## PREFACE

The current contract period is a continuation of a long-term study with the goal to determine the importance of freshwater inflow in maintaining benthic productivity. All of the following scientific contributions have been performed during the contract periods, and acknowledged support, or partial support, by the Texas Water Development Board, Water Research Planning Fund, authorized under the Texas Water Code sections 15.402 and 16.058(e). This support was administered by the department under interagency cooperative contract numbers: (1986-87) 0757, 8-483-607, 9-483-705, 90-483-706, 91-483-787, 92-483-300, 93-483-352, 94-483-003, 95-483-068, 96-483-132, and most recently 97-483-199.

This is an iterative report, much like the Texas Parks and Wildlife, Data Management Series. Data is added to the time series, and the whole time series is reported so that year-to-year comparisons can be made. The report has several sections. First, all contributions that acknowledged the Texas Water Development Board for support during the entire project length are reported. These contributions represent the products of the research project. Second, is a compilation of biological and hydrographical data obtained over the course of the study. Third, is a compilation of all the sediment data on nitrogen losses that has been collected to date.

## **ACKNOWLEDGEMENTS**

I must acknowledge the significant contributions of Mr. Rick Kalke. Rick began the first sampling study of Lavaca Bay in 1984. He is an outstanding field person and taxonomist. The work reported on in this study could not have been performed without him. Carroll Simanek also provided significant help in data management. We obviously are collecting and processing a large amount of data. Input, proof-reading and maintenance of this large data set is a daunting task that Carroll handles very well. This work has also benefitted by discussions with colleagues at the Texas Water Development Board (TWDB), e.g., Gary Powell, William Longley, and David Brock who have provided much help and guidance.

The Texas estuarine research reported here has been supplemented by other projects. The Lower Colorado River Authority recently supplemented the long-term study in Matagorda Bay by adding funding to sample additional stations in the Eastern arm of Matagorda Bay to study the effects of the diversion of the Colorado River. Several studies of the Laguna Madre were made possible by a program funded by the Texas Advanced Technology Program and Advanced Research Program. Long-term studies on the Nueces Estuary have been recently funded by the Texas Sea Grant Program and the Corpus Christi Bay National Estuary Program (CCBNEP). Both of these project utilized stations originally established by the TWDB projects in 1988. The primary focus of the Sea Grant program was to determine the role of climatic variability in controlling productivity in estuaries. In the CCBNEP study, TWDB stations were used as reference stations for assessing anthropogenic effects due to storm drain outfalls.

## INTRODUCTION

The primary goal of the current research program is to define quantitative relationships between marine resource populations and freshwater inflows to the State's bays and estuaries. However, we know that there is year-to-year variability in the population densities and successional events of estuarine communities. This year-to-year variability is apparently driven by long-term, and global-scale climatic events that affect the rates of freshwater inflow. Therefore, this report documents long-term changes in populations and communities that are influenced by freshwater inflow. The best indicator of productivity is the change in biomass of the community.

A secondary goal of the current research program is to quantify the loss of nitrogen in Texas estuaries. Nitrogen is the key element that limits productivity. A simple budget would account for nitrogen entering the bay via freshwater inflow, how it is captured and transformed into biomass, and finally how it is lost from the ecosystem. One aspect of nitrogen loss is very poorly understood: How much nitrogen is buried and lost from the system? We report here nitrogen content changes with respect to sediment depth. Presumably nitrogen is labile in the upper, biologically active, layers of sediment, and refractory at depth. Therefore, it is important to determine the sediment depth at which nitrogen content is at a low and constant value.

This study is a continuation of freshwater inflow studies that began in 1984. The goals have evolved over the years to reflect the synthesis of new information and the management needs of the Texas Water Development Board (TWDB). The original studies (1984-1986) were designed to determine the effect of inflow on Lavaca Bay. One station used during that study is still being sampled. San Antonio Bay was studied in 1987, and the Nueces Estuary (Nueces and Corpus Christi Bays) were studied in 1988. Long-term studies of the Lavaca-Colorado and Guadalupe Estuaries began in 1990. Although, there is ten years worth of data in some cases, we have not sampled over two entire wet-dry cycles. We have sampled over one and one-half cycles. We are currently beginning to enter a dry cycle. The completion of this research will take about two more years and should end when we enter the next wet cycle, which will be heralded by the next El Niño event.

