

# **Guidelines for the Prevention and Treatment of Hepatitis C and Cirrhosis**

**Federal Bureau of Prisons  
Clinical Practice Guidelines**

**June 2009**

Clinical guidelines are made available to the public for informational purposes only. The Federal Bureau of Prisons (BOP) does not warrant these guidelines for any other purpose, and assumes no responsibility for any injury or damage resulting from the reliance thereof. Proper medical practice necessitates that all cases are evaluated on an individual basis and that treatment decisions are patient-specific. Consult the BOP Clinical Practice Guidelines Web page to determine the date of the most recent update to this document:  
<http://www.bop.gov/news/medresources.jsp>.

## What's New in this Document?

The BOP *Guidelines for Prevention and Treatment of Viral Hepatitis*, last published in October 2005, covered Hepatitis A, Hepatitis B, and Hepatitis C. This new guideline separates out the recommendations for Hepatitis C and presents the following updates:

- A 10-step process for detecting, evaluating, and treating chronic hepatitis C in the BOP is outlined ([Table 3](#), on page 3, and [Appendix 2](#)).
- Four criteria are provided to determine if, at the time of the initial evaluation, antiviral treatment is *not recommended* ([Appendix 2–Step 3a](#)):
  - (1) Pegylated interferon is contraindicated.
  - (2) The inmate will be incarcerated for an insufficient period of time for completing treatment.
  - (3) The inmate has an unstable medical or mental health condition precluding hepatitis C treatment.
  - (4) The inmate refuses treatment.
- Laboratory testing: The previous edition of these guidelines made a distinction between quantitative and qualitative HCV RNA tests. With improvements in the sensitivity of quantitative assays (sensitivities of 10-50 IU/mL), there is no longer a need for qualitative assays. This document now simply refers to “HCV RNA assays.” Note that the same laboratory test should be used both before and during therapy. RIBA testing for confirmation of HCV infection is *no longer recommended*.
- Recommendations regarding the ongoing monitoring of inmates who have chronic hepatitis C, but who are *not* on therapy, are clarified ([Appendix 2–Step 3b](#)).
- Guidance on the assessment of liver fibrosis is updated. Criteria for liver biopsy are outlined in [Appendix 2–Step 5](#). The AST/Platelet Ratio Index (APRI) is a promising proxy measure of the degree of liver fibrosis. It is calculated using commonly available lab values (see [Table 4](#), page 5 for calculation formula). The APRI value should be used to prioritize referrals for liver biopsy. A reference chart is provided that compares liver biopsy result scoring systems for staging of hepatic fibrosis ([Table 5](#), page 7).
- Specific criteria for initiating hepatitis C treatment are clarified ([Appendix 2–Step 6](#)), including:
  - (1) Genotype 2 or 3 (with no biopsy performed).
  - (2) Significant liver biopsy result (IASL/Ludwig/Metavir  $\geq 2$ ; and Ishak  $\geq 3$ ), regardless of genotype.
  - (3) Evidence of [compensated cirrhosis](#) with or without biopsy.
- The *Hepatitis C Monitoring Schedule* ([Appendix 3](#)) is an at-a-glance chart, listing recommended laboratory and clinical evaluations (at baseline, pretreatment, and ongoing).
- Updated treatment recommendations are discussed on pages 13–15. A chart of Chronic Hepatitis C Treatment Response categories is provided ([Appendix 2–Step 9](#)). *Timelines for HCV Treatment Decisions* display treatment recommendations, based on the HCV RNA virologic response over time ([Appendix 4a](#) and [Appendix 4b](#)).
- Treatment recommendations for inmates co-infected with HIV and HCV are updated (page 15).
- Guidelines for managing HCV treatment-associated cytopenias are outlined ([Appendix 2–Step 9](#)).
- Guidelines for management of exposures to hepatitis C are updated ([Table 8](#), page 19).

## 1. Purpose

The Federal Bureau of Prisons (BOP) Clinical Practice Guidelines for the *Prevention and Treatment of Hepatitis C and Cirrhosis* provide recommendations for the medical management of federal inmates with hepatitis C, or who are otherwise at risk of infection.

## 2. Transmission of Hepatitis C Virus

Hepatitis C virus (HCV) is a single-stranded, enveloped, RNA virus with multiple genotypes and subtypes. Genotype 1 is predominant in the United States. HCV is transmitted primarily by direct percutaneous exposures to infectious blood. Modes of transmission are summarized below in Table 1.

**Table 1. Modes of Transmission of Hepatitis C Virus**

<p><b>Percutaneous Exposure to Infectious Blood (primary mode)</b></p> <ul style="list-style-type: none"><li>▶ Injection drug use</li><li>▶ Transmission of contaminated blood products (prior to July 1992)</li><li>▶ Tattooing with shared sharps in jails or prisons (potential mode)</li></ul> <p><b>Other Modes of Transmission (inefficient)</b></p> <ul style="list-style-type: none"><li>▶ Sexual contact (increased risk for inmates with history of STD or multiple sexual partners)</li><li>▶ Congenital transmission (risk of 5–6%)</li></ul> <p><b>Ways HCV is <i>not</i> transmitted</b></p> <ul style="list-style-type: none"><li>▶ Breast feeding</li><li>▶ Kissing, sneezing, hugging, coughing</li><li>▶ Food or water</li><li>▶ Casual contact, including sharing eating utensils or drinking glasses</li></ul> <p><b>Note:</b> Most inmates diagnosed with HCV infection have behavioral risk factors for acquiring HCV and were infected prior to incarceration. Low levels of HCV transmission between inmates have been documented via seroincidence studies and contact investigations. However, large HCV outbreaks have not been reported in the correctional setting.</p>
--

## 3. Acute Hepatitis C Infection

### Diagnosis of Acute HCV Infection

Acute HCV infection is diagnosed when there is *circumstantial evidence* of new infection (such as recent exposure to a known HCV-infected inmate) or the presence of *clinical features* of acute hepatitis (jaundice, nausea, anorexia, and malaise), and where the other causes of hepatitis have been excluded. Acute hepatitis C rarely causes fulminant hepatic failure. However, superinfected persons who also have underlying chronic hepatitis B infection are at greater risk for severe hepatitis.

The *mean incubation period*, from transmission of HCV infection to the onset of symptoms, is 6–7 weeks (range: 2–26 weeks); however, only 20–30% of newly infected persons are actually symptomatic. Serum ALT levels increase 4–12 weeks after acute HCV infection. HCV RNA is detectable in serum within days to 8 weeks following infection. Antibodies to HCV (anti-HCV) are detectable 3 months after infection in 90% of patients. A subset of those with acute HCV infection spontaneously clear the virus.

Laboratory criteria for diagnosis of acute hepatitis C are summarized below in Table 2.

**Table 2. Laboratory Criteria for Diagnosis of Acute Hepatitis C**

<p><b>Confirmation of acute hepatitis C is confirmed by <i>all</i> of the following:</b></p> <ol style="list-style-type: none"><li>1) <b>Marked elevation in ALT</b> (&gt;7 times the upper limit of normal, with or without symptoms of acute hepatitis); <b>and</b></li><li>2) <b>Negative tests for acute hepatitis A</b> (IgM anti-HAV) <b>and acute hepatitis B</b> (IgM anti-HBc); <b>and</b></li><li>3) <b>A positive anti-HCV screening immunoassay</b> (enzyme immunoassay, EIA, or chemoluminescence immunoassay, CIA) that is confirmed with <i>one of the following</i>:<ul style="list-style-type: none"><li>▶ An immunoassay with a signal to cut-off ratio predictive of a true positive for that assay; or</li><li>▶ An HCV RNA assay. (HCV RNA may be detected 1–3 weeks after exposure. However, viremia may be transient post-exposure, i.e., a negative HCV RNA does not rule out acute HCV infection.)</li></ul></li></ol>
---

## Treatment of Acute HCV Infection

Inmates diagnosed with acute hepatitis C should be considered for antiviral therapy, in consultation with a physician who has expertise in managing hepatitis C. Treatment can be delayed for 8 to 12 weeks after acute onset of hepatitis to allow for spontaneous resolution of the infection. Patients should be considered for treatment with at least pegylated interferon. The benefits of including ribavirin in the regimen are unclear; therefore, decisions about its use should be made on a case-by-case basis. The optimal duration of a treatment regimen for acute infection is unknown. It is reasonable to treat for at least 12 weeks; however, up to a total of 24 weeks may be considered. After 12 weeks of treatment, an HCV RNA assay should be obtained to assess the response to treatment.

## 4. Chronic Hepatitis C Infection

### Natural History of Chronic HCV Infection

Most persons infected with HCV develop chronic infection; however, a small subset of newly infected persons are able to clear the virus spontaneously. Chronic HCV infection frequently results in high levels of HCV RNA in the blood, ranging from  $10^5$  to  $10^7$  international units (IU)/mL, despite the presence of HCV antibodies. The majority of persons with chronic HCV infection are asymptomatic. Chronic HCV infection has an unpredictable course, frequently characterized by fluctuations in ALT levels that may or may not be associated with significant liver disease. Approximately one-third of persons with chronic HCV infection have no laboratory or biopsy evidence of liver disease.

A small, but significant subset of persons with chronic HCV infection develop progressive fibrosis of the liver that leads to cirrhosis. Transfusion-acquired HCV is more likely to lead to cirrhosis. High levels of alcohol consumption, older age at the time of infection, HIV infection, chronic HBV infection, and male gender are associated with an increased risk of disease progression. However, neither the degree of viremia (“viral load”) nor the HCV genotype affect the progression of liver disease. Other factors that appear to increase the risk of cirrhosis, and decrease the response to antiviral therapy, include: hepatic steatosis, marked necroinflammation on biopsy, and certain host immunologic characteristics. Once cirrhosis develops in persons with chronic HCV infection, the risk of hepatocellular carcinoma (HCC) is about 1–4% per year. HCV accounts for one-third of the cases of HCC in the U.S. each year.

## Stepwise Approach for Detecting, Evaluating, and Treating Chronic Hepatitis C

Current antiviral treatment for hepatitis C has significant limitations in terms of both efficacy and toxicity. With this in mind, the BOP has developed a stepwise, systematic approach to hepatitis C detection, evaluation, and treatment. Table 3 below lists the ten steps in this process.

**Table 3. Steps for Detecting, Evaluating, and Treating Chronic Hepatitis C in the BOP**

<p><b>Step 1.</b> Appropriately screen inmates for hepatitis C.</p> <p><b>Step 2.</b> Provide initial medical follow-up for anti-HCV positive inmates.</p> <p><b>Step 3a.</b> Determine if hepatitis C treatment is <i>not</i> recommended.</p> <p><b>Step 3b.</b> Monitor HCV-infected inmates who are <i>not</i> on treatment.</p> <p><i>For inmates who may be eligible for hepatitis C treatment, proceed as follows:</i></p> <p><b>Step 4.</b> Obtain HCV RNA assay and HCV genotype.</p> <p><b>Step 5.</b> Assess liver fibrosis and need for a liver biopsy.</p> <p><b>Step 6.</b> Determine if treatment should be initiated.</p> <p><b>Step 7.</b> Conduct a pre-treatment evaluation.</p> <p><b>Step 8.</b> Determine appropriate treatment and obtain informed consent.</p> <p><b>Step 9.</b> Manage side effects and monitor treatment response.</p> <p><b>Step 10.</b> Assess for sustained viral response (SVR).</p>
--

Following is a discussion of Steps 1–10 for detecting, evaluating, and treating chronic hepatitis C. The actual components of each step are presented in [Appendix 2](#).

### **[Step 1.](#) Appropriately screen inmates for hepatitis C.**

**Inmate Education:** Appropriately trained personnel should provide newly incarcerated inmates with educational information on the transmission, natural history, and medical management of HCV infection, in accordance with BOP policy. Health education efforts should make use of the BOP peer-oriented video on infectious diseases, *Staying Alive*, as well as [Appendix 1](#), *Inmate Fact Sheet on Hepatitis C Viral Infections*, and other available patient educational tools (see [Appendix 7](#)).

**Screening Criteria:** For *sentenced inmates* with hepatitis C risk factors, screening is recommended at the prevention baseline visit. In addition, all inmates with certain clinical conditions should be screened for hepatitis C, *regardless of sentencing status*. [Appendix 2–Step 1](#) lists the risk factors and clinical indications that should trigger screening for hepatitis C viral infection.

**Screening Method:** The preferred screening test for HCV infection is an immunoassay (e.g., EIA or CIA) that measures antibodies to HCV antigens.

**Screening of Non-Sentenced Inmates:** Unless clinically indicated, screening should ordinarily not be pursued for asymptomatic, highly mobile, non-sentenced inmates. However, non-sentenced inmates who have a history of injection drug use or other high-risk behaviors for HCV should be provided with counseling. Education should cover the risks for HCV infection, as well as behaviors that would reduce transmission of HCV infection during incarceration and upon release. Referrals to community HCV testing sites should be made when appropriate. **Exception:** *Long-term inmates in BOP detention facilities should be screened for HCV infection in accordance with the guidelines for sentenced inmates.*

**Refusal of Testing:** Sentenced inmates who have HCV risk factors—and refuse testing at the baseline visit—should be counseled about HCV testing during periodic preventive health visits.

**Step 2. Provide initial medical follow-up for anti-HCV positive inmates.**

**Baseline Evaluation:** A baseline clinician evaluation should be conducted for all inmates who are anti-HCV positive. At minimum, this evaluation should include the following:

- **Targeted history and physical examination:** Evaluate for signs and symptoms of liver disease, quantify prior alcohol consumption, and determine risk behaviors for acquiring HCV infection. Attempt to estimate and document the earliest possible date of infection, including when risk factors for exposures started and stopped, e.g., the time period in which the inmate engaged in injection drug use. Evaluate for other possible causes of liver disease, especially alcoholism, nonalcoholic steatohepatitis (NASH), iron overload, and autoimmune hepatitis.
- **Laboratory tests:** Recommended baseline laboratory tests are listed in [Appendix 3](#). However, until it is determined that an inmate is a potential candidate for treatment (see *Steps 3a–b*, below), *do not* obtain an HCV RNA, or an HCV genotype, or a liver biopsy.

**Patient Education:** Inmates diagnosed with chronic HCV infection should be counseled by a health care provider regarding the natural history of the infection, potential treatment options, and specific measures to prevent transmitting HCV infection to others (both during incarceration and upon release). Key messages about preventing HCV transmission for inmates are listed in [Appendix 1](#). Sources for hepatitis C patient educational materials are listed in [Appendix 7](#).

**Preventive Health Measures:** All inmates who are anti-HCV positive should be evaluated to assess the need for the preventive health interventions outlined in [Appendix 2–Step 2](#).

