## Tropical Rainfall Measuring Mission's Clouds and the Earth's Radiant Energy System

The Clouds and the Earth's Radiant Energy System (CERES) instrument is one of five instruments that will be flown aboard the Tropical Rainfall Measuring Mission (TRMM) observatory. The data from the CERES instrument will be used to study the energy exchanged between the Sun; the Earth's atmosphere, surface and clouds; and space.

### Balancing the Earth's Energy Budget

The Earth's daily weather and climate are controlled by the balance between the amount of solar energy received by the Earth (both by its surface, and its atmosphere and clouds) and the amount of energy emitted by the Earth into space. Scientists have been working for decades to understand this critical energy balance - to understand the budget of incoming and outgoing energy, called the Earth's radiation budget.

A major portion of the energy received from the Sun is at short wavelengths while the majority of energy emitted by the surface of the Earth and by clouds is at long wavelengths. Increases in the amounts of greenhouse gases (gases in the atmosphere that absorb the long wavelength energy emitted by the Earth) can lead to a warming of the Earth's surface. Such changes may, in turn, cause changes in the Earth's weather and climate. Some of the shortwave radiation from the Sun is also reflected back into space by clouds and small particles in the atmosphere called aerosols. Major sources of aerosols include wind-blown dust, emissions from the burning of fossil fuels such as gasoline, and the

burning of forests and agricultural fields (biomass burning).

### Cloud Effects

One of the most intriguing questions facing climate modelers today is how clouds affect the Earth's climate and vice versa. The U.S. Global Change Research Program classifies understanding the role of clouds and the Earth's energy budget as its highest scientific priority. Understanding cloud effects requires a detailed knowledge of how clouds absorb and reflect incoming shortwave solar energy, as well as how they absorb and re-emit outgoing longwave energy. For example, low, thick clouds primarily reflect incoming solar energy back to space causing cooling. Thin, high clouds, however, primarily trap outgoing longwave energy and produce warming. To date, satellite studies have found that clouds have an overall net cooling effect on the Earth.

Analyses of satellite data also have shown that clouds which form over water are very different from clouds which form over land. These differences affect the way clouds reflect sunlight back into space and how much longwave energy emitted by the Earth is absorbed by clouds and re-emitted. For example, over the equatorial Pacific Ocean during El Niño events, there is a significant decrease in the amount of energy emitted by the Earth due to increased cloudiness. El Niño events occur when portions of the Pacific Ocean become considerably warmer than normal. Clouds appear over the relatively

warmer portions of the eastern Pacific and decrease over the relatively cooler western Pacific. These changes can affect weather patterns around the world.

### Water Vapor Effects

Water vapor in the atmosphere also affects our daily weather and climate, though scientists are only beginning to understand how this complex mechanism works. Water vapor acts like a greenhouse gas, absorbing outgoing longwave energy. Because water vapor also condenses to make clouds, an increase in water vapor in the atmosphere also may increase the amount of clouds.

### The CERES Instrument

The CERES instrument is based on NASA Langley's highly successful Earth Radiation Budget Experiment which used three satellites to provide global energy budget measurements from 1984 to 1993.

CERES will measure the energy at the top of the atmosphere, as well as estimate energy levels within the atmosphere and at the Earth's surface. Using information from very high resolution cloud imaging instruments on the same spacecraft, CERES also will determine cloud properties, including cloud-amount, altitude, thickness, and the size of the cloud particles. All of these measurements are critical for advancing our understanding of the Earth's total climate system and further improving climate prediction models.

Five CERES instruments will be flown on multiple satellites starting with TRMM, followed by a launch on the Earth Observing System (EOS)-AM satellite in 1998 and the EOS-PM satellite in 2000. Follow-up CERES satellite missions are planned to create a continuous 15-year history of highly accurate energy budget and cloud data for enhanced climate analyses.

### Educational Outreach Programs

School children worldwide will be involved in the CERES program, enabling them to be part of a scientific project. As a CERES instrument passes over, students will make local observations to determine the types of clouds over their school, the clouds' altitudes and how much of the sky is covered by clouds. Via the Internet, the students will then place their data in the NASA Langley Distributed Active Archive Center where the data will be stored for further analysis by the CERES science team.

TRMM is NASA's first mission dedicated to observing and understanding the tropical rainfall and how this rainfall affects the global climate. It is a joint mission with the National Space Development Agency of Japan. The primary instruments for measuring precipitation are the Precipitation Radar, the

TRMM Microwave Imager, and the Visible and Infrared Scanner. Additionally, TRMM will carry the Lightning Imaging Sensor and CERES. These instruments can all function individually or in combination with one another.

More information on CERES is available via the Internet at:
