EXECUTIVE SUMMARY

ES1.1 INTRODUCTION

This Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) analyzes the potential environmental consequences that may result from the United States (U.S.) Department of the Navy's Proposed Action and alternatives. The Proposed Action presented in this EIS/OEIS addresses ongoing and proposed activities within the Navy's existing Hawaii Range Complex (HRC) and represents current and anticipated future use of the "existing footprint." This EIS/OEIS contains analysis of research, development, test, and evaluation (RDT&E) of new technologies used by the Navy and other Federal agencies, including the Missile Defense Agency.

This EIS/OEIS has been prepared by the Department of the Navy in compliance with the National Environmental Policy Act (NEPA) of 1969 (42 United States Code [U.S.C.] § 4321 et seq.) and Executive Order (EO) 12114, *Environmental Effects Abroad of Major Federal Actions*.

The Navy is the lead for the EIS/OEIS; the National Marine Fisheries Service (NMFS), Missile Defense Agency, U.S. Department of the Army, and the U.S. Department of Energy are cooperating agencies. Additionally, the Navy has worked with experts from the State of Hawaii and other Federal agencies to ensure that the effects on the environment of the Navy's Proposed Action are fully assessed in this document.

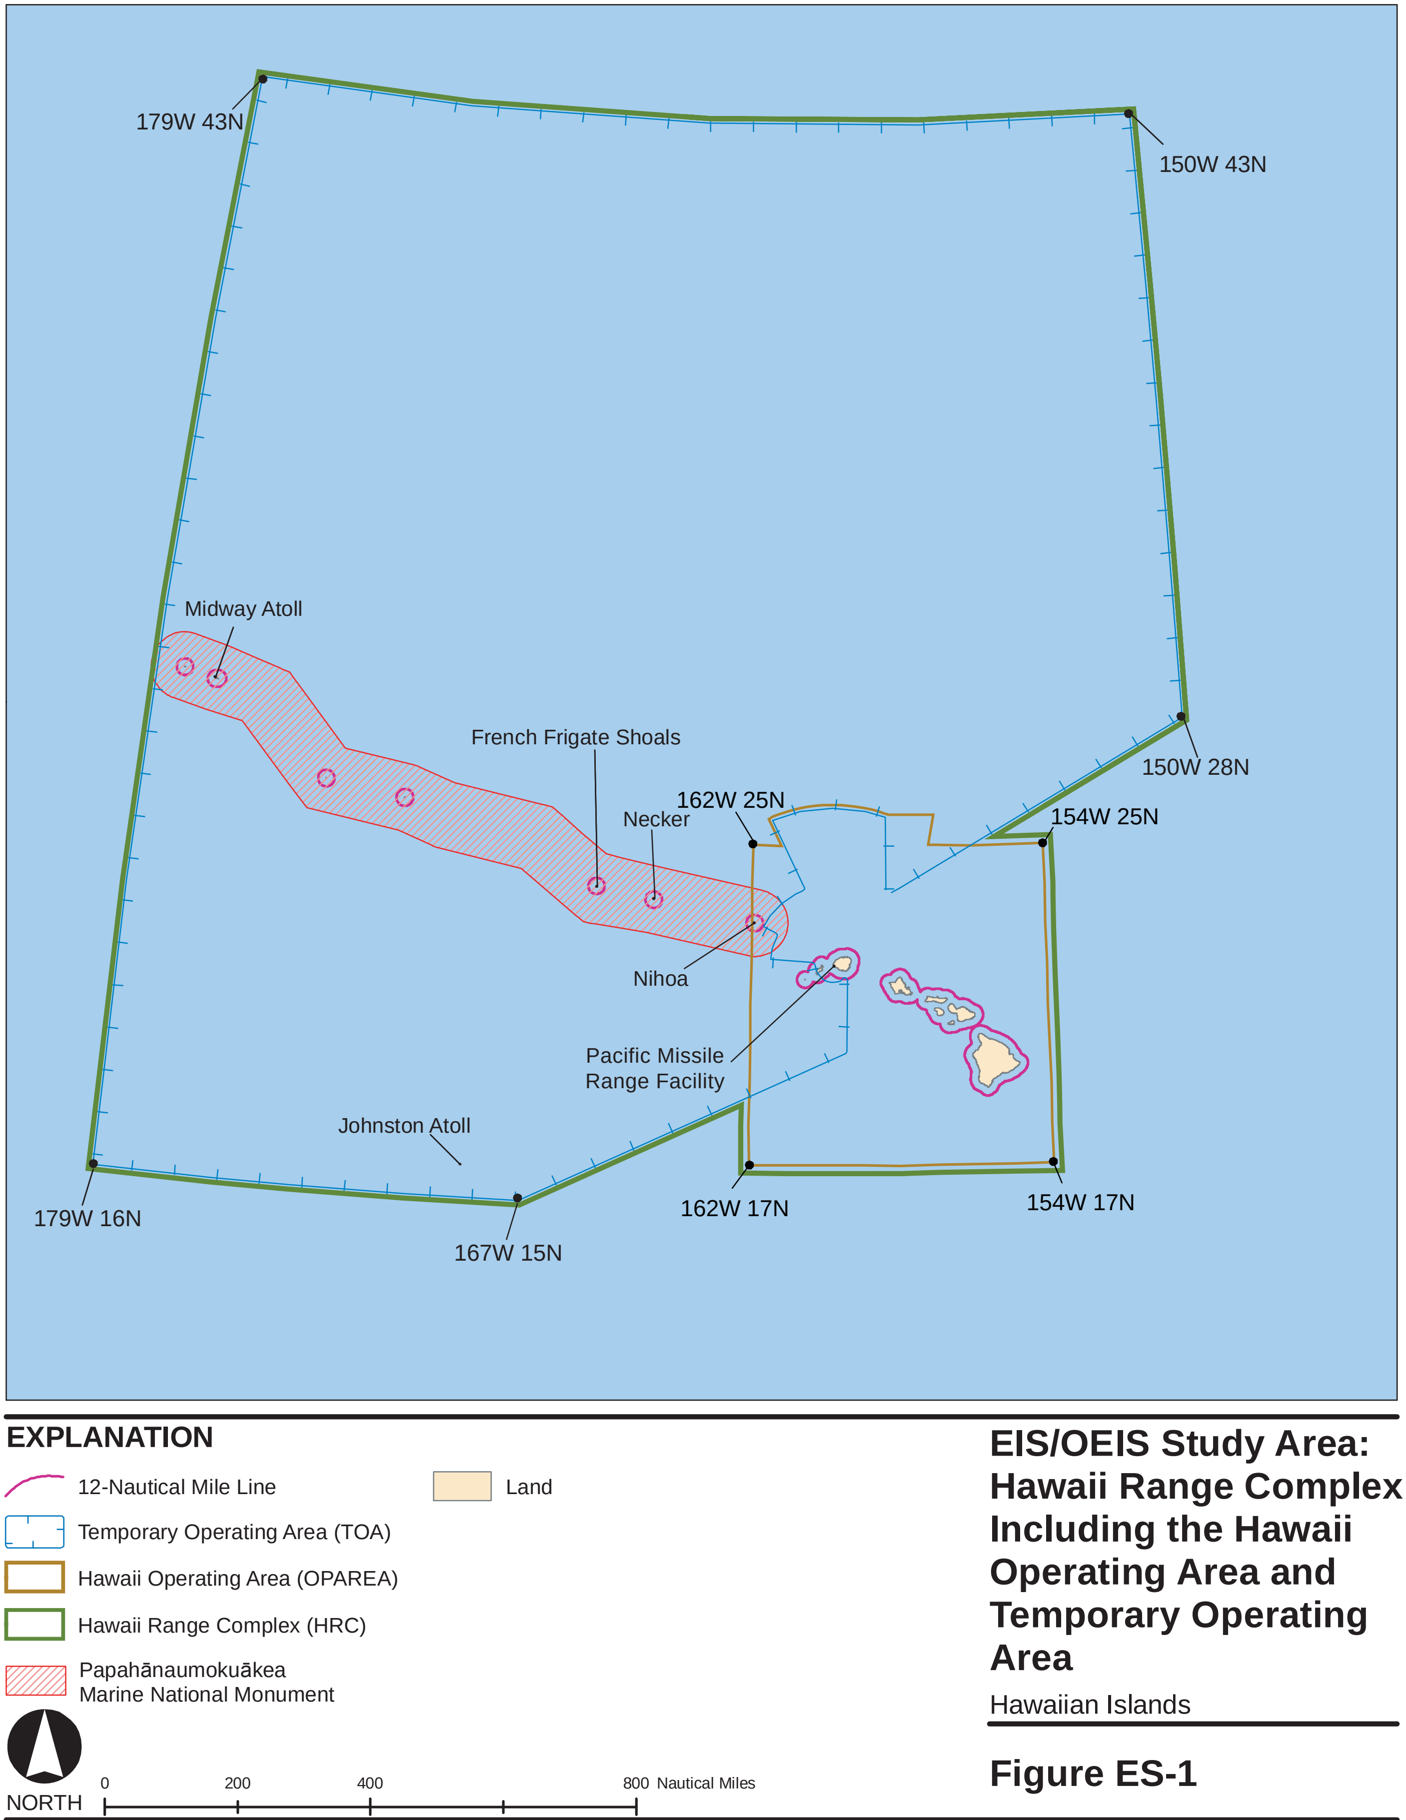
The HRC geographically encompasses the open ocean (outside 12 nautical miles [nm] from land), offshore waters (within 12 nm from land), and onshore areas located on or around the islands of the Hawaiian Islands chain (Figure ES-1).

There are three component areas of the HRC: (1) the Hawaii Operating Area (OPAREA) (includes surface and subsurface ocean areas and special use airspace); (2) the Temporary Operating Area (TOA) (composed of sea and airspace north and west of Kauai for RDT&E activities); and (3) various Navy land ranges and other Services' land for military training and RDT&E activities.

ES1.2 PURPOSE AND NEED

The purpose of the Proposed Action is to achieve and maintain fleet readiness using the HRC to support and conduct current, emerging, and future training and RDT&E activities, and enhance training resources through investment on the ranges. The mission of the HRC is to support naval operational readiness by providing a realistic, live training environment for forces assigned to the Pacific Fleet, the Fleet Marine Force, and other users.

The need for the Proposed Action is to enable the Navy to meet its statutory responsibility under Title 10 Sections 5013 and 5062 to organize, train, equip, and maintain combat-ready naval forces and to successfully fulfill its current and future global mission of winning wars, deterring aggression, and maintaining freedom of the seas. Activities involving RDT&E for Department of Defense (DoD) or Navy systems are an integral part of this readiness mandate.



EIS/OEIS Study Area: Hawaii Range Complex Including the Hawaii Operating Area and Temporary Operating Area

Hawaiian Islands

Figure ES-1

The HRC plays a vital part in the execution of this naval readiness mandate. The Hawaii area is home to a large concentration of U.S. naval forces. Naval forces based in Hawaii and those transiting across the Pacific Ocean use and rely on the HRC because of its capabilities and strategic location in the mid-Pacific region. The Navy's Proposed Action is essential to ensure the continued vitality of this training resource.

ES1.2.1 WHY THE NAVY TRAINS

The U.S. military is maintained to ensure the freedom and safety of all Americans both at home and abroad. In order to do so, Title 10 of the U.S.C requires the Navy to "maintain, train and equip combat-ready naval forces capable of winning wars, deterring aggression and maintaining freedom of the seas." Modern war and security operations are complex. Modern weaponry has brought both unprecedented opportunity and innumerable challenges to the Navy. Smart weapons, used properly, are accurate and allow the Navy to accomplish its mission with greater precision and less destruction than in past conflicts. U.S. military personnel must train regularly with these modern, complex weapons in order to understand their capabilities, limitations, and operation. Modern military actions require teamwork between hundreds or thousands of people, and their various equipment, vehicles, ships, and aircraft, all working individually and as a coordinated unit to achieve success. Navy training addresses all aspects of the team, from the individual to joint and coalition teamwork. To do this, the Navy employs a building-block approach to training. Training doctrine and procedures are based on operational requirements for deployment of naval forces. Training proceeds on a continuum, from teaching basic and specialized individual military skills, to intermediate skills or small unit training, to advanced, integrated training events, culminating in multi-service (Joint) exercises, coalition or combined exercises (with allied nations participating), or pre-deployment certification events.

In order to provide the experience so important to success and survival, training must be as realistic as possible. The Navy often employs simulators and synthetic training to provide early skill repetition and to enhance teamwork, but live training in a realistic environment is vital to success. Live training requires sufficient sea and airspace to maneuver tactically, realistic targets and objectives, simulated opposition that creates a realistic enemy, and instrumentation that monitors the events and provides essential feedback.

Range complexes, like the HRC, provide a controlled and safe environment with threat-representative targets that allow Navy forces to conduct realistic training as Navy men and women undergo all phases of the graduated buildup needed for combat-ready deployment. The range complexes are designed to provide the most realistic training in the most relevant environments, replicating to the greatest extent possible the operational stresses of warfare. The integration of undersea ranges and OPAREAs with land training ranges, safety landing fields, and amphibious landing sites are critical to this realism, allowing execution of multi-dimensional exercises in complex scenarios. The live-fire phase of training is fundamental to the adequate assessment of weapon precision under stressful conditions. Live training, most of it accomplished in the waters off the United States' coasts, will remain the cornerstone of readiness as the Navy prepares its military forces for a security environment characterized by uncertainty and surprise.

ES1.2.2 STRATEGIC IMPORTANCE OF THE EXISTING HAWAII RANGE COMPLEX

The HRC is used for training and assessment of operational forces, missile training, RDT&E of military systems and equipment, and other military activities. The HRC is characterized by a unique combination of attributes that make it a strategically important range complex for the Navy. These attributes include:

- Proximity to the homeport of Pearl Harbor
- Proximity to the Western Pacific
- Proximity to military families based in Hawaii
- New training terrain for west coast based naval forces

Refer to Section 1.3.5 of Chapter 1.0 for a detailed description of these attributes.

The large training area available to deployed forces within the HRC allows training to take place using a geographic scope that replicates possible real world events, with the channels between islands providing geography necessary for opposed transit scenarios. The presence of the instrumented tracking ranges at the Pacific Missile Range Facility (PMRF) as well as DoD-controlled warning areas and special use airspace also allow safe and structured training with sufficient flexibility to interject tactical challenges to enhance realism for exercise participants. Exercise participants at sea can conduct air strike sorties to Pohakuloa Training Area (PTA) and an Expeditionary Strike Group (ESG) can conduct amphibious landing on DoD beaches, while each simultaneously conducts Anti-Submarine Warfare (ASW) training. Finally, the presence of submarines homeported at Pearl Harbor allows for a readily available opposition force during the training event without having to transit to participate in the exercise events.

ES1.3 SCOPE AND CONTENT OF THE EIS/OEIS

The Navy’s analysis of environmental effects under NEPA includes areas of the HRC that lie within the territorial seas, which extend 12 nm from land. The environmental effects in the ocean areas that are outside of U.S. territorial seas are analyzed under EO 12114 and associated implementing regulations.

ES1.3.1 NATIONAL ENVIRONMENTAL POLICY ACT (NEPA)

In 1969, Congress enacted NEPA, which provides for the consideration of environmental issues in Federal agency planning and decision-making. Regulations for Federal agency implementation of the act were established by the President’s Council on Environmental Quality (CEQ). NEPA requires that Federal agencies prepare an EIS if the agency’s proposed action might significantly affect the quality of the human environment. The EIS must disclose significant environmental impacts and inform decision makers and the public of the reasonable alternatives to the proposed action. Presidential Proclamation 5928, issued December 27, 1988, extended the exercise of United States sovereignty and jurisdiction under international law to 12 nm; however, the Proclamation expressly provides that it does not extend or otherwise alter existing Federal law or any associated jurisdiction, rights, legal interests, or obligations.

However, as a matter of policy, the Navy analyzes environmental effects and actions within 12 nm under NEPA and those effects occurring beyond 12 nm under the provisions of EO 12114.

This EIS/OEIS provides an assessment of the potential environmental impacts associated with sustainable range usage and enhancements within the Navy's HRC. The Navy completed the Supplement to the 2002 Rim of the Pacific (RIMPAC) Programmatic Environmental Assessment in May 2006 and the Undersea Warfare Exercise (USWEX) Programmatic Environmental Assessment in October 2007. This EIS/OEIS analyzes the continuation of these exercises in the baseline analysis. It also analyzes Navy training that currently occurs or is proposed to occur in open ocean, offshore, and onshore areas of the HRC.

The first step in the NEPA process is the publication of a Notice of Intent (NOI) to prepare an EIS. The NOI provides an overview of the proposed action and the scope of the EIS. The NOI for this project was published in the *Federal Register* on August 29, 2006, and in five local newspapers (i.e., *Honolulu Advertiser*, the *Honolulu Star Bulletin*, the *Maui News*, the *Hawaii Tribune Herald*, and the *Garden Island*) on September 2, 4, and 5, 2006.

Scoping is an early and open process for developing the "scope" of issues to be addressed in the EIS and for identifying significant issues related to a proposed action. During scoping, the public helps define and prioritize issues and convey these issues to the agency through both oral and written comments. The scoping period for the HRC EIS/OEIS began with the publication of an NOI. The scoping period lasted 46 days, concluding on October 13, 2006. Four scoping meetings were held on September 13, 14, 16, and 18, 2006 on the islands of Maui, Oahu, Hawaii, and Kauai, respectively. The scoping meetings were held in an open house format, presenting informational posters and written information, and making Navy staff and project experts available to answer participants' questions. Additionally, a court reporter was available to record participants' oral comments. This format allowed the public to interact informally, one-on-one, with project representatives or comment formally, on the record, to representatives of the Navy.

In addition to the scoping meetings, the public could make comments through a toll-free telephone number, by sending an email, or by mailing a written comment. Issues identified by the public were provided to resource specialists working on the EIS/OEIS to ensure that all comments were considered during the preparation of the document.

After scoping, the Draft EIS/OEIS was prepared to provide an assessment of the potential impacts of the Proposed Action and alternatives on the environment. Public hearings were conducted during the review process in Kauai (Lihue), Oahu (Honolulu), Maui (Wailuku), and Hawaii (Hilo). The Draft EIS/OEIS was circulated for public review and the comment period concluded on September 17, 2007. Approximately 2,500 public comments were received and appropriately incorporated into this EIS/OEIS. Responses to public comments on the Draft EIS/OEIS may be found in Chapter 13.0.

During the scoping and public review process, members of the public and non-governmental environmental organizations expressed concerns on a variety of topics. One of the issues receiving the most comments related to the potential effects associated with mid-frequency active (MFA) sonar use and testing in the HRC. These concerns are addressed in this EIS/OEIS.

The Navy recognizes that the potential impact on marine mammals caused by the use of sonar is controversial. Based on continued coordination with NMFS, the Navy has used best available science as the basis to assess impacts on marine mammals caused by MFA and high-frequency active (HFA) sonar used by a particular torpedo. The best available science has been used as a basis for development of the "Risk Function" model for predicting potential exposures of marine mammals to Navy MFA and HFA sonar use that will result in behavioral effects. What this model cannot do yet is to include in its calculations reductions in the behavioral effects estimates resulting from all of the procedures that the Navy has in place to protect marine mammals. These include personnel training, pre- and post-exercise surveys, power-down and power-off requirements for the sonar when mammals are within certain distances of the sound source, and passive detection of marine mammals.

During the public hearings, it was clear that many of those voicing concern were unaware that the training and testing activities proposed for the HRC are not new activities and have been occurring for approximately 40 years. No known marine mammal strandings directly related to Navy activities have occurred during this time. Nonetheless, by design, the Navy has taken an approach to modeling that calculates the maximum potential exposures to marine mammals to account for uncertainties in existing scientific data.

Since the publication of the Draft EIS/OEIS, the Navy, in coordination with the NMFS, re-analyzed the effects that MFA sonar has on marine mammals. This re-evaluation and consequent proposed changes to the Draft EIS/OEIS led the Navy to prepare a Supplement to the Draft EIS/OEIS. Accordingly, this EIS/OEIS incorporates the following changes and associated environmental analysis as presented in the Supplement to the Draft EIS/OEIS:

- Modifications to the analytical methodology used to evaluate the effects of MFA sonar on marine mammals;
- Changes to the amount and types of sonar allocated to each of the alternatives; and,
- The development of a new alternative.

The NOI for the Supplement to the Draft EIS/OEIS was published in the *Federal Register* on January 17, 2008. The Supplement to the Draft EIS/OEIS was circulated for public review, and the comment period ended on April 7, 2008. Responses to all comments on the Supplement to the Draft EIS/OEIS are presented in Chapter 14.0 of this document.

There is a 30-day wait period following the publication of the Notice of Availability of the Final EIS/OEIS in the Federal Register. At the conclusion of this wait period, the Navy will decide the action it will implement through its Record of Decision (ROD) which will be published in the Federal Register. The ROD will summarize the final decision and identify the selected alternative, describe the public involvement and agency decision-making processes, and present commitments to specific mitigation measures. The selected decision can then be implemented.

ES1.3.2 EXECUTIVE ORDER (EO 12114)

Environmental effects in the areas that are beyond the U.S. territorial sea are analyzed under EO 12114 and associated implementing regulations.

ES1.3.3 MARINE MAMMAL PROTECTION ACT, ENDANGERED SPECIES ACT COMPLIANCE

The Marine Mammal Protection Act (MMPA) of 1972 established, with limited exceptions, a moratorium on the “taking” of marine mammals in waters or on lands under U.S. jurisdiction. Section 101(a)(5) of the MMPA directs the Secretary of Commerce to allow, upon request, the incidental, but not intentional, taking of marine mammals by U.S. citizens who engage in a specified activity (exclusive of commercial fishing). In support of the Proposed Action, the Navy applied for a Letter of Authorization from NMFS pursuant to Section 101(a) (5) (A) of the MMPA. NMFS intends to publish a proposed rule for public comment coincident with the publication of this EIS/OEIS, and anticipates issuing the final authorization toward the end of Calendar Year 2008.

On January 23, 2007, the Deputy Secretary of Defense exempted all military readiness activities employing MFA sonar or Improved Extended Echo Ranging (IEER) sonobuoys from compliance with the requirements of the MMPA for a period of 2 years. This exemption is limited to Major Exercises or training and RDT&E activities within established operating areas or established DoD maritime ranges. This National Defense Exemption (NDE) remains in effect until January 23, 2009 or authorization under the MMPA, whichever is earliest.

The NDE will cover MFA sonar and IEER sonobuoy activities on the HRC until an MMPA authorization is issued for these activities or the NDE expires whichever is earliest. While the NDE remains applicable (until an MMPA authorization is issued), the Navy will continue to employ the marine mammal mitigation measures outlined in Chapter 6.0 of this EIS/OEIS to protect marine mammals while training with the use of MFA sonar. These measures include safety zones around ships and trained lookouts based on coordination of science-based measures with NMFS. Additional measures that may be required as a result of the MMPA authorization would be implemented once authorization is received.

The Endangered Species Act (ESA) requires that Federal agencies, in consultation with the responsible wildlife agency, ensure that proposed actions are not likely to jeopardize the continued existence of any endangered species or threatened species, or result in the destruction or adverse modification of a critical habitat. Regulations implementing the ESA consultation requirement also include those actions that “may affect” a listed species or adversely modify critical habitat.

As part of the environmental documentation for this EIS/OEIS, and as an MMPA permit applicant, the Navy entered into early consultation procedures with NMFS, endangered species division. The Navy has been actively engaged in consultation with NMFS regarding the potential effects on ESA-listed species from the conduct of the activities outlined in this EIS/OEIS. In accordance with 50 Code of Federal Regulations (CFR) §402.11, prior to the issuance of the ROD, NMFS will issue a Preliminary Biological Opinion documenting its determination as to whether the activities conducted in the HRC are likely to jeopardize the continued existence of ESA-listed species, or result in the destruction or adverse modification of critical habitat. Additionally, a preliminary Incidental Take Statement will accompany the preliminary Biological Opinion. Because the Section 7 consultation is simultaneously conducted internally to address NMFS' issuance of an MMPA authorization, an Incidental Take Statement for marine mammals cannot be issued until an MMPA authorization is issued.

The Preliminary Biological Opinion and Preliminary Incidental Take Statement do not exempt the Navy from the prohibitions of Section 9 of the ESA. Further, the Navy has determined that activities occurring in the HRC prior to the issuance of an MMPA authorization (e.g., RIMPAC, USWEX, etc.) may affect endangered species in the HRC, and may incidentally take ESA-listed species, thus requiring consultation under the ESA and an associated Incidental Take Statement. As such, the Navy and NMFS are engaged in a separate Section 7 consultation on these specified activities. A separate Biological Opinion and Incidental Take Statement will be issued, as appropriate, for this subset of specified activities, which will occur prior to the issuance of the MMPA authorization and be covered by the NDE.

ES1.3.4 OTHER ENVIRONMENTAL REQUIREMENTS CONSIDERED

The Navy must comply with a variety of other Federal environmental laws, regulations, and EOs. These include (among other applicable laws and regulations):

- Migratory Bird Treaty Act;
- Coastal Zone Management Act;
- Rivers and Harbors Act;
- Magnuson-Stevens Fishery Conservation and Management Act;
- Clean Air Act;
- Federal Water Pollution Control Act (Clean Water Act);
- National Historic Preservation Act;
- EO 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations
- EO 13045, Environmental Health and Safety Risks to Children;
- EO 13423, *Strengthening Federal Environmental, Energy and Transportation Management;*
- EO 13089, *Coral Reef Protection;* and
- National Marine Sanctuaries Act.

In addition, laws and regulations of the State of Hawaii appropriate to Navy actions are identified and addressed in this EIS/OEIS. To the extent practicable, this document will be used as the basis for any required consultation and coordination.