**Step 3a. Determine if hepatitis C treatment is *not recommended*.**

Next, determine if treatment for hepatitis C is *not recommended* based on the following four criteria:

1. **Pegylated interferon is contraindicated.** Inmates with chronic HCV infection who are being considered for antiviral therapy should first be assessed for contraindications to interferon, as listed in [Appendix 2–Step 3a](#). Inmates with contraindications to interferon cannot be treated for hepatitis C. **Note:** *Those with contraindications to ribavirin can be considered for peginterferon monotherapy.*
2. **The inmate will be incarcerated for an insufficient period of time for completing treatment.** Inmates who are candidates for hepatitis C treatment, but whose anticipated length of stay will not allow sufficient time to complete therapy, should *ordinarily* not be started on antiviral therapy unless continuation of treatment within the community is deemed likely. This includes inmates housed in short-term BOP detention facilities (including pre-trial and non-sentenced federal detainees), or

inmates whose anticipated release date will not allow sufficient time to complete treatment.

The potential for interruption of antiviral therapy for hepatitis C places an inmate at risk for a number of adverse outcomes, including: *treatment failure*, if the course of treatment is not completed, and *adverse effects from medications*, if the inmate does not receive the required laboratory and clinical monitoring upon release or transfer.

*Note: Inmates entering BOP custody who are currently being treated for hepatitis C should be maintained on antiviral therapy (unless medically contraindicated). They should be evaluated and monitored in accordance with BOP guidelines. Consult with a Central Office physician if there are questions regarding continuation of therapy.*

- 3. The inmate has an unstable medical or mental health condition which precludes hepatitis C treatment**, e.g., refractory HIV-infection with AIDS, uncontrolled diabetes mellitus, life-threatening COPD or CHF, or uncontrolled depression.
- 4. The inmate refuses treatment.** Inmates should initially be provided with counseling about hepatitis C treatment. If an inmate then refuses the possibility of treatment, the refusal should be documented in the medical record.

**If any one of the above four criteria are present, hepatitis C treatment should not be pursued.**

*Document in the medical record why hepatitis C treatment is not currently recommended. No further hepatitis C testing is indicated at this time, including HCV RNA testing, HCV genotyping, or liver biopsy.* However, continue to monitor the inmate, as discussed in Step 3b below.

**Step 3b. Monitor HCV-infected inmates who are *not* on treatment.**

HCV-infected inmates for whom treatment is *not recommended* should continue to be followed in the Chronic Care Clinic, and evaluated periodically to determine if hepatitis C treatment should be reconsidered. Monitoring recommendations are outlined in [Appendix 2–Step 3b](#).

*For inmates who may be eligible for hepatitis C treatment, proceed as follows:*

**Step 4. Obtain HCV RNA assay *and* HCV genotype.**

**HCV RNA:** The detection of anti-HCV by immunoassay in a person who has risk factors for acquiring HCV infection strongly suggests prior infection. However, before initiating antiviral therapy, an HCV RNA level (viral load) is required in order to confirm chronic infection and guide therapy. If the HCV RNA level is undetectable, the individual can be considered uninfected. Possible explanations include either host clearance of viremia or a “false-positive” immunoassay result.

**Notes:**

- (1) Strict adherence to current reference laboratory test processing guidelines for HCV RNA test samples is essential; viral RNA is unstable, and false negative tests may result from inadequate or inappropriate processing.*
- (2) For monitoring purposes, it is important to use the same laboratory test before and during therapy.*
- (3) The RIBA supplemental test is no longer recommended for diagnosing chronic HCV infection.*

**HCV Genotype:** An HCV genotype must also be obtained prior to treatment initiation and should be requested in conjunction with the initial HCV RNA. The HCV genotype significantly influences the evaluation strategy, patient counseling messages, the decision to treat, and the duration of therapy.

Treatment response varies markedly by HCV genotype. Those with genotypes 2 or 3 have a 70-80% response rate to pegylated interferon/ribavirin therapy, compared to a 40–45% response rate for genotype 1. Repeat genotype testing is not indicated, except in the rare instance when re-infection is suspected.

**Step 5. Assess liver fibrosis and need for a liver biopsy.**

In patients with chronic hepatitis C, liver biopsy has been the primary means for determining the stage of the liver disease and the need for treatment. In general, patients treated for HCV should have “more than portal fibrosis.” General criteria for liver biopsy are outlined in [Appendix 2–Step 5](#). Those with genotype 1 will ordinarily require a biopsy. *Inmates with genotype 2 or 3 usually do not need a biopsy unless they are HIV-infected or another source of liver disease is suspected.*

**Calculation of APRI:** Recent data indicate that the degree of liver fibrosis is correlated with the AST/Platelet Ratio Index (APRI), a simple ratio of two common lab values. Higher APRI values have been associated with higher stages of liver fibrosis on biopsy. Therefore, BOP institutions should utilize APRI values when prioritizing referral of inmates with genotype 1, 4, 5, or 6 for liver biopsies. Inmates who have an APRI of less than 0.5 are lower priority for biopsy; inmates who have an APRI of greater than 0.5 are higher priority for biopsy—with the higher the APRI, the higher the priority for biopsy. The APRI calculation is provided below in Table 4.

**Table 4. AST/Platelet Ratio Index (APRI) Calculation**

<b>Formula:</b> $\{AST \div \text{lab upper limit of normal (ULN)}^* \text{ for AST} \times 100\} \div \{\text{platelet count} \div 1,000\}$	
<b>Simple example:</b>	<b>Calculation of APRI:</b>
AST = 80	$\{AST \div ULN \times 100\} \div \{\text{platelet count} \div 1,000\}$
AST laboratory ULN = 40	$\{80 \div 40 \times 100\} \div \{100,000 \div 1,000\}$
Platelet count = 100,000	$200 \div 100 = \mathbf{2.0} = \text{APRI}$
* Use “upper limit of normal (ULN)” value that is used by the laboratory that ran the AST test.	

- **Interpretation of Liver Biopsy Results:** Histologically, fibrosis progresses along a continuum, with portal fibrosis representing an earlier stage of fibrosis and cirrhosis representing a late (or advanced) stage of fibrosis. The intermediate stages of fibrosis—periportal fibrosis and bridging fibrosis—as determined histologically, are generally recognized as the most appropriate stage for initiating treatment. These intermediate stages of fibrosis correlate with the IASL, Ludwig and Metavir Stages “2” and “3,” and the Ishak stages “3” and “4.” Regardless of genotype, treatment should be considered with liver biopsy results as follows: IASL, Batts & Ludwig, or Metavir  $\geq$  Stage 2; or Ishak  $\geq$  Stage 3.

The primary scoring systems for staging hepatic fibrosis on liver biopsy are compared in Table 5 (next page).

**Table 5. Scoring Systems for Hepatic Fibrosis (IASL Ishak, Metavir, and Batts & Ludwig)**

Score	IASL	Batts & Ludwig	Metavir	Ishak
0	No fibrosis	No fibrosis	No fibrosis	No fibrosis
1	Mild fibrosis	Fibrous portal expansion	Periportal fibrotic expansion	Fibrosis expansion of some portal areas, with or without short fibrous septa
2	<b>Moderate fibrosis</b>	<b>Rare bridges or septae</b>	<b>Periportal septae (&gt;1 septum)</b>	Fibrous expansion of most portal areas, with or without short fibrous septa
3	<b>Severe Fibrosis</b>	<b>Numerous bridges or septae</b>	<b>Portal-central septae</b>	<b>Fibrous expansion of most portal areas, with occasional portal-portal bridging</b>
4	<b>Cirrhosis</b>	<b>Cirrhosis</b>	<b>Cirrhosis</b>	<b>Fibrous expansion of most portal areas, with marked bridging (portal-portal and portal-central)</b>
5				<b>Marked bridging (portal-portal and portal-central) with occasional nodules (incomplete cirrhosis)</b>
6				<b>Cirrhosis, probable or definite</b>

**Note:** The shaded areas with the **bolded** text indicate a significant liver biopsy result with a degree of fibrosis for which antiviral therapy should be considered.

**Reference:** Ghany, et al. AASLD practice guidelines. Diagnosis, management and treatment of hepatitis C: an update. *Hepatology*. 2009; 49:1356-1358.

**Step 6. Determine if treatment should be initiated.**

Current HCV treatment has some significant limitations in terms of both efficacy and toxicity. Each inmate with chronic hepatitis C should be evaluated carefully to assess the relative risks and benefits of the following: beginning therapy immediately, delaying therapy, or deferring treatment indefinitely. Prior to initiating treatment, inmates should be counseled about the potential benefits of treatment—the likelihood of achieving a sustained viral response (SVR)—as well as the potential side effects. The rationale for treatment decisions should be documented in the medical record.

**Indications for Antiviral Therapy:** Antiviral therapy is generally indicated for inmates with chronic hepatic C if they present with at least one of the following:

- Genotype 2 or 3 (with no biopsy performed).
- Significant liver biopsy result (either IASL, Batts & Ludwig, or Metavir  $\geq$  Stage 2; or Ishak  $\geq$  Stage 3), regardless of genotype.
- Evidence of compensated cirrhosis—with or without biopsy. (Compensated cirrhosis is defined as bilirubin  $<1.5$  mg/dL; INR  $<1.5$ ; albumin  $>3.4$  g/dL; and platelet count  $>75,000/\text{mm}^3$ ; as well as *no evidence of*: ascites, esophageal varices, or hepatic encephalopathy).

**Special Considerations Related to Initiating Antiviral Therapy:** The following co-morbidities, while not absolute contraindications, should be carefully assessed when considering whether or not to initiate antiviral treatment.

- **Mental illness:** Interferon can cause or exacerbate depression, and does cause some mood changes in virtually all patients. Therefore, inmates who have a history of major depression should be screened by a psychologist or a psychiatrist, and receive counseling on the risk of relapse of their depression posed by interferon treatment. For these patients, careful consideration should be given to prophylactic treatment of depression. Utilize an SSRI (or the antidepressant that was most successful in treating the patient's prior episodes of depression) for a period of three-to-six months prior to initiating interferon therapy. Similarly, other major psychiatric illnesses such as bipolar disorder, schizophrenia, and schizoaffective disorder should be well-controlled with stable doses of medication for at least six months prior to initiating interferon. Inmates with severe axis II diagnoses should be assessed by a mental health professional for their ability to comply with the frequent clinical and laboratory monitoring that is required for the safe administration of pegylated interferon and ribavirin.
- **Alcohol:** HCV-infected inmates with significant alcohol abuse histories should receive specific counseling messages. Heavy and prolonged alcohol use is an independent risk factor for the development of cirrhosis, and alcohol accelerates the progression of HCV-related fibrosis. *Hepatitis C treatment without abstinence from alcohol is unlikely to be of benefit.* The treatment response to peginterferon plus ribavirin is significantly reduced in individuals who drink more than 30 grams of alcohol per day, and perhaps with lower levels of consumption, as well.

An inmate's unwillingness to abstain from alcohol intake while incarcerated is a potential indicator of alcoholism and should be evaluated. Effective treatment for alcoholism should be offered in prison to as many HCV-infected inmates as possible, whether or not they have been administered hepatitis C treatment or have responded to such treatment.

- **Substance abuse:** Inmates who are significant abusers of substances other than alcohol may have a number of medical issues that can affect or be affected by hepatitis C treatment. Injection drug users are often at risk for HIV, HBV, endocarditis, and possible re-infection with HCV. Amphetamine and cocaine abuse may result in cardiovascular complications. Ongoing substance use in the controlled environment of prison or jail is, at best, an indicator that the inmate is not taking adequate responsibility for his or her overall health. Treatment decisions must be individualized where these issues are present.

**Patient Counseling:** In weighing treatment options, the following factors should be considered and discussed with the inmate:

- For those with chronic hepatitis C infection, the risk of developing cirrhosis ranges from 5% to 25%, and usually occurs over a period of 25—30 years after initial infection.
- It is difficult to predict which HCV-infected persons will develop cirrhosis *or* who will respond to treatment.
- The rate of sustained viral response varies significantly by genotype: 70–80% for genotypes 2 and 3, compared to only 40–45% for genotype 1.
- Although current antiviral therapy is usually well-tolerated, there are many—and sometimes serious—side effects to antiviral therapy.
- Close adherence to the drug regimen is essential to increase the likelihood of “cure.”
- Future hepatitis C treatments may be more effective and better tolerated than those currently available.
- Patients must be willing to be treated and willing to conform to the treatment requirements, including abstinence from alcohol and illicit drugs.

- Treatment during pregnancy is generally contraindicated. Because treatment with ribavirin is known to be teratogenic, pregnancy must be avoided during treatment and for the six months after treatment is completed—in both female patients and the female partners of male patients.

### **Step 7. Conduct a pre-treatment evaluation.**

Inmates should be evaluated by a physician and screened for other medical conditions that may complicate antiviral therapy. Lab work and tests should be obtained in accordance with the time frames enumerated in the BOP Algorithm for Treatment of Hepatitis C – Approval Form (BP-A803.060).

- **Laboratory tests:** See [Appendix 3](#) for list of recommended baseline laboratory tests.
- **Baseline assessment of visual acuity.**
- **Funduscopy** for inmates with diabetes or other ophthalmologic disorders.
- **Pregnancy test for all female inmates:** Ribavirin may cause fetal abnormalities. All female inmates of childbearing potential must have a pregnancy test *immediately prior to* initiating therapy and *monthly* thereafter up to at least 6 months post-treatment.
- **Cardiac risk assessment:** A basic cardiac risk assessment, performed by a clinician prior to treatment initiation, is critical because the hemolysis associated with ribavirin may precipitate angina pectoris. An electrocardiogram should be obtained in inmates with preexisting cardiac disease. Symptomatic inmates should be carefully evaluated for cardiac disease prior to initiating treatment.
- **Other patient-specific diagnostic tests** as medically indicated.
- **Mental health evaluation:** Before prescribing interferon and ribavirin therapy, a psychiatrist or psychologist should perform a mental health evaluation: to determine if mental health treatment is warranted prior to antiviral therapy and whether ongoing mental health assessments are needed during treatment.
  - ▶ The evaluation should include an assessment of axis I and axis II diagnoses, including a comprehensive alcohol and substance abuse history and a suicide risk assessment. Interferon therapy has been associated with changes in mood and affect in most individuals. In a small percentage of patients undergoing interferon therapy, significant depression, suicide attempts, and completed suicides have resulted. A patient’s history of depression or suicide attempts should prompt heightened vigilance on the part of the treating providers; however, since the absence of such a history does not appear to lessen the risk of these side effects from interferon, *all patients should be carefully monitored for changes in mood.*
  - ▶ Other mental illnesses or conditions, if not treated or not in remission, may adversely affect the inmate’s ability to successfully complete a course of antiviral treatment, due to issues of compliance or to an inability to tolerate even mild side effects.
- **Evaluation of inmates with compensated cirrhosis:** Prior to treatment initiation, inmates with suspected or biopsy-confirmed, compensated cirrhosis should have a liver-spleen ultrasound or abdominal CT scan, and measurements of alpha-fetoprotein. If the ultrasound result points to the possibility of portal hypertension (marked splenomegaly, ascites, retrograde flow through the portal vein), then an upper endoscopy screening for esophageal varices should be performed. CT often reveals esophageal varices, which must then be endoscopically visualized to determine size and extent. *If hepatocellular carcinoma (HCC) or decompensated cirrhosis is diagnosed, antiviral therapy is contraindicated.*

**Step 8. Determine appropriate treatment and obtain informed consent.**

**Standard Treatment:** The current, standard treatment for chronic hepatitis C involves once-weekly injections of pegylated interferon (peginterferon alfa) and daily oral ribavirin. For persons who have contraindications to ribavirin, peginterferon can be administered as monotherapy. *Ribavirin is completely ineffective as monotherapy and should never be prescribed without interferon.*

- Standard duration of treatment is based on genotype:

<b>Genotypes 1</b>	48 weeks
<b>Genotypes 2, 3</b>	24 weeks

- The optimal duration of treatment for genotypes 4, 5, 6, or non-typable HCV is unknown; these patients should be treated with the 48-week course recommended for genotype 1.
- The duration of treatment will vary, based on the documented response to treatment and the occurrence of side effects (see [Appendix 2–Step 9](#) and [Appendices 4a](#) and [4b](#)).
- Inmates who have contraindications to ribavirin, regardless of genotype, should be treated with a 48-week course of pegylated interferon alone.
- Detailed drug dosages, monitoring parameters, and potential side effects are outlined in [Appendix 2–Step 8](#) and [Appendix 5](#).
- Treatment of chronic hepatitis C is complex and may require expert consultation.

