REVIEW OF THE REVISED ANALYTICAL PLAN FOR EPA'S SECOND PROSPECTIVE ANALYSIS - BENEFITS AND COSTS OF THE CLEAN AIR ACT 1990-2020

An Advisory by a Special Panel of the Advisory Council on Clean Air Compliance Analysis

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON D.C. 20460

OFFICE OF THE ADMINISTRATOR
SCIENCE ADVISORY BOARD

May 20, 2004

EPA-SAB-COUNCIL-ADV-04-004

The Honorable Michael O. Leavitt
Administrator
U.S. Environmental Protection Agency
1200 Pennsylvania Avenue, NW
Washington, DC 20460

Subject: Review of the Draft Analytical Plan for EPA's Second Prospective Analysis – Benefits and Costs of the Clean Air Act, 1990-2020: An Advisory by the Advisory Council for Clean Air Compliance Analysis

Dear Administrator Leavitt:

Congress established the US EPA Advisory Council for Clean Air Compliance Analysis Council (the Council) to review the data and methodologies to be used for the 812 Analyses and make recommendations on their use. Section 812 of the Clean Air Act Amendments of 1990 also requires the Council to review the findings made in reports developed under Section 812, and "make recommendations to the Administrator concerning the validity and utility of such findings." A Special Panel of the Council presents in this document a review of the Agency's *Draft Analytical Plan for EPA's Second Prospective Analysis - Benefits and Costs of the Clean Air Act, 1990-2020*.

The Draft Analytical Plan reflects the Agency's design for the Second Prospective "812 Analysis." The series of Section 812 reports produced by the Agency are the flagship examples of benefit-cost analysis of environmental regulation in the U.S. These analyses have assisted the Agency in developing methods used in quantifying benefits and costs for rules issued by EPA pursuant to the 1990 amendments to the Clean Air Act. Those benefits have been recognized by OMB as constituting the majority of quantified benefits attributable to federal regulation over the ten-year period, October 1, 1992 to September 30, 2002. (OMB 2003 Report, *Informing Regulatory Decisions: 2003 Report to Congress on the Costs and Benefits of Federal Regulations and Unfunded Mandates on State, Local, and Tribal Entities*).

The 812 Analyses were initially mandated as ongoing biennial reports to Congress. The Council understands that the 1995 Reports Elimination and Sunset Act removed the requirement for the Agency to report to Congress. However, the Council strongly advocates that the Agency continue to conduct these important benefit-cost assessments as Clean Air regulations continue to evolve. These analyses provide a rigorous example for other regulatory impact assessments and serve an important educational role for the Agency. Information requirements identified in the 812 Analysis stimulate important research both inside and outside the Agency.

The Council emphasizes that the 812 Analyses are not merely a perfunctory accounting exercise, but an ambitious and difficult enterprise that pushes the Agency to the frontiers of science in many different disciplines. To an extent unmatched in almost any other benefit-cost assessment, these analyses require the creative synthesis of knowledge across many interrelated fields--from engineering to atmospheric chemistry to meteorology to epidemiology and ecosystems science to toxicology to economics and a number of other specialties.

A significant portion of the value of the 812 Analyses lies in the extent to which they can shape future regulations and legislation. Their role is not limited merely to assessment of the 1990 Clean Air Act. For example, the Agency learns much from the 812 Analyses that can guide strategic planning for the programs of the Office of Air and Radiation.

In this report, the Council emphasizes the notion of a "Section 812 Learning Laboratory," as well as several technical points that deserve the Administrator's attention. These include scenario development, mortality risk valuation (which is both important and controversial), the role of Quality Adjusted Life Years (QALYs) in assessment of the benefits of implementing the Clean Air Act, uncertainty analysis and characterization, computable general equilibrium (CGE) modeling for capturing indirect costs and benefits, and approaches to discounting. Highlights for these topics and others are presented in our Executive Summary.

The Council received 37 formal charge questions in May 2003 from the Agency concerning technical questions related to data and methodologies identified in the *Analytical Plan* for possible use in the Second Prospective Analysis. This Council report addresses overarching questions concerning the analytical framework for the analysis and detailed questions related to economic analysis. This report supplements previous reports provided by the Council's subcommittees on emissions estimation and health effects analysis issues raised by the *Analytical Plan*. A third subcommittee, the Ecological Effects Subcommittee (EES) has just been constituted. Its perspective and advice will be available for future advice.

We appreciate the opportunity to review the Analytical Plan and to provide you with advice on the design of the Agency's approach so that the resulting study will have the most validity and utility for the Agency and Congress. The Council would be pleased to expand on any of the findings described in this report and we look forward to your response.

Sincerely,

/Signed/

Dr. Trudy Ann Cameron, Chair
Advisory Council on Clean Air
Compliance Analysis

Advisory Council on Clean Air Compliance Analysis
Special Council Panel for the Review of the Third 812 Analysis

CHAIR
Dr. Trudy Ann Cameron, University of Oregon, Eugene, OR

MEMBERS
Dr. David T. Allen, University of Texas, Austin, TX

Ms. Lauraine Chestnut, Stratus Consulting Inc, Boulder, CO

Dr. Lawrence Goulder, Stanford University, Stanford, CA

Dr. James Hammitt, Harvard University, Boston, MA

Dr. F. Reed Johnson, Research Triangle Institute, Research Triangle Park, NC

Dr. Charles Kolstad, University of California, Santa Barbara, CA

Dr. Lester B. Lave, Carnegie Mellon University, Pittsburgh, PA

Dr. Virginia McConnell, Resources for the Future, Washington, DC

Dr. Bart Ostro, California Office of Environmental Health Hazard Assessment (OEHHA), Oakland, CA

Dr. V. Kerry Smith, North Carolina State University, Raleigh, NC

OTHER SAB MEMBERS
Dr. Dale Hattis, Clark University, Worcester, MA

CONSULTANTS
Dr. John Evans, Harvard University, Portsmouth, NH

Dr. Thomas S. Wallsten, University of Maryland, College Park, MD

SCIENCE ADVISORY BOARD STAFF
Dr. Angela Nugent, Washington, DC

NOTICE

This report has been written as part of the activities of the EPA Advisory Council on Clean Air Compliance Analysis (Council), a public advisory group providing extramural scientific information and advice to the Administrator and other officials of the Environmental Protection Agency. The Council is structured to provide balanced, expert assessment of scientific matters related to problems facing the Agency. This report has not been reviewed for approval by the Agency and, hence, the contents of this report do not necessarily represent the views and policies of the Environmental Protection Agency, nor of other agencies in the Executive Branch of the Federal government, nor does mention of trade names of commercial products constitute a recommendation for use. Reports of the Council are posted on the EPA website at http://www.epa.gov/sab.

Table of Contents

1. EXECUTIVE SUMMARY

EPA requested that the Council provide detailed advice on 37 technical questions related to the planned Second Prospective Analysis. Overall, the Agency's general approach to this major benefit-cost analysis has become much more mature and complex with this third undertaking. The Council's response to each charge question begins with a set of bulleted points that highlight the key issues in the discussion. Here, the Council summarizes the most important recommendations for strengthening the Agency's plans for conducting the 812 Analysis. The points are ordered roughly in terms of the Council Special Panel's sense of the importance of the topic.

The first three issues highlighted below—the "Learning Laboratory," uncertainty, and issues of integration and consistency—are pervasive. Related to them, several other issues have importance of special note: (1) discounting; (2) the indirect costs revealed by Computable General Equilibrium models; (3) the Value of a Statistical Life; and (4) development of methods for assessing benefits associated with ecological effects and regulation of air toxics. These controversial issues have posed challenges in past 812 Analyses and will likely reappear in the course of future benefit-cost analyses by the Agency. They will continue to demand the Agency's close attention.

The Learning Laboratory. The series of 812 Analyses, if they are to incorporate the state of the art in relevant disciplines, must involve auxiliary activities that can be collected under an umbrella that might be termed the "812 Learning Laboratory." The Council advises the Agency to develop a public and expert process to review new data and methods for upcoming 812 Analyses carefully and to evaluate the rationale for incorporating new data and methods in subsequent analyses. When warranted, these approaches can then be moved into the mainstream for the next 812 Analysis, replacing less suitable data or methods used in previous studies. Candidates for the Learning Laboratory process include broadly cross-cutting issues that will have implications not just for the 812 Analyses, but for many other benefit-cost analyses conducted at the Agency and elsewhere, including a number of the issues itemized directly below.

Uncertainty. The Council applauds the Agency's intentions to incorporate much more recognition of uncertainty in the Second Prospective Analysis than was present in the First Prospective Analysis. In the Second Prospective Analysis, the Agency intends to address the pervasiveness of uncertainty in both its cost and its benefit estimates. Those elements that are both highly uncertain and have the potential to change the results significantly should be the focus of sensitivity analyses. The results of these sensitivity analyses should be presented in close proximity to the central estimates in summary tables of Clean Air Act Amendment (CAAA) impacts. Sensitivity/uncertainty analysis needs to be an iterative process to identify and assess the significance of key uncertainties in each step of the assessment. As a practical matter, only a selected set of the most influential uncertainties should be quantitatively followed all the way through to the final results. The Council advises the Agency to develop its uncertainty analyses with reference to the recommendations in reports of the National Research Council

(2002) and OMB (2003). It also advises the Agency to utilize the list of "key uncertainties" from the First Prospective Analysis as a framework.

In the Executive Summary of the planned Prospective Analysis and in the body of the text itself, the Agency should report its best central estimate as the "base case." Alternative cases should be associated with likelihoods of these cases and any provision of a "low" alternative estimate should be balanced by a corresponding "high" alternative estimate. Pivotal assumptions should be clearly identified and the need for additional research on these issues should be emphasized.

Issues of Integration, Consistency, and Validation. The 812 Analyses have become a more complex modeling enterprise, and public and OMB scrutiny has increased with respect to federal efforts that use models as the basis for developing policy tools. Thus, the Council Special Panel emphasizes the importance of choosing consistent and compatible modeling assumptions across all components of the analysis. Especially important issues arise in this regard in the areas of discounting and computable general equilibrium (CGE) analysis. The Council also advises the Agency to consider approaches for assuring data quality and providing intermediate information about analytical results that will improve the quality of the overall analysis and increase the transparency of the benefit-cost exercise, while not resulting in substantial costs to the Agency.

Discounting. The Prospective Analysis will derive discounted values of the projected benefits and costs resulting from Clean Air Act emissions reductions for selected future years. Such discounting should be performed using a "social discount rate" throughout the analysis, unless the Agency wants to show discounted private costs as perceived by an individual firm. The Council commends the Agency drawing attention to the challenges and uncertainties associated with the choice of social discount rate. The Council urges the Agency to employ a range of values – perhaps between 3 and 7 percent, with a central case of 5 percent – for the social discount rate in its assessments.

Indirect Costs and Use of Computable General Equilibrium Models. Incorporation of indirect "spillover" costs of air quality regulations is important and these costs should continue to receive close attention. CGE models have the capability to reveal indirect costs and other consequences of air quality regulations that spill over into unregulated sectors, not just to better estimate the direct costs of regulation on regulated sectors. The current Analytical Plan describes CGE methods only for "post-processing" and relegates them to secondary status compared to engineering estimates of compliance costs. Ideally, general equilibrium modeling should enjoy similar status to direct cost calculations, even though each of the main CGE models proposed for use in the 812 Analysis has some limitations. CGE models and econometric models for costs are not competing methods, but complementary methods. Indirect costs should be defined and itemized more clearly in the Analytical Plan. Ongoing comparisons of the predicted and actual costs of air quality regulations will be important to the evolution of the ongoing Section 812 Analyses.

Value of Human Health Risk Reductions Associated with Reductions in Air Pollution. Ideally, uncertainty analysis with respect to Value of a Statistical Life (VSL) assumptions

requires information about the distribution of VSL estimates corresponding to risks and populations that are similar to those relevant for the CAAA. The marginal distribution of all empirical VSL estimates derived across all contexts is unlikely to be appropriate for this purpose, as is any arbitrary convenient assumption about distributional shape. Unfortunately, there are very few, if any, values in the literature that are derived in a context that is a sufficiently close match for this policy context. Instead, the playing field is occupied by unexplained large differences in VSL estimates, even those derived in very similar (e.g. workplace) contexts.

The Panel does not wish to encourage the strategy, pursued in the first analytical blueprint, of excluding a variety of VSL studies on fairly arbitrary criteria because the are "unsuitable." Resolution of this issue awaits the findings of further comprehensive meta-analyses. While the results of different meta-analyses continue to come in, the Council might lean toward recommending reliance on the Viscusi-Aldy estimates of VSLs based on U.S. studies. However, these are limited to wage-risk studies and it is probably premature to conclude that the Viscusi-Aldy analysis provides the last word. The Agency should not rely exclusively on the Kochi et al. meta-analysis, which has not yet been peer-reviewed and published.

The Council understands the Agency's interest in conducting cost-effectiveness analysis since this is being required by OMB in addition to benefit-cost analysis for major regulations. The Council has had difficulty, however, in coming to full agreement about the appropriateness of Quality Adjusted Life Years (QALYs) for use in this context. The limitations of the measure have led some members to want to recommend against using it at all, but others are more comfortable endorsing exploratory efforts to apply the measure, even though they also acknowledge the same limitations. The deliberations of the Institute of Medicine's Committee to Evaluate Measures of Health Benefits for Environmental, Health, and Safety Regulations can be expected to be of considerable value in resolving some of the Council's concerns. In addition, the Council wants to emphasize that there are important limitations of any cost-effectiveness analysis for a regulatory program as broad as the Clean Air Act Amendments, because there are many other classes of benefits besides human health benefits to be taken into consideration. While cost-effectiveness analyses do not belong in the main 812 Analysis, because the latter is defined as a benefit-cost analysis, the Council recognizes that the Agency may wish to develop alternative cost-effectiveness analyses and these are appropriate for consideration with the "Learning Laboratory."

Concerning morbidity, the Agency should continue to use Willingness-to-Pay (WTP) estimates for morbidity values, rather than cost-of-illness (COI) estimates, should these be available. Where WTP is unavailable, COI estimates can be used as placeholders, awaiting further research, provided suitable caveats are included in the analysis. The Dickie and Ulery study is a valuable addition to the repertoire of empirical results concerning WTP for acute respiratory illnesses and symptoms, although it is not so superior as to supercede all earlier studies.

Ecological Effects. Human health risk reductions may be the most substantial benefit from the CAAA, but they are not the only important benefit. Benefits to ecosystems and other welfare benefits such as visibility are likely to be substantial and are still receiving limited attention. The Council nevertheless recognizes substantial challenges in quantitative assessment

of these benefits. The greater heterogeneity in ecosystems services makes it even more difficult to produce estimates of the benefits from their protection than for the protection of human health. Ecological effects to be valued must be limited to those effects for which there is a defensible, rather than just speculative, link between air emissions and service flows. The Council strongly objects to using inappropriate or unsupported placeholder values in the absence of better information.

The advice of the new Council Ecological Effects Subcommittee (EES) may be able to stimulate more progress in the analytical work in this area, as well as the development of greater expertise on this issue than is presently available. The Council also notes that the Science Advisory Board (SAB) Committee on Valuing the Protection of Ecological Systems and Services (C-VPESS) will be providing advice generally to the Agency on this topic. The Council plans to follow the progress of this new Committee closely for insights helpful to the 812 process.

Hazardous Air Pollutants. Appropriate methods for measuring the benefits of reducing hazardous air pollutants continue to present a challenge for the 812 Analysis. Great uncertainty about the character and magnitude of health effects at ambient exposure levels will continue to hamper valuation efforts, but the potential importance of this category of benefit necessitates continued careful attention to this task.

2. INTRODUCTION

2.1. Background

The purpose of this Advisory is to continue the Council's advice to the Agency in developing the third in a series of statutorily mandated comprehensive analyses of the total costs and total benefits of programs implemented pursuant to the CAAA. Section 812 of the CAAA of 1990 requires the EPA periodically to assess the effects of the 1990 CAA on the "public health, economy and the environment of the United States" and to report the findings and results of the assessments to Congress. Section 812 also established the Council and gave it the following mission: "to review the data and methodology used to develop the 812 Analysis and to advise the EPA Administrator concerning the utility and relevance of the Study." EPA has, to date, completed two assessments and received the advice of the Council on them: *The Benefits and Costs of the Clean Air Act: 1970 to 1990* (published 1997) and *The Benefits and Costs of the Clean Air Act, 1990 to 2010* (published 1999).

In this document, a special panel of the Council provides a review of the May 12, 2003 Analytical Plan for the study, and revisions to that plan dated July 8, 2003. The Analytical Plan is more formally titled *Benefits and Costs of the Clean Air Act 1990-2020: Revised Analytical Plan for EPA's Second Prospective Analysis*. The Analytical Plan reflects earlier advice that the Council provided in September 2001 in its earlier Advisory concerning a draft version of the Analytical Plan (EPA-SAB-COUNCIL-ADV-01-004).

In the course of this review of the 2003 Analytical Plan, the Council has reviewed the Agency's major goals, objectives, methodologies, and analytical choices for the Section 812 Analysis before the analysis will be implemented. In its review of the Analytical Plan, the Council and its panel and subcommittees were guided by the charge questions as identified in the CAAA of 1990.[1]

a. Are the input data used for each component of the analysis sufficiently valid and reliable for the intended analytical purpose?
b. Are the models, and the methodologies they employ, used for each component of the analysis sufficiently valid and reliable for the intended analytical purpose?
c. If the answer to either of the two questions above is negative, what specific alternative assumptions, data or methodologies does the Council recommend the Agency consider using for the second Prospective Analysis?

The Agency provided the Council with additional detailed charge questions for its consideration. These detailed charge questions were initially provided to the Council in May

[1] Specifically, subsection (g) of CAA §312 (as amended by §812 of the amendments) states: *(g) The Council shall -- (1) review the data to be used for any analysis required under this section and make recommendations to the Administrator on the use of such data, (2) review the methodology used to analyze such data and make recommendations to the Administrator on the use of such methodology; and (3) prior to issuance of a report required under subsection (d) or (e), review the findings of such report, and make recommendations to the Administrator concerning the validity and utility of such findings.*"

2003 and were then revised and resubmitted in July 2003. The final set of 37 charge questions is included in Appendix A. Appendix A also indicates charge questions that have been addressed in detail by the Council's Air Quality Modeling Subcommittee (AQMS) and Health Effects Subcommittee (HES) and documented in their two reports, which have been reviewed and finalized by the Council.[2]

The Council envisions that its new Ecosystems Effects Subcommittee (EES) will provide additional expertise to assist the Council in responding fully to Charge Questions 18-20 concerning ecological assessment and valuation, for which only provisional, limited responses are given in this report.

2.2. Process for Developing this Advisory

To address the charge questions identified by the Agency regarding the Analytical Plan, the SAB Staff Office, with the advice of the Council Chair, formed a Special Council Panel for the Review of the Third 812 Analysis to provide the Council with additional expertise in the areas of expert elicitation, uncertainty analysis and statistical and subjective probability. The Staff Office also issued a call for new membership on the Council's AQMS and its HES.

The Council Special Panel held a public teleconference on May 28, 2003 to plan its approach for providing advice. Those members participating in the teleconference voted to cancel a planned face-to-face meeting during June 11-13, 2003, pending more information about those portions of the Analytical Plan that were to be revised. The majority of these revisions were completed and submitted to the Council on July 8, 2003. The Council held one teleconference on July 11, 2003 and another on July 15, 2003, where a subset of the charge questions considered most urgent by the Agency were addressed. Those charge questions were 1, 2, 3, 7, 8, and 9. Teleconferences on September 23, 2003 and September 24, 2003 continued this discussion and also addressed charge questions 32 and 33. A teleconference on October 23, 2003 reviewed the draft report on discussion to that point. Discussion of question 1 (Project Goals and Analytical Sequence), question 3 (Alternative Pathways) and question 9 (Discounting) raised the need for additional information from the Agency, so discussion was deferred to November 5-6, 2003 when the first face-to-face meeting of the Panel was held in Washington, D.C. Subsequent teleconferences were held on December 19, 2003, December 22, 2003, and March 18, 2004.

In addition to the advice provided in this document, the Council's AQMS has met to address issues concerning the Agency's plans for estimating emissions and the HES has met to address the Agency's plan to assess health effects. The advice developed by these Council Subcommittees is provided in separate reports.

---

[2] The *Advisory on Plans for Emissions Estimation Presented in the May 12, 2003 Analytical Plan: An Advisory by the Air Quality Modeling Subcommittee of the Advisory Council for Clean Air Compliance Analysis* (EPA-SAB-COUNCIL-ADV-04-001), and the *Advisory on Plans for Health Effects Analysis in the Analytical Plan for EPA's Second Prospective Analysis – Benefits and Costs of the Clean Air Act, 1990-2020: An Advisory by the Health Effects Subcommittee of the Advisory Council for Clean Air Compliance Analysis* (EPA-SAB-COUNCIL-ADV-04-002).

3. PROJECT GOALS AND ANALYTICAL SEQUENCE

3.1. Charge Question 1

Does the Council support the study goals, general analytical framework, disaggregation plan, analytical sequence, and general analytical refinements defined in chapter 1? If there are particular elements of these plans which the Council does not support, are there alternatives the Council recommends?

3.2. Summary of Council Response

- The series of 812 Analyses, if they are to incorporate the state of the art in relevant disciplines, must involve auxiliary activities that can be collected under an umbrella that might be termed the "812 Learning Laboratory." Of course, the main policy analysis in each cycle must be based upon fully vetted methods and data. However, the expectation of changes and improvements in methods should be institutionalized by an ongoing process of formal evaluation of proposed enhancements. As enhancements are carefully reviewed and the reasons for them thoroughly understood, they can be moved into the next main policy analysis, replacing inferior approaches used in previous studies. Candidates for the Learning Laboratory process include broadly cross-cutting issues that will have implications not just for the 812 Analyses, but for many other benefit-cost analyses conducted at the Agency and elsewhere.

- Disaggregation is a very desirable strategy which should be pursued to the extent that analytical resources permit, subject to the constraints imposed by nonlinearities and general equilibrium effects. The Council supports the Agency's plans to report costs and benefits disaggregated by major economic sectors as an important addition for the Second Prospective Analysis.

- Air toxics remain an important issue in the 812 Analysis. The benzene case study is a good start, but much more work is still necessary. Case studies on a few selected Hazardous Air Pollutants (HAPs) are merely a beginning.

- Human health risk reductions may be the most substantial benefit from the CAA, but they are not the only important benefit. Benefits to ecosystems and other welfare benefits such as visibility are likely to be substantial and are still receiving limited attention. The Council nevertheless recognizes substantial challenges in quantitative assessment of these benefits.

- Chapter 1 of the 812 Analysis should address the pervasiveness of uncertainty in cost and benefit estimates, but then identify the methods the Agency will use to identify the most important areas of uncertainty. Those elements that are both highly uncertain and have the potential to significantly change the results should be the focus of

sensitivity analyses. The results of these sensitivity analyses should be presented in close proximity to the central estimates in summary tables of CAAA impacts. Sensitivity/uncertainty analysis needs to be an iterative process to identify and assess the significance of key uncertainties in each step of the assessment. Only a selected set of the most influential uncertainties should be quantitatively followed all the way through to the final results.

3.3. Section 812 Analysis as a Learning Laboratory

The Council emphasizes that the Agency's Prospective Analyses address important policy questions with a very broad audience. As a result, these analyses attract significant public attention. This status poses challenges for the Agency's efforts to innovate and reflect new research insights on a continuous basis. Any recommendations to modify existing methodologies to take advantage of the most up-to-date insights from the relevant literature may be viewed with suspicion by different groups of stakeholders if their interests are affected by these methodological changes. To protect the Agency's credibility, there is a need to balance innovation in methods against the appearance of manipulation of results to achieve some implicit predefined objective.

These concerns seem to require that the long-term analysis protocol for the Prospective Analyses distinguish three separate classes of Agency activities:

a. "Policy Evaluations" - Analyses included as part of the formal 812 Analyses. These activities are based on established and fully vetted methods, even if the inputs are somewhat less than ideal (e.g. they may be identified as resorting to the best available approximations for some needed measurements).

b. "Satellite or Experimental Evaluations" – These activities use proposed methods and new techniques that have not yet been fully vetted. The models currently used in Policy Evaluations, such as those included in 812 Analyses, may embody some assumptions that deserve examination either on the basis of new data, or *a priori* on the basis of theory. The need for improved models may be readily acknowledged, and exploratory Satellite/Experimental Evaluations will address this need.[3]

c. "Formal Review and Discussion" – These activities will precede the development of Satellite/Experimental Evaluations. The Agency needs to make a commitment to involve the research community in discussions that assess possible new methods through workshops or conferences, detailed and comprehensive reviews of unofficial analyses, and evaluation of their implications in working papers and

[3] In these evaluative activities, the Agency would parallel the Bureau of Economic Analysis (BEA) satellite accounts for the national income and product accounts, or the provisional or unofficial price indexes developed by Bureau of Labor Statistics (BLS). In each of these analogous classes, the research staff of the relevant agency develops and publishes results designated as exploratory. These exploratory results are carefully documented and are intended for general review and criticism. However, they would not be used for policy making or included in 812 Analysis at this stage.

published articles. For example, this approach has been taken in price index development at the BLS.

All three classes of activities should probably be ongoing, all the time. This formal process would institutionalize the recognition that methodological innovations over time are a natural and expected part of progress on this front. This process would also emphasize that changes in methodology require full disclosure and discussion of the implications of new methods – both their strengths and their weaknesses. The disclosure and discussion process is not simply a matter of refereed publication followed by Agency adoption of new methods. Instead, it is one of attaining broad public understanding of the assumptions involved in different approaches and acceptance of the reasons for changes in methodologies.

At present, this tiered approach to methodological innovation is not an established component of the Agency's research in support of policy, although there have been occasional instances. The Council Special Panel recommends that this component be given serious consideration. It is only through a commitment to internal but widely circulated public efforts to review, evaluate and understand new methods that the Agency can promote necessary analytical innovations, yet avoid the appearance of strategic manipulation of the process.

Additional discussion of the Learning Laboratory may be found in Section 14.5 of this Advisory Report

3.4. Disaggregation

The Council commends the Agency's willingness to disaggregate, something that the Council has recommended for some time. In an ideal world, the disaggregation would be at the level of individual regulatory decisions so that the Agency, Congress, and society would know whether each regulation should be tightened or loosened. Effort toward disaggregation to the level of individual sectors is an important step. The next steps beyond sectoral disaggregation might be limited regulation-by-regulation disaggregation and/or some cautious region-by-region disaggregation (although this is likely to be more feasible for selected benefits than for costs).

There remain some important constraints on the task of disaggregation. The Council understands that it is often impossible to separate the benefits or costs of abating one pollutant versus another. Analytical resource constraints must also be accommodated. The Council also warns that the benefits and/or the costs associated with different sectors, regulations, or regions may not be additively separable because of nonlinearity or interaction effects among the disaggregated entities. In addition, general-equilibrium adjustments may shift incidence among sectors and regions. These complications make the process of disaggregating benefits and costs more difficult. However, decision makers often are interested in sectoral and regional effects. Providing disaggregated estimates wherever possible will increase the usefulness of the analysis in policy making.

The Council suggests that the Agency consider disaggregating by region or program on a case-by-case basis, where costs are significant or other policy needs are well articulated, and then evaluating the result.

3.5. Air Toxics

The plan to address the particular benefits and costs of abating toxics is a step forward and the Council endorses this effort. Although the proposed case study on benzene will be very helpful, the assessment of air toxics for 812 Analyses should not be expected to stop there. For example, Congress mandated maximum achievable control technology (MACT) for a list of chemicals, but the chemicals on this list were not identified by any rigorous systematic analysis. This mandate has imposed substantial costs on the economy without any formal assessment of either its benefits or its costs.

The Agency is entering a period when it must examine the residual risk after MACT to determine whether more stringent regulations are required in some cases. One role of the Section 812 Analyses is to explore new methods relevant to the assessment of environmental management strategies. This is a good reason for the Second Prospective Analysis to address the task of benefit-cost analysis with respect to the control of air toxics. The Agency is likely to find that MACT is supported by benefit-cost analysis for some chemicals and not supported for others. These insights will be important to the Administrator, to Congress, and to society more generally. While some environmental laws are implemented with a safety standard in mind, rather than an efficiency standard, environmental laws should be implemented so as to be consistent with the best available scientific information.

The benzene study was recommended in the last round of Council advice primarily because of the relatively greater availability of data on this HAP. It would be useful to have the Agency propose some other target examples for case studies. Whether these can actually be pursued in the context of the Second Prospective Analysis is questionable, but assessment of HAPs should be a priority among longer-term assessment tasks facing the Agency.

As a starting point for future analyses, perhaps the Agency should pick at least one chemical that is likely to have regulatory benefits exceed costs, and at least one chemical that will have costs exceed benefits. This would constitute a useful demonstration exercise that could reveal what resources are required for this type of air toxics analysis. Alternatively, some argument can be made that it would be preferable to see a more representative sample of HAPs being analyzed, for example, those from relatively small sources, such as perchlorethylene from dry cleaning establishments, or chromate from plating operations. These tend to be from isolated sources, rather than major sectors, and to be common in urban areas.

Are case studies really useful in the formal benefit-cost analysis of the Section 812 Analysis? Perhaps not directly, but the Council advocates these exercises as part of "progress toward a goal," rather than suggesting that they represent any intermediate or final input to the current benefit-cost analysis. More complete and more formal analysis of air toxics is certainly needed as the Section 812 analytical process matures. As in the case of certain aspects of the calculation of non-market economic benefits, the air toxics tasks fall into the category of methods development, or contributions to the evolution of a body of knowledge—efforts that are relevant to the ongoing Section 812 analytical activity. Fostering valuable new research is a tangential goal of the 812 process.

3.6. Non-health benefits

Mortality risk reduction benefits are about 90% of total benefits quantified in the previous Section 812 Analyses. But it is likely to be implausible to most people (and most members of Congress) that non-mortality health benefits are small, or that benefits other than human health benefits are tiny or immeasurable. The Analytical Plan touches on visibility as a non-health effect. More contentious, and potentially very important, are the benefits from protection of the natural environment (ecosystems) stemming from the CAA.

In the first round of advice from the Council to the Agency concerning the Second Prospective Analysis (EPA-SAB-COUNCIL-ADV-01-004), the Council emphasized that the Costanza et al. (1998) method was an inappropriate way to approach the task of ecosystem benefits estimation. However, the Agency cannot ignore this category of benefits or continue simply to characterize their valuation as intractable. Certainly the planned case study is too little. Delays in bringing online the new subcommittee of the Council, the EES, and the SAB C-VPESS may lead to corresponding delays in any advice that can be provided to the Agency concerning the challenges presented by valuation needs in this area. Nevertheless, the importance of this category of benefits should be recognized in the Prospective Analysis.

3.7. Uncertainty

Uncertainty will be addressed much more comprehensively in the Council's discussion of Chapter 9 of the Analytical Plan. However, with respect to the overview of the Agency's goals in Chapter 1, it would be helpful to see more attention to the pervasiveness of the problem of uncertainty, especially where linearity assumptions are crucial and tenuous. Uncertainty analysis is something that needs to be ongoing throughout the assessment process. Informed judgments need to be made about what might be the key sources of uncertainty, and the potential consequences of this uncertainty, in each step of the assessment.

However, this does not mean that every alternative model and alternative assumption needs to be tracked all the way through the assessment to the bottom line. The Council does not wish to lead the Agency down an intractable path of including so many alternative models and alternative assumptions that the assessment loses its focus and coherence. For example, it is vitally important that the electric utility cost analysis involve some assessment of how sensitive the cost results are to different assumptions about the future price of natural gas and general economic growth, and some discussion of this exploration should be reported in the Second Prospective Analysis. Those elements that are both highly uncertain and have the potential to change the results significantly should be the focus of sensitivity analyses. The results of these sensitivity analyses should be presented in close proximity to the central estimates in summary tables of CAAA impacts.

4. SCENARIO DEVELOPMENT AND ALTERNATIVE PATHWAYS

4.1. Agency Charge Questions

Charge Question 2: Does the Council support the choices for analytical scenarios defined in Chapter 2? Are there alternative or additional scenarios the Council recommends EPA consider for inclusion in the analysis?

Charge Question 3: Does the Council support the alternative compliance pathway estimation and comparison methodology described in chapter 2, including the specification of alternative compliance pathways which may not reflect precisely constant emissions or air quality outcomes between scenarios due (primarily) to the non-continuous nature and interaction effects of emission control options?

4.2. Summary of Council Response

- Agency Charge Question 3 was made largely obsolete by revisions in the Analytical Plan that were made clear to the Council at its November 4-5, 2003 meeting and thus this Council report does not address the question.

- The evolving baseline assumptions for the 812 Analysis need to be carefully benchmarked against realized values of key forecasts from previous editions of the analysis, and sensitivity analysis with respect to key assumptions will be important.

- Care must be taken to ensure that key assumptions affecting different components of the overall 812 Analysis (discount rates, income growth projections, substitutability) are consistent across all the models used in the analysis.

- The "with CAAA" and "without CAAA" scenarios are neither observable nor likely to materialize exactly as described. They are artificial constructs. However, they should at least be internally consistent.

- The Agency should make it very clear to the audience for the 812 Analysis to what extent the post-2000 benefits of the CAAA are expected to stem from the prevention of deterioration in air quality versus absolute improvements from 1990 conditions.

- The evolutionary nature of regulations pursuant to the CAAA means that it is difficult to forecast future benefits and costs based solely on knowledge of the shape of current regulations. The Agency needs to be clearer about how feedback and regulatory evolution will be modeled.

- Finally, the Council applauds the Agency's transition to short turn-around air-quality models that will enhance opportunities for sensitivity analyses.

4.3. Benchmarking and sensitivity analysis

First, the Council recommends changing the description of the different scenarios from "pre-CAAA and post-CAAA" to "with CAAA and without CAAA." This simple change will eliminate confusion between differences over time and counterfactual differences over alternative scenarios, which is the intended distinction.

To evaluate the implications of the proposed update of the 1990 Baseline Emissions assumptions, it would be helpful to have an explicit comparison of how the proposed update to the 1990 baseline differs from the earlier 1990 baseline. The Second Prospective Analysis should compare the ambient pollution concentrations implied by the 1990 baseline used in the First Prospective Analysis versus the new baseline, and each ambient concentration should be compared with the 1990 actual monitored values for each pollutant. This could be done for targeted metropolitan areas (e.g., the Los Angeles air basin).