ES1.4 PROPOSED ACTION AND ALTERNATIVES

The Proposed Action presented in this EIS/OEIS addresses ongoing and proposed activities within the Navy's existing HRC and contains analyses of RDT&E of new technologies used by the Navy and other Federal agencies.

ES1.4.1 ALTERNATIVES DEVELOPMENT

NEPA requires that an EIS evaluate the environmental consequences of a range of reasonable alternatives. Guidance for the development of alternatives is provided in CEQ regulations (40 CFR § 1502.14) and Navy procedures described in 32 CFR § 775. Reasonable alternatives must meet the stated purpose and need of the Proposed Action.

ES1.4.2 ALTERNATIVES ELIMINATED FROM FURTHER CONSIDERATION

The Navy eliminated alternatives from further consideration. Specifically, the following alternatives (described in Chapter 2.0) were not carried forward for analysis:

- Reduction or Elimination of Training in the Hawaii Range Complex
- Alternative Locations for Training Conducted in the Hawaii Range Complex
- Computer Simulation Training

After careful consideration, none of these alternatives meet the Navy's purpose and need for the Proposed Action.

ES1.4.3 ALTERNATIVES CONSIDERED

Alternatives were selected based on their ability to meet the following criteria, which were developed from the purpose and need for the Proposed Action: (1) use existing Navy ranges and facilities in and around Hawaii; (2) be consistent with the stated current and emerging requirements for the range complex; (3) achieve training tempo requirements based on Fleet deployment schedules; (4) meet the requirements of DoD Directive 3200.15, Sustainment of Ranges and Operating Areas; (5) implement new training requirements and RDT&E activities; and (6) support realistic training that replicates expected operating environments for naval forces. Four alternatives are analyzed in the EIS/OEIS, including three action alternatives (Alternatives 1, 2, and 3) and the No-action Alternative.

ES1.4.3.1 No-Action Alternative

The No-action Alternative is required by CEQ regulations as a baseline against which the impacts of the Proposed Action are compared. In the EIS/OEIS, the No-action Alternative is represented by baseline training and RDT&E operations at current levels, including more than 9,300 training and RDT&E activities in the HRC annually. Training events, including those that make up Major Exercises (RIMPAC Exercise and five USWEXs) and RDT&E activities, would continue at the baseline levels. Ongoing training events include Anti-Air Warfare, Amphibious Warfare, Anti-Surface Warfare, ASW, Electronic Combat, Mine Warfare, Naval Special Warfare, and Strike Warfare Exercises. The No-action Alternative includes support activities such as

Command and Control, in-port ship and aircraft support, and personnel support. RDT&E activities occur primarily at one of two locations in Hawaii: PMRF and Naval Undersea Warfare Center Detachment Pacific ranges.

ES1.4.3.2 Alternative 1

Alternative 1 includes all ongoing Navy training associated with the No-action Alternative, and proposes an increased number of such training events. The Navy proposes to increase both the tempo and the frequency of training exercises in the HRC. Alternative 1 includes the addition of Field Carrier Landing Practice (FCLP), a series of touch-and-go landings to train and qualify pilots for aircraft carrier landings at PMRF airfield on Kauai and Marine Corps Base Hawaii (MCBH) on Oahu. The Navy proposes to enhance and add RDT&E activities above current levels.

ES1.4.3.3 Alternative 2

Alternative 2 would include all of the activities described in Alternative 1, plus a further increased tempo and frequency of training events, future RDT&E programs at PMRF, and the addition of Major Exercises, such as supporting three Carrier Strike Groups training at the same time.

ES1.4.3.4 Alternative 3 (Preferred Alternative)

The only difference between Alternative 2 and Alternative 3 is the amount of MFA/HFA sonar usage. Alternative 3 would include all of the training associated with Alternative 2. As described under Alternative 2, Alternative 3 would provide increased flexibility in training activities by increasing the tempo and frequency of training events, future and enhanced RDT& E activities, and the addition of Major Exercises. Alternative 3 would consist of sonar usage as analyzed under the No-action Alternative. Sonar hours for Alternative 3 and effects associated with ASW training would be identical to that presented under the No-action Alternative.

Alternative 3 is the preferred alternative because it allows the Navy to meet its future non-ASW training and RDT&E mission objectives while maintaining historic levels of ASW training to avoid increases in potential effects to marine mammals in the HRC. At this time, the Navy believes that its ASW requirements will be met based on the No-action Alternative sonar hours.

ES1.5 SPORTS DATA

The data from the Sonar Positional Reporting System (SPORTS) provided a foundation for the sonar hours analyzed under each of the Alternatives. SPORTS is a database tool established by Commander, U.S. Fleet Forces Command in mid-2006. All commands employing MFA sonar and sonobuoys are required to populate the SPORTS database by reporting MFA sonar use. A review by senior officers determined that SPORTS data would be used in this EIS/OEIS in conjunction with previous planning data to assist in determining the amount of MFA sonar use for purposes of modeling potential effects on marine mammals.

The types of sonar sources used as part of ASW activities within the HRC are listed below:

- Surface ship sonar (AN/SQS-53 and AN/SQS-56)
- Helicopter dipping sonar (AN/AQS-22)
- Aircraft deployed sonobuoys (AN/SSQ-62)
- Submarine sonar (BQQ-10, BQQ-5, BSY-1)
- MK-48 torpedo

Table ES-1 presents a comparison of the sonar used for each of the alternatives analyzed. The majority of training and RDT&E activities in the HRC involve five types of narrowband sonars. Exposure estimates are calculated for each sonar according to the manner in which it operates. For example, the AN/SQS 53 and AN/SQS 56 are hull-mounted, MFA surface ship sonars that operate for many hours at a time (although sound is output—the “active” portion—only a small fraction of that time), so it is most useful to calculate and report surface ship sonar exposures per hour of operation. The BQQ-10 submarine sonar is also reported per hour of operation. However, the submarine sonar is modeled as pinging only twice per hour. The AN/AQS-22 is a helicopter-deployed sonar, which is lowered into the water, pings several times, and then moves to a new location; this sonar is used for localization and tracking a suspected contact as opposed to searching for contacts. For the AN/AQS-22, it is most helpful to calculate and report exposures per dip. The AN/SSQ-62 is a sonobuoy that is dropped into the water from an aircraft or helicopter and pings about 10 to 30 times in an hour. For the AN/SSQ-62, it is most helpful to calculate and report exposures per sonobuoy. For the MK-48 torpedo the sonar is modeled for a typical training event and the MK-48 reporting metric is the number of torpedo runs. See Table J-2 of Appendix J for a presentation of the deployment platform, frequency class, the metric for reporting exposures, and the units for each sonar.

Note that sonar usage for Alternative 3 and effects associated with ASW training would be identical to that presented under the No-action Alternative.

Table ES-1. Summary of Sonar Usage for Each Alternative

No-action Totals		
	Source	**Modeled**
	53	1,284 hours
	56	383 hours
	Dipping	1,010 dips
	Sonobuoy	2,423 buoys
	MK-48	313 runs
	Submarine	200 hours
Alternative 1 Totals		
	Source	**Modeled**
	53	1,788 hours
	56	551 hours
	Dipping	1,517 dips
	Sonobuoy	3,127 buoys
	MK-48	317 runs
	Submarine	200 hours

Table ES-1. Summary of Sonar Usage for Each Alternative (Continued)

	Source	Modeled
Alternative 2 Totals		
	Source	**Modeled**
	53	2,496 hours
	56	787 hours
	Dipping	1,763 dips
	Sonobuoy	3,528 buoys
	MK-48	374 runs
	Submarine	200 hours
Alternative 3 Totals		
	Source	**Modeled**
	53	1,284 hours
	56	383 hours
	Dipping	1,010 dips
	Sonobuoy	2,423 buoys
	MK-48	313 runs
	Submarine	200 hours

ES1.6 SUMMARY OF ENVIRONMENTAL EFFECTS

Environmental effects which might result from the implementation of the Navy's Proposed Action or alternatives have been analyzed in this EIS/OEIS. Resource areas analyzed included airspace, biological resources, cultural resources, hazardous materials and waste, health and safety, noise, water resources, geology and soils, land use, socioeconomics, transportation, and utilities. A summary of effects on the above-referenced resources where applicable have been addressed in Table ES-2 for Open Ocean areas, Table ES-3 for the Northwestern Hawaiian Islands, Tables ES-4 for Kauai, Tables ES-5 for Oahu, Table ES-6 for Maui, and Table for ES-7 for Hawaii. A detailed analysis of effects is provided in Chapter 4.0.

A comparison of the environmental impacts of the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 is presented in Tables ES-2 through ES-7. These tables summarize the conclusions of the analyses made for each of the areas of environmental consideration based on the application of the described methodology. Only those activities for which a potential environmental concern was determined at each location are described for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3.

ES1.6.1 CUMULATIVE IMPACTS

The analysis of cumulative impacts considers the effects of the Proposed Action in combination with other past, present, and reasonably foreseeable future actions taking place in the project area, regardless of what agency or person undertakes these actions. This EIS/OEIS analyzes cumulative impacts associated with implementation of Navy-sponsored activities and other non-Navy activities in the region. The cumulative project list includes over 140 Federal, State, and local projects ranging from minor construction to major infrastructure type projects, as well as various military training projects. Other activities included Commercial Fishing, Commercial and Recreational Vessel Traffic, Coastal Development Activities, Environmental Contamination and

Biotoxins, and Scientific Research Permits. Potential cumulative impacts resulting from other relevant projects (such as those listed above) combined with the Proposed Action addressed in this EIS/OEIS were determined to be less than significant.

ES1.6.2 MITIGATION MEASURES

The Navy is a global environmental leader. As part of the Navy's commitment to sustainable use of resources and environmental stewardship, the Navy incorporates mitigation measures that are protective of the environment into all of its activities. The Navy's current mitigation measures reflect a balance between training requirements and the Navy's important role in ensuring environmental protection. These measures have been the subject of extensive discussions between NMFS and the Navy, and evaluated for mission impacts, probable effectiveness, and the ability to implement. Mitigation measures are described in detail in Chapter 6.0.

Mitigation measures identified to reduce effects or ensure no future impacts occur are provided in Table ES-8.

ES1.6.3 OTHER NEPA CONSIDERATIONS

ES1.6.3.1 Conflicts with Federal, State, and Local Land Use Plans, Policies, and Controls for the Area Concerned

Based on an evaluation of consistency with statutory obligations, the Navy's proposed training and RDT&E activities for the HRC do not conflict with the objectives or requirements of Federal, State, regional, or local plans, policies, or legal requirements. The proposed training and RDT&E activities would not alter the use of the sites that currently support missile testing. Enhancement of the HRC would be in accordance with applicable Federal, State, and local planning plans and policies. The DoD maintains Federal jurisdiction for on-installation land use.

ES1.6.3.2 Energy Requirements and Conservation Potential

The proposed training and RDT&E activities include increased training events in the HRC. In order to implement the proposed training and RDT&E activities, increased amounts of fossil fuels would be required to power the increased use by ships and aircraft. These fuels are currently in adequate supply from either Navy owned sources or from commercial distributors. The required electricity demands would be met by the existing electrical generation infrastructure on the Hawaiian Islands. Anticipated energy requirements of the continued use and enhancement of the HRC would be well within the energy supply capacity of all facilities. Energy requirements would be subject to any established energy conservation practices at each facility. No additional power generation capacity other than the potential use of generators would be required for any of the training and RDT&E activities. The use of energy sources has been minimized wherever possible without compromising safety, training, or testing events. No additional conservation measures related to direct energy consumption by the proposed training and RDT&E activities are identified.

ES1.6.3.3 Irreversible or Irretrievable Commitment of Resources

The proposed training and RDT&E activities would have an irreversible or irretrievable effect due to the use of nonrenewable energy sources: hydrocarbon fuels for aircraft, vessels, and vehicles. However, among the alternative training scenarios there are no significant differences in the cost of fuel and the climatic consequences of large-scale combustion of hydrocarbon fuel. Implementation of the proposed training and RDT&E activities would not result in the destruction of environmental resources so as to cause the potential uses of the environment of the HRC to be limited. The proposed training and RDT&E activities would not adversely affect the biodiversity or cultural integrity within the HRC including the open ocean, offshore, onshore, or human environment.

ES1.6.3.4 Relationship Between Short-Term Environmental Impact and Long-Term Productivity

The Navy is committed to sustainable range management. Effective, sustainable range management addresses both short- and long-term effects on the human environment and strives to ensure the long-term productivity and availability of vital range training resources. The Navy is committed to the co-use of the HRC and surrounding areas with the general public and, for the open ocean areas, international community. This commitment to co-use is incorporated in the Navy's long-term range management and will enhance the long-term productivity of the range and surrounding areas for the public and commercial interests.

Table ES-2. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Open Ocean

Resource Category	Open Ocean
Airspace	No-action: No airspace impacts were identified in the analysis presented in Chapter 4.0. Any potential impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, compliance with Department of Defense (DoD) Directive 4540.1, Office of the Chief of Naval Operations Instruction (OPNAVINST) 3770.4A, OPNAVINST 3721.20, and continued close coordination with the Federal Aviation Administration (FAA). No modifications or need for additional airspace are required. Alternative 1: No airspace impacts were identified in the analysis presented in Chapter 4.0. Any potential impacts on airspace from increased training activities, increased research, development, test, and operation (RDT&E) activities, planned test and evaluation activities, Hawaii Range Complex (HRC) enhancements, and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: No airspace impacts were identified in the analysis presented in Chapters 4.0. Any potential impacts on airspace from increases in training activities, additional RDT&E activities, and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Biological Resources (Open Ocean)	No-action: The modeling quantification of exposures to marine mammals from operation of MFA/HFA sonar and underwater detonations does not predict any marine mammal mortalities. Modeling quantification does not predict any marine mammal exposed to sonar or explosives in excess of the onset of permanent threshold shift; there are no exposures indicative of Level A injury. Modeling does predict TTS and sub-TTS Level B harassments of marine mammals, however, the results from this modeling are presented without consideration of mitigation measures employed per Navy standard operating procedures. The likelihood that many marine mammals can be readily detected, standard mitigation measures involving range clearance procedures should reduce the number of these exposures. There will be no impacts to sea turtles. To reiterate, based on the history of Navy activities in the HRC, and analysis in this document, military readiness activities are not expected to result in any Level A injury or mortalities to marine mammals. However, given the frequency of naturally occurring marine mammal strandings in Hawaii (e.g. natural mortality), it is conceivable that a stranding could co-occur within the timeframe of a Navy exercise even though the stranding may be unrelated to Navy activities. Based on NMFS' recommendation that Navy consider scientific uncertainty and potential for mortality, the Navy is requesting 20 serious injury or mortality takes for 7 commonly-stranded, non ESA-listed species and 3 species of beaked whales present within the HRC (2 mortality takes per species). These are bottlenose dolphin, Kogia *spp*., melon-headed whale, pantropical spotted dolphin, pygmy killer whale, short-finned pilot whale, striped dolphin, Cuvier's beaked whale, Longman's beaked whale, and Blainville's beaked whale Alternative 1: Any anticipated or potential impacts on biological resources from increased training activities, RDT&E activities, and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Any anticipated impacts on biological resources from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Biological Resources (Open Ocean) impacts would be the same as those described under the No-action Alternative. Chapters 4.0 and 5.0 discuss Open Ocean and Offshore impacts in detail. Appendix J provides details on the acoustic modeling approach.
Cultural Resources	No-action: Cultural resources that occur in the Open Ocean Area are generally deeply submerged and inherently protected from the effect of all types of activity. Both the probability of encountering submerged resources and the probability of causing adverse effect on those resources are extremely low regardless of the action alternative being considered. To even further lower the probability of effect, areas where known submerged cultural resources exist will be avoided for operational activities involving expended material, debris dispersion, or underwater detonation. Procedures are in place to minimize any effects on underwater cultural resources. In accordance with Section 106 of the National Historic Preservation Act (36 CFR Part 800), cultural resources mitigation measures as described in various sections of Chapter 4.0 would be implemented. Alternative 1: Impacts on cultural resources from increased training activities, RDT&E activities, and Major Exercises (e.g., RIMPAC) would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on cultural resources from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss Open Ocean and Offshore impacts in detail.

Table ES-2. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Open Ocean (Continued)

Resource Category	Open Ocean
Hazardous Materials and Waste	No-action: Implementation of the No-action Alternative would not result in significant impacts associated with the use of hazardous materials. The Navy has appropriate plans in place to manage hazardous materials used and generated. Hazardous materials will continue to be controlled in compliance with OPNAVINST 5090.1B. Fragments of expended training materials, e.g. ammunition, bombs and missiles, targets, sonobuoys, chaff, and flares, could be deposited on the ocean floor. The widely dispersed, intermittent, minute size of the material minimizes the impact. Wave energy and currents will further disperse the materials. Alternative 1: Implementation of Alternative 1 would not result in significant impacts associated with the use of hazardous materials. Impacts from hazardous materials and waste from increased training activities, RDT&E activities, and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Implementation of Alternative 2 would not result in significant impacts associated with the use of hazardous materials. Impacts from hazardous materials and waste from additional increases in training activities, RDT&E activities, and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.
Health and Safety	No-action: Implementation of the No-action Alternative would not affect public health and safety. Any potential risk to public health and safety is minimized through standard operating procedures and compliance with DoD Directive 4540.1, OPNAVINST 3770.4 and Commander, Naval Surface Force, U.S. Pacific Fleet (COMNAVSURFPAC) Instruction 3120.8F. The Navy notifies the public of hazardous activities through the use of Notices to Airmen (NOTAMs) and Notices to Mariners (NOTMARs). Alternative 1: Implementation of Alternative 1 would not affect public health and safety. Any potential impacts on health and safety from the additional training activities, RDT&E activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Implementation of Alternative 2 would not affect public health and safety. Any potential impacts on health and safety from the additional training activities, RDT&E activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.
Noise	No-action: Implementation of the No-action Alternative would not incrementally affect noise within the HRC. Activities are remote, infrequent, and lack sensitive receptors. In addition, training activities do not have an effect on sensitive noise receptors because these activities are typically conducted away from populated areas and most sensitive noise receptors. Standard operating procedures are used to ensure the area is clear of civilian vessels or other non-participants. The public is notified of the location, date, and time of the hazardous activities via NOTMARs, thereby precluding any acoustical impacts on sensitive receptors. Alternative 1: Implementation of Alternative 1 would not incrementally affect noise within the HRC. Impacts from noise from increased training activities, RDT&E activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Implementation of Alternative 2 would not incrementally affect noise within the HRC. Impacts from noise from additional training activities, RDT&E activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.
Water Resources	No-action: Potential water quality impacts associated with the implementation of the No-action Alternative are transitory in nature and would not reach a level of significance. No long-term significant impacts on water quality are anticipated. Impacts are not anticipated due to the small quantities of materials relative the extent of the sea ranges and large volumes of water in which they will be dispersed. Alternative 1: Impacts on water resources from increase training activities, RDT&E activities, and Major Exercises are not anticipated. Any potential impacts would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on water resources from increased training activities, future RDT&E activities, and Major Exercises are not anticipated. Any potential impacts would be minimized as described above in the No-action Alternative. Alternative 3: Water Resources impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.

Note: Impacts on Biological Resources (Onshore), Geology and Soils, Land Use, and Utilities are not applicable. Impacts discussed for biological resources in the Open Ocean apply to both offshore and onshore areas. There are no impacts on Air Quality, Socioeconomics or Transportation due to site activities under the No-action Alternative, Alternative 1, Alternative 2 or Alternative 3.

Table ES-3. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Northwestern Hawaiian Islands

Resource Category	Northwestern Hawaiian Islands
Biological Resources (Offshore and Onshore)	No-action: Some current flight trajectories could result in missiles such as the Terminal High Altitude Area Defense (THAAD) flying over portions of the Papahānaumokuākea Marine National Monument. Preliminary results of debris analysis indicate that debris is not expected to severely harm threatened, endangered, migratory, or other endemic species on or offshore of Nihoa and Necker Islands. The probability for debris to hit birds, seals, or other wildlife will be extremely low. Quantities of falling debris will be low and widely scattered so as not to present a toxicity issue. Falling debris will also have cooled down sufficiently so as not to present a fire hazard for vegetation and habitat. If feasible, consideration will be given to alterations in the missile flight trajectory, to further minimize the potential for debris impacts. Alternative 1: There are no additional proposed activities or exercises that would affect the Northwestern Hawaiian Islands; ongoing activities would be minimized as described above in the No-action Alternative. Alternative 2: There are no additional proposed activities or exercises that would affect the Northwestern Hawaiian Islands; ongoing activities would be minimized as described above in the No-action Alternative. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses in detail the factors that influenced this analysis.
Cultural Resources	No-action: Missile defense activities, including THAAD, have the potential to generate debris that falls within areas of the Papahānaumokuākea Marine National Monument. Debris analyses of the types, quantities, and sizes associated with the Pacific Missile Range Facility missile activities indicate that the potential to impact land resources of any type on Nihoa or Necker is low and extremely remote. In addition, trajectories can be altered under certain circumstances to further minimize the potential for impacts. Future missions will include consideration of missile flight trajectory alterations, if feasible, to minimize the potential for debris within these areas. As a result, impacts on cultural resources within the Northwestern Hawaiian Islands are not expected. Alternative 1: There are no additional proposed activities or exercises that would affect the Northwestern Hawaiian Islands; the potential for impacts from ongoing activities would be minimized as described above in the No-action Alternative. Alternative 2: There are no additional proposed activities or exercises that would affect the Northwestern Hawaiian Islands; the potential for impacts from ongoing activities would be minimized as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.