**Pretreatment consent:** Pegylated interferons and ribavirin have significant potential side effects, which are outlined in [Appendix 5](#) and should be discussed with the patient prior to treatment initiation. The “Consent to Treatment of Interferon/Ribavirin” (form BP-A806.060, available on Sallyport) must be reviewed with the inmate and then signed by the inmate and the attending physician, *prior to administering the first dose.*

**Step 9. Manage side effects and monitor treatment response.**

Recommended baseline, pre-treatment, and ongoing clinical evaluations and laboratory studies are summarized in [Appendix 3, Hepatitis C Treatment Monitoring Schedule](#). At a minimum, inmates receiving antiviral treatment should be clinically evaluated at *weeks 1, 2, and 4*, and then *monthly* thereafter. At each visit, patients should be assessed for drug side effects and potential complications. Those with compensated cirrhosis, HIV infection, or other co-morbid conditions will require more frequent monitoring, as will those who develop significant side effects or complications during therapy. While inmates are taking interferon, psychiatry and psychology consultations should be provided, as clinically indicated.

Throughout the patient’s treatment for hepatitis C, the clinician’s evaluations should be directed at inquiring about the common side effects of interferon and ribavirin in order to make decisions about dose adjustments; investigate new symptoms such as chest pain, dyspnea, or visual changes; or reassure the inmate that he or she is experiencing “normal” side effects of treatment.

**Assessment and Management:** Assessment and management of the more frequently occurring side effects from HCV treatment are discussed below.

- Flu-like symptoms:** Muscle aches, headaches, and low-grade fevers are experienced by over 80% of patients taking interferon. Patients should be counseled to expect these symptoms, usually about 48

hours after the weekly injection, and resolving 24–48 hours before the next injection. These symptoms usually appear after the third or fourth dose of pegylated interferon, and tend to subside after about 3 months of treatment. Acetaminophen, up to 2 grams per day, and increased fluid intake may be recommended to manage these symptoms. Flu-like symptoms can be treated prophylactically by administering 1 gram of acetaminophen 30 minutes prior to peginterferon injection. ***Nonsteroidal anti-inflammatory agents (NSAIDs) ordinarily should not be prescribed because of hepatotoxicity and the underlying liver disease.***

- **Mood changes:** Virtually all inmates on interferon will experience at least some irritability. This should be discussed at each visit to determine if other symptoms of depression are developing. A low threshold for initiating an SSRI should be maintained while inmates are taking interferon.
- **Rashes:** A variety of dermatologic conditions are associated with both the HCV infection and the interferon/ribavirin treatment. New rashes during treatment are usually mild and self-limited, or respond to topical low-potency corticosteroids.
- **Chest pain:** New onset of chest pain during HCV treatment should be presumed to be angina pectoris until proven otherwise. The development of anemia during treatment can precipitate angina in individuals with occult coronary artery stenosis.
- **Visual disturbances:** Ischemic retinopathy and retinal or vitreous hemorrhages can occur during interferon therapy, though rarely. The risk may be greater in diabetic patients. These inmates should be counseled to immediately report any changes in vision. A baseline retinal examination prior to treatment is recommended for diabetics and those with preexisting ophthalmologic disorders, with fundoscopic examinations performed periodically and as clinically indicated during treatment.
- **Hair loss:** Alopecia areata occurs in approximately 20% of patients on HCV treatment. Inmates should be advised of this possibility, but also informed that this is self-limited after completion of treatment.
- **Thyroid dysfunction:** Approximately 4% of persons treated with interferon develop thyroid dysfunctions that may result in irreversible thyroid dysfunction—even with cessation of drug therapy. The occurrence of *hypothyroidism* usually can be managed with hormone replacement therapy while continuing interferon, on a case-by-case basis. Occurrence of *hyperthyroidism* usually necessitates discontinuation of interferon.
- **Anemia:** A common complication of antiviral therapy is anemia. Ribavirin causes a dose-related hemolysis; whereas, interferon can suppress red blood cell production. Patients who develop refractory anemia, progressive anemia beyond 8 weeks of treatment, or develop anemia late in the course of therapy should have a thorough evaluation for other treatable causes of anemia, such as iron deficiency anemia, gastrointestinal blood loss, and excessive menstrual blood loss. Specific strategies for managing drug-induced anemia are dependent on the degree of anemia, the presence of complicating co-morbidities such as heart disease, and the patient's virologic response to antiviral therapy. Guidance regarding drug dosage adjustments, and criteria for the use of recombinant erythropoietin, are outlined in [Appendix 2–Step 9](#).
- **Neutropenia:** Interferon-induced bone marrow suppression may cause neutropenia. The majority of the patients who develop neutropenia while on interferon have few serious side effects. Patients with cirrhosis are at higher risk of neutropenic complications, such as sepsis, and should be followed closely. Specific strategies for neutropenia management are dependent on the degree of neutropenia, the extent of liver disease, the presence of co-morbidities that predispose to infection, and the patient's virologic response to antiviral therapy. Guidance regarding interferon dosage adjustments and criteria for the use of granulocyte colony stimulating factor are outlined in [Appendix 2–Step 9](#).

- **Thrombocytopenia:** Thrombocytopenia from bone marrow suppression is a potentially serious complication of interferon therapy, particularly in patients with cirrhosis who may have low platelet counts from the liver disease itself. Patients with thrombocytopenia should be monitored closely while on antiviral therapy. Interferon should be dose-adjusted or discontinued, based on the degree of thrombocytopenia, as outlined in [Appendix 2–Step 9](#).

**Treatment Duration and Maintenance:** The recommended duration of antiviral therapy varies by HCV genotype, and assessment of the patient’s response to therapy is based on HCV RNA test results at certain intervals in the treatment process, as shown in Table 6 below.

**Table 6. HCV Treatment Response Categories**

Testing Interval	If HCV RNA test shows ...	The result is considered ...
End of week 4*	Undetectable HCV RNA	<b>RVR</b> – rapid viral response
End of week 12*	≥2 log <sub>10</sub> reduction in HCV RNA	<b>EVR</b> – early viral response
End of recommended treatment period	Undetectable HCV RNA	<b>ETR</b> – end of treatment response (at treatment completion)
24 weeks later**	Undetectable HCV RNA	<b>SVR</b> – sustained viral response (potential cure)

\* The viral response at week 4 and week 12 is closely correlated with treatment success.  
\*\* For more information on assessing patients for SVR, see Step 10.

**Recommended treatment duration for genotypes 1, 4, 5, and 6:**

- ▶ The standard recommended duration of treatment for genotypes 1, 4, 5, and 6 is 48 weeks.
- ▶ Failure to achieve an EVR at 12 weeks is considered treatment failure. *Treatment should be discontinued.*
- ▶ If an EVR at 12 weeks is achieved, but HCV RNA is still detectable, the HCV RNA test should be repeated at 24 weeks of treatment. Detectable HCV RNA at 24 weeks is considered treatment failure. *Discontinue treatment.*
- ▶ If the patient fails to achieve an RVR at 4 weeks, but does have an EVR at 12 weeks, then 48 weeks of treatment is usually sufficient.
- ▶ It may be beneficial to extend treatment for a total of 72 weeks if the patient did not have an RVR at 4 weeks *and/or* had an EVR at 12 weeks but still had detectable virus at that time.
- ▶ For patients who achieve an RVR at 4 weeks, but experience significant side effects, 24 weeks of treatment may be sufficient. Discontinuation of therapy after at least 24 weeks of treatment can be considered on a case-by-case basis in consultation with an expert.

**Recommended treatment duration for genotypes 2 and 3:**

- ▶ The standard recommended treatment duration for genotypes 2 and 3 is 24 weeks.
- ▶ Failure to achieve an EVR at 12 weeks is considered treatment failure. *Discontinue treatment.*
- ▶ For patients who achieve an RVR at 4 weeks, but experience significant side effects, 16 weeks of treatment may be sufficient. Discontinuation of therapy after 16–20 weeks of therapy can be considered on a case-by-case basis in consultation with an expert.

➡ See [Appendices 4a and 4b, Timeline for HCV Treatment Decisions](#), to see these recommendations in flowchart format.

**Step 10. Assess for sustained viral response (SVR).**

An HCV RNA test should be obtained 24 weeks after the treatment is completed. A sustained viral response (SVR) is defined as undetectable HCV RNA at 24 weeks after completion of the treatment. If an SVR is achieved, the infection is considered eradicated. Patients who achieve an SVR should have an HCV RNA test obtained one year following the end of their treatment. Those who have undetectable HCV RNA at this time can be discontinued from the Chronic Care Clinic (unless there are other medical problems or concerns regarding the possibility of re-infection).

**Considerations Regarding Re-Treatment:** Patients who do not achieve an SVR from antiviral therapy can be categorized as having a “non-response” or “relapse,” as defined in [Appendix 2–Step 9](#). Re-treatment of relapsers and nonresponders should be considered on a case-by-case basis with the approval of the Central Office HSD, and with consideration of the following guidance:

- For nonresponders and relapsers to *non-pegylated* interferon (with or without ribavirin), re-treatment with pegylated interferon alfa and ribavirin should be considered on a case-by-case basis. Regardless of genotype, the duration of re-treatment is at least 48 weeks (in those who demonstrate a virologic response).
- Non-responders and relapsers to a regimen of pegylated interferon and ribavirin will ordinarily not be re-treated.
- For inmates who are eligible for re-treatment, it should only be considered for those who are the most likely to benefit from therapy and who are at significant risk of disease progression.
- Consensus interferon (interferon alfacon-1) is not recommended as an alternative re-treatment for nonresponders to a pegylated interferon and ribavirin regimen, due to the need for daily administration, as well as low response rates.
- Long-term antiviral maintenance therapy for nonresponders has been found to be ineffective and should not be prescribed.

**Note:** *This is the last of the steps in the Stepwise Approach for Detecting, Evaluating, and Treating Chronic Hepatitis C. Section 4. “Chronic Hepatitis C Infection” continues below.*

\*\*\*\*\*

## Complicating Medical Conditions

### Compensated and Decompensated Cirrhosis

**Compensated cirrhosis** is defined as: bilirubin <1.5 mg/dL; INR <1.5; albumin >3.4 g/dL; and platelet count >75,000/mm<sup>3</sup>; as well as *no evidence of*: ascites by liver ultrasound, esophageal varices by upper endoscopy, or hepatic encephalopathy.

**Decompensated cirrhosis** is defined as: evidence of significant liver disease (such as ascites, encephalopathy, marked thrombocytopenia, and bleeding esophageal varices), as well as loss of liver synthetic function (e.g., albumin ≤ 3.4 g/dL, and INR ≥1.5).

Inmates with HCV-related *compensated cirrhosis* can usually be treated with a standard regimen of pegylated interferon with ribavirin. However, they have a higher rate of associated side effects and should be monitored more closely.

Inmates with hepatitis C and evidence of *decompensated cirrhosis* should be referred to a Medical Referral Center for medical management. Antiviral therapy is ordinarily contraindicated in such patients, particularly if there is evidence of ascites or hepatic encephalopathy. Inmates with an isolated lab value indicating mild impairment in hepatic synthetic function, e.g., slightly depressed albumin or elevated INR, should be considered for treatment on a case-by-case basis.

### **Renal Insufficiency**

Persons with HCV infection have an increased risk of renal disease that may be associated with cryoglobulinemia, and histologic findings that resemble idiopathic membranoproliferative glomerulonephritis (MPGN). Clinical manifestations include hematuria, proteinuria that is often in the nephrotic range, and a variable degree of renal insufficiency. Inmates with moderate-to-severe kidney disease (e.g., nephrotic syndrome, elevated plasma creatinine concentration, new hypertension, fibrosis, or tubulointerstitial disease on biopsy) should be considered for antiviral therapy for HCV infection, even in the absence of a degree of liver disease that ordinarily warrants antiviral therapy. Specific treatment regimens should be individualized in consultation with a Central Office physician and available physician experts. Ribavirin should not be administered if the creatinine is  $\geq 1.5$  mg/dL or the estimated GFR is  $< 50$  mL/min. Dose adjustments should be considered if the GFR is between 51–75 mL/min. Ribavirin should not be administered to patients on dialysis.

### **Hemodialysis**

The goal of treating hepatitis C in persons with end-stage renal disease is to reduce the progression of liver disease and/or to clear the HCV infection in patients who may later undergo renal transplantation. Evaluation of these patients is complicated by several factors: (1) ALT levels are more likely to be normal or near-normal in hemodialysis patients, even in the presence of significant fibrosis; (2) the need for a liver biopsy must be balanced against the increased risk of severe bleeding; and (3) hepatitis C treatment should be considered prior to referring the inmate for transplant (in consultation with a nephrologist). Subspecialty referral is required. Those on hemodialysis must be treated with interferon monotherapy (not with ribavirin). See [Appendix 5](#) for dosing with hemodialysis.