The description in the First Prospective Analysis suggests that a scaling factor was used to adjust the projected ambient air quality in 2000 and 2010. This scaling factor was apparently derived by taking the ratio of modeled target year to modeled base year and applying this ratio to scale base year concentrations (whether monitored directly or estimated using Voronoi Neighbor Averaging) to get the projected target year concentration. This type of benchmarking, of backcasted simulations to actual observed outcomes in 1990 and 2000, should be possible in the Second Prospective Analysis. It would help policy-makers understand the sensitivity of the results from air quality models to changes in the emissions profiles used in the analysis.

4.4. Consistency: economic activity and incomes

At the time the analysis was done for the First Prospective Analysis, expectations for economic activity were completely different than the realities experienced between 1999 and 2003. There is no discussion of how the recent slowdown in economic activity is being incorporated into the projections for 2000, 2010, and 2020. There must be some discussion of this linkage. A component of the uncertainty analysis will have to consider the status of the aggregate economy, including any assumptions about when there may be a return to a more robust growth pattern. Otherwise, the exercise might seem foolish.

There should be some explicit discussion of the connections between assumptions about economic activity at the aggregate level and the corresponding assumptions about household income growth that underlie the benefit measures. These assumptions should be consistent throughout the analysis. The Agency needs to make its "central case" economic assumptions clear, although the Council notes that there will continue to be considerable uncertainty about the nature of the relationship between economic activity and emission rates. Even a well-defined central case assumption about future levels of economic activity will not lead to an unambiguous forecast about pollutant emissions.

There is a need for sensitivity analysis concerning any assumptions about the baseline level of overall macroeconomic growth. However, the need to understand uncertainty about baseline growth rates for the economy as a whole is distinct from the need to understand the uncertainty about any differences in growth rates across individual sectors of the economy. It is

possible that assessments of the behavior of particular sectors are excessively dependent upon the predictions of just a small set of models. These models are, in general, rather highly aggregated and have been developed for different purposes than those for which they are being used in the Second Prospective Analysis. The Agency should use alternative models and solicit expert judgment on these issues, perhaps via a workshop. Rather than starting with the predictions of these models, it is important to step back and evaluate each model's assumptions and the sensitivity of its predictions to these assumptions.

Consistency is also an important issue in several other places in the Analytical Plan. For example, there is some discussion of meta-analysis with respect to the value of a statistical life to be used in the analysis. In the context of this discussion, there is mention of the prospect of making adjustments to VSL estimates to account for differences in income levels of the original study populations. How do these proposed income adjustments correspond to the income changes that are part of the general equilibrium consequences of the effects of air quality regulations on costs of production and therefore upon factor demands?

Finally, the underlying assumptions of different types of models used in the Analysis must be compatible. Most procedures for benefits assessment based on revealed preferences of individuals hinge crucially upon non-separability between pollution levels and observable behaviors. It is highly inconsistent to require non-separability in support of the valuation portion of the analysis that supports the benefits estimates, yet to preclude it in the general equilibrium assessment of cost estimates. How are the insights from Williams (2002, 2003) concerning health effects and optimal environmental policy to be incorporated as adjustments? Will there be scenarios to test the sensitivity of the cost estimates to these adjustments?

4.5. Artificiality of scenarios

Scenarios are being developed for the Second Prospective Analysis for 1990, 2000, 2010, etc. Obviously, some of the analysis needs to be done well before the point in time when the outcome levels for all activities in all periods are known. The First Prospective Analysis was done in 1997. At that time, the scenario data for 1990 was presumably based on actual levels of economic activity and actual emissions. In 1997, however, the scenario for 2000 could not have been based on realized levels of economic activity or emissions. There will have been a number of important variables intended to capture the consequences of the CAAA by 2000 that would have needed to be forecasted.

From the perspective of 2004, how well do the 1997 *ex ante* levels (assumed for the year 2000 for these "with CAAA" values of the variables) compare to the levels actually realized, now that the data for 2000 are available? If what was observed when the actual data for 2000 became available was different from what was assumed in 1997 for the "with CAAA" scenario, what were the reasons and what were the differences? The Agency needs to be concerned with level of economic activity and with the levels of emissions resulting from that level of economic activity. If there are any important "lessons" from the 1997 analysis, what do they imply for the Second Prospective Analysis, in terms of accuracy in forecasting the level and mix of economic activity with and without the CAAA regulations in place?

In forecasting future conditions under the "with CAAA" and "without CAAA" scenarios, a number of concerns may be relevant. For example, some non-attainment areas will remain out of attainment. It is also difficult to fully anticipate all of the general equilibrium consequences of the CAAA regulations. Looking into the future, both the baseline and the control cases are based on hypothetical scenarios defined to meet the specific mandates of the CAAA. All of these scenarios involve some necessary simplification, so that neither the baseline nor the control scenarios is intended to be an exactingly accurate forecast of future real conditions. Conceding the need to simplify, however, it is still not clear from the description of the different scenarios how a couple of important issues are to be addressed:

a. If firms are currently minimizing costs, increased emission controls imply higher costs and, under the assumptions of most CGE models, higher prices. These price increases will change the distribution of economic activities by sector and the resulting levels of emissions from each sector. How are these general equilibrium consequences of emissions controls to be handled? Shouldn't there be comparisons that allow uncertainties in aggregate economic activity and technical change to be described, especially as one attempts to forecast activity levels and emissions further into the future (e.g., beyond 2010)?

b. What is the nature of the feedback loop to measure changes in household incomes in response to these policies? At a minimum, one should be able to deal with Hazilla-Kopp, Jorgenson-Wilcoxen type computations of the effects of policy on their measures of costs. The price vectors derived from these models include wages and returns to capital, so it should be possible to evaluate the implied changes in household incomes. This type of interconnectedness is very relevant to the process of scenario development. It is not clear in the Analytical Plan whether there are inconsistencies across components in the different assumptions about how economic activity affects the outcomes.

It is a daunting task to accommodate fully all of the general equilibrium interactions in the economy that will ensue from environmental regulations with the scope and impact of the CAAA. The abilities of researchers to build sufficiently complex models are still evolving. The Agency, however, should stay focused on the fundamental importance of the fact that the level and mix of activity in the US economy is a function of CAAA implementation. One cannot hold fixed the level and mix of economic activities, independent of the regulatory regime. Thus, it is not relevant to consider "with CAAA" and "without CAAA" scenarios that do not reflect the endogeneity of economic activity. For smaller and more local regulatory interventions, it might be a reasonable approximation to assume that the level and mix of economic activities would not be affected by the presence or absence of the regulation, but this assumption almost certainly cannot be made for the CAAA.

In an extreme example, imagine that clean air regulations mandated the installment of equipment that was expensive to both purchase and operate. But suppose that this equipment was completely ineffective at reducing air emissions of pollutants. The pollution control equipment itself would contribute nothing to the reduction of emissions. However, by affecting marginal and fixed costs and output prices, and therefore altering the output and shut-down

decisions of firms and the incomes of factor owners, these regulations would have a measurable effect on total emissions.

The description of the proposed analysis could be enhanced if the Agency could provide a clearer specification of its plans in terms of selecting the levels and mixes of economic activities under the different regulatory scenarios. The issue of the level and mix of economic activity needs to be presented separately from the discussion of aggregate emissions. If only emissions are presented, one cannot benchmark the baseline and control scenarios in terms of what they imply for the levels of economic activity.

4.6. Trajectories after 2000: preventing deterioration

The Council now understands that the shapes of the time profiles in Exhibit 2-1 of the draft Analytical Plan are not factual, and that the diagram is merely a schematic designed to identify the different reference periods. However, the "without-CAAA" and "with-CAAA" trajectories in this diagram, if at all realistic, suggest to readers that for 2010 and 2020, the benefits of the CAAA may result to a significant degree from how high emissions would have risen without it. It will be important to communicate to policy makers that a significant share of the benefits that the Second Prospective Analysis is likely to identify for 2010 and 2020 stem from the prevention of air quality deterioration that would otherwise have occurred.

4.7. The moving target problem

The inventory of new regulations and changes since the first Prospective Analysis (pages 2-9 and 2-10) highlights that the Clean Air Act was designed to be an evolving regulatory process [e.g., with periodic reviews of the National Ambient Air Quality Standards (NAAQS)]. This adaptive evolution allows for adjustments and/or additions to the arsenal of regulations and emission control strategies in response to new scientific or engineering knowledge and technological innovations.

Some previous regulations have precipitated technological innovations (e.g. as with automobile emission controls) that have allowed the achievement of greater emissions reductions, at lower costs, than were originally expected. At the same time, most standards have been held the same or tightened due to new information that some of the human health and environmental effects of air pollution are worse than originally thought. All this means that assessing the future costs and benefits of the CAAA is like trying to hit a moving target. There is no remedy for this, but it remains a limitation of the entire assessment exercise that should be emphasized to policy-makers.

The NAAQS are a complication in forecasting scenarios for the Section 812 Analysis. Are the emission controls currently in place and those expected to come on line in the future, under the CAAA, going to be sufficient to meet the NAAQS? If not, then more emissions limits or control requirements will presumably have to be implemented. These modifications will be driven (or constrained) by NAAQS attainment schedules and SIP schedules.

The discussion on page 1-3 of the Analytical Plan seems to imply that there will be some mechanism in the analytical process to periodically assess progress toward meeting the NAAQS

under a particular scenario. If the growth in emissions is larger than anticipated, this assessment could potentially trigger feedback in the form of additional emissions reductions requirements (with their associated costs and benefits). However, it is not as clear in Chapter 2 of the Analytical Plan that this feedback will be incorporated.

One of the most important scenarios may be the "additional controls" scenario (i.e. going beyond current CAAA requirements). This scenario is likely to be more relevant than the alternative pathways scenarios initially suggested in the current Plan. It is listed as a scenario in the current Plan, but little detail is provided (Chapter 2). This scenario seems important because it may stimulate discussion about what the alternatives may be for different emissions source categories, and may suggest least-cost directions for future policy.

4.8. Treatment of NAAQS Compliance

At the November 5th meeting of the Council, Mr. James Neumann of Industrial Economics presented new information on the planned treatment of NAAQS compliance in the construction of the post-1990 control scenarios. The bullets on the relevant slide said:

> "The 1997 revisions to the Particulate Matter (PM) and Ozone National Ambient Air Quality Standards (NAAQS) will not be included in the Post-CAAA scenario because of the uncertainty associated with the continuing development of implementation plans. The Agency intends to use the 'beyond-the-CAAA' federal-level control scenarios to inform development of the implementation plans for 1997 NAAQS revisions. This approach will help the Agency determine the air quality shortfalls in individual non-attainment areas to comply with the NAAQS revisions."

The Council recognizes the computational convenience of the baseline of no-additional-PM/Ozone NAAQS compliance measures. Presenting intermediate results on this basis can be seen as part of measures the Agency is taking to increase the transparency of its calculations.

However, the Council is very concerned that this incomplete NAAQS compliance baseline does not correctly represent the full actual legal requirements of the 1990 CAAA. The Council urges the Agency to calculate and present its final results for the post-CAAA scenario in terms of full likely implementation of the post-CAAA requirements. Because the details of what will be needed for this "full implementation" are not fully defined at present, the Council urges the Agency to consider a range of plausible implementation scenarios to bracket the likely range of PM and ozone NAAQS compliance pathways. Utilizing this bracketed range as the baseline, some effects of the "beyond-the-CAAA" federal level control scenarios may then be seen in part as displacing the need for some of the higher-cost NAAQS compliance measures and in part as achieving PM and ozone control beyond that formally required for NAAQS compliance.

5. COST ESTIMATES

5.1. Charge Question 7

Does the Council support the plans for estimating, evaluating, and reporting compliance costs described in chapter 4? If there are particular elements of these plans which the Council does not support, are there alternative data or methods the Council recommends?

5.2. Summary of Council Response

The Council generally supports the Agency's plans and makes several important recommendations to improve the Agency's approach.

- Econometric models for abatement costs are limited by their incomplete coverage but they can sometimes offer insights not available from engineering estimates of compliance costs, in particular, with respect to the impacts of abatement activity on total factor productivity. Econometric models are one important source of the stylized facts about economic relationships that are used to calibrate CGE models.

- Indirect costs on regulated industries should be defined and itemized more clearly. Direct abatement costs are the focus of the cost analysis in the Analytical Plan, but in some cases, indirect costs on these same industries or in other markets could be very important. If the range of possible indirect costs, including productivity effects, process changes, and spillover effects in other markets are identified for major regulations, those likely to be most significant can be measured.

- Comparison of the predicted and actual costs of air quality regulations will be important to the evolution of the ongoing Section 812 Analyses.

- Assumptions about the effect of learning on abatement costs need to be carefully thought-out and supported by the literature in this area. A distinction can be made between learning and technological changes in many cases. Both learning and technological change effects are likely to be heterogeneous across sectors and processes. The Agency should employ the best information currently available about learning effects, limit the use of speculative estimates, and clearly identify additional research needs in qualifying the approach used in the current analysis. It will be appropriate to tailor the level of detail to the significance of the sector. For example, it will be important to evaluate carefully how the Agency plans to handle learning for the electrical generating unit (EGU) sector and for the mobile source sector.

- The Integrated Planning Model (IPM) appears to be a reasonable choice for modeling emissions and costs from the EGU sector. However, if policies in certain regions prevent efficient pricing, or if emissions allowances in some scenarios are not grandfathered, there will be a need to adjust the results. The Council also advises the Agency to explain more clearly the way the IPM model handles the changes in prices in the energy sector and their effects on the demand for electricity.

- Future conditions in energy markets may have strong implications for realized abatement costs. Sensitivity of the benefit-cost results to alternative assumptions about energy markets may be an important dimension of the 812 Analysis.

- Other concerns with respect to abatement costs include some caveats about comparisons with the Pollution Abatement and Control Expenditures (PACE) data, the need for consistency in discounting assumptions, some questions about the use of ControlNet, the NAAQS and PACE data, and the relative cost of abatement via market-based instruments versus command and control.

5.3. Econometric models and costs

Econometric models allow the researcher, in principle, to address indirect effects and behavioral responses to changes in regulations. These models can be used to 1) suggest the magnitude of additional costs beyond direct pollution abatement expenditures, and 2) provide parameters and functions for use in CGE models.

The econometric methods section in the Analytical Plan looks at several different cost studies of specific industries that have tried to isolate the full incremental costs to these industries from abatement activities. The Agency's current method for estimating industry costs focuses on the direct cost of abatement equipment required by the regulations. The value of these econometric studies is that they can suggest the magnitude of the additional costs (or savings) to firms as a result of the direct abatement expenditures. Hence, they suggest whether these indirect effects are important enough that the Agency should worry about capturing them in the 812 Analyses.

One type of indirect cost stems from the impacts of abatement activity on total factor productivity. Barbera and McConnell (1990) find some evidence of reductions in total factor productivity in five industries as a result of abatement equipment, but the magnitude of the effect is relatively small. Gray and Shadbegian (1994) and Joshi, Lave, Shih and McMichael (1997) also find evidence of effects on total factor productivity. The estimated effects are relatively large for the steel industry.

The other industry study described in Chapter 4 of the analytical plan is that by Morgenstern, Pizer and Shih (2001). This study examines the extent to which a dollar of abatement expenditure can be expected to result in more or less than $1 of expenditure on other non-environmental factors of production in four polluting industries (i.e. are direct abatement expenditures strongly complementary with other inputs, such as specialized labor?). They do not find strong evidence that direct abatement expenditures either over or under-estimate the total costs associated with controls. If anything, there is some indication that abatement expenditures may overstate full costs for some industries.

On net, there is mixed evidence about whether estimating abatement costs by just calculating direct abatement expenditures through engineering cost functions will result in under- or over-estimates of costs in individual industries. At a minimum, the Council advises the

Agency to review the evidence from this literature and make a judgment about whether to do any adjustment to the forecast of future costs on the basis of the empirical evidence.

The limitations of econometric cost estimation raised on page 4-7 of the Analytical Plan apply with equal force to engineering estimates of future compliance costs, because similar assumptions must be made about factor prices, levels of output produced, and so on. These estimates must be made just as far into the future for engineering cost models as for econometric models. Thus, it is difficult to argue that the described limitations are a particular disadvantage for econometric cost forecasting models as opposed to other types of cost forecasting models. Because these types of assumptions must also be made for CGE modeling, how will these separate estimates be reconciled? This issue is not well explained in the Analytical Plan.

In areas where new control technology is needed or costs are highly uncertain, econometric techniques are not a good substitute for uncertainty analysis, since such techniques rely on observed choices by firms. When no empirical data exist concerning new technologies, expert judgment may be the only available source for information about likely costs.

5.4. Direct costs versus broader definitions of costs

In the Analytical Plan for the Second Prospective Analysis, the major thrust of the effort to estimate costs is still to forecast the direct abatement costs associated with the CAAA. However, the Analytical Plan does make a number of attempts at capturing broader, more complete estimates of costs. But indirect costs, in the context of the Analytical Plan, are not presently defined very clearly. Whatever the Agency has in mind when it refers to "indirect costs," it needs to be spelled out explicitly. It is important to identify what these more-complete measures of cost include and how different they might be from narrowly defined engineering cost estimates.

Some of the relevant indirect costs include costs borne within industries, but other costs stem from productivity effects. Econometric studies can shed some light on how important these additional costs might be. Other relevant indirect costs stem from process changes. Treatment of the effect of learning on costs is addressed in detail below.

Other indirect costs stem from price changes and their effects on consumer behavior in the goods market and in the labor market. Regulations change prices, which can change behavior. For example, in emissions inspection and maintenance (I/M) programs, significant emissions-related repair costs appear to be inducing some drivers to sell their vehicles outside of the I/M area. Both out-of-area vehicle sales and early scrappage as a result of these programs have both costs and benefits beyond the usual direct effects measured for the program. [See evidence from the Colorado I/M program, ENVIRON (2003)].

5.5. Validation against realized historical costs

Earlier comments by the Council have emphasized that it is important to try to validate the assumptions underlying key scenarios in the 812 Analysis. A major refinement in the Second Prospective Analysis will be to enhance validation of the cost forecasts by comparison with

historical data and with the results from models which are alternatives to those used in the analysis. This task is very important and the Council enthusiastically commends the Agency's attempts to do more of this. Earlier *ex ante* cost (and emissions reductions) forecasts should be compared, where possible, with *ex post* measurement of these costs in subsequent Prospective Analyses.

CAAA regulations are in many cases designed to encourage innovations and technological advancement to reduce emissions at lower costs. Market based regulations are explicitly designed to do so, but other regulations, such as automobile emission limits, have also reduced emissions at lower costs. The Council notes that the CAA has reduced emissions at lower costs than were originally expected. Comparisons with *ex post* costs are not just a matter of validating previous forecasts, but are also an indication of the effectiveness of the CAA and a potentially important part of the story concerning the costs and benefits of the CAA.

Of course, it will be important to assess whether technologies or processes have changed compared to expectations when the *ex ante* forecasts were made. *Ex post* assessments of the success of prior cost forecasts must be made for the same regulatory program as was assumed in the *ex ante* prediction exercise, and the same baseline must be used. The predictive model in general may perform well if it is run using the right assumptions, even though it predicts less well if the forecasted determinants of its predictions are less accurate. Predicting the future is never an easy task.

5.6. Learning

The discussion of learning in the Analytical Plan could be enhanced by a careful distinction between learning and technological change. There can be a tendency to confound learning and technological change. Learning can be interpreted as those improvements in productivity and associated cost reductions that are derived from a firm's growing experience with a new technology. Overall, the impact of technological change may be hard to separate from subsequent learning effects, but the impact of technological change arises directly from the introduction of new technology itself, such as new equipment or new software. Some technological innovations will require little or no associated learning to show their full effect on productivity. Others will require considerable learning.

It is not clear whether the Agency proposes to account for measured "learning curves" in the sense of the observed empirical relationships between declines in unit costs with increases in cumulative output produced using a given technique or process. (See Argote and Epple, 1990). Most analyses of learning curves have examined empirical relationships. To the committee's knowledge, the only effort to frame learning curves in an economic context was by Auerswald et al. (2000).

The Council is concerned that the Agency is oversimplifying the default 80% rule for learning effects. The influence of "learning" on compliance costs received much emphasis in the document, but the 80% rule for all sectors for a doubling of cumulative production is a gross oversimplification, even though it is an improvement over entirely failing to acknowledge the effect of the learning process on costs. It is hard to come up with a better suggestion than the 80% rule, but there has been growing experience with compliance costs over the last three

decades and it will be important to do the analysis that will allow the rule to be refined. For example, there is likely to be great variance across sectors in the extent to which "learning" can be assumed to decrease compliance costs over time.

A comment was made during the Council's deliberations that the RFF HAIKU model accommodates learning via assumptions about technological change and the Argonne AMIGA model accommodates learning through adjustments to hurdle rates for new technology adoption. Neither of these statements were carefully explained or developed. A review and evaluation of the specific learning assumptions in each framework requires careful specification of exactly what is being represented in each model.

The Agency should consider the econometrics of doubling outputs and the empirical evidence about scale economies. The sophistication of these models varies widely across applications. Some models consider a pure learning effect in the form of technical change, while others consider differences in the scale of production and changes in the mix of inputs. It is not even clear that a pure "learning effect" can be empirically isolated.

Peretto and Smith (2001) conducted a 48-study meta-analysis of the effects of learning on compliance costs. This meta-analysis focused only on energy industries. A PDF file for a recent final report to the U.S. Department of Energy has been provided to the Agency. In that report, pp. 20-25 and Tables 2-9 summarize the database and a preliminary analysis that was conducted for all learning curve studies that the authors could identify, including published and unpublished research.

As the tables in Peretto and Smith document, a diverse set of industries is covered. Unfortunately, none of the studies in the meta-analysis adopted a framework that would be consistent with conventional neoclassical models. While the work of Peretto and Smith remains at an early stage for a meta-analysis, the tables certainly document a simple inventory of what is known. The evidence one can glean from these tables is unfortunately at odds with published literature that claims there is empirical support for the 80% rule.

The preliminary results of the Peretto and Smith meta-analysis can thus be characterized as "pretty grim." One would like to identify a range of alternative values by sector for learning effects, but the extant studies vary greatly in terms of their quality. The central tendency of the magnitude of estimated learning effects suggested by the meta-analysis depends on choices related to quality control. The distinction between learning via changes in process versus learning related to "management technique" matters, especially in the service sector.

As research into learning effects matures, uncertainty analysis needs to be incorporated to insulate the bottom line from any vulnerability to this problem. There will be deviations from the 80% rule for cost savings. These are likely to differ not just across industries or sectors, but across processes (for example, taking nitrogen oxides (NOx) out of coal and gas combustion). These cost savings may be an important issue, but capturing them may require corrections all the way down to the process level, not just to the industry level.

The "learning rule" for costs will be refined and tailored to different contexts with the emergence of additional credible research. Until then, the Agency cannot afford to pursue the same level of detail everywhere, since identifying process- and sector-specific estimates will be very labor-intensive. It would seem most appropriate to tailor the level of detail to the significance of the sector. For example, it will be important to evaluate carefully how the Agency plans to handle learning for the EGU sector. The Agency should employ the best information currently available about learning effects, limit the use of speculative estimates, and clearly identify additional research needs in qualifying the approach used in the current analysis.

Appendix C contains additional detail on costs and learning.

5.7. IPM versus HAIKU models for cost estimates

The Draft Analytical Plan states that the IPM will be used for utility cost estimates. The IPM model is national in scope, but involves 26 modeling regions for the United States power market. In many of these regions there is, and will continue to be, fairly stringent economic regulation of the utility sector. Any model that assumes efficient markets may not adequately capture what is going on. Thus, a capability to do some analysis of EGU environmental regulation at the regional level will continue to be important. However, while regional impacts are certainly policy-relevant, the Council re-affirms its concerns about the general equilibrium consequences of regulation and the difficulty of distinguishing regional effects because of cost spillovers via product, labor, and capital markets.

Some researchers who work with utility sector models emphasize the need for any such model to have a well-developed demand side. When prices go up, there must be some feedback effect upon demand. If demand is exogenous and serves as an input to the model, it is not clear how changes in electricity prices or alternative scenarios about the costs and prices are built into the model. An understanding of this is also important to determine whether this part of the assessment is consistent with assumptions made throughout the analysis about energy prices and elasticities. Sufficient information to allow a comparison of IPM with HAIKU or other models would also be helpful to the Council in developing an understanding the advantages and disadvantages of the IPM model relative to other alternatives.

For future analyses, the Agency should consider a more detailed comparison of the IPM model with other utility-sector models in terms of methods, assumptions and results. This would provide important information about the advantages and disadvantages of the IPM model and would aid in understanding whether its results are consistent with other assumptions made throughout the analysis.

The IPM model does appear to take account of utility purchase and sale of emission allowances. The initial allocation of those allowances can be very important for the outcome in terms of the final allocation of control responsibility and the resulting costs of control, especially if allowance markets are thin or if unequal market power rests in the hands of some traders. The IPM model assumes that allowances are to be grandfathered based on allocations allowed by the CAAA. It would be helpful to know whether the model might allow for alternative assumptions in order to examine the importance of this assumption.

5.8. Uncertain future energy demand conditions

Relative prices of natural gas and assumptions about their future trajectories will be very important to the forecasting of future costs of the CAAA. The Analytical Plan is not clear about how assumptions about natural gas prices will be made and supported. These assumptions have direct implications for the calculated costs of the CAAA. If the price of natural gas, a cleaner fuel, is much higher than initial estimates, then more of other dirtier fuels will be substituted and more air quality controls will be needed. Future natural gas prices are a major source of uncertainty in cost forecasts. Sensitivity analysis with respect to different assumptions about these prices will likely be an important part of the uncertainty section of the Second Prospective Analysis.

It will also be important for the Agency to be clear about how demand is determined for the electricity produced by EGUs, and how these demands are regionalized in the models used for cost estimation. Will energy demand models be integrated with the CGE model? In general, fuel prices, energy demand conditions, the competitiveness of different regional (energy) markets, and technical progress assumptions are key ingredients in the forecasting of costs for the utility sector.

5.9. Competing risks due to higher energy prices

The Council's report must acknowledge that one Council Special Panel member has drawn attention to the suggestion that the Agency's benefit-cost analysis should not ignore the impact upon health, including both mortality and morbidity for adults and children, from increased energy costs due to air quality regulations (specifically, higher electricity prices). The low-income elderly appear to be especially vulnerable to higher energy costs. This subgroup also appears to be at high health risk for PM exposure. There was a question as to whether it is relevant to compare the direct health risk to the elderly from PM with the indirect health risks stemming from higher energy prices operating through, for example, lesser ability to pay for air conditioning during heat waves or adequate heating during severely cold weather.

It could also be argued that the Agency should consider the health impact of increased prices from air pollution emission controls in other sectors of the economy, such as transportation. There are tradeoffs between fuel economy (and its air quality effects) and vehicle weight (and its safety implications) that may be equally important in determining competing risks to be considered in formulating air quality regulations. These tradeoffs are considered in the literature on "risk-risk analysis." Other considerations are related to the "richer is safer" literature (also called "health-health analysis," where risks are mediated through changes in disposable incomes). There is also a literature that tries to quantify how regulatory (or other) costs can simultaneously reduce health for some populations, in addition to improving it for others, in ways that might not be fully anticipated. For example, regulation may also reduce vehicle miles traveled and thereby reduce the risk of highway accident deaths.

The "health-health" approach is useful in policy comparison settings where one looks only at the beneficial health effects of an intervention and ignores the costs. The Council notes that this approach is not as useful, however, in the context of the 812 Analyses, where both health effects and costs are explicitly considered. Such a benefits-only approach would be a new

strategy. Since benefit-cost analysis accounts for the costs directly, there is a risk of double counting when the analysis includes both costs and foregone benefits. By foregone benefits is meant the specific goods, such as better health that people give up when they incur regulatory costs, through the richer-is-safer pathway. If the adverse health consequences of higher prices are to be considered for inclusion in the 812 Analysis, there will need to be a careful justification for why these costs are not captured directly by the decreases in incomes that are already likely to be part of the explicit costs. This can happen, in principle, when there are externalities involved, but the literature on the existence of such externalities is insufficiently developed. There is also a risk when undertaking a piecemeal accounting of selected general equilibrium effects without considering others. Some secondary effects will be harmful to health, but others will be beneficial. If it is appropriate to address some secondary effects, it is appropriate to consider all of them.

A further difficulty in the richer-is-safer literature is that the empirical estimates are difficult because of the problem of sorting out causality. Income and health are likely to be jointly endogenous. Higher income is likely to promote health, but health may also promote income, and additional factors may contribute to both. The most useful papers in the richer-is-safer literature probably include Chapman and Hariharan (1994, 1996), Keeney (1990, 1997), Lindahl (2002), Lutter, Morrall, and Viscusi (1999), Ruhm (2000, 2003), Smith (1999), and Viscusi (1994).

5.10. Miscellaneous

Problems with Pollution Abatement Cost and Expenditures (PACE) Survey data comparisons must be acknowledged. Some of the problems with the PACE data on costs of air pollution control for utilities (identified on page 4-5 of the Analytical Plan) will also afflict direct engineering cost estimates. Neither approach to the calculation of control costs includes process changes or integration of abatement with other firm activities, nor do they include insurance costs. It is important to determine how previous cost forecasts might not be expected to match realized reported PACE costs. Has the Agency determined whether there are any other unique or specialized opportunities to examine data on actual costs or expenditures on air pollution control by electric utilities besides the PACE data? If so, it will be important to take advantage of any reasonable opportunity to validate cost assumptions.

Consistency in interest rate assumptions is another consideration. Throughout the 812 Analysis, there is a need to enforce consistency in key assumptions. For example, is the interest rate being used to annualize costs consistent across sectors and models, and consistent with the discount rates being used to compare benefits across different time periods? A 5% interest rate is used in the cost analysis. The plan is to convert fixed capital costs to a real capital cost and then to annualize using this interest rate. If 5% is used here, it should also be used elsewhere in the analysis when the same types of time tradeoffs are at stake. The Council revisits the discount/interest issue in more detail in the sections devoted to charge questions about Discounting and about Results Aggregation and Reporting.

In general, there needs to be more explanation of how ControlNet will be used to develop costs of alternative scenarios. Under certain of the scenarios that will be developed (for example, in the “alternative pathways” proposed in the initial version of the Analytical Plan or

some revision to those), sectors will require either more or fewer controls depending on the assumptions of the scenario. How are these reallocations of abatement responsibility to be implemented with the ControlNet model? There are many options for control. How is it decided which controls will be used? Even under command and control regulations, there can be various possible ways of achieving goals. How will forecasts be generated concerning how firms will choose between different compliance strategies?

The model used to evaluate some of the scenarios will need to allow for the impacts of changing factor prices. Does ControlNet allow for changes in factor prices? Page 4-6 of the Analytical Plan says it does, but the document is not clear about how. Is it necessary to make specific assumptions about a variety of elasticities, for example? Does ControlNet allow process changes to be built into cost scenarios for alternative pathways (top of page 4-11)? How?

Market Based Incentives (MBI) may be lower-cost solutions than command and control. In an interesting paper on costs of pollution control, Harrington, Morgenstern and Nelson (2000) found that MBI as pollution control policies have tended to have both lower costs and greater emissions reductions than predicted. This implies that regulations that allow market based solutions should be treated differently in terms of cost estimates. Is this being accounted for in the analysis?

6. COMPUTABLE GENERAL EQUILIBRIUM MODELING

6.1. Charge Question 8

EPA seeks advice from the Council concerning the choice of Computable General Equilibrium (CGE) model which EPA intends to use as a post-processor to gauge the general equilibrium effects of the various control scenarios. In the first 812 Analysis –the retrospective– EPA used the Jorgenson/Wilcoxen model to gauge the general equilibrium effects of returning to the economy the reported compliance expenditures which formed the basis of the retrospective study direct cost estimates. This model has since been refined in many ways, and EPA considers both the Jorgenson/Wilcoxen/Ho and AMIGA to be acceptable tools. Although a final decision on model choice can be deferred until later in the analysis, EPA has tentative plans to use the AMIGA model because of its greater sectoral disaggregation, better industrial sector matching with CAA-affected industries, richer representation of relevant production and consumption technologies, and better model validation opportunities due to its use of open code. However, AMIGA is limited given its inability to deal with dynamics over time. Does the Council support the current, tentative plan to use the AMIGA model for this purpose? If not, are there alternative model choices or selection criteria the Council recommends?

6.2. Summary of Council Response

- The choice of a CGE model should be moved up in the analytical sequence, since CGE models can illuminate the likely emissions consequences of regulations as well as identify indirect costs or spillovers.

- Incorporation of spillover costs of air quality regulations is important and these costs should continue to receive close attention.

- CGE models have the capability to reveal spillovers of air quality regulations into unregulated sectors, not just to better estimate the direct costs of regulation on regulated sectors. The current Analytical Plan describes CGE methods for "post-processing," using estimates of direct cost estimates as inputs. However, this tends to leave an impression of relegating them to a secondary status. General equilibrium modeling should enjoy similar status to direct cost calculations and should not be subordinate to them.

- Each of the main CGE models which are proposed for use in the 812 Analysis has some limitations. The Jorgenson-Ho-Wilcoxen (JHW) model has a longer track record and has been more extensively reviewed. The extent of substitutability in the AMIGA model represents a cause for concern to the Council.

- The AMIGA model needs to be revisited by the Council after the Agency can provide a fuller characterization of its assumptions and can compare and contrast its elements with other available models, including the new EMPAX CGE model currently under development. The issue of substitution is especially important. The current description, which seems to limit substitution to own-price elasticities, is inadequate.

The Council needs a specific detailed comparison of the structural elements in the AMIGA model versus the EMPAX model versus the more-established JHW CGE model.

- The Council advocates a serious effort to accommodate the consequences of possible tax interactions in the 812 Analysis. Considerable sensitivity analysis is indicated, however, since simple formulas for the magnitudes of tax interactions for regulations imposed on particular sectors have not yet been identified.

- CGE models and econometric models for costs are not competing methods, but complementary methods. Econometric results, where available and appropriate, are generally more desirable than expert judgment for calibrating the parameters of CGE models. However, where no econometric estimates exist for key parameters, expert judgment is essential.

6.3. Costs outside the regulated market

Theory and empirical work suggest that some of the most important costs of environmental regulations are manifested outside of the regulated market. The structure of substitution implied by the specification of production and preference functions as well as the characterization of intermediate goods in these models will affect how important the model implies these effects will be. In some circumstances these secondary impacts may be of greater magnitude than the impacts in the targeted sector or industry. Thus it seems important for the Agency to consider these impacts in its assessment. The Council commends the Agency for its commitment to addressing these impacts.

