreements or regulations that generically prevent civil programs from being conducted in current or former defense facilities –

ATR is currently hosting civil radioisotope production programs. However, when comparable alternatives exist that allow civil programs to be hosted in facilities that are eligible for international monitoring, it is preferable to maintain a separation between defense and civil programs.

Table ES-4 shows the detailed assessment grades for each alternative and option described in the Draft NI PEIS (the alternatives and options are shown in Table ES-2). The alternative and option assessments are performed using the methods described in Section 3 (incorporating each of the facility assessments with a generic transportation assessment in a “weak link” analysis). The generic transportation assessment (see Section 8.3) found no significant nonproliferation impact associated with nuclear material transportation.

In Alternatives 1 through 4 (U.S. Pu-238 production alternatives) the assessments are fully determined by the Pu-238 processing facility assessment (REDC, FDPF, and FMEF). Furthermore, under the No Action Alternative and Alternative 5, the alternative assessments are determined by a generic assessment of the Russian Pu-238 purchase option (presented in Section 8.2). The Russian Pu-238 purchase option suffers from similar nonproliferation uncertainties and concerns as FDPF. In addition, the status of Russian domestic safeguards of ANM is largely unknown. Moreover, since there is currently no Russian moratorium on spent fuel reprocessing, and neptunium recovery is part of the Russian reprocessing flowsheet, the Russian inventory of separated weapons-usable neptunium could continue to increase, even if smaller quantities of neptunium were destroyed in the production of Pu-238.

## ES-7 CONCLUSIONS AND RECOMMENDATIONS

### ES-7.1 OVERALL ASSESSMENT OF MISSIONS PROPOSED IN THE DRAFT NI PEIS

*There are currently no U.S. nonproliferation policies, laws, regulations or international agreements that preclude the use of any of the facilities in the manner described in the Draft NI PEIS.* The overall missions (independent of selected facilities) proposed in the Draft NI PEIS are evaluated by using the methods presented in Section 3.

**Medical, Industrial, and Research Isotope Production.** *There are no significant identified concerns demonstrating how, within the bounds of the description given in the Draft NI PEIS, the pursuit of the medical, industrial, and research isotope production mission is contrary to U.S. nonproliferation objectives as defined by any assessment factor. Therefore, this mission is graded as ● fully meets nonproliferation objectives.*

**Plutonium-238 Production.** *With the exception of the third technical assessment factor, reduction in attractiveness of material forms (see Section 3), there are no significant identified concerns demonstrating how, within the bounds of the description given in the Draft NI PEIS, the pursuit of the Pu-238 production mission is contrary to U.S. nonproliferation objectives as defined by the remaining technical and policy assessment factors. Therefore, these remaining factors are graded as ● fully meets nonproliferation objectives. In the case of the third technical assessment factor, the process of producing, recovering, and purifying Pu-238 requires that neptunium also be recovered, purified, and recycled. However, in the event that Pu-238 production is resumed in the United States, the total separated stocks of neptunium will be reduced over time in an irreversible manner since there is a moratorium on U.S. spent fuel reprocessing – the activity that could lead to the production of additional stocks of separated neptunium. This overall reduction in a weapons-usable material stock is a partial mitigation of the identified concern. Even so, there is significant uncertainty raised with respect to the third technical assessment factor, and that single factor is graded as ● might raise nonproliferation concerns. However, it should be pointed out that this issue is unavoidable (unless the United States elects to neither produce*

# NONPROLIFERATION IMPACT ASSESSMENT

**Table ES-4. Assessments of Alternatives and Options as Defined in the Draft NI PEIS**

<i>Alternatives</i>	<i>Options</i>	<i>Technical Factors</i>			<i>Policy Factors</i>			
		Assuring Against Theft or Diversion	Facilitating Cost-Effective International Monitoring	Resulting in Final Material Forms from which Retrieval is More Difficult than from Original Material Forms	Maintaining Consistency with U.S. Nonproliferation Policy	Avoiding Encouragement of Plutonium Reprocessing	Building Confidence that the U.S. (Russia)* is not Producing Material for Nuclear Weapons	Supporting Negotiation of a Verifiable FMCT
<i>No Action Alternative*</i>	1	●	●	○	●	●	●	●
	2	●	●	○	●	●	●	●
	3	●	●	○	●	●	●	●
	4	●	●	○	●	●	●	●
<i>Alternative 1: Restart FFTF</i>	1	●	●	●	●	●	●	●
	2	●	○	●	●	●	●	○
	3	●	●	●	●	●	●	●
	4	●	●	●	●	●	●	●

	2	●	○	●	●	●	●	○
	3	●	●	●	●	●	●	●
<i>Alternative 5: Permanently Deactivate FFTF (with no new missions)*</i>	-	●	●	○	●	●	●	●

\* Under the No Action Alternative (Options 1-4) and Alternative 5, the Russian Pu-238 purchase option is considered.

- Fully meets nonproliferation objectives
- Might raise nonproliferation concerns
- Raises nonproliferation concerns

nor purchase Pu-238) and impacts all alternatives and options, including the No Action Alternative and Alternative 5: permanently deactivate FFTF with no new missions at U.S. facilities.