### **HBV and HCV Co-Infections**

Coexistent infection with both HBV and HCV is estimated to be present in 10–15% of individuals with chronic hepatitis, cirrhosis, or hepatocellular carcinoma. HCV superinfection in HBsAg carriers appears to reduce HBV DNA levels in serum and liver tissues and to increase the rate of HBsAg seroconversion. Most patients who have dual HCV and HBV infections have detectable serum HCV RNA, but undetectable or low HBV DNA levels, which indicates that HCV is the predominant cause of liver disease in these patients. However, in about one-third of patients, levels of HBV DNA and HCV RNA fluctuate over time. Liver disease in co-infected individuals is usually more severe than in patients infected by HBV alone. Patients with dual HBV and HCV infection may also have a higher rate of HCC, compared to patients infected by either virus alone, particularly those who are anti-HCV and HBeAg positive.

*Antiviral therapy for inmates with HBV and HCV co-infections should be initiated with great caution, and only in consultation with a specialist, due to the uncertainty of the risks and benefits of treatment and the lack of a recommended treatment regimen. All cases that may be candidates for treatment should be reviewed with a physician with expertise in viral hepatitis treatment, and should be approved via the Central Office nonformulary review process.*

## HIV and HCV Co-Infections

The usual approach for screening for HCV infection should be applied to HIV-infected inmates. HIV-infected person with unexplained liver disease, a CD4 + T-cell count  $<500$  cells/mm<sup>3</sup>, and who are anti-HCV negative should have an HCV RNA assay obtained.

Patients co-infected with HIV and HCV have a 2-fold increased risk of cirrhosis compared to those with HCV infection alone; thus they are high priority among potential candidates for treatment. However, HCV treatment response rates are lower in HIV-infected patients, and they have a higher risk of serious adverse effects. Listed below are general recommendations related to the treatment of HCV/HIV co-infection. Prior to initiating treatment, consultation with an expert is recommended.

- 1. Co-infected patients whose HIV infection is controlled and who have a significant liver biopsy result** (either IASL, Batts & Ludwig, or Metavir  $\geq$  Stage 2; or Ishak  $\geq$  Stage 3) **should be considered for HCV antiviral therapy.**
- 2. Treatment for HIV and HCV infections should *not* be initiated simultaneously.** If the inmate is a strong candidate for HIV treatment (AIDS or CD4+ T-cell count  $<350$  cells/mm<sup>3</sup>), he or she should be treated first with HIV antiretroviral therapy. If not, consider initiating HCV antiviral therapy prior to initiating HIV treatment. It is generally recommended that several months elapse after initiating HIV antiretroviral therapy prior to initiating HCV treatment—so that adverse effects associated with the antiretroviral therapy can be distinguished from those associated with HCV treatment.
- 3. Patients should be treated with peginterferon alfa and ribavirin at doses similar to those with HCV mono-infection.**
- 4. The recommended standard duration of HCV treatment is at least 48 weeks, regardless of genotype.**
- 5. Drug interactions/contraindications/adverse reactions:**
  - ▶ Didanosine should not be co-administered with either interferon or ribavirin due to the increased risk of pancreatitis and lactic acidosis.
  - ▶ Zidovudine can cause severe neutropenia and anemia when co-administered with interferon. When possible, patients receiving zidovudine (AZT) should be switched to an equivalent antiretroviral agent before beginning therapy with ribavirin.
  - ▶ Ribavirin should not be administered to a patient who is on two or more nucleoside reverse transcriptase inhibitors (NRTIs), due to the increased risk of pancreatitis and lactic acidosis.
  - ▶ Patients with HIV infection are at greater risk of hepatotoxicity with interferon/ribavirin therapy, particularly if they are on a HAART regimen. Ritonavir and nevirapine have been specifically implicated in some studies, although other studies suggest an increased risk with any HAART regimen. *ALT levels should be monitored every 1–2 months while on therapy.*
  - ▶ Cytopenias related to HCV treatment are more common. Erythropoietin and granulocyte colony stimulating factors may be required in order to continue therapy.
- 6. Monitor closely those co-infected inmates for whom treatment is deferred** (see [Appendix 2, Step 3b](#)). Calculate an APRI (see [Table 4](#), page 6 ) every 6 months. Re-biopsy should occur within 3 years.

## Latent TB and Chronic HCV Co-Infection

Inmates with latent TB infection (LTBI) and chronic HCV infection should be considered for isoniazid treatment. They should be monitored for hepatotoxicity in accordance with the same guidelines

established for latent TB patients who do not have HCV infection. All inmates require screening for symptoms of hepatitis while taking isoniazid. Those inmates with baseline ALT elevations also warrant periodic monitoring of their ALT levels.

Co-infected inmates can be treated concurrently for hepatitis C and LTBI; however, it is advisable to initiate LTBI treatment first, assess if it is tolerated, and then start hepatitis C treatment six months later. If both treatments are started at the same time, and elevations of ALT occur, it is not possible to determine which is the offending agent. Isoniazid should be discontinued in inmates with marked elevations in ALT or significant signs or symptoms of hepatitis, in accordance with BOP Guidelines for the Management of Tuberculosis.

## **5. Management of Cirrhosis**

### **Transplantation Issues**

Liver transplantation is the treatment of choice for patients with hepatic failure from chronic HBV and HCV infections. However, the lack of available donor organs limits this option, not only for inmate populations, but also for the general population. Split-liver transplantation from living donors is a promising option that may, in the foreseeable future, expand transplantation options to patients with liver failure. Even when donor livers are available, transplantation may be unsuccessful due to high rates of re-infection and progressive liver disease in the transplanted organ.

Nevertheless, inmates with hepatic failure from viral hepatitis should be assessed for eligibility for liver transplantation on a case-by-case basis by evaluating patient-specific factors such as the following: MELD scores that help predict patient mortality, medical contraindications for transplantation, mental health stability, evidence of ongoing substance abuse, criminal history factors that may negate successful transplantation, and patient motivation (as evidenced by adherence to current treatment recommendations). Inmates who are potential candidates for liver transplantation should be advised of the limited access to donor livers and, where available, be referred to local transplant centers for evaluation. If transplantation during incarceration is not feasible, inmates should be evaluated for early release, taking into consideration public safety concerns, local correctional policies, and governing laws and regulations.

### **Morbidity Assessment Based on MELD Scores**

The Model for End-Stage Liver Disease (MELD) predicts liver disease severity and the risk of three-month mortality using a “score” that is based on serum creatinine, serum total bilirubin, and prothrombin time (INR). In a study of patients with end-stage liver disease, who were awaiting liver transplantation, three-month mortality was closely correlated with MELD scores: MELD <9, mortality = 2%; MELD = 20–29, mortality = 20%; MELD = 30–39, mortality = 53%; MELD ≥40, mortality = 71%.

The value of MELD as a predictor of mortality is limited by its dependency on serum creatinine, which can fluctuate with changes in fluid status. MELD is a better predictor of mortality for particular populations than for any given individual. Nevertheless, MELD provides useful information for assessing the morbidity of inmates with end-stage liver disease.

All inmates with decompensated cirrhosis should have a MELD score determined to assess their mortality risk. MELD scores should be recalculated over several weeks for inmates with shifting fluid status. The MELD score can be calculated by utilizing a calculator provided by the United Network for Organ

Sharing, available at <http://www.unos.org/resources/MeldPeldCalculator.asp?index=98>. Data required includes: date of birth, bilirubin, creatinine, INR, and dialysis status. Inmates with MELD scores of 30 or greater should be considered for Medical Referral Center designation.

*Note: The MELD score predicts mortality, independent of clinical parameters such as hepatic encephalopathy, ascites, and variceal bleeding. These significant complications of cirrhosis, however, should also be considered in referring patients for Medical Referral Center designation.*

## Preventive Measures

The following preventive measures should be considered for inmates with cirrhosis:

- **Immunize** against influenza (annually), pneumococcal pneumonia, and hepatitis A and B (unless immune).
- **Provide patient education:**
  - ▶ Eat a low-salt, low-fat, “heart healthy” diet.
  - ▶ Completely abstain from alcohol during incarceration and after release.
  - ▶ Avoid iron supplements and potentially hepatotoxic medications, such as nonsteroidal inflammatory drugs (NSAIDs).
- **Perform a baseline upper endoscopy** to screen for esophageal varices. (Follow-up annual screening can be considered on a case-by-case basis, but the benefit of repeated screening is unclear. Once esophageal varices have been identified, the risk of future variceal hemorrhage is 25–35%.)
- **Prescribe nonselective beta-blocker therapy, such as propranolol or nadolol, for inmates with large esophageal varices or red wale markings on endoscopy.** The dose of beta-blocker should be titrated weekly to reduce the resting heart rate by 25%—without reducing the pulse to less than 55 beats/minute or the systolic blood pressure to lower than 90 mm Hg.
- **Provide primary and secondary prophylaxis for spontaneous bacterial peritonitis (SBP)** with an antibiotic such as ciprofloxacin, or trimethoprim-sulfamethoxazole (TMP-SMX). Primary prophylaxis generally involves limited treatment periods in high risk patients, such as those with upper gastrointestinal hemorrhage. Secondary prophylaxis is indicated in patients with a history of one or more prior episodes of SBP. Oral medication options include: ciprofloxacin, 750 mg weekly; or TMP-SMX DS, one tablet daily.
- **Provide prophylaxis against hepatic encephalopathy, and be alert for the common factors which cause exacerbations of encephalopathy.** Lactulose is the mainstay of both treatment and prophylaxis for hepatic encephalopathy. Lactulose lowers the gut pH and converts NH<sub>3</sub> (ammonia) to NH<sub>4</sub>, which is non-absorbable and thus excreted in the stool. Certain antibiotics such as neomycin are also sometimes prescribed to alter the gut flora and thereby decrease ammonia production. However, good, controlled studies are lacking that clearly support the use of antibiotics over lactulose; moreover, long-term use of antibiotics has the potential for bacterial overgrowth syndromes. Neomycin also has potential nephrotoxicity and ototoxicity.

The dose of lactulose (10 grams/15mL) is patient-specific, typically starting at 15–30 mL once or twice daily until the patient is having two or three soft stools per day. If this dose does not adequately address the cognitive impairments, the dose may need to be increased, causing more frequent, semi-liquid stools.

Lactulose enemas are the treatment of choice for somnolent patients with encephalopathy who are unresponsive to verbal and/or painful stimuli. One liter of 20% lactulose is infused per rectum every

hour until the patient becomes arousable. Inmates with abnormal vital signs, low pulse oximetry, or periods of apnea should be hospitalized or placed on an inpatient unit at an MRC for this treatment.

Common factors which exacerbate hepatic encephalopathy are:

- ▶ Excess dietary protein intake.
  - ▶ GI bleeding.
  - ▶ Infections (increased temperature results in dehydration).
  - ▶ Sedative/hypnotic and opiate use (even at “typical” doses).
  - ▶ Overzealous diuresis with loop diuretics. (Decreased potassium and decreased plasma volume result in increased ammonia levels. Titrate diuretics incrementally, and correct hypokalemia when detected.)
- **Screen for hepatocellular carcinoma (HCC).** Inmates with chronic HCV infection and cirrhosis are at increased risk for HCC. Although the optimal screening strategy is uncertain, a liver ultrasound should be considered every six months as the safest and most cost-effective approach. Screening should be conducted regardless of whether or not the inmate has been treated for hepatitis C. Serum alpha-fetoprotein screening is of limited use, since it is not usually elevated to a significant level until the tumor is at least 2 cm—which is easily detectable on ultrasound in virtually all patients. CT scanning should ordinarily not be used in lieu of ultrasound for HCC screening, due to the high radiation exposure that would be anticipated over ten or more years of biannual scans.

HCC screening should begin when the inmate is found to have cirrhosis—whether by history, by liver biopsy, by presentation of decompensation such as bleeding esophageal varices or hepatic encephalopathy, or based on a pattern of clinical or laboratory findings. Ultrasound screening should be conducted on any HCV-infected inmate with the typical laboratory findings of cirrhosis, which include an inverted AST/ALT ratio, an albumin less than 3.4, and a platelet count less than 120–140K. An AST to platelet ratio index (APRI) significantly greater than 1.5 is also strongly suggestive of cirrhosis, and may be used as an independent marker to start screening for HCC (see [Table 4](#) on page 6 for calculation).
  - **Manage pruritus.** Pruritus in cirrhosis is thought to be due to increased bile acids from cholestasis, as well as possibly an increased production of endogenous opioids. Cholestatic pruritus may be caused by enhanced concentrations of bile salts in the systemic circulation and peripheral tissues, which is seen in patients with primary biliary cirrhosis and chronic renal failure. Intestinal anion exchange resins such as cholestyramine, colestipol, and colesevelam bind many hydrophobic bile acids in the intestine and inhibit enterohepatic reuptake of intestinal bile salts; they are effective in decreasing disease-related, enhanced concentrations that can cause cholestatic pruritus. Sertraline, at 75–100 mg daily, has been found to be effective in patients suffering from various forms of cholestasis. Naltrexone, an opioid antagonist, at 12.5–50 mg per day, may also be effective. Exogenously administered narcotics can contribute to pruritus, so the patient’s need for these medications should be carefully evaluated in the context of the management of pruritus.
  - **Manage depression.** Inmates with cirrhosis often have comorbid depression, especially when they have decompensated cirrhosis and are struggling with ascites, wasting, and encephalopathy. Although any of the SSRIs may be effective, most require approximately 50% dose reduction to accommodate delayed hepatic metabolism. Avoid SSRIs with a long half-life, e.g., fluoxetine. Sedating antidepressants such as mirtazapine, doxepin, trazodone, and amitriptyline should be either avoided or prescribed in very low doses, due to their potential for adding to the cognitive impairments of hepatic encephalopathy.

## 6. Infection Control

### Patient Education

During orientation to the institution and when appropriate during clinical evaluations, *all* inmates should be counseled on the importance of preventing blood exposures among themselves. They should be advised about the exposure inherent in sharing items such as toothbrushes and razors, as well as during unsafe behaviors such as injection drug use, tattooing, and sexual contact with other inmates (see [Appendix 1](#), *Inmate Fact Sheet*).

### Reporting

Each institution should have a surveillance system for notifiable infectious diseases, in accordance with BOP policy. Acute hepatitis C is a reportable condition in many states. Inmates with acute hepatitis C should be reported to local or state authorities where required and to the Central Office HSD. Inmates with chronic HCV infection should be reported to the local or state health authorities where required.

### Containment

Inmates with acute hepatitis C and chronic HCV infection do not require isolation, but should be counseled on the specific measures necessary for preventing transmission of HCV to others—during incarceration and upon release (see [Appendix 1](#)). Standard infection control precautions should be used in managing these inmates (see *Infection Control Practices* below).

### Infection Control Practices

Infection control practices for preventing transmission of blood borne pathogens are outlined in [Appendix 6](#), including safe practices for injections and diabetes care. Each BOP institution should provide infection control training to staff who have responsibilities that involve percutaneous procedures, including practical demonstration of aseptic techniques and instruction on reporting exposures or breaches. Inmate workers should also receive infection control training that is applicable to their duties, e.g., clean-up and disinfection following a blood spill, and reporting exposures from incidents involving spray or splash of blood or accidental puncture.

Each institution should designate specific staff members to assess the facility's compliance with infection control guidelines. The assessment should include observation of relevant staff and inmate workers, and tracking use of infection control supplies.

### Infection Control for Hemodialysis

- **Screening:** Inmates on hemodialysis who do not have chronic HCV infection should be screened regularly for newly acquired HCV infection. Their serum ALT levels should be measured monthly, and their anti-HCV should be measured by an immunoassay semi-annually. Hemodialysis patients who are found to have a positive anti-HCV screening immunoassay should have an HCV RNA assay performed.
- **Infection control:** Infection control measures to prevent HCV transmission during hemodialysis should be implemented in accordance with CDC guidelines. So long as these measures are conducted properly, inmates with HCV infection who are receiving dialysis do not need to be isolated from other

patients or dialyzed separately on dedicated machines. Dialyzers used for inmates with HCV infection can be reused.

The hemodialysis machine and its components can be vehicles for patient-to-patient transmission of blood borne viruses and pathogenic bacteria. Written protocols should be in place regarding sterilization, disinfection, and cleaning of medical devices and instruments. These protocols should include external surfaces and waste containers, which can be contaminated when the dialyzers are primed, when blood tubing is draped or clipped to waste containers, and when items are placed on machine surfaces. In addition to the Standard Precautions, more stringent precautions should be implemented in hemodialysis units because of the increased potential for cross-contamination. Examples of more stringent measures include restricting the use of common supplies, instruments, medications, and medication trays, and prohibiting the use of a common medication cart.

### Contact Investigation

Contact investigations should be initiated for inmates with acute hepatitis C who have been incarcerated during the two-week to six-month period prior to disease onset. Inmates with acute hepatitis C should be interviewed for information regarding possible sources of exposure (see Table 7 below). As locally required, acute hepatitis C should be reported to public health authorities.

**Table 7. Contact Investigation Interview for Acute Hepatitis C**

<ul style="list-style-type: none"><li>• Incarceration in BOP facility during 2-week to 6-month period prior to illness onset?</li><li>• Close contact person with confirmed or suspected hepatitis C?</li><li>• Cell-mate or dorm-mate of person with acute hepatitis?</li><li>• Injection drug use?</li><li>• Sexual partners?</li><li>• Recent hospitalization or recent dental work?</li><li>• Recent IV infusions, injections, glucometer use, or dialysis?</li><li>• Recent tattoo or body piercing? Other contact with human blood?</li></ul>
---

### Post-Exposure Management

- **Emergent care:** Wounds and skin sites that have been in contact with blood or bloody body fluids should be washed with soap and water. Exposed mucous membranes should be flushed with water. *Squeezing the wound or treating with topical antiseptics is not recommended.*
- **Counseling:** Inmates with percutaneous or mucosal exposures to blood should be assessed by a qualified health care provider and counseled regarding their risk of acquiring HCV infection, the natural history of HCV infection, and the recommendations for post-exposure management.
- **Post-exposure follow-up:** No vaccine or passive immunization is available to prevent acquisition of HCV infection following an exposure. The following guidelines should be used for managing inmate exposures to HCV:
  - ▶ Whenever feasible, the source individual's blood should be tested for anti-HCV (unless that person's infection status is already known).
  - ▶ Individuals with a known hepatitis C exposure, or if status of the source individual is unknown, should be referred for a medical evaluation and follow-up. Recommended post-exposure follow-up is outlined below in Table 8 (next page).
  - ▶ The National Clinician's Post-Exposure Prophylaxis PEPLINE is available 24-hours for consultation on exposures to blood borne pathogens: **1-888-448-4911**.

- ▶ Inmates with evidence of newly acquired HCV infection should be appropriately counseled and referred for further medical evaluation, including possible treatment for acute hepatitis C.
- ▶ Acute cases of hepatitis C should be reported as required and a contact investigation initiated (see "Reporting" on page 18) and "Contact Investigation" on page 19).

**Table 8. Recommended Post-Exposure Follow-Up for Hepatitis C**

<p><b>Baseline:</b> anti-HCV &amp; ALT</p> <p><b>4 Months:</b> anti-HCV &amp; ALT</p> <ul style="list-style-type: none"><li>▶ If anti-HCV (+), then obtain HCV RNA.</li><li>▶ If HCV RNA (+), then evaluate for treatment.</li></ul> <p><b>6 months:</b> If 4-month anti-HCV is negative, then obtain anti-HCV &amp; ALT.</p> <ul style="list-style-type: none"><li>▶ If anti-HCV negative, then STOP follow-up.</li><li>▶ If anti-HCV (+), then obtain HCV RNA.</li><li>▶ If HCV RNA (+), then evaluate for treatment.</li></ul>
---

## Definitions

**APRI (AST Platelet Ratio Index)** is a score based upon commonly available lab values that is sometimes used to assess the degree of liver fibrosis (see [Table 4](#), on page 6 for calculation).

**Absolute contraindication** is a condition or factor that by itself precludes a specific intervention.

**Anti-HCV** is the antibody to HCV core and nonstructural proteins, detectable from several weeks to months after clinical hepatitis.

**Anti-HCV screening assay** is an immunoassay such as an enzyme immunoassay (EIA) or a chemiluminescence immunoassay (CIA); it is used to screen for HCV infection by measuring antibodies to HCV antigens.

**Compensated cirrhosis** is defined as: bilirubin  $<1.5$  mg/dL; international normalized ratio (INR)  $<1.5$ ; albumin  $>3.4$  g/dL; and platelet count  $>75,000/\text{mm}^3$ ; as well as no evidence of: ascites by liver ultrasound, esophageal varices by upper endoscopy, or hepatic encephalopathy.

**Decompensated cirrhosis** is defined as: evidence of significant liver disease (such as ascites, encephalopathy, marked thrombocytopenia, and bleeding esophageal varices), as well as loss of liver synthetic function (e.g., albumin  $\leq 3.4$  g/dL, and international normalized ratio (INR)  $\geq 1.5$ ).

**Early viral response (EVR)** during treatment of chronic hepatitis C is a minimum two log ( $2 \log_{10}$ ) decrease in the level of HCV RNA (compared to pretreatment levels) after the first 12 weeks of treatment, as measured by an HCV RNA assay.

**End of treatment response (ETR)** after antiviral treatment of chronic hepatitis C is the absence of detectable HCV RNA immediately after the completion of a course of treatment (usually 24 weeks for genotypes 2 and 3, and 48 weeks for genotype 1).

**Hepatic steatosis**, also known as “fatty liver,” is the collection of excessive amounts of triglycerides and other fats inside liver cells.

**Hepatitis C** is an acute or chronic viral hepatitis caused by an RNA virus that is transmitted primarily by percutaneous contact with blood.

**HCV** is hepatitis C virus, an enveloped, single-stranded RNA virus.

**MELD or Model for End-stage Liver Disease** is a validated, disease severity index that uses age, creatinine, bilirubin, and prothrombin time to predict mortality.

**Nonresponse** to treatment for chronic hepatitis C is defined as detectable HCV RNA throughout treatment.

**Rapid viral response (RVR)** during treatment of chronic hepatitis C is defined as undetectable HCV RNA after the first 4 weeks of treatment.

**Relapse** associated with the treatment for chronic hepatitis C is defined as undetectable viremia during and/or at the end-of-treatment, but then subsequent detection of HCV RNA virus after treatment is stopped.

**Relative contraindication** is a condition or factor that may preclude a specific intervention when considered in conjunction with other criteria.

**RIBA (anti-HCV)** is the recombinant immunoblot assay that measures antibodies to HCV antigens through immunoblot technology. RIBA is no longer routinely used to confirm HCV infection.

**Standard precautions** are protective measures to be used for all patient/inmate contacts in situations where infections can be transmitted by contaminated blood and body fluids. Precautions include: (1) the wearing of gloves and other personal protective equipment that provide an impervious barrier when soiling is likely; (2) procedures for protective handling of contaminated materials and equipment (e.g., using puncture-resistant devices and leak-proof protection); and (3) routine cleaning of all contaminated surfaces and equipment.

**Steatosis** (see [Hepatic Steatosis](#) above)

**Sustained viral response (SVR)** after antiviral treatment of chronic hepatitis C is the absence of detectable HCV RNA in the serum 24 weeks after the treatment is completed; it is measured by an HCV RNA assay.

## Appendix 1. Inmate Fact Sheet on Hepatitis B & C Viral Infections

<b>Am I at risk for infection with hepatitis B &amp; C viruses?</b>
You may be at risk for infection with hepatitis B or hepatitis C viruses if you have ever injected drugs or had sex with an infected partner. People who received blood transfusions before 1992 may also be at risk. Talk to a health care provider about the risks of infection that affect you personally.
<b>How can I prevent getting hepatitis B or hepatitis C viral infection while I am in prison?</b>
<ul style="list-style-type: none"><li>• Do not have sex with other inmates, shoot drugs, or get a tattoo or body piercing.</li><li>• Do not share tooth brushes, razors, nail files or clippers, or other personal items that might have blood on them.</li></ul>
<b>Why should I be tested for hepatitis B or hepatitis C viral infection?</b>
You should be tested if you are at risk. That way, if tests show that you have hepatitis B or C, doctors can monitor your health and decide whether you need treatment. It's also important for <i>you</i> to know if you have hepatitis B or C, so that you can take precautions to prevent infecting other people—including your unborn child if you or your partner become pregnant.
<b>How do I get tested for hepatitis B and hepatitis C viral infection?</b>
A simple blood test can determine if you are infected.
<b>Are hepatitis B and C viruses dangerous to my health?</b>
Most people with hepatitis B and C can remain healthy. However, a small but significant number do develop serious liver disease. Treatments for hepatitis B and C are fairly effective, and we expect that new medications in the future will work even better. Talk to a health care provider to better understand your level of risk for liver disease and to discuss your treatment plan.
<b>How can I prevent giving hepatitis B or C viral infection to others?</b>
<ul style="list-style-type: none"><li>• First, remember that you can spread this infection even if you feel fine!</li><li>• Do not shoot drugs or have sex with other inmates.</li><li>• Do not share personal items that might have your blood on them, such as tooth brushes, nail files or clippers, or razors.</li><li>• Cover your cuts and skin sores to keep your blood from contacting other people.</li><li>• If you are being released, talk to a health care provider about specific ways you can reduce the risks of spreading hepatitis C to others. For example, in addition to the precautions you are already taking, do not donate blood, semen, or body organs.</li></ul>

## Appendix 2. Stepwise Approach for Detecting, Evaluating & Treating Chronic Hepatitis C

*Outlined below are steps for detecting, evaluating, and treating hepatitis C. Refer to the text, beginning on page 3 for further information about each step.*

### **Step 1. Appropriately screen for hepatitis C.**

- **Assess for presence of hepatitis C risk factors:**
  - Presence of Certain Clinical Conditions (*regardless of sentencing status*)**
    - Chronic hemodialysis (screen ALT monthly and anti-HCV semi-annually)
    - Elevated ALT levels of unknown etiology
    - Evidence of extrahepatic manifestations of HCV (mixed cryoglobulinemia, membranoproliferative glomerulonephritis, or porphyria cutanea tarda)
  - Presence of Hepatitis C Risk Factors (*sentenced inmates only*)**
    - Ever injected illegal drugs or shared equipment
    - Received tattoos or body piercings while in jail or prison
    - HIV-infected or chronic HBV infection
    - Received a blood transfusion or organ transplant before 1992, or received clotting factor transfusion prior to 1987
    - History of percutaneous exposure to blood
    - Ever received hemodialysis
- **Screen for anti-HCV (EIA or CIA) if risk factors are present or if inmate requests a test.**

### **Step 2. Provide initial medical follow-up for anti-HCV positive inmates.**

- **Take a medical history and perform a physical examination.**
- **Try to establish duration of HCV infection by history, e.g., time period of injection drug use**
- **Obtain baseline labs** (see [Appendix 3](#)).
- **Evaluate inmate for other potential causes of liver disease.**
- **Initiate patient counseling** (see patient education resources—[Appendix 1](#) and [Appendix 7](#)).
- **Initiate preventive health measures listed below.**

#### **Preventive Health Measures for Inmates with Chronic HCV Infection**

- **Hepatitis B vaccine:** Indicated for inmates with chronic HCV infection. For foreign-born inmates, consider prescreening for hepatitis B immunity prior to vaccination. *Inmates with evidence of liver disease should be priority candidates for hepatitis B vaccination.*
- **Hepatitis A vaccine:** Indicated for inmates with chronic HCV infection who have other evidence of liver disease. For foreign-born inmates, consider prescreening for hepatitis A immunity prior to vaccination.
- **Pneumococcal vaccine:** Offer to all HCV-infected inmates with cirrhosis.
- **Influenza vaccine:** Offer to all HCV-infected inmates annually. Inmates with cirrhosis are high priority for influenza vaccine.
- **Hepatocellular carcinoma (HCC) screening:** Data supporting specific parameters for HCC screening are lacking. For patients with both cirrhosis *and* chronic HCV infection, some experts recommend screening by liver ultrasound every six months
- **Esophageal varices screening:** Consider an upper endoscopy for any inmate with known cirrhosis, and for those with suspected cirrhosis who are not candidates for liver biopsy.

*(continued on next page)*

## Appendix 2. Stepwise Approach for Detecting, Evaluating & Treating Chronic Hepatitis C

(continued)

### Step 3a. Determine if hepatitis C treatment is *not recommended*.

Hepatitis C treatment is **not recommended** if any of the following four conditions are present:

**(1) Contraindications to peginterferon:**

- Severe uncontrolled psychiatric disease, particularly depression with current suicidal risk.
- History of solid organ transplant (renal, heart, or lung)
- Certain autoimmune disorders, e.g., autoimmune hepatitis
- Uncontrolled endocrine disorders, e.g., diabetes, thyroid disease
- Serious concurrent medical diseases, such as severe: hypertension, heart failure, coronary heart disease, COPD
- Decompensated cirrhosis (see text, page 13)
- Platelet count  $<75,000/\text{mm}^3$  or ANC  $<1,500$  cells/ $\text{mm}^3$
- Documented nonadherence to prior therapy, or failure to complete pretreatment evaluation process
- Ongoing injection drug use or alcohol use
- Hypersensitivity to interferon

**(2) Inmate will be incarcerated for an insufficient period of time to complete treatment.**

**(3) Inmate has an unstable medical or mental health condition which precludes antiviral therapy.**

**(4) Inmate refuses treatment.**

**If any one of the above four conditions are present, then STOP further treatment-related work-up.** No further HCV testing—i.e., HCV RNA, genotype, liver biopsy—is indicated at this time. If conditions change, reconsider for hepatitis C treatment.