6.4. Just *ex post* cost spillovers? Or emissions projections too?

It is not clear in the Analytical Plan how the engineering cost estimates will be linked to CGE models. As a rule, the engineering studies used to estimate compliance costs distinguish: a) fixed or investment-related costs required for new equipment (or retrofitting of specific add-on technologies) to be added to existing plant and equipment; and b) increased operating costs. CGE models usually characterize production activities with a composite of neoclassical production (or cost) functions and input requirement functions (or input-output materials). These are often defined at levels of aggregation that do not match the detail used to develop the engineering cost estimates. As a result, some linkage must be developed. This implies adjustments to input measures, input price measures, parameters or technical coefficients. The relationship between CGE cost measures and engineering-based compliance cost measures will be affected by the nature of the assumptions made in these types of reconciliations.

The Analytical Plan needs to be clear about whether: a) CGE modeling will be done after the main direct-cost analysis, as an additional step with the sole objective of producing more-comprehensive estimates of overall costs by capturing cost spillovers into other sectors or b) CGE models will also be used early in the analysis to help clarify emissions projections by recognizing possible interactions among regulated industries and outside these industries.

The existing text of the Analytical Plan suggests that the CGE modeling would serve largely as a check on the direct cost estimates from the engineering and sector studies. This suggests that the CGE analysis largely covers the same impacts as the other models, and it implies a subordinate role for the CGE modeling. This characterization does not to convey the main purpose or significance of the CGE modeling enterprise.

While CGE models can indeed give information on the direct costs, they are especially important in capturing indirect cost-impacts that cannot be considered by the other analyses. For such impacts, there seems to be no substitute for CGE models. Thus, the discussion of the purpose of CGE analysis should be modified.

CGE models can gauge how regulations indirectly affect demand and supply conditions in related sectors. These changes can influence emissions levels as well as economic costs. These general equilibrium impacts on emissions can be important. The Analytical Plan emphasizes the use of CGE models on the cost side, but the impact on emissions is potentially important as well. These indirect impacts on emissions should be explored.

6.5. Competing CGE models

The Jorgenson-Ho-Wilcoxen (JHW) model has many antecedents in the literature, has continually improved over the years, and has a long history of peer review. While it is not perfect, it does capture a number of processes that are crucial to our understanding of the responses of the economy to air quality regulation. The most important virtues of the JHW model are:

a. attention to margins of substitution among factors, inputs, and goods that seem most important *a priori*,
b. a serious empirical (econometric) basis for most of its parameters,
c. careful modeling of saving behavior, capital demands and technological change,
d. significant degree of sectoral disaggregation, and
e. incorporation of pre-existing distortionary taxes. (The significance of this last feature is discussed below.)

Like all models, however, this model also has some acknowledged limitations. These include:

a. an overly optimistic specification of the sectoral mobility of capital (it is assumed to be perfectly mobile),
b. excessively elastic savings behavior, and
c. the absence of explicit modeling of natural resource stocks (such as the exhaustibility of domestic petroleum stocks) and associated extraction-cost implications.

However, for the purpose of gauging the general equilibrium cost impacts, this model is, overall, probably a good choice. One attractive feature of the JHW model is that it has been extensively peer-reviewed and is “about as good as it gets” among the class of thoroughly vetted models.

It will be important to explain further the choice of CGE model, even if it is to be used only for "post-processing" tasks. It is the Council's opinion that the criteria for choice of a CGE model should consider all of the features just listed for the JHW model, and possibly more. As CGE development continues, researchers will become more aware of the implications of other simplifying assumptions incorporated in existing models.

However, beyond just the JHW model, the Analytical Plan also refers to a newer contender, the AMIGA model, as a possible vehicle for CGE analysis, and the Agency is now also apparently considering the EMPAX model. The EMPAX model is still under development but may be available and vetted soon enough to consider for the Second Prospective Analysis. As of the present point in this review process, few members of the Council are sufficiently familiar with the details of the AMIGA model and have no specific information about the proposed structure for the EMPAX model.

It is important for Agency staff to provide briefing materials so that the Council is able to review these models carefully during the evaluation process before making any suggestions about their relative suitability. The Agency has provided some limited review materials. However, the Council wishes to make it clear that it is the Agency's responsibility, not the Council's, to inventory the properties of each competing model and make arguments for why one might be preferred over the others. For subsequent phases of the review process, the Agency may have time to build such an analysis, which would serve to justify the Agency's planned selection to a broader audience than just the Council.

In contrast to the JHW model, the AMIGA model has no track record in peer-reviewed journals. It is a "new entrant." There is one paper forthcoming. It will be necessary for the Agency to examine the model very closely to compensate for the lack of peer review, and/or to wait until some external independent peer review has taken place. It will be important to assess the relationship between current conditions and the prediction of the AMIGA or EMPAX models based on earlier conditions, to see how well these alternative models can predict realized historical outcomes. This needs to be done to reinforce our confidence in how well the alternative CGE models might perform in predicting future developments.

On pages 4-23, the document describes a number of what are described as "minor concerns" about the AMIGA model. The last is described as follows: "…for consumption of goods other than transportation and housing-related services, *the model's implicit assumption of zero substitutability may not be supported empirically*" (emphasis added). The Analytical Plan does not contain sufficient information about the AMIGA model for the reader to understand this comment. If it implies that the AMIGA model assumes that all commodities except housing and transportation are consumed in fixed proportions, then this is a very restrictive assumption.

During the October 23, 2003 teleconference of the Council Special Panel, the Council was provided with additional information about AMIGA indicating that the model does feature substitutability in that it embodies price elasticities for all goods and services relevant to households, and there is labor, capital and energy substitutability among producers. However, despite the presence of own-price elasticities in these models, the Council remains concerned about how the model's specification constrains the extent of cross-price elasticities.

The "deadweight losses" due to taxation occur because these taxes drive a wedge between buyer's gross prices and the seller's net prices of a variety of goods. If demands for some goods are unresponsive to the prices of other goods, quantities traded of these goods will not change when these other goods are taxed and the analysis may not be able to capture these deadweight losses fully. It may be the case, however, that the description of this aspect of the model in the Analytical Plan is just prone to misinterpretation.

The Council wishes to emphasize that use of the AMIGA model, if it does indeed embody limited substitutability assumptions, would be inconsistent with the objective of a CGE analysis. That objective is to reflect inter-sectoral substitution effects of the costs that arise from environmental policies. If AMIGA is limited in terms of cross-price elasticities, a choice to use AMIGA by the Agency would reduce the standing of the CGE analysis in relationship to other cost analyses.

6.6. Principles for CGE model selection

The Council strongly supports the Agency's plans to coordinate a workshop concerning the array of CGE models available for Agency use. The insights to be drawn from such a Workshop will be helpful to the Council's future deliberations as well. In the Council teleconference of December 22, 2003, the suggestion was put forward that the Council could be of assistance to the Agency by beginning to formulate an outline of appropriate criteria for CGE model selection—a "statement of principles." The inventory of included and excluded features for existing models such as the JHW model (outlined in the last section) might provide a reasonable starting point. A good CGE model should be characterized, among other things, by:

a. attention to margins of substitution among inputs and among outputs,
b. a serious empirical basis for as many parameters as possible,
c. careful modeling of saving behavior, capital demands and technological change, including relevant elasticities
d. a significant degree of sectoral disaggregation,
e. incorporation of pre-existing distortionary taxes,
f. reasonable assumptions about the degree of sectoral mobility of capital,
g. explicit modeling of the status of natural resource stocks and associated extraction-cost implications.

In discussions with Agency staff in the March 18, 2004 teleconference, the Agency asked for specific guidance with respect to major options in selecting and using CGE models in current and future Prospective Analyses. The options being considered by the Agency include:

Option 1. A single post-processing CGE run that reveals some of the first-order general equilibrium considerations on the cost and benefits sides of the exercise, but with no up-front integration and reconciliation of CGE and sectoral models, except to ensure consistent input assumptions such as population growth;
Option 2. Moving the CGE effort up to the front of the analysis, but only integrating it with cost-side considerations, in order to capture indirect costs to the extent possible;

Option 3. Like Option 2, but also including some exogenous estimates of how the CAAA affects labor productivity and availability in order to capture some of the indirect benefits of air quality regulations

Option 4. Run the entire analytical sequence with feedback into the CGE model. This approach would involve a full run of the analytic sequence as described in the revised analytical plan (to obtain a first approximation of the scenario-specific values for both cost and benefit effects for the with- and without-CAAA scenarios), followed by a second set of full runs (including supplemental and disaggregated runs) starting with a reconfigured CGE.

The Council recognizes the currently overwhelming burden that the ideal approach, summarized as Option 4, would place upon the Agency. Option 1 would be the easiest and quickest approach, but would provide too little integration, in the view of the Council. Option 2 would represent some progress over this strategy, and Option 3 would be preferred.

The best current strategy for the Agency would be to incorporate experimental applications using more-integrated CGE models into the "Learning Laboratory" dimension of the research program in support of future Prospective Analyses. The best short-term implementation will need to reflect the opportunity costs of resources that could otherwise be used to enhance other aspects of the main analysis for the current Section 812 Analysis. The best long-term strategy will be to continue to explore means whereby advancing computing technologies and increasingly sophisticated CGE models can be exploited to allow greater and greater integration of CGE calculations into the main benefit-cost assessment.

6.7. The tax-interaction effect

Two years ago, in its preliminary review of the Draft Analytical Plan, the Council was disappointed about the Agency's treatment of the tax interaction effect. The literature indicates that the tax interaction effect is not just a second-order effect, but a first-order effect and therefore needs greater status in the analysis. The Council endorses the Agency's commitment to attend to this effect in the Second Prospective Analysis, because the effect is important and stems from the impact of environmental regulations on relative prices. In particular, to the extent that regulations raise costs and lead to higher output prices, they raise the prices of goods in general. This effectively lowers the real returns to factors of production (e.g., the real wage). To the extent that pre-existing taxes have already reduced factor supplies below the efficient level, the further reduction in factor returns stemming from higher goods prices produces a first-order efficiency loss. This is the tax-interaction effect. In several studies, this effect involves a greater cost than the direct cost or compliance cost in the regulated market [see: Bovenberg and Goulder (1997); Fullerton and Metcalf (2002); Goulder et al. (1997); Goulder and Robertson (2003); Parry (1995); Parry et al. (1999) and Schöb (1997)].

The Council notes, however, that the Revised Analytical Plan's characterization of the tax-interaction effect has some problems. The Plan correctly points out that there is uncertainty surrounding the magnitude and sign of the tax-interaction effect. However, it incorrectly concludes from this that the central case estimates should assume that this effect is zero. It is more appropriate to use a best estimate of the mean of the tax-interaction effect.

Both theoretical and empirical studies consistently indicate that, in realistic settings, the tax-interaction effect involves a positive cost. Moreover, for environmental regulations that do not raise revenue – for example, performance standards, technology mandates, or freely allocated emissions permits – there is no "revenue-recycling effect" to offset the tax-interaction effect. For these regulations, if the required emissions reduction is a small percent of baseline emissions, the tax-interaction effect can be several times larger than the direct costs.

The tax-interaction effect will be smaller to the extent that the regulated commodity is an especially strong complement to leisure. However, even in this case this effect will generally imply an extra cost rather than a reduction in cost. The regulated commodity would have to be an extremely strong leisure complement to switch the sign of the tax-interaction effect.

The Committee endorses a balanced approach to CGE modeling, so that indirect benefits as well as indirect costs are considered. There may also be a benefits-side tax-interaction effect. The general equilibrium effects of compliance costs are critical and so also may be the general equilibrium effects of beneficial health changes. Abatement of air pollution by the CAAA is intended to create positive health effects. It is just as important that the analysis include the general equilibrium consequences of improved health status on labor availability and productivity and therefore on the costs of labor and the costs of health care. Morbidity certainly has indirect effects on productivity that need to be recognized. The general health consequences of changes in the ambient levels of pollutants need to be considered, not just mortality.

The impact of regulations on labor productivity and the associated "benefit-side" tax-interaction effect is indeed an important issue and has been analyzed specifically by Williams (2002, 2003). This beneficial effect offsets the adverse tax-interaction effect described in the previous section. However, Williams's work indicates that, in general, this offset is not likely to be large enough to entirely undo the adverse tax-interaction effect. Thus it seems appropriate to assume in the central case that the tax-interaction effect does raise costs.

On page 4-26, the Analytical Plan suggests that: "Improvements in CGE models that the Agency is considering for this analysis have made it possible to account for tax interaction effects more precisely." The Council assumes that this comment pertains only to indirect effects on the cost side of the analysis, not the benefits. Part of the tax interaction effect can be addressed in CGE models, but no existing CGE model will capture all of it. At a minimum, the Williams (2002, 2003) adjustments for the productivity-enhancing consequences of health improvements due to environmental regulations need to be considered.

There are in fact a number of citations concerning the health benefits of emissions controls for labor productivity and their spillovers into less-regulated sectors. The Council is aware of several papers on this topic. Some of these papers (e.g., Espinosa and Smith, 1995) demonstrate how non-separability between pollutants and private goods, a prerequisite for such beneficial spillovers, can be incorporated into CGE models.

Two of the already-published papers in this literature are Espinosa and Smith (1995) and Smith and Espinosa (1996).[4] These papers use an updated version of the Harrison-Rutherford-

[4] The fifth one is a conceptual paper Schwartz and Repetto (2000)

Wooton model that includes measures of particulate matter, sulfur dioxides, and nitrogen oxides as non-separable influences on consumer preferences. The model includes eleven regions and six goods and three factors in each region. International trade and transboundary pollution are included. There is a simple air diffusion model between the different countries in Europe. The model relies on the concentration response functions presented in Desvousges, Johnson, and Banzhaf (1998) and uses estimates of willingness to pay that are adjusted for each country. A newer paper that addresses the tax interaction effects, Espinosa and Smith (2000) is under review for publication.

The tax interaction effect should be an explicit dimension of the presentation of costs. The precise methods for including tax interaction considerations in the Second Prospective Analysis are not adequately described in the current Analytical Plan. The Council could be more confident in its advice on this matter if the Analytical Plan included more specific details on these issues, including a description of how engineering cost estimates will be linked to the CGE models for the analysis of tax interaction effects.

It should be noted that the Analytical Plan's suggestion of a 25-35% increase in costs due to the tax interaction effect in the current document may be a result of miscommunication in, or misinterpretation of, the earlier Council review of the Draft Analytical Plan. The indirect cost consequences of the tax interaction effect can differ by orders of magnitude and can be vastly larger when regulations actually result in little abatement and when there is no revenue recycling. For the sulfur dioxide emissions covered by Title IV, it may be appropriate to make the assumption of a 25-30% increase in costs, but such an assumption is unlikely to be universally appropriate.

The question thus remains as to how large a cost impact the Agency might assume for tax interactions. The Agency could address this issue two ways. First, it can employ its commissioned CGE model or models to evaluate the costs of specific regulations. The tax-interaction effect should be embodied in the aggregate cost impacts obtained from such models. Second, the Agency should consult results from other, prior CGE studies of particular regulations. This second step will be useful as a cross-check on the results from the Agency's commissioned model or models. Moreover, this second step may be necessary to obtain general equilibrium cost estimates in some instances, since there will surely be some particular regulations that the commissioned model or models cannot capture.

Given the uncertainties surrounding the magnitude of the tax-interaction effect and of cost-impacts in general, it is very important that the Agency require considerable sensitivity analysis in its CGE assessments. Past applications of the JHW model have tended to skimp on sensitivity analysis.

6.8. Tension between CGE, econometric models

The Analytical Plan rejects econometric methods for developing cost estimates but accepts CGE models. This sort of top-down approach in the cost calculations, embracing CGE models, is puzzling. The Council feels that both types of models should be informative. Their implications should be convergent and a plurality of methods is desirable. However, it is

possible that the implications of the different approaches will not be convergent. If this is the case, then there is a clear need for more basic research to resolve the conflicts.

Are CGE models sufficiently comprehensive? Some members of the Council have voiced a concern about whether even the largest CGE models are large enough. These are based on empirical studies of individual industries, but more coverage is certainly needed. There is not presently enough coverage by empirical studies to permit reliance on econometric models exclusively. CGE models are calibrated on a selection of empirical results and researchers can then rely upon plausible assumptions, informed by expert opinion, to fill in for missing information.

There could, however, be more use of engineering and expert judgment when empirical results from econometric models are absent. The analysis could proceed based on expert judgments, using an engineering "bottom-up" strategy. For example, assumptions about the availability of natural gas will be critical to forecasts. Even the experts do not know enough about the determinants of availability of natural gas to base the modeling assumptions on existing empirical results, so the analysis may need to rely more heavily on engineering expert judgment.

7. DISCOUNTING

7.1. Charge Question 9

In the two previous 812 Analyses, the primary cost estimates reflected use of a 5 percent real discount rate, which an earlier Council endorsed as a reasonable compromise between a 3 percent real rate considered by EPA to be an appropriate estimate of the consumption rate of interest or rate of social time preference and a 7 percent rate, OMB's estimate of the opportunity cost of capital. Limited sensitivity testing was also conducted in the previous 812 Analyses by substituting 3 and 7 percent rates to annualize the benefit and cost streams. EPA's new Economics Guidelines (peer-reviewed by the SAB EEAC) call for using both a 3 and a 7 percent rate. A recent draft of new OMB economic guidelines suggests providing results based on both 3 and 7 percent discount rates, while also acknowledging the need for further efforts to refine analytical policies for discounting methods and rates. EPA plans on following both sets of Guideline documents by using both 3 and 7 percent in our core analyses. It is true that this will require presentation of two sets of results – one based on each rate. This may not be necessary given the expected insensitivity of the overall results to the discount rate assumption. Does the Council support this approach? If not, are there alternative rates, discounting concepts, methods, or results presentation approaches the Council recommends?

7.2. Summary of Council Response

- The Prospective Analysis is concerned with arriving at discounted values of the benefits and costs that may extend into the future for Clean Air Act emissions reductions in selected years. Such discounting should be performed using a "social discount rate." The Council commends the Agency's having drawn attention to the challenges and uncertainties associated with the choice of social discount rate.

- The Council urges the Agency to employ a range of values – perhaps between 3 and 7 percent – for the social discount rate in its assessments. Given the difficulties of pinning down the "right" social discount rate, it is important to apply these alternative values and examine the robustness of results to the alternative values. While the Council supports using a "low" (3 percent) and "high" value (7 percent), it emphasizes the importance of using a central value as well. This will offer a "central" case and facilitate interpretation of the Agency's estimates. It is important to employ a central value in the main analysis. In addition, the sensitivity analysis should include this central value as well as "low" and "high" values for the social discount rate.

- The benefit-cost calculations in the Prospective Analysis are social benefits and costs. To calculate such benefits and costs, the social rate of discount should be applied. This holds even for calculating the present discounted (social) value of firms' compliance costs. On the other hand, if one wants to indicate what the costs are, as perceived by the firm, it is appropriate to employ the firm's own opportunity cost of capital. This provides information on the cost impact to the firm in question, but does not represent the overall cost to society. It is important to emphasize that such

calculations should not be used to calculate the overall (social) costs or benefits from the Clean Air Act.

7.3. Theory

The Prospective Analysis is concerned with arriving at discounted values of the benefits and costs from the Clean Air Act. Such discounting should be performed using a "social discount rate," which is the rate used to translate future consumption flows into equivalent current flows. (This is different from a "utility discount rate," which converts future utilities into equivalent utilities in the present.)

When costs and benefits are not identically distributed over time, the discount rate assumptions in the analysis will be important. Under these conditions, different discount rates will yield differences in the relative magnitudes of discounted benefits and discounted costs (as well as differences in absolute magnitudes). The Council commends the Agency's having drawn attention to the challenges and uncertainties associated with the choice of social discount rate.

The theoretical literature offers two alternative approaches for determining a social discount rate. The "demand-side" approach [articulated, for example, by Arrow et al. (1996)], defines the social discount rate as the sum of a pure social rate of time preference and an adjustment term reflecting future changes in the marginal utility of consumption (future goods may be worth less at the margin as people get richer). Even if one assumes a value of zero for the first term, declining marginal utility of consumption can yield a positive second term and thus a positive value for this social discount rate.

An alternative approach is the "supply-side" approach, which has been articulated, for example, by Lind (1982) and Diamond and Mirrlees (1971). This approach defines the social discount rate as the shadow price of capital, which in turn is the real-world trade-off between present and future consumption implied by the marginal productivity of capital. This shadow price is related to market interest rates.

Neither approach dominates the other. Under the demand-side approach, the social discount rate is inherently a subjective concept: it depends on the value of the pure social rate of time preference, a parameter that cannot be established empirically. (In contrast, an individual's pure time preference rate can be gauged empirically.) Under the supply side approach, the social discount rate has a closer tie to observable phenomena – market interest rates (as representing the shadow value of capital). An attraction of the supply-side approach is that if the social rate of discount is equated to the shadow value of capital, then a policy that withstands the benefit-cost test using that discount rate will offer the potential for a Pareto improvement. Although this feature has some appeal, it can be argued that the ethically appropriate social discount rate need not equal the shadow price of capital. Defenders of the demand-side approach argue that intergenerational equity may call for a social discount rate different from the actual rate of exchange between current and future consumption implied by the shadow price of capital.

These theoretical considerations imply that, in practice, one cannot pinpoint the "correct" social discount rate. Neither of the two approaches can identify a social discount rate with precision. Under the demand-side approach, the rate depends importantly on the social rate of

time preference, but analysts offer differing views as to the best value for this parameter. [Ramsey (1928) argued that it should be zero; Solow (1974) and Arrow et al. (1996) suggest higher values.] Moreover, one's view of the appropriate value can differ depending on the context of the choice. The choice context includes the time horizon over which the discounting is to occur, the sizes of the benefits and costs at stake, and a number of sociodemographic factors. See also Warner and Pleeter (2001) and Harrison et al. (2002).

Under the supply-side approach, the rate (in principle) is given by the shadow price of capital, but in practice this shadow price cannot be measured with precision. As discussed by Lind (1990) and Freeman (1992), the shadow price or social opportunity cost of capital depends on the extent to which a public project crowds out private investment or private consumption. If the gross of tax rate of return to an investment is r_g and the after-tax or net return to household savers is r_n, then the social opportunity cost will be a weighted average of these two returns, with the weights reflecting the relative amounts of investment crowding-out and consumption crowding-out. Pinpointing the social opportunity cost is impossible because the crowding-out proportions cannot be determined precisely. Moreover, real-world complications in capital markets imply that the Lind-Freeman formula will not perfectly describe the shadow price of capital. These complications include restrictions on capital flows, externalities associated with investments, and the inability to pool risks perfectly. The 7% rate advocated by the Office of Management and Budget is one plausible estimate of the social discount rate that stems from the supply-side approach. But estimates of this shadow price vary significantly. Typical estimates are in the range of 4-10 percent.

7.4. The Social Discount Rate and Firms' Opportunity Costs of Capital

In general, the social discount rate will not coincide with a given firm's opportunity cost of capital. This is the case even when one applies the supply-side approach and identifies the social discount rate with the society's shadow price of capital. (Society's shadow price – or the opportunity cost of investment in terms of future consumption – need not equal a given firm's opportunity cost of capital. On the other hand, if the firm has access to fluid capital markets, its opportunity cost might approximate the social opportunity cost of capital.)

Even as the Agency has acknowledged, the strong theoretical basis for relying on social discount rates and for using a consistent discount rate throughout the analysis, the Agency has explained to the Council that the linear programming-based IPM model is configured to predict the private profit-maximizing decisions of firms with respect to capital investments. These individual firms' behavioral responses will be dictated by their own opportunity cost of capital, which can differ from the social discount rate. The IPM is designed to predict what firms are likely to do, rather than what they should do, if they were being managed by a social planner. There is no need to over-ride firm-specific private discount rates if the purpose of the analysis is to estimate costs to the firm. However, if costs generated from the model are used to characterize the overall costs of abatement, then the analysis should use the social rate of discount.

There is apparently some possibility that it may be feasible to manipulate the structure of the IPM model to allow an intervention into the capital investment outcomes for firms, arraying

these temporally and applying to them the social discount rate. To determine the feasibility of this approach, further analysis will be needed.

This analysis should address the difficulty in choosing between or in integrating these two perspectives for measuring the present value of net benefits from regulations and measuring the annual benefits and costs of regulations. If one adopts the social rate of discount perspective the capital costs incurred by firms would not be annualized at the private discount rate. Capital costs would be included in the present value calculation in the year when they were incurred and discounted along with operating costs in that year using the social rate. Annualizing these capital costs at the social rate would not reflect firms' private costs of the relevant regulations.

7.5. Importance of Applying a Range of Values for the Social Discount Rate

Thus, assessments of the "right" social discount rate vary both because there are two alternative approaches and because each approach can yield a range of values. Under these circumstances it is appropriate and crucial for the Agency to employ a range of values for the social discount rate in its benefit and cost assessments. The demand-side approach often leads to values in the range of 1-4 percent. The supply side approach generally leads to somewhat higher values. Based on these considerations, the Council urges the Agency to employ a range of values – perhaps between 3 and 7 percent – for the social discount rate in its assessments. Given the difficulties of pinning down the "right" social discount rate, it is important to apply these alternative values and examine the robustness of results to the alternative values.

While the Council supports using a "low" (3 percent) and "high" value (7 percent), it emphasizes the importance of using a central value as well. This will offer a "central" case and facilitate interpretation of the Agency's estimates. It is important to employ a central value in the main analysis. In addition, the sensitivity analysis should include this central value as well as "low" and "high" values for the social discount rate.

The sensitivity of the conclusions to different discount rates and different assumptions about time profiles needs to be featured prominently. The Council addresses this issue further in its discussion of the material in Chapter 11 of the Revised Analytical Plan.

8. ECOLOGICAL EFFECTS ASSESSMENT AND VALUATION

8.1. Agency Charge Questions Related to Ecological Effects Assessment And Valuation

Charge Question 18. Does the Council support the plans described in chapter 7 for: (a) qualitative characterization of the ecological effects of Clean Air Act-related air pollutants, (b) an expanded literature review, and (c) a quantitative, ecosystem-level case study of ecological service flow benefits? If there are particular elements of these plans which the Council does not support, are there alternative data or methods the Council recommends?

Charge Question 19. Initial plans described in chapter 7 reflect a preliminary EPA decision to base the ecological benefits case study on Waquoit Bay in Massachusetts. Does the Council support these plans? If the Council does not support these specific plans, are there alternative case study designs the Council recommends?

Charge Question 20. Does the Council support the plan for a feasibility analysis for a hedonic property study for valuing the effects of nitrogen deposition/eutrophication effects in the Chesapeake Bay region, with the idea that these results might complement the Waquoit Bay analysis?

8.2. Summary of Council Response

The Council did not include experts in ecological sciences in the development of this report, because it awaited the formation of its new EES (Ecological Effects Subcommittee) to help address issues specifically related to assessment of ecological effects linked to implementation of the CAA. The Council plans to receive a draft report from the EES related to the ecological assessment components of charge question and then to review and approve such a report to the Agency as the final installment of the Council's advice on the draft Analytical Plan.

The Council is proceeding to provide advice to the Agency on aspects of the Charge Questions tractable at this time, with the caveat that future advice will follow. A summary of the current advice follows.

- Ecological effects to be valued must be limited to those effects for which there is a defensible, rather than just speculative, link between air emissions and service flows. The Council strongly objects to using inappropriate or unsupported placeholder values in the absence of better information.

- The greater heterogeneity in ecosystems services makes it even more difficult to produce estimates of the benefits from their protection than for the protection of human health. The input of the Council's new EES may be able to stimulate the development of greater expertise on this issue than is presently available. The SAB's new C-VPESS, whose work has just begun, may also provide advice for the Council to consider, as C-VPESS provides advice to the Agency generally.

- There is a clear need for a better conceptual basis for valuation of ecological effects, which would also permit the proposed case studies to be integrated as components of a larger model. Ongoing attention to new literature will be important.

8.3. Emphasizing Verifiable Connections

In the First Prospective Analysis, the Agency identified a limited number of ecological impacts that were amenable to quantitative analysis because there existed a defensible link between changes in air emissions and a corresponding service flow for which there are peer-reviewed money values. However, the only monetized benefits, based on displaced treatment costs, were not reported in the primary central benefit estimates because there are few effects for which a defensible link exists between changes in air emissions and a corresponding service flow evaluated in peer-reviewed valuation studies. There has been little increase in the inventory of available value estimates in the intervening four years since the First Prospective Analysis, so the Agency proposes to use the same approach for the second Prospective Analysis.

8.4. Valuing Statistical Ecosystems?

The Council's earlier efforts to render greater parallels between the way researchers think about valuing human health and valuing ecosystem health speculated that it might be possible to think about "statistical ecosystems" the same way one thinks about "statistical lives" in the sense that most environmental stressors do not wipe out entire ecosystems with certainty (analogous to killing individual people with certainty). Instead, they compromise the viability of a wide variety of ecosystems to some degree, resulting in the collapse of some fraction of these systems, although the identity of these particular systems cannot be identified *ex ante.* (This is analogous to compromising the health of many different people, resulting in the deaths of a few people, although these individuals cannot be identified *ex ante*).

However, the Council now recognizes the importance of heterogeneity across human health risks in arriving at monetary valuation estimates, as well as the likelihood that these problems can only be more complicated when ecosystems are being considered, rather than human health. Ecosystems are vastly more heterogeneous than humans. The number of dimensions across which the willingness to pay function for risk reductions for ecosystems may vary is likely to be much greater than the number of relevant dimensions for human heath risk reductions. The Council now has reservations about attempting to push the "statistical ecosystems" analogy in conceptualizing techniques for determining ecosystem benefits.

Although the language did originate from previous Council deliberations, the Council encourages the Agency to drop the "value of a statistical ecosystem" term. The term implies that it is possible to elicit reliably the public's preferences for reducing risks to ecosystems. While the possibility of obtaining such values for hypothetical risk reductions is an interesting research question, such an approach may be a distraction from the task of removing the primary impediments to improved value estimates. As the Agency acknowledges elsewhere, these impediments include poor understanding of concentration-response functions for ecological resources and poor understanding of linkages between physical effects and service flows. In addition, it has proven challenging to describe changes in ecological service flows in terms that are meaningful to the public. Finally, research on valuing health risks, which are far more tangible to most survey respondents, has encountered difficulties in eliciting reliable estimates for small changes in relatively small baseline risks.

8.5. Using Available Quantitative Information

The Agency's plans to qualitatively characterize the ecological effects of the Clean Air Act-related air pollutants is thorough and appropriately focused on a broad characterization of ecosystem services. However, more could be done to make use of quantitative information that is available. Although it must be acknowledged that neither the available data nor the available analytical tools are sufficiently developed to provide a comprehensive quantitative assessment of the ecological benefits of the CAAA, there is some quantitative information available for some components of such an assessment that can help to characterize the nature of the progress expected as a result of the CAAA. The Agency included this type of information in the first Prospective Analysis. The Agency should continue to do so and perhaps increase its prominence in the report. This information includes:

a. Air quality models can provide quantitative estimates of expected reductions in acid deposition (sulfate and nitrate), nitrogen deposition, and ambient ozone concentrations, which are the primary air pollutants of concern for ecological effects. Some emissions and/or deposition data may also be available for important hazardous air pollutants (HAPs), such as mercury. This information can be presented spatially on maps to illustrate the scope of the improvements that can be expected.

b. Even though quantitative dose-response estimation may not be feasible at this time, some quantitative measures of effects of air pollution on ecosystems are available. These include:

    1. the extent of acidification in lakes and streams and the implications for reductions in some aquatic species,
    2. the locations and sizes of estuaries with degraded quality because of eutrophication and other effects of excess nitrogen and the implications such as lost habitat for spawning, and
    3. locations where forests show evidence of pollution-related stress, etc., and implications for forest health and diversity.

The analysis should provide some nation-wide characterization of the actual extent of identified ecological effects along with a description of their implications. It should also provide information about the expected reductions in pollutant exposures associated with these effects that may be attained due to the CAAA. These two classes of information will help provide some context for the more detailed case study proposed for examining the benefits of reducing excess nitrogen in one estuary. They will also begin to support a link between the current conceptual discussion of ecosystem services and the likely quantitative social benefits of the CAAA. This framework will also place in some context the few specific benefits that have already been approximately quantified, such as improved recreational fishing in the Adirondacks and increased yields for commercial forests.

8.6. Integration between Conceptual Basis and Case Studies

The Analytical Plan would benefit from a better connection between the discussion of a conceptual basis for valuing ecosystem services and the proposed case studies described in the

document. In general, there should be a more serious attempt to connect the developments in literature on ecosystems and the strategies being developed by the Agency. For example, the Agency should begin to pursue some of the ideas contained in Sanchirico and Wilen (2001), Finnoff and Tschirhart (2003), and Smith (2003).

8.7. Inadvisability of Using Placeholder Values

The revised Analytical Plan acknowledges the disagreements among Council members reviewing the initial Analytical Plan for the Second Prospective Analysis. The main point here is that regardless of the validity of the Costanza et al. (1988) estimate of the total value of the world's ecosystems (which was advocated by a minority of Council members as a starting point for a placeholder value for ecosystem benefits), a total value for an ecosystem does not communicate useful information about the value of avoiding different types of incremental quality-degrading effects of air pollution at levels relevant to the CAAA.

The Council is sympathetic to the concerns that leaving the ecological benefits incompletely quantified may leave the perhaps erroneous impression that they are unimportant. However, the Council deems it prudent for the Agency to reject using a placeholder value because it introduces purely speculative values that provide little guidance for resolving persistent uncertainties. Furthermore, the use of speculative values could undermine the credibility of the analysis as a whole.

8.8. Awaiting Insights from EES and the SAB's C-VPESS

While the Council would like to be able to offer some clear resolution on the issue of ecosystem valuation, the state of the science in this area is at present insufficiently developed to allow anyone to be conclusive. The Council expects that its new EES will provide needed scientific advice in the future on how to characterize and quantify ecological effects of implementation of the CAAA. The Council expects to receive a draft report containing advice related to the ecological assessment components of Charge Questions 18 through 20 from the EES in the future and to complete the Council response to those charge questions at that time.

In addition, the Council notes that the separate SAB's C-VPESS has been charged with providing advice to the Agency generally on how to improve knowledge, methodologies, practice, and research. The results of its work, just begun, should prove useful to inform future 812 Analyses and will be of interest to the Council.

8.9. Agency Plans for Conducting an Ecological Benefits Case Study

Based on the information provided to the Council and the current perspective of Council Special Panel members (who did not include ecological science among their expertise set) the Council believes that if the case studies involve relatively modest opportunity costs, they will provide some data of interest to the Section 812 process, but the findings will by no means be generalizable. Advice of the new EES will be valuable on this issue.