Note: No impacts on Air Quality, Airspace, Geology and Soils, Hazardous Materials and Waste, Health and Safety, Land Use, Noise, Socioeconomics, Transportation, Utilities, and Water Resources are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Air Quality	No-action: Air quality conditions will not differ from existing conditions. Compliance with standard operating procedures and air permits will continue to minimize impacts. Emissions generated by base activities do not affect the regional air quality. The tempo of launch events will continue to be managed by range activities in order to stay within the limits of current agreements. Alternative 1: Potential impacts on air quality from increased training activities, RDT&E activities, HRC enhancements, and Major Exercises would be minimized as described in the No-action Alternative. Construction would create fugitive dust emissions, diesel exhaust emissions; no change in regional air quality due to compliance with standard operating procedures for construction, including implementation of dust suppression methods and a vehicle maintenance program. No change to regional air quality is anticipated. Alternative 2: Impacts on air quality from increased training activities, RDT&E activities, and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. No change to regional air quality status is anticipated. Alternative 3: Air Quality impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Infrequent emissions associated with intermittent use of diesel generators; no change in current regional air quality. Alternative 1: Increased use of diesel generators; construction would create fugitive dust emissions, diesel exhaust emissions, and VOCs; no change in regional air quality due to compliance with standard operating procedures for construction, including implementation of dust suppression methods and a vehicle maintenance program is anticipated. No change to regional air quality is anticipated. Alternative 2: Impacts from increased training activities and Major Exercises would be minimized as described above in Alternative 1. Alternative 3: Air Quality impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Infrequent emissions associated with intermittent use of diesel generators; no change in current regional air quality. Alternative 1: Increased use of diesel generators; construction would create fugitive dust emissions, diesel exhaust emissions, and VOCs; no change in regional air quality due to compliance with standard operating procedures for construction, including implementation of dust suppression methods and a vehicle maintenance program is anticipated. No change to regional air quality is anticipated. Alternative 2: Impacts from increased training activities, and Major Exercises would be minimized as described in Alternative 1. Alternative 3: Air Quality impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Airspace	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields will continue to be minimized through standard operating procedures, compliance with DoD Directive 4540.1, OPNAVINST 3770.4A, OPNAVINST 3721.20, and continued close coordination with the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from ongoing activities, increased training activities, increase RDT&E activities, planned test and evaluation activities, or HRC enhancements would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from ongoing activities, additional Major Exercises, increased training exercises, or additional RDT&E activities would be minimized as described in the No-action alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1 and Alternative 2 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Biological Resources (Offshore and Onshore)	No-action: Activities take place in current operating areas, with no expansion. Compliance with relevant Navy policies and procedures during these training activities will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No impacts from electromagnetic radiation generation to wildlife are anticipated. Alternative 1: Impacts on biological resources from increased training activities, RDT&E activities, and HRC enhancements would be minimized as described above in the No-action Alternative. Because construction-related noise would be localized, intermittent, and occur over a relatively short-term, the potential for impacts on biological resources would be minimal. Additional electromagnetic radiation would not affect wildlife. Sound levels from FCLPs would be similar to existing sound levels on the runway. Alternative 2: Impacts on biological resources from increased training activities, RDT&E activities, and Major Exercises would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Additional it is anticipated that electromagnetic radiation would not affect wildlife. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion anticipated. Compliance with relevant Navy policies and procedures during these training activities will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Currently there are no impacts from electromagnetic radiation generation to wildlife. Alternative 1: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Effects on wildlife from construction-related noise and presence of additional personnel would be minimal. Additional electromagnetic radiation is not anticipated to affect wildlife. Alternative 2: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Additional electromagnetic radiation is not anticipated to affect wildlife. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion anticipated. Compliance with relevant Navy policies and procedures will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Currently there are no impacts from electromagnetic radiation generation to wildlife. Alternative 1: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Effects on wildlife from construction-related noise and presence of additional personnel would be minimal. Additional electromagnetic radiation is not anticipated to affect wildlife Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Additional electromagnetic radiation is not anticipated to affect wildlife. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Cultural Resources	No-action: Activities occur in designated areas and sensitive areas are avoided. Any potential for impacts on cultural resources are offset through compliance with the PMRF Integrated Cultural Resources Management Plan (ICRMP) and standard operating procedures. Alternative 1: Any potential impacts from increased training activities, RDT&E activities, and HRC enhancements would be minimized as described above in the No-action Alternative. Alternative 2: Any potential impacts from increased training activities, RDT&E activities, and Major Exercises (e.g., RIMPAC) would be minimized as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Makaha Ridge has been surveyed for archaeological, historical, and Native Hawaiian resources and none have been identified. As a result, No-action Alternative activities will not affect any cultural resources. Alternative 1: An increase in the tempo and frequency of training activities would not affect any cultural resources because Makaha Ridge has been surveyed for cultural resources and there are none present. If archaeological or Native Hawaiian resources are unexpectedly encountered during HRC enhancements, the Hawaii SHPO would be notified. Alternative 2: Any potential impacts and proposed mitigations would be the same as described in Alternative 1. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2 and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.
Geology and Soils	No-action: Ongoing training activities and exercises will continue to have minimal direct impact on the beach and inland areas, and soils are not being permanently affected. Alternative 1: New construction would follow standard methods to control erosion during construction. Soil disturbance would be limited to the immediate vicinity of the construction area and would be of short duration. Base personnel would exercise best management practices to reduce soil erosion. Alternative 2: Impacts would be minimized as described above in Alternative 1. Alternative 3: Geology and Soils impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Hazardous Materials and Waste	No-action: PMRF/Main Base has appropriate plans and standard operating procedures in place to manage hazardous materials and waste. Alternative 1: Impacts from hazardous materials and waste from increased training activities, RDT&E activities, and HRC enhancements would be minimized as described above in the No-action Alternative. Any construction activities would comply with standard operating procedures and adhere to the existing hazardous management plans. Alternative 2: Impacts from hazardous materials and waste from additional increases in training activities, RDT&E activities and additional Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Alternative 3: Hazardous Materials and Wastes impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Makaha Ridge currently has appropriate plans in place to manage hazardous materials and waste. Alternative 1: The increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Any construction activities would comply with standard operating procedures and adhere to the existing hazardous management plans. Alternative 2: Impacts from hazardous materials and waste from additional increases in training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Hazardous Materials and Wastes impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Kokee currently has appropriate plans in place to manage hazardous materials and waste. Alternative 1: The increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Any construction activities would comply with standard operating procedures and adhere to the existing hazardous management plans. Alternative 2: Impacts from additional increases in training activities and Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Alternative 3: Hazardous Materials and Wastes impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Health and Safety	No-action: Risk to public health and safety is will continue to be minimized through compliance with standard operating procedures, policies, and plans. Alternative 1: Impacts on health and safety from additional training activities, RDT&E activities, HRC enhancements, and Major Exercises would be minimized as described above in the No-action Alternative. Construction would be in accordance with USACE Safety and Health Requirements Manual. Alternative 2: Impacts on health and safety from additional training activities, RDT&E activities, and additional Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will continue to minimize impacts. All location(s) are away from the public which results in no adverse public health and safety issues. Alternative 1: Impacts on health and safety from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Construction would be in accordance with USACE Safety and Health Requirements Manual. Alternative 2: Impacts on health and safety from additional training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will continue to minimize impacts. Alternative 1: Impacts on health and safety from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Construction would be in accordance with USACE Safety and Health Requirements Manual. Alternative 2: Impacts on health and safety from additional training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Land Use	No-action: Land uses and Agricultural Preservation Initiative are compatible with PMRF activities. The continuation of activities will be consistent to the maximum extent practicable with the Hawaii Coastal Zone Management Program. Closure of public recreational areas during hazardous activities will continue Alternative 1: Land use is compatible with increased training activities, training activities, RDT&E activities, HRC enhancements, and Major Exercises; additional closure of public recreation areas during hazardous activities is anticipated. Addition of FCLPs would not alter current land use patterns. Alternative 2: Land uses would be compatible with proposed increased training activities, training activities, RDT&E activities, and additional Major Exercises; additional closure of public recreation areas during hazardous activities is anticipated. Alternative 3: Land Use impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Noise	No-action: PMRF maintains a hearing protection program and has standard operating procedures in place that minimize impacts. Beach access to the areas of each of the exercises is restricted for the duration of the exercise. Alternative 1: Impacts from noise from increased training activities (including FCLPs), RDT&E activities, and HRC enhancements would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from noise from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Socioeconomics	No-action: Beneficial impacts on economy and community on Kauai. Alternative 1: Small increase in beneficial impacts on economy on Kauai from increased training activities, future RDT&E activities, and Major Exercises. Alternative 2: Small increase in beneficial impacts on economy on Kauai from increased training activities, future RDT&E activities, and additional Major Exercises. Alternative 3: Socioeconomic impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Transportation	No-action: No impacts identified for the transportation system; PMRF events are discrete and intermittent. Transportation of ordnance and liquid propellants are conducted in accordance with established procedures. Alternative 1: Minimal increase in average daily traffic due to increased training activities, HRC enhancements, and Major Exercises. Traffic generated by construction personnel would be temporary and would result in minor additional traffic. Major exercises are discrete and intermittent with minimal temporary increase in traffic. Alternative 2: No additional traffic would be generated for increased training activities, RDT&E activities, and additional Major Exercises above what would be generated for Alternative 1. Alternative 3: Transportation impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis,	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Utilities	No-action: Current utility capacity meets demands. Alternative 1: Electricity demand, potable water consumption, wastewater generated, and solid waste disposal would be handled by existing facilities. Alternative 2: Additional electricity demand, potable water consumption, wastewater generated and solid waste disposal would be handled by existing facilities. Operation of a high-energy laser would require 30 megawatts of power (additional documentation would be required). Alternative 3: Utility impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Water Resources	No-action: Compliance with standard operating procedures and policies will continue to minimize impacts. Training activities have minimal impact on beach and inland areas and surface drainage is not permanently affected. Emissions from launches and exercises do not significantly affect water resources. Alternative 1: Impacts on water resources from increased training activities, RDT&E activities, HRC enhancements, and Major Exercises would be minimized as described in the No-action Alternative. Slight increase in missile launch emissions would not significantly affect water quality. Construction activities associated with HRC enhancements would follow standard operating procedures minimizing potential impacts from accidental spills of hazardous materials. Alternative 2: Impacts on water resources from increased training activities, RDT&E activities, HRC enhancements, and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Water Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai

Resource Category	Hawaii Air National Guard Kokee	Kamokala Magazines	Niihau	Kaula
Airspace	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Continued close coordination with the FAA and PMRF regarding continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways, and jet routes will continue to minimize impacts. Alternative 1: Impacts on airspace from ongoing activities, increased training activities, RDT&E activities or HRC investments would be minimized as described above in the No-action Alternative. No new airspace proposal or any modification to existing airspace is anticipated. Alternative 2: Impacts on airspace from ongoing activities, additional Major Exercises, increased training exercises, or additional RDT&E activities or HRC investments would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Biological Resources (Offshore and Onshore)	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion anticipated. Compliance with relevant Navy policies and procedures will continue to minimize the effects on wildlife. Currently there are no impacts from electromagnetic radiation generation to wildlife. Alternative 1: Impacts on biological resources from increased training activities would be minimized as described above in the No-action Alternative. Additional electromagnetic radiation is not anticipated to affect wildlife. Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy policies and procedures during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No impacts from electromagnetic radiation generation to wildlife. Alternative 1: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Minimal impacts on biological resources from construction; additional electromagnetic radiation would not affect wildlife.	No-action: Currently there are minimal impacts on vegetation; Mitigation measures are in place that reduce or eliminate any potential impacts on marine mammals. Currently there are minimal impacts on migratory seabirds. Alternative 1: Training Activities and Major Exercises take place in current operating areas, with no expansion anticipated. Compliance with relevant Navy, NMFS, and USFWS policies and procedures during these training activities would minimize the effects on vegetation and wildlife.

Table ES-4B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	Hawaii Air National Guard Kokee	Kamokala Magazines	Niihau	Kaula
Biological Resources (Offshore and Onshore) (Continued)			Alternative 2: Impacts on biological resources from increased training activities and Major Exercises would be as described above in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Alternative 2: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. No potential impacts on migratory seabird populations. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Cultural Resources	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	No-action: There are no known cultural resources sites within the ROI for Kaula; therefore, there will be no impacts on cultural resources from training activities or Major Exercises. Alternative 1: There are no known cultural resources sites within the ROI for Kaula; therefore, there will be no impacts on cultural resources from increased training activities. Alternative 2: There will be no impacts on cultural resources from any additional increases in training activities because there are no known cultural resources within the Kaula ROI. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2.

Table ES-4B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	Hawaii Air National Guard Kokee	Kamokala Magazines	Niihau	Kaula
Geology and Soils	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Impacts are currently minimized due to concentrating targeting on the southeast tip of the island. Alternative 1: Impacts from Increased training and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from increased training and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Geology and Soils impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Hazardous Materials and Waste	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: PMRF currently has procedures in place to manage hazardous materials and waste. Storage and transportation or ordnance is conducted in accordance with established DOT, DoD, and Navy safety procedures. Alternative 1: Impacts would be minimized as described in the No-action Alternative. Alternative 2: Impacts would be minimized as described in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: PMRF currently has appropriate plans in place to manage hazardous materials and waste. Alternative 1: Impacts from the increase in training activities and Major Exercises would be minimized as described in the No-action Alternative. Any construction activities would comply with standard operating procedures and adhere to the existing hazardous management plans. Alternative 2: Impacts from additional increases in training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	Hawaii Air National Guard Kokee	Kamokala Magazines	Niihau	Kaula
Health and Safety	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Compliance with existing health and safety plans and procedures will continue to minimize impacts. No change in the type of ordnance stored and no increase safety risks. Storage and transportation of ordnance are conducted in accordance with established DOT, DoD and Navy safety procedures. Alternative 1: Impacts would be minimized as described above in the No-action Alternative. The factors that influenced this analysis. Alternative 2: Impacts would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with existing health and safety plans and procedures will continue to minimize impacts. Location of radar and electronic warfare sites away from the public results in no adverse public health and safety issues. Alternative 1: Impacts from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Construction would be in accordance with USACE Safety and Health Requirements Manual. Alternative 2: Impacts from additional training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with existing health and safety plans and procedures will continue to minimize health and safety risks. Alternative 1: Impacts from additional training activities would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from additional training activities would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2.
Land Use	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Land use is compatible with Navy activities. The continuation of activities will remain consistent to the maximum extent practicable with the Hawaii Coastal Zone Management Program. Alternative 1: Land use is compatible with increased activities and Major Exercises. Alternative 2: Land use is compatible with increased activities and Major Exercises. Alternative 3: Land use impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Note: No impacts at Port Allen, Kikiaola Small Boat Harbor, or Mt. Kahili are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. No impacts on Air Quality, Geology and Soils, Noise, Socioeconomics, Transportation, Utilities, and Water Resources are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Naval Station Pearl Harbor	Ford Island	Naval Inactive Ship Maintenance Facility, Pearl Harbor
Biological Resources (Offshore and Onshore)	No-action: Procedures and policies are in place to minimize the potential for impacts on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No impacts on essential fish habitat. Alternative 1: Impacts on biological resources from increased activities and Major Exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts on biological resources from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize the potential for impacts on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No impacts on essential fish habitat. No critical habitat has been identified. Alternative 1: Impacts on biological resources from increased activities and Major Exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts on biological resources from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize impacts on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Minor and localized impacts on fish. No impacts on essential fish habitat. Alternative 1: Impacts on biological resources from increased activities and Major Exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts on biological resources from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Cultural Resources	No-action: To minimize any potential impacts, activities will continue to be conducted in accordance with the policies, guidelines, and standard operating procedures outlined in the Pearl Harbor Naval Complex Integrated Cultural Resources Management Plan (ICRMP), or any other agreement documents promulgated since completion of the ICRMP. There are no significant cultural resources within the direct ROI for activities. The Loko Okiokiolepe fishpond is the closest National Register property (approximately half a mile north of the EOD Shore Range). Alternative 1: Any potential impacts from increased training activities would be minimized as described above in the No-action Alternative. Alternative 2: Any potential impacts from additional increases in training activities would minimized as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: There are no training or Major Exercises with the potential to affect cultural resources. Alternative 1: Installation of equipment to support the ATF [Acoustic Test Facility] would be conducted in accordance with the Pearl Harbor Naval Complex ICRMP and would require coordination with the Navy Region Hawaii's cultural resource coordinator. Alternative 2: There are no new Major Exercises or training activities with the potential to affect cultural resources. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.

Table ES-5A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Naval Station Pearl Harbor	Ford Island	Naval Inactive Ship Maintenance Facility, Pearl Harbor
Hazardous Materials and Waste	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Naval Inactive Ship Maintenance Facility, Pearl Harbor has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Impacts from the increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from additional increases in training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Hazardous Materials and Wastes impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Socioeconomics	No-action Beneficial impacts on economy and community on Oahu. Alternative 1: Current Beneficial impacts would continue. Small increase in beneficial impacts on economy on Oahu from increased RDT&E and Major Exercises. Alternative 2: Current Beneficial impacts would continue. Small increase in beneficial impacts on economy on Oahu from increased training activities, and additional Major Exercises. Alternative 3: Socioeconomic impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Water Resources	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: There are no training activities, RDT&E activities, or Major Exercises with the potential to affect water resources. Alternative 1: There are no training activities, RDT&E activities, or Major Exercises with the potential to affect water resources. HRC enhancements would adhere to standard operating procedures for construction to minimize and avoid adverse impacts on water quality. Alternative 2: Impacts would be minimized as described above in Alternative 1. Alternative 3: Water Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Note: No impacts on Air Quality, Airspace, Geology and Soils, Health and Safety, Land Use, Noise, Transportation, and Utilities, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	EOD Range NAVMAG Pearl Harbor West Loch	Lima Landing	Puuloa Underwater Range
Biological Resources (Offshore and Onshore)	No-action: Procedures and policies are in place to minimize impacts on biological resources. Intrusive noise could startle noise-sensitive wildlife in the vicinity. Alternative 1: Impacts from increased activities and training exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from additional increases in activities and training exercises would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize impacts on biological resources. Minor and localized impacts on fish. No impacts on essential fish habitat. Alternative 1: Impacts from increased activities and exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Minor and localized impacts on fish. Alternative 2: Impacts from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize impacts on biological resources. Minor and localized impacts on fish. No impacts on essential fish habitat. Any effects from noise, shock, or residual chemicals will be localized and temporary. Alternative 1: Impacts from increased activities and Major Exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Cultural Resources	No-action: There are no ongoing training activities with the potential to affect cultural resources because there are no cultural resources present in the ROI. Alternative 1: Increasing training activities would not affect cultural resources because there are no cultural resources present in the ROI. Alternative 2: Additional increases in training activities would not affect cultural resources because there are no cultural resources present in the ROI. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: There are no cultural resources within the ROI for Lima Landing's underwater demolition activities therefore no effects on cultural resources are expected. Any changes to the location of these activities would be coordinated with the Navy Region, Hawaii, cultural resources coordinator Alternative 1: Because there are no cultural resources within the ROI, no impacts on cultural resources are expected from increased training. Alternative 2: Because there are no cultural resources within the ROI, no impacts on cultural resources are expected from additional increases in training. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: There are no cultural resources within the ROI for Puuloa Underwater Range activities; therefore no effects on cultural resources are expected. Alternative 1: Because there are no cultural resources within the ROI, no impacts on cultural resources are expected from increased training. Alternative 2: Because there are no cultural resources within the ROI, no impacts on cultural resources are expected from increased training. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	EOD Range NAVMAG Pearl Harbor West Loch	Lima Landing	Puuloa Underwater Range
Geology and Soils	No-action: Policies and procedures are in place to minimize any impacts. EOD training is not expected to affect the geology of the Range; no construction or excavation is planned. Minor contamination of surface soil. Alternative 1: Impacts from increased training activities would be minimized as described above in the No-action Alternative Alternative 2: Impacts from additional Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Geology and Soils impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Hazardous Materials and Waste	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Lima Landing has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Impacts from the increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from additional increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Puuloa Underwater Range has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Impacts from the increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	EOD Range NAVMAG Pearl Harbor West Loch	Lima Landing	Puuloa Underwater Range
Health and Safety	No-action: Compliance with standard operating procedures will continue to minimize impacts. Location away from the public results in no adverse public health and safety issues. Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will minimize impacts. Location away from the public results in no adverse public health and safety issues. Demolition activities are conducted in accordance with COMNAVSURFPAC Instruction 3120.8F. Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will minimize impacts. Location away from the public results in no adverse public health and safety issues. Demolition activities are conducted in accordance with COMNAVSURFPAC Instruction 3120.8F Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Water Resources	No-action: Intermittent, short-term discharges of minute amounts of munitions constituents into surface waters and have no effect on water resources. Alternative 1: Increases in training activities would not significantly affect water resources. Alternative 2: Additional increases in training activities would not significantly affect water resources. Alternative 3: Water Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Note: No impacts on Air Quality, Airspace, Land Use, Noise, Socioeconomics, Transportation, and Utilities, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5C. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Naval Defensive Sea Area	CG Station Barbers Point/Kalaeola Airport	Marine Corps Base Hawaii
Airspace	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, and coordination with the State of Hawaii, U.S. Coast Guard, Kalaeloa Airport, and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures and continued close coordination with the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities, and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from ongoing activities, increased training activities, and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Biological Resources (Offshore and Onshore)	No-action: Procedures and policies are in place to minimize impacts on biological resources. No essential fish habitat affected. Alternative 1: Impacts would be minimized as described above in the No-action Alternative. Increased activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts would be minimized as described above in the No-action Alternative. Increased activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy and Coast Guard policies and procedures during these training activities will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Alternative 1: Impacts from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Marine Corps and Navy procedures and policies are in place to minimize impacts on biological resources and prevent introduction of invasive species. Alternative 1: Impacts from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 2: Impacts from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5C. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	Naval Defensive Sea Area	CG Station Barbers Point/Kalaeola Airport	Marine Corps Base Hawaii
Cultural Resources	No-action: There are no known historic properties (i.e., cultural resources eligible for or listed in the National Register) located within the ROI for the Naval Defensive Sea Area; therefore, there will be no impacts on cultural resources from training and RDT&E operations under the No-action. Alternative 1: Because there are no known historic properties within the ROI, increased training activities and Major Exercises will have no impacts on cultural resources. Alternative 2: Because there are no known historic properties within the ROI, additional increases in training activities and Major Exercises will have no impacts on cultural resources. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	No-action: Activities occur in designated areas and sensitive areas are avoided. Compliance with the standard operating procedures and policies minimizes impacts. If cultural resources are unexpectedly encountered the Hawaii SHPO will be notified. Alternative 1: Any impacts from increased training activities would be treated as described above in the No-action Alternative. Alternative 2: Any impacts from additional increases in training activities would be treated as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Health and Safety	No-action: Compliance with standard operating procedures will minimize impacts. The activities will be completely contained and the area cleared resulting in no adverse public health and safety issues. Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-5C. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	Naval Defensive Sea Area	CG Station Barbers Point/Kalaeola Airport	Marine Corps Base Hawaii
Noise	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Coast Guard Air Station Barbers Point has appropriate plans in place to manage noise levels. Noise produced is expected to stay within the existing noise contours. Alternative 1: Minor impacts are anticipated for areas near the airport from increased activities, training exercises, and Major Exercises. Alternative 2: Minor impacts are anticipated for areas near the airport from increased activities, training exercises, and Major Exercises. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: MCBH maintains a hearing protection program that will continue to minimize impacts. Noise levels that reach off-post are mitigated by public notification and restricting training to daylight hours. Alternative 1: Increased training activities would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Note: No impacts on Air Quality, Geology and Soils, Hazardous Materials and Waste, Land Use, Socioeconomics, Transportation, Utilities, and Water Resources, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5D. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	MCTAB	Hickam AFB	Wheeler Army Airfield
Airspace	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, and coordination with the Air Force, Honolulu International Airport, and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, and coordination with the Army and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities would be minimized as described in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Biological Resources (Offshore and Onshore)	No-action: MCTAB and Navy procedures and policies are in place to minimize impacts on biological resources and prevent introduction of invasive species. Alternative 1: Increased training activities would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Hickam AFB and Navy procedures and policies are in place to continue to minimize impacts on biological resources and prevent introduction of invasive species. Chapter 4.0 discusses the factors that influenced this analysis. Alternative 1: Increased training activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Army and Navy procedures and policies are in place to minimize impacts on biological resources and prevent introduction of invasive species. No critical habitat has been identified on Wheeler Army Airfield. Alternative 1: Increased training activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5D. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	MCTAB	Hickam AFB	Wheeler Army Airfield
Cultural Resources	No-action: Activities occur in designated areas and sensitive areas are avoided. Compliance with standard operating procedures and policies minimizes impacts. If cultural resources are unexpectedly encountered the Bellows AFS cultural resources coordinator will be notified. Alternative 1: Any impacts from increased training activities would be treated as described above in the No-action Alternative. Alternative 2: Any impacts from additional increases in training activities would be treated as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.

Note: No impacts on Air Quality, Geology and Soils, Hazardous Materials and Waste, Health and Safety, Land Use, Noise, Socioeconomics, Transportation, Utilities, and Water Resources, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5E. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Makua Military Reservation	Kahuku Training Area	Dillingham Military Reservation
Biological Resources (Offshore and Onshore)	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy and Army policies, procedures, and plans during these training activities will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Critical habitat and sensitive areas will be avoided where possible. Alternative 1: Impacts from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy and Army policies, procedures, and plans during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No-action: Activities occur in designated areas and sensitive areas are avoided. Compliance with standard operating procedures, policies, and plans minimizes impacts. If cultural resources are unexpectedly encountered the Hawaii SHPO (if the find is made by Marine Corps or Navy) or the Schofield Barracks cultural resources manager (if the find occurs during Army activities) will be notified. Alternative 1: Any impacts from increased training activities would be treated as described above in the No-action Alternative. Alternative 2: Any impacts from additional increases in training activities would be treated as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5E. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	Makua Military Reservation	Kahuku Training Area	Dillingham Military Reservation
Health and Safety	No-action: Compliance with standard operating procedures and plans will continue to minimize impacts. Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Noise	No-action: Makua Military Reservation maintains a hearing protection program that will minimize impacts. Alternative 1: Increased training activities would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Note: No impacts on Air Quality, Airspace, Geology and Soils, Hazardous Materials and Waste, Land Use, Socioeconomics, Transportation, Utilities, and Water Resources, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5F. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Ewa Training Minefield	Barbers Point Underwater Range	Naval Undersea Warfare Center
Biological Resources (Offshore and Onshore)	No-action: Procedures and policies are in place to minimize impacts on biological resources. Minor and localized impacts on fish. Any effects from noise, shock, or residual chemicals will continue to be localized and temporary. Alternative 1: Increased activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize impacts on biological resources. Minor and localized impacts on fish. No impacts on essential fish habitat. Alternative 1: Increased activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Alternative 2: Increased activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	SESEF - No-action: Procedures and policies are in place to minimize impacts on biological resources. Alternative 1: Impacts from increased activities would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from increased activities would be minimized as described in the No-action Alternative. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis. FORACS - No-action: Procedures and policies are in place to minimize impacts on biological resources Alternative 1: Impacts from increased activities would be minimized as described in the No-action Alternative. Alternative 2: Impacts from increased activities would be minimized as described in the No-action Alternative. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Hazardous Materials and Waste	No-action: Ewa Training Minefield has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Increases in training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 2: Additional increases in training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Barbers Point Underwater Range has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Increases in training activities and Major Exercises would be minimized as described above in the No-action Alternative Alternative 2: Additional increases in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-5F. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Ewa Training Minefield	Barbers Point Underwater Range	Naval Undersea Warfare Center
Health & Safety	No-action: Compliance with standard operating procedures will minimize impacts. Demolition activities are conducted in accordance with COMNAVSURFPAC Instruction 3120.8F. Alternative 1: The additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: The additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will minimize impacts. Demolition activities are conducted in accordance with COMNAVSURFPAC Instruction 3120.8F. Alternative 1: The additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: The additional training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	SESEF & FORACS - No-action: Compliance with standard operating procedures will minimize impacts. Alternative 1: The increased RDT&E activities would be minimized as described above in the No-action Alternative. Alternative 2: The increased RDT&E activities would be minimized as described in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Note: No impacts on Air Quality, Airspace, Cultural Resources, Geology and Soils, Land Use, Noise, Socioeconomics, Transportation, Utilities, and Water Resources, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean. No impacts at Keehi Lagoon, Kaena Point, Mt. Kaala, Wheeler Network Communications Control, Mauna Kapu Communication Site, or Makua Radio/Repeater/Cable Head are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3.

Table ES-6. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Maui

Resource Category	Maui Offshore
Biological Resources (Offshore and Onshore)	No-action: Compliance with policies and procedures will continue to minimize impacts on biological resources. Alternative 1: Impacts on biological resources from increased training activities would be minimized as described in the No-action Alternative. The Portable Undersea Tracking Range would be used in areas around Maui with water depths less than 300 feet. Other than the temporary disturbance to marine species during instrumentation installation and recovery, no impacts would be expected to occur. Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Impacts on biological resources would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Note: No impacts on Air Quality, Airspace, Cultural Resources, Geology and Soils, Hazardous Materials and Waste, Health and Safety, Land Use, Noise, Socioeconomics, Transportation, Utilities, or Water Resources are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean. No impacts at the Maui Space Surveillance Site, the Shallow Water Minefield Sonar Training Area, the Maui High Performance Computing Center, or the Sandia Maui Haleakala Facility are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3.