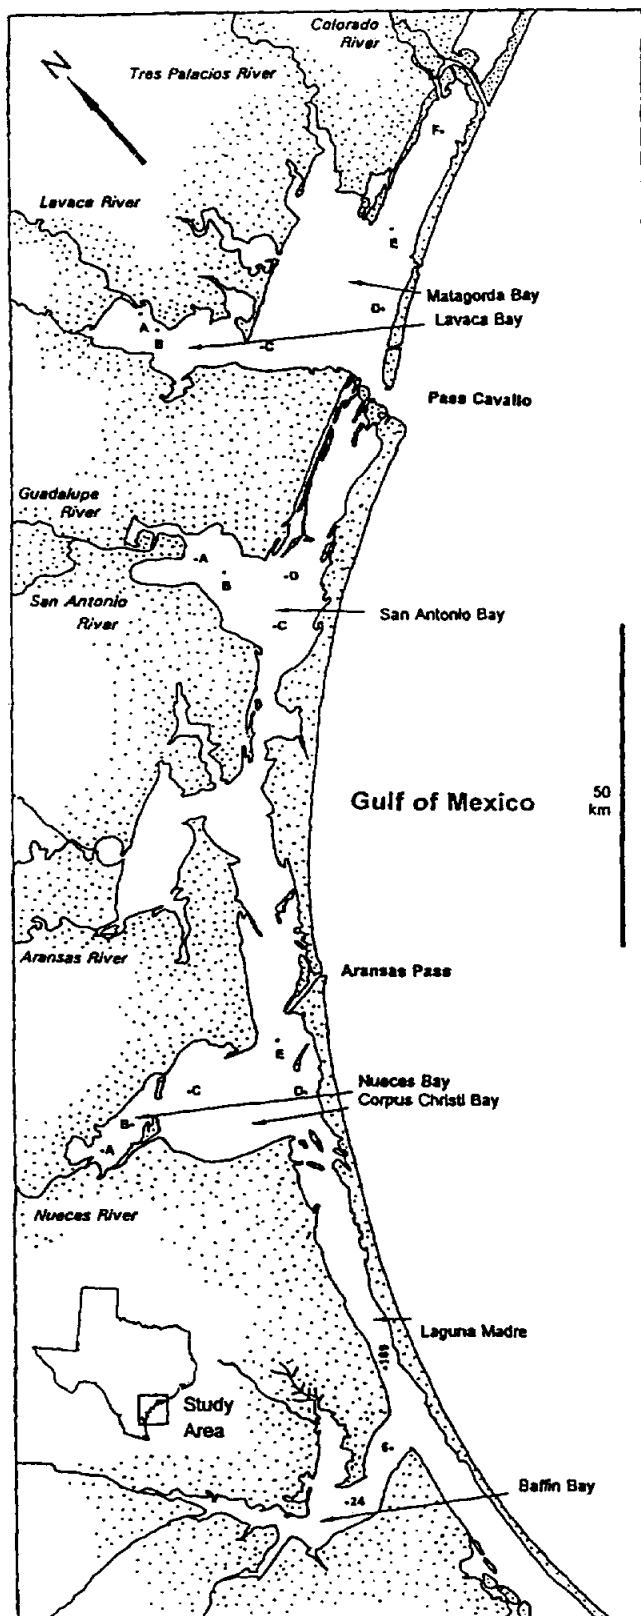

## METHODS

### *Study Design and Area*

There are seven major estuarine systems along the Texas coast. Each system receives drainage from one to three major rivers. The northeastern most estuaries receive more freshwater inflow than the southwestern estuaries. Two estuarine systems were studied in detail (Figure 1). Both systems have similar freshwater inflow characteristics, but the Lavaca-Colorado Estuary has direct exchange of marine water with the Gulf of Mexico via Pass Cavallo, whereas the Guadalupe Estuary does not. To assess ecosystem-wide variability stations in the freshwater influenced and marine influenced zones were chosen. Two stations, which replicate each of the two treatment effects (freshwater and marine) influence, were sampled. Generally these stations were along the major axis of the estuarine system leading from river mouth to the foot of the estuary near the barrier island. This design avoids pseudoreplication, where only one station has the characteristic of the main effect, and it is not possible to distinguish between station differences and treatment differences.