Pursuant to prior Council advice, the Agency proposes to conduct a prototype case study of a specific site. The Agency has solicited the Council's views on selection of one of two

possible sites: Waquoit Bay in Massachusetts and the Chesapeake Bay. The Agency suggests several criteria for selecting an appropriate site. It is not clear how the Agency may have weighted these criteria in comparing the relative advantages of the two sites. The following table suggests some possible qualitative evaluations based on the Agency's site descriptions.

Comparison of Qualitative Site Evaluation Ratings		
Criterion	**Waquoit Bay**	**Chesapeake Bay**
1. Well-documented impacts to a particular ecosystem function or service	Good	Fair
2.a. Quantifiable ecological endpoints	Very Good	Good
2.b. Quantifiable economic endpoints	Good	Very Good
3. Available monetary values for at least some endpoints	Good	Good
4. Take advantage of existing EPA initiatives to maximize use of available resources, avoid redundant research, and demonstrate multiple applications of ongoing projects	Good	Very Good

Chesapeake Bay is weakest in the area of criterion 1--documented impacts to functions or services. Chesapeake Bay is a very large and complicated ecosystem that is challenging to model. In contrast, Waquoit Bay is a small, almost laboratory-sized system. However, the size and complexity of the Chesapeake Bay provides opportunities for quantifying more endpoints, including potential impacts on commercially important species and property values.

Oddly, the Agency mentions only in passing that Chesapeake Bay is more representative of the estuaries affected by air pollution emissions and that Waquoit Bay provides little opportunity for potential benefits transfers. Nevertheless, the Agency indicates its intention to use Waquoit Bay for the primary case study because there are available dose-response models for ecological indicators. Chesapeake Bay will be used only for a property value study. If the Agency's primary goal is to demonstrate "current deficiencies in our knowledge about both the physical effects of air quality on ecological services and the value to society of these effects," then the atypical availability of dose-response models for Waquoit Bay may argue against that choice. Chesapeake Bay appears to provide a far richer opportunity to conduct a prototype study in a realistic setting.

The discussion of the economic valuation component of the Waquoit Bay study is inadequate. It does not use the "direct use," "indirect use," and "non-use" approach the Agency has used elsewhere. There should be a more detailed articulation of how the ecosystem services in question are connected to valuation methods, as well as a discussion of what is being left out.

In general, there seems to be no strong sentiment among Council Special Panel members to recommend modifying the Agency's proposed strategy. There is some concern that the proposed case studies seem like a fairly weak response to a very serious data problem. For example, it might be difficult to detect the relatively small incremental effects of air pollution on

water quality on property values in the Chesapeake Bay region. Some members were mildly supportive of taking advantage of the relatively abundant data concerning Waquoit Bay, even if this particular resource is not particularly representative.

The Council plans to work with the newly formed EES in developing further advice related to this charge question.

8.10. Plans for a Hedonic Property Study

The Agency should begin to develop an infrastructure for combining different sources of information about demand for ecosystem services. The emerging literature on preference calibration holds promise for integrating hedonic property value estimates with travel cost demand estimates and other related evidence about demand for these types of non-market goods as a function of environmental quality.

In the proposed Chesapeake Bay property value application, the same specification of ecosystem services and their explicit connection to what can be "valued" with hedonic property value needs to be described. The Council asks how this analysis relates to recreational fishing considerations and points out that the Agency has not noted the overlap discussed by McConnell (1990) and Parsons (1991).

This would seem to be an opportunity for a preference calibration exercise (Smith et al., 2002) combining the Leggett and Bockstael (2000) hedonic study with the extensive travel cost recreational demand work.

As with the Waquoit Bay application, the discussion is too vague to offer specific guidance. There needs to be a detailed description of services, approaches used for valuation and discussion of how the phenomena that can be measured relate to the ecosystem services provided by this resource.

9. ECONOMIC VALUATION – PLANS

9.1. Charge Question 21

Does the Council support the plans described in chapter 8 for economic valuation of changes in outcomes between the scenarios? If there are particular elements of these plans which the Council does not support, are there alternative data or methods the Council recommends?

9.2. Summary of Council Response

- There are a number of additional resources that the Agency can consider in developing estimates of a variety of non-mortality benefits of the CAAA.

- Charge questions 22-25 deal specifically with plans for evaluating health outcomes, which are the most important of the endpoints listed in Chapter 8. This generic charge question apparently relates primarily to non-health, distributional and ecological effects.

9.3. Distributional Effects

The Agency's plans for identifying distributional impacts are somewhat cryptic. The Analytical Plan simply states that the Agency will assess distributional consequences across age, income, and racial sub-populations using Census county-level data for the year 2000. In light of the Agency's (and earlier Council) concerns about their ability to disaggregate costs and benefits geographically, it seems odd they are not concerned about disaggregating even further by sub-population. It is indeed possible to measure benefits to different sociodemographic groups in physical terms and report unmonetized benefits by beneficiary group. However, while some valuation models report the effect of income, there is very little known about age-specific and race-specific preferences for environmental services.

9.4. Worker Productivity

The Agency plans to follow the same approach to worker productivity as they did in the first assessment. They will use the study by Crocker and Horst (1981) on the effect of ozone concentrations on worker productivity. As it does for other endpoints involving productivity losses and the value of time, the Agency will use mean or median wage rate. However, the relevant outcomes are impacts on marginal product and the marginal value of time in a given activity. Average wage rates are, at best, crude proxies for the average marginal product. Averages may either overstate or understate marginal values.

Here and elsewhere, the Agency treats the value of time far too simplistically. Economists have studied market and nonmarket time values extensively over the last 25 years in areas such as labor, transportation, and recreation economics. The Agency should evaluate empirical alternatives to using market wage rates to value time. Where the Agency is

constrained to use wage rates for pragmatic reasons, they should evaluate the likely direction of bias and incorporate that assessment in the uncertainty analysis.

For specialized references on the Value of Time, see Appendix C, which contains a bibliography.

9.5. Miscellaneous Welfare Effects (Visibility and Soiling/Materials Damage)

Visibility. There are some published visibility valuation studies available. Some evaluation of the visibility benefits for eastern and western parks based on the meta-analysis in Smith and Osborne (1996) seems warranted. This meta-analysis offers the Agency an opportunity to adjust statistically for the different approaches used to estimate visibility benefits across different studies. The more-recent Beron et al. (2001) residential hedonic property value (HPV) analysis of the housing-price effects of visibility changes should also be considered.

The Agency proposes combining the estimates from Chestnut and Rowe (1990b,c) with the preference-calibration approach to benefits transfer for valuing changes in visibility at national parks. The preference-calibration approach is preferred to previous *ad hoc* transfer methods. Nevertheless, like any transfer method, it is constrained by the quality and relevance of the original study estimates and the data available to support specification of calibration parameters. While the Agency is currently sponsoring a major visibility study, the complete results will not be available in time for this assessment. In the meantime, the Agency's only recourse is to report appropriate error bounds for existing estimates.

Quantified benefits from the improvement of visibility in the Second Prospective Analysis are limited to recreational visibility benefits in the primary estimates. The Agency indicated that the main residential visibility study at its disposal had been judged to be too old to use. There is now additional research that is more recent (e.g., Beron, Murdoch and Thayer, 2001). As much as any other category, visibility benefits have figured large in empirical air quality benefits estimates from hedonic property value models. The Agency should review the available studies, revisiting the older ones and adding the newer ones, and develop an approach for including residential visibility values in the primary estimates. There is no doubt that such benefits exist and the available studies, both contingent valuation and hedonic property value, provide a substantial amount of information about the likely magnitude of these benefits. Additional effort on this front can help reduce errors in benefits calculations stemming from omitted categories of benefits.

It is possible, independent of the Beron, Murdoch and Thayer (2001) paper, to consider evaluating stated preference studies concerning residential visibility. Beyond residential visibility, the recreational visibility studies are also rather old, dating back to 1990, and detailed literature reviews and attempts to reconcile differences in results have not been updated recently (e.g., Chestnut and Rowe, 1990a). The Electrical Power Research Institute (EPRI) is sponsoring a visibility study conducted by Dr. Anne Smith of Charles River Associates. The Agency should establish contact with this research team and remain abreast of its work.

An important issue that needs to be addressed in a quantitative assessment of residential visibility values from both the contingent valuation and the hedonic property value studies is that

visual air quality is inextricably associated, in terms of people's perceptions, with their concern about potential health effects. Points on this issue include:

a. CV studies found that some subjects could not ignore their concerns about potential health effects when answering questions about visibility. Some approach to separating these values is needed. Results showed visibility aesthetics were 20% to 40% of value for air quality changes as a whole in residential areas.
b. Responses to contingent valuation (CV) questions for public goods, such as air quality, may include altruistic values for other households as well as for the respondent. But this is an issue with all CV studies for public goods and should not be a reason to completely ignore the study results.
c. Hedonic property value studies, even when using an objective measure of visual air quality, can be expected to yield results that reflect values for the aesthetics of air quality as well as concerns about health effects. The Council suggests that the Agency consider the possibility of using marginal WTP estimates for a few cities (LA, Chicago, and others) where recent hedonic studies are available for comparative evaluation with health effects (see Taylor and Smith, 2000). Doing so would be approximately consistent with implicit logic of preference calibration, but would be simpler to implement.

The CV and hedonic studies each have strengths and weaknesses, but considered together they likely provide enough information for a quantitative assessment with some acceptable amount of uncertainty.

Materials Damage. The Agency cites obsolete estimates from the 1970's and plans to monetize soiling damages with new estimates of the demand for cleaning products and services. This approach has problems similar to using cost-of-illness estimates to value health. Costs are not the same as benefits. In this case, cleaning expenditures neglect aesthetic losses. The Agency seems unaware of several more recent studies that have updated the initial "Mathtech" study. For example, Harrison et al. (1993) obtained updated estimates from Mathtech.

In addition to soiling damages, air pollution can corrode metals and other materials, leading to potential productivity losses and damage to structures and historic monuments. Most of these effects are not included in the demand for cleaning products and services. Acres International Limited (1991) estimated replacement costs for some of these damages. As in other areas, the Agency should provide appropriate caveats and discuss reasons that estimates are likely to understate materials damage benefits.

Appendix C includes a separate bibliography on the subject of Materials Damage.

Recreational Fishing; Forestry: The Agency plans to use an updated version of Montgomery and Needleman's random-utility model for New York state recreational angling values. Is it is possible to extend the geographic coverage beyond the Adirondack region?

10. USE OF VSL META-ANALYSES

10.1. Agency Charge Questions Related to Use of VSL Meta-Analysis

Charge Question 22: EPA's current analytic blueprint calls for an expert-judgment project on VSL determination that would produce a probability distribution over the range of possible VSL values for use in the 812 project. EPA is not sure how much priority to give to this project. A much simpler alternative would be for EPA to specify a plausible range of VSL values. One option would be to use a range bounded by $1 million (based roughly on the lower bound of the interquartile range from the Mrozek-Taylor meta-analysis) and $10 million (based roughly on the upper bound of the interquartile range of the Viscusi-Aldy meta-analysis). This range would match that reflected in EPA's sensitivity analysis of the alternative benefit estimate for the off-road diesel rulemaking. The range would then be characterized using a normal, half-cosine, uniform or triangular distribution over that range of VSL values. EPA would then ask this Committee to review this distribution. This approach could be done relatively quickly, based on the reviews and meta-analyses commissioned to date, and would allow a formal probability analysis to proceed, without suggesting that the Agency is trying to bring more precision to this issue than is warranted by the available science.

Charge Question 23: Pursuant to SAB Council advice from the review of the first draft analytical blueprint, EPA reviewed a number of meta-analyses –either completed or underway– developed to provide estimates for the value of statistical life (VSL) to be applied in the current study. EPA plans to consult with the Council (and coordinate this consultation with the EEAC) on how best to incorporate information from the Kochi et al (2002) meta-analysis, other published meta-analyses (Mrozek and Taylor and Viscusi and Aldy), and recent published research to develop estimates of VSL for use in this study. In addition, EPA plans to implement two particular adjustments to the core VSL values: discounting of lagged effects and longitudinal adjustment to reflect changes in aggregate income. Does the Council support these plans, including the specific plans for the adjustments described in chapter 8? If the Council does not support these plans, are there alternative data or methods the Council recommends?

Charge Question 31: EPA plans to work with the Council and the EEAC to develop revised guidance on appropriate VSL measures. We hope to include the Kochi et al (2002) meta-analysis, other recent meta-analysis, recent publications, and the 3 literature reviews sponsored by EPA. (A separate charge question pertaining to this element of EPA's VSL plan is presented below). In addition, EPA plans to conduct a follow-on meta-regression analysis of the existing VSL literature to provide insight into the systematic impacts of study design attributes, risk characteristics, and population attributes on the mean and variance of VSL. Does the Council support the plans described in chapter 9 for conducting this meta-regression analysis? If the Council does not support this analysis or any particular aspect of its design, are there alternative approaches which the Council recommends for quantifying the impact of study design attributes, risk characteristics, and population attributes on the mean and variance of VSL?

Charge Question 37: Does the Council support including the Kochi et al. (2002) meta-analysis as part of a larger data base of studies to derive an estimate for the value of avoided premature mortality attributable to air pollution? Are there additional data, models, or studies the Council recommends? Does the SAB think that EPA should include Kochi et al. 2003 if not accepted for publication in a peer reviewed journal by the time the final 812 report is completed?

10.2. Summary of Council Response

The Council has combined the responses to charge questions 22, 23, 31, and 37 and has provided additional discussion concerning the use of VSLs in Appendix B of this Council Report. Major summary points appear below.

- Since the Panel's initial receipt of the Analytical Plan, the plan for an expert-judgment project on VSLs has been dropped from the blueprint. The expert elicitation exercise is no longer an active portion of this charge question.

- Uncertainty analysis with respect to VSL values requires information about the distribution of VSL estimates. The univariate distribution of all empirical VSL point estimates derived across all contexts is unlikely to be appropriate for this purpose, as is any arbitrary convenient distributional shape for this univariate distribution.

- Discounting of effects when there is a latency period is advisable, but the literature on discount rates for future financial outcomes and future health states is not clear on whether straightforward discounting using an exponential model and a common rate will be appropriate. Sensitivity analysis and caveats are recommended.

- Adjustments for future changes in aggregate income levels are being based on very limited empirical evidence and should be considered placeholder efforts at present. It would be preferable in the future if these adjustments were made in the context of a formal model of preferences and the relevant elasticities. Placeholder efforts should be clearly identified as such and accompanied by strong caveats. The First Prospective Analysis included (in an Appendix) WTP values for human health adjusted for real income growth. This type of analysis may be a candidate for the recommended "Learning Laboratory" or preliminary analyses discussed earlier.

- The Panel recommends a primary focus, at this juncture, on the Viscusi-Aldy estimates based on U.S. studies, although work in the direction of the Kochi et al. analysis is encouraged. Ultimately, mean and variance estimates of the VSL measures for the Prospective Analysis should be based on the conditional expectations from a model that includes empirically relevant variables for the risk context and relevant characteristics of the population affected by the CAAA. Developing such a model should be a priority for future research and meta-analysis efforts.

- It is certainly reasonable to expect that the Second Prospective Analysis would consider insights derived from the other VSL meta-analyses (e.g., Mrozek and

Taylor, and Kochi et al.). The Council recommends that, to the extent VSL measures are developed as conditional expectations from a meta-analysis, they should rely primarily on published peer review studies. However, as the Council's general comments on approaches to methodological innovation imply, the meta-analyses that best serve Agency needs will not always be published in the usual academic outlets. In cases where the analysis is not published, we would recommend an independent peer review be undertaken that considers the specific elements of the intended use.

- Continual evolution of the relevant literatures justifies development by the Agency of a more formal laboratory phase for evaluation of potential methodological innovations. A "satellite benefit-cost analysis," based on updated methodologies, could serve as a forum for evaluation of new methods before these innovations are formally and widely adopted by the Agency for the Section 812 Analyses and other analyses. This is a suitable activity for the "Learning Laboratory."

10.3. Expert Judgment - VSLs

The Agency desires to bound the range of plausible VSL values and define a distribution from which to select a central value and use in the uncertainty analysis. The proposed range of $1 million to $10 million is a reasonable placeholder, given the state of the knowledge about empirical values in different contexts. The Council Special Panel understands that some distribution is needed from which to draw alternative point values of the VSL for simulations of the effect of uncertainty about VSL values. However, the Council Special Panel does not agree with arbitrary assignment of some convenient distribution (e.g., normal, half-cosine, uniform or triangular) for the range of values. The choice of distribution needs to be empirically supported as much as possible. Why not compare Mrozek-Taylor versus Viscusi-Aldy meta-analyses, using the latter's re-estimates with a sample consisting of one observation per study? The Agency could use these estimates to derive a mean and variance of the relevant conditional distribution from that model "configured" for the policy analysis. For now, this probably means excluding studies that are clearly out of bounds in terms of the policy context, such as wage-risk studies that look at only one occupation (e.g., police).

The Council strongly advises that the issue of context be given high priority as the Agency pursues more meta-analyses that include more than just wage-risk studies (including future revisions of the Kochi et al. meta-analysis). The ideal VSL distribution to employ would be the conditional distribution of VSL values, derived for contexts that most closely match the risks and affected populations relevant to the CAAA. This VSL does not necessarily lie in the middle of the overall marginal distribution of empirical VSL estimates across the entirety of the broad range of contexts examined in the literature. Before this conditional policy-relevant distribution can be defined, however, empirical work needs to determine what aspects of context matter to individuals in valuing mortality risk reductions. Estimates in the literature should not be excluded if the contexts in which they are derived differ in ways that do not significantly affect the VSL results. This issue is discussed further in subsequent sections of this chapter.

10.4. Adjusting for latencies, income growth?

Latency in health effects, as well as cessation lags, means that a comprehensive assessment of mortality risk reduction benefits must take into account individual discounting. In discounting individual health effects, there remains an important question as to whether the usual convenient exponential form of discounting is an appropriate assumption, given the numerous empirical anomalies related to discounting behavior. There are also unresolved questions about the difference in discount rates concerning future health, as opposed to future financial status. While the Council concurs that future benefits need to be discounted, there is no consensus in the literature concerning how to do this. As a practical matter, pending additional research, the Agency should adopt discounting assumptions that are consistent with the rest of the Analytical Plan and include sensitivity analysis and caveats.

The Council has reviewed the SAB report, *An SAB Report on EPA's White Paper Valuing the Benefits of Fatal Cancer Risk Reduction* (EPA-SAB-EEAC-00-013), as well as the background documents of the recommendations for adjusting willingness to pay estimates for reductions in health effects and mortality risks to reflect changes in real income (i.e., memoranda to Jim DeMocker from Kleckner and Neumann dated June 3, 1999 and September 30, 2000). The Council agrees with the general principle that the willingness to pay to reduce mortality risks is likely to increase with growth in real income. The same increase should be assumed for the WTP for serious nonfatal health effects. However, our primary concern with the Agency's proposal to include an adjustment for real income growth in the primary estimates for the Second Prospective Study is the weakness of the available empirical evidence that can be used to determine what this adjustment should be. Three factors underlie our concerns:

a. The meta-analyses cited as a basis for the estimates for income elasticities do not have measures of income to develop estimates of the income elasticity. Both Mrozek and Taylor (2002) and Viscusi and Aldy (2003) clearly note they do not have income measures. Mrozek and Taylor use hourly earnings as a "proxy" for income in a relationship (i.e., one specification for their meta-analysis summary functions) describing the slopes of hourly earnings equations with respect to job risk. Viscusi and Aldy use annual earnings in this same role. Both summary functions could then be interpreted as simply reflecting non-linearities in the estimates of this slope (an ex ante marginal rate of substitution between wages and risk, not a WTP).

b. The other evidence cited in these memos is primarily from non-U.S. studies [e.g., Persson et al. (1995), Kristrom and Riera (1996), Miller and Guria (1991), Miller (2000), Jones-Lee et al. (1985)] where the context may well be quite different and imply tradeoffs that are not relevant to the U.S. situation. The Council recommended against using wage risk hedonic studies conducted outside the U.S. in meta analysis summaries of the VSL for similar reasons. Furthermore, many of the income elasticity estimates are derived from comparing WTP estimates from different countries. There may be many reasons other than income differences that may explain why these WTP estimates differ across countries The Council's concern over this issue is compounded because cross-country comparisons are the only empirical evidence supporting the high adjustment factor of 1.0 for the

values for mortality risk. Most of the estimates from within the U.S. are less than 0.5. In addition, several of the studies relate to changes in aspects of environmental quality that are not related to health or mortality risk.

c. The Agency's logic for assessment of benefits uses unit values per case of relevant morbidity to develop annual estimates of the aggregate benefits from specific policies affecting that health outcome. The concentration-response functions provide estimates of the changes in cases associated with the proposed policy. These unit values are derived transforming results that are based on WTP (or marginal WTP) measures. To account for the effects of income on these unit benefit measures properly, both estimates of the income elasticity of WTP and a basis for evaluating how income influences other factors that contribute to the unit value measure are needed. In some cases this will be straightforward. In others it will not.

   Palmquist (2003), for example, has demonstrated that when weak complementarity and Willig's (1978) restriction are used to recover a measure of the economic benefits of a quality change, then one can assume that the income elasticity of the marginal WTP for the change in environmental quality is equal to the income elasticity of demand for the private good serving as the weak complement. This same condition can be used to imply the unit benefit of a change in quality does ***not*** change with income. It is important to acknowledge that this is a restriction that affects the interpretation of available estimates. It does not mean that WTP per case does not change. Rather, it means that to develop estimates of the WTP, analysts assumed that WTP per case did not change, so those studies would not provide information that would allow anyone to judge the responsiveness of the WTP per unit to income.

Given the limitations and uncertainties in the available empirical evidence, the Council does not support the use of the proposed adjustments for aggregate income growth as part of the primary analysis. It is appropriate to continue to include this as a sensitivity analysis and to continue to look for stronger empirical evidence from which to derive adjustment factors. The Council realizes that this advice differs from the somewhat stronger endorsement of this adjustment that was given in previous Council recommendations (EPA Advisory Council on Clean Air Compliance Analysis, 2001). However, after taking a close look at the available literature and proposed interpretations of the available evidence, the Council concludes that moving these adjustments into the realm of "primary estimates" is premature. The case of cancer valuation may have some special circumstances because the issue involves a discounting because of the latency period as well as an adjustment for real income growth, both of which have limited empirical support for specific numbers.

Any income adjustments in the present analysis fall within the category of satellite or exploratory analyses that may be developed as supplementary to the primary analysis as one of the activities of the proposed Learning Laboratory. As such, they would be intended to stimulate discussion and review, rather than constituting a primary component of an analysis intended to be used in evaluating a policy. In any provisional analysis, it may be possible to place bounds on

the likely errors that would accompany simple approximations to likely income effects. If an adjustment of this type is considered essential even at this stage in the analytical process, the Agency should be especially prudent in qualifying it and present the results in a format that is as transparent as possible. This would include explaining in detail how any income adjustments have been accomplished and why they are deemed to be necessary.

It is worth emphasizing that as soon as the Agency begins to manipulate VSL estimates to reflect anticipated changes in real incomes, it opens the door to arguments that VSLs should also be adjusted for other long-run changes. These might include other changes in budget constraints, such as alterations to the relative prices of medical care. Or, they could include shifts in typical indicators of preferences, such as trends in the sociodemographic mix in the population (e.g., changes in the age distribution).

The Agency should also be aware that if monetary values for health risk reductions are to be adjusted for income growth, so should be all of the other demand-based benefit measurements entertained in the Section 812 Analyses. It may be difficult to defend making income-growth adjustments only to one component of the benefits algebra.

In the longer term, consideration should be given to obtaining income-based adjustments to VSLs (or even other types of adjustments) through preference calibration techniques. These methods hold promise for generating forecasts that are consistent with the relevant elasticities (see Smith, Pattanayak, and Van Houtven, 2003).

10.5. Available meta-analyses

Three meta-analyses were discussed in the Agency's evaluation of summary measures for the available VSL estimates (Mrozek and Taylor, 2002, Viscusi and Aldy, 2003, and Kochi, Hubbell, and Kramer, 2003). The three meta-analyses differ in several key respects, including:

a. The number of observations included from each study;
b. The format of the observations (e.g., actual estimates, use of group means, and other transformations of the primary estimates);
c. The sample composition – U.S. studies, international, revealed and stated preference;
d. The set of independent variables used for controls (e.g., inclusion of industry effects);
e. Bayesian means versus regression summaries;
f. Published versus unpublished summaries.

The background for the charge questions tends to focus attention on the selection of a single meta-analysis as the basis for developing the primary VSL estimate of reductions in mortality risk for the next Prospective Analysis. However, the charge questions explicitly refer to the "systematic impacts of study design attributes, risk characteristics, and population attributes on the mean and variance of VSL." The earlier meta-analysis strategies tended to miss the opportunity to combine the insights from all studies to influence how summary measures are constructed and used. The Council recommends that future meta-analyses, including revisions to the Kochi et al. analysis, give priority to examination of how values for mortality risk reductions

may vary systematically with study design attributes, risk characteristics, and population attributes. Insights gained should be used to guide selection of VSL results for use in specific policy analysis applications.

Equally important, the sensitivity of VSL estimates from meta-summary equations to the sample composition (i.e., which studies are included) and to the controls used (i.e., which study features are explicitly modeled) suggests that it would be prudent to use the resulting lessons from this research in at least three ways:

a. If one meta-analysis, such as Viscusi and Aldy (2003) is selected, evaluate the sensitivity of the conditional expectation to the baseline risk and other control variables selected in measuring the conditional prediction.

b. Evaluate the variance in the conditional prediction as a function of the values for the independent variables included in the model in relation to the mean values for these variables for the sample used to estimate the model.

c. Consider the effects of inclusion or exclusion of independent variables or observations on the coefficient estimate for the risk measure. The data sets used in these studies are generally available for attempts at replication, so this type of comparison can be readily undertaken and would permit evaluation of the sensitivity of the VSL estimate to assumptions made, based on the available literature.

In general, it does not seem prudent to extend the sample to include studies for labor markets outside the U.S. The terms of employment, information about safety conditions, fringe benefits (e.g., health insurance), etc., are likely to be so different that one could not be sure that differences attributed to income or risk levels were in fact due to these variables.

10.6. Interpreting CV measures as opposed to wage-risk measures

One advantage asserted for the Kochi et al. study is the inclusion of CV evidence concerning VSLs. However, there is an important issue that has not been adequately discussed when CV results are included with revealed preference wage-risk results concerning VSLs. Calculating a VSL point estimate from CV results implicitly accepts a proportionality assumption between *ex ant*e WTP and the risk change.

The proper theoretical interpretation of the CV measures is as an *ex ante* option price for a risk change. If OP denotes the value for a risk reduction from P0 to P1 (with P1 < P0), and the P's designate the probability of death before and after the risk reduction, theory implies:

Equation 1: OP = f (P0, P1 , and other variables)

The comma between P0 and P1 implies that linear proportionality in (P0 - P1) is an approximation, not a feature implied by theory. Thus, to rewrite equation (1) as equation (2) below, where the option price associated with a risk reduction is proportional to the size of the risk reduction (as well as being a function of a number of other variables) and then to

approximate VSL as in equation (3) by normalizing upon a 1.00 risk change, adds additional untested assumptions.

Equation 2: $$OP = (P_0 - P_1) \cdot g(\text{other variables})$$

Equation 3: $$VSL \approx \frac{OP}{(P_0 - P_1)} = g(\text{other variables})$$

A meta-analysis that includes CV studies to expand the range of risk changes (or the types of risks considered) will accomplish this objective. However, it also changes the summary measure from an *ex ante* marginal rate of substitution to a linear approximation. Unfortunately, this added condition makes it difficult to evaluate whether the resulting differences in summary results between CV and wage-risk studies should be attributed to these additional assumptions implicitly added to the model or to the expansion in the range or types of risks.

Nevertheless, the Council recognizes that CV-based studies offer unique opportunities to examine the empirical influence of many additional factors on the resulting estimates of VSLs. Despite the potential difficulty in rendering their findings compatible with those from revealed preference wage-risk studies, CV studies have the potential to make important contributions to our understanding of how consumers value risk reductions and it is important to take advantage of these opportunities.

10.7. Emerging considerations

As recent unpublished research by Cameron and DeShazo seems to suggest, the terms identified in equations (1), (2), and (3) above, and other things, may well be very important to the *ex ante* option price measured for the risk change. This research is presently available only as early reports from a detailed CV study. Nonetheless, it reaffirms the notion that it may be important to evaluate the sensitivity of the conditional expectation of the VSL to the conditioning variables used in its construction.

The Council's discussion also supported efforts to refocus attention on incremental WTP for an incremental risk change, rather than the traditional, but potentially confusing construct that is a VSL. The Panel's discussion urged the Agency to consider including an introduction to the concept the Agency is using as a benefit measure, its likely link to the conditions of daily living and illness preceding death, as well as to any latency and temporal issues associated with exposure and increased risk of death.

The Panel recognizes that the current state of research makes it unlikely that empirical measures can immediately be developed that reflect all of these concerns. Nonetheless, the discussion led to a consensus that the Panel should urge Agency staff to consider careful qualification and sensitivity analysis for the measure used to monetize mortality risk reductions.

10.8. Which meta-analyses to use

In general, the Council Special Panel recommends that the Kochi et al. meta-analysis should not be given any particular prominence among the alternative meta-analyses used for determining one appropriate measure to use for the VSL. There are several reasons:

a. The Kochi study is still unpublished. While it can sometimes be difficult to publish further meta-analyses when others are already in the literature, the Agency should not rely disproportionately on the Kochi study before it has been thoroughly peer-reviewed. The standards for peer-review obviously differ across journals and even across reviewers, but reliable peer-review can also be accomplished outside of the journal publication process. Both Mrozek and Taylor (2001) and Viscusi and Aldy (2003), however, have already appeared in the peer-reviewed literature.

b. There are problems in the derivation of the variance of the VSL estimates. Some appear to be typographical errors. The researchers apparently faced some problems in terms of unobserved (or unreported) covariances among parameter estimates. However, it might be possible to derive estimates of variance in mean annual wage from the current population survey (CPS) or other sources, and use this information to fill in some of the blanks. It is not clear whether one should use a predicted wage or an actual mean wage. Overall, this is a careful study but, like all meta-analyses, it needs to address the potential impact of some of its key assumptions on the results of the analysis before it is possible to assess their importance.

c. The use of author-specific means of VSL (p. H-12 to H-13) is troublesome if the different estimates have been derived from different samples.

If called upon to recommend just a single meta-analysis at this point, the Council Panel would recommend a primary focus on the Viscusi-Aldy estimates based on U.S. wage studies. However, as the 812 process evolves over time, the Council has recommended a commitment to satellite or provisional analysis to test new methods in a policy relevant format. This would assure that the Agency did not miss opportunities to incorporate insights from new research as it emerges. It would also signal a commitment to understanding the full implications of methodology change before it was adopted as the "Agency Practice."

Ultimately, variance estimates for the VSL measures predicted for a risk context and an affected population similar to those relevant to the CAAA should be based on the variance in the conditional expectation from a model that includes empirically relevant variables for risk context and population characteristics. Developing such a model should be a priority for future research and meta-analysis efforts.

10.9. Unpublished meta-analyses?

The Council was asked explicitly to address the question of unpublished meta-analyses. In general, the Council believes a peer-reviewed study will have greater professional credibility

than one that has not met this standard. The Panel has some reservations about basing an analysis with the gravity of the Second Prospective Analysis on unpublished research, but has even greater reservations about using entirely non-peer-reviewed research. Each of the available meta-analytic studies has different advantages and shortcomings so that no single study should be the sole basis for information about the distribution to be used for the VSL in the Second Prospective Analysis.

This is another reason for creating an ongoing commitment by the Agency to engage in activities that serve as laboratories for methodological developments. Based on innovations in the literature, new methods and new meta-analyses will continue to be developed and applied to policy issues. First, they should be used for evaluative purposes. Results designated as explicitly as "exploratory" can be disseminated in Agency working papers to evaluate the implications of new proposals for analysis. This process serves a role that parallels the peer review process. However, it is more focused and relevant to Agency needs because the appropriate policy context is being considered. These satellite benefit cost analyses could then provide a forum for exchange and evaluation of new methods before they are formally adopted for specific analyses that would be submitted as the Agency's official evaluation of a proposed regulation.

11. QALY-BASED COST EFFECTIVENESS

11.1. Charge Question 24:

For the 812 Report, EPA has decided to perform a cost-effectiveness analysis of the Clean Air Act provisions using quality-adjusted life years as the measure of effectiveness. This is the standard approach used in medicine and public health and this type of analysis has previously been recommended by the SAB. Moreover, the recent NAS Report (2002) on benefits analysis discussed how this method could be applied to the health gains from air pollution control.

a. Do you agree that QALYs are the most appropriate measure of effectiveness for this type of analysis? Would you suggest any alternative measures to replace or supplement the QALY measure? (This question relates to effectiveness measures, not monetary benefit measures as used in benefit-cost analysis).

b. OMB has suggested that EPA plan a workshop with clinicians, social scientists, decision analysts and economists to examine how the specific diseases and health effects in the 812 Report should be handled with respect to longevity impact and health-related preference. Participants would have knowledge of the relevant clinical conditions, the related health preference studies, and the stated-preference literature in economics. The recent RFF conference has laid the groundwork for this type of workshop. Is there a superior approach to making sure that the CEAQALY project is executed in a technically competent fashion and that the details of the work receive in-depth technical input in addition to the broad oversight provided by this Committee?

c. Does the Council support the specific plans for QALY-based cost-effectiveness described in the current draft blueprint? If the Council does not support specific elements of these plans, are the alternative data, methods, or results presentation approaches which the Council recommends?

11.2. Summary of Council Response:

The Council understands the Agency's interest in conducting a cost-effectiveness analysis since this is being required by OMB in addition to benefit-cost analysis for major regulations. Some cost-effectiveness analysis for the Section 812 Analysis has also been suggested in previous Council recommendations (EPA Advisory Council on Clean Air Compliance Analysis, 2001). In this Advisory, the Council cautions the Agency to proceed carefully in this regard and keep the primary focus on the benefit-cost analysis.

- This Council has had difficulty coming to full agreement about recommendations regarding the appropriateness of QALYs for use in this context. The limitations of the measure have led some members to want to recommend against using it at

all. Other members acknowledge the limitations, but are more comfortable endorsing exploratory efforts by the Agency to apply the measure in a cost-effectiveness analysis.