Table ES-7. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Hawaii

Resource Category	Pohakuloa Training Area	Bradshaw Army Airfield	Kawaihae Pier
Airspace	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, coordination with PTA Range Control and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, coordination with PTA Range Control and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2 and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Biological Resources (Offshore and Onshore)	No-action: Training Activities and Major Exercises will take place in current operating areas, with no expansion. Compliance with relevant Navy policies, procedures, and plans during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Alternative 1: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 2: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: These activities are limited in scope and are not anticipated to impact the areas beyond the airfield itself. Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy policies, procedures, and plans during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Alternative 1: Impacts on biological resources from increased training activities would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy policies and procedures during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Sensitive biological resource areas are avoided. Alternative 1: No increases in training events at Kawaihae Pier are expected. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-7. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Hawaii (Continued)

Resource Category	Pohakuloa Training Area	Bradshaw Army Airfield	Kawaihae Pier
Cultural Resources	No-action: Activities occur in designated areas and sensitive areas are avoided. Compliance with standard operating procedures and policies minimizes impacts. If cultural resources are unexpectedly encountered then the PTA cultural resources manager will be contacted. Alternative 1: Any impacts from increased training activities would be treated as described above in the No-action Alternative. Alternative 2: Any impacts from additional increases in training activities would be treated as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: There are no training or Major Exercises with the potential to affect cultural resources at Bradshaw Army Airfield. Policies and procedures are in place to minimize any potential impacts. Alternative 1: Because there is no training or Major Exercises with the potential to affect cultural resources at Bradshaw Army Airfield, no impacts on cultural resources are expected. To avoid impacts from any HRC enhancements, activities would be coordinated with the PTA cultural resources manager. Policies and procedures are in place to minimize any potential impacts. Alternative 2: Because there is no training or Major Exercises with the potential to affect cultural resources at Bradshaw Army Airfield, no impacts on cultural resources are expected. To avoid impacts from any HRC enhancements, activities would be coordinated with the PTA cultural resources manager. Policies and procedures are in place to minimize any potential impacts. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.
Health and Safety	No-action: Compliance with existing health and safety plans and procedures will minimize impacts. Alternative 1: Impacts on health and safety from the additional training activities and HRC enhancements would be minimized as discussed above in the No-action Alternative. Alternative 2: Impacts on health and safety from the additional training activities and Major Exercises would be minimized as discussed above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-7. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Hawaii (Continued)

Resource Category	Pohakuloa Training Area	Bradshaw Army Airfield	Kawaihae Pier
Noise	No-action: PTA will continue to maintain a hearing protection program that will minimize impacts. Alternative 1: Increased training activities would take place at existing locations; no expansion of the area would be involved. Noise impacts would be minimized as discussed above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Noise impacts would be minimized as discussed above in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Note: No impacts on Air Quality, Geology and Soils, Hazardous Materials and Waste, Land Use, Socioeconomics, Transportation, Utilities, and Water Resources are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-8. Summary of Mitigation Measures

Resource Category*	Open Ocean	Northwestern Hawaiian islands	Kauai
Air Quality	None	None	Modify or renew current Title V permit for PMRF/Main Base for testing and operation of the Maritime Directed Energy Test Center.
Airspace	Depending on the intensity of the proposed lasers, nomenclature would need to be added to aeronautical charts, and certain test events could require Notices to Airmen (NOTAMs) and Notices to Mariners (NOTMARs).	None	Depending on the intensity of the lasers, nomenclature would need to be added to aeronautical charts, and certain test events could require NOTAMs and NOTMARs.
Biological Resources	Train personnel in lookout/watchstander duties. Always at least three people on watch with binoculars. At least two additional personnel on watch during ASW exercises. All personnel engaged in passive acoustic sonar operation to monitor for marine mammal vocalizations. During MFA sonar operations use all available sensor and optical systems (such as night vision goggles). Use only passive capability of sonobuoys when marine mammals are detected within 200 yards. When marine mammals are detected by any means within 1,000 yards of the sonar dome (the bow), the ship or submarine will limit active transmission levels to at least 6 decibels (dB) below normal operating levels. If need for power-down should arise, Navy to follow the requirements as though they were operating at 235 dB—the normal operating level. Operate sonar at lowest practicable level, not to exceed 235 dB, except as required to meet tactical training objectives Helicopters to observe/survey vicinity of an ASW Operation for 10 minutes before first deployment of active (dipping) sonar in the water. Do not dip sonar within 200 yards of a marine mammal and cease pinging if a marine mammal closes within 200 yards after pinging has begun.	None	Target areas are determined to be clear of marine mammals and sea turtles prior to commencement of exercises. Within 1 hour prior to initiation of Expeditionary Assault activities, landing routes and beach areas are surveyed for the presence of sensitive wildlife. An exercise is halted if marine mammals are detected on the beach or in a target area. Pressure wash vehicles on the mainland to prevent spread of invasive plants. Shield night lighting to the extent practical. Foster the reestablishment of native vegetation Monitor and treatment to eliminate establishing exotic species. Prohibit living plants brought from mainland. Work with owners of Niihau Ranch to develop Hawaiian monk seal and green turtle monitoring programs. Training operations to avoid any beach area with green turtle nests. Seasonal use of Kaula during periods when humpback whales are not present. Survey the waters off Kaula to ensure that no whales are present. Limit the impact area to the southern tip of Kaula. RIMPAC exercises use non-explosive rounds on Kaula.

Table ES-8. Summary of Mitigation Measures (Continued)

Resource Category*	Open Ocean	Northwestern Hawaiian islands	Kauai
Biological Resources (Continued)	Navy to coordinate with local NMFS Stranding Coordinator. Submit report containing discussion of nature of the effects, if observed, based on both modeled results of real-time events and sightings of marine mammals. Operating area must be determined clear of marine mammals and sea turtles prior to detonation. Pre-exercise observation of the area to start 30 minutes before and after commencement of Demolition and Ship Mine Countermeasures Operations. All weapons firing would be conducted during the period 1 hour after official sunrise to 30 minutes before official sunset. Establish exclusion zone with a radius of 1.0 nm around each target. Conduct series of surveillance over-flights within exclusion and safety zones, prior to and during the exercise, when assets are available and if safe and feasible. Monitored exclusion zone by passive acoustic means, when assets are available. If a protected species observed within the exclusion zone is diving, delay firing until animal is re-sighted outside the exclusion zone, or 30 minutes have elapsed. Prepare after action report.		

Table ES-8. Summary of Mitigation Measures (Continued)

Resource Category*	Open Ocean	Northwestern Hawaiian islands	Kauai
Cultural Resources	None	Within program requirements, alter missile trajectories to minimize the potential for debris to fall in the vicinity of Necker and Nihoa islands.	Avoid operations/construction in areas with known cultural resources. Monitoring all ground-disturbing activities and construction in medium and high sensitivity archaeological areas. Provide briefings about cultural resources to project personnel. Spray water on vegetation in immediate areas of launch vehicle prior to launch. Use open spray nozzle when possible to minimize erosion damage. Conduct post-burn archaeological surveys. Implement data recovery/research and documentation program. If unanticipated cultural resources are encountered (particularly human remains) during any activity, all activities will cease in the immediate vicinity of the find. Applicable procedures would be implemented and appropriate individuals contacted.
Geology and Soils	N/A	None	Navy minimizes the impact on Kaula by managing the targeting to the southeast tip of the island.
Hazardous Materials and Waste	None	None	Before any facility modifications, the areas to be modified would be surveyed for asbestos and lead-based paint.
Health and Safety	Ensure that no shipping is located within the hazard range of the longest-range weapon being fired for that event.	None	PMRF would develop and implement the necessary Standard Operating Procedures and range safety requirements necessary to provide safe operations associated with future high-energy laser tests. Appropriate remedial procedures would be taken before initiation of potentially hazardous laser operations on PMRF.
Noise	Limits have been set by DoD and OSHA to prevent damage to human hearing.	None	Limits have been set by DoD and OSHA to prevent damage to human hearing. All public, civilian, and nonessential personnel are required to be outside of ground hazard areas where expected noise levels will be below the 115 dBA limit for short-term exposure.

*No mitigation measures have been identified for Land Use, Socioeconomics, Transportation, Utilities, or Water Resources.

Table ES-8. Summary of Mitigation Measures (Continued)

Resource Category*	Oahu	Maui	Hawaii
Airspace	FAA coordination would include discussions regarding the anticipated number of aircraft including FCLP operations.	None	None
Biological Resources	Mitigation measures to protect critically endangered plants include: controlling threats, improving conditions for recruitment, propagation, and reintroduction, development of Implementation Plans that outline required mitigations to offset training risks and to stabilize the targeted plant and animal populations, and implementation of a Wildland Fire Management Plan. Only sandy areas that avoid/minimize potential impacts on coral are used for explosive charges in less than 40 feet of water. Where necessary, pre-exercise surveys for turtles conducted to avoid feeding and nesting areas. Conducting surveys prior to use of amphibious launch vehicles to ensure that humpback whales are not disturbed. Beach and offshore waters are monitored for presence of marine mammals and sea turtles 1 hour before and during Major Exercises, if any are seen, exercise is delayed until the animals leave the area.	None	Impacts on rare plants minimized by locating training activities away from areas with sensitive species, fencing to enclose sensitive species for protection from ungulates, fire and fuel corridors, fire breaks, additional surveys for threatened and endangered species, and continued sensitive plant propagation efforts. All off-road driving is prohibited. All fenced areas are off-limits. All lava tubes and sinkholes are off-limits. Digging is only permitted in previously disturbed areas. Hydrographic survey is performed to map out the precise Expeditionary Assault transit routes through sandy bottom areas. Personnel entering Bradshaw Army Airfield briefed on the guidelines set forth in the PTA Ecosystem Management Plan.
Cultural Resources	In the event unanticipated cultural remains are identified (particularly human remains), all operations will cease in the immediate vicinity and appropriate military branch protocols followed.	None	In the event unanticipated cultural remains are identified (particularly human remains), all operations will cease in the immediate vicinity and appropriate military branch protocols followed.
Hazardous Materials and Waste	Training operations in the Naval Defensive Sea Area are restricted to vessels owned and operated by military and DoD personnel.	None	Before any facility modifications, the areas to be modified would be surveyed for asbestos and lead-based paint.
Health and Safety	Ensure that no shipping is located within the hazard range of the longest-range weapon being fired for that event.	None	None
Noise	Limits have been set by DoD and OSHA to prevent damage to human hearing. Personnel required to work in noise hazard areas are required to use appropriate hearing protection to bring noise levels within established safety levels. Public notification and restricting training in Waimanalo Bay to daylight hours.	None	None

*No mitigation measures have been identified for Air Quality, Geology and Soils, Land Use, Socioeconomics, Transportation, Utilities, or Water Resources.

HAWAII RANGE COMPLEX (HRC)

Lead Agency for the EIS:	U.S. Department of the Navy
Title of the Proposed Action:	Hawaii Range Complex
Affected Jurisdiction:	Kauai, Honolulu, Maui, and Hawaii Counties
Designation:	Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS)

Abstract

This Final EIS/OEIS has been prepared by the U.S. Department of the Navy (Navy) in compliance with the National Environmental Policy Act (NEPA) of 1969 (42 United States Code § 4321 et seq.); the Council on Environmental Quality (CEQ) Regulations for Implementing the Procedural Provisions of NEPA (Title 40 Code of Federal Regulations [CFR] §§ 1500-1508); Navy Procedures for Implementing NEPA (32 CFR § 775); and Executive Order 12114 (EO 12114), *Environmental Effects Abroad of Major Federal Actions*. The Navy has identified the need to support and conduct current, emerging, and future training and research, development, test, and evaluation (RDT&E) activities in the Hawaii Range Complex (HRC). The alternatives—the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3—are analyzed in this Final EIS/OEIS. All alternatives include an analysis of potential environmental impacts associated with the use of mid-frequency active (MFA) and high-frequency active (HFA) sonar. The No-action Alternative stands as no change from current levels of HRC usage and includes HRC training, support, and RDT&E activities, Major Exercises, and maintenance of the technical and logistical facilities that support these activities and exercises. Alternative 1 includes all ongoing training associated with the No-action Alternative, an increased tempo and frequency of such training (including increases in MFA and HFA sonar use), a new training event (Field Carrier Landing Practice), enhanced and future RDT&E activities, enhancements to optimize HRC capabilities, and an increased number of Major Exercises. Alternative 2 includes all of the training associated with Alternative 1 plus additional increases in the tempo and frequency of training (including additional increases in MFA and HFA sonar use), enhanced RDT&E activities, future RDT&E activities, and additional Major Exercises, such as supporting three Strike Groups training at the same time. Alternative 3 would include all of the training and RDT&E activities associated with Alternative 2. The difference between Alternative 2 and Alternative 3 is the amount of MFA/HFA sonar usage. As described under Alternative 2, Alternative 3 would provide increased flexibility in training activities by increasing the tempo and frequency of training events, future and enhanced RDT&E activities, and the addition of Major Exercises. Alternative 3 would consist of the MFA/HFA sonar usage as analyzed under the No-action Alternative. Alternative 3 is the Navy's preferred alternative.

This Final EIS/OEIS addresses potential environmental impacts that result from activities that occur under the No-action Alternative and proposed activities that would occur under Alternatives 1, 2, and 3. This EIS/OEIS also addresses changes and associated environmental analyses that were presented in the Supplement to the Draft EIS/OEIS. Environmental resource topics evaluated include air quality, airspace, biological resources (open ocean, offshore, and onshore), cultural resources, geology and soils, hazardous materials and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources.

Executive Summary

EXECUTIVE SUMMARY

ES1.1 INTRODUCTION

This Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) analyzes the potential environmental consequences that may result from the United States (U.S.) Department of the Navy's Proposed Action and alternatives. The Proposed Action presented in this EIS/OEIS addresses ongoing and proposed activities within the Navy's existing Hawaii Range Complex (HRC) and represents current and anticipated future use of the "existing footprint." This EIS/OEIS contains analysis of research, development, test, and evaluation (RDT&E) of new technologies used by the Navy and other Federal agencies, including the Missile Defense Agency.

This EIS/OEIS has been prepared by the Department of the Navy in compliance with the National Environmental Policy Act (NEPA) of 1969 (42 United States Code [U.S.C.] § 4321 et seq.) and Executive Order (EO) 12114, *Environmental Effects Abroad of Major Federal Actions*.

The Navy is the lead for the EIS/OEIS; the National Marine Fisheries Service (NMFS), Missile Defense Agency, U.S. Department of the Army, and the U.S. Department of Energy are cooperating agencies. Additionally, the Navy has worked with experts from the State of Hawaii and other Federal agencies to ensure that the effects on the environment of the Navy's Proposed Action are fully assessed in this document.

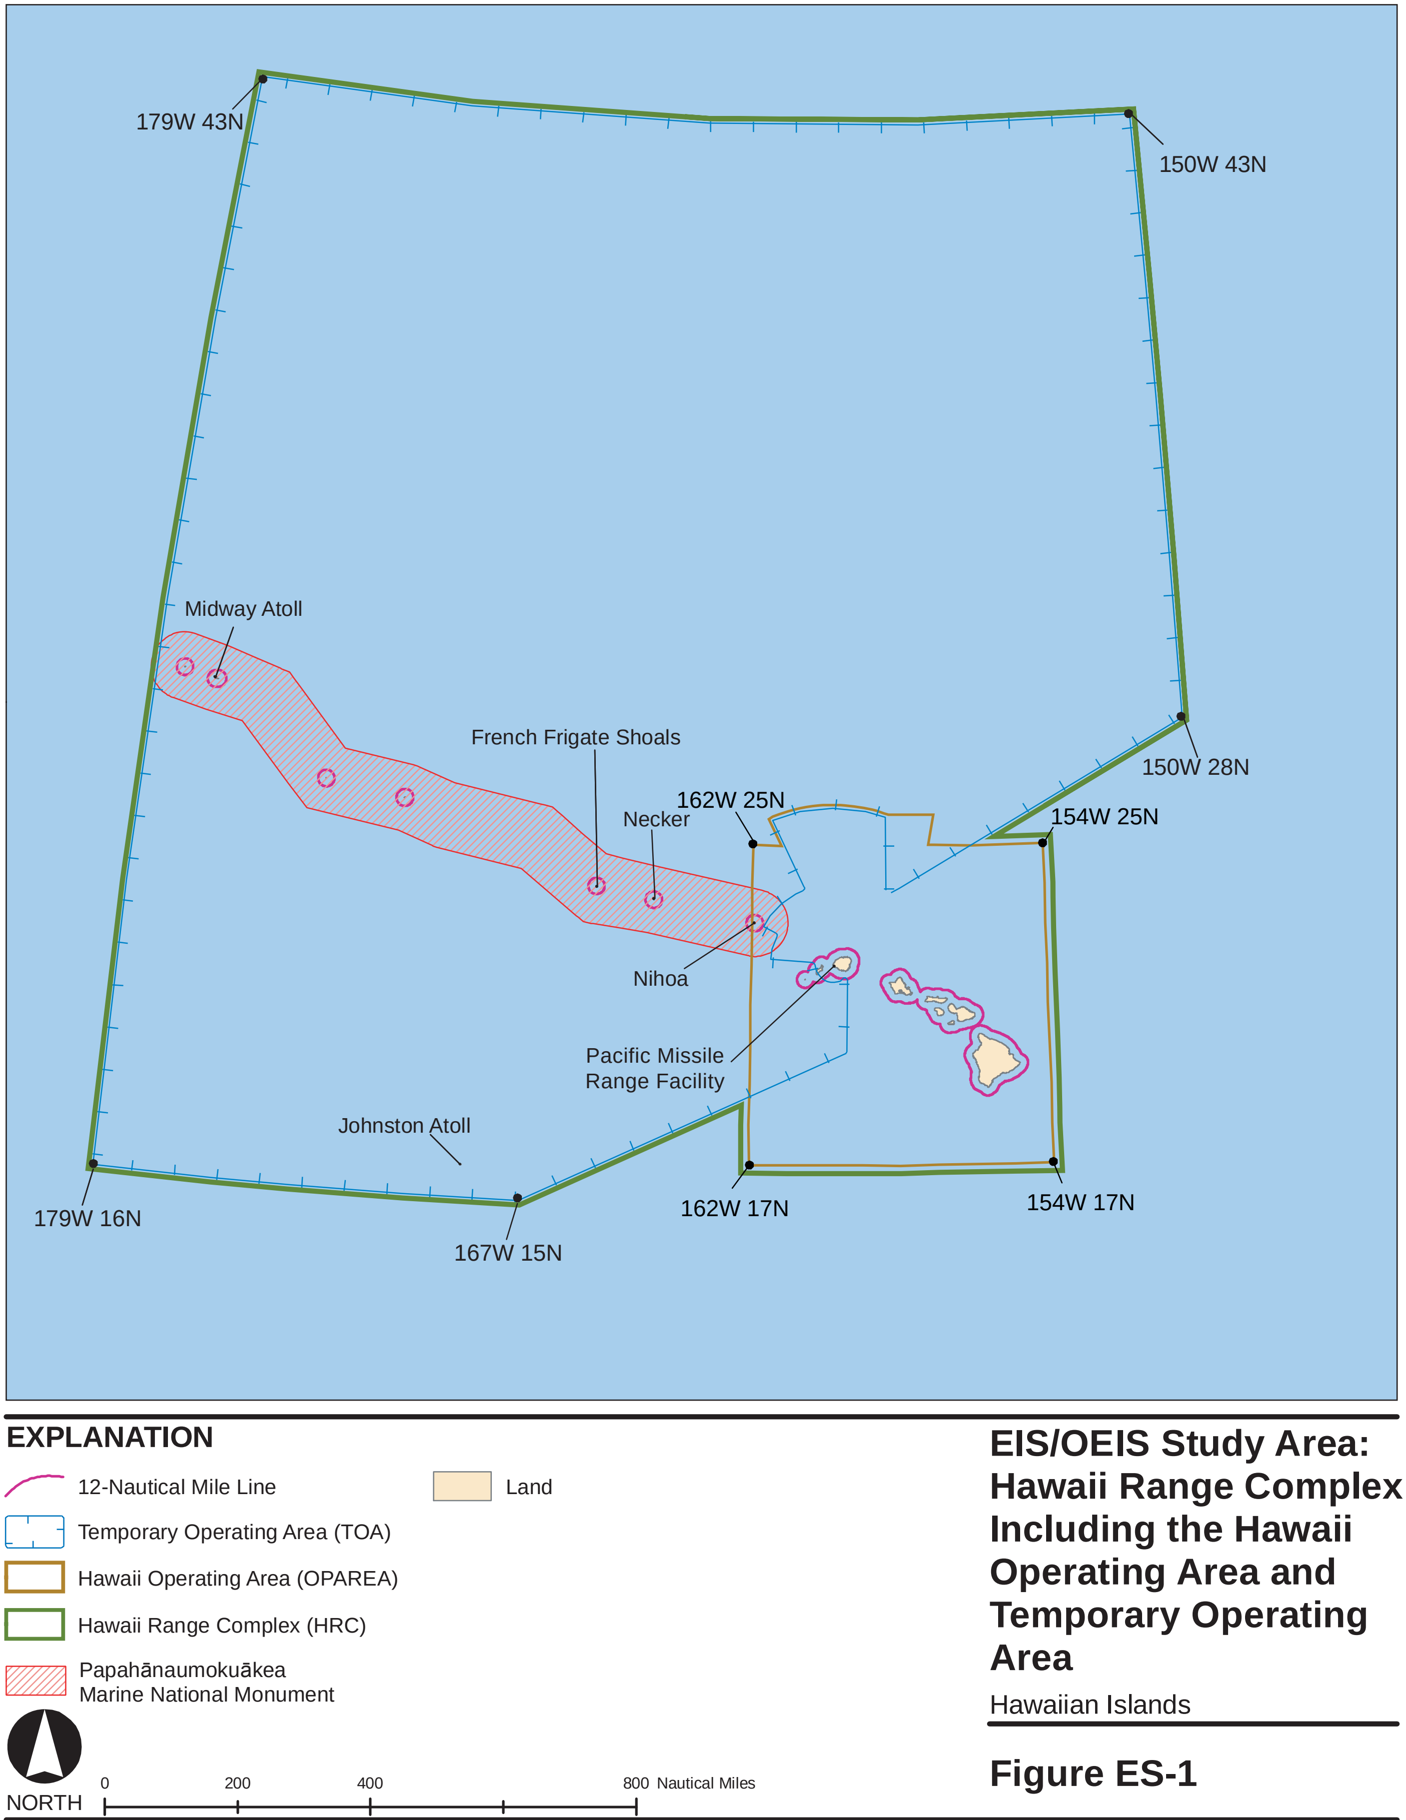
The HRC geographically encompasses the open ocean (outside 12 nautical miles [nm] from land), offshore waters (within 12 nm from land), and onshore areas located on or around the islands of the Hawaiian Islands chain (Figure ES-1).

There are three component areas of the HRC: (1) the Hawaii Operating Area (OPAREA) (includes surface and subsurface ocean areas and special use airspace); (2) the Temporary Operating Area (TOA) (composed of sea and airspace north and west of Kauai for RDT&E activities); and (3) various Navy land ranges and other Services' land for military training and RDT&E activities.

ES1.2 PURPOSE AND NEED

The purpose of the Proposed Action is to achieve and maintain fleet readiness using the HRC to support and conduct current, emerging, and future training and RDT&E activities, and enhance training resources through investment on the ranges. The mission of the HRC is to support naval operational readiness by providing a realistic, live training environment for forces assigned to the Pacific Fleet, the Fleet Marine Force, and other users.

The need for the Proposed Action is to enable the Navy to meet its statutory responsibility under Title 10 Sections 5013 and 5062 to organize, train, equip, and maintain combat-ready naval forces and to successfully fulfill its current and future global mission of winning wars, deterring aggression, and maintaining freedom of the seas. Activities involving RDT&E for Department of Defense (DoD) or Navy systems are an integral part of this readiness mandate.



EIS/OEIS Study Area: Hawaii Range Complex Including the Hawaii Operating Area and Temporary Operating Area

Hawaiian Islands

Figure ES-1

The HRC plays a vital part in the execution of this naval readiness mandate. The Hawaii area is home to a large concentration of U.S. naval forces. Naval forces based in Hawaii and those transiting across the Pacific Ocean use and rely on the HRC because of its capabilities and strategic location in the mid-Pacific region. The Navy's Proposed Action is essential to ensure the continued vitality of this training resource.

ES1.2.1 WHY THE NAVY TRAINS

The U.S. military is maintained to ensure the freedom and safety of all Americans both at home and abroad. In order to do so, Title 10 of the U.S.C requires the Navy to "maintain, train and equip combat-ready naval forces capable of winning wars, deterring aggression and maintaining freedom of the seas." Modern war and security operations are complex. Modern weaponry has brought both unprecedented opportunity and innumerable challenges to the Navy. Smart weapons, used properly, are accurate and allow the Navy to accomplish its mission with greater precision and less destruction than in past conflicts. U.S. military personnel must train regularly with these modern, complex weapons in order to understand their capabilities, limitations, and operation. Modern military actions require teamwork between hundreds or thousands of people, and their various equipment, vehicles, ships, and aircraft, all working individually and as a coordinated unit to achieve success. Navy training addresses all aspects of the team, from the individual to joint and coalition teamwork. To do this, the Navy employs a building-block approach to training. Training doctrine and procedures are based on operational requirements for deployment of naval forces. Training proceeds on a continuum, from teaching basic and specialized individual military skills, to intermediate skills or small unit training, to advanced, integrated training events, culminating in multi-service (Joint) exercises, coalition or combined exercises (with allied nations participating), or pre-deployment certification events.

In order to provide the experience so important to success and survival, training must be as realistic as possible. The Navy often employs simulators and synthetic training to provide early skill repetition and to enhance teamwork, but live training in a realistic environment is vital to success. Live training requires sufficient sea and airspace to maneuver tactically, realistic targets and objectives, simulated opposition that creates a realistic enemy, and instrumentation that monitors the events and provides essential feedback.