**Civil Nuclear Energy Research and Development.** The DOE Office of Nuclear Energy has included Accelerator Transmutation of Waste (ATW) as one of many possible future civil nuclear energy R&D missions as a placeholder in the event that the U.S. Government decides to pursue this technology. Currently, the Department is performing technical paper studies and planning studies (*e.g.*, the “ATW Road Map”) to assist Congress with fiscal and program planning. These efforts are also being reviewed by the independent Nuclear Energy Advisory Committee (NERAC) Subcommittee on the Accelerator Transmutation of Waste, which, in its report of May 23, 2000, recommended that, a study should be launched to identify potential proliferation concerns associated with ATW and possible approaches to mitigate identified concerns. A comprehensive nonproliferation impact assessment of the ATW program plan will be performed by the Office of Arms Control and Nonproliferation prior to proceeding beyond paper studies with actual fuels materials testing in support of ATW (or other technologies that include or imply closed fuel cycle technologies). As such, the nonproliferation impact of a possible future ATW program is not considered in this NI NIA since it is not a well-defined, principal identified mission at this time. It will, however, be considered in a future nonproliferation impact assessment if the ATW Program moves forward. With respect to other identified civil nuclear energy R&D missions, there *are no significant identified concerns* demonstrating how, within the bounds of the description given in the Draft NI PEIS, the pursuit of these missions is contrary to U.S. nonproliferation objectives as defined by any assessment factor. In fact, the development of proliferation resistant nuclear fuels and technologies are a significant feature of the intended R&D program. Therefore, this mission is graded as ● *fully meets nonproliferation objectives*.

### ES-7.2 NONPROLIFERATION MOST AND LEAST FAVORABLE ALTERNATIVES AND OPTIONS

Since the assessments of alternatives and options are largely determined by the Pu-238 processing facility assessments, the options that use the REDC and FMEF have the most favorable assessments, and the options that use the FDPF have the least favorable assessments. The No Action Alternative and Alternative 5 use the Russian Pu-238 purchase option. These alternatives score between most and least favorable. As a result, the *most favorable nonproliferation alternatives and options* are:

- Alternative 1: Restart FFTF, Options 1, 3, 4, and 6
- Alternative 2: Use Only Existing Facilities, Options 1, 3, 4, 6, 7, and 9
- Alternative 3: Construct New Accelerator(s), Options 1 and 3
- Alternative 4: Construct New Research Reactor, Options 1 and 3

The *least favorable nonproliferation alternatives and options* are:

- Alternative 1: Restart FFTF, Options 2 and 5
- Alternative 2: Use Only Existing Facilities, Options 2, 5, and 8
- Alternative 3: Construct New Accelerator(s), Option 2
- Alternative 4: Construct New Research Reactor, Option 2

### ES-7.3 SPECIAL CONSIDERATIONS FOR ALTERNATIVE 1: RESTART FFTF

If the Nuclear Infrastructure Record of Decision elects to restart FFTF (under any option), there are some special considerations. To codify the assumptions underlying the conclusion that restart of the FFTF fully

## NONPROLIFERATION IMPACT ASSESSMENT

meets U.S. nonproliferation policy objectives, the Nuclear Infrastructure Record of Decision should include the following commitments:

- The FFTF will not be configured to operate as a breeder reactor (breeding ratio equal to or greater than one) or to optimize the production of plutonium.
- Spent MOX fuel irradiated in the FFTF will not be reprocessed.
- During the period that the FFTF is fueled with Hanford MOX fuel, an analysis will be undertaken by the RERTR program to determine whether the reactor can be fueled with LEU fuel, and if this is shown to be technically feasible, the reactor will be fueled with LEU fuel following the consumption of existing MOX fuel (Hanford and, possibly, German MOX fuel).
- A nonproliferation impact assessment will be prepared on the ATW program prior to the test irradiation of ATW fuels materials in the FFTF.
- The FFTF will remain available for international monitoring.

### **ES-7.4 NONPROLIFERATION UNCERTAINTIES, CONCERNS, AND MITIGATION APPROACH**

There are a limited number of nonproliferation concerns and uncertainties that might be mitigated to increase the number of alternatives and options that have optimum nonproliferation qualities for the missions described in the Draft NI PEIS. These concerns are associated with the U.S. and Russian facilities used to process and recover Pu-238.

- If managed access can be granted to the FDPF, sufficient for verification of an FMCT, the uncertainties and concerns associated with the use of FDPF for the Pu-238 processing mission would be effectively mitigated (with the exception of the material forms technical factor).
- If the United States had sufficient confidence concerning the rigor of Russian controls on ANM, this uncertainty would be effectively mitigated.
- If Russia were to implement a moratorium on spent nuclear fuel reprocessing, the material forms technical factor would be partially mitigated to “● might raise nonproliferation concerns” – similar to the U.S. Pu-238 program assessments, since Russia would no longer be able to add to its stocks of separated neptunium.
- If managed access can be granted to the Russian facility responsible for Pu-238 and neptunium recovery, sufficient for verification of an FMCT, the uncertainties associated with the use of a Russian facility for the Pu-238 processing mission would be effectively mitigated (with the exception of the material forms technical factor).