- There are important limitations of any cost-effectiveness analysis that need to be recognized. Focusing exclusively on human health effects relegates the other benefits of the CAAA to the sidelines. There are also other problems with respect to the selection of an effectiveness measure for reductions in human health risks (e.g., QALY).

- The Council's reservations about QALYs stem primarily from concerns about QALY weights on health state attributes being inconsistent with the utility-theoretic models that underlie benefit-cost analysis unless excessively strong assumptions are made. All members agree that there should be no attempt to develop utility-based monetary valuations for QALYs (such as WTP per QALY) as these are conceptually inconsistent approaches.

- The deliberations of the Institute of Medicine's Committee to Evaluate Measures of Health Benefits for Environmental, Health, and Safety Regulations can be expected to be of considerable value in resolving some of the Council's concerns. This study was requested by the Office of Information and Regulatory Affairs of the Office of Management and Budget and is supported by a consortium of federal agencies that are responsible for assessing and reducing environmental, occupational, and consumer risks to health and safety. The committee's report will not be available until late in 2005. The Council advises that the Agency forestall any efforts to conduct cost-effectiveness analysis using QALYs until that report is available.

11.3. Challenges and limitations of CEA

Cost-effectiveness analysis (CEA) calculates costs per unit of effectiveness. A metric of effectiveness therefore needs to be defined that reflects the expected outcomes of the program. Benefit-cost analysis (BCA) estimates net benefits, which is an indication of how much better off society as a whole is likely to be if the program is implemented. In BCA both costs and benefits are defined in terms of changes in well-being or utility, and both are quantified in monetary units. In BCA, analysts' measurements of benefits are grounded conceptually in individual preferences.

Although the conceptual basis for valuation of benefits in BCA is clear, the empirical implementation is fraught with difficulties and limitations, especially when the primary effects of a program are non-market goods and services, such as protection of human life and health and quality of the natural environment. CEA, therefore, has some appeal because it avoids the need to determine how much better off individuals are with the program. It simply measures the effect in some selected metric, such as numbers of acres restored, number of deaths prevented, number of accidents prevented, etc. The calculation of the cost per unit of effect is helpful in determining which of several programs, designed to achieve the same goal, is most cost-

effective. However, it does not inform about whether the program is worthwhile, i.e., whether the value of the benefit of the program exceeds the costs. CEA also says nothing about how to allocate resources among programs that achieve different effects (e.g., saving trees or saving people).

The Council concedes that CEA is widely used in other public-health domains and that some users of the Second Prospective Analysis will wish to compare the cost-effectiveness of the CAAA as a form of public health policy with the cost-effectiveness of other health programs. CEA comparisons may be a reasonable way to approach alternative medical treatments where all of the benefits of each alternative treatment accrue as changes in health status. For the CAAA, however, a strategy that attributes all of the costs of the policy only to the increases in health status does not provide a valid comparison, regardless of the health measure used (QALY, lives saved, life-years saved, etc.). There are other non-human-health benefits associated with the CAAA (e.g.., ecosystem benefits). Furthermore, since the costs of the policy are joint costs that cannot be attributed separately to the different classes of benefits from the CAAA, there is no way to apportion these costs to arrive at a cost just for the health changes produced. Apportioning these costs is essential before any meaningful cost-effectiveness comparison can be attempted between the CAAA and private medical interventions as alternative means of improving human health. Researchers have invested heavily in the fine-tuning of standardized cardinal physical measures for human health improvements, but these measures cannot capture the broader benefits of clean air policies.[5]

The proposed remedy for this problem is to calculate net costs by subtracting all the non-health benefits that have been monetized in the benefits assessment. Such a procedure, however, remains a less than satisfactory solution when there are many potential non-health benefits that are poorly measured or not quantified at all. Some Council members find this approach troubling because it mixes benefit-cost analysis with cost-effectiveness. The Council acknowledges elsewhere in this report that the task of monetizing ecosystem benefits is a particularly difficult one. In general, when policy costs are non-separable and additional benefits cannot readily be monetized, it is extremely difficult to arrive at a cost that applies only to the health outcomes produced.

Separability in preferences is also a pervasive concern in cost-effectiveness analysis. Some of the important nuances in the QALY-WTP discussion hinge upon the extent to which health affects the marginal utility of income or wealth. The possibility that marginal utility of income depends on health means that WTP for health, environmental quality, or anything else may depend on health. This implies that one should account for the effect of population heterogeneity in health states when estimating WTP.[6]

[5] One Council member points out that omitted non-health benefits of clean air policies are also a qualification affecting formal benefit-cost analyses, so this problem is not exclusive to QALY analysis. The two methods merely handle this problem differently.

[6] Different members of the Council express different degrees of concern about the consequences of assuming separability between health and income.

11.4. QALYs as a Measure of Effectiveness

The Council acknowledges that it has previously recommended that QALYs be considered as candidate measures for "units of physical benefit" for the human health benefits of air quality improvements. Nevertheless, the composition of the Council has changed over time and the opinions of some of its members have been influenced by new information. Some of this information was provided in a special conference hosted by Resources for the Future entitled "Valuing Health Outcomes: An Assessment of Approaches" which took place in Washington, DC, on February 12-14, 2003. The subject matter of the conference was "the conceptual and empirical bases for alternative health-benefit measures, the ways in which such measures are used and could be used in policymaking, and whether the choice of measure would actually make a difference in policy outcomes." In attendance were diverse groups of "experts, government officials, and stakeholders," and the tenor of much of the discussion concerned the relative appropriateness of cost-per-QALY measures versus WTP measures.

It is likely that the Second Prospective Analysis will provide sufficient detail about benefits and costs that some audiences will be tempted to make cost-effectiveness calculations even if the Agency does not provide them. However, in view of the standards to which the Council has held other dimensions of the Section 812 Analysis, QALY-based analyses should be subjected to comparable scrutiny. The usual applications for QALY-based cost-utility comparisons involve only well-defined human-health benefits. The Clean Air Act and its amendments do not fit neatly into this framework. Members of the Council have articulated a number of additional specific reservations about the use of QALYs in the context of the Section 812 Analyses. These reservations concern consumer sovereignty and representativeness, ordinality versus cardinality, heterogeneity in health states, and the notion of willingness to pay for a QALY. Details about these concerns appear in Appendix F.

The Council would prefer to present the Agency with an unambiguous conclusion on the QALY cost-effectiveness matter. However, after several rounds of discussion on the topic, spanning several meetings, the Council has been unable to reach a unified view. The Council agrees that the jury is still out on whether QALY cost-effectiveness measures can be successfully adapted, in the future, to reflect both sufficiently general consumer preferences and the full array of non-human-health benefits also stemming from air quality improvements. Some Council members note that there is likely to be strong demand for QALY measures; others are firm in their convictions that the Agency should not be pressured by the wide acceptance of what they believe to be incorrect practices into using them in the Second Prospective Analysis.

The Council thus supports the Agency's plan to do a benefit-cost analysis as the main analysis and to treat any cost-effectiveness analysis as an ancillary calculation. In the current round, QALY-based methods should, at best, be included among the various methods and procedures to be considered for the "Learning Laboratory" where possible future enhancement are explored, tested and vetted by experts in all relevant fields.

11.5. Summary:

The Agency seems obliged, in complying with OMB guidance, to consider cost-effectiveness measures. The current Council, however, would prefer that the Agency *not* interpret this mandate as specifically requiring that this cost-effectiveness analysis take the form of explicit cost-per-QALY assessments. While QALYs may capture the majority of benefits from private individual medical treatments such as surgeries or medications, QALYs are not able to fold in all of the diverse benefits of a public good like clean air. Clean air may produce substantial human health benefits, but it may also provide substantial benefits to ecosystems. In general, it is not possible to accurately attribute shared costs to different categories of benefits. Only with an assumption of complete separability among costs and benefits across human health and other benefits can non-health benefits be treated as cost offsets and netted out of the cost-effectiveness calculations. Assessment of this separability assumption is a task for the Learning Laboratory the Council is advising the Agency to develop to support the Section 812 Analyses.

In cases such as the Section 812 Analysis, it may currently be possible to go no further than describing the costs and listing the array of known, estimated, and speculative physical benefits from the Clean Air Act and its amendments. QALYs could of course be entertained as one category of these physical benefits, but it should be made clear that overly simple cost-per-QALY calculations will be biased upward for the Section 812 Analysis, relative to alternative, exclusively health-enhancing, programs with which stakeholders may wish to make comparisons. If separability could indeed be assumed and if the monetary value of the non-health benefits is first subtracted from costs, then the cost-effectiveness ratio is biased upward if and only if the monetary benefits of the non-health effects are underestimated.[7] Without separability, it may not even be possible to sign the direction of the resulting bias.

The Council advises the Agency to determine whether this type of accounting, with costs and an enumeration of all classes of physical benefits (perhaps including, but not limited to QALYs) would satisfy the OMB requirement for cost-effectiveness analysis. However, the core of the Second Prospective Analysis should concentrate on using generally accepted and thoroughly vetted benefit-cost methodologies, as the proposed main analysis currently does. The Council does not endorse any substantial effort to calculate QALYs or benefits in the form of WTP per QALY as part of the main analytic agenda for current Section 812 assessment. The Council recommends that the Agency reserve judgment on this matter at least until the Institute of Medicine report becomes available in late 2005. The mandate to conduct some type of cost-effectiveness analysis suggests that the Agency devote attention to alternative strategies for meeting this mandate. However, the Agency should explore candidate methods under the category of Learning Laboratory activities, rather pursuing such analyses on an equal footing with the main benefit-cost analysis. In general, cost-effectiveness analyses should be presented as "alternative" analyses even when (or if) they are mainstreamed into future Prospective Analyses.

[7] In this situation, however, the net benefits in any benefit-cost analysis will also be biased in a way that makes the CAAA look less favorable.

12. MORBIDITY EFFECTS

12.1. Charge Question 25

EPA plans to use updated unit values for a number of morbidity effects, as described in chapter 8. Of particular note, EPA plans to rely on a study by Dickie and Ulery (2002) to provide heretofore unavailable estimates of parental WTP to avoid respiratory symptoms in their children. This study is not yet published and has limitations concerning response rate and sample representativeness; however, EPA expects the study to be published prior to completion of the economic valuation phase of this analysis. Does the Council support the application of unit values from this study, contingent on its acceptance for publication in a peer-reviewed journal? If the Council does not support reliance on this study, are there other data or methods for valuation of respiratory symptoms in children which the Council recommends?

12.2. Summary of Council Response:

- The Agency should continue to use WTP estimates for morbidity values, rather than cost-of-illness (COI) estimates, should these be available. Where WTP is unavailable, COI estimates can be used as placeholders, awaiting further research, provided these decisions offer suitable caveats.

- The Dickie and Ulery study is a valuable addition to the repertoire of empirical results concerning WTP for acute respiratory illnesses and symptoms, although it is not so superior as to supercede all earlier studies.

- Values for "bad asthma days" might be approximated by transfer of results for respiratory-related minor restricted activity days, pending the development of updated results on this topic.

- The Analysis could still benefit from new estimates of WTP to reduce the risk of non-fatal heart attacks. Current COI estimates assuming average lost earnings over 5 years do not comport entirely with all evidence in the literature concerning employment and earnings effects.

- Where mortality valuations subsume pre-mortality morbidity, the Agency should be careful to avoid double-counting. Where values for the two health states, morbidity and lost life-years, can be separated, both should be counted.

12.3. General Points

The primary challenge for the Agency in determining monetary values for morbidity health effects is to match the valuation exercise as closely as possible to the definition of the health effect in the studies being used as the basis for the relevant concentration-response function. The Agency has done a good job with this in applying the available literature and making appropriate adjustments when possible, such as for the average severity for chronic bronchitis cases. The Council cautions that the closeness of the match should continue to be

taken into account as new health effects and economic valuation studies become available. Improvements in matches may be possible as new studies emerge.

The Council recommends that, in general, all available valuation studies that pass reasonable quality and applicability standards should be considered when developing a range of values for a particular morbidity category. Most studies have limitations but these vary for different studies. Considering the results from all available studies provides a more reliable basis for valuation and a more realistic picture of the uncertainty in the estimates. It may be appropriate to give some studies more weight than others based on their various strengths and weaknesses and relevance for a given health effect.

The Agency should continue to use WTP estimates when these are available, rather than COI estimates. However, it is useful to compare available WTP estimates to available COI estimates, as the Agency is doing for some morbidity categories such as chronic bronchitis, because this may help provide a general sense of credibility for the WTP estimates that are based on survey elicitation or revealed preference estimation approaches. However, it is important to recognize that the COI estimates are not appropriate alternative estimates to be substituted for WTP estimates because they do not reflect the preferred concept of valuation.

It is nevertheless appropriate to use COI estimates when WTP estimates are not available, such as the Agency proposes to do for non-fatal heart attacks. It is reasonable to presume that this strategy typically understates WTP values. However, it is important to keep in mind that an individual's WTP to prevent an illness may not fully reflect the costs covered by insurance. This could result in a situation where a COI value may exceed an individual's WTP when medical costs are substantial and are covered to a significant extent by health insurance.

12.4. Acute respiratory illnesses and symptoms

Dickie and Ulery (2002) is a good addition to the WTP literature for acute respiratory illnesses and should be included in the set of studies used as the basis for the values for these health effects. However, it is not so superior that it should supercede all previous studies. It should simply be added to the pool of studies available for valuing acute respiratory illness or symptoms in adults.

The Council urges some caution in interpreting the Dickie and Ulery results in the context of previous morbidity studies. The estimates are based on an unrepresentative convenience sample of Mississippi households that are more educated and have higher incomes than the general population. There are also some concerns about response rates. In addition, the authors employ a repeated CV elicitation format. This format has not been subject to the validity testing of more conventional formats. When the problem involves eliciting tradeoffs among multiple symptoms, durations, and costs, stated-choice conjoint analysis is an alternative with better-known theoretical and empirical properties.

Dickie and Ulery provide information on WTP values for preventing acute respiratory illness in children that has not been available from previous studies. The results suggest that parents value the prevention of acute respiratory illness in their children at about twice the value they place on the same prevention for themselves. The estimates of WTP values for preventing

illnesses in children from this study are appropriate to use for comparable pollution-related health effects. The ratio of values for adults to those for children is appropriate to use when only adult values are available. It would also be appropriate to compare adult values for the same illnesses from other studies, adjusted using this ratio, to the results from Dickie and Ulery for children.

Dickie and Ulery's Table 7 reports results from other WTP studies. Overall, the Dickie and Ulery results suggest that the current Agency values for respiratory illnesses, especially for children, are probably too low. This table also raises questions about the estimates selected for use in the previous Prospective Analysis. Those numbers are generally lower than the numbers shown in the Dickie and Ulery table although they appear to be based on a similar set of studies. These apparent differences in the interpretation of the previous literature need to be reconciled.

It would also be useful to take a look at the results of Johnson et al. (2000). Although this study was done in Canada it was a nicely designed choice format approach for valuation of short-term respiratory and cardiovascular symptoms of varying severities. Given the limited number of U.S. studies, the uncertainties about differences in preferences between the U.S. and Canada may be acceptable given the additional information the study provides. An important concern with the Canadian study is that the health care type payment vehicle may be affected by the availability in Canada of a public health care system. One Council member (who is also an author of the Johnson et al. (2000) study) noted that all health care costs are not covered by the Canadian health care system. This is similar to the situation in the United States where many people have health insurance, but some out-of-pocket expenses are still incurred.

12.5. Asthma exacerbations

The HES has recommended that asthma exacerbations be added back into the base case estimates, so some economic valuation of these will be needed. (EPA Council, 2004). The Agency stopped using the estimates of WTP for preventing a "bad asthma day" (Rowe and Chestnut, 1985) because of concerns about matching the definition of a bad asthma day to the epidemiology results used to calculate asthma exacerbations. The endpoint was defined in the original study to reflect the heterogeneity in the severity of asthma symptoms in a particular panel of asthma patients.

However, the challenges of matching available valuation estimates to the epidemiology evidence is an issue for all of the acute respiratory illnesses or symptoms. Rather than exclude a study because of these transfer uncertainty issues, it may be preferable to consider all the available valuation studies on respiratory symptoms such as coughing, wheezing or shortness of breath for those with diagnosed asthma and the general population.

As a whole, these studies suggest a reasonable range of WTP values for these types of symptoms. Preventing asthma exacerbations can be presumed to be at least as valuable as preventing similar symptoms in the general population. The HES has noted that asthma exacerbations are likely to result in some level of activity restriction. Thus, even if a specific value for preventing asthma exacerbations is uncertain given available information, it may be reasonable to presume that preventing an asthma exacerbation is at least as valuable as preventing a respiratory-related minor restricted activity day.

12.6. Non-fatal heart attack

Lacking a WTP estimate for reducing the risk of having a non-fatal heart attack, the Agency is basing a valuation for this effect on a COI estimate. This will likely understate the total welfare effect, as acknowledged by the Agency. It is reasonable to presume hospitalization for a non-fatal heart attack, and the 5-year medical costs seem appropriate as there is often significant follow-up treatment after an initial heart attack. However, it does remain somewhat uncertain whether air pollution exposure causes a heart attack that would not have otherwise occurred, or merely causes it to occur earlier than it otherwise would have. This cannot be determined based on the available epidemiology results for this health effect. It remains an important research question whether air pollution is a factor contributing to the development of the underlying coronary heart disease (as it has been associated with onset of some chronic respiratory diseases). However, a heart attack does cause damage that might not have otherwise occurred until much later, if at all, so it is appropriate to include follow-up costs linked to the heart attack.

Cropper and Krupnick (1990) is cited as the source of estimates on lost earnings resulting from non-fatal heart attack. This study provides results of a unique analysis that may not be available elsewhere in which labor force participation and reduced earnings for those who remain employed, are both estimated for several chronic health conditions. The data used for this analysis, however, are fairly dated as they are drawn from a Social Security survey on disabilities conducted in 1978.

Results from Krupnick and Cropper show a decline in earnings through age 65 for those who experience a first heart attack between age 45 and 54, but no significant loss in earnings for those aged 55 and older, or for those under age 45. This is not consistent with the assumption used in the proposed estimates which is that everyone suffers the average earnings lost for 5 years only. Wages can be updated to current levels. However, if treatments for heart attack have changed significantly since 1978, then estimated effects on employment and earning may be out-of-date.

12.7. Chronic Bronchitis

Charge Question 15 asks whether premature mortality implications of morbidity endpoints should be added. The HES recommendation is that mortality risks from chronic conditions caused by air pollution exposure should be presumed to be captured in the prospective cohort studies. The HES has recommended against alternative estimates that totally exclude the prospective cohort mortality risk studies. Thus, adding mortality risks associated with chronic conditions that have been linked to pollution exposures in other studies would potentially result in double counting mortality risks. Consistent with this interpretation, the valuations for the chronic illnesses should not include value for any associated increase in mortality risk.

The results in Viscusi et al. (1991) provide the basis for the chronic bronchitis valuation estimates. Respondents to this survey were not told anything about changes in life expectancy associated with the condition so there is no reason to expect their responses to reflect any significant concern for this.

13. UNCERTAINTY ANALYSIS - PLANS

13.1. Charge Questions Concerning Uncertainty Addressed in this Report

Charge Question 26. Does the Council support the plans described in chapter 9 for estimating and reporting uncertainty associated with the benefit and cost estimates developed for this study? If there are particular elements of these plans which the Council does not support, are there alternative data, models, or methods the Council recommends?

Charge Question 27. Does the Council support the plans described in chapter 9 for the pilot project to develop probability-based estimates for uncertainty in the compliance cost estimates? If the Council does not support this pilot project, or any particular aspect of its design, are there alternative approaches to quantifying uncertainty in cost estimates for this analysis which the Council recommends?

13.2. Summary of Council Response to Charge Question 26

- The Revised Analytical Plan sets ambitious goals for improved treatment of uncertainty. However, due to the lack of detail in Chapter 9, the Council Panel has had some difficulty in evaluating the proposed actions implementing those plans.

- The Revised Analytical Plan does offer specific proposals for analysis of uncertainty in components of the benefit-cost analysis. The Council Panel endorses two of these (i.e., the plan for a pilot study of expert judgment on dose-response for particulate matter and the ozone mortality meta analysis) with small reservations noted below, but has reservations about others.

- The Council Panel's larger criticism of the Revised Analytic Plan is that it offers little insight about either how these specific components were chosen as the focus of more detailed analysis or about how information from these component analyses will be combined to yield useful information about the overall level of uncertainty in the analysis of net benefits of air pollution control, the major contributors to that uncertainty, or of the priorities for research to reduce such uncertainties.

- The Second Prospective Analysis should address the pervasiveness of uncertainty in cost and benefit estimates. Those elements that are both highly uncertain and have the potential to have a significant impact on the results should be the focus of sensitivity analyses. Sensitivity/uncertainty analysis needs to be an iterative process to identify and assess the significance of key uncertainties in each step of the assessment. Only a selected set of the most influential uncertainties should be quantitatively followed all the way through to the final results.

- The Council advises the Agency to develop its uncertainty analyses with reference to the recommendations in reports of the National Research Council (2002) and OMB (2003). It also advises the Agency to use the list of "key uncertainties" from the first Prospective Analysis as a framework.

13.3. Detailed Comments Related to Charge Question 26

The Revised Analytical Plan sets ambitious goals for improved treatment of uncertainty. However, due to the lack of detail in Chapter 9, the Council Panel has had some difficulty in evaluating the proposed actions implementing those plans.

The Agency proposes to follow the guidance in the National Research Council (2002) and in the September 2001 Council report, which recommended that "parameter uncertainty and as many types of model uncertainty as possible, be treated within a probabilistic framework" (page 9-4). Chapter 9, however, is relatively brief. It provides mainly broad discussion, with little additional specific content on how uncertainty analysis will be accomplished.

The Plan discusses utilization of an expert in the field of uncertainty analysis and developing a lexicon and taxonomy. The Council agrees that it is important to have a common language and agreed-upon methods for analysis of uncertainty. However, the Council believes that the NAS (2002) and Council (2001) reports, and various standard references cited in these and other reports such as OMB (2003), already provide the Agency with a workable taxonomy and a basis upon which to implement uncertainty analysis.

The Agency has suggested uncertainty analysis projects in four specific areas:

a. A pilot project to use expert judgment to better characterize the current state of knowledge about the concentration-response function for PM induced mortality;
b. A meta-analysis of ozone mortality concentration response coefficients;
c. An attempt to characterize better the uncertainty in estimating the changes in air pollution concentrations likely to result from emissions reductions; and
d. An investigation of uncertainty in estimates of air pollution control costs.

Based on briefings received at its November 5-6, 2003 meeting, the Council also understands that the Agency no longer intends to undertake a study of the uncertainty in estimates of the VSL, an additional area that was also discussed in the draft Analytical Plan.

The Council advises the Agency to develop the uncertainty analyses plans listed above with reference to the recommendations in the above-mentioned reports. It also advises the Agency to use the list of "key uncertainties" from the first Prospective Analysis as a framework.

The Council and its subcommittees have considered three of the four[8] specific proposed efforts for addressing uncertainty and have provided more-detailed comments on each of them elsewhere (either in this report or in the supporting HES report). Our comments about each plan are summarized below:

a. PM Expert Judgment Pilot Project – The Council generally supports the use of expert judgment to inform policy analysis; commends the Agency for moving in this direction; understands their hesitancy to move too quickly; supports the pilot

[8]Plans for this fourth project will be addressed by the Council's Air Quality Modeling Subcommittee when the Agency has more details about the choice of models and the modeling protocols that would be employed.

study; questions whether it is advantageous to use the results of the pilot study in support of a major regulatory initiative; advises that the project be subjected to a careful peer review; and urges the Agency to invest adequate resources, time and managerial attention to further development of this approach so that it can be used to inform the Third Prospective Review of the Clean Air Act. [See Advisory Council on Clean Air Compliance Analysis, (2004) especially the HES Response to Charge Question 29, for further detail.]

b. Ozone Mortality Meta-analysis – While a meta-analysis of ozone mortality data may be useful, the Council does not regard the plan for uncertainty analysis on ozone as adequate. [See Advisory Council on Clean Air Compliance Analysis, (2004) especially the HES Response to Charge Question 30, for further detail.]

c. Control Cost Uncertainty Analysis -- As discussed in more detail in sections 13.4 - 13.10, the Council believes that the focus of this project on uncertainty in engineering cost-estimates is poorly founded and recommends greater attention to issues such as:

1) what is left out or not counted in the cost estimates (welfare effects, process and productivity changes);
2) uncertainty about the introduction and penetration of new technologies (e.g., penetration of alternative fuel vehicles);
3) economic changes (energy prices, aggregate economic activity), and
4) the extent of learning in different industries -- in future efforts in this area. See the Council response to Charge Question 27 in this report for further detail.

Uncertainty analysis is vital to the integrity of the Prospective Analysis. Thus, the Council Special Panel also recommends that the Agency take the following steps to strengthen its overall approach: a) provide an explicit description or justification of the rationale underlying the identification of these areas as the critical targets for improved characterization of uncertainty; b) develop a strategy for using the results from these specific projects to better characterize the extent of the uncertainty in estimates of the net benefits expected from the CAA; and c) provide sufficient detail about the specific plans for the projects listed above to permit a constructive critical review of the Agency's plans. The Council sees this area as a priority for the Agency and for the advice it will provide to strengthen the 812 process.

In Chapter 9 the Agency mentions that it plans to develop an approach that "will involve EPA experts working together to identify the major sources of uncertainty in (emissions and air quality modeling) and then working with a combination of off-line tools and formal and informal elicitation processes to develop a representation of uncertainty in emissions and, perhaps, key air chemistry calculations that can be used in downstream analysis" (page 9-7). Such an "alternative approach" to traditional deterministic benefit-cost analysis seems like an excellent objective for the Agency, consistent with the recommendations of NAS (2002) and the September 2001 Council report. The Council Panel is not aware of detailed plans to develop this "alternative

approach." Without further detail it is difficult for the Council to offer constructive criticism of these plans.

During the period since the Analytical Plan and the charge questions were initially presented to the Council, many of the activities described in Chapter 9 have been initiated and the PM expert judgment pilot project has been completed.
The Council suggests that the Agency may wish to develop more detailed plans for its uncertainty analysis for review by the Council in 2004, after the pilot project on PM mortality has been completed. The Council recommends that the Agency again review the guidance and references cited in the 2002 National Research Council report (especially chapter 5), the September 2001 Council report, and the 2003 OMB report.

An important goal for the Second Prospective 812 Report should be the identification of the most important uncertainties associated with the costs and benefits of air pollution, so that the Agency can more effectively target research and improved analytical methods to reduce uncertainties and improve the characterization of remaining uncertainties in subsequent 812 Analyses of the costs and benefits of air pollution. The Council believes that more emphasis should be placed on identifying key uncertainties and associated research priorities.

While the Council recognizes the evolutionary nature of the Agency's development and use of methodologies for uncertainty analysis, it is unfortunate that the text of Chapter 9 does not contain more specific plans for identifying which are the most important factors underlying cost and benefit uncertainties and for developing appropriate methodological approaches to characterize such uncertainties. Uncertainty analysis should be carried out as an iterative process, using initial characterizations of uncertainty to guide subsequent efforts to characterize important uncertainties more precisely using available data and expert judgment.

The Council suggests that the list of "key uncertainties" from the First Prospective Analysis (Table 9-1) could play a larger and more important role in developing the approach to characterizing uncertainties in costs and benefits (and consequent decisions about the most valuable allocation of scarce analytical resources). The Council hopes the guidance from its current reports and further interaction between Agency staff and the Council in 2004, can lead to an improved plan for characterizing these uncertainties in the most effective way for the Second Prospective Analysis, given the constraints under which the Agency must carry out the Second Prospective Analysis.

13.4. Summary of Council Response to Charge Question 27 Concerning the Compliance Cost Pilot

- Just including uncertainty in engineering costs is an important improvement over the First Prospective Analysis. The Council advises the Agency to explore uncertainty in more than just engineering cost estimates. Other sources of cost uncertainty will also be important and should not be neglected.

13.5. General Discussion

The pilot project on costs described in Chapter 9 is the Agency's major new effort for examining uncertainty with respect to costs. The proposed analysis will make an effort to identify the key parameters of existing cost models and then attempt to quantify uncertainty around these (primarily engineering) cost parameters. The Council sees this as a reasonable initial approach to examining uncertainty on the cost side, especially if the cost variation is a reflection of learning and/or technological progress that will likely occur over the 20 year horizon of the analysis. However, the nature of the uncertainty being measured is not completely clear from the description. In general, the Council would like to urge the Agency to be as transparent as possible about the types of uncertainty in costs and how each is treated in the analysis.

An exclusive focus on quantifying engineering control costs would be likely to understate overall cost uncertainties. However, starting with uncertainties in engineering compliance costs is natural because engineering estimates of capital and operating costs are certainly the most visible types of costs that are directly attributable to regulatory compliance. And the very fact that there has been little effort in the past to assess uncertainties in these probably warrants some effort, particularly in the light of: a) the enormous effort that is going into quantification of uncertainty on the benefits side, and b) the evidence that for certain regulatory actions the costs have been overestimated, especially in the case of market based policies such as the sulfur dioxide rules of the 1990 CAAA.

13.6. Sensitivity or Influence Analysis

The plan is to perform a type of sensitivity or influence analysis to determine which parameters of the various cost models (e.g., IPM and ControlNet) have the greatest effect on overall cost estimates. These parameters could include, for example, the coefficient on the cost of Selective Non-Catalytic Reduction (SCNR) capital or the prices of certain precious metals used for catalysts. The Council sees this as a reasonable way to identify the key parameters driving costs within the cost models being used in the analysis. However, there can also be model uncertainty – the models may not reflect how the regulations will be implemented over time.

13.7. Other Sources of Cost Uncertainty

Although the engineering costs are a reasonable place to start looking at cost uncertainties, the Council strongly urges the Agency to delineate all areas of cost uncertainty and explore others in this analysis. It seems likely that considerable additional uncertainty in costs pertains to what is left out or not counted in the cost estimates (tax interaction effects, process and productivity changes), uncertainty about the introduction and penetration of new technologies (e.g., penetration of alternative fuel vehicles), economic changes (energy prices, aggregate economic activity), and the extent of learning in different industries. Some of these may be included in the scenarios, such as the influence of uncertainty in future energy prices, but others could be considered for future uncertainty efforts

Indirect Costs. Another area that could be explored is the magnitude of indirect costs. Direct environmental control costs are measured or calculated, but productivity effects, process changes, etc,. are not included as part of these costs. There are empirical studies of these effects that could be drawn upon to calculate distributions. For example, the non-environmental costs increase by some expected amount as a result of the requirement to abate in an affected industry (e.g., Morgenstern, Pizer and Shih (2001), Barbera and McConnell (1990), and others). It should be noted that purchasing new capital equipment, which may sometimes occur as part of modernization efforts stimulated by compliance requirements, may have positive as well as negative influences on productivity.

Learning Assumptions. Learning effects have been documented in manufacturing. The manufacture of more units is associated with reduced unit costs at a predictable rate as efficiencies are realized in utilizing available equipment. Designs can also be modernized in the light of practical operating experience. It is well worth assessing the body of experience concerning how the increasingly widespread use of particular types of pollution control equipment is associated with reductions in unit capital and operating costs.

One area of promise for uncertainty analysis is to allow some uncertainty around the learning assumptions discussed in Chapter 4. There are a few empirical studies, as well as the possibility of eliciting expert judgment about learning for different industries or processes. The study distributed by the Agency, "Assessing the Impact of Progress and Learning Curves on Clean Air Act Compliance Costs," (Manson et al., 2002) provides a literature review and summary of the issue. This study suggests three reasons why costs may change over time: learning by doing over time, innovation and technological change, and cost-reducing changes in regulatory design.

The study focuses only on the first of these and shows some of the empirical analyses that have been done to estimate such learning effects for scrubbers and nitrogen oxide source reductions. In chapter 4, the draft Analytical Plan seems to be assuming an 80% rule for this type of learning for many industries. Some quantitative uncertainty analysis around this rule, including sensitivity analysis concerning how long the learning process persists over time, could be done for the industries where learning is anticipated.

13.8. Compliance and Enforcement Assumptions and Consistency Requirements

In general, the costs and emissions reductions components of the uncertainty analysis must be consistent. There is another common "80% rule" concerning practical rates of compliance with environmental regulations that should not be confused with a similar rule concerning learning and productivity effects. This incomplete compliance reduces costs, but is also associated with a corresponding 20% reduction in likely benefits that would be achieved with full compliance with the implemented rules. The cost and emissions reduction assumptions must be consistent. To the extent that uncertainty in costs reflects uncertainty in what controls are used or in how effectively they are used, emissions will also be affected. Compliance assumptions are worth assessing in more detail and are well worth including as part of an overall uncertainty analysis.

14. DATA QUALITY AND INTERMEDIATE DATA PRODUCTS

14.1. Charge Question 32

Does the Council support the plans described in chapter 10 for evaluating the quality of data inputs and analytical outputs associated with this study, including the planned publication of intermediate data products and comparison of intermediate and final results with other data or estimates? If the Council does not support these plans, are there alternative approaches, intermediate data products, data or model comparisons, or other data quality criteria the Council recommends? Please consider EPA's Information Quality Guidelines in this regard.

14.2. Summary of Council Response

- The validation exercises described in Chapter 10 of the Draft Plan are necessary and appropriate, but a number of pitfalls, limitations and qualifications are noted.

- The revised Analytical Plan, by itself, is insufficiently clear about what it envisions as "meta-data" for public dissemination. It is not necessarily raw data, but pre-processed data that can be used to replicate intermediate results. The Agency needs clearer guidelines concerning the type and scope of information that will be made public during the course of the analysis and what will be provided only when the analysis is complete.

- Preliminary release of raw data, intermediate data, intermediate models, and other analytical components will certainly improve the transparency of the benefit-cost exercise, but may result in substantial costs to the Agency. The Council supports contemporaneous release along with the final Analysis (or even *ex post* release of intermediate data and models) as a tool to inform future Prospective Analyses, but not necessarily the current analysis.

- In considering the future of the Section 812 analytical process and the sharing of intermediate data and models with outside researchers, the Agency may wish to consider more fully some alternative mechanisms for engaging third-party researchers in validation exercises. Peer review of requests for data or models, focused calls for external activity, and collaboration or other formalized interactions with external researchers might be considered. These activities may be appropriate to consider as part of the Learning Laboratory effort discussed in this Advisory.

- The outlined activities in the Intermediate Data Products section are, in many cases, simply too terse to permit thorough evaluation by the Council. Some examples of useful intermediate and related data might have been suggested.