Range complexes, like the HRC, provide a controlled and safe environment with threat-representative targets that allow Navy forces to conduct realistic training as Navy men and women undergo all phases of the graduated buildup needed for combat-ready deployment. The range complexes are designed to provide the most realistic training in the most relevant environments, replicating to the greatest extent possible the operational stresses of warfare. The integration of undersea ranges and OPAREAs with land training ranges, safety landing fields, and amphibious landing sites are critical to this realism, allowing execution of multi-dimensional exercises in complex scenarios. The live-fire phase of training is fundamental to the adequate assessment of weapon precision under stressful conditions. Live training, most of it accomplished in the waters off the United States' coasts, will remain the cornerstone of readiness as the Navy prepares its military forces for a security environment characterized by uncertainty and surprise.

ES1.2.2 STRATEGIC IMPORTANCE OF THE EXISTING HAWAII RANGE COMPLEX

The HRC is used for training and assessment of operational forces, missile training, RDT&E of military systems and equipment, and other military activities. The HRC is characterized by a unique combination of attributes that make it a strategically important range complex for the Navy. These attributes include:

- Proximity to the homeport of Pearl Harbor
- Proximity to the Western Pacific
- Proximity to military families based in Hawaii
- New training terrain for west coast based naval forces

Refer to Section 1.3.5 of Chapter 1.0 for a detailed description of these attributes.

The large training area available to deployed forces within the HRC allows training to take place using a geographic scope that replicates possible real world events, with the channels between islands providing geography necessary for opposed transit scenarios. The presence of the instrumented tracking ranges at the Pacific Missile Range Facility (PMRF) as well as DoD-controlled warning areas and special use airspace also allow safe and structured training with sufficient flexibility to interject tactical challenges to enhance realism for exercise participants. Exercise participants at sea can conduct air strike sorties to Pohakuloa Training Area (PTA) and an Expeditionary Strike Group (ESG) can conduct amphibious landing on DoD beaches, while each simultaneously conducts Anti-Submarine Warfare (ASW) training. Finally, the presence of submarines homeported at Pearl Harbor allows for a readily available opposition force during the training event without having to transit to participate in the exercise events.

ES1.3 SCOPE AND CONTENT OF THE EIS/OEIS

The Navy's analysis of environmental effects under NEPA includes areas of the HRC that lie within the territorial seas, which extend 12 nm from land. The environmental effects in the ocean areas that are outside of U.S. territorial seas are analyzed under EO 12114 and associated implementing regulations.

ES1.3.1 NATIONAL ENVIRONMENTAL POLICY ACT (NEPA)

In 1969, Congress enacted NEPA, which provides for the consideration of environmental issues in Federal agency planning and decision-making. Regulations for Federal agency implementation of the act were established by the President's Council on Environmental Quality (CEQ). NEPA requires that Federal agencies prepare an EIS if the agency's proposed action might significantly affect the quality of the human environment. The EIS must disclose significant environmental impacts and inform decision makers and the public of the reasonable alternatives to the proposed action. Presidential Proclamation 5928, issued December 27, 1988, extended the exercise of United States sovereignty and jurisdiction under international law to 12 nm; however, the Proclamation expressly provides that it does not extend or otherwise alter existing Federal law or any associated jurisdiction, rights, legal interests, or obligations.

However, as a matter of policy, the Navy analyzes environmental effects and actions within 12 nm under NEPA and those effects occurring beyond 12 nm under the provisions of EO 12114.

This EIS/OEIS provides an assessment of the potential environmental impacts associated with sustainable range usage and enhancements within the Navy's HRC. The Navy completed the Supplement to the 2002 Rim of the Pacific (RIMPAC) Programmatic Environmental Assessment in May 2006 and the Undersea Warfare Exercise (USWEX) Programmatic Environmental Assessment in October 2007. This EIS/OEIS analyzes the continuation of these exercises in the baseline analysis. It also analyzes Navy training that currently occurs or is proposed to occur in open ocean, offshore, and onshore areas of the HRC.

The first step in the NEPA process is the publication of a Notice of Intent (NOI) to prepare an EIS. The NOI provides an overview of the proposed action and the scope of the EIS. The NOI for this project was published in the *Federal Register* on August 29, 2006, and in five local newspapers (i.e., *Honolulu Advertiser*, the *Honolulu Star Bulletin*, the *Maui News*, the *Hawaii Tribune Herald*, and the *Garden Island*) on September 2, 4, and 5, 2006.

Scoping is an early and open process for developing the "scope" of issues to be addressed in the EIS and for identifying significant issues related to a proposed action. During scoping, the public helps define and prioritize issues and convey these issues to the agency through both oral and written comments. The scoping period for the HRC EIS/OEIS began with the publication of an NOI. The scoping period lasted 46 days, concluding on October 13, 2006. Four scoping meetings were held on September 13, 14, 16, and 18, 2006 on the islands of Maui, Oahu, Hawaii, and Kauai, respectively. The scoping meetings were held in an open house format, presenting informational posters and written information, and making Navy staff and project experts available to answer participants' questions. Additionally, a court reporter was available to record participants' oral comments. This format allowed the public to interact informally, one-on-one, with project representatives or comment formally, on the record, to representatives of the Navy.

In addition to the scoping meetings, the public could make comments through a toll-free telephone number, by sending an email, or by mailing a written comment. Issues identified by the public were provided to resource specialists working on the EIS/OEIS to ensure that all comments were considered during the preparation of the document.

After scoping, the Draft EIS/OEIS was prepared to provide an assessment of the potential impacts of the Proposed Action and alternatives on the environment. Public hearings were conducted during the review process in Kauai (Lihue), Oahu (Honolulu), Maui (Wailuku), and Hawaii (Hilo). The Draft EIS/OEIS was circulated for public review and the comment period concluded on September 17, 2007. Approximately 2,500 public comments were received and appropriately incorporated into this EIS/OEIS. Responses to public comments on the Draft EIS/OEIS may be found in Chapter 13.0.

During the scoping and public review process, members of the public and non-governmental environmental organizations expressed concerns on a variety of topics. One of the issues receiving the most comments related to the potential effects associated with mid-frequency active (MFA) sonar use and testing in the HRC. These concerns are addressed in this EIS/OEIS.

The Navy recognizes that the potential impact on marine mammals caused by the use of sonar is controversial. Based on continued coordination with NMFS, the Navy has used best available science as the basis to assess impacts on marine mammals caused by MFA and high-frequency active (HFA) sonar used by a particular torpedo. The best available science has been used as a basis for development of the “Risk Function” model for predicting potential exposures of marine mammals to Navy MFA and HFA sonar use that will result in behavioral effects. What this model cannot do yet is to include in its calculations reductions in the behavioral effects estimates resulting from all of the procedures that the Navy has in place to protect marine mammals. These include personnel training, pre- and post-exercise surveys, power-down and power-off requirements for the sonar when mammals are within certain distances of the sound source, and passive detection of marine mammals.

During the public hearings, it was clear that many of those voicing concern were unaware that the training and testing activities proposed for the HRC are not new activities and have been occurring for approximately 40 years. No known marine mammal strandings directly related to Navy activities have occurred during this time. Nonetheless, by design, the Navy has taken an approach to modeling that calculates the maximum potential exposures to marine mammals to account for uncertainties in existing scientific data.

Since the publication of the Draft EIS/OEIS, the Navy, in coordination with the NMFS, re-analyzed the effects that MFA sonar has on marine mammals. This re-evaluation and consequent proposed changes to the Draft EIS/OEIS led the Navy to prepare a Supplement to the Draft EIS/OEIS. Accordingly, this EIS/OEIS incorporates the following changes and associated environmental analysis as presented in the Supplement to the Draft EIS/OEIS:

- Modifications to the analytical methodology used to evaluate the effects of MFA sonar on marine mammals;
- Changes to the amount and types of sonar allocated to each of the alternatives; and,
- The development of a new alternative.

The NOI for the Supplement to the Draft EIS/OEIS was published in the *Federal Register* on January 17, 2008. The Supplement to the Draft EIS/OEIS was circulated for public review, and the comment period ended on April 7, 2008. Responses to all comments on the Supplement to the Draft EIS/OEIS are presented in Chapter 14.0 of this document.

There is a 30-day wait period following the publication of the Notice of Availability of the Final EIS/OEIS in the Federal Register. At the conclusion of this wait period, the Navy will decide the action it will implement through its Record of Decision (ROD) which will be published in the Federal Register. The ROD will summarize the final decision and identify the selected alternative, describe the public involvement and agency decision-making processes, and present commitments to specific mitigation measures. The selected decision can then be implemented.

ES1.3.2 EXECUTIVE ORDER (EO 12114)

Environmental effects in the areas that are beyond the U.S. territorial sea are analyzed under EO 12114 and associated implementing regulations.

ES1.3.3 MARINE MAMMAL PROTECTION ACT, ENDANGERED SPECIES ACT COMPLIANCE

The Marine Mammal Protection Act (MMPA) of 1972 established, with limited exceptions, a moratorium on the “taking” of marine mammals in waters or on lands under U.S. jurisdiction. Section 101(a)(5) of the MMPA directs the Secretary of Commerce to allow, upon request, the incidental, but not intentional, taking of marine mammals by U.S. citizens who engage in a specified activity (exclusive of commercial fishing). In support of the Proposed Action, the Navy applied for a Letter of Authorization from NMFS pursuant to Section 101(a) (5) (A) of the MMPA. NMFS intends to publish a proposed rule for public comment coincident with the publication of this EIS/OEIS, and anticipates issuing the final authorization toward the end of Calendar Year 2008.

On January 23, 2007, the Deputy Secretary of Defense exempted all military readiness activities employing MFA sonar or Improved Extended Echo Ranging (IEER) sonobuoys from compliance with the requirements of the MMPA for a period of 2 years. This exemption is limited to Major Exercises or training and RDT&E activities within established operating areas or established DoD maritime ranges. This National Defense Exemption (NDE) remains in effect until January 23, 2009 or authorization under the MMPA, whichever is earliest.

The NDE will cover MFA sonar and IEER sonobuoy activities on the HRC until an MMPA authorization is issued for these activities or the NDE expires whichever is earliest. While the NDE remains applicable (until an MMPA authorization is issued), the Navy will continue to employ the marine mammal mitigation measures outlined in Chapter 6.0 of this EIS/OEIS to protect marine mammals while training with the use of MFA sonar. These measures include safety zones around ships and trained lookouts based on coordination of science-based measures with NMFS. Additional measures that may be required as a result of the MMPA authorization would be implemented once authorization is received.

The Endangered Species Act (ESA) requires that Federal agencies, in consultation with the responsible wildlife agency, ensure that proposed actions are not likely to jeopardize the continued existence of any endangered species or threatened species, or result in the destruction or adverse modification of a critical habitat. Regulations implementing the ESA consultation requirement also include those actions that “may affect” a listed species or adversely modify critical habitat.

As part of the environmental documentation for this EIS/OEIS, and as an MMPA permit applicant, the Navy entered into early consultation procedures with NMFS, endangered species division. The Navy has been actively engaged in consultation with NMFS regarding the potential effects on ESA-listed species from the conduct of the activities outlined in this EIS/OEIS. In accordance with 50 Code of Federal Regulations (CFR) §402.11, prior to the issuance of the ROD, NMFS will issue a Preliminary Biological Opinion documenting its determination as to whether the activities conducted in the HRC are likely to jeopardize the continued existence of ESA-listed species, or result in the destruction or adverse modification of critical habitat. Additionally, a preliminary Incidental Take Statement will accompany the preliminary Biological Opinion. Because the Section 7 consultation is simultaneously conducted internally to address NMFS' issuance of an MMPA authorization, an Incidental Take Statement for marine mammals cannot be issued until an MMPA authorization is issued.

The Preliminary Biological Opinion and Preliminary Incidental Take Statement do not exempt the Navy from the prohibitions of Section 9 of the ESA. Further, the Navy has determined that activities occurring in the HRC prior to the issuance of an MMPA authorization (e.g., RIMPAC, USWEX, etc.) may affect endangered species in the HRC, and may incidentally take ESA-listed species, thus requiring consultation under the ESA and an associated Incidental Take Statement. As such, the Navy and NMFS are engaged in a separate Section 7 consultation on these specified activities. A separate Biological Opinion and Incidental Take Statement will be issued, as appropriate, for this subset of specified activities, which will occur prior to the issuance of the MMPA authorization and be covered by the NDE.

ES1.3.4 OTHER ENVIRONMENTAL REQUIREMENTS CONSIDERED

The Navy must comply with a variety of other Federal environmental laws, regulations, and EOs. These include (among other applicable laws and regulations):

- Migratory Bird Treaty Act;
- Coastal Zone Management Act;
- Rivers and Harbors Act;
- Magnuson-Stevens Fishery Conservation and Management Act;
- Clean Air Act;
- Federal Water Pollution Control Act (Clean Water Act);
- National Historic Preservation Act;
- EO 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations
- EO 13045, Environmental Health and Safety Risks to Children;
- EO 13423, *Strengthening Federal Environmental, Energy and Transportation Management;*
- EO 13089, *Coral Reef Protection;* and
- National Marine Sanctuaries Act.

In addition, laws and regulations of the State of Hawaii appropriate to Navy actions are identified and addressed in this EIS/OEIS. To the extent practicable, this document will be used as the basis for any required consultation and coordination.

ES1.4 PROPOSED ACTION AND ALTERNATIVES

The Proposed Action presented in this EIS/OEIS addresses ongoing and proposed activities within the Navy's existing HRC and contains analyses of RDT&E of new technologies used by the Navy and other Federal agencies.

ES1.4.1 ALTERNATIVES DEVELOPMENT

NEPA requires that an EIS evaluate the environmental consequences of a range of reasonable alternatives. Guidance for the development of alternatives is provided in CEQ regulations (40 CFR § 1502.14) and Navy procedures described in 32 CFR § 775. Reasonable alternatives must meet the stated purpose and need of the Proposed Action.

ES1.4.2 ALTERNATIVES ELIMINATED FROM FURTHER CONSIDERATION

The Navy eliminated alternatives from further consideration. Specifically, the following alternatives (described in Chapter 2.0) were not carried forward for analysis:

- Reduction or Elimination of Training in the Hawaii Range Complex
- Alternative Locations for Training Conducted in the Hawaii Range Complex
- Computer Simulation Training

After careful consideration, none of these alternatives meet the Navy's purpose and need for the Proposed Action.

ES1.4.3 ALTERNATIVES CONSIDERED

Alternatives were selected based on their ability to meet the following criteria, which were developed from the purpose and need for the Proposed Action: (1) use existing Navy ranges and facilities in and around Hawaii; (2) be consistent with the stated current and emerging requirements for the range complex; (3) achieve training tempo requirements based on Fleet deployment schedules; (4) meet the requirements of DoD Directive 3200.15, Sustainment of Ranges and Operating Areas; (5) implement new training requirements and RDT&E activities; and (6) support realistic training that replicates expected operating environments for naval forces. Four alternatives are analyzed in the EIS/OEIS, including three action alternatives (Alternatives 1, 2, and 3) and the No-action Alternative.

ES1.4.3.1 No-Action Alternative

The No-action Alternative is required by CEQ regulations as a baseline against which the impacts of the Proposed Action are compared. In the EIS/OEIS, the No-action Alternative is represented by baseline training and RDT&E operations at current levels, including more than 9,300 training and RDT&E activities in the HRC annually. Training events, including those that make up Major Exercises (RIMPAC Exercise and five USWEXs) and RDT&E activities, would continue at the baseline levels. Ongoing training events include Anti-Air Warfare, Amphibious Warfare, Anti-Surface Warfare, ASW, Electronic Combat, Mine Warfare, Naval Special Warfare, and Strike Warfare Exercises. The No-action Alternative includes support activities such as

Command and Control, in-port ship and aircraft support, and personnel support. RDT&E activities occur primarily at one of two locations in Hawaii: PMRF and Naval Undersea Warfare Center Detachment Pacific ranges.

ES1.4.3.2 Alternative 1

Alternative 1 includes all ongoing Navy training associated with the No-action Alternative, and proposes an increased number of such training events. The Navy proposes to increase both the tempo and the frequency of training exercises in the HRC. Alternative 1 includes the addition of Field Carrier Landing Practice (FCLP), a series of touch-and-go landings to train and qualify pilots for aircraft carrier landings at PMRF airfield on Kauai and Marine Corps Base Hawaii (MCBH) on Oahu. The Navy proposes to enhance and add RDT&E activities above current levels.

ES1.4.3.3 Alternative 2

Alternative 2 would include all of the activities described in Alternative 1, plus a further increased tempo and frequency of training events, future RDT&E programs at PMRF, and the addition of Major Exercises, such as supporting three Carrier Strike Groups training at the same time.

ES1.4.3.4 Alternative 3 (Preferred Alternative)

The only difference between Alternative 2 and Alternative 3 is the amount of MFA/HFA sonar usage. Alternative 3 would include all of the training associated with Alternative 2. As described under Alternative 2, Alternative 3 would provide increased flexibility in training activities by increasing the tempo and frequency of training events, future and enhanced RDT& E activities, and the addition of Major Exercises. Alternative 3 would consist of sonar usage as analyzed under the No-action Alternative. Sonar hours for Alternative 3 and effects associated with ASW training would be identical to that presented under the No-action Alternative.

Alternative 3 is the preferred alternative because it allows the Navy to meet its future non-ASW training and RDT&E mission objectives while maintaining historic levels of ASW training to avoid increases in potential effects to marine mammals in the HRC. At this time, the Navy believes that its ASW requirements will be met based on the No-action Alternative sonar hours.

ES1.5 SPORTS DATA

The data from the Sonar Positional Reporting System (SPORTS) provided a foundation for the sonar hours analyzed under each of the Alternatives. SPORTS is a database tool established by Commander, U.S. Fleet Forces Command in mid-2006. All commands employing MFA sonar and sonobuoys are required to populate the SPORTS database by reporting MFA sonar use. A review by senior officers determined that SPORTS data would be used in this EIS/OEIS in conjunction with previous planning data to assist in determining the amount of MFA sonar use for purposes of modeling potential effects on marine mammals.

The types of sonar sources used as part of ASW activities within the HRC are listed below:

- Surface ship sonar (AN/SQS-53 and AN/SQS-56)
- Helicopter dipping sonar (AN/AQS-22)
- Aircraft deployed sonobuoys (AN/SSQ-62)
- Submarine sonar (BQQ-10, BQQ-5, BSY-1)
- MK-48 torpedo

Table ES-1 presents a comparison of the sonar used for each of the alternatives analyzed. The majority of training and RDT&E activities in the HRC involve five types of narrowband sonars. Exposure estimates are calculated for each sonar according to the manner in which it operates. For example, the AN/SQS 53 and AN/SQS 56 are hull-mounted, MFA surface ship sonars that operate for many hours at a time (although sound is output—the “active” portion—only a small fraction of that time), so it is most useful to calculate and report surface ship sonar exposures per hour of operation. The BQQ-10 submarine sonar is also reported per hour of operation. However, the submarine sonar is modeled as pinging only twice per hour. The AN/AQS-22 is a helicopter-deployed sonar, which is lowered into the water, pings several times, and then moves to a new location; this sonar is used for localization and tracking a suspected contact as opposed to searching for contacts. For the AN/AQS-22, it is most helpful to calculate and report exposures per dip. The AN/SSQ-62 is a sonobuoy that is dropped into the water from an aircraft or helicopter and pings about 10 to 30 times in an hour. For the AN/SSQ-62, it is most helpful to calculate and report exposures per sonobuoy. For the MK-48 torpedo the sonar is modeled for a typical training event and the MK-48 reporting metric is the number of torpedo runs. See Table J-2 of Appendix J for a presentation of the deployment platform, frequency class, the metric for reporting exposures, and the units for each sonar.

Note that sonar usage for Alternative 3 and effects associated with ASW training would be identical to that presented under the No-action Alternative.

Table ES-1. Summary of Sonar Usage for Each Alternative

No-action Totals		
	Source	**Modeled**
	53	1,284 hours
	56	383 hours
	Dipping	1,010 dips
	Sonobuoy	2,423 buoys
	MK-48	313 runs
	Submarine	200 hours
Alternative 1 Totals		
	Source	**Modeled**
	53	1,788 hours
	56	551 hours
	Dipping	1,517 dips
	Sonobuoy	3,127 buoys
	MK-48	317 runs
	Submarine	200 hours

Table ES-1. Summary of Sonar Usage for Each Alternative (Continued)

	Source	Modeled
Alternative 2 Totals		
	Source	**Modeled**
	53	2,496 hours
	56	787 hours
	Dipping	1,763 dips
	Sonobuoy	3,528 buoys
	MK-48	374 runs
	Submarine	200 hours
Alternative 3 Totals		
	Source	**Modeled**
	53	1,284 hours
	56	383 hours
	Dipping	1,010 dips
	Sonobuoy	2,423 buoys
	MK-48	313 runs
	Submarine	200 hours

ES1.6 SUMMARY OF ENVIRONMENTAL EFFECTS

Environmental effects which might result from the implementation of the Navy's Proposed Action or alternatives have been analyzed in this EIS/OEIS. Resource areas analyzed included airspace, biological resources, cultural resources, hazardous materials and waste, health and safety, noise, water resources, geology and soils, land use, socioeconomics, transportation, and utilities. A summary of effects on the above-referenced resources where applicable have been addressed in Table ES-2 for Open Ocean areas, Table ES-3 for the Northwestern Hawaiian Islands, Tables ES-4 for Kauai, Tables ES-5 for Oahu, Table ES-6 for Maui, and Table for ES-7 for Hawaii. A detailed analysis of effects is provided in Chapter 4.0.

A comparison of the environmental impacts of the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 is presented in Tables ES-2 through ES-7. These tables summarize the conclusions of the analyses made for each of the areas of environmental consideration based on the application of the described methodology. Only those activities for which a potential environmental concern was determined at each location are described for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3.

ES1.6.1 CUMULATIVE IMPACTS

The analysis of cumulative impacts considers the effects of the Proposed Action in combination with other past, present, and reasonably foreseeable future actions taking place in the project area, regardless of what agency or person undertakes these actions. This EIS/OEIS analyzes cumulative impacts associated with implementation of Navy-sponsored activities and other non-Navy activities in the region. The cumulative project list includes over 140 Federal, State, and local projects ranging from minor construction to major infrastructure type projects, as well as various military training projects. Other activities included Commercial Fishing, Commercial and Recreational Vessel Traffic, Coastal Development Activities, Environmental Contamination and

Biotoxins, and Scientific Research Permits. Potential cumulative impacts resulting from other relevant projects (such as those listed above) combined with the Proposed Action addressed in this EIS/OEIS were determined to be less than significant.

ES1.6.2 MITIGATION MEASURES

The Navy is a global environmental leader. As part of the Navy's commitment to sustainable use of resources and environmental stewardship, the Navy incorporates mitigation measures that are protective of the environment into all of its activities. The Navy's current mitigation measures reflect a balance between training requirements and the Navy's important role in ensuring environmental protection. These measures have been the subject of extensive discussions between NMFS and the Navy, and evaluated for mission impacts, probable effectiveness, and the ability to implement. Mitigation measures are described in detail in Chapter 6.0.

Mitigation measures identified to reduce effects or ensure no future impacts occur are provided in Table ES-8.

ES1.6.3 OTHER NEPA CONSIDERATIONS

ES1.6.3.1 Conflicts with Federal, State, and Local Land Use Plans, Policies, and Controls for the Area Concerned

Based on an evaluation of consistency with statutory obligations, the Navy's proposed training and RDT&E activities for the HRC do not conflict with the objectives or requirements of Federal, State, regional, or local plans, policies, or legal requirements. The proposed training and RDT&E activities would not alter the use of the sites that currently support missile testing. Enhancement of the HRC would be in accordance with applicable Federal, State, and local planning plans and policies. The DoD maintains Federal jurisdiction for on-installation land use.

ES1.6.3.2 Energy Requirements and Conservation Potential

The proposed training and RDT&E activities include increased training events in the HRC. In order to implement the proposed training and RDT&E activities, increased amounts of fossil fuels would be required to power the increased use by ships and aircraft. These fuels are currently in adequate supply from either Navy owned sources or from commercial distributors. The required electricity demands would be met by the existing electrical generation infrastructure on the Hawaiian Islands. Anticipated energy requirements of the continued use and enhancement of the HRC would be well within the energy supply capacity of all facilities. Energy requirements would be subject to any established energy conservation practices at each facility. No additional power generation capacity other than the potential use of generators would be required for any of the training and RDT&E activities. The use of energy sources has been minimized wherever possible without compromising safety, training, or testing events. No additional conservation measures related to direct energy consumption by the proposed training and RDT&E activities are identified.

ES1.6.3.3 Irreversible or Irretrievable Commitment of Resources

The proposed training and RDT&E activities would have an irreversible or irretrievable effect due to the use of nonrenewable energy sources: hydrocarbon fuels for aircraft, vessels, and vehicles. However, among the alternative training scenarios there are no significant differences in the cost of fuel and the climatic consequences of large-scale combustion of hydrocarbon fuel. Implementation of the proposed training and RDT&E activities would not result in the destruction of environmental resources so as to cause the potential uses of the environment of the HRC to be limited. The proposed training and RDT&E activities would not adversely affect the biodiversity or cultural integrity within the HRC including the open ocean, offshore, onshore, or human environment.

ES1.6.3.4 Relationship Between Short-Term Environmental Impact and Long-Term Productivity

The Navy is committed to sustainable range management. Effective, sustainable range management addresses both short- and long-term effects on the human environment and strives to ensure the long-term productivity and availability of vital range training resources. The Navy is committed to the co-use of the HRC and surrounding areas with the general public and, for the open ocean areas, international community. This commitment to co-use is incorporated in the Navy's long-term range management and will enhance the long-term productivity of the range and surrounding areas for the public and commercial interests.