### Step 3b. Monitor HCV-infected inmates who are *not on treatment*.

- Have a plan for each inmate:** Outline the plan clearly on the Problem List/Health Summary.
- Get baseline laboratory evaluations:** Obtain baseline labs as specified in [Appendix 3](#).
- Follow-up labs:**
  - Every 6 months: ALT, AST, bilirubin, albumin, and INR
  - Every year: CBC (with differential & platelets). Calculate APRI (see [Table 4](#), page 6 for formula).
  - Other labs as clinically indicated, e.g., A1C (diabetics); TSH and free T4 (if hyperthyroid).
- Repeat liver biopsies:** The determination regarding the timing of re-biopsy (for those inmates whose treatment is deferred) should be based on subsequent increases in the AST/Platelet Ratio Index (APRI)\* and/or evidence of steatosis or inflammation. Those who develop clinical evidence of liver disease should be priority candidates for re-biopsy. If the APRI  $< 0.5$ , there is a lower risk of disease progression; if the APRI  $> 0.5$ , there is a higher risk.

**Note: The following tests are generally NOT indicated for inmates not on treatment.**

- **HCV RNA and HCV genotype:** These tests are not needed unless treatment is indicated. *Do not* periodically check HCV RNA values for inmates who are not currently candidates for treatment. There is no correlation between HCV RNA levels and the risk or rate of disease progression.
- **Alpha fetoprotein:** Unless cirrhosis is known or strongly suspected, alpha fetoprotein is unnecessary because the risk for hepatocellular carcinoma in HCV infection does not begin until the development of cirrhosis.
- **Liver ultrasound or CT examinations:** Similarly, do not perform periodic liver ultrasound or CT examinations unless cirrhosis is present or there is another definitive indication.
- **Serum ammonia levels:** In a patient with known liver disease, the serum ammonia level has no prognostic value; nor can it be used for monitoring the effectiveness of medications such as lactulose. Serum ammonia levels are only useful in a delirious patient whose diagnosis is uncertain.

(continued on next page)

## Appendix 2. Stepwise Approach for Detecting, Evaluating & Treating Chronic Hepatitis C

(continued)

<b>↓ For inmates who may be eligible for hepatitis C treatment, proceed as follows. ↓</b>
<b>Step 4. Obtain HCV RNA assay and HCV genotype.</b>
<p>Before initiating antiviral therapy, an <b>HCV RNA</b> (viral load) is required in order to confirm chronic infection and guide therapy. If the HCV RNA level is undetectable, the individual can be considered uninfected.</p> <p>The <b>HCV genotype</b> should be ordered in conjunction with the initial HCV RNA test. In general, the test for genotype is not repeated—unless re-infection is suspected.</p>
<b>Step 5. Assess liver fibrosis and need for a liver biopsy.</b>
<ul style="list-style-type: none"> <li>□ <b>Determine if a liver biopsy is indicated based upon the criteria below:</b> <ul style="list-style-type: none"> <li>□ <b>HIV infection:</b> High priority for liver biopsy, regardless of genotype.</li> <li>□ <b>Other liver disease suspected:</b> High priority for liver biopsy, regardless of genotype, e.g., homozygous hemochromatosis.</li> <li>□ <b>Genotypes 1, 4, 5, 6:</b> Biopsy is generally recommended. Prioritize referral of inmates for biopsy based on the AST/Platelet Ratio Index (APRI), which is calculated as follows (see example, page 6): <b>Formula:</b> <math display="block">\{AST \div \text{lab upper limit of normal (ULN) for AST} \times 100\} \div \{\text{platelet ct} \div 1,000\}</math>If APRI &lt;0.5, lower risk of progression; if APRI ≥0.5, higher risk.</li> <li>□ <b>Genotypes 2, 3:</b> Biopsy is <i>not needed</i> prior to treatment (except if HIV-infected or other type of liver disease is known or suspected). See note(*) in <a href="#">Appendix 3</a>.</li> <li>□ <b>Compensated cirrhosis:</b> Decide about liver biopsy on a case-by-case basis, in consultation with a hepatitis C expert. Either perform a liver biopsy as soon as possible, or treat empirically <i>without</i> biopsy confirmation.</li> <li>□ <b>Decompensated cirrhosis:</b> Liver biopsy and treatment are generally not indicated (see text, page 13)</li> </ul> </li> </ul>
<b>Step 6. Determine if treatment should be initiated.</b>
<ul style="list-style-type: none"> <li>□ <b>Identify if any of the following indications for antiviral therapy are present:</b> <ul style="list-style-type: none"> <li>□ <b>Genotype 2 or 3</b> with no biopsy performed.</li> <li>□ <b>Liver biopsy reveals chronic hepatitis with significant fibrosis:</b> (IASL, Batts&amp;Ludwig, or Metavir ≥2, or Ishak ≥3)—regardless of genotype (see <a href="#">Table 5</a>, page 7).</li> <li>□ <b>Compensated liver disease</b> (bilirubin &lt;1.5 mg/dL; INR &lt;1.5; albumin &gt;3.4 g/dL; and platelets &gt;75,000/mm<sup>3</sup>; as well as no evidence of: ascites, esophageal varices, or hepatic encephalopathy).</li> <li>□ <b>Review special considerations related treatment initiation</b> (i.e., mental illness, substance abuse, adherence concerns). See pages 7–8.</li> <li>□ <b>Counsel patient regarding the pros and cons of initiating hepatitis C treatment</b> (see page 8).</li> <li>□ <b>Determine if patient is willing to be treated and to adhere to treatment requirements.</b></li> <li>□ <b>Document rationale for decisions about treatment in the medical record.</b></li> </ul> </li> </ul>
<i>(continued on next page)</i>

## Appendix 2. Stepwise Approach for Detecting, Evaluating & Treating Chronic Hepatitis C

(continued)

### Step 7. Conduct a pre-treatment evaluation.

Assure that all recommended pre-treatment evaluations have been completed within the time frames enumerated in the "Treatment Approval Form" (BOP-A803.060).

- **Laboratory tests:** See [Appendix 3](#) for list of recommended pre-treatment tests and evaluations.
  - **Interferon**—The patient should have the following acceptable labs for treatment initiation: absolute neutrophil count >1500/cells/mm<sup>3</sup>; platelets >75,000/mm<sup>3</sup>.  
**Note:** When starting treatment with platelet counts between 75–90,000, consult first with a physician with expertise in treatment of hepatitis C.
  - **Ribavirin**—The patient should have the following acceptable for treatment initiation: Hemoglobin >13 g/dL (men) or >12 g/dL (women); creatinine <1.5 mg/dL (or creatinine clearance >50 mL/min).  
**Note:** Some experts recommend that an acceptable starting hemoglobin is >12 g/dL (men) or >11 g/dL (women).
- **Assess for contraindications to ribavirin** (and if present consider interferon monotherapy).
  - Thalassemias (sickle cell anemia) or other hemoglobinopathy.
  - Significant cardiac disease (arrhythmias, angina, CABG, MI) in the past 12 months.
  - Pregnancy or unwillingness to use contraception in both female patients and female partners of male patients.
  - Renal dialysis or creatinine clearance ≤ 50 mL/min.
  - Hypersensitivity to ribavirin
- **Pregnancy test:** Because ribavirin may cause fetal abnormalities, all female inmates of childbearing potential must have a pregnancy test immediately prior to initiating therapy, and monthly thereafter. Continue with monthly tests until 6 months after treatment is completed.
- **Cardiac risk assessment:** Prior to therapy, a cardiac risk assessment is critically important because hemolysis associated with ribavirin may precipitate angina pectoris. Also, obtain an ECG for inmates with preexisting cardiac disease.
- **Mental health evaluation** is critically important prior to initiating treatment due to the severe psychotropic effects of interferon.
- **Compensated cirrhosis:** Obtain liver-spleen ultrasound (preferred) or abdominal CT-scan, and measurements of alpha fetoprotein, prior to treatment initiation. A screening upper endoscopy is indicated if the ultrasound suggests portal hypertension.

### Step 8. Determine appropriate treatment and obtain informed consent.

- **Standard treatment for hepatitis C:** pegylated interferon *plus* ribavirin
  - ▶ If contraindications to ribavirin exist, then the appropriate treatment is monotherapy with peginterferon. *Ribavirin should never be given as monotherapy.*
  - ▶ Standard dosing is outlined on the next page. See [Appendix 5](#) for information on dosing with renal failure and HIV/HCV co-infection, and when interferon is used as monotherapy.
- **Obtain informed consent** after reviewing potential side effects (form BOP-A806.060).

(Step 8 is continued on the next page.)

**Appendix 2. Stepwise Approach for Detecting, Evaluating & Treating Chronic Hepatitis C**

(continued)

<b>Step 8. Determine appropriate treatment and obtain informed consent.</b> (continued)					
Dosing for antiviral therapy is complicated. The two types of pegylated inteferons are dosed differently. Moreover, the dosing of ribavirin depends on the type of peginterferon being used.					
<b>Ribavirin should be administered on pill-line.</b> Capsules should be taken with food.					
<b>Peginterferon alfa 2b (Peg-Intron®) and Ribavirin—Dosing in Combination Therapy</b>					
Peg-Intron® is administered subcutaneously, once weekly. The dosing chart below is based on a recommended dose of 1.5 micrograms (mcg) per kilogram per week (regardless of HCV genotype). Peginterferon alfa 2b (Peg-Intron®) comes in four different vial strengths. Utilize the appropriate vial strength related to the patient's weight.					
<b>Note:</b> Dosing for Peg-Intron® monotherapy is different. See <a href="#">Appendix 5</a> .					
Body Weight (pounds)	Peginterferon Dosing (subcutaneously, once weekly)			Ribavirin Dosing (mg)	
	Vial Strength (microgram/0.5 mL)	Dose to Administer (1.5 mcg/kg/wk)	Volume to Administer (mL)	Every AM	Every PM
<88	50	50	0.5	400	400
88–111	80	64	0.4	400	400
112–133	80	80	0.5	400	400
134–144	120	96	0.4	400	400
145–166	120	96	0.4	400	600
167–188	120	120	0.5	400	600
189–231	150	150	0.5	400	600
> 231	150	150	0.5	600	600
<b>Peginterferon alfa 2a (Pegasys®) and Ribavirin—Dosing in Combination Therapy</b>					
<b>Peginterferon alfa 2a</b> (Pegasys®)	180 micrograms subcutaneously once weekly (regardless of weight). <b>Note:</b> Dosing for Pegasys monotherapy is the same as when it is used with ribavirin.				
<b>Ribavirin</b> (Rebetol®, Copegus® or generic (bio-equivalent))	<b>Genotype 1, 4, 5, 6 (based on patient's weight):</b> <b>&lt;75kg (&lt;165 lb) →</b> total daily dose of 1000 mg administered as: 400 mg orally every morning 600 mg orally every evening <b>≥75kg (≥165 lb) →</b> total daily dose of 1200 mg administered as: 600 mg orally every morning 600 mg orally every evening  <b>Genotype 2, 3 →</b> total daily dose of 800 mg administered as: 400 mg orally twice daily (regardless of weight)				
(continued on next page)					

## Appendix 2. Stepwise Approach for Detecting, Evaluating & Treating Chronic Hepatitis C

(continued)

<b>Step 9. Manage side effects and monitor treatment response.</b>		
<p><input type="checkbox"/> <b>Monitor for treatment side effects:</b> See <a href="#">Appendix 3</a> for treatment monitoring schedule for recommended baseline, pre-treatment, and ongoing clinical evaluations and laboratory studies. See the next page of Step 9 for <i>Guidelines for Adjusting Therapy for CBC Changes</i>.</p> <p><b>Common toxicities to assess at each clinician visit include:</b></p> <p><input type="checkbox"/> flu-like symptoms    <input type="checkbox"/> mood changes    <input type="checkbox"/> rashes    <input type="checkbox"/> chest pain  <input type="checkbox"/> dyspnea/cough    <input type="checkbox"/> thrombocytopenia    <input type="checkbox"/> anemia    <input type="checkbox"/> neutropenia</p>		
<p><input type="checkbox"/> <b>Monitor for treatment response based on the following virologic end-points:</b></p>		
<b>Chronic Hepatitis C Treatment Response Categories</b>		
<b>Response</b>	<b>Time Frame</b>	<b>Result*</b>
<b>RVR</b> Rapid viral response	After 4 weeks of treatment	HCV RNA undetectable
<b>EVR</b> Early viral response	After 12 weeks of treatment	$\geq 2 \log_{10}$ HCV RNA decrease**
<b>ETR</b> End of treatment response	At end of treatment	HCV RNA undetectable
<b>SVR</b> Sustained viral response	24 wks after treatment completed	HCV RNA undetectable
<b>Relapse</b>	Undetectable viremia during and/or at the end of treatment, but virus is detectable sometime after treatment is stopped.	
<b>Non-response</b>	Detectable HCV RNA throughout treatment.	
<p>* Throughout the course of treatment, use the same lab for HCV RNA assays so that results are comparable.  ** <math>2 \log_{10}</math> decrease = by factor of <math>10^2</math>, e.g., if baseline HCV RNA = 720,000 → then a <math>2 \log_{10}</math> decrease = 7,200</p>		
<p><input type="checkbox"/> <b>Determine the appropriate duration of therapy:</b> Treatment duration is based on genotype, virologic response, and the occurrence of major side effects. See also the text on page 12 and the flow charts in <i>Appendices 4a</i> and <i>4b</i>.</p> <ul style="list-style-type: none"> <li>• <b>Genotypes 1, 4, 5, 6: Standard treatment duration = 48 weeks</b> <ul style="list-style-type: none"> <li>▶ If no EVR → discontinue treatment = treatment failure.</li> <li>▶ If EVR, but HCV RNA is still detectable at 12 weeks → repeat HCV RNA test at 24 weeks. If HCV RNA is still detectable at 24 weeks → discontinue therapy = treatment failure.</li> <li>▶ If an RVR was not attained and/or HCV RNA was still detectable at 12 weeks, and HCV RNA is undetectable at 24 weeks → consider extending treatment to 72 weeks.</li> <li>▶ If significant side effects occur and RVR was achieved, can consider shortening treatment to at least 24 weeks (in consultation with an expert).</li> </ul> </li> <li>• <b>Genotypes 2, 3: Standard treatment duration = 24 weeks</b> <ul style="list-style-type: none"> <li>▶ If no EVR → discontinue therapy = treatment failure.</li> <li>▶ If significant side effects occur and RVR was achieved → consider shortening treatment to at least 16–20 weeks (in consultation with an expert).</li> </ul> </li> </ul>		
(Step 9 is continued is on the next page.)		