- It is difficult to evaluate the Agency's plans for Intermediate Data Products with respect to Scenario Development because the range of proposed scenarios seems still to be evolving.

- Obviously, consistency checking is important throughout the Analysis, not just *ex post.* It is also important for the Analytical Plan to be clearer about what is to be compared in consistency checks and how big a difference would be enough to worry about.

- Before comparing the intermediate results of the Second Prospective Analysis with other sources of similar information, it will be important that there be some theoretical basis for expecting similarities. Comparisons based on the out-of-sample extensions of models estimated in very different contexts should be subjected to particular scrutiny.

- Along with a careful accounting of differences between the Second Prospective Analysis and other analyses, there must be an effort to understand the most likely sources of any differences.

- The Agency may have the resources or the authority to assemble intermediate data that would also be valuable to other researchers but is not presently generally available. In the process of encouraging external consistency checking, the Agency could create public goods of great value to the external research community.

- In future Prospective Analyses, consistency checks might be expanded to include assessments of the degree of correspondence between model predictions and other major sources of data about economic activity, emissions profiles, and estimates of health and ecosystem benefits.

14.3. General Advice

The Agency plans to rely upon two methods for enhancing data quality: a) publishing detailed model outputs to expose the data to scrutiny by third parties (Intermediate Data Products); and b) comparing certain "produced data" (e.g., model output) with counterpart real data (Consistency Checks).

These are both good ideas and will clearly strengthen the findings of the Second Prospective Analysis. Given the constraints faced by the Agency in meeting the schedule for Section 812 Analyses, the Council supports these two methods. Over the longer term, however, and looking toward future Analyses, a relevant question is whether the planned validation exercises will continue to be sufficient. In the Council's view, these current strategies constitute an appropriate approach to validation under time and resource constraints, but more could potentially be done in each of these two categories in future Analyses.

The discussion that follows reflects the thoughts of Council members concerning the general task of "validation." The Council recognizes that the term validation means something very specific to the Agency. The Council uses the term in this report in the more general sense. The Council does not intend that the Agency should immediately comply with all of these suggestions. Instead, the Council's intent is to provide some reflections on the Agency's current

strategy and where it might lead (as information technologies evolve and if sufficient resources could be made available).

With respect to the first of the two validation approaches (i.e., publishing detailed model outputs, termed Intermediate Data Products), many third parties will be interested in more than just model output. One reasonable objective is to enhance confidence in the main results by validating the computations used in various modeling components. For instance, to ascertain whether a CGE model is producing reliable results, validation involves examining far more than just the outputs. One needs to "look under the hood." Third parties will be interested not only in data inputs, but in the algorithms used in intermediate calculations. For instance, abatement cost curves may be important inputs into a cost model and their assumed or estimated nature will be of significant relevance to validation exercises. The Council suggests that the Agency keep in mind the broader research value of making available to outside researchers, where possible, not just the data articulated in Figure 10-1, but the key intermediate data used in the sequence of models and the algorithms used to process it.

The second of the two approaches: consistency checks--comparing produced data with counterpart real data--is a great idea *a priori*. However, this endeavor is limited by the availability of appropriate real data. In the case of direct costs and CGE results, it is suggested that comparisons will be made with the PACE data. Although this is a lofty goal, it is unclear exactly how this will be accomplished. The devil is in the details. How will data on expenditures specifically for pollution control be compared to abatement costs under a counterfactual scenario, let alone the data for total economic costs? In principle, this is a worthwhile undertaking, but the Council strongly encourages that these proposed methods be fleshed out in greater detail.

14.4. Refinements of Input Data

The Council focused its discussions of intermediate data products on scenario development, direct cost estimation, economic valuation of benefits, and computable general equilibrium results. It also discussed advice from the HES and the AQMS.

The Council supports the Agency's plan to make available through its web site the intermediate information and data products produced in the course of the 812 Analysis. The BENMAP system appears to be an invaluable tool for both generation and widespread understanding of the analysis and its results. In particular, it will enhance understanding of the assumptions used in constructing the aggregates of results, as well as the consequences of alternative aggregation approaches and assumptions.

It may be helpful for the Agency to perform some other consistency checks on the air quality from emissions and predicted population exposures in the form of calculations of regional or national "intake fractions" (ratios of total population aggregate intake to aggregate emissions) for pollutants that are not thought to result from secondary reactions in the atmosphere. Finally, some comparison of predicted and observed levels of monitored pollutants should be possible, at least for the year 2000.

One missing element of the discussion is a plan to utilize the results of these "consistency checks" to derive useful feedback for both the main effect estimations and the various parts of the uncertainty analysis.

As an example on the emissions side, one important type of input into the assessment of emissions uncertainties can be the amount of change (and the reasons for change) between older and newer estimates of particular emissions from particular classes of sources for recent past years. For example, one can compare previous year-2000 emissions estimates and more recent estimates for the same or a comparable year. The following steps might be suggested for analyzing the implications of such revisions:

a. Assess and document the changes. The material presented in Exhibit 8 (of Chapter 2) of the Draft Analytical Plan and the accompanying text is a good start on this process.
b. Try to understand the reasons for the changes; and what they imply about the likely uncertainty in the revised estimates.
c. Assess the degree of "surprise" (i.e., where possible, compare the extent of each change with the prior belief about the uncertainty in the estimate).

Historically, even in fields with well-established procedures for estimating uncertainties (such as measurements of elementary particle masses by physicists), it is found that traditional statistical procedures for estimating standard errors, etc., systematically understate actual uncertainties as later calculated by comparing improved measurements with older measurements and previously estimated uncertainties. For some examples, see Shlyakhter and Kammen (1992), Shlyakhter (1994a, 1994b) and Hattis and Burmaster (1994).

These surprises occur because traditional statistical uncertainty estimation approaches tend to be based solely on random sampling-error uncertainties in the data, neglecting what frequently turn out to be appreciable systematic or calibration errors [see Shlyakhter (1994a, 1994b)]. Developing fair estimates of uncertainties for the CAAA benefit and cost projections will require analysts to have inputs that can be interpreted in terms of both types of uncertainty. Systematic evaluation of the extent and reasons for changes in successive sets of emissions estimates will be a start toward providing invaluable inputs to the overall uncertainty analysis.

As an example on the health side, there is an opportunity to document the history of changing estimates of the overall magnitude of the particle-related mortality problem, as indexed by successively more refined measures of particle exposure—from smoke shade to total suspended particulate to sulfate, to PM10 and now PM2.5. From the magnitude and the trends indicated from these comparisons, experts could perhaps be led to adjust/expand their current uncertainty estimates in the light of plausible opportunities for refining our risk assessments further in the next decade or two—e.g., effects of still-smaller sized particles, improved dosimeters based on particle mass deposited in specific respiratory locations, particle surface area or particle number metrics, and particles from higher versus lower potency sources, etc.

Another suggestion is that although the text of the Analytical Plan refers to data controls, there is considerable value in having clearly stated data quality objectives and a specific

comprehensive data quality assurance (QA) protocol. These objectives should be derived from the context of the 812 Analysis and should guide the design and presentation of the intermediate data products to best serve the needs of specific audiences for the data. There are probably two broad types of users whose differing needs should be kept in mind: a) policy and staff advisors whose main goal may be to just understand the basis of the 812 Analysis and its conclusions, and also b) highly sophisticated analysts who wish to do their own professional evaluations of specific risk and benefit issues based on some of the data generated by Agency and its 812 Analysis contractors. With the needs of these two groups in mind, the disclosure and ready availability of the intermediate data products should greatly enhance the value of the 812 Analysis for both public and private sector decision-makers.

14.5. Potential for a Learning Laboratory Approach

The Council believes that the Agency's interest in involving outside researchers in the analysis is admirable as a guiding principle for future Prospective Analyses. The Council considers the Learning Laboratory approach described in Section 3.3 as a productive avenue to pursue for improving data quality by involving outside researchers in the review of important intermediate data products.

In regard to the Learning Laboratory, the Council notes an analogy to the Stanford Energy Modeling Forum. As discussed in Section 3.3 of this report, the Council notes that the ongoing Section 812 Prospective Analyses represent a potentially valuable laboratory for understanding the methods used for constructing a comprehensive benefit-cost of environmental regulation. While it is probably not feasible for the Second Prospective Analysis, the Agency might begin to plan for a process for evaluating the constituent models and for learning from these evaluations. A possible approach, broached by the Council in 2001, is to examine formally several models that purport to address the same issue. This is how the Stanford Energy Modeling Forum (EMF) compares different models. The Agency could target key databases or key modeling steps with specific analytical issues in mind and invite internal and external researchers to address these issues using competing approaches.

One approach to the external validation process might be to use the project's web site to pose specific problems and proposed solutions. Where appropriate, data and preliminary analysis related to a particular problem could be provided to encourage involvement and suggestions from outside experts. It might be constructive to explore the feasibility of engaging outside researchers specifically to address mission-critical research questions. This could be accomplished by inviting requests for original data and access to non-proprietary models so that these outside researchers can coordinate their own, possibly regional, analytical interest with the Agency's need for different types of validation exercises. It may be appropriate that these requests be peer-reviewed to ensure that the costs to the Agency of compliance with such requests represents an appropriate use of scarce Agency resources. There might be specific opportunities for these outside researchers to identify the types of data to which they would most like to gain access. An Agency workshop might be a suitable vehicle to bring together Agency modeling needs and researchers with expertise in the relevant area.

The Agency's comparative advantage in assembling key data from diverse sources could facilitate third-party research by making these data available. For example, one Council member

has indicated that it would be desirable to provide some mechanism for requesting the data developed in the detailed runs of air diffusion models for selected areas, such as the South Coast Air Basin in California. This would allow researchers who are working with regional models that have the spatial resolution to accommodate these data the opportunity to use them.

External research on issues relevant to the Second Prospective Analysis would also be aided by availability of morbidity and mortality data at a level of spatial resolution finer than the county-level information available in the Compressed Mortality Files from the National Center for Health Statistics. For example, deaths from potentially air-pollution-related causes on a five-kilometer grid scale would be greatly valuable, but individual researchers have difficulty gaining access to this type of information.

14.6. Itemized limitations in data review

Members of the Council feel that there are some limitations in the current plans for data review:

a. The benefits analysis information as outlined briefly in Chapter 10, page 10-2, is inadequate. Results are described as being produced at the state level and by pollutant-endpoint combination. The outline identifies "some of the uncertainties inherent in projections of state-level results ten or twenty years into the future" as the focus of likely meta-data validation exercises.

b. Detailed input information and assumptions embodied in the CGE analysis are essential to evaluating the outputs of that analysis.

c. The Council will defer to the HES in evaluating the Agency's approach to morbidity and mortality estimates. However, the Council encourages the Agency to stay on top of any emerging or future opportunities to assemble health statistics on related (actual) health conditions that might be associated with morbidity or mortality rates due to air quality. Various prospective cohort studies may be a valuable resource in determining disease incidence and there is a great need to assemble all available health status databases and panels to identify the incidence of different diseases for areas that are particularly polluted. Given the expense of assembling these databases, the Agency should look for opportunities to make those already assembled available for additional research and analysis.

14.7. Consistency Checks

Chapter 10 also outlines the Agency's plans for internal consistency checks. This summary appears to treat consistency checking as something that happens after models have been constructed and populated with the necessary parameters. In fact, calibration is a necessary and integral feature of model development. Given the numerous assumptions and simplifications required to build models, it is always necessary to check model performance against known, observed values and make necessary adjustments to improve accuracy. The Council hopes that ongoing consistency checking is standard practice in the Section 812 Analyses.

What is to be compared in making consistency checks? Comparing one model's predictions with another model's predictions, rather than with observational data, is more problematic. Different models use different inputs and employ different analytical structures. Thus it often is unclear whether prediction differences are a result of differences in the input data or differences in the models themselves. (The Agency refers to differences in scenarios and differences in modeling approach.) Sometimes it is possible to use one model's data with another model's structure and vice versa to isolate the cause of the discrepancy.

Inevitably, researchers will have to cope with the question of how to resolve inconsistencies. It often is unclear how big the inconsistencies have to be to raise concerns, given inherent modeling uncertainties and measurement error in the data. How much of a discrepancy is a big discrepancy? The public problem-solving procedure facilitated by publicly available data might be useful in developing a professional consensus about how to resolve or explain discrepancies.

The Council notes that there is actually only a modest possibility of doing consistency checks. The Agency must keep in mind that only one of the "with" and "without" scenarios can actually be observed. Scenarios involving recent years (e.g., 2000) allow us to observe what happened under the "with" case. In the future, both "with" and "without" become projections. Existing surveys such as the PACE refer to regulations that were imposed, not regulations that are projected to be imposed. Thus, even the PACE data do not support *ceteris paribus* comparisons. It is particularly difficult to do plausibility checks when two different projections are being compared, since either projection could be questionable. In the usual context for comparison in benefit-cost analyses, known is either a baseline or a change. That is, in the retrospective study, one knew actual conditions and projected what happened if the Agency did nothing further to regulate beyond 1970. In the Prospective Analyses, both the baseline and the regulated cases are projected. Thus, there is not a known reference or baseline.

Using models to project expected quantities out-of-sample, when non-overlapping data has been used to estimate each model, can be risky. For example, transfer of models from US cities to Mexico City predicted so many deaths from air pollution that the number would have amounted to between one-third and one-half of all deaths in that city, a prediction that is implausible. The challenge lies in how to extrapolate the results of studies outside their ranges. Linear extrapolation is clearly not reliable. Nonlinear estimation may offer improvements, but any outside forecasting needs to be subjected to plausibility tests.

The Agency mentions several specific consistency checks. In particular, they plan to compare BenMAP model predictions to actual incidence data. The model predicts changes based on regulatory changes relative to the baseline scenario. The Agency notes the inconsistency of trying to compare marginal changes with absolute levels for 2000, but suggests no strategy for checking BenMAP predictions against observational data. Ideally, one would look for a natural experiment where exposures changed, then replicate this change in exposure in the context of the Section 812 models to check predicted marginal changes from these models against observed marginal changes in the natural experiment.

The Agency's statement about economic valuation consistency checks is similarly ambiguous. They suggest comparing unit WTP estimates with COI values. Again, these generally are not congruent measures. Depending on how WTP is obtained, it may only measure pain and suffering, or it may include some components of lost productivity and cost of treatment. Estimated COI values often include only a relatively easily observed subset of the components of the social cost of illness. Moreover, COI estimates often rely on average wage and treatment costs rather than marginal values. Thus the problem of comparing marginal changes with observed averages may crop up in this context, as well.

14.8. Understanding sources of differences

A full understanding of the sources of differences in the costs and benefits between the First and Second Prospective Analyses is critical for interpreting the results of the Second Prospective Analysis. The Agency appears to be considering a number of possible ways to make those comparisons. Comparison of outcomes at the most disaggregated levels is important. An Appendix is suggested on p. 10-4 of the revised Analytical Plan. At what level of detail would the comparison of results be provided in this Appendix?

Because this Prospective Analysis will be undertaking more disaggregated analyses, with results by source category and even by provision in some cases, there may be possibilities to compare the results, particularly for the 2000 time frame, to other studies that have been done. Are the results consistent with those from other studies? There could be some attempt to suggest what might give rise to the differences.

14.9. Intermediate outcomes and consistency checking

Any component of the Section 812 Prospective Analyses that leads up to the calculation of final costs and benefits is an "intermediate product" of the analysis. Many of these intermediate products summarize relationships that are used to reach the eventual benefit and cost calculations. These estimated or assumed relationships afford many opportunities for benchmarking the analysis against other studies or against real data. For example, there may be future opportunities to examine the incidence of lung disease by industrial sector for workers, or lung disease against census tracts or zip codes for place of residence. Morbidity information is naturally more difficult to pin down than mortality, since most illnesses are not reportable, whereas the causes of death are. However, assembling whatever information is available on morbidity stemming from air-quality-related disease could be extremely valuable. Public perceptions of air-quality-related health risks will influence the perceived benefits of air quality management and thus individual WTP the costs incurred due to regulation.

14.10. Additional specific recommendations

If not for the current analysis, then potentially for future analyses, the Council suggests that some of the following activities might be considered as candidates for addition to the Agency's consistency-checking regimen:

a. There does not appear to be a plan to make public the economic projections underlying the emissions estimates and to reference these emissions estimates to

actual levels of economic activity in sectoral, regional, or aggregate terms. Levels of economic activity are critically important determinants of emissions and it will be important for these assumptions to be scrutinized as the Agency moves into producing subsequent Prospective Analyses.

b. Results at the state level and by pollutant-endpoint combination should be matched to other economic data at the same spatial resolution to offer future opportunities for cross checks. For example, there should be adequate consideration of Census economic information on household income.

c. There might be comparisons of the assumptions about future economic activity embodied in the Second Prospective Analysis to actual levels of economic activity by sector and region in actual years covered and with independent national projects. For example, this task could employ regional Federal Reserve Bank statistics and forecasts, or forecasts prepared by other federal sources.

d. The analysis might include more-explicit consideration of time profiles of concentrations prior to 2000 (actual ambient readings) in comparison to the levels and time profiles projected for future policy effects.

e. There might be more attention in future analyses to the morbidity states that may precede mortality outcomes. What do the available epidemiological results suggest for the incidence of new serious lung and heart conditions? Whether or not these can be proven to be related to air quality, they can influence public perceptions concerning the urgency of air quality management.

f. The analysis might be accompanied by comparison of benefits estimates to household income and to WTP estimates for air quality improvements from current hedonic or random utility models for specific areas. This practice has historical precedents and can be used as a gauge of plausibility for the benefits estimates incorporated in the analysis.

15. RESULTS AGGREGATION AND REPORTING

15.1. Charge Question 33

Does the Council support the plans described in Chapter 11 for the aggregation and presentation of analytical results from this study? If the Council does not support these plans, are there alternative approaches, aggregation methods, results presentation techniques, or other tools the Council recommends?

15.2. Summary of Council Response

- Reporting of central and alternative cases should be associated with likelihoods of these cases and any provision of a "low" alternative estimate should be balanced by a corresponding "high" alternative estimate. Pivotal assumptions should be clearly identified and the need for additional research on these issues should be emphasized.

- The Council urges the Agency to dispense with benefit-cost ratios and focus attention on net benefits estimates as the appropriate summary measure in benefit-cost analysis.

- The Council understands the Agency's current reluctance to take the somewhat heroic steps necessary to process the time profiles of benefits and costs into net present value (NPV) estimates. However, the Council urges the Agency to persist in its efforts toward this important goal in planning for future Analyses. In the meantime, the Agency must more clearly explain its rationale for annualizing costs but not calculating present discounted values of net benefits.

- As problematic as disaggregation may be, the Agency should anticipate strong demand for this type of information by policy-makers and stakeholders.

- There is insufficient information in Chapter 11 to permit a thorough review of the Agency's plans to disaggregate net benefits by sector.

- Spatial disaggregation is problematic, in general, because of all the connections among markets that give rise to general equilibrium consequences from the regulation of any one plant or industry. The Agency is advised to proceed very cautiously in terms of spatial disaggregation and only in special cases.

- A more through explanation of the inadvisability of further disaggregation by title of the CAAA would help readers understand why no such further disaggregation is planned.

15.3. General Observations

The Council's discussion of this Charge Question was separated rather artificially into a segment on costs and a separate segment on benefits. In this write-up, elements of the discussion that are relevant to both topics have been combined.

The Council notes that the strategy of reporting a "primary" estimate and an "alternative" can be misleading to the public if the alternative estimate combines conservative assumptions on several dimensions and results in a "low" estimate of net benefits. At the very least, if a "low" alternative is offered, so should be a "high" alternative, so readers are not left with the impression that the "true" case is half-way between the primary estimate and the low alternative. Providing only a low alternative invites biased inferences. Computational challenges preclude a full continuous distribution for the range of possible outcomes, for which standard confidence intervals could be constructed. However, information about the full distribution of possible results should be a goal to which the Agency aspires.

If the Agency continues to present sensitivity analyses concerning alternative scenarios, it is essential to associate with each of these alternatives some sense of their relative likelihood. Failure to do so encourages readers to employ a uniform distribution, which is almost certainly inappropriate.

Even at the intermediate data level, there should be more effort to explain how probability weights will be used to combine alternative point estimates of the magnitudes of key relationships. For example, with the ozone/mortality association, suppose there are three credible estimates. If all three estimates are close, then their average could be used. But what if one estimate is very different? The Second Prospective Analysis central case will presumably use the "best estimate" of this relationship. How will that value be determined?

In reporting its main results, the Council encourages the Agency to give particular prominence to the key assumptions and methodological choices that may be driving the results. Clear identification of these pivotal aspects of the analysis will emphasize the need for additional research on these topics and help focus the research community upon finding solutions.

15.4. Primary Results

The revised Draft Analytical Plan proposes some changes relative to procedures used in the first Prospective Analysis. For example, the Agency acknowledges previous SAB comments about reporting benefit-cost (B/C) ratios. They plan to report B/C ratios in this study, but de-emphasize them relative to net-benefit estimates. The role of "appropriate explanation" is important to help readers avoid well-known problems with using B/C ratios for decision making.

However, the Council does not favor ANY use of benefit-cost ratios. This concept does not have a consistent economic interpretation. Consequently, these ratios do not offer new information. If there is a concern that some portion of the constituency for the analysis will be more comfortable thinking in terms of benefit-cost ratios, the calculated benefit-cost ratio should be no more prominent than being mentioned in a footnote. The Agency should take a lead in shifting the emphasis to net benefits information, as opposed to benefit-cost ratios. If benefit-cost ratios are introduced at all, they should be qualified carefully.

It is true that any policy or project with positive net benefits will also have a benefit-cost ratio greater than one, if both benefits and costs were known with certainty. However, in ranking projects with net benefits greater than zero (or less than zero) the net benefits and benefit-cost criteria can give conflicting rankings. Also, given greater attention to uncertainty, the net benefits approach has much to recommend it. The variance of a difference in two random variables is generally easier to calculate than the distribution of a ratio of two random variables. An emphasis on benefit-cost ratios would require consideration of how the variance in the ratio of two random variables (uncertain benefits over uncertain costs) was derived. There are approaches (e.g., Goodman and Hartley (1958), Goodman (1960, 1962), and Bohrnstedt and Goldberger, 1969) but this seems to add needless complexity.

15.5. Future forecasts and present value calculations

In the Second Prospective Analysis, the cumulative or present discounted value of costs, benefits, and net benefits will not be presented. The reason given in the Draft Analytical Plan is that the time paths of costs and benefits are not linear. An example provided is which there may be high up-front costs, with benefits in later years Analogous problems can afflict benefits estimates, since multi-period chronic health effects must also be taken into account.

Part of this problem is dealt with, implicitly, in the so-called "annual" estimates. For example, the annual costs in each reported year (2000, 2010, and 2020) are average annual costs. If there are up-front capital costs, these are annualized (capitalized forward using an assumed interest rate) to get the annual estimates for the target years. The Council accepts the Agency's plans, for the Second Prospective Analysis, not to report cumulative estimates in the form of present discounted values, but recommends that the nature of the annual estimates should be made clearer and they should be called "forecasted average annualized costs and benefits."

The Analytical Plan states that changing the discount rate will have little effect on the results, because no net present value estimates are calculated. However, changing the discount rate does affect the annualized results in various ways, including the cost estimates if capital costs have been capitalized forwards to produce estimates of average annual costs. The Plan should be clearer about the specific interest rates used to annualize the costs of firms (where private rates may sometimes influence individual firms' predicted behavior but social rates should in general be used for collective decision-making), as opposed to the appropriate social discount rates needed to compute the present value of net benefits.

Some members of the Council agree with the proposal to delete discussion of the approximate present value of net benefits given the current quality of the components available to calculate it. The practices that will be used to estimate the time profiles of costs and benefits (in particular, the lack of good techniques for interpolation between discrete forecasting years) make these time profiles difficult to rely upon. Further effort to calculate present values would not really be justified on the basis of the underlying quality of these time profiles. Any present value calculations would exaggerate the precision with which these time profiles can be calculated.

Nevertheless, other members of the Council express considerable unease about the fact that present discounted net benefits are, in principle, the criterion upon which judgments are based (prior to the introduction of distributional considerations). When benefits and costs are distributed unevenly over time, it is necessary to determine whether overall present discounted net benefits are positive. By neglecting NPV calculations, the Analysis does not provide what is needed to inform policy-makers.

The Council is troubled by the Agency's explanation that it has decided not to provide annual interpolations of net-benefit estimates between target years because of the difficulty of quantifying uncertainties related to interpolation. Different strategies for interpolation could be used and the sensitivity of the NPV calculations to these differences could be assessed. If the Agency reports carefully upon the methods used to fill in the intervening years (latency of benefits, durability of costs), then the resulting NPV calculations would be suitably qualified.

The Agency explained to the Council that the exorbitant data requirements for air quality modeling for the intervening years in the main forecasts were the rate-determining factor in filling in trajectories of costs and benefits for intervening years over the forecasting horizon. However, there would seem to be some prospect of improving upon simple linear interpolation by taking advantage of the richness of emissions trends. The Council urges the Agency to continue to grapple with possible alternative techniques for interpolating the disparate time patterns of benefits and costs and working towards plausible NPV results in future Prospective Analyses.

15.6. Disaggregation

Chapter 11 of the revised Analytical Plan is advertised to concern "Results Aggregation and Reporting," although its subject matter could more informatively be termed "Results Disaggregation and Reporting." The central issue is the extent to which costs and/or benefits should be disaggregated spatially (e.g., by state), by CAAA Title, or by sector.

The Agency notes some potential problems with sectoral and spatial disaggregation, attributed to factors such as nonlinearities, jointness, and incidence dispersion through related markets. These problems can result in subadditivity or superadditivity when aggregating up from component estimates or disaggregating down from total estimates. However, because sectoral and geographic incidence is of considerable interest to policy makers, it may be necessary to plan for adding evaluation of alternative (at least partial) disaggregation schemes to the already long list of sensitivity and uncertainty analyses that this study, or perhaps future Prospective Analyses, will require.

Any attempts at sectoral decomposition of benefits and costs must be compared and reconciled with sectoral analyses from the CGE models to be used in this enterprise. Explanations for any anticipated or realized discrepancies between sectoral and aggregated analyses should be clarified. The current description refers to "non-linearities" as the source of potential discrepancies, but this explanation needs to be clearer. In the discussion of sectoral reporting, it is not clear what sectoral breakdown will be used.

The Council, in its previous review, argued strongly against spatial disaggregation of the costs of the CAAA. The general equilibrium consequences of air quality interventions are propagated widely throughout the economy, acting as they do through goods markets, labor markets, and capital markets. In its 2001 review, due to these issues of incidence, the Council advised against spatial disaggregation of costs. The Analytical Plan adopts that suggestion with a nicely phrased argument and explanation.

However, some types of air quality regulations that affect only local or regional air quality, rather than broader areas, may have sufficiently localized benefits that it is reasonable to address spatially disaggregated benefits estimates. Stratospheric ozone concentrations or the effect of carbon emissions on world climate clearly do not fall into this category. Spatial disaggregation of benefits should be contemplated only when the Agency has access to spatially delineated projections for ambient concentrations of pollution. This could offer opportunity for local or regional estimates of benefits derived from hedonic property value and hedonic wage studies.

Although there are many regulations for which it makes no sense to spatially disaggregate costs, for the general equilibrium reasons already mentioned, there may still be a few exceptions. It must be acknowledged that there will occasionally be vocal demands for spatial disaggregation by policy makers. It may be important for the Agency to anticipate demands that it examine costs and benefits by geographical area for some provisions of the CAAA, for some sources, but only where costs and benefits are sufficiently localized for the exercise to be meaningful.

For example, additional local controls to meet NAAQS may have costs and benefits that are borne primarily, although not entirely, within the region. Certain future policies may make sense in some regions and not in others. State-by-state costs and benefits probably will not capture the right geographic areas, but it seems important to consider regional disaggregation for some cases.

Even judicious spatial disaggregation of benefits is not without potential complications, however. The example in the Plan of the geographic dispersion of cost incidence from power plant emission-control investments in Indiana may also apply to benefits in a general-equilibrium analysis. Improved health that enhances worker productivity may benefit a firm's shareholders and customers in distant locations. The Agency's example of how to allocate visibility benefits accruing to visitors to a national park is a good illustration of where problems may arise. The physical improvement occurs at the national park, but the beneficiaries are park visitors who live elsewhere. Should their benefits be associated with the location of the park, or the location of their residence? In many cases, geographic disaggregation will involve arbitrary judgments that may be difficult to defend. Fortunately, these are rather minor examples. By far the largest share of measured total benefits from the CAAA appears to stem from human health improvements that can be captured fairly reliably at the census tract level.

The Council also urged previously that the Agency should pursue disaggregating costs by Title. Although this is not explicitly treated in the text of Chapter 11, Table 11-2 suggests that costs will be aggregated over Titles I through IV. The Council would a priori prefer more

disaggregation by Title and suggests that the Plan present reasons why this is not possible or desirable. The 2001 Council review of the first Draft Analytical Plan clarified some of the reasons for limiting disaggregation by title, but too few of these reasons appear in the revised Draft Analytical Plan.

The Analytical Plan focuses on monetized benefits and costs. Chapter 11 does not describe any planned reporting of cost-effectiveness measures in the Second Prospective Analysis. The First Prospective Analysis provided some auxiliary cost-per-life-saved measures. Given that the results from the Second Prospective Analysis are to be calculated and reported on a more disaggregated basis, there may be some cases where these cost-effectiveness estimates can be provided and would be helpful to the constituency's understanding of the effects of the CAAA. The Council acknowledges, however, that when policies provide benefits that are broader than simply improvements in human health, cost-per-life-saved measures can be misleading (e.g., when there may be substantial ecosystem benefits). This issue received attention in the earlier section on QALY-based cost effectiveness.

APPENDIX A: LIST OF SAB REVIEW CHARGE QUESTIONS AND RELATED CHAPTERS IN THE AGENCY DRAFT ANALYTICAL PLAN AS RECEIVED FROM EPA ON JULY 3, 2003

Chapter 1: Project Goals and Analytical Sequence

1. Does the Council support the study goals, general analytical framework, disaggregation plan, analytical sequence, and general analytical refinements defined in chapter 1? If there are particular elements of these plans which the Council does not support, are there alternatives the Council recommends?

Chapter 2: Scenario Development

2. Does the Council support the choices for analytical scenarios defined in chapter 2? Are there alternative or additional scenarios the Council recommends EPA consider for inclusion in the analysis?

3. Does the Council support the alternative compliance pathway estimation and comparison methodology described in chapter 2, including the specification of alternative compliance pathways which may not reflect precisely constant emissions or air quality outcomes between scenarios due (primarily) to the non-continuous nature and interaction effects of emission control options?

Chapter 3: Emissions Estimation (Addressed by the Air Quality Modeling Subcommittee Report, EPA Advisory Council on Clean Air Compliance Analysis, 2004a))

4. Does the Council support the plans for estimating, evaluating, and reporting emissions changes as defined in chapter 3? If there are particular elements of these plans which the Council does not support, are there alternative data or methods the Council recommends?

5. Chapter 3 of the analytical plan describes several alternative approaches considered by EPA for estimating non-EGU emissions growth rates. These options reflect different relative emphasis between two conflicting analytical objectives: (1) extensive refinement of the geographically differentiated, source-specific economic activity growth estimates embedded in EGAS 4.0, and (2) maintaining the current project schedule and budget. EPA plans to use “approach #4”, a compromise option which targets the most important source categories for potential refinement. Does the Council support the initial plan to use “approach #4”? If the Council does not support the use of approach #4, are there other approaches –including either the approaches described in chapter 3 or others identified by the Council– which the Council suggests EPA consider?

6. Some state-supplied emissions data incorporated in the 1999 National Emissions Inventory (NEI) –the core emissions inventory for this analysis– incorporate different emissions factors from those used in MOBILE6, the mobile source emissions model EPA plans to use for estimating emissions changes between scenarios. Of particular importance, some of the emissions factors embedded in California's EMFAC model may be significantly different from factors used in MOBILE6. EPA considered three options for estimating emissions changes in California, which are described in chapter 3. EPA plans to implement option #3 based on the belief that the emission factors embedded by California in its EMFAC model may be more accurate for their particular state than the factors incorporated in MOBILE6. Does the Council support the plan to implement option #3? If the Council does not support the adoption of option #3, are there other options –including either the options described in chapter 3 or others identified by the Council– which the Council suggests EPA consider?

Chapter 4: Cost Estimates

7. Does the Council support the plans for estimating, evaluating, and reporting compliance costs described in chapter 4? If there are particular elements of these plans which the Council does not support, are there alternative data or methods the Council recommends?

8. EPA seeks advice from the Council concerning the choice of Computable General Equilibrium (CGE) model which EPA intends to use as a post-processor to gauge the general equilibrium effects of the various control scenarios. In the first 812 Analysis –the retrospective– EPA used the Jorgenson/Wilcoxen model to gauge the general equilibrium effects of returning to the economy the reported compliance expenditures which formed the basis of the retrospective study direct cost estimates. This model has since been refined in many ways, and EPA considers both the Jorgenson/Wilcoxen/Ho and AMIGA to be acceptable tools. Although a final decision on model choice can be deferred until later in the analysis, EPA has tentative plans to use the AMIGA model because of its greater sectoral disaggregation, better industrial sector matching with CAA-affected industries, richer representation of relevant production and consumption technologies, and better model validation opportunities due to its use of open code. However, AMIGA is limited given its inability to deal with dynamics over time. Does the Council support the current, tentative plan to use the AMIGA model for this purpose? If not, are there alternative model choices or selection criteria the Council recommends?

9. In the two previous 812 Analyses, the primary cost estimates reflected use of a 5 percent real discount rate, which an earlier Council endorsed as a reasonable compromise between a 3 percent real rate considered by EPA to be an appropriate estimate of the consumption rate of interest or rate of social time preference and a 7 percent rate, OMB's estimate of the opportunity cost of capital. Limited sensitivity testing was also conducted in the previous 812 Analyses by substituting 3 and 7 percent rates to annualize the benefit and cost streams. EPA's new Economics Guidelines (peer-reviewed by the SAB EEAC) call for using both a 3 and a 7 percent rate. A recent draft of new OMB economic guidelines suggests providing results based on both 3 and 7 percent discount rates, while

also acknowledging the need for further efforts to refine analytical policies for discounting methods and rates. EPA plans on following both sets of Guideline documents by using both 3 and 7 percent in our core analyses. It is true that this will require presentation of two sets of results – one based on each rate. This may not be necessary given the expected insensitivity of the overall results to the discount rate assumption. Does the Council support this approach? If not, are there alternative rates, discounting concepts, methods, or results presentation approaches the Council recommends?