Table ES-2. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Open Ocean

Resource Category	Open Ocean
Airspace	No-action: No airspace impacts were identified in the analysis presented in Chapter 4.0. Any potential impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, compliance with Department of Defense (DoD) Directive 4540.1, Office of the Chief of Naval Operations Instruction (OPNAVINST) 3770.4A, OPNAVINST 3721.20, and continued close coordination with the Federal Aviation Administration (FAA). No modifications or need for additional airspace are required. Alternative 1: No airspace impacts were identified in the analysis presented in Chapter 4.0. Any potential impacts on airspace from increased training activities, increased research, development, test, and operation (RDT&E) activities, planned test and evaluation activities, Hawaii Range Complex (HRC) enhancements, and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: No airspace impacts were identified in the analysis presented in Chapters 4.0. Any potential impacts on airspace from increases in training activities, additional RDT&E activities, and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Biological Resources (Open Ocean)	No-action: The modeling quantification of exposures to marine mammals from operation of MFA/HFA sonar and underwater detonations does not predict any marine mammal mortalities. Modeling quantification does not predict any marine mammal exposed to sonar or explosives in excess of the onset of permanent threshold shift; there are no exposures indicative of Level A injury. Modeling does predict TTS and sub-TTS Level B harassments of marine mammals, however, the results from this modeling are presented without consideration of mitigation measures employed per Navy standard operating procedures. The likelihood that many marine mammals can be readily detected, standard mitigation measures involving range clearance procedures should reduce the number of these exposures. There will be no impacts to sea turtles. To reiterate, based on the history of Navy activities in the HRC, and analysis in this document, military readiness activities are not expected to result in any Level A injury or mortalities to marine mammals. However, given the frequency of naturally occurring marine mammal strandings in Hawaii (e.g. natural mortality), it is conceivable that a stranding could co-occur within the timeframe of a Navy exercise even though the stranding may be unrelated to Navy activities. Based on NMFS' recommendation that Navy consider scientific uncertainty and potential for mortality, the Navy is requesting 20 serious injury or mortality takes for 7 commonly-stranded, non ESA-listed species and 3 species of beaked whales present within the HRC (2 mortality takes per species). These are bottlenose dolphin, Kogia *spp*., melon-headed whale, pantropical spotted dolphin, pygmy killer whale, short-finned pilot whale, striped dolphin, Cuvier's beaked whale, Longman's beaked whale, and Blainville's beaked whale Alternative 1: Any anticipated or potential impacts on biological resources from increased training activities, RDT&E activities, and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Any anticipated impacts on biological resources from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Biological Resources (Open Ocean) impacts would be the same as those described under the No-action Alternative. Chapters 4.0 and 5.0 discuss Open Ocean and Offshore impacts in detail. Appendix J provides details on the acoustic modeling approach.
Cultural Resources	No-action: Cultural resources that occur in the Open Ocean Area are generally deeply submerged and inherently protected from the effect of all types of activity. Both the probability of encountering submerged resources and the probability of causing adverse effect on those resources are extremely low regardless of the action alternative being considered. To even further lower the probability of effect, areas where known submerged cultural resources exist will be avoided for operational activities involving expended material, debris dispersion, or underwater detonation. Procedures are in place to minimize any effects on underwater cultural resources. In accordance with Section 106 of the National Historic Preservation Act (36 CFR Part 800), cultural resources mitigation measures as described in various sections of Chapter 4.0 would be implemented. Alternative 1: Impacts on cultural resources from increased training activities, RDT&E activities, and Major Exercises (e.g., RIMPAC) would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on cultural resources from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss Open Ocean and Offshore impacts in detail.

Table ES-2. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Open Ocean (Continued)

Resource Category	Open Ocean
Hazardous Materials and Waste	No-action: Implementation of the No-action Alternative would not result in significant impacts associated with the use of hazardous materials. The Navy has appropriate plans in place to manage hazardous materials used and generated. Hazardous materials will continue to be controlled in compliance with OPNAVINST 5090.1B. Fragments of expended training materials, e.g. ammunition, bombs and missiles, targets, sonobuoys, chaff, and flares, could be deposited on the ocean floor. The widely dispersed, intermittent, minute size of the material minimizes the impact. Wave energy and currents will further disperse the materials. Alternative 1: Implementation of Alternative 1 would not result in significant impacts associated with the use of hazardous materials. Impacts from hazardous materials and waste from increased training activities, RDT&E activities, and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Implementation of Alternative 2 would not result in significant impacts associated with the use of hazardous materials. Impacts from hazardous materials and waste from additional increases in training activities, RDT&E activities, and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.
Health and Safety	No-action: Implementation of the No-action Alternative would not affect public health and safety. Any potential risk to public health and safety is minimized through standard operating procedures and compliance with DoD Directive 4540.1, OPNAVINST 3770.4 and Commander, Naval Surface Force, U.S. Pacific Fleet (COMNAVSURFPAC) Instruction 3120.8F. The Navy notifies the public of hazardous activities through the use of Notices to Airmen (NOTAMs) and Notices to Mariners (NOTMARs). Alternative 1: Implementation of Alternative 1 would not affect public health and safety. Any potential impacts on health and safety from the additional training activities, RDT&E activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Implementation of Alternative 2 would not affect public health and safety. Any potential impacts on health and safety from the additional training activities, RDT&E activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.
Noise	No-action: Implementation of the No-action Alternative would not incrementally affect noise within the HRC. Activities are remote, infrequent, and lack sensitive receptors. In addition, training activities do not have an effect on sensitive noise receptors because these activities are typically conducted away from populated areas and most sensitive noise receptors. Standard operating procedures are used to ensure the area is clear of civilian vessels or other non-participants. The public is notified of the location, date, and time of the hazardous activities via NOTMARs, thereby precluding any acoustical impacts on sensitive receptors. Alternative 1: Implementation of Alternative 1 would not incrementally affect noise within the HRC. Impacts from noise from increased training activities, RDT&E activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Implementation of Alternative 2 would not incrementally affect noise within the HRC. Impacts from noise from additional training activities, RDT&E activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.
Water Resources	No-action: Potential water quality impacts associated with the implementation of the No-action Alternative are transitory in nature and would not reach a level of significance. No long-term significant impacts on water quality are anticipated. Impacts are not anticipated due to the small quantities of materials relative the extent of the sea ranges and large volumes of water in which they will be dispersed. Alternative 1: Impacts on water resources from increase training activities, RDT&E activities, and Major Exercises are not anticipated. Any potential impacts would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on water resources from increased training activities, future RDT&E activities, and Major Exercises are not anticipated. Any potential impacts would be minimized as described above in the No-action Alternative. Alternative 3: Water Resources impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.

Note: Impacts on Biological Resources (Onshore), Geology and Soils, Land Use, and Utilities are not applicable. Impacts discussed for biological resources in the Open Ocean apply to both offshore and onshore areas. There are no impacts on Air Quality, Socioeconomics or Transportation due to site activities under the No-action Alternative, Alternative 1, Alternative 2 or Alternative 3.

Table ES-3. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Northwestern Hawaiian Islands

Resource Category	Northwestern Hawaiian Islands
Biological Resources (Offshore and Onshore)	No-action: Some current flight trajectories could result in missiles such as the Terminal High Altitude Area Defense (THAAD) flying over portions of the Papahānaumokuākea Marine National Monument. Preliminary results of debris analysis indicate that debris is not expected to severely harm threatened, endangered, migratory, or other endemic species on or offshore of Nihoa and Necker Islands. The probability for debris to hit birds, seals, or other wildlife will be extremely low. Quantities of falling debris will be low and widely scattered so as not to present a toxicity issue. Falling debris will also have cooled down sufficiently so as not to present a fire hazard for vegetation and habitat. If feasible, consideration will be given to alterations in the missile flight trajectory, to further minimize the potential for debris impacts. Alternative 1: There are no additional proposed activities or exercises that would affect the Northwestern Hawaiian Islands; ongoing activities would be minimized as described above in the No-action Alternative. Alternative 2: There are no additional proposed activities or exercises that would affect the Northwestern Hawaiian Islands; ongoing activities would be minimized as described above in the No-action Alternative. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses in detail the factors that influenced this analysis.
Cultural Resources	No-action: Missile defense activities, including THAAD, have the potential to generate debris that falls within areas of the Papahānaumokuākea Marine National Monument. Debris analyses of the types, quantities, and sizes associated with the Pacific Missile Range Facility missile activities indicate that the potential to impact land resources of any type on Nihoa or Necker is low and extremely remote. In addition, trajectories can be altered under certain circumstances to further minimize the potential for impacts. Future missions will include consideration of missile flight trajectory alterations, if feasible, to minimize the potential for debris within these areas. As a result, impacts on cultural resources within the Northwestern Hawaiian Islands are not expected. Alternative 1: There are no additional proposed activities or exercises that would affect the Northwestern Hawaiian Islands; the potential for impacts from ongoing activities would be minimized as described above in the No-action Alternative. Alternative 2: There are no additional proposed activities or exercises that would affect the Northwestern Hawaiian Islands; the potential for impacts from ongoing activities would be minimized as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapters 4.0 and 5.0 discuss in detail the factors that influenced this analysis.

Note: No impacts on Air Quality, Airspace, Geology and Soils, Hazardous Materials and Waste, Health and Safety, Land Use, Noise, Socioeconomics, Transportation, Utilities, and Water Resources are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Air Quality	No-action: Air quality conditions will not differ from existing conditions. Compliance with standard operating procedures and air permits will continue to minimize impacts. Emissions generated by base activities do not affect the regional air quality. The tempo of launch events will continue to be managed by range activities in order to stay within the limits of current agreements. Alternative 1: Potential impacts on air quality from increased training activities, RDT&E activities, HRC enhancements, and Major Exercises would be minimized as described in the No-action Alternative. Construction would create fugitive dust emissions, diesel exhaust emissions; no change in regional air quality due to compliance with standard operating procedures for construction, including implementation of dust suppression methods and a vehicle maintenance program. No change to regional air quality is anticipated. Alternative 2: Impacts on air quality from increased training activities, RDT&E activities, and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. No change to regional air quality status is anticipated. Alternative 3: Air Quality impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Infrequent emissions associated with intermittent use of diesel generators; no change in current regional air quality. Alternative 1: Increased use of diesel generators; construction would create fugitive dust emissions, diesel exhaust emissions, and VOCs; no change in regional air quality due to compliance with standard operating procedures for construction, including implementation of dust suppression methods and a vehicle maintenance program is anticipated. No change to regional air quality is anticipated. Alternative 2: Impacts from increased training activities and Major Exercises would be minimized as described above in Alternative 1. Alternative 3: Air Quality impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Infrequent emissions associated with intermittent use of diesel generators; no change in current regional air quality. Alternative 1: Increased use of diesel generators; construction would create fugitive dust emissions, diesel exhaust emissions, and VOCs; no change in regional air quality due to compliance with standard operating procedures for construction, including implementation of dust suppression methods and a vehicle maintenance program is anticipated. No change to regional air quality is anticipated. Alternative 2: Impacts from increased training activities, and Major Exercises would be minimized as described in Alternative 1. Alternative 3: Air Quality impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Airspace	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields will continue to be minimized through standard operating procedures, compliance with DoD Directive 4540.1, OPNAVINST 3770.4A, OPNAVINST 3721.20, and continued close coordination with the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from ongoing activities, increased training activities, increase RDT&E activities, planned test and evaluation activities, or HRC enhancements would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from ongoing activities, additional Major Exercises, increased training exercises, or additional RDT&E activities would be minimized as described in the No-action alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1 and Alternative 2 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Biological Resources (Offshore and Onshore)	No-action: Activities take place in current operating areas, with no expansion. Compliance with relevant Navy policies and procedures during these training activities will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No impacts from electromagnetic radiation generation to wildlife are anticipated. Alternative 1: Impacts on biological resources from increased training activities, RDT&E activities, and HRC enhancements would be minimized as described above in the No-action Alternative. Because construction-related noise would be localized, intermittent, and occur over a relatively short-term, the potential for impacts on biological resources would be minimal. Additional electromagnetic radiation would not affect wildlife. Sound levels from FCLPs would be similar to existing sound levels on the runway. Alternative 2: Impacts on biological resources from increased training activities, RDT&E activities, and Major Exercises would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Additional it is anticipated that electromagnetic radiation would not affect wildlife. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion anticipated. Compliance with relevant Navy policies and procedures during these training activities will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Currently there are no impacts from electromagnetic radiation generation to wildlife. Alternative 1: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Effects on wildlife from construction-related noise and presence of additional personnel would be minimal. Additional electromagnetic radiation is not anticipated to affect wildlife. Alternative 2: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Additional electromagnetic radiation is not anticipated to affect wildlife. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion anticipated. Compliance with relevant Navy policies and procedures will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Currently there are no impacts from electromagnetic radiation generation to wildlife. Alternative 1: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Effects on wildlife from construction-related noise and presence of additional personnel would be minimal. Additional electromagnetic radiation is not anticipated to affect wildlife Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Additional electromagnetic radiation is not anticipated to affect wildlife. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Cultural Resources	No-action: Activities occur in designated areas and sensitive areas are avoided. Any potential for impacts on cultural resources are offset through compliance with the PMRF Integrated Cultural Resources Management Plan (ICRMP) and standard operating procedures. Alternative 1: Any potential impacts from increased training activities, RDT&E activities, and HRC enhancements would be minimized as described above in the No-action Alternative. Alternative 2: Any potential impacts from increased training activities, RDT&E activities, and Major Exercises (e.g., RIMPAC) would be minimized as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Makaha Ridge has been surveyed for archaeological, historical, and Native Hawaiian resources and none have been identified. As a result, No-action Alternative activities will not affect any cultural resources. Alternative 1: An increase in the tempo and frequency of training activities would not affect any cultural resources because Makaha Ridge has been surveyed for cultural resources and there are none present. If archaeological or Native Hawaiian resources are unexpectedly encountered during HRC enhancements, the Hawaii SHPO would be notified. Alternative 2: Any potential impacts and proposed mitigations would be the same as described in Alternative 1. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2 and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.
Geology and Soils	No-action: Ongoing training activities and exercises will continue to have minimal direct impact on the beach and inland areas, and soils are not being permanently affected. Alternative 1: New construction would follow standard methods to control erosion during construction. Soil disturbance would be limited to the immediate vicinity of the construction area and would be of short duration. Base personnel would exercise best management practices to reduce soil erosion. Alternative 2: Impacts would be minimized as described above in Alternative 1. Alternative 3: Geology and Soils impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Hazardous Materials and Waste	No-action: PMRF/Main Base has appropriate plans and standard operating procedures in place to manage hazardous materials and waste. Alternative 1: Impacts from hazardous materials and waste from increased training activities, RDT&E activities, and HRC enhancements would be minimized as described above in the No-action Alternative. Any construction activities would comply with standard operating procedures and adhere to the existing hazardous management plans. Alternative 2: Impacts from hazardous materials and waste from additional increases in training activities, RDT&E activities and additional Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Alternative 3: Hazardous Materials and Wastes impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Makaha Ridge currently has appropriate plans in place to manage hazardous materials and waste. Alternative 1: The increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Any construction activities would comply with standard operating procedures and adhere to the existing hazardous management plans. Alternative 2: Impacts from hazardous materials and waste from additional increases in training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Hazardous Materials and Wastes impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Kokee currently has appropriate plans in place to manage hazardous materials and waste. Alternative 1: The increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Any construction activities would comply with standard operating procedures and adhere to the existing hazardous management plans. Alternative 2: Impacts from additional increases in training activities and Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Alternative 3: Hazardous Materials and Wastes impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Health and Safety	No-action: Risk to public health and safety is will continue to be minimized through compliance with standard operating procedures, policies, and plans. Alternative 1: Impacts on health and safety from additional training activities, RDT&E activities, HRC enhancements, and Major Exercises would be minimized as described above in the No-action Alternative. Construction would be in accordance with USACE Safety and Health Requirements Manual. Alternative 2: Impacts on health and safety from additional training activities, RDT&E activities, and additional Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will continue to minimize impacts. All location(s) are away from the public which results in no adverse public health and safety issues. Alternative 1: Impacts on health and safety from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Construction would be in accordance with USACE Safety and Health Requirements Manual. Alternative 2: Impacts on health and safety from additional training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will continue to minimize impacts. Alternative 1: Impacts on health and safety from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Construction would be in accordance with USACE Safety and Health Requirements Manual. Alternative 2: Impacts on health and safety from additional training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Land Use	No-action: Land uses and Agricultural Preservation Initiative are compatible with PMRF activities. The continuation of activities will be consistent to the maximum extent practicable with the Hawaii Coastal Zone Management Program. Closure of public recreational areas during hazardous activities will continue Alternative 1: Land use is compatible with increased training activities, training activities, RDT&E activities, HRC enhancements, and Major Exercises; additional closure of public recreation areas during hazardous activities is anticipated. Addition of FCLPs would not alter current land use patterns. Alternative 2: Land uses would be compatible with proposed increased training activities, training activities, RDT&E activities, and additional Major Exercises; additional closure of public recreation areas during hazardous activities is anticipated. Alternative 3: Land Use impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Noise	No-action: PMRF maintains a hearing protection program and has standard operating procedures in place that minimize impacts. Beach access to the areas of each of the exercises is restricted for the duration of the exercise. Alternative 1: Impacts from noise from increased training activities (including FCLPs), RDT&E activities, and HRC enhancements would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from noise from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Socioeconomics	No-action: Beneficial impacts on economy and community on Kauai. Alternative 1: Small increase in beneficial impacts on economy on Kauai from increased training activities, future RDT&E activities, and Major Exercises. Alternative 2: Small increase in beneficial impacts on economy on Kauai from increased training activities, future RDT&E activities, and additional Major Exercises. Alternative 3: Socioeconomic impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	PMRF/Main Base	Makaha Ridge	Kokee
Transportation	No-action: No impacts identified for the transportation system; PMRF events are discrete and intermittent. Transportation of ordnance and liquid propellants are conducted in accordance with established procedures. Alternative 1: Minimal increase in average daily traffic due to increased training activities, HRC enhancements, and Major Exercises. Traffic generated by construction personnel would be temporary and would result in minor additional traffic. Major exercises are discrete and intermittent with minimal temporary increase in traffic. Alternative 2: No additional traffic would be generated for increased training activities, RDT&E activities, and additional Major Exercises above what would be generated for Alternative 1. Alternative 3: Transportation impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis,	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Utilities	No-action: Current utility capacity meets demands. Alternative 1: Electricity demand, potable water consumption, wastewater generated, and solid waste disposal would be handled by existing facilities. Alternative 2: Additional electricity demand, potable water consumption, wastewater generated and solid waste disposal would be handled by existing facilities. Operation of a high-energy laser would require 30 megawatts of power (additional documentation would be required). Alternative 3: Utility impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Water Resources	No-action: Compliance with standard operating procedures and policies will continue to minimize impacts. Training activities have minimal impact on beach and inland areas and surface drainage is not permanently affected. Emissions from launches and exercises do not significantly affect water resources. Alternative 1: Impacts on water resources from increased training activities, RDT&E activities, HRC enhancements, and Major Exercises would be minimized as described in the No-action Alternative. Slight increase in missile launch emissions would not significantly affect water quality. Construction activities associated with HRC enhancements would follow standard operating procedures minimizing potential impacts from accidental spills of hazardous materials. Alternative 2: Impacts on water resources from increased training activities, RDT&E activities, HRC enhancements, and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Water Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai

Resource Category	Hawaii Air National Guard Kokee	Kamokala Magazines	Niihau	Kaula
Airspace	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Continued close coordination with the FAA and PMRF regarding continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways, and jet routes will continue to minimize impacts. Alternative 1: Impacts on airspace from ongoing activities, increased training activities, RDT&E activities or HRC investments would be minimized as described above in the No-action Alternative. No new airspace proposal or any modification to existing airspace is anticipated. Alternative 2: Impacts on airspace from ongoing activities, additional Major Exercises, increased training exercises, or additional RDT&E activities or HRC investments would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Biological Resources (Offshore and Onshore)	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion anticipated. Compliance with relevant Navy policies and procedures will continue to minimize the effects on wildlife. Currently there are no impacts from electromagnetic radiation generation to wildlife. Alternative 1: Impacts on biological resources from increased training activities would be minimized as described above in the No-action Alternative. Additional electromagnetic radiation is not anticipated to affect wildlife. Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy policies and procedures during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No impacts from electromagnetic radiation generation to wildlife. Alternative 1: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Minimal impacts on biological resources from construction; additional electromagnetic radiation would not affect wildlife.	No-action: Currently there are minimal impacts on vegetation; Mitigation measures are in place that reduce or eliminate any potential impacts on marine mammals. Currently there are minimal impacts on migratory seabirds. Alternative 1: Training Activities and Major Exercises take place in current operating areas, with no expansion anticipated. Compliance with relevant Navy, NMFS, and USFWS policies and procedures during these training activities would minimize the effects on vegetation and wildlife.

Table ES-4B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	Hawaii Air National Guard Kokee	Kamokala Magazines	Niihau	Kaula
Biological Resources (Offshore and Onshore) (Continued)			Alternative 2: Impacts on biological resources from increased training activities and Major Exercises would be as described above in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Alternative 2: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. No potential impacts on migratory seabird populations. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Cultural Resources	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	No-action: There are no known cultural resources sites within the ROI for Kaula; therefore, there will be no impacts on cultural resources from training activities or Major Exercises. Alternative 1: There are no known cultural resources sites within the ROI for Kaula; therefore, there will be no impacts on cultural resources from increased training activities. Alternative 2: There will be no impacts on cultural resources from any additional increases in training activities because there are no known cultural resources within the Kaula ROI. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2.

Table ES-4B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	Hawaii Air National Guard Kokee	Kamokala Magazines	Niihau	Kaula
Geology and Soils	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Impacts are currently minimized due to concentrating targeting on the southeast tip of the island. Alternative 1: Impacts from Increased training and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from increased training and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Geology and Soils impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Hazardous Materials and Waste	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: PMRF currently has procedures in place to manage hazardous materials and waste. Storage and transportation or ordnance is conducted in accordance with established DOT, DoD, and Navy safety procedures. Alternative 1: Impacts would be minimized as described in the No-action Alternative. Alternative 2: Impacts would be minimized as described in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: PMRF currently has appropriate plans in place to manage hazardous materials and waste. Alternative 1: Impacts from the increase in training activities and Major Exercises would be minimized as described in the No-action Alternative. Any construction activities would comply with standard operating procedures and adhere to the existing hazardous management plans. Alternative 2: Impacts from additional increases in training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-4B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Kauai (Continued)

Resource Category	Hawaii Air National Guard Kokee	Kamokala Magazines	Niihau	Kaula
Health and Safety	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Compliance with existing health and safety plans and procedures will continue to minimize impacts. No change in the type of ordnance stored and no increase safety risks. Storage and transportation of ordnance are conducted in accordance with established DOT, DoD and Navy safety procedures. Alternative 1: Impacts would be minimized as described above in the No-action Alternative. The factors that influenced this analysis. Alternative 2: Impacts would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with existing health and safety plans and procedures will continue to minimize impacts. Location of radar and electronic warfare sites away from the public results in no adverse public health and safety issues. Alternative 1: Impacts from additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Construction would be in accordance with USACE Safety and Health Requirements Manual. Alternative 2: Impacts from additional training activities and Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with existing health and safety plans and procedures will continue to minimize health and safety risks. Alternative 1: Impacts from additional training activities would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from additional training activities would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2.
Land Use	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Land use is compatible with Navy activities. The continuation of activities will remain consistent to the maximum extent practicable with the Hawaii Coastal Zone Management Program. Alternative 1: Land use is compatible with increased activities and Major Exercises. Alternative 2: Land use is compatible with increased activities and Major Exercises. Alternative 3: Land use impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Note: No impacts at Port Allen, Kikiaola Small Boat Harbor, or Mt. Kahili are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. No impacts on Air Quality, Geology and Soils, Noise, Socioeconomics, Transportation, Utilities, and Water Resources are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Naval Station Pearl Harbor	Ford Island	Naval Inactive Ship Maintenance Facility, Pearl Harbor
Biological Resources (Offshore and Onshore)	No-action: Procedures and policies are in place to minimize the potential for impacts on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No impacts on essential fish habitat. Alternative 1: Impacts on biological resources from increased activities and Major Exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts on biological resources from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize the potential for impacts on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. No impacts on essential fish habitat. No critical habitat has been identified. Alternative 1: Impacts on biological resources from increased activities and Major Exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts on biological resources from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize impacts on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Minor and localized impacts on fish. No impacts on essential fish habitat. Alternative 1: Impacts on biological resources from increased activities and Major Exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts on biological resources from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Cultural Resources	No-action: To minimize any potential impacts, activities will continue to be conducted in accordance with the policies, guidelines, and standard operating procedures outlined in the Pearl Harbor Naval Complex Integrated Cultural Resources Management Plan (ICRMP), or any other agreement documents promulgated since completion of the ICRMP. There are no significant cultural resources within the direct ROI for activities. The Loko Okiokiolepe fishpond is the closest National Register property (approximately half a mile north of the EOD Shore Range). Alternative 1: Any potential impacts from increased training activities would be minimized as described above in the No-action Alternative. Alternative 2: Any potential impacts from additional increases in training activities would minimized as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: There are no training or Major Exercises with the potential to affect cultural resources. Alternative 1: Installation of equipment to support the ATF [Acoustic Test Facility] would be conducted in accordance with the Pearl Harbor Naval Complex ICRMP and would require coordination with the Navy Region Hawaii's cultural resource coordinator. Alternative 2: There are no new Major Exercises or training activities with the potential to affect cultural resources. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.