The Lavaca River empties into Lavaca Bay, which is connected to Matagorda Bay. Matagorda Bay also has freshwater input from the Colorado and Tres Palacios River. Over a 47-year period (1941-1987) the Lavaca-Colorado Estuary received an average of  $3.800 \times 10^9 \text{ m}^3 \text{ y}^{-1}$  with a standard deviation of  $2.080 \text{ m}^3 \text{ y}^{-1}$  ( $3.080 \pm 1.686 \times 10^6 \text{ ac-ft y}^{-1}$ ) of freshwater input, and the freshwater balance (input-output) was  $3.392 \times 10^9 \text{ m}^3 \text{ y}^{-1}$  with a standard deviation of  $2.345 \times 10^9 \text{ m}^3 \text{ y}^{-1}$  ( $2.750 \pm 1.901 \times 10^6 \text{ ac-ft y}^{-1}$ ) (TDWR, 1980a; TWDB unpublished data). Four Stations were occupied along the axis of the system. Two stations were in Lavaca Bay (A and B), and two stations were in Matagorda Bay (C and D) (Figure 3). Depths of stations A, B, C, and D were 1.3 m, 2.0 m, 3.1 m, and 4.2 m, respectively. Five field trips were performed. Station A in Lavaca Bay was the same station 85 sampled in 1984-1986 (Jones et al., 1986).

The San Antonio River joins the Guadalupe River that flows into San Antonio Bay. Over a 46-year period the Guadalupe Estuary received an average of  $2.896 \times 10^9 \text{ m}^3 \text{ y}^{-1}$  with a standard deviation of  $1.597 \text{ m}^3 \text{ y}^{-1}$  ( $2.347 \pm 1.295 \times 10^6 \text{ ac-ft y}^{-1}$ ) of freshwater input, and the freshwater balance (input-output) was  $2.624 \times 10^9 \text{ m}^3 \text{ y}^{-1}$  with a standard deviation of  $1.722 \times 10^9 \text{ m}^3 \text{ y}^{-1}$  ( $2.127 \pm 1.396 \times 10^6 \text{ ac-ft y}^{-1}$ ) (TDWR, 1980b; TWDB unpublished data). This system was studied from January through July 1987. Four stations were occupied: freshwater influenced stations at the head of the bay (station A) and at mid-bay (station B), and two marine influenced stations near the Intracoastal Waterway, one at the southwestern foot of the bay (station C) and one at the

southeastern foot of the bay (station D) (Fig. 1). Stations were sampled five times in the first year. All stations were in shallow water. Depths of stations A, B, C, and D were 1.3 m, 1.9 m, 2.0 m, and 1.6 m, respectively.

#### *Hydrographic Measurements*

Salinity, conductivity, temperature, pH, dissolved oxygen, and redox potential were measured at the surface and bottom at each station during each sampling trip. Measurements were made by lowering a probe made by Hydrolab Instruments. Salinities levels are automatically corrected to 25°C. The manufacturer states that the accuracy of salinity measurements are 0.1 ppt. When the Hydrolab instrument was not working, water samples were collected from just beneath the surface and from the bottom in jars, and refractometer readings were made at the surface.

**Figure 1.** The Texas Coastal Bend lagoonal estuaries with major rivers, tidal inlets, and station locations.

### *Geological Measurements*

Sediment grain size analysis was also performed. Sediment core samples were taken by diver and sectioned at depth intervals 0-3 cm and 3-10 cm. Analysis followed standard geologic procedures (Folk, 1964; E. W. Behrens, personal communication). Percent contribution by weight was measured for four components: rubble (e.g. shell hash), sand, silt, and clay. A 20 cm<sup>3</sup> sediment sample was mixed with 50 ml of hydrogen peroxide and 75 ml of deionized water to digest organic material in the sample. The sample was wet sieved through a 62 µm mesh stainless steel screen using a vacuum pump and a Millipore Hydrosol SST filter holder to separate rubble and sand from silt and clay. After drying, the rubble and sand were separated on a 125 µm screen. The silt and clay fractions were measured using pipette analysis.

### *Biological Measurements*

Sediment was sampled with core tubes held by divers. The macrofauna were sampled with a tube 6.7 cm in diameter, and sectioned at depth intervals of 0-3 cm and 3-10 cm. Three replicates were taken within a 2 m radius. Samples were preserved with 5% buffered formalin, sieved on 0.5 mm mesh screens, sorted, identified to the lowest taxonomic level possible, and counted.

Each macrofauna sample was also used to measure biomass. Individuals were combined into higher taxa categories, i.e., Crustacea, Mollusca, Polychaeta, Ophiuroidea, and all other taxa were placed together in one remaining sample. Samples were dried for 24 h at 55 °C, and weighed. Before drying, mollusks were placed in 1 N HCl for 1 min to 8 h to dissolve the carbonate shells, and washed with fresh water.

### *Sediment Nitrogen Measurements*

All Texas estuaries have been studied. The Sabine-Neches and Trinity-San Jacinto Estuaries were sampled in 1993. The Lavaca-Colorado and Guadalupe Estuaries were sampled in 1990, and resampled in 1992. The Nueces Estuary and Baffin Bay were sampled in 1991. Our approach is to take sediments cores and measure nitrogen changes with respect to sediment depth. Cores are taken to a depth of 1 m. One-cm sediment sections are taken at the depth intervals listed. The sediment is dried, ground up, and homogenized. Carbon and nitrogen content, as a percent dry weight of sediment, is measured using a CHN analyzer.

*Station Locations*

Estuary	Station	Latitude (N)	Longitude (W)
Sabine-Neches	1	29.57.134	93.49.484
	2	29.54.399	93.48.462
	3	29.52.293	93.51.319
	4	29.51.596	93.51.319
	5	29.49.591	93.51.420

## RESULTS

### *Hydrographic Data*

Hydrographic measurements. Abbreviations: STA=Station, Z=Depth, SAL(R)=Salinity by refractometer, SAL(M)=Salinity by meter, COND=Conductivity, TEMP=Temperature, DO=dissolved oxygen, and ORP=oxidation redox potential. Missing values show with a period.

#### Lavaca-Colorado Estuary

### Nutrient Concentrations

Nutrient measurements take during sampling. Water depth is in m. Nutrient concentrations are in umol/l.

#### Lavaca-Colorado Estuary

### Biomass Data

Biomass is measured for taxonomic groupings. Average number and biomass from 3 replicates per m<sup>2</sup>.