Chapter 5: Air Quality Modeling

10. Does the Council support the plans described in chapter 5 for estimating, evaluating, and reporting air quality changes associated with the analytical scenarios? If there are particular elements of these plans which the Council does not support, are there alternative data, models, or methods the Council recommends? (To be addressed by the Air Quality Modeling Subcommittee when the Agency has more details about the choice of models and the modeling protocols that would be employed.)

Chapter 6: Human Health Effects Estimation (Addressed by the Health Effects Subcommittee, EPA Advisory Council on Clean Air Compliance Analysis, 2004b)

11. Does the Council support the plans described in chapter 6 for estimating, evaluating, and reporting changes in health effect outcomes between scenarios? If there are particular elements of these plans which the Council does not support, are there alternative data or methods the Council recommends?

12. EPA seeks advice from the Council regarding the technical and scientific merits of incorporating several new or revised endpoint treatments in the current analysis. These health effect endpoints include:

a. Premature mortality from particulate matter in adults 30 and over, PM (Krewski et al., 2000);
b. A PM premature mortality supplemental calculation for adults 30 and over using the Pope 2002 ACS follow-up study with regional controls;
c. Hospital admissions for all cardiovascular causes in adults 20-64, PM (Moolgavkar et al., 2000);
d. ER visits for asthma in children 0-18, PM (Norris et al., 1999);
e. Non-fatal heart attacks, adults over 30, PM (Peters et al., 2001);
f. School loss days, Ozone (Gilliland et al., 2001; Chen et al., 2000);
g. Hospital admissions for all respiratory causes in children under 2, Ozone (Burnett et al., 2001); and,
h. Revised sources for concentration-response functions for hospital admission for pneumonia, COPD, and total cardiovascular: Samet et al., 2000 (a PM10 study), to Lippmann et al., 2000 and Moolgavkar, 2000 (PM2.5 studies).

13. EPA seeks advice from the Council regarding the merits of applying updated data for baseline health effect incidences, prevalence rates, and other population

characteristics as described in chapter 6. These updated incidence/prevalence data include:

a. Updated county-level mortality rates (all-cause, non-accidental, cardiopulmonary, lung cancer, COPD) from 1994-1996 to 1996-1998 using the CDC Wonder Database;
b. Updated hospitalization rates from 1994 to 1999 and switched from national rates to regional rates using 1999 National Hospital Discharge Survey results;
c. Developed regional emergency room visit rates using results of the 2000 National Hospital Ambulatory Medical Care Survey;
d. Updated prevalence of asthma and chronic bronchitis to 1999 using results of the National Health Interview Survey (HIS), as reported by the American Lung Association (ALA), 2002;
e. Developed non-fatal heart attack incidence rates based on National Hospital Discharge Survey results;
f. Updated the national acute bronchitis incidence rate using HIS data as reported in ALA, 2002, Table 11;
g. Updated the work loss days rate using the 1996 HIS data, as reported in Adams, et al. 1999, Table 41;
h. Developed school absence rates using data from the National Center for Education Statistics and the 1996 HIS, as reported in Adams, et al., 1999, Table 46.
1. Developed baseline incidence rates for respiratory symptoms in asthmatics, based on epidemiological studies (Ostro et al. 2001; Vedal et al. 1998; Yu et al; 2000; McConnell et al., 1999; Pope et al., 1991).

14. EPA plans to initiate an expert elicitation process to develop a probability-based method for estimating changes in incidence of PM-related premature mortality. Plans for this expert elicitation are described in chapter 9 of this blueprint, and a separate charge question below requests advice from the Council pertaining to the merits of the design of this expert elicitation. EPA recognizes, however, the possibility that this expert elicitation process may not be fully successful and/or may not be completed in time to support the current 812 Analysis. Therefore, in order to facilitate effective planning and execution of the early analytical steps which provide inputs to the concentration-response calculations, EPA seeks advice from the Council regarding the scientific merits of alternative methods for estimating the incidences of PM-related premature mortality, including advice pertaining to the most scientifically defensible choices for the following specific factors:

a. Use of cohort mortality studies, daily mortality studies, or some combination of the two types of studies
b. Selection of specific studies for estimating long-term and/or short-term mortality effects
c. Methods for addressing –either quantitatively or qualitatively– uncertain factors associated with the relevant concentration-response function(s), including:

    i. Shape of the PM mortality C-R function (e.g., existence of a threshold),

ii. PM causality,
iii. PM component relative toxicity, and
iv. PM mortality effect cessation lag structure
v. Cause of death and underlying health conditions for individuals dying prematurely due to chronic and/or short term exposures to particulate matter
vi. The use of ambient measures of exposure for estimating chronic health effects, given recent research reviewed in the NAS (2002) report that questions the implications of using ambient measures in cohort studies

15. EPA estimates of benefit from particulate control may underestimate the impact of nonfatal cardiopulmonary events on premature mortality and life expectancy. For the base analyses, which rely on cohort evidence, the limited follow-up periods for the cohorts may not fully capture the impacts of nonfatal cardiovascular events on premature mortality later in life. For the alternative analyses –including cost-effectiveness analyses– which rely more on acute studies and life-expectancy loss, the years of life are estimated only for fatal events. Yet nonfatal events such as myocardial infarction reduce a person's life expectancy by a substantial percentage.

a. Do you agree that EPA, in the 812 Analyses, should adjust benefit estimates to account for the mortality effects of non-fatal cardiovascular and respiratory events?
b. What medical studies and mathematical models of disease might be useful to review or use if EPA moves in this direction?
c. When the nonfatal events are valued in economic terms, should EPA assume that the published unit values for morbidity already account for the life-expectancy loss or should an explicit effort be made to monetize the resulting longevity losses?

16. In recent EPA rulemakings, EPA's "base estimate" of benefit from PM control has been based on cohort epidemiological studies that characterize the chronic effects of pollution exposure on premature death as well as capturing a fraction of acute premature mortality effects. If these chronic effects occur only after repeated, long-term exposures, there could be a substantial latency period and associated cessation lag. As such, a proper benefits analysis must consider any time delay between reductions in exposure and reductions in mortality rates. For the acute effects, such as those considered in EPA's alternative benefit analyses, the delays between elevated exposure and death are short (less than two months), and thus time-preference adjustments are not necessary.

a. In the previous 812 Analysis and in recent rulemakings, EPA assumed a weighted 5-year time course of benefits in which 25% of the PM-related mortality benefits were assumed to occur in the first and second year, and 16.7% were assumed to occur in each of the remaining 3 years. Although this procedure was endorsed by SAB, the recent NAS report (2002) found "little justification" for a 5-year time course and recommended that a range of assumptions be made with associated

probabilities for their plausibility. Do you agree with the NAS report that EPA should no longer use the deterministic, 5-year time course?

b. One alternative EPA is considering is to use a range of lag structures from 0 to 20-30 years, with the latter mentioned by NAS in reference to the Nyberg et al PM lung cancer study, with 10 or 15 years selected as the mid-point value until more definitive information becomes available. If this simple approach is used, should it be applied to the entire mortality association characterized in the cohort studies, or only to the difference between the larger mortality effect characterized in the cohort studies and the somewhat smaller effect found in the time series studies of acute exposure? Should judgmental probabilities be applied to different lags, as suggested by NAS?

c. Another option under consideration is to construct a 3-parameter Weibull probability distribution for the population mean duration of the PM mortality cessation lag. The Weibull distribution is commonly used to represent probabilities based on expert judgment, with the 3-parameter version allowing the shaping of the probability density function to match expected low, most likely, and expected high values. EPA is still considering appropriate values for the low, most likely, and expected high values –and therefore for the Weibull shape and location parameters– and EPA is interested in any advice the Council wishes to provide pertaining to the merits of this approach and/or reasonable values for the probability distribution.

17. In support of Clear Skies and several recent rule makings the Agency has presented an Alternative Estimate of benefits as well as the Base Estimate. EPA developed the Alternative Estimate as an interim approach until the Agency completes a formal probabilistic analysis of benefits. NAS (2002) reinforced the need for a probabilistic analysis. The Alternative Estimate is not intended as a substitute method and needs to be considered in conjunction with the Base Estimate. Presentation of Base and Alternative estimates in the 812 Report may not be necessary if the probability analysis planned for the 812 Report is successful. While the Base Estimate assumes that acute and chronic mortality effects are causally related to pollution exposure, the Alternative Estimate assumes only acute effects occur or that any chronic effects are smaller in size than assumed in the Base Estimate. The Council's advice is sought on the following matters:

a. It has been noted by some particle scientists that the size of estimates based on time series studies that incorporate a distributed lag model, accounting for effects of 30 to 60 days after elevated exposure, may be similar in size to some interpretations of the results from the cohort studies. Does the Council agree that it is a reasonable alternative to use an estimate of the concentration-response function consistent with this view? If the Council agrees with the assumption, can it suggest an improved approach for use in an Alternative Estimate? The agency also seeks advice on appropriate bounds for a sensitivity analysis of the mortality estimate to be used in support of the Alternative Estimate.

b. An assumption that a specific proportion of the PM-related premature mortality incidences are incurred by people with pre-existing Chronic Obstructive

Pulmonary Disease (COPD) and that these incidences are associated with a loss of six months of life, regardless of age at death. If these values are not valid, what values would be more appropriate? Do you recommend a sensitivity analysis of 1 to 14 years (with the latter based on standard life tables), as included in the draft regulatory impact analysis of the proposed nonroad diesel rule?

c. An assumption that the non-COPD incidences of PM-related premature mortality are associated with a loss of five years of life, regardless of age at death. If these values are not valid, what values would be more appropriate? Do you recommend a sensitivity analysis of 1 to 14 years (with the latter based on standard life tables), as included in the draft regulatory impact analysis of the proposed Nonroad diesel rule?

d. Additional quantified and/or monetized effects are those presented as sensitivity analyses to the primary estimates or in addition to the primary estimates, but not included in the primary estimate of total monetized benefits. While no causal mechanism has been identified for chronic asthma and ozone exposure, there is suggestive epidemiological evidence.

i. Two studies suggest a statistical association between ozone and new onset asthma for two specific groups: children who spend a lot of time exercising outdoors and non-smoking men. We seek SAB comment on our approach to quantifying new onset asthma in the sensitivity analyses.

ii. Premature mortality associated with ozone is not currently separately included in the primary analysis because the epidemiological evidence is not consistent. We seek SAB comment on our approach to quantifying ozone mortality in the sensitivity analyses.

iii. Does the Council agree that there is enough data to support a separate set of health impacts assessment for asthmatics? If so, does the approach proposed by the Agency address the uncertainty in the literature?

Chapter 7: Ecological Effects

18. Does the Council support the plans described in chapter 7 for (a) qualitative characterization of the ecological effects of Clean Air Act-related air pollutants, (b) an expanded literature review, and (c) a quantitative, ecosystem-level case study of ecological service flow benefits? If there are particular elements of these plans which the Council does not support, are there alternative data or methods the Council recommends?

19. Initial plans described in chapter 7 reflect a preliminary EPA decision to base the ecological benefits case study on Waquoit Bay in Massachusetts. Does the Council support these plans? If the Council does not support these specific plans, are there alternative case study designs the Council recommends?

20. Does the Council support the plan for a feasibility analysis for a hedonic property study for valuing the effects of nitrogen deposition/eutrophication effects in the

Chesapeake Bay region, with the idea that these results might complement the Waquoit Bay analysis?

Chapter 8: Economic Valuation

21. Does the Council support the plans described in chapter 8 for economic valuation of changes in outcomes between the scenarios? If there are particular elements of these plans which the Council does not support, are there alternative data or methods the Council recommends?

22. EPA's current analytic blueprint calls for an expert-judgment project on VSL determination that would produce a probability distribution over the range of possible VSL values for use in the 812 project. EPA is not sure how much priority to give to this project. A much simpler alternative would be for EPA to specify a plausible range of VSL values. One option would be to use a range bounded by $1 million (based roughly on the lower bound of the interquartile range from the Mrozek-Taylor meta-analysis) and $10 million (based roughly on the upper bound of the interquartile range of the Viscusi-Aldy meta-analysis. This range would match that reflected in EPA's sensitivity analysis of the alternative benefit estimate for the off-road diesel rulemaking. The range would then be characterized using a normal, half-cosine, uniform or triangular distribution over that range of VSL values. EPA would then ask this Committee to review this distribution. This approach could be done relatively quickly, based on the reviews and meta-analyses commissioned to date, and would allow a formal probability analysis to proceed, without suggesting that the Agency is trying to bring more precision to this issue than is warranted by the available science.

23. Pursuant to SAB Council advice from the review of the first draft analytical blueprint, EPA reviewed a number of meta-analyses –either completed or underway– developed to provide estimates for the value of statistical life (VSL) to be applied in the current study. EPA plans to consult with the Council (and coordinate this consultation with the EEAC) on how best to incorporate information from the Kochi et al (2002) meta-analysis, other published meta-analyses [Mrozek and Taylor and Viscusi and Aldy], and recent published research to develop estimates of VSL for use in this study. In addition, EPA plans to implement two particular adjustments to the core VSL values: discounting of lagged effects and longitudinal adjustment to reflect changes in aggregate income. Does the Council support these plans, including the specific plans for the adjustments described in chapter 8? If the Council does not support these plans, are there alternative data or methods the Council recommends?

24. For the 812 Report, EPA has decided to perform a cost-effectiveness analysis of the Clean Air Act provisions using quality-adjusted life years as the measure of effectiveness. This is the standard approach used in medicine and public health and this type of analysis has previously been recommended by the SAB. Moreover, the recent NAS Report (2002) on benefits analysis discussed how this method could be applied to the health gains from air pollution control.

a. Do you agree that QALYs are the most appropriate measure of effectiveness for this type of analysis? Would you suggest any alternative measures to replace or supplement the QALY measure? (This question relates to effectiveness measures, not monetary benefit measures as used in benefit-cost analysis).
b. OMB has suggested that EPA plan a workshop with clinicians, social scientists, decision analysts and economists to examine how the specific diseases and health effects in the 812 Report should be handled with respect to longevity impact and health-related preference. Participants would have knowledge of the relevant clinical conditions, the related health preference studies, and the stated-preference literature in economics. The recent RFF conference has laid the groundwork for this type of workshop. Is there a superior approach to making sure that the CEAQALY project is executed in a technically competent fashion and that the details of the work receive in-depth technical input in addition to the broad oversight provided by this Committee?
c. Does the Council support the specific plans for QALY-based cost-effectiveness described in the current draft blueprint? If the Council does not support specific elements of these plans, are the alternative data, methods, or results presentation approaches which the Council recommends?

25. EPA plans to use updated unit values for a number of morbidity effects, as described in chapter 8. Of particular note, EPA plans to rely on a study by Dickie and Ulery (2002) to provide heretofore unavailable estimates of parental willingness to pay to avoid respiratory symptoms in their children. This study is not yet published and has limitations concerning response rate and sample representativeness; however, EPA expects the study to be published prior to completion of the economic valuation phase of this analysis. Does the Council support the application of unit values from this study, contingent on its acceptance for publication in a peer-reviewed journal? If the Council does not support reliance on this study, are there other data or methods for valuation of respiratory symptoms in children which the Council recommends?

Chapter 9: Uncertainty Analysis

26. Does the Council support the plans described in chapter 9 for estimating and reporting uncertainty associated with the benefit and cost estimates developed for this study? If there are particular elements of these plans which the Council does not support, are there alternative data, models, or methods the Council recommends?

27. Does the Council support the plans described in chapter 9 for the pilot project to develop probability-based estimates for uncertainty in the compliance cost estimates? If the Council does not support this pilot project, or any particular aspect of its design, are there alternative approaches to quantifying uncertainty in cost estimates for this analysis which the Council recommends?

28. Does the Council support the plans described in chapter 9 for the pilot project to develop probability-based estimates for uncertainty in the emissions and air quality

modeling estimates? If the Council does not support this pilot project, or any particular aspect of its design, are there alternative approaches to quantifying uncertainty in emissions and/or air quality concentration estimates for this analysis which the Council recommends? (To be addressed by the Air Quality Modeling Subcommittee when the Agency has more details about the choice of models and the modeling protocols that would be employed.)

29. Does the Council support the plans described in chapter 9 for the expert elicitation pilot project to develop a probability-based PM2.5 C-R function for premature mortality, including in particular the elicitation process design? If the Council does not support the expert elicitation pilot project, or any particular aspect of its design, are there alternative approaches the Council recommends for estimating PM-related mortality benefits for this analysis, including in particular a probabilistic distribution for the C-R function to reflect uncertainty in the overall C-R function and/or its components?

30. EPA plans to develop estimates of an independent mortality effect associated with ozone, as described in chapter 9. Does the Council support the use of the most recent literature on the relationship between short-term ozone exposure and daily death rates, specifically that portion of the literature describing models which control for potential confounding by PM2.5? Does the Council agree with the use of that literature as the basis for deriving quantified estimates of an independent mortality impact associated with ozone, especially in scenarios where short-term PM2.5 mortality estimates are used as the basis for quantifying PM mortality related benefits? Does the Council support the plans described in chapter 9 for the pilot project to use this literature to develop estimates of the ozone related premature mortality C-R function using the three alternative meta-analytic approaches? If the Council does not support this pilot project, or any particular aspect of its design, are there alternative approaches to quantifying ozone-related premature mortality which the Council recommends?

31. EPA plans to work with the Council and the EEAC to develop revised guidance on appropriate VSL measures. We hope to include the Kochi et al (2002) meta-analysis, other recent meta-analysis, recent publications, and the 3 literature reviews sponsored by EPA.(a separate charge question pertaining to this element of EPA's VSL plan is presented below). In addition, EPA plans to conduct a follow-on meta-regression analysis of the existing VSL literature to provide insight into the systematic impacts of study design attributes, risk characteristics, and population attributes on the mean and variance of VSL. Does the Council support the plans described in chapter 9 for conducting this meta-regression analysis? If the Council does not support this analysis or any particular aspect of its design, are there alternative approaches which the Council recommends for quantifying the impact of study design attributes, risk characteristics, and population attributes on the mean and variance of VSL?

Chapter 10: Data Quality and Intermediate Data Products

32. Does the Council support the plans described in chapter 10 for evaluating the quality of data inputs and analytical outputs associated with this study, including the

planned publication of intermediate data products and comparison of intermediate and final results with other data or estimates? If the Council does not support these plans, are there alternative approaches, intermediate data products, data or model comparisons, or other data quality criteria the Council recommends? Please consider EPA's Information Quality Guidelines in this regard.

Chapter 11: Results Aggregation and Reporting

33. Does the Council support the plans described in Chapter 11 for the aggregation and presentation of analytical results from this study? If the Council does not support these plans, are there alternative approaches, aggregation methods, results presentation techniques, or other tools the Council recommends?

Appendix D: Stratospheric Ozone Analysis

34. Does the Council support the plans describe in Appendix D for updating the estimated costs and benefits of Title VI programs? If the Council does not support these plans, are there alternative data, models, or methods the Council recommends?

Appendix E: Air Toxics Case Study

35. Does the Council support the plans described in Appendix E for the benzene case study, including the planned specific data, models, and methods, and the ways in which these elements have been integrated? If the Council does not support these plans, are there alternative data, models, or methods the Council recommends?

36. A cessation lag for benzene-induced leukemia is difficult to estimate and model precisely due to data limitations, and EPA plans to incorporate a five-year cessation lag as an approximation based on available data on the latency period of leukemia and on the exposure lags used in risk models for the Pliofilm cohort (Crump, 1994 and Silver et al., 2002). Does the SAB support adoption of this assumed cessation lag? If the Council does not support the assumed five-year cessation lag, are there alternative lag structures or approaches the Council recommends? (Addressed by the Health Effects Subcommittee, EPA Advisory Council on Clean Air Compliance Analysis, 2004b)

Appendix H: Meta-analysis of VSL

37. Does the Council support including the Kochi et al. (2002) meta-analysis as part of a the larger data base of studies to derive an estimate for the value of avoided premature mortality attributable to air pollution? Are there additional data, models, or studies the Council recommends? Does the SAB think that EPA should include Kochi et al. 2003 if not accepted for publication in a peer reviewed journal by the time the final 812 report is completed?

APPENDIX B: LIST OF ACRONYMS

AQMS - Air Quality Modeling Subcommittee

CAA - Clean Air Act

CAAA - Clean Air Act Amendment

B/C - Benefit-Cost

BCA - Benefit-cost Analysis

BLS - Bureau of Labor Statistics

CEA - Cost-effectiveness Analysis

CGE - Computable General Equilibrium

COI - Cost of Illness

Council - The Advisory Council for Clean Air Compliance Analysis

C-VPESS - SAB Committee on Valuing the Protection of Ecological Systems and Services

EES - Ecological Effects Subcommittee

EGU - Electrical Generating Unit

Electrical Power Research Institute - EPRI

HAP - Hazardous Air Pollutant

HES - Health Effects Subcommittee

I/M - Inspection and Maintenance

IPM - Integrated Planning Model

JHW - Jorgenson-Ho-Wilcoxen

MACT - Maximum Achievable Control Technology

MBI - Market Based Incentives

NAAQS - National Ambient Air Quality and Standards

NO_x - Nitrogen Oxides

NPV - Net Present Value

PACE - Pollution Abatement and Control Expenditures

PM - Particulate Matter

QALYs- Quality-Adjusted Life-Years

VSL - Value of Statistical Life

VOC - Volatile Organic Compounds

VSLY - Value of a Statistical Life-Year

WTP - Willingness-to-Pay

APPENDIX C: ADDITIONAL DISCUSSION CONCERNING COSTS AND LEARNING

The assortment of published models that yield markedly different point estimates for learning effects are frequently inconsistent with neoclassical economics in terms of the use of factor inputs. To be deemed admissible, it would also be desirable for a study to meet higher standards in terms of accounting for technical change.

For cost-savings due to learning, there is a potentially very important question of whether firms enjoy advantages, or suffer penalties, for early implementation of technologies. Being a "first mover" may limit opportunities for learning from the experiences of other firms.

It is not clear that cumulative output is the sole, or best, indicator of learning effects on the eventual costs of abatement activities. The time horizon over which cost reductions due to learning will be exhausted is also not clear. Costs just a few months out may differ substantially from the cost levels that can be attained in the long-term steady-state, even when cumulative production is identical. Eighteen months out, costs can be a little lower, or a lot lower, than the level to which they may fall with early learning.

Process versus industry-specific. It should be emphasized in the 812 Analysis that the 80% rule of thumb for learning effects is a gross oversimplification. For example, the effect of learning on compliance costs is more likely to be process-specific, rather than industry specific. Thus it may be inappropriate just to make different assumptions across industries. Instead, the correct "representative" learning effect may depend upon the mix of processes used in each industry.

Desirability/attainability of one number for learning. Despite the preliminary results of the meta-analysis and the absence of any real weight-of-the-evidence conclusions concerning learning effects, it would still be helpful to come up with a best estimate to use for assumptions about cost reductions from experience with compliance technologies. It would be easiest if it were safe to assume a single "learning effect" in the form of an unbiased estimate, neither too high nor too low. However, the effect of learning on costs is likely to display considerable systematic heterogeneity across pollutants and technologies. There is unlikely to be a single "one-size-fits-all" number that is satisfactory for all contexts.

Is it preferable to make an inaccurate adjustment for learning (e.g., when it is not known whether the adjustment should be 10% or 20%) rather than make no adjustment at all, which is known definitely to be incorrect (i.e., there need to be some downward adjustment to costs as a result of learning, but the appropriate magnitude of this adjustment is unclear)? The question of just how much must be known before the Agency is warranted in making a quantitative adjustment permeates many aspects of the Analytical Plan, not just the learning issue, and merits more thought and discussion. In principle, what is desired is the best unbiased estimate, but where is the threshold of empirical evidence needed to decide upon the appropriate magnitude of that quantitative adjustment?

For example, in its review of the Draft Analytical Plan, two years ago, a majority on the Council agreed that there was insufficient evidence to support using for ecosystem benefits a particular percentage of the Costanza et al. (1998) estimates of total value of the earth's ecosystems. This conclusion was reached in part because there was not sufficient evidence to determine the appropriate percentage of these ecosystems values that would have been lost or reduced without the CAAA.

The Council feels it would be inappropriate to endorse adjustments that have minimal empirical verification as to their specific quantitative values. The cumulative effect of too many such adjustments puts the entire assessment process at risk of losing objective credibility and becoming more a product of subjectivity and political negotiation. The Council encourages the Agency to explore the likely consequences of adjustments that are within the realm of possibility, but not to build in any specific unsupported value for specific adjustments.

APPENDIX E: ADDITIONAL DISCUSSION CONCERNING THE USE OF VSLs

This appendix covers material that can be classified as "experimental" or "methods development." It emphasizes some shortcomings of existing practices with respect to VSLs. The Agency is advised to anticipate changes in the state of the art in human health benefits valuation that may be appropriate to incorporate in future 812 Analyses as these updated approaches are vetted and as the justification for them becomes more widely understood.

The Council first wishes to highlight persistent conceptual problems stemming from the use of "the VSL." Normalizing WTP to a 1.00 risk reduction is arbitrary and has proven to be confusing to non-specialists and therefore open to being used in a strategically misleading fashion. As a device for combining WTP estimates based on different risk changes, any arbitrary normalization is equally appropriate and a more policy-relevant risk change would be preferable for normalization, even if this necessitates a change in traditions.

That WTP should be close to proportional to the size of the risk change has theoretical support and would be enormously convenient. However, empirical tests of this theory are very difficult, with hedonic wage data and contingent valuation studies tending to produce results at odds with this assumption. More information on this important aspect of VSL implementation would be valuable.

WTP for risk reductions should be presumed to be heterogeneous across risks and individuals, unless demonstrated otherwise. It is important that the proposed meta-analyses are designed to recognize this.

Existing meta-analyses have tended to maintain the hypothesis that there exists a single immutable VSL (or a simple VSL function that depends mostly on income levels). The early Agency posture suggested that this unknown VSL merely needed to be revealed by somehow combining VSL estimates from different studies.

The studies that form the raw material for meta-analysis may be compromised to varying degrees by their subjects having had incomplete information about risk. Credible meta-analyses should address these problems as well.

The Agency should proceed cautiously in adopting the results of existing or new meta-analyses as the basis for some assumed distribution for the WTP that will be appropriate for the Second Prospective Analysis. The contexts of the constituent studies may not adequately match the policy context where the WTP is needed.

E.1. VSLs vs. Micromorts

The concept of the value of a statistical life has unnecessarily impeded clear communication with risk managers about the public's value for small changes in health risks. However, the Council acknowledges that it is not in the Agency's best interest to attempt to take

the lead by proposing fundamental changes in the way economists traditionally have thought about valuing mortality risks. Such initiatives properly comes from the academic community. However, the Council wishes to draw the Agency's attention to ideas and approaches that are likely to develop in the literature over the next few years. Even without adopting a substantially different perspective on mortality risk valuation, the Agency can report mortality values in ways that are less susceptible to misinterpretation by non-experts in the constituency for the Section 812 reports. Specifically, the Agency should exercise more precision in describing and qualifying the measures of mortality risk reduction it currently uses. Whenever the concept of a VSL is introduced, the Agency should identify the VSL explicitly as a normalization relative to a particular baseline risk. The corresponding range of untransformed WTP estimates for the policy-relevant range of risk changes should be provided for comparison.

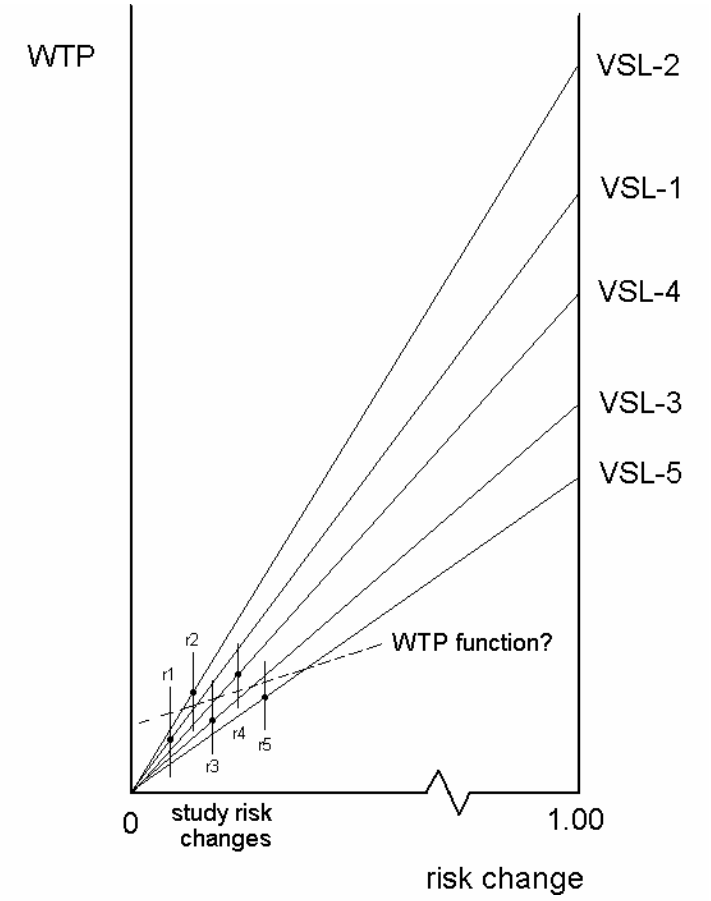
VSL is defined as the marginal rate of substitution (MRS), namely the (local) difference in income that will leave an individual equally well off in the face of a difference in mortality risk. It is well recognized in the literature that this MRS depends on baseline risk, income, and may well depend on other characteristics of the risk and the individual. The units in which this MRS is described are arbitrary (e.g., dollars per pound, pennies per ton, etc.). By focusing on "the Value of a Statistical Life," we have arbitrarily adopted as our units "dollars per 1.00 risk change."

The population WTP for a specified risk reduction is defined as the sum of individuals' WTP for the individual risk reductions. For example, if a policy change reduces fatality risk this year by Δr for everyone in a population of size N, the population WTP for this change can be calculated as vN, where v is the population average WTP for a Δr reduction in the chance of dying this year. This same population value is often described as the product of the average VSL and the expected number of "lives saved" by the risk reduction. Using the normalization of dollars per 1.0 risk change, VSL is defined as $v / \Delta r$, and "lives saved" is equal to the expected number of deaths averted this year, i.e., $N \Delta r$.

While this alternative formulation, in terms of the average VSL and the number of "lives saved," is mathematically equivalent to the population WTP (i.e., the product of the average WTP and the population size), it is potentially misleading. It suggests that the value of each "life saved" is equal to the average VSL, and that one only needs to know the expected number of "lives saved" in order to calculate population WTP. In addition to other factors, VSL is likely to depend on the size of the individual risk reduction Δr, and so the population WTP for a change that "saves one life" may depend on whether the change reduces many people's risk by a small amount or reduces a small number of people's risk by a large amount.

The arbitrary choices made with respect to the normalization of VSLs unnecessarily court objections from non-specialists who confuse "The Value of a Statistical Life" (the economists' technical term for an extrapolated linear approximation to a marginal measure) with "The Value of Life" in the sense of some measure of the intrinsic value of one human life with certainty. Long ago, Howard (1984) proposed the term "micromort," meaning the value of a one-in-a-million risk reduction, which would translate into one one-millionth of our usual $5-6 million VSL, or just 5 to 6 dollars. This metric would be less misleading than the VSL, but unfortunately it has never achieved currency. There is no imperative to choose a 1.00 risk

change as the intervening metric for scaling. Scaling all estimates to the risk change relevant for some specific policy is just as valid, and would lead to the identical mathematical result for aggregate WTP for a risk reduction policy.



There are other potential concerns about empirical measures of WTP for risk reductions. Suppose that we are trying to combine the information about WTP for risk reductions from five different studies, each involving one particular (different) risk reduction, r1 through r5, as in the figure. (With any luck, there will be standard errors on the underlying WTP estimates, as shown, so there will be corresponding standard errors on the resulting individual studies' estimates of VSLs, although these are not depicted in the diagram.)

If we use the WTP and risk information from each study to impute the associated VSL for a 1.00 risk change, the numbers may vary widely, as shown. It is these different VSL estimates that most meta-analyses seek to "average" according to formulas of different complexity and sophistication. By taking some type of average of the five separate VSLs, we can infer an average WTP for risk reductions that controls for the different risks across studies. However, if the true WTP function tracks along the dashed line, and if the policy context concerns a risk change that is, say, slightly larger than r5, then the WTP that would be inferred from the average VSL would be an inappropriate estimate.

The individual WTP point values depicted in the diagram may also differ because of other types of heterogeneity across the contexts wherein they were derived. In that case, it would of course be inappropriate to average these results, even after normalization to a common 1.00 risk change.

VSLs are based on empirical data concerning choices in the neighborhood of very small risks and small risk differences. Outside of this domain, we can really say nothing about WTP for much larger risks and risk changes. The implicit extrapolation to a 1.00 risk change that produces a VSL is understood by specialists to be purely a convenient device to control for variations in the sizes of risk reductions across the studies that yield these estimates. Unfortunately, this is often not understood as such by non-specialists.

E.2. Proportionality

The VSL can be viewed simply as a strategy for getting around the fact that WTP from different studies corresponds to different sized risk changes. It would be inappropriate to average the individual WTP estimates without acknowledging that they apply to different risk changes. The issue of proportionality of estimated WTP for risk reduction and magnitudes of these risk reductions has been raised previously (e.g., Hammitt and Graham, 1999). Certainly, if we wish to maintain the hypothesis that there exists a single one-size-fits-all VSL that is the same for all possible risk reductions, then the estimated WTP for different risk reductions ought to be proportional to the sizes of the risk reductions in question. This constitutes a requirement for a very specific type of "scope test." However, not all empirical estimates of WTP functions produce parameters that are consistent with this requirement. Some studies show negligible effects of risk changes on WTP. Such a result is clearly problematic for valuing mortality risks. However, other studies reveal estimates that suggest that WTP is not strictly proportional to the size of the risk change.

Stated-preference (e.g., contingent valuation) studies almost invariably show that WTP is an increasing but concave function of risk reduction. Revealed-preference studies (e.g., hedonic wage studies) typically do not tell us anything about how WTP depends on the magnitude of the risk change because we model workers as choosing jobs from a continuous set of jobs that differ in wage and risk, and typically do not have information on what jobs (and risks) an individual rejects.