Table ES-5A. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Naval Station Pearl Harbor	Ford Island	Naval Inactive Ship Maintenance Facility, Pearl Harbor
Hazardous Materials and Waste	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Naval Inactive Ship Maintenance Facility, Pearl Harbor has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Impacts from the increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from additional increases in training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Hazardous Materials and Wastes impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Socioeconomics	No-action Beneficial impacts on economy and community on Oahu. Alternative 1: Current Beneficial impacts would continue. Small increase in beneficial impacts on economy on Oahu from increased RDT&E and Major Exercises. Alternative 2: Current Beneficial impacts would continue. Small increase in beneficial impacts on economy on Oahu from increased training activities, and additional Major Exercises. Alternative 3: Socioeconomic impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Water Resources	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: There are no training activities, RDT&E activities, or Major Exercises with the potential to affect water resources. Alternative 1: There are no training activities, RDT&E activities, or Major Exercises with the potential to affect water resources. HRC enhancements would adhere to standard operating procedures for construction to minimize and avoid adverse impacts on water quality. Alternative 2: Impacts would be minimized as described above in Alternative 1. Alternative 3: Water Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Note: No impacts on Air Quality, Airspace, Geology and Soils, Health and Safety, Land Use, Noise, Transportation, and Utilities, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	EOD Range NAVMAG Pearl Harbor West Loch	Lima Landing	Puuloa Underwater Range
Biological Resources (Offshore and Onshore)	No-action: Procedures and policies are in place to minimize impacts on biological resources. Intrusive noise could startle noise-sensitive wildlife in the vicinity. Alternative 1: Impacts from increased activities and training exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from additional increases in activities and training exercises would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize impacts on biological resources. Minor and localized impacts on fish. No impacts on essential fish habitat. Alternative 1: Impacts from increased activities and exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Minor and localized impacts on fish. Alternative 2: Impacts from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize impacts on biological resources. Minor and localized impacts on fish. No impacts on essential fish habitat. Any effects from noise, shock, or residual chemicals will be localized and temporary. Alternative 1: Impacts from increased activities and Major Exercises would be minimized as described in the No-action Alternative. Activities would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative and Alternative 1. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Cultural Resources	No-action: There are no ongoing training activities with the potential to affect cultural resources because there are no cultural resources present in the ROI. Alternative 1: Increasing training activities would not affect cultural resources because there are no cultural resources present in the ROI. Alternative 2: Additional increases in training activities would not affect cultural resources because there are no cultural resources present in the ROI. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: There are no cultural resources within the ROI for Lima Landing's underwater demolition activities therefore no effects on cultural resources are expected. Any changes to the location of these activities would be coordinated with the Navy Region, Hawaii, cultural resources coordinator Alternative 1: Because there are no cultural resources within the ROI, no impacts on cultural resources are expected from increased training. Alternative 2: Because there are no cultural resources within the ROI, no impacts on cultural resources are expected from additional increases in training. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: There are no cultural resources within the ROI for Puuloa Underwater Range activities; therefore no effects on cultural resources are expected. Alternative 1: Because there are no cultural resources within the ROI, no impacts on cultural resources are expected from increased training. Alternative 2: Because there are no cultural resources within the ROI, no impacts on cultural resources are expected from increased training. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	EOD Range NAVMAG Pearl Harbor West Loch	Lima Landing	Puuloa Underwater Range
Geology and Soils	No-action: Policies and procedures are in place to minimize any impacts. EOD training is not expected to affect the geology of the Range; no construction or excavation is planned. Minor contamination of surface soil. Alternative 1: Impacts from increased training activities would be minimized as described above in the No-action Alternative Alternative 2: Impacts from additional Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Geology and Soils impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Hazardous Materials and Waste	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Lima Landing has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Impacts from the increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from additional increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Puuloa Underwater Range has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Impacts from the increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional increase in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5B. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	EOD Range NAVMAG Pearl Harbor West Loch	Lima Landing	Puuloa Underwater Range
Health and Safety	No-action: Compliance with standard operating procedures will continue to minimize impacts. Location away from the public results in no adverse public health and safety issues. Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will minimize impacts. Location away from the public results in no adverse public health and safety issues. Demolition activities are conducted in accordance with COMNAVSURFPAC Instruction 3120.8F. Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will minimize impacts. Location away from the public results in no adverse public health and safety issues. Demolition activities are conducted in accordance with COMNAVSURFPAC Instruction 3120.8F Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Water Resources	No-action: Intermittent, short-term discharges of minute amounts of munitions constituents into surface waters and have no effect on water resources. Alternative 1: Increases in training activities would not significantly affect water resources. Alternative 2: Additional increases in training activities would not significantly affect water resources. Alternative 3: Water Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Note: No impacts on Air Quality, Airspace, Land Use, Noise, Socioeconomics, Transportation, and Utilities, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5C. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Naval Defensive Sea Area	CG Station Barbers Point/Kalaeola Airport	Marine Corps Base Hawaii
Airspace	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, and coordination with the State of Hawaii, U.S. Coast Guard, Kalaeloa Airport, and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures and continued close coordination with the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities, and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from ongoing activities, increased training activities, and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Biological Resources (Offshore and Onshore)	No-action: Procedures and policies are in place to minimize impacts on biological resources. No essential fish habitat affected. Alternative 1: Impacts would be minimized as described above in the No-action Alternative. Increased activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Alternative 2: Impacts would be minimized as described above in the No-action Alternative. Increased activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy and Coast Guard policies and procedures during these training activities will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Alternative 1: Impacts from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Marine Corps and Navy procedures and policies are in place to minimize impacts on biological resources and prevent introduction of invasive species. Alternative 1: Impacts from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 2: Impacts from increased activities and additional Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5C. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	Naval Defensive Sea Area	CG Station Barbers Point/Kalaeola Airport	Marine Corps Base Hawaii
Cultural Resources	No-action: There are no known historic properties (i.e., cultural resources eligible for or listed in the National Register) located within the ROI for the Naval Defensive Sea Area; therefore, there will be no impacts on cultural resources from training and RDT&E operations under the No-action. Alternative 1: Because there are no known historic properties within the ROI, increased training activities and Major Exercises will have no impacts on cultural resources. Alternative 2: Because there are no known historic properties within the ROI, additional increases in training activities and Major Exercises will have no impacts on cultural resources. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	No-action: Activities occur in designated areas and sensitive areas are avoided. Compliance with the standard operating procedures and policies minimizes impacts. If cultural resources are unexpectedly encountered the Hawaii SHPO will be notified. Alternative 1: Any impacts from increased training activities would be treated as described above in the No-action Alternative. Alternative 2: Any impacts from additional increases in training activities would be treated as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Health and Safety	No-action: Compliance with standard operating procedures will minimize impacts. The activities will be completely contained and the area cleared resulting in no adverse public health and safety issues. Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-5C. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	Naval Defensive Sea Area	CG Station Barbers Point/Kalaeola Airport	Marine Corps Base Hawaii
Noise	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Coast Guard Air Station Barbers Point has appropriate plans in place to manage noise levels. Noise produced is expected to stay within the existing noise contours. Alternative 1: Minor impacts are anticipated for areas near the airport from increased activities, training exercises, and Major Exercises. Alternative 2: Minor impacts are anticipated for areas near the airport from increased activities, training exercises, and Major Exercises. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: MCBH maintains a hearing protection program that will continue to minimize impacts. Noise levels that reach off-post are mitigated by public notification and restricting training to daylight hours. Alternative 1: Increased training activities would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Note: No impacts on Air Quality, Geology and Soils, Hazardous Materials and Waste, Land Use, Socioeconomics, Transportation, Utilities, and Water Resources, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5D. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	MCTAB	Hickam AFB	Wheeler Army Airfield
Airspace	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, and coordination with the Air Force, Honolulu International Airport, and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, and coordination with the Army and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities would be minimized as described in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Biological Resources (Offshore and Onshore)	No-action: MCTAB and Navy procedures and policies are in place to minimize impacts on biological resources and prevent introduction of invasive species. Alternative 1: Increased training activities would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Hickam AFB and Navy procedures and policies are in place to continue to minimize impacts on biological resources and prevent introduction of invasive species. Chapter 4.0 discusses the factors that influenced this analysis. Alternative 1: Increased training activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Army and Navy procedures and policies are in place to minimize impacts on biological resources and prevent introduction of invasive species. No critical habitat has been identified on Wheeler Army Airfield. Alternative 1: Increased training activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5D. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	MCTAB	Hickam AFB	Wheeler Army Airfield
Cultural Resources	No-action: Activities occur in designated areas and sensitive areas are avoided. Compliance with standard operating procedures and policies minimizes impacts. If cultural resources are unexpectedly encountered the Bellows AFS cultural resources coordinator will be notified. Alternative 1: Any impacts from increased training activities would be treated as described above in the No-action Alternative. Alternative 2: Any impacts from additional increases in training activities would be treated as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.

Note: No impacts on Air Quality, Geology and Soils, Hazardous Materials and Waste, Health and Safety, Land Use, Noise, Socioeconomics, Transportation, Utilities, and Water Resources, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5E. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Makua Military Reservation	Kahuku Training Area	Dillingham Military Reservation
Biological Resources (Offshore and Onshore)	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy and Army policies, procedures, and plans during these training activities will continue to minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Critical habitat and sensitive areas will be avoided where possible. Alternative 1: Impacts from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. No-action: Activities occur in designated areas and sensitive areas are avoided. Compliance with standard operating procedures, policies, and plans minimizes impacts. If cultural resources are unexpectedly encountered the Hawaii SHPO (if the find is made by Marine Corps or Navy) or the Schofield Barracks cultural resources manager (if the find occurs during Army activities) will be notified. Alternative 1: Any impacts from increased training activities would be treated as described above in the No-action Alternative. Alternative 2: Any impacts from additional increases in training activities would be treated as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-5E. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu (Continued)

Resource Category	Makua Military Reservation	Kahuku Training Area	Dillingham Military Reservation
Health and Safety	No-action: Compliance with standard operating procedures and plans will continue to minimize impacts. Alternative 1: Impacts from the additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from the additional training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Noise	No-action: Makua Military Reservation maintains a hearing protection program that will minimize impacts. Alternative 1: Increased training activities would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Note: No impacts on Air Quality, Airspace, Geology and Soils, Hazardous Materials and Waste, Land Use, Socioeconomics, Transportation, Utilities, and Water Resources, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-5F. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Ewa Training Minefield	Barbers Point Underwater Range	Naval Undersea Warfare Center
Biological Resources (Offshore and Onshore)	No-action: Procedures and policies are in place to minimize impacts on biological resources. Minor and localized impacts on fish. Any effects from noise, shock, or residual chemicals will continue to be localized and temporary. Alternative 1: Increased activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Increased activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Procedures and policies are in place to minimize impacts on biological resources. Minor and localized impacts on fish. No impacts on essential fish habitat. Alternative 1: Increased activities and Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described in the No-action Alternative. Alternative 2: Increased activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Impacts would be minimized as described above in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	SESEF - No-action: Procedures and policies are in place to minimize impacts on biological resources. Alternative 1: Impacts from increased activities would be minimized as described above in the No-action Alternative. Alternative 2: Impacts from increased activities would be minimized as described in the No-action Alternative. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis. FORACS - No-action: Procedures and policies are in place to minimize impacts on biological resources Alternative 1: Impacts from increased activities would be minimized as described in the No-action Alternative. Alternative 2: Impacts from increased activities would be minimized as described in the No-action Alternative. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.
Hazardous Materials and Waste	No-action: Ewa Training Minefield has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Increases in training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 2: Additional increases in training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Barbers Point Underwater Range has appropriate plans in place to manage hazardous materials used and generated. Alternative 1: Increases in training activities and Major Exercises would be minimized as described above in the No-action Alternative Alternative 2: Additional increases in training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Hazardous Materials and Waste impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-5F. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Oahu

Resource Category	Ewa Training Minefield	Barbers Point Underwater Range	Naval Undersea Warfare Center
Health & Safety	No-action: Compliance with standard operating procedures will minimize impacts. Demolition activities are conducted in accordance with COMNAVSURFPAC Instruction 3120.8F. Alternative 1: The additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: The additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Compliance with standard operating procedures will minimize impacts. Demolition activities are conducted in accordance with COMNAVSURFPAC Instruction 3120.8F. Alternative 1: The additional training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: The additional training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	SESEF & FORACS - No-action: Compliance with standard operating procedures will minimize impacts. Alternative 1: The increased RDT&E activities would be minimized as described above in the No-action Alternative. Alternative 2: The increased RDT&E activities would be minimized as described in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Note: No impacts on Air Quality, Airspace, Cultural Resources, Geology and Soils, Land Use, Noise, Socioeconomics, Transportation, Utilities, and Water Resources, are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean. No impacts at Keehi Lagoon, Kaena Point, Mt. Kaala, Wheeler Network Communications Control, Mauna Kapu Communication Site, or Makua Radio/Repeater/Cable Head are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3.

Table ES-6. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Maui

Resource Category	Maui Offshore
Biological Resources (Offshore and Onshore)	No-action: Compliance with policies and procedures will continue to minimize impacts on biological resources. Alternative 1: Impacts on biological resources from increased training activities would be minimized as described in the No-action Alternative. The Portable Undersea Tracking Range would be used in areas around Maui with water depths less than 300 feet. Other than the temporary disturbance to marine species during instrumentation installation and recovery, no impacts would be expected to occur. Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Alternative 3: Impacts on biological resources would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Note: No impacts on Air Quality, Airspace, Cultural Resources, Geology and Soils, Hazardous Materials and Waste, Health and Safety, Land Use, Noise, Socioeconomics, Transportation, Utilities, or Water Resources are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean. No impacts at the Maui Space Surveillance Site, the Shallow Water Minefield Sonar Training Area, the Maui High Performance Computing Center, or the Sandia Maui Haleakala Facility are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3.

Table ES-7. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Hawaii

Resource Category	Pohakuloa Training Area	Bradshaw Army Airfield	Kawaihae Pier
Airspace	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, coordination with PTA Range Control and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Airspace impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Impacts on airspace from continued activities and activities to controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, or airports and airfields are minimized through standard operating procedures, coordination with PTA Range Control and the FAA. No modifications or need for additional airspace is required. Alternative 1: Impacts on airspace from increased training activities and Major Exercises would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on airspace from increased training activities and additional Major Exercises would be minimized as described above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2 and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.
Biological Resources (Offshore and Onshore)	No-action: Training Activities and Major Exercises will take place in current operating areas, with no expansion. Compliance with relevant Navy policies, procedures, and plans during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Alternative 1: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Alternative 2: Impacts on biological resources from increased training activities and Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: These activities are limited in scope and are not anticipated to impact the areas beyond the airfield itself. Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy policies, procedures, and plans during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Alternative 1: Impacts on biological resources from increased training activities would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds are anticipated. The intensity and duration of wildlife startle responses decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: Training Activities and Major Exercises take place in current operating areas, with no expansion. Compliance with relevant Navy policies and procedures during these training activities will minimize the effects on vegetation and wildlife, as well as limit the potential for introduction of invasive plant species. Sensitive biological resource areas are avoided. Alternative 1: No increases in training events at Kawaihae Pier are expected. Impacts would be minimized as described above in the No-action Alternative. Alternative 2: Impacts on biological resources from increased training activities and additional Major Exercises would be minimized as described in the No-action Alternative. Temporary, short-term startle effects from noise to wildlife and birds anticipated. The intensity and duration of wildlife startle responses may decrease with the number and frequency of exposures. Alternative 3: Biological Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.

Table ES-7. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Hawaii (Continued)

Resource Category	Pohakuloa Training Area	Bradshaw Army Airfield	Kawaihae Pier
Cultural Resources	No-action: Activities occur in designated areas and sensitive areas are avoided. Compliance with standard operating procedures and policies minimizes impacts. If cultural resources are unexpectedly encountered then the PTA cultural resources manager will be contacted. Alternative 1: Any impacts from increased training activities would be treated as described above in the No-action Alternative. Alternative 2: Any impacts from additional increases in training activities would be treated as described above in the No-action Alternative. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	No-action: There are no training or Major Exercises with the potential to affect cultural resources at Bradshaw Army Airfield. Policies and procedures are in place to minimize any potential impacts. Alternative 1: Because there is no training or Major Exercises with the potential to affect cultural resources at Bradshaw Army Airfield, no impacts on cultural resources are expected. To avoid impacts from any HRC enhancements, activities would be coordinated with the PTA cultural resources manager. Policies and procedures are in place to minimize any potential impacts. Alternative 2: Because there is no training or Major Exercises with the potential to affect cultural resources at Bradshaw Army Airfield, no impacts on cultural resources are expected. To avoid impacts from any HRC enhancements, activities would be coordinated with the PTA cultural resources manager. Policies and procedures are in place to minimize any potential impacts. Alternative 3: Cultural Resources impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	Analysis of any potential impacts from training and RDT&E operations under the No-action, Alternative 1, Alternative 2, and Alternative 3 has been performed. Analysis indicates that neither short- nor long-term impacts are anticipated from the proposed alternatives.
Health and Safety	No-action: Compliance with existing health and safety plans and procedures will minimize impacts. Alternative 1: Impacts on health and safety from the additional training activities and HRC enhancements would be minimized as discussed above in the No-action Alternative. Alternative 2: Impacts on health and safety from the additional training activities and Major Exercises would be minimized as discussed above in the No-action Alternative. Alternative 3: Health and Safety impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Table ES-7. Summary of Environmental Impacts for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, Hawaii (Continued)

Resource Category	Pohakuloa Training Area	Bradshaw Army Airfield	Kawaihae Pier
Noise	No-action: PTA will continue to maintain a hearing protection program that will minimize impacts. Alternative 1: Increased training activities would take place at existing locations; no expansion of the area would be involved. Noise impacts would be minimized as discussed above in the No-action Alternative. Alternative 2: Increased training activities and additional Major Exercises would take place at existing locations; no expansion of the area would be involved. Noise impacts would be minimized as discussed above in the No-action Alternative. Alternative 3: Noise impacts would be the same as those described under Alternative 2. Chapter 4.0 discusses the factors that influenced this analysis.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.	A review of this environmental resource against training and RDT&E operations under the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 was performed. Analysis indicated that the proposed alternatives would not result in either short-or-long term impacts for this resource.

Note: No impacts on Air Quality, Geology and Soils, Hazardous Materials and Waste, Land Use, Socioeconomics, Transportation, Utilities, and Water Resources are anticipated due to site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Impacts on Biological Resources are also discussed under Open Ocean.

Table ES-8. Summary of Mitigation Measures

Resource Category*	Open Ocean	Northwestern Hawaiian islands	Kauai
Air Quality	None	None	Modify or renew current Title V permit for PMRF/Main Base for testing and operation of the Maritime Directed Energy Test Center.
Airspace	Depending on the intensity of the proposed lasers, nomenclature would need to be added to aeronautical charts, and certain test events could require Notices to Airmen (NOTAMs) and Notices to Mariners (NOTMARs).	None	Depending on the intensity of the lasers, nomenclature would need to be added to aeronautical charts, and certain test events could require NOTAMs and NOTMARs.
Biological Resources	Train personnel in lookout/watchstander duties. Always at least three people on watch with binoculars. At least two additional personnel on watch during ASW exercises. All personnel engaged in passive acoustic sonar operation to monitor for marine mammal vocalizations. During MFA sonar operations use all available sensor and optical systems (such as night vision goggles). Use only passive capability of sonobuoys when marine mammals are detected within 200 yards. When marine mammals are detected by any means within 1,000 yards of the sonar dome (the bow), the ship or submarine will limit active transmission levels to at least 6 decibels (dB) below normal operating levels. If need for power-down should arise, Navy to follow the requirements as though they were operating at 235 dB—the normal operating level. Operate sonar at lowest practicable level, not to exceed 235 dB, except as required to meet tactical training objectives Helicopters to observe/survey vicinity of an ASW Operation for 10 minutes before first deployment of active (dipping) sonar in the water. Do not dip sonar within 200 yards of a marine mammal and cease pinging if a marine mammal closes within 200 yards after pinging has begun.	None	Target areas are determined to be clear of marine mammals and sea turtles prior to commencement of exercises. Within 1 hour prior to initiation of Expeditionary Assault activities, landing routes and beach areas are surveyed for the presence of sensitive wildlife. An exercise is halted if marine mammals are detected on the beach or in a target area. Pressure wash vehicles on the mainland to prevent spread of invasive plants. Shield night lighting to the extent practical. Foster the reestablishment of native vegetation Monitor and treatment to eliminate establishing exotic species. Prohibit living plants brought from mainland. Work with owners of Niihau Ranch to develop Hawaiian monk seal and green turtle monitoring programs. Training operations to avoid any beach area with green turtle nests. Seasonal use of Kaula during periods when humpback whales are not present. Survey the waters off Kaula to ensure that no whales are present. Limit the impact area to the southern tip of Kaula. RIMPAC exercises use non-explosive rounds on Kaula.

Table ES-8. Summary of Mitigation Measures (Continued)

Resource Category*	Open Ocean	Northwestern Hawaiian islands	Kauai
Biological Resources (Continued)	Navy to coordinate with local NMFS Stranding Coordinator. Submit report containing discussion of nature of the effects, if observed, based on both modeled results of real-time events and sightings of marine mammals. Operating area must be determined clear of marine mammals and sea turtles prior to detonation. Pre-exercise observation of the area to start 30 minutes before and after commencement of Demolition and Ship Mine Countermeasures Operations. All weapons firing would be conducted during the period 1 hour after official sunrise to 30 minutes before official sunset. Establish exclusion zone with a radius of 1.0 nm around each target. Conduct series of surveillance over-flights within exclusion and safety zones, prior to and during the exercise, when assets are available and if safe and feasible. Monitored exclusion zone by passive acoustic means, when assets are available. If a protected species observed within the exclusion zone is diving, delay firing until animal is re-sighted outside the exclusion zone, or 30 minutes have elapsed. Prepare after action report.		

Table ES-8. Summary of Mitigation Measures (Continued)

Resource Category*	Open Ocean	Northwestern Hawaiian islands	Kauai
Cultural Resources	None	Within program requirements, alter missile trajectories to minimize the potential for debris to fall in the vicinity of Necker and Nihoa islands.	Avoid operations/construction in areas with known cultural resources. Monitoring all ground-disturbing activities and construction in medium and high sensitivity archaeological areas. Provide briefings about cultural resources to project personnel. Spray water on vegetation in immediate areas of launch vehicle prior to launch. Use open spray nozzle when possible to minimize erosion damage. Conduct post-burn archaeological surveys. Implement data recovery/research and documentation program. If unanticipated cultural resources are encountered (particularly human remains) during any activity, all activities will cease in the immediate vicinity of the find. Applicable procedures would be implemented and appropriate individuals contacted.
Geology and Soils	N/A	None	Navy minimizes the impact on Kaula by managing the targeting to the southeast tip of the island.
Hazardous Materials and Waste	None	None	Before any facility modifications, the areas to be modified would be surveyed for asbestos and lead-based paint.
Health and Safety	Ensure that no shipping is located within the hazard range of the longest-range weapon being fired for that event.	None	PMRF would develop and implement the necessary Standard Operating Procedures and range safety requirements necessary to provide safe operations associated with future high-energy laser tests. Appropriate remedial procedures would be taken before initiation of potentially hazardous laser operations on PMRF.
Noise	Limits have been set by DoD and OSHA to prevent damage to human hearing.	None	Limits have been set by DoD and OSHA to prevent damage to human hearing. All public, civilian, and nonessential personnel are required to be outside of ground hazard areas where expected noise levels will be below the 115 dBA limit for short-term exposure.

*No mitigation measures have been identified for Land Use, Socioeconomics, Transportation, Utilities, or Water Resources.

Table ES-8. Summary of Mitigation Measures (Continued)

Resource Category*	Oahu	Maui	Hawaii
Airspace	FAA coordination would include discussions regarding the anticipated number of aircraft including FCLP operations.	None	None
Biological Resources	Mitigation measures to protect critically endangered plants include: controlling threats, improving conditions for recruitment, propagation, and reintroduction, development of Implementation Plans that outline required mitigations to offset training risks and to stabilize the targeted plant and animal populations, and implementation of a Wildland Fire Management Plan. Only sandy areas that avoid/minimize potential impacts on coral are used for explosive charges in less than 40 feet of water. Where necessary, pre-exercise surveys for turtles conducted to avoid feeding and nesting areas. Conducting surveys prior to use of amphibious launch vehicles to ensure that humpback whales are not disturbed. Beach and offshore waters are monitored for presence of marine mammals and sea turtles 1 hour before and during Major Exercises, if any are seen, exercise is delayed until the animals leave the area.	None	Impacts on rare plants minimized by locating training activities away from areas with sensitive species, fencing to enclose sensitive species for protection from ungulates, fire and fuel corridors, fire breaks, additional surveys for threatened and endangered species, and continued sensitive plant propagation efforts. All off-road driving is prohibited. All fenced areas are off-limits. All lava tubes and sinkholes are off-limits. Digging is only permitted in previously disturbed areas. Hydrographic survey is performed to map out the precise Expeditionary Assault transit routes through sandy bottom areas. Personnel entering Bradshaw Army Airfield briefed on the guidelines set forth in the PTA Ecosystem Management Plan.
Cultural Resources	In the event unanticipated cultural remains are identified (particularly human remains), all operations will cease in the immediate vicinity and appropriate military branch protocols followed.	None	In the event unanticipated cultural remains are identified (particularly human remains), all operations will cease in the immediate vicinity and appropriate military branch protocols followed.
Hazardous Materials and Waste	Training operations in the Naval Defensive Sea Area are restricted to vessels owned and operated by military and DoD personnel.	None	Before any facility modifications, the areas to be modified would be surveyed for asbestos and lead-based paint.
Health and Safety	Ensure that no shipping is located within the hazard range of the longest-range weapon being fired for that event.	None	None
Noise	Limits have been set by DoD and OSHA to prevent damage to human hearing. Personnel required to work in noise hazard areas are required to use appropriate hearing protection to bring noise levels within established safety levels. Public notification and restricting training in Waimanalo Bay to daylight hours.	None	None

*No mitigation measures have been identified for Air Quality, Geology and Soils, Land Use, Socioeconomics, Transportation, Utilities, or Water Resources.