**Appendix 2. Stepwise Approach for Detecting, Evaluating & Treating Chronic Hepatitis C**

(continued)

<b>Step 9. Manage side effects and monitor treatment response. (continued)</b>		
<b>Guidelines for Adjusting Therapy for CBC Changes</b>		
<b>Value</b>	<b>Peginterferon/Ribavirin Adjustment and Supportive Treatment</b>	
<b>Hemoglobin (Hgb)</b>		
<b>10–11 g/dL</b>	<ul style="list-style-type: none"> <li>□ <b>Peginterferon</b> → No change.</li> <li>□ <b>Ribavirin</b> →                             <ul style="list-style-type: none"> <li>▶ If no or minimal symptoms, then no dose modification.</li> <li>▶ If symptomatic, decrease ribavirin by 200 mg/day.</li> </ul> </li> </ul>	<p><b>Candidates for erythropoietin:</b> Rule out other causes of anemia. If anemia persists at 2 weeks after reducing ribavirin—and there is no hypertension—then consider erythropoietin, especially if the patient demonstrates a virologic response. Erythropoietin should be considered primarily for patients who are cirrhotic, post-transplant, or HIV/HCV co-infected</p> <p><b>Dosage:</b> Epoetin alfa 40,000 units subcutaneously weekly <b>Goal:</b> Hemoglobin 12 g/dL</p>
<b>8.5–10 g/dL</b>	<ul style="list-style-type: none"> <li>□ <b>Peginterferon</b> →                             <ul style="list-style-type: none"> <li>▶ <b>Peginterferon alfa 2a</b> (Pegasys) → No change.</li> <li>▶ <b>Peginterferon alfa 2b</b> (Peg-Intron) → Reduce 50% (*see note).</li> </ul> </li> <li>□ <b>Ribavirin</b> → ↓ to 600 mg daily (200 mg AM &amp; 400mg PM)</li> </ul>	
<b>&lt;8.5 g/dL</b>	<ul style="list-style-type: none"> <li>□ <b>Peginterferon</b> →                             <ul style="list-style-type: none"> <li>▶ <b>Peginterferon alfa 2a</b> (Pegasys) → No change.</li> <li>▶ <b>Peginterferon alfa 2b</b> (Peg-Intron) → Discontinue until resolved.</li> </ul> </li> <li>□ <b>Ribavirin</b> → Discontinue until resolved.</li> </ul>	
If hemoglobin is <12g/dL for over 4 weeks at the reduced/adjusted dose, then discontinue ribavirin.		
<b>Absolute Neutrophil Count (ANC)</b>		
<b>&lt;750</b>	<ul style="list-style-type: none"> <li>□ <b>Peginterferon</b> →                             <ul style="list-style-type: none"> <li>▶ <b>Peginterferon alfa 2a</b> (Pegasys) → Reduce dose to 135 microgram/week (75% dose).</li> <li>▶ <b>Peginterferon alfa 2b</b> (Peg-Intron) → Reduce to a 50% dose—see note* below.</li> </ul> </li> <li>□ <b>Ribavirin</b> → No change.</li> </ul>	
<b>&lt;500</b>	<ul style="list-style-type: none"> <li>□ <b>Peginterferon &amp; Ribavirin</b> → Discontinue both until resolved.</li> </ul>	<p><b>Granulocyte Colony Stimulating Factor (G-CSF):</b> If the patient is responding to treatment and neutropenia persists despite reduced peginterferon dose, consider G-CSF (in consultation with an expert ) for patients who are cirrhotic, post-transplant, or HIV/HCV co-infected.</p> <p><b>Dosage:</b> Filgrastim 300 microgram subcu. daily. <b>Goal:</b> ANC &gt;1500</p>
<b>Platelets</b>		
<b>&lt;50,000</b>	<ul style="list-style-type: none"> <li>□ <b>Peginterferon</b> →                             <ul style="list-style-type: none"> <li>▶ <b>Peginterferon alfa 2a</b> (Pegasys) → Reduce dosage to 90 micrograms/week (50% dose) (*see note).</li> <li>▶ <b>Peginterferon alfa 2b</b> (Peg-Intron) → Discontinue until resolved.</li> </ul> </li> <li>□ <b>Ribavirin</b> → If on Peg-Intron, then discontinue ribavirin.</li> </ul>	
<b>&lt;30,000</b>	<ul style="list-style-type: none"> <li>□ <b>Peginterferon</b> → Discontinue until resolved.</li> <li>□ <b>Ribavirin</b> → Discontinue until resolved.</li> </ul>	
<p><b>*Note:</b> While the manufacturer recommends reducing dose to 50%, recent data suggest that lowering the dose to this extent may significantly reduce the likelihood of achieving an SVR. Some experts recommend a 25% dose reduction with close monitoring of hematologic parameters.</p>		
<b>Step 10. Assess for sustained viral response (SVR).</b>		
<p>An SVR is defined as undetectable HCV RNA at 24 weeks after treatment is completed. If HCV RNA is undetectable at the end of treatment, obtain an HCV RNA test 6 months later to assess for an SVR. Obtain a final HCV RNA test 12 months post-treatment. See text on page 13.</p>		

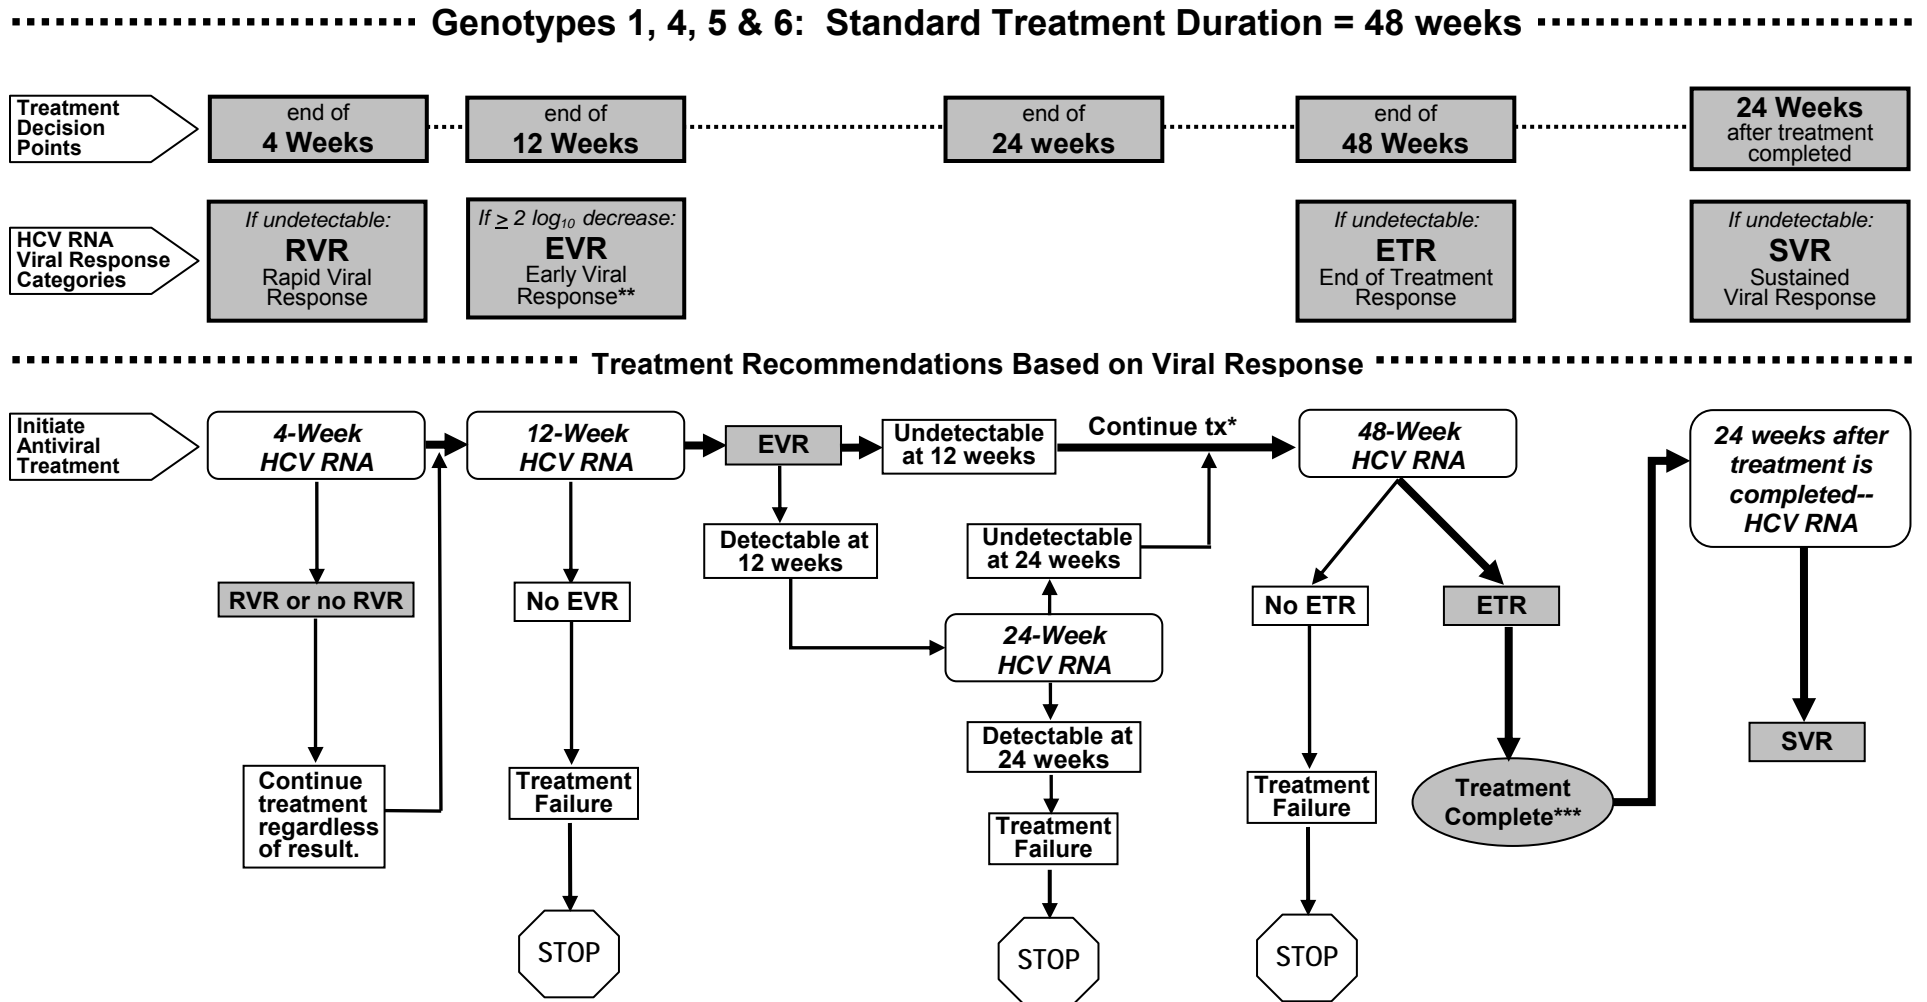

### Appendix 3. Hepatitis C Treatment Monitoring Schedule

Evaluation	Baseline (anti-HCV positive)	Pre- Treat- ment	Ongoing Monitoring (by week of treatment)														24 wks post treat- ment	12 mos post treat- ment				
			1	2	3	4	8	12	16	20	24	28	32	36	40	44			48			
Clinician evaluation	X	X	X	X		X	X	X	X	X	X	X	X	X	X	X	X	X	X	X		
HIV, HBsAg, HBsAb, Anti-HAV (IgG)	X																					
CBC + diff + platelets	X	X	X	X		X	every 4-8 weeks during treatment															
ALT & creatinine	X	X	X	X		X															X	X
AST, bilirubin, alkaline, phosphatase, albumin, INR	X	X	Periodically and if signs and symptoms of liver disease																			
*Ferritin, iron saturation, ANA	X																					
HCV RNA		X				X		X	as indicated and at end of treatment											X	X	
HCV genotype		X																				
Liver biopsy		<i>if indicated</i>																				
Mental health evaluation		X	<i>if indicated</i>																			
Depression		X	<i>assess for signs and symptoms of depression at each clinician visit</i>																			
Urine toxicology		X	<i>if indicated</i>																			
Visual acuity		X																				
Funduscopy exam (if other ophthalmologic dx or diabetes)		X	<i>periodically and as clinically indicated</i>																			
TSH, Free T4		X					X			X			X			X						
Triglycerides		X					X			X			X			X						
ECG (preexisting CHD)		<i>if indicated</i>	<i>if indicated</i>																			
Urine pregnancy test (if childbearing potential)		X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	monthly x 6 mos	

\* Conduct further diagnostic evaluations as clinically warranted to identify other potential causes of the patient's liver disease such as hemochromatosis, Wilson's disease, or autoimmune hepatitis (e.g., serum iron, serum copper, ESR). If any of these conditions are diagnosed or are strongly suspected, a liver biopsy should be performed prior to treatment regardless of genotype.

§ More HCV RNA tests may be warranted during course of treatment depending upon results of previous HCV RNA assays (see [Appendices 4a](#) and [4b](#)).

**Appendix 4a. Timeline for HCV Treatment Decisions (Based on Viral Response)—Genotypes 1, 4, 5, and 6**

\* If significant side effects occur, and an RVR at 4 weeks was achieved, then shortening the treatment to at least 24 weeks can be considered with expert consultation.

\*\* 2 log<sub>10</sub> decrease = decrease by a factor of 10<sup>2</sup> (100), i.e., if baseline viral load = 720,000, then 2 log decrease = 7200.