Washington, DC 20585

Dear Mr. Wahlquist:

Recent changes in the NASA Deep Space Systems (DSS) program have led to modifications in our planned launch dates and spacecraft configurations for the Europa Orbiter, Pluto-Kuiper Express, and Solar Probe missions. These modifications have been driven by changes in the launch vehicle and technology maturity status, and are based upon the best information and the limited funds available.

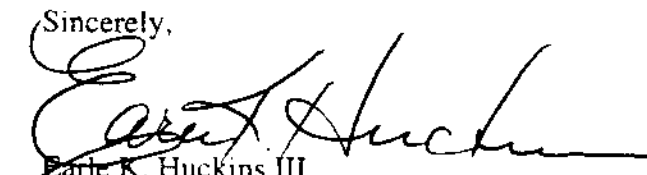

Under a proposed plan, the Pluto-Kuiper Express mission would be launched in 2004. Due to cost profile constraints, the baseline mission plan is to utilize the F5 generator "as is" as the primary power source. It is expected that DOE and the Jet Propulsion Laboratory (JPL) in Pasadena, California, will work together to develop a test and inspection program to verify the flight worthiness of the F5 generator.

A proposed plan for the Europa Orbiter mission is to launch in 2006 (with a fallback option for a 2007 launch). A proposed plan for the Solar Probe mission is to launch in 2007 (with a fallback option for a 2008 launch). Both of these missions could possibly utilize the option of a proposed new power system based on a Stirling technology generator. NASA Headquarters and JPL will work closely with DOE to establish requirements that will ensure that this new power system will meet the flight needs of these missions.

As a result of the proposed DSS program changes, NASA Headquarters no longer has an identifiable planned requirement for Small Radioisotope Thermoelectric Generator (SRTG) power systems. Therefore, NASA Headquarters requests that all SRTG development efforts for DSS spacecraft missions be halted. In addition, investigations into the utilization of the E8 and Multi-Hundred Watt systems for DSS applications should be stopped. The closure of these activities will permit reprogramming the funds to support the start-up of the Stirling system development.

As always, your support for the development of spacecraft power systems is greatly appreciated.

Sincerely,

Earle K. Huckins III  
Deputy Associate Administrator  
for Space Science

SUBJECT: Pluto-Kuiper Express Mission and Reformulation of  
the Deep Space Systems Program

I have concluded, for programmatic and technical reasons, that it is not feasible to implement the Pluto-Kuiper Express (PKE) mission as currently conceived. I, therefore, direct you to immediately stop all work in support of PKE development as currently conceived.

In anticipation of a new science roadmap for Outer Planet Exploration, you are further directed to begin developing a technology plan that would support a mission to Pluto and the Kuiper Belt, to arrive at Pluto no later than 2020. Clearly, a central objective of this technology plan should be to reduce flight time to Pluto substantially from what is currently achievable.

You are also directed to continue all activities necessary to support a launch of the Europa Orbiter mission in January 2006.

The Acting Science Director for Solar System Exploration, Dr. Jay T. Bergstralh, will be in contact with your staff regarding other aspects of the new Outer Planets Science Roadmap. If you or your staff have any questions, please feel free to contact Dr. Bergstralh at (202) 358-0313.

Mr. Earl Wahlquist  
Associate Director  
Office of Space and Defense  
Power Systems  
U.S. Department of Energy (DOE)  
1000 Independence Avenue, SW  
Washington, DC 20585

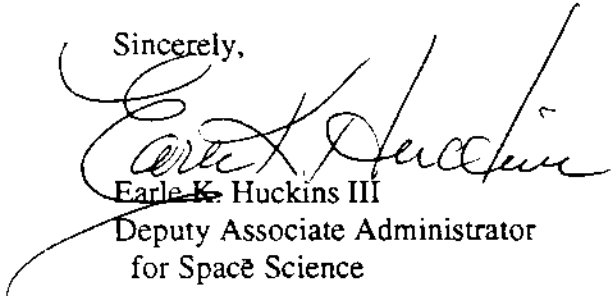

Dear Mr. Wahlquist:

The Office of Space Science recently concluded, for programmatic and technical reasons, that it is not feasible to implement the Pluto-Kuiper Express (PKE) mission as currently conceived. We have directed the Jet Propulsion Laboratory to stop all work in support of the current PKE development and to continue all activities necessary to support a launch of the Europa Orbiter (EO) mission in January 2006. Therefore, the mission planning guidance provided to you in our May 22, 2000, letter needs to be updated.

While the design baseline for the EO mission includes the use of Stirling technology radioisotope generators, a viable backup power system is needed in order to support the 2006 launch. Current power estimates indicate that both the F-5 and E-8 generators would be required to support the mission. Your mission planning should consider maintaining the viability of both F-5 and E-8 generators as EO backups.

NASA relies on DOE's capability to produce and provide Radioisotope Power Systems (such as Stirling) that are essential for planning and implementing deep space and long lived space exploration missions. Your continued support is appreciated.

Sincerely,

Earle K. Huckins III  
Deputy Associate Administrator  
for Space Science