### Lavaca-Colorado Estuary

## DISCUSSION

### *Long-Term Change in Benthos*

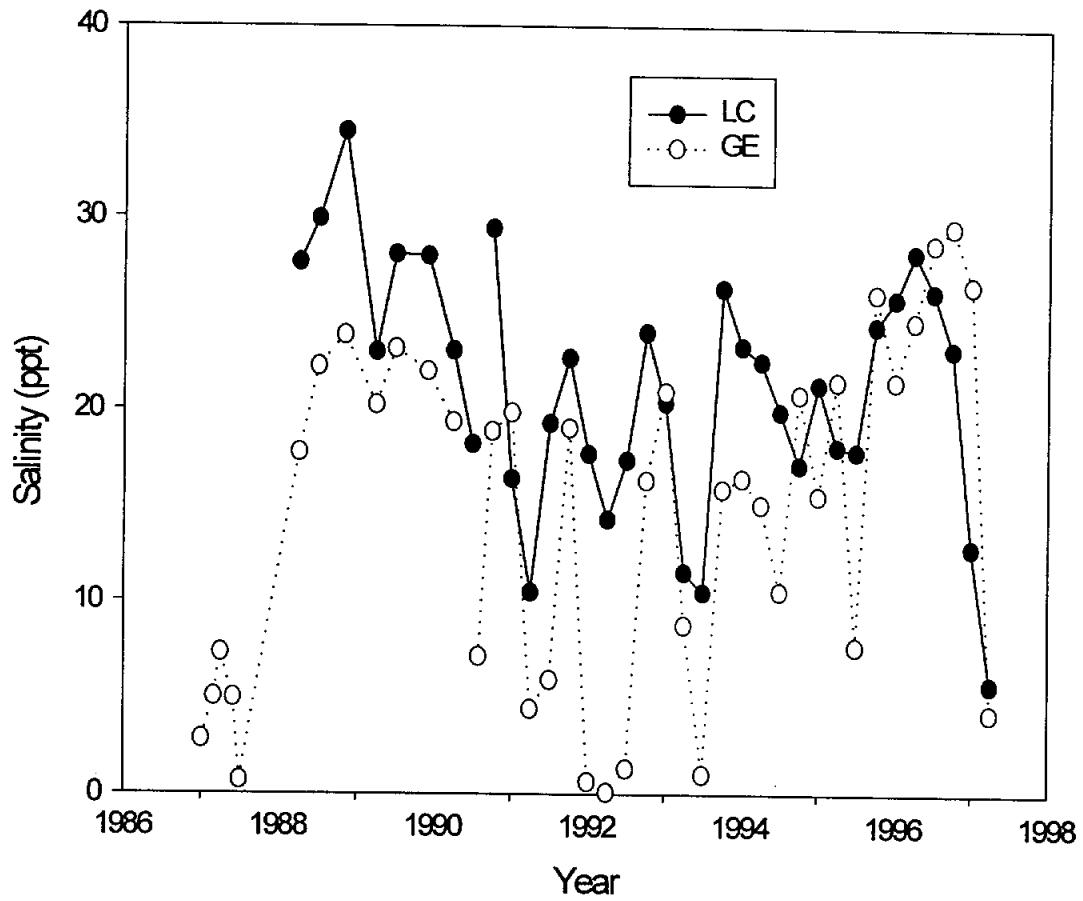

The Lavaca-Colorado and Guadalupe Estuaries are similar in the amount of freshwater inflow they receive, but different in two key attributes. The Lavaca-Colorado Estuary ( $910 \text{ km}^2$  at mean tide) is almost twice as large as the Guadalupe Estuary ( $579 \text{ km}^2$  at mean tide). The Lavaca-Colorado also has direct exchange of marine water with the Gulf of Mexico via Pass Cavallo and the Matagorda Ship Channel. Because it is smaller and has restricted exchange, the Guadalupe generally has lower salinities (average 14 ppt from 1987-1997) than the Lavaca-Colorado (average 20 ppt from 1988-1997). This indicates that freshwater inflow has a greater effect on the upper part of San Antonio Bay than on Lavaca Bay. This conclusion is supported by several pieces of data. The salinity time series show that at any given time the salinities are lower in the Guadalupe, both estuarine-wide, and particularly at stations A and B in both estuaries. The amount of total carbon in sediments is much greater in the Guadalupe than in the Lavaca-Colorado (Montagna, 1991). Carbon content of Lavaca-Colorado sediments and Guadalupe-station D sediments are about 1%, but carbon content in the Guadalupe at station C is 3%, and at stations A and B around 4%. The carbon data indicate that organic matter is being trapped or not exported from the Guadalupe Estuary. Profiles of nitrogen content exhibit the same trends found in carbon, but there is less difference in total nitrogen content between the estuaries, both being about 0.05% (Montagna, 1991). Sediment texture is similar in both estuaries, and are characterized by silt-clay sediments, with increasing grain sizes from the upper to the lower parts of the estuaries.

Macrofauna abundance and biomass is generally larger in the Guadalupe Estuary than in the Lavaca-Colorado Estuary. The average abundance in the Lavaca-Colorado among all times and stations was  $12,028 \text{ individuals} \cdot \text{m}^{-2}$ , and the average biomass was  $4.98 \text{ g} \cdot \text{m}^{-2}$ . The average abundance in the Guadalupe among all times and stations was  $22,100 \text{ individuals} \cdot \text{m}^{-2}$ , and the average biomass was  $8.18 \text{ g} \cdot \text{m}^{-2}$ . The differences between the estuaries is probably due to the greater ratio of the volume of inflow relative to size of the bays. Diversity is generally greater in the Lavaca-Colorado Estuary (average 16 species found per station-date sampling period) than in the Guadalupe Estuary (average 11 species found per station-date sampling period). These results indicate that freshwater inflow is less diluted by marine water in the Guadalupe Estuary, so we find higher benthic productivity. The greater Gulf exchange in the Lavaca-Colorado leads to more oceanic species present in the that estuary, so we find higher diversity.