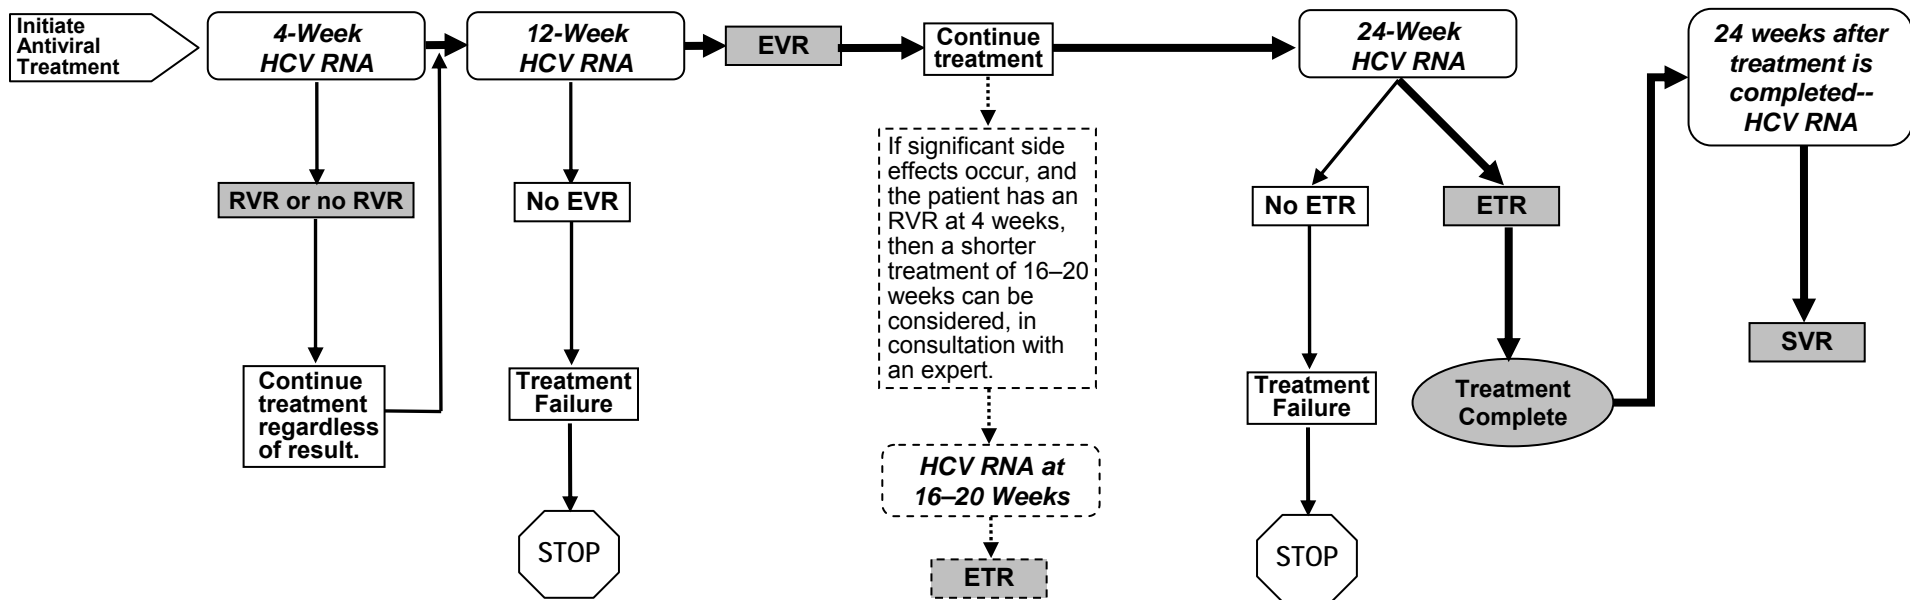

\*\*\* If HCV RNA was detectable at 4 weeks and/or at 12 weeks, extending therapy to 72 weeks should be considered.

**Appendix 4b. Timeline for HCV Treatment Decisions (Based on Viral Response)—Genotypes 2 and 3**

..... **Genotypes 2 & 3: Standard Treatment Duration = 24 weeks** .....

..... **Treatment Recommendations Based on Viral Response** .....

\* 2 log<sub>10</sub> decrease = decrease by a factor of 10<sup>2</sup> (i.e., if baseline viral load = 720,000, then 2 log decrease = 7200).

## Appendix 5. Interferon/Ribavirin Drug Information

DESCRIPTION			
<b>Peginterferon</b>	A long-acting, synthetic interferon that is indicated for use alone or in combination with ribavirin for the treatment of chronic hepatitis C.		
<b>Ribavirin</b>	A nucleoside analogue with antiviral activity. It is used in conjunction with peginterferon for treatment of hepatitis C. <i>Ribavirin should not be used alone as monotherapy for hepatitis C.</i>		
FORMULATIONS			
<b>Peginterferon</b>	Two formulations are available for subcutaneous injection: <ul style="list-style-type: none"> <li>▶ Peginterferon alfa-2a (Pegasys®)</li> <li>▶ Peginterferon alfa-2b (Peg-Intron®)</li> </ul> There is no demonstrated difference in efficacy between the two formulations. However, dosing for Peg-Intron® is more complicated than for Pegasys®.		
<b>Ribavirin</b>	Several formulations of 200 mg tablets or capsules are available for oral administration, including two brand-name versions: Copegus® and Rebetol®. The generic versions are less expensive and equivalent to the branded drugs.		
STANDARD DOSING			
For standard dosing of Pegasys® and Peg-Intron®, see <a href="#">Appendix 2—Step 8</a> .			
DOSING IN CERTAIN CLINICAL CIRCUMSTANCES			
<b>Monotherapy with Peginterferon alfa 2a (Pegasys®):</b> 180 micrograms (mcg) subcutaneously, once weekly, regardless of weight. ( <b>Note:</b> Dosing for Pegasys® as monotherapy is the same as when it is used in conjunction with ribavirin.)			
<b>Monotherapy with Peginterferon alfa 2b (Peg-Intron®):</b> The recommended dosing of Peg-Intron® when it is used as monotherapy (without ribavirin) is 1.0 microgram/kg. See chart below.			
Body Weight (pounds)	Vial Strength (microgram/0.5 mL)	Amount to Administer (micrograms/week)	Volume to Administer (mL)
≤100	50	40	0.4
101–124	50	50	0.5
125–159	80	64	0.4
160–195	80	80	0.5
196–234	120	96	0.4
235–300	120	120	0.5
301+	150	150	0.5
<b>Renal Dysfunction: Peg-Intron®:</b> In patients with moderate renal function (CrCl of 30–50 mL/min), the Peg-Intron dose should be reduced by 25%. If severe renal function impairment (CrCl 10–29 mL/min), including hemodialysis, reduce dose by 50%. If renal function decreases during treatment, discontinue treatment. <b>Pegasys®:</b> In patients with impaired renal function, signs and symptoms of interferon toxicity should be closely monitored. Doses of Pegasys should be adjusted accordingly. Use with caution if CrCl <50 mL/min. <b>Ribavirin</b> is not indicated in patients with a CrCl ≤50 mL/min.			
<b>Hemodialysis: Pegasys®:</b> Reduce dose to 135 micrograms subcutaneously, once weekly. <b>Peg-Intron®:</b> Reduce dose by 50%. Ribavirin is not indicated.			
<b>HIV/HCV Co-infection:</b> Treat for at least 48 weeks, regardless of genotype. See text, page 15.			
<i>Continued</i>			

**Appendix 5. Interferon/Ribavirin Drug Information (continued)**

CONTRAINDICATIONS	
<b>Peginterferon</b>	
<ul style="list-style-type: none"> <li>▶ Severe uncontrolled psychiatric disease, particularly depression with current suicidal risk.</li> <li>▶ History of solid organ transplant (renal, heart, or lung)</li> <li>▶ Certain autoimmune disorders, e.g., autoimmune hepatitis</li> <li>▶ Uncontrolled endocrine disorders, e.g., diabetes, thyroid disease</li> <li>▶ Serious concurrent medical diseases, such as severe: hypertension, heart failure, CHD, COPD</li> <li>▶ Decompensated cirrhosis (see <a href="#">Definitions</a>, page 22)</li> <li>▶ Platelet count &lt;75,000/mm<sup>3</sup> or ANC &lt;1,500 cells/mm<sup>3</sup></li> <li>▶ Documented nonadherence to prior therapy, or failure to complete pretreatment evaluation process</li> <li>▶ Ongoing injection drug use or alcohol use</li> <li>▶ Hypersensitivity to interferon</li> </ul>	
<b>Ribavirin</b>	
<ul style="list-style-type: none"> <li>▶ Thalassemia or other hemoglobinopathy</li> <li>▶ Significant cardiac disease (arrhythmias, angina, CABG, MI) in the past 12 months</li> <li>▶ Pregnancy or unwillingness to use contraception in both female patients and in female partners of male patients.</li> <li>▶ Renal dialysis</li> <li>▶ Serum creatinine ≥1.5 mg/dL or creatinine clearance ≤50 mL/min</li> <li>▶ Hemoglobin ≤12 g/dL in men or ≤11 g/dL in women</li> <li>▶ Hypersensitivity to ribavirin</li> </ul>	
MAJOR SIDE EFFECTS	
<b>Peginterferon:</b> May cause or aggravate fatal or life-threatening neuropsychiatric, autoimmune, ischemic, and infectious disorders.	
<b>Ribavirin:</b> Has a primary clinical toxicity of <i>hemolytic anemia</i> . Since ribavirin-associated anemia has been known to lead to myocardial infarction, it is contraindicated in patients with significant or unstable cardiac disease. <i>Significant teratogenic effects</i> have been noted in all animal species exposed to ribavirin. Pregnancy should be prevented during therapy, and for the six months after the completion of therapy, <i>in both female patients and female partners of male patients</i> .	
SIDE EFFECTS	
<b>Peginterferon</b>	<ul style="list-style-type: none"> <li>▶ Autoimmune disorders: can result in development or exacerbation of disorders</li> <li>▶ Bone marrow suppression: can cause severe cytopenias (see <i>Appendix 2, Step 9</i>)</li> <li>▶ Cardiovascular disorders: hypertension, arrhythmias, and myocardial infarction</li> <li>▶ Cerebrovascular disorders: ischemic and hemorrhagic cerebrovascular events</li> <li>▶ Colitis: ulcerative and hemorrhagic/ischemic colitis sometimes fatal</li> <li>▶ Dermatologic effects: alopecia, pruritis, and local injection site reaction</li> <li>▶ Endocrine disorders: hypo- or hyperthyroidism, hypo- or hyperglycemia &amp; diabetes</li> <li>▶ Flu-like symptoms: fever, myalgia, fatigue, headache</li> <li>▶ Gastrointestinal effects: nausea, vomiting, diarrhea, and anorexia</li> <li>▶ Hypersensitivity (anaphylaxis and angioedema): severe &amp; acute</li> <li>▶ Infections (bacterial, fungal and viral): can be severe and sometimes fatal</li> <li>▶ Hepatic failure and hepatitis exacerbations with hepatic decompensation and death</li> <li>▶ Neuropsychiatric symptoms: life threatening or fatal neuropsychiatric reactions</li> <li>▶ Ophthalmologic disorders: loss of vision, retinopathy including macular edema</li> <li>▶ Pancreatitis (sometimes fatal)</li> <li>▶ Pulmonary disorders: dyspnea, pulmonary infiltrates, pneumonia and sarcoidosis</li> <li>▶ Renal failure</li> <li>▶ Seizures</li> <li>▶ Triglyceride elevations</li> </ul>
<i>continued on next page</i>	

**Appendix 5. Interferon/Ribavirin Drug Information** *(continued)*

<b>SIDE EFFECTS</b> <i>(continued)</i>	
<b>Ribavirin</b>	<p><b>Black Box Warnings:</b></p> <ul style="list-style-type: none"> <li>▶ <b>Hemolytic Anemia Warning</b> (primarily in the first two weeks of therapy)</li> <li>▶ <b>Pregnancy Warning.</b> Negative pregnancy test is required pre-therapy.</li> <li>▶ <b>Respiratory Warning</b> for patients requiring assisted ventilation</li> </ul> <hr/> <ul style="list-style-type: none"> <li>▶ Cardiovascular effects: fatal and non-fatal myocardial infarction</li> <li>▶ Dermatologic effects: alopecia, pruritis, and rashes</li> <li>▶ Flu-like symptoms: myalgia, fatigue and headache</li> <li>▶ Gastrointestinal effects: nausea, anorexia, and vomiting</li> <li>▶ Hematologic: neutropenia, and thrombocytopenia (see <i>Appendix 2, Step 9</i>)</li> <li>▶ Hepatic decompensation and death</li> <li>▶ Hypersensitivity—acute: anaphylaxis, angioedema and bronchoconstriction</li> <li>▶ Pulmonary symptoms: dyspnea, pneumonia and pulmonary infiltrates</li> <li>▶ Teratogen (significant), carthogenesis and mutagenesis,</li> </ul>

## Appendix 6. Infection Control Practices for Hepatitis C

<p><b>General Infection Control Practices—All Correctional Staff</b></p> <p>Use Standard Precautions. Wear gloves when it can be reasonably anticipated that contact with blood or other body fluids (except sweat) could occur. Wash hands regularly. Immediately report any exposures to blood, including accidental needle sticks or other sharps, splashes or sprays of blood into eyes or mouth, or human bites.</p>
<p><b>General Infection Control Practices—All Health Care Staff</b></p> <ul style="list-style-type: none"> <li>▶ Wear gloves when it can be reasonably anticipated that contact with the following could occur: blood or other potentially infectious materials, mucous membranes, non-intact skin, or potentially contaminated intact skin (e.g., skin of a patient incontinent of stool or urine).</li> <li>▶ Remove gloves and promptly discard after contact with a patient and/or the surrounding environment (including medical equipment), using proper technique to prevent hand contamination. Follow with proper hand washing.</li> <li>▶ Promptly contain, clean-up, and disinfect surfaces contaminated with blood.</li> <li>▶ Regularly and appropriately use proper hand hygiene.</li> <li>▶ Non-disposable patient care items must be cleaned, disinfected, or sterilized, as appropriate.</li> <li>▶ Implement measures to prevent cross-contamination during patient care (e.g., dialysis, vascular access, cauterizing, dental procedures, etc.).</li> <li>▶ Do not carry supplies and medications in pockets. Once supplies have been taken to the bedside or patient station, the non-used supplies or medications should not be used for another patient.</li> </ul>
<p><b>Safe Injection Practices</b></p> <ul style="list-style-type: none"> <li>▶ Use sharps with engineered sharp injury protection to eliminate or minimize exposures.</li> <li>▶ Use aseptic technique in handling medications and injection equipment to avoid microbial contamination of sterile injection equipment or infusions—including syringes, needles, and intravenous (IV) tubing.</li> <li>▶ Health care staff should adhere to proper infection control practices during the preparation and administration of injected medications.</li> <li>▶ Whenever possible, the CDC recommends that single-use vials be used, and that if multi-dose vials must be used, each medication vial should be restricted to a single patient and properly labeled as such.</li> <li>▶ Do not use bags or bottles of intravenous solution as a common source supply for multiple patients.</li> <li>▶ Never administer medications from the same syringe to more than one patient, even if the needle is changed.</li> <li>▶ Never enter a vial with a syringe or needle that has been used for a patient if there is any possibility that the medication might be used for another patient.</li> <li>▶ Medications should be drawn up in a designated “clean” medication area that is not adjacent to areas where potentially contaminated items are placed.</li> <li>▶ Discard medication vials upon expiration or any time that there are concerns regarding the sterility of the medication.</li> <li>▶ Consider a syringe or needle/cannula to be contaminated once it has been used to enter or connect to a patient’s intravenous infusion bag or administration set.</li> </ul>
<p><b>Safe Practices for Diabetes Care</b></p> <ul style="list-style-type: none"> <li>▶ Never re-use needles, syringes, or lancets.</li> <li>▶ Restrict use of finger stick capillary blood sampling devices to individual patients. Consider single-use lancets that permanently retract upon puncture.</li> <li>▶ Dispose of used finger stick devices and lancets at the point of use, in a safety-approved, stationary sharps container.</li> <li>▶ When feasible, assign glucometers to individual patients.</li> </ul>