For example, compensating-wage-differential estimates are based on fitting a regression model to data on individual workers' wages, occupational fatality risks, and other variables such as education and job experience that influence wages. This regression estimates how wages vary with occupational fatality risk, holding other factors constant. Each worker is assumed to prefer the job he holds to other jobs that are potentially available to him, which are characterized by the regression. Setting the independent variables equal to the worker's characteristics, the regression is interpreted as describing how the set of jobs available to him differ in wage and risk.

Many of the studies that yield WTP estimates do so for only a single common risk difference for all subjects, so there is too little information in any single study to assess the effect of the size of the risk change on WTP. Some sort of preference calibration exercise would be necessary in order to combine all of the available estimates.

E.3. Heterogeneity: Context-dependent WTP

Many practitioners seem to lose sight of the subtlety that the VSL is not a physical constant, like the constant of gravitation (6.673 ± 0.003) x 10-8 cm3gm-1s-2 , or the mass of a hydrogen atom (1.67339 ± 0.0031) x 10-24 g. Instead, VSL is an artifact of human preferences. It is based on willingness to pay for risk reduction, which depends on the marginal (dis)utility of risk and on the marginal utility of income. While it may be possible to identify some regularities across types of people in these two marginal utilities, it is conceivable that they are essentially unique to each person. Therefore, so can be the corresponding VSL.

The contexts for empirical studies concerning risk tradeoffs differ in many more ways besides just the risk change they consider. The types of risk and the characteristics of the individuals experiencing these risks can also lead to heterogeneity in WTP. If the policy context is not "in the middle" of the range of study contexts, then it can be potentially very misleading to assume that the "average VSL" implied by the range of available studies is a good measure of WTP to reduce the specific risk in the specific affected population for the policy under consideration.

The Council agrees that it is important to look at how estimated VSLs depend on characteristics of the individual (e.g., age, life expectancy), characteristics of the risk (e.g., latency, accompanying morbidity, voluntariness), and any other relevant factors. To the extent that WTP may not be a precisely proportional function of the size of the risk change, it will also be important to look more closely at the relationship between WTP estimates for different studies, concerning different specified risk changes, and to assess whether the proportionality assumption is generally tenable.

E.4. Problems with Meta-analyses

The meta-analysis in the Kochi paper, like many other meta-analyses, is premised on the assumption that there is a simple VSL relationship that is merely revealed with different degrees of bias and noise by different studies. At best, unfortunately, the underlying construct is probably a complex VSL function. This function has many, many arguments. VSL is either known or strongly suspected to depend on the nature of the risk (severity, latency, voluntariness, etc.) and on the attributes of the individual who is considering this risk (age, gender, health status, etc.). VSL is also likely to depend upon the manner in which the demand information behind it is elicited (from self-selected employment decisions, housing choices, stated preference surveys, etc.). If only this last source of heterogeneity existed, we might be confident that techniques for pooling VSL estimates across studies would be a sensible exercise. Unfortunately, we can be fairly confident that there is fundamental heterogeneity in preferences with respect to risk, so that there is no reason, a priori, to expect that any summary statistic across studies corresponds to any single underlying "true" VSL.

The distribution of VSLs to be "averaged" in a meta-analysis is an artifact of the range of contexts (types of risks and affected populations) analyzed in the list of studies contributing to the meta-analysis. If this distribution of contexts does not correspond to the context pertinent to the environmental policy in question, then the "meta-analysis VSL" may have little to do with people's willingness to pay the costs of this policy.

E.5. WTP and Incomplete Information

It is important to recognize two explanations for why people's empirical decisions about mortality risk may differ from conventional theory: a) the individuals may be ill-informed or may make mistakes (e.g., cognitive errors), and b) the theory may be oversimplified or wrong. It is likely that most people would like to make decisions in a way that optimizes their risk reduction spending (i.e., equal marginal spending per unit risk reduction) across various domains (e.g., housing, employment choices). However, they do not do so in practice because of information limitations and well-known errors in decision making about risk.

Some published research has made an attempt to sort out which of the factors that lead to differences between perceived risk and simple theory are simply cognitive errors (e.g., susceptibility to framing effects), and which are attributes of preferences potentially meriting normative recognition (e.g., distribution of benefits and risks of activity; such as voluntariness) (see Hammitt, 2000b).

In general, economists are inclined to defer to "consumer sovereignty" in measuring the types of tradeoffs people are willing to make. In the event of misinformation or cognitive problems, however, good policy should probably over-ride consumer errors where possible and simulate what would have been consumers' WTP under similar conditions, but with complete and accurate information.

E.6. What to do in the near term

The Agency needs to verify that the distribution of risk reductions over which each meta-analysis has been estimated, and the context for these reductions, at least corresponds to the types of risk reductions relevant to the Clean Air Act and its amendments. The Panel continues to support meta-analyses of willingness to pay for risk reductions, but discourages the Agency from leaving the impression that it is searching for a single one-size-fits-all VSL. Instead, it should be a maintained hypothesis that heterogeneity matters. Heterogeneity should be ignored only if it can be shown to be inconsequential. The benefits from mortality (and morbidity) risk reduction attributed to a particular policy should be commensurate with the size and nature of the risk reduction and with the attributes of the affected populations.

It seems worth speculating that researchers' habit of talking in terms of conventional VSLs has much to do with the recent public relations problems concerning the "senior death discount." This different VSL for seniors was embodied in the alternative net benefits calculations associated with some recent analyses by the Agency. The public backlash to this differential seems to have been attributable almost entirely to the use of the VSL concept, which led the public to think that the issue at stake is the "*value* of a senior." In reality, the issue at stake is much closer to "how much money should we as a society pay for small risk reductions for seniors, and should it be the same as the amount paid for the same benefits for middle-aged individuals and children." In particular, it is worth questioning whether we should, as a society, oblige people through regulations to pay more for health risk reductions than they would choose to pay if they were to buy these risk reductions privately, themselves. It is essential to steer the press and the public towards the legitimacy of individual preferences and the corresponding demands (consumer sovereignty), rather than sticking with the arbitrary unit choice that expresses a marginal rate of substitution between risk changes and income as the "value of life."

The word "value" is assumed by non-economists to be something intrinsic. Demand for risk reductions is not intrinsic and immutable, independent of context. It is subjective and individual, and measured differences in this demand across subpopulations and risk contexts should be honored wherever they are verifiable and based on complete information about those risks.

If WTP for small risk reductions can be shown to be approximately proportional to the size of these risk reductions over the relevant domain of the WTP function, the Panel believes it would be less inflammatory to present the marginal rate of substitution expression in terms of risk changes of a size that are pertinent to policy choices. The Panel recommends that the Agency consider converting VSL estimates into units with a less potentially misleading denominator (micromorts, millimorts, picomorts, etc.) and presenting these estimates in tandem with ordinary VSL estimates, if not in lieu of them.

APPENDIX F: SPECIFIC RESERVATIONS ABOUT THE USE OF QALYS IN THE CONTEXT OF THE SECTION 812 ANALYSES

Members of the Council have articulated a number of specific reservations about the use of QALYs in the context of the Section 812 Analyses. These reservations concern consumer sovereignty and representativeness, ordinality versus cardinality, and heterogeneity in health states. Details about these concerns follow.

F.1. Consumer sovereignty and representativeness:

Much progress has been made over the last dozen years in rendering QALY weights more fully representative of general population preferences, but some of the assumptions they require still trouble economists. There is no basis in economics for QALY weights based solely on the opinions of experts. Consumer sovereignty is a hallmark of the economic framework for benefit-cost analysis. The weights on different health states--used in the aggregation of a vector of health state characteristics into a one-dimensional index of well-being--should be based on the tradeoffs that a representative sample of consumers is willing to make between those states.

State-of-the-art QALY-weight estimates used to convert a bundle of health-state attributes into a one-dimensional index now tend to be determined ex ante with respect to the degraded health states in question, by random samples from the population of consumers, so there is a greater expectation that these weights are representative. Departures from this strategy are sometimes justified as approximations, but acknowledged to be conceptually inferior. The Agency, if it elects to use QALYs in future cost-effectiveness calculations, should insist upon weights that are based on general public/consumer preferences, rather than experts' opinions, and that these weights reflect ex ante rather than ex post tradeoffs. This was a recommendation of the Panel on Cost-Effectiveness (see Gold et al. 1996). Some members of the Council are concerned, however, that there do not yet exist sufficient numbers of general-population estimates of QALY weights for the Agency to be confident in any estimates it might use.

F.2. Ordinality versus cardinality.

Economics is clear that tradeoffs with respect to health need not necessarily be expressed in terms of the marginal utility derived from a health attribute divided by the marginal utility derived from money (which is the manipulation that produces a WTP estimate for changes in health states). Any numeraire will do. The choice of a monetary unit is merely convenient. WTP measures the rate of substitution between some change in a health state (or lottery over health states) and income, where income is a measure of the consumption of "all other goods and services." In contrast, QALY weights measure the rate of substitution between a change in health state and length of life, so length of life is the numeraire. To this point, then, the marginal rates of substitution in both the WTP and QALY approaches require only ordinality in preferences. The subtle difference, however, is that while empirical QALY studies typically elicit ordinal utility scales, they give the scale a real zero (i.e. death), which gives the scale ratio properties,

In the case of QALYs, the shift to a cardinal interpretation seems to come about in one of two ways. The first is when practitioners want to add QALYs across people. This creates a need to interpret QALYs as measuring interpersonally-comparable utilities, so that sums of QALYs across people can remain consistent with utilitarian welfare. Many QALY practitioners clearly treat QALYs as cardinal by adding utility across time and across individuals. Second, if practitioners want to evaluate uncertain health risks by calculating expected QALYs, it seems necessary to assume that QALYs reflect a von Neumann-Morgenstern utility function, which is necessary for the expected value to be a meaningful summary of utility under uncertainty. (It is of course also necessary to assume that expected utility theory is consistent with human behavior). QALYs are derived from von Neumann-Morgenstern utility under uncertainty. However, in practice, QALY calculations violate the postulates of expected-utility theory by treating an *ex ante* interval utility scale as if it were an *ex post* ratio utility scale.

In the case of WTP calculations, it is not necessary to rely on direct interpersonal utility comparisons, so it is likewise unnecessary to think about WTP as a cardinal utility measure. WTP can be summed across individuals because the Kaldor-Hicks compensation principle provides for this to be a way to identify potential Pareto improvements. In contrast, any analogy to the idea of Pareto improvements is harder to apply to the QALY story, since the idea of winners actually compensating losers by handing over some of their net improvements in health seems like it would be impossible, even in principle. The analogy to the Kaldor-Hicks intuition would still suggest that the net health gains of winners should exceed the net health losses to losers. Across many simultaneous health-improvement policies with different distributions of winners and losers, if net gains across all programs exceed net losses across all programs, society as a whole would be better off in terms of health.

F.3. Heterogeneity in health states

QALY practitioners have focused on heterogeneity in health states and the desire for a one-dimensional index of health that controls for this heterogeneity. WTP researchers have emphasized utility-theoretic strategies in support of benefit-cost analysis, but early empirical estimates did not distinguish between health states beyond just "alive" versus "dead." The latest generations of empirical WTP analyses now incorporate information about disease types, age differences, latencies in effects, comorbidity, and other types of heterogeneity. Most economists would agree that the ideal approaches to both benefit-cost analysis and cost-effectiveness analysis should include both adequate recognition of heterogeneity in health effects and a utility-theoretic framework. QALY approaches are relatively strong on the first count, but lacking on the second count. WTP approaches are strong on the second count, and gaining rapidly in terms of the first.

F.4. Economic benefit analysis using QALYs?

A cul-de-sac in the QALY-WTP literature attempts to bring the medical decision-making and economic approaches to efficiency questions somewhat closer together. Some QALY researchers have considered the *demand* for the improved health states offered by different policies, not just the *costs* of these improvements. Instead of just cost-effectiveness analysis, something approaching a full benefit-cost analysis can be sought. See Hirth, et al. (2000),

Hammitt (2002), Klose (2003), and Gyrd-Hansen (2003). Even in this endeavor, though, the standardization of health units embodied in a QALY still tends to raise objections from economists. One QALY-based WTP method has two steps: a) model QALYs as a function of a wide array of health state attributes and calculate the non-economic cardinal QALY index for a specified bundle of health attributes, then b) determine WTP for a QALY with the assumption that each QALY has equal value. Some studies have also tried (incorrectly) to derive WTP per QALY using VSL, or to regress WTP estimates on QALY estimates from the same sample. However, there has been little sustained interest in using such estimates to evaluate health outcomes.

In conducting a WTP analysis, it is reasonable to question whether an intervening QALY step is even necessary. The economic approach is presently evolving to model WTP directly as a function of heterogeneous health state attributes--in one step. This approach models WTP to avoid a future health state as a function of the vector of attributes of that health state, allowing inferences about the marginal WTP for distinct health state attributes, holding other attributes constant. Forcing WTP to fit a QALY model seems to place unnecessary and perhaps undesirable constraints on WTP. There is no reason why an individual would have to place the same monetary value on every QALY. This implies linearity of WTP with respect to changes in life expectancy, an assumption that does not appear to be supported empirically (e.g., Krupnick et al., 2002).

APPENDIX G: BIOSKETCHES OF MEMBERS OF THE SPECIAL COUNCIL PANEL FOR THE REVIEW OF THE THIRD 812 ANALYSIS

Dr. Trudy Ann Cameron (Council Chair)

Dr. Trudy Ann Cameron is the Raymond F. Mikesell Professor of Environmental and Resource Economics at the University of Oregon. She holds a Ph.D. in Economics from Princeton University (*82), and was a member of the faculty in Economics at UCLA for seventeen years before moving to UO in January of 2002. She has served as a member of the board of directors, as well as vice-president, of the Association of Environmental and Resource Economics, and as an associate editor for the Journal of Environmental Economics and Management and the American Journal of Agricultural Economics. For the EPA's Science Advisory Board, she has served on the Environmental Economics Advisory Committee and the Economics and Assessment Working Group of the Children's Health Protection Advisory Committee, and she now chairs the Advisory Council for Clean Air Compliance Analysis. Dr. Cameron's research concentrates on the methodology of non-market resource valuation, with special emphasis on econometric techniques for the analysis of stated preference survey data. Her recent projects have included a study of popular support (i.e., willingness to pay) for climate change mitigation programs (funded by the National Science Foundation). A current project, begun at UCLA with former colleague JR DeShazo, uses stated preference survey methods to elicit household choices that reveal willingness to pay to avoid illness, injury, and death. The "value of a statistical life" is a key ingredient in the benefit-cost analysis of many environmental, health, and safety regulations, and this project seeks to more clearly identify how the context of such choices influences the public's willingness to pay for such policies.

Dr. David Allen

Dr. David Allen is the Gertz Professor of Chemical Engineering and the Director of the Center for Energy and Environmental Resources at the University of Texas at Austin. His research interests lie in environmental reaction engineering, particularly issues related to air quality and pollution prevention. He is the author of four books and over 125 papers in these areas. The quality of his research has been recognized by the National Science Foundation (through the Presidential Young Investigator Award), the AT&T Foundation (through an Industrial Ecology Fellowship) and the American Institute of Chemical Engineers (through the Cecil Award for contributions to environmental engineering). Dr. Allen was a lead investigator in one of the largest and most successful air quality studies ever undertaken: the Texas Air Quality Study (www.utexas.edu/research/ceer/texaqs). His current research is focused on using the results from that study to provide a sound scientific basis for air quality management in Texas. In addition, Dr. Allen is actively involved in developing Green Engineering educational materials for the chemical engineering curriculum. His most recent effort is a textbook on design of chemical processes and products, jointly developed with the U.S. EPA. Dr. Allen received his B S. degree in Chemical Engineering, with distinction, from Cornell University in 1979. His M.S. and Ph.D. degrees in Chemical Engineering were awarded by the California Institute of Technology in 1981 and 1983. He has held visiting faculty appointments at the California

Institute of Technology, the University of California, Santa Barbara, and the Department of Energy.

Ms. Lauraine G. Chestnut

Ms. Lauraine G. Chestnut, Managing Economist at Stratus Consulting Inc., is an economist who specializes in the quantification and monetary valuation of human health and environmental effects associated with air pollutants. She has 20 years of experience with Stratus Consulting and its predecessors working for clients including the U.S. Environmental Protection Agency, California Air Resources Board, Environment Canada, World Bank, and Asian Development Bank, quantifying the damages of air pollution, including human health effects, visibility aesthetics, materials damages, and crop damage. She has conducted original economic and survey research to estimate the value to the public of protecting human health and visibility aesthetics from the effects of air pollution. She has developed quantification models to estimate the health benefits of reductions in air pollutants that have been used to assess the benefits of provisions of the Clean Air Act in the U.S., proposed Canadian air quality standards, air quality standards in Bangkok, and elsewhere. Ms. Chestnut has published articles related to this work in Land Economics, Environmental Research, Journal of the Air and Waste Management Association, and Journal of Policy Analysis and Management, and as chapters in the following titled books: Valuing Cultural Heritage, Air Pollution and Health, and Air Pollution's Toll on Forests and Crops. Ms. Chestnut managed an epidemiology and economic study of the health effects of particulate air pollution in Bangkok, working closely with the Thai Pollution Control Department, the School of Public Health at Chulalongkorn University, and the World Bank. Ms. Chestnut co-authored publications on the Bangkok studies in the Journal of the Air and Waste Management Association, Environmental Health Perspectives, American Journal of Agricultural Economics, Journal of Exposure Analysis and Environmental Epidemiology. Ms. Chestnut received a B.A. in economics from Earlham College, Richmond, Indiana, in 1975, and an M.A. in economics from the University of Colorado, Boulder, in 1981. She is a member of the Association of Environmental and Resource Economists and of the Air and Waste Management Association.

Dr. John Evans

Dr. Evans is Senior Lecturer in Environmental Science at Harvard School of Public Health, where he serves as co-director of the Program in Environmental Science and Risk Management. He holds a B.S.E. (Industrial Engineering) and a M.S. (Water Resources Management) from the University of Michigan and earned his S.M. and Sc.D. in Environmental Health Sciences at Harvard. Dr. Evans has worked in the field of risk analysis for over twenty years and has emphasized the importance of characterizing uncertainty in estimates of health risks in his research. He has experience in uncertainty analysis and has conducted several studies using formally elicited expert judgment to describe uncertainty in environmental health risks. His recent work has examined the role of decision and value of information analysis in setting priorities for environmental research. Dr. Evans has been a member of the Society for Risk Analysis since it was founded; has served as the Chair of the New England Chapter, and as both a member of the Editorial Board of the SRA's journal Risk Analysis and as an area editor of Risk Analysis. He was a member of the NAS Committee on Estimating the Health Benefits of Air

Pollution Regulations and also served on the EPA Science Advisory Board (Drinking Water Committee). Dr. Evans' current research funding comes largely (over 90%) from the Government of Kuwait. In the past his work has been funded by a number of sources, including the US EPA Office for Research and Development, the Mexican Government (through subcontracts with MIT), several corporations and individuals (through contracts with and/or gifts to the Harvard Center for Risk Analysis), Health Canada, and the US Nuclear Regulatory Commission.

Dr. Lawrence H. Goulder

Dr. Lawrence H. Goulder is the Shuzo Nishihara Professor in Environmental and Resource Economics at Stanford University. He is also a Senior Fellow of Stanford's Institute for International Studies and Institute for Economic Policy Research, a Research Associate at the National Bureau of Economic Research, and a University Fellow of Resources for the Future. He is a member of the EPA's Science Advisory Board's Environmental Economics Advisory Committee. Dr. Goulder's research examines the environmental and economic impacts of U.S. and international environmental policies. He has focused on policies to reduce emissions of "greenhouse gases" that contribute to climate change, and on "green tax reform," revamping the tax system to introduce taxes on pollution and reduce taxes on labor effort or investment. His analyses of environmental policies often employ a general equilibrium analytical framework that integrates the economy and the environment and links the activities of government, industry, and households. His work considers both the aggregate benefits and costs of various policies as well as the distribution of policy impacts across industries, income groups, and generations. Some of his work is interdisciplinary, involving collaborations with climatologists and biologists. Dr. Goulder graduated from Harvard College with an A.B. in philosophy in 1973. He obtained a master's degree in musical composition from the Ecole Normale de Musique de Paris in 1975 and earned a Ph.D. in economics from Stanford in 1982.

Dr. James K. Hammitt

James K. Hammitt is Associate Professor of Economics and Decision Sciences and Director of the program in Environmental Science and Risk Management at the Harvard School of Public Health. His teaching and research concern the development and application of quantitative methods—including benefit-cost, decision, and risk analysis—to health and environmental policy in both industrialized and developing countries. Research interests include the management of long-term environmental issues such as global climate change and stratospheric-ozone depletion, the evaluation of corollary benefits and countervailing risks associated with risk-control measures, and the characterization of social preferences over health and environmental risks using revealed-preference and contingent-valuation methods. Professor Hammitt is a member of the National Academy of Sciences Committee on Implications of Dioxin in the Food Supply, the American Statistical Association Committee on Energy Statistics (the Advisory Committee to the US Energy Information Administration), and the National Science Foundation panel for Decision, Risk and Management Science. He holds degrees in Applied Mathematics (A.B., Sc.M.) and Public Policy (M.P.P., Ph.D.) from Harvard University. Previously, he was Senior Mathematician at the RAND Corporation and on the faculty of the RAND Graduate School of Policy Studies.

Dr. Dale Hattis

Dr. Dale Hattis is Research Professor with the Center for Technology Environment and Development (CENTED) of the George Perkins Marsh Institute at Clark University. For the past twenty-seven years he has been engaged in the development and application of methodology to assess the health ecological and economic impacts of regulatory actions. His work has focused on the development of methodology to incorporate interindividual variability data and quantitative mechanistic information into risk assessments for both cancer and non-cancer endpoints. Specific studies have included quantitative risk assessments for hearing disability in relation to noise exposure, renal effects of cadmium reproductive effects of ethoxyethanol, neurological effects of methyl mercury and acrylamide, and chronic lung function impairment from coal dust four pharmacokinetic-based risk assessments for carcinogens (for perchloroethylene ethylene oxide butadiene and diesel particulates), an analysis of uncertainties in pharmacokinetic modeling for perchloroethylene, and an analysis of differences among species in processes related to carcinogenesis. He has recently been appointed as a member of the Environmental Health Committee of the EPA Science Advisory Board and for several years he has served as a member of the Food Quality Protection Act Science Review Board. Currently he is also serving as a member of the National Research Council Committee on Estimating the Health-Risk-Reduction Benefits of Proposed Air Pollution Regulations. The primary source of his recent cooperative agreement support is the U.S. Environmental Protection Agency and specifically the Office of Research and Development's National Center for Environmental Assessment. This research includes: (1) Age related differences in susceptibility to carcinogenesis; towards a quantitative analysis of empirical data. Instrument number (Term: April 2002-Sept 2003); (2) Methods for evaluating human interindividual variability regarding susceptibility to particulates (Term Sept 98--September 2002); and (3) also funding from the State of Connecticut to work on Child/Adult differences in pharmacokinetic parameters, as a subcontractor as part of a cooperative agreement. He has been a councilor and is a Fellow of the Society for Risk Analysis and serves on the editorial board of its journal Risk Analysis. He holds a Ph.D. in Genetics from Stanford University and a B.A. in biochemistry from the University of California at Berkeley.

Dr. F. Reed Johnson

Dr. F. Reed Johnson is Principal Economist at Research Triangle Institute. He was recently named as one of the first four RTI Fellows. He has served on the economics faculties of Illinois State University, Simon Fraser University, the Stockholm School of Economics, the University of Stockholm, Linköping University, and the U.S. Naval Academy. He currently is Adjunct Professor of Public Policy at the University of North Carolina at Chapel Hill. He is also a member of RTI's Scientific Advisory Council. From 1994 to 2001 he was Vice President for Research and Development at Triangle Economic Research. He previously worked as an economist in the Office of Policy Analysis, U.S. Department of the Interior, and in the Office of Policy, Planning, and Evaluation, U.S. Environmental Protection Agency.

Dr. Johnson received his B.A. degree in economics from Occidental College in 1970 and his Ph.D. degree in economics from the State University of New York, Stony Brook in 1974. He has been awarded a Brookings Economic Policy Fellowship and two Fulbright-Hayes scholarships to Sweden. As a staff member in the U.S. Environmental Protection Agency's environmental economics research program during the 1980s, Dr. Johnson helped pioneer development of basic nonmarket valuation techniques. These techniques are now widely used for benefit-cost analysis in health and environmental economics. He has designed and analyzed numerous surveys for measuring willingness to pay for health-risk reduction and improved environmental quality. His current research includes developing improved conjoint analysis methods for quantifying patient and physician preferences for health-care interventions and health risks.

Dr. Charles Kolstad

Charles Kolstad is the Donald Bren Professor of Environmental Economics and Policy at the University of California, Santa Barbara, where he is jointly appointed in the Department of Economics and the Bren School of Environmental Science and Management. Most of Prof. Kolstad's research has been in the area of regulation, particularly environmental regulation. Recently, he has also done work in environmental valuation theory. He is particularly interested in the role of information in environmental decision-making and regulation. Currently he has a major research project on the role of uncertainty and learning in controlling the precursors of climate change. His past work in energy markets has focused on coal and electricity markets, including the effect of air pollution regulation on these markets. Prof. Kolstad is the editor of Resource and Energy Economics, has been an Associate Editor of the Journal of Environmental Economics & Management (JEEM), and is currently on the editorial board of Land Economics and JEEM. Dr. Kolstad is the president of the Association of Environmental and Resource Economists(AERE). He has also served on AERE's Board of Directors. With over 100 publications, he has published in a variety of journals including the American Economic Review, Journal of Political Economy, Review of Economic Studies, Review of Economics and Statistics, Land Economics and The Journal of Environmental Economics and Management (JEEM). He received his Ph.D. from Stanford (1982), his M.A. from Rochester and his B.S. from Bates College.

Dr. Lester B. Lave

Dr. Lester B. Lave is University Professor and Higgins Professor of Economics at Carnegie Mellon University, with appointments in the Business School, Engineering School, and the Public Policy School. Reed College granted him a B.A. and Harvard University a Ph.D. in economics. His research has focused on health, safety, and environmental issues, from the effect of air pollution on mortality to estimating the benefits and costs of automobile safety standards, risk analysis of carcinogenic chemicals, testing the carcinogenicity of chemicals, valuing natural resources and global climate change. As a Senior Fellow at the Brookings Institution from 1978-1982, he investigated a variety of regulatory and risk analysis issues. Lave has served as a consultant to a large number of federal and state agencies, as well as corporations. He was elected to the Institute of Medicine of the National Academy of Sciences, is a past president of the Society for Risk Analysis, and has served on many committees of the National Academy of sciences, AAAS, American Medical Association, and Office of Technology Assessment. Dr. Lave is the director of the Carnegie Mellon University university-wide Green Design Initiative (Practical Pollution Prevention). This program is focused on using pollution prevention and sustainable development to boost economic development. The program has partnerships with leading companies to address these issues and design produces and processes for the environment. Although it is only four years old, the program has already received extensive support from IBM, the National Science Foundation, then Department of Energy, the Environmental Protection Agency, Texaco, the American Plastics Council, AT&T, Xerox, NCR, General Motors, Ford, Chrysler, Union Carbide, Alco, and other industrial Companies. Lave is also a principal in the Carnegie Mellon Global Change Center sponsored by NSF.

Dr. Virginia McConnell

Dr. Virginia D. McConnell is currently Senior Fellow at Resources for the Future and Professor of Economics at the Baltimore Campus of the University of Maryland (UMBC). She is currently a member of several EPA Advisory Committees, including the EPA Clean Air Act Advisory Committee, Subcommittee on Mobile Sources Technical Review, and the Chesapeake Bay Program Advisory Committee, Air Subcommittee. She recently served on a National Academy of Sciences Panel, Board on Environmental Studies and Toxicology, to evaluate vehicle emission inspection programs. In the past, she worked with the President's Commission on Environmental Quality, and was awarded a Gilbert White Fellowship at Resources for the Future. She received a B.A. in Economics from Smith College in 1969 and Ph.D. in Economics from the University of Maryland in 1978. Her research interests are in the general area of air pollution and urban transportation, and more recently on the link between urban growth, transport and the environment. She has just completed work on a review article on 'Vehicles and the Environment' for the International Yearbook of Environmental and Resource Economics. Her published work has focused on evaluation of policies and policy design for the reduction of vehicle pollution; analysis of the productivity effects of environmental regulations; the effect of environmental regulations on firm location; and transport externalities and urban structure. In addition, she is currently studying the role of economic incentive policies for achieving goals of more efficient urban growth.

Dr. D. Warner North

Dr. D. Warner North is president and principal scientist of NorthWorks, Inc., a consulting firm in Belmont, California, and consulting professor in the Department of Management Science and Engineering at Stanford University. Over the past thirty years Dr. North has carried out applications of decision analysis, risk analysis, and benefit-cost analysis for electric utilities in the US and Mexico, for the petroleum and chemical industries, and for US government agencies with responsibility for energy and environmental protection. He has served as a member and consultant to the Science Advisory Board of the US Environmental Protection Agency since 1978, and as a Presidentially-appointed member of the US Nuclear Waste Technical Review Board (1989-1994). Dr. North is a co-author of many reports dealing with environmental risk for the National Research Council of the National Academy of Sciences, including "Risk Assessment in the Federal Government: Managing the Process" (1983), "Improving Risk Communication" (1989),"Science and Judgment in Risk Assessment" (1994), and "Understanding Risk: Informing Decisions in a Democratic Society" (1996). Dr. North was a member of the Board on Radioactive Waste Management of the National Research Council from 1995 until 1999. He was the chair for the steering and advisory committees for the International Workshop on the Disposition of High-Level Radioactive Waste, held November 4-5, 1999, and leading to the National Research Council report, "Disposition of High-Level Waste and Spent Nuclear Fuel: The Continuing Societal and Technical Challenges," published in June 2001. Dr. North is a past president (1991-92) of the international Society for Risk Analysis, a recipient of the Frank P. Ramsey Medal from the Decision Analysis Society in 1997 for lifetime contributions to the field of decision analysis, and the 1999 recipient of the Outstanding Risk Practitioner Award from the Society for Risk Analysis. Dr. North received his Ph.D. in operations research from Stanford University and his B.S. in physics from Yale University.

Dr. Bart Ostro

Bart Ostro, Ph.D., is currently the Chief of the Air Pollution Epidemiology Unit, Office of Environmental Health Hazard Assessment, California Environmental Protection Agency. His primarily responsibilities are to formulate the Agency's recommendations for state ambient air quality standards and to investigate the potential health effects of criteria air pollutants. His previous research on mortality and morbidity effects of air pollution, has contributed to the determination of federal and state air pollution standards for ozone and particulate matter. Dr. Ostro was also a co-author of the EPA regulatory impact analysis that was a basis for the federal ban of lead in gasoline. Dr. Ostro has served as a consultant with several federal and international institutions including the World Health Organization and the World Bank, and with several foreign governments including Mexico, Indonesia, Italy, the European Union, Thailand, and Chile. H e currently serves on the National Academy of Sciences' Committee on Estimating the Health Risk Reduction Benefits of Proposed Air Pollution Regulations, and is on the Scientific Oversight Committee for ATHENA (Air Pollution Health Effects in Europe and North America) for the Health Effects Institute. Dr. Ostro received a Ph.D. in Economics from Brown University and a Certification in Environmental Epidemiology from the State of California. He has published over 60 articles on air pollution epidemiology and environmental economics in peer reviewed journals. His current research interests involve conducting epidemologic studies on the mortality and morbidity effects of criteria air pollutants, examining the health effects of

traffic, and quantifying the health benefits and associated uncertainties related to air pollution control.

Dr. V. Kerry Smith

Dr. V. Kerry Smith is University Distinguished Professor and Director, Center for Environmental and Resource Economic Policy in the Department of Agricultural and Resource Economics at North Carolina State University, and he is a University Fellow in the Quality of the Environment Division of Resources for the Future. Since October 2000 he has been a member of the Advisory Council on Clean Air Compliance Analysis of the U.S. Environmental Protection Agency's Science Advisory Board, and in 2001 he was a member of the Arsenic Rule Benefits Review Panel of EPA's SAB. Dr. Smith received his AB in Economics from Rutgers University in 1966 and his Ph.D. in Economics there in 1970. He presented the Federick V. Waugh Lecture for the American Agricultural Economics Association in 1992, and at the 2002 AAEA annual meeting he was named an association fellow, the association's most prestigious honor. In addition to the AAEA , he is a member of the American Economic Association, the Southern Economic Association, the Association of Environmental and Resource Economists, and numerous other professional associations. He has held editorial positions with the Journal of Environmental Economics and Management, Land Economics, Review of Economics and Statistics, and other professional journals. His research interests include non-market valuation of environmental resources, role of public information in promoting private risk mitigation, environmental policy and induced technical change, non-point source pollution and nutrient policy.

Dr. Thomas Wallsten

Dr. Thomas S. Wallsten is a professor in the Department of Psychology and in the Program in Cognitive Science and Neuroscience. He received his Ph.D. from the University of Pennsylvania in 1969, did a postdoctoral fellowship at the University of Michigan in 1970, and then joined the faculty at the University of North Carolina, Chapel Hill. He was professor of psychology and director of the Cognitive Science program when he left UNC-CH in 2000. Over the past years he was a visiting professor or visiting scholar at the University of Chicago, Duke University, Haifa University in Israel, and University of Oldenburg in Germany. He is a mathematical and cognitive psychologist with expertise in subjective probability, judgment, choice, decision behavior, and related areas of decision science and cognitive psychology. His current research focuses on subjective probability encoding and representation, communication of opinion, and human information processing under uncertainty. This research has been supported over the past 30 years primarily by grants from the National Science Foundation (NSF), with occasional additional support from other agencies. Current grants are from NSF and the Air Force Office of Scientific Research. Among his advisory roles, he was editor of the Journal of Mathematical Psychology from 1990-1994, associate editor of Psychometrika from 1984-1988, associate editor of the Journal of Experimental Psychology: Learning, Memory, and Cognition from 2000-2003, and on numerous editorial boards. He served in various advisory roles for NSF: During 1995-1997 on the grant review panel for Methodology, Measurement, and Statistics Program in the Division of Social, Behavioral, and Economic Research; in 2000 as a member of the Committee of Visitors for Social, Behavioral, and Economic Sciences

Directorate; in 2003 as a member of the Committee of Visitors for the Behavioral and Cognitive Sciences Directorate; in 1998 on an ad hoc NSF-EPA grant review panel. In 2002, he was a grant review panel member for the Cognition and Student Learning Program of the Department of Education Office of Educational Research and Improvement.