**Figure 2** Long-term change in salinity in two estuaries.

The time series data show that there are large year-to-year fluctuations in both estuaries for both freshwater inflow and benthic community response. We have a continuous cycle of drought and flood conditions. The flood cycles are coincident with El Niño events in the western Pacific Ocean. So, climatic cycles in Texas are apparently caused by global changes. These cycles regulate freshwater inflow, and thus, directly affect the biological communities. The variability in the freshwater inflow cycle results in predictable changes in the estuary. Our study of the Guadalupe Estuary demonstrates the biological effects of this cycle. Flood conditions

**Figure 2** Long-term change in salinity in two estuaries.

The time series data show that there are large year-to-year fluctuations in both estuaries for both freshwater inflow and benthic community response. We have a continuous cycle of drought and flood conditions. The flood cycles are coincident with El Niño events in the western Pacific Ocean. So, climatic cycles in Texas are apparently caused by global changes. These cycles regulate freshwater inflow, and thus, directly affect the biological communities. The variability in the freshwater inflow cycle results in predictable changes in the estuary. Our study of the Guadalupe Estuary demonstrates the biological effects of this cycle. Flood conditions

abundances generally decreased during this drought period to the lowest recorded. As predicted in last years report (Montagna, 1991; p. 41) there were increased densities in the spring of 1992. The large flood of 1992 should result in densities increasing to the  $20,000 \cdot m^{-2}$  range during 1993. Time series analysis requires at least three cycles to have occurred. When we have enough data, we can fit the data to time series models.

### *Nitrogen Losses*

If nitrogen enters bays via rivers and it is buried, then we would expect higher nitrogen values in sediments at the head of estuaries. This is because river empties into the secondary bay, and more nitrogen should be trapped in the upper reaches of the bay. The station trends in all estuaries confirm this hypothesis (Figures 3 - 9). The only estuary where the trend is not strong is in the Sabine-Neches Estuary (Figure 3).

If nitrogen is utilized, or transformed in the biologically active labile zone, then there should be higher values in upper layers of sediment and lower values at lower layers in the refractory zone. This hypothesis is confirmed by the trends seen in the estuary-wide average nitrogen content (Figure 10). The labile zone appears to be between 20 and 40 cm in most estuaries. Nitrogen content in most estuarine sediment is 0.08 to 0.15 percent at the surface, and declines to 0.04 to 0.08 percent. That the refractory zone is as deep as 40 cm is surprising, but this could be due to anthropogenic influences, e.g., shrimping and dredging. It is very difficult to know how much area sampled is subject to these disturbances. An alternative hypothesis to a labile and refractory zone is that there is simply more nitrogen coming into bays today than at previous times. This would also explain the vertical distribution of nitrogen content in sediments. In contrast, Laguna Madre has the highest nitrogen content, 0.2 at the surface and 0.15 at depth, due to seagrass detritus.

Man can influence another key component that affects nitrogen loss. In general, it is thought that the sedimentation rate in Texas estuaries is about 1 cm per 100 years (Behrens, 1980). However, recent water projects, particularly dams, have probably decreased this rate. An average nitrogen background level, i.e., the average content at about 40 cm is about 0.05%. The average surface nitrogen content is about 0.1%, so the change between the labile and refractory zone is a factor of 2. This implies that half of the nitrogen arriving at the sediment surface is lost to the system via burial.

## CONCLUSION

The main difference between the Guadalupe and Lavaca-Colorado Estuaries relate to both size and Gulf exchange. Freshwater inflow has a larger impact on the smaller-restricted Guadalupe Estuary than in the Lavaca-Colorado. Both the smaller size and restricted inflow have synergistic effects, thus the Guadalupe is generally fresher and has higher carbon content than the Lavaca-Colorado. These conditions lead to higher benthic productivity in the Guadalupe Estuary. On the other hand, higher salinities and invasion of marine species is responsible for a more diverse community in Lavaca-Colorado Estuary. There is long-term, year-to-year variability in inflow that drives benthic community succession, and results in different levels of productivity from year-to-year. It is now apparent that the long-term changes may be related to global climate cycles, e.g., El Niño events in the western Pacific Ocean. By October 1993, we will have sample one complete cycle from beginning to end to beginning.

Nitrogen is lost within the top 20 cm of sediment. Profiles of nitrogen content do not generally decline with depth beyond the top 20 cm. Laguna Madre sediments has the highest nitrogen content of all Texas estuaries.