1.0 Purpose and Need for the Proposed Action

1.0 PURPOSE AND NEED FOR THE PROPOSED ACTION

1.1 INTRODUCTION

This Environmental Impact Statement/Overseas Environmental Impact Statement (hereafter referred to as the EIS/OEIS) has been prepared by the Navy in compliance with the National Environmental Policy Act (NEPA) of 1969 (42 United States [U.S.] Code [U.S.C.] § 4321 et seq.); the Council on Environmental Quality (CEQ) Regulations for Implementing the Procedural Provisions of NEPA (Title 40 Code of Federal Regulations [CFR] §§ 1500-1508 [2005]); Navy Procedures for Implementing NEPA (32 CFR Part 775 [2005]); and Executive Order (EO) 12114, *Environmental Effects Abroad of Major Federal Actions*. The NEPA process ensures that environmental effects of proposed major Federal actions are considered in the decision-making process. EO 12114 requires environmental consideration for actions that may significantly harm the environment of the global commons. This EIS/OEIS satisfies the requirements of both NEPA and EO 12114.

The U.S. Department of the Navy (Navy) has prepared this Final EIS/OEIS to assess the potential environmental impacts associated with ongoing and proposed Naval activities (described in detail in Chapter 2.0) within the Navy's existing Hawaii Range Complex (HRC). Following publication of the Draft EIS/OEIS in July 2007, the Navy, in coordination with the National Marine Fisheries Service (NMFS), conducted a re-evaluation of the analysis in that document. This re-evaluation subsequent to identification of new information led the Navy to prepare a Supplement to the Draft EIS/OEIS, which was released to the public in February 2008.

This EIS/OEIS incorporates the following changes and associated environmental analysis as presented in the Supplement to the Draft EIS/OEIS:

- Modifications to the analytical methodology used to evaluate the effects of mid-frequency active (MFA) and high-frequency active (HFA) sonar on marine mammals;
- Changes to the amount and types of sonar allocated to each of the alternatives; and,
- Development of a new alternative.

This document also responds to public comments received on both the Draft EIS/OEIS and the Supplement to the Draft EIS/OEIS.

The Proposed Action would support and maintain U.S. Pacific Fleet training and assessments of current capabilities, and research, development, test, and evaluation (RDT&E) activities, and associated range capabilities (including hardware and infrastructure improvements in the HRC). Training and RDT&E do not include combat operations, operations in direct support of combat, or other activities conducted primarily for purposes other than training. The Assistant Secretary of the Navy (Installations & Environment) will determine which alternative (or combination of proposed activities) analyzed in the EIS/OEIS satisfies both the level and mix of training to be conducted and the range capabilities enhancements to be made within the HRC that will best meet the needs of the Navy given that all reasonably foreseeable environmental impacts have been considered.

1.2 OVERVIEW OF THE HAWAII RANGE COMPLEX

A range complex is an organized and designated set of specifically bounded geographic areas which can encompass a landmass, body of water (above or below the surface), and airspace used to conduct training of naval and other military forces and personnel, and RDT&E of military systems and equipment. A range complex can consist of several ranges, operating areas (OPAREAs), and special use airspace. These areas can be under strict control of the Department of Defense (DoD) or its agencies, or can be shared among several agencies. The Hawaiian Islands are located close to the middle of the Pacific Ocean. San Francisco lies 2,400 miles to the east, while Asia is 4,000 miles west of the islands. The entire Hawaiian Islands chain extends 2,050 miles from the main island of Hawaii to the Kure Atoll. The entire chain, except for Federal property of Midway Atoll, is part of the State of Hawaii (Figure 1.2-1).

The HRC geographically encompasses open ocean (outside 12 nautical miles [nm] from land), offshore (within 12 nm from land), and onshore areas located on or around the major islands of the Hawaiian Islands chain. The offshore areas extend from 16 degrees north latitude to 43 degrees north latitude and from 150 degrees west longitude to 179 degrees west longitude, forming an area approximately 1,700 nm by 1,600 nm. The component areas of the HRC include:

- The Hawaii OPAREA consisting of 235,000 square nautical miles [nm^2]) of surface and subsurface ocean areas and special use airspace for military training and RDT&E activities. In addition, various Navy land ranges and other Services' land for military training and RDT&E activities are also considered part of the Hawaii OPAREA (Figure 1.2-2) and
- The Temporary Operating Area (TOA) consisting of 2.1 million nm^2 of sea and airspace for RDT&E activities (Figure 1.2-3).

The Hawaii OPAREA includes the Pacific Missile Range Facility (PMRF) on Kauai, which is both a Fleet training range and a Fleet and DoD RDT&E range. PMRF includes 1,020 nm^2 of instrumented ocean area at depths between 1,800 feet and 15,000 feet. Also included in the Hawaii OPAREA are designated warning and training areas, airspace, water ranges, land ranges, airfields, the Pearl Harbor Naval Defensive Sea Area, and open ocean areas. The Hawaii OPAREA also includes the southern tip of the Papahānaumokuākea Marine National Monument (Monument) where part of the 50-nm buffer around the islands within the Monument extends into the traditionally used exercise area and adjacent ranges at PMRF. The Monument's buffer area within the Hawaii OPAREA encompasses about 4,300 nm^2 of the entire Monument's approximately 140,000 nm^2. As provided in Presidential Proclamation 8031, "Activities and exercises of the Armed Forces of the United States" are allowed within the Monument by the terms of the Presidential Proclamation which created the Monument.

EIS/OEIS Study Area: Hawaii Range Complex Including the Hawaii Operating Area and Temporary Operating Area

Hawaiian Islands

Figure 1.2-3

For range management and scheduling purposes, the Hawaii OPAREA is divided into numerous sub-component ranges or training areas used to conduct training events and RDT&E of military hardware, personnel, tactics, munitions, explosives, and electronic combat systems, as described in detail in Chapter 2.0.

Because of the vast size of the HRC and Hawaii OPAREA, multiple training and RDT&E activities can occur at the same time, without interfering with each other. For reference purposes Figure 1.2-4 illustrates the size and extent of the Hawaii OPAREA by superimposing the State of California across the major Hawaiian Islands. Individual Fleet training and RDT&E activities can occur up to 200 to 300 nm apart and 100 to 200 nm offshore of any island.

The Hawaii OPAREA provides the geography, infrastructure, space, and location necessary to accomplish complex military training and RDT&E activities. The large size of the Hawaii OPAREA allows training that involves complicated scenarios and large numbers of training participants within a complex geographic setting (i.e., channels between islands, varying bathymetry, etc.). The presence of the underwater instrumented tracking ranges offshore of PMRF as well as DoD-controlled warning areas and special use airspace also enable training to proceed in a safe and structured manner while retaining the flexibility for training controllers to interject tactical challenges that enhance realism for training participants. In the Hawaii OPAREA, forces can engage in training involving events at PMRF on Kauai simultaneously with Anti-Submarine Warfare (ASW) events offshore and in the open ocean. Submarines homeported at Pearl Harbor are available as opposition forces during training events without having to undertake long transits to participate in those events. Maritime patrol aircraft based at Marine Corps Base Hawaii (MCBH) also contribute additional training and assessment capabilities.

1.3 BACKGROUND

As its highest priority, the HRC will support the Fleet Response Training Plan (FRTP) readiness processes as revised in 2006 in the Fleet Response Plan (Commander, U.S. Fleet Forces Command, 2006). One of the obligations of the Navy, pursuant to Title 10 of the U.S.C., is to ensure that the men and women, Sailors and officers, sent to sea on behalf of the United States are fully trained and ready for deployment on short notice, as a combat-ready naval force and for other non-combat missions assigned to them. In addition, combat forces must have available to them the changes and improvements that new technologies can provide. These emerging technologies must be researched, developed, tested, and evaluated before being made widely available for use. The Navy meets these training and testing responsibilities across the open oceans and on its range complexes.

For more than a century, Hawaii has been a place where the Navy has trained its Sailors and repaired and replenished the ships of the United States at Pearl Harbor. In the 1920s, a submarine base was established at Pearl Harbor, creating a need for the training of Sailors and officers serving in the undersea environment. As world tensions increased in the 1930s and early 1940s, the Navy rapidly increased its presence and number of facilities in Hawaii. The Pacific Fleet established its headquarters at Pearl Harbor on February 1, 1941. Ten months later, on December 7, 1941, the Fleet was attacked at Pearl Harbor, propelling America into World War II. The Pacific was the site of World War II’s most decisive naval battles. Naval

forces in Hawaii remained vital to U.S. interests throughout the mid-century, as control of the seas provided advantages to allied forces during the Korean and Vietnam Wars. Since 1968, a multinational sea-power exercise given the name “Rim of the Pacific” (RIMPAC) has been conducted within the Hawaii OPAREA, testing the abilities of a number of the navies of the Pacific Rim to function together. Participating Pacific Rim nations have included Australia, Japan, Republic of Korea, Indonesia, Malaysia, Singapore, Chile, Peru, and Canada. Today, the Navy’s presence in Hawaii remains of essential strategic and operational importance to U.S. national interests.

Over 20 years ago, acoustic monitoring devices were placed at PMRF on the ocean floor off the west coast of Kauai to detect and track underwater activity. These acoustic systems, known as Barking Sands Tactical Underwater Range (BARSTUR) and Barking Sands Underwater Range Expansion (BSURE), provide a unique evaluative tool that offers specific information in tracking participants’ movements and responses during naval training. PMRF is now the world’s largest military test and training range capable of supporting subsurface, surface, air, and space training events, as well as RDT&E and marine mammal research. It consists of instrumented underwater ranges, controlled airspace, and a TOA covering 2.1 million nm^2 of ocean. Since its establishment, PMRF has provided major range services for training, tactics development, and RDT&E of air, surface, and subsurface weapons systems for the Navy, other DoD agencies, allies, and private industry.

Today, more than 20 surface ships and submarines are homeported in Hawaii. Specialty forces, including Navy divers and explosive ordnance disposal technicians, also conduct vital training within the Hawaii OPAREA. The Sailors and officers assigned to these homeported ships and submarines, those awaiting sea duty, and Strike Groups (a naval force comprising one or more capital ships, several combatant ships and one or more attack submarines) transiting through the Pacific, as well as naval forces of foreign allies, must maintain their proficiencies to allow them to be ready and qualified to be deployed when ordered to do so at short notice. The HRC, including the Hawaii OPAREA, provides extensive, remote, and strategic training areas and facilities that enable Navy personnel to maintain and strengthen these required proficiencies.

1.3.1 NAVY’S AT SEA POLICY

In December of 2000, the Under Secretary of the Navy issued a memorandum for the Chief of Naval Operations and the Commandant of the Marine Corps entitled “Compliance with Environmental Requirements in the Conduct of Naval Exercises or Training at Sea” that has come to be known as the “At Sea Policy.” The Navy’s At Sea Policy sets forth how the Navy would update and upgrade its compliance with the body of environmental law which applies to these exercises and training—at sea and at the Navy’s range complexes. The policy applies to training at sea, including the conduct of joint (multi-service) and combined (multi-nation) exercises, which are also known as military readiness activities, as that term is defined in Section 315(f) of Public Law 107-314. Training, including joint and combined exercises, does not include combat operations, operations in direct support of combat, or other activities conducted primarily for purposes other than training.

The memorandum directed the Navy’s Fleet commanders to develop an approach to environmental compliance for the Fleet training ranges and training areas within their respective areas of responsibility, including ranges used for RDT&E activities. Major Exercises and training occurring within a range or OPAREA could be included with the compliance effort for the applicable range or OPAREA. The approach would involve a “comprehensive analysis of the environmental impacts of a class of undertakings repetitive in nature or of similar effect and recurring within the same geographical area, so as to avoid or mitigate adverse effects on the extent practicable consistent with the accomplishment of the military training and exercise activities under review.” Fleet commanders were similarly directed to review RDT&E ranges to the extent they are used for Fleet training.

For the HRC, the Commander, U.S. Pacific Fleet is conducting a programmatic geography-based approach to environmental analysis, complying with NEPA and EO 12114, reviewing the present and reasonably foreseeable activities at each range complex. In accordance with the At Sea Policy, this analysis provides a description of existing training and RDT&E activities and reasonably foreseeable alternative levels of activity within the HRC, and an analysis of the environmental consequences of training and RDT&E activities and alternative levels of activity. Included are Major Exercises, routine training, and RDT&E activities conducted within or projected to be conducted within the HRC, as well as planned upgrades to the HRC to ensure its sustainability. This document builds upon the *Pacific Missile Range Facility Enhanced Capability Final Environmental Impact Statement* prepared and completed in 1998 for the facilities at PMRF and training and RDT&E activities under PMRF’s control.

1.3.2 WHY THE NAVY TRAINS

The U.S. military is maintained to ensure the freedom and safety of all Americans both at home and abroad. In order to do so, Title 10 of the U.S.C. requires the Navy to “maintain, train and equip combat-ready naval forces capable of winning wars, deterring aggression and maintaining freedom of the seas.” Modern war and security operations are complex. Modern weaponry has brought both unprecedented opportunity and innumerable challenges to the Navy. Smart weapons, used properly, are very accurate and actually allow the military services to accomplish their missions with greater precision and far less destruction than in past conflicts. But these modern smart weapons are very complex to use. U.S. military personnel must train regularly with them to understand their capabilities, limitations, and operation. Modern military actions require teamwork between hundreds or thousands of people, and their various equipment, vehicles, ships, and aircraft, all working individually and as a coordinated unit to achieve success. These teams must be prepared to conduct activities in multiple warfare areas simultaneously in an integrated and effective manner. Navy training addresses all aspects of the team, from the individual to joint and coalition teamwork. To do this, the Navy employs a building-block approach to training. Training doctrine and procedures are based on operational requirements for deployment of naval forces. Training proceeds on a continuum, from teaching basic and specialized individual military skills, to intermediate skills or small unit training, to advanced, integrated training events, culminating in multi-service (Joint) exercises or pre-deployment certification events.

To provide the experience so important to success and survival, training must be as realistic as possible. The Navy often employs simulators and synthetic training to provide early skill repetition and to enhance teamwork, but live training in a realistic environment is vital to success. Live training is the only vehicle available to ensure naval forces develop and maintain the ability to conduct integrated warfare across a wide spectrum of situations. This requires sufficient sea and airspace to maneuver tactically, realistic targets and objectives, opposition that creates a realistic enemy, and instrumentation to objectively monitor the events and learn to correct errors.

Range complexes provide a controlled and safe environment with threat representative targets that enable Navy forces to conduct realistic combat-like training as they undergo all phases of the graduated buildup needed for combat-ready deployment. Navy's ranges and OPAREAs provide the space necessary to conduct controlled and safe training scenarios representative of those that Navy men and women would have to face in actual combat. The range complexes are designed to provide the most realistic training in the most relevant environments, replicating to the best extent possible the operational stresses of warfare. The integration of undersea ranges and OPAREAs with land training ranges, safety landing fields, and amphibious landing sites are critical to this realism, allowing execution of multi-dimensional exercises in complex scenarios. They also provide instrumentation that captures the performance of Navy tactics and equipment in order to provide the feedback and assessment that is essential for constructive criticism of personnel and equipment. The live-fire training facilitates assessment of the Navy's ability to place weapons on target with the required level of precision while under a stressful environment. Live training, most of it accomplished in the waters off the United States' coasts, will remain the cornerstone of readiness as the Navy transforms its military forces for a security environment characterized by uncertainty and surprise.

Navy training activities focus on achieving proficiency in eight functional areas encompassed by Navy operations. These functional areas, known as Primary Mission Areas (PMARs), are: Anti-Air Warfare (AAW), Amphibious Warfare (AMW), Anti-Surface Warfare (ASUW), ASW, Mine Warfare (MIW), Strike Warfare (STW), Electronic Combat (EC), and Naval Special Warfare (NSW). Each training event addressed in the EIS/OEIS is categorized under one of the PMARs.

The HRC is used for training of operational forces, RDT&E of military equipment, and other military activities. As with each Navy range complex, the primary mission of the HRC is to provide a realistic training environment for naval forces to ensure that they have the capabilities and high state of readiness required to accomplish assigned missions.

Training is focused on preparing for worldwide deployment. Naval forces generally deploy in specially organized units called Strike Groups. A Strike Group may be organized around one or more aircraft carriers, together with several surface combatant ships and submarines, collectively known as a Carrier Strike Group (CSG). A naval force known as a Surface Strike Group (SSG) consists of three or more surface combatant ships. A Strike Group may also be organized around a Marine Expeditionary Unit (MEU)[1] embarked on amphibious ships accompanied by surface combatant ships and submarines, known as an Expeditionary Strike Group (ESG). The Navy and Marine Corps deploy CSGs, SSGs, and ESGs on a continuous basis. The number and composition of Strike Groups deployed, and the schedule for deployment, are determined based on the worldwide requirements and commitments.

Pre-deployment training is governed by the Navy's FRTP. The FRTP sets a deployment cycle for the Strike Groups that includes three phases: (1) basic, intermediate, and advanced pre-

[1] The MEU is a battalion-sized (1,500 Marines) Marine Air Ground Task Force or MAGTF. MAGTFs consist of ground combat, aviation combat, combat logistics, and command and control elements, and vary in size depending on the nature of the intended mission.

deployment training and certification, (2) deployment, and (3) post-deployment sustainment, training, and maintenance. While several Strike Groups are always deployed to provide a global naval presence, Strike Groups must also be ready to “surge” on short notice in response to directives from the National Command Authority. One objective of the FRTP is to provide this surge capability. The FRTP calls for the ability to train and deploy six CSGs in a very short period, and two more in stages soon thereafter. Established in 2003, the FRTP calls for changes in the Fleet training cycle, including acceleration of the cycle and near-simultaneous execution of similar training events. Deployment schedules are not fixed, but must remain flexible and responsive to the Nation’s security needs. The capability and capacity of ranges such as the HRC to support the entire training continuum must be available as needed.

The deployment of naval forces, including those that train in the HRC, is determined by the combatant commanders (a senior military commander with a large, geographically demarked area of responsibility) based on worldwide requirements and commitments. In order to meet these requirements, naval forces are geographically apportioned. The dynamic requirements of national security affect the deployment of naval forces. As a result, deployment schedules are not fixed, but remain flexible, often changing to meet the Nation’s security needs. Real world contingencies drive the training schedule in relation to when and where the naval forces are required. The support necessary to conduct required pre-deployment training, particularly training range support, must therefore be available as needed.

Specific to ASW, continued training and use of active sonar systems is vital. Modern diesel-electric submarines are designed to suppress emitted noise levels specifically to counter and defeat passive sonar technology. Passive sonar involves listening for any sounds inadvertently emitted by a potentially hostile submarine, which are then used to detect, localize and track it. As a result, modern diesel-electric submarines have been designed to be quieter through the use of improved technology and to “hide” in the naturally occurring noise levels of the shallow waters of coastal environments. The result is that a modern diesel-electric submarine operating on battery power is nearly undetectable to naval forces using only passive sonar. Accordingly, sonar, initially developed during World War I, has been improved and deployed on U.S. naval vessels since the mid-1920s. Although the Navy continues evaluating technologies to locate and track submarines, active sonar remains the most viable means of locating and tracking submarines.

1.3.3 TACTICAL TRAINING THEATER ASSESSMENT AND PLANNING PROGRAM

The Tactical Training Theater Assessment and Planning (TAP) Program serves as the Navy’s range sustainment program. The purpose of TAP is to support Navy objectives that: (1) promote use and management of ranges (such as the HRC) in a manner that supports national security objectives and a high state of combat readiness, and (2) ensures the long-term viability of range assets while protecting human health and the environment. The TAP Program focuses specifically on the sustainability of ranges, OPAREAs, and airspace areas that support the FRTP.

The Navy’s Required Capabilities Document (RCD) is a product of the TAP Program. The purpose of the RCD is to quantitatively define the required range capabilities that would allow Navy ranges to support mission-essential training. The RCD provides guidelines for range requirements, but is not range-specific. The Navy, therefore, has developed an analysis of its requirements for each range complex (U.S. Department of Defense, 2006). These analyses:

- Provide comprehensive descriptions of ranges, OPAREAs and training areas within a given range complex;
- Assess training activities currently conducted within the range complex;
- Identify investment needs and strategy for maintenance, range improvement and modernization;
- Develop a strategic vision for range operations with a long-term planning horizon;
- Provide range complex sustainable management principles and practices, to include environmental stewardship and community outreach; and
- Identify encroachments on ranges, and evaluate the potential impacts of encroachments on training and RDT&E.

Also of note is that the Base Realignment and Closure Commission 2005 process, leading to the decisions of the Congress and the President, examined availability of ranges to support closure recommendations. HRC is specifically retained as a needed range.

1.3.4 MISSION OF THE HAWAII RANGE COMPLEX

The strategic mission of the HRC is to support naval operational readiness by providing a realistic, live training environment for forces assigned to the Pacific Fleet, the Fleet Marine Force, and other users. As its highest priority, the HRC will support the FRTP readiness processes as revised in 2006 in the Fleet Response Plan (Commander, U.S. Fleet Forces Command, 2006) and Commander, Fleet Forces Command (CFFC) Instruction 3501.3, Fleet Training Strategy. The strategic mission implements the strategic vision and includes management objectives and the HRC concept of training events.

The Commander, U.S. Pacific Fleet and CFFC strategic vision for this complex is for it to remain the principal Navy training venue in the middle Pacific with the capability and capacity to support current, emerging, and future training requirements. The capabilities of the HRC must be sustained, upgraded, modernized, and transformed as new weapons systems achieve initial operational capability, new threat capabilities emerge, and new technologies offer improved training opportunities. More specifically, the range complex must be capable of providing:

- Advanced-level training of Strike Groups pursuant to the FRTP, including realistic opposing force and electronic threat replication to support training of integrated and joint forces
- Joint training events as a compatible and interoperable component of the emerging Joint National Training Capability (JNTC)
- Intermediate-level and basic-level training of Navy forces across all primary mission areas pursuant to the requirements of the FRTP

- Sustainment training as a "backyard" range[2] for surface ships, submarines, aviation squadrons, special warfare, and explosive ordnance disposal units based in Hawaii, and specialized support for units based elsewhere on the West Coast and in the western Pacific
- Sophisticated instrumented range facilities for ASW and MIW training for ships, aircraft, and submarines
- Alignment of the HRC infrastructure with Naval Force structure, including accommodating new weapons, systems, and platforms (vessels and aircraft) as they are introduced into the Fleet
- Sustainable range management and planning that provides for consolidated range communications and scheduling; institutionalizes standardized data management practices; and protects and conserves range resources for current and future training requirements
- Support for allies' military training and RDT&E activities.

1.3.5 STRATEGIC IMPORTANCE OF THE EXISTING HAWAII RANGE COMPLEX

The existing HRC is the only range complex in the mid-Pacific Region and is used for training and assessment of operational forces, missile training, RDT&E of military systems and equipment, and other military activities. The HRC is characterized by a unique combination of attributes that make it a strategically important range complex for the Navy. These attributes include:

Proximity to the Homeport of Pearl Harbor. The Hawaii OPAREA surrounds the major homeport of Pearl Harbor where a large number of ships and submarines are based. Hawaii is also the home for Navy aircraft from five operational squadrons and encompasses seven major Navy commands. Training and assessment events, such as the Undersea Warfare Exercise (USWEX), occur in the Hawaii OPAREA, before the deployed forces report to Commander, U.S. SEVENTH Fleet in the Western Pacific and/or Commander, U.S. FIFTH Fleet in the Middle East. The USWEX simulates a real-world submarine threat and gives an ESG or CSG the opportunity to conduct realistic ASW training. It also provides the U.S. Pacific Fleet an opportunity to assess the Navy's ASW capabilities using a fully certified Strike Group.

Proximity to the Western Pacific. Hawaii serves as an ideal en route training location for units deploying to the western Pacific Ocean or Middle East from the U.S. west coast. Maritime Patrol aircraft are located at Marine Corps Base, Hawaii (MCBH), and submarines are based at Pearl Harbor. Both play an important role in ASW training. The co-location of these assets assists in conducting ASW training in Hawaii in support of naval forces that are being deployed to the Western Pacific and Middle East. Much of this training is managed by Commander, U.S. Pacific Fleet's ASW experts who are located in Pearl Harbor.

Proximity to Military Families. Hawaii is home to thousands of military families. The Navy and Marine Corps strive, and in many cases are required by law, to track and where possible limit

[2]A "backyard range" is a range facility located in close proximity to homeports and stations, and it is a critical component of naval readiness.

"personnel tempo," meaning the amount of time Sailors and Marines spend deployed away from home. Personnel tempo is an important factor in family readiness, morale, and retention. The availability of the HRC as a "backyard" training range is critical to Navy efforts in these areas.

Training Terrain. Since most west coast based naval forces have been training in the continental United States for a period as long as 18 months prior to deployment, the Hawaii area provides an opportunity to work in an unfamiliar environment, and to make real-time adjustments just as Sailors and Marines will have to do when they reach the SEVENTH or FIFTH Fleet areas of responsibility.

The large training area available to deploy forces within the HRC allows training to take place on a geographic scale that replicates possible real world events, with the channels between islands serving as strategic choke-points to ocean commerce. The presence of the instrumented tracking ranges at PMRF as well as DoD-controlled warning areas and special use airspace also enable training to proceed in a safe and structured manner while retaining the flexibility for controllers to interject tactical challenges to enhance realism for training participants. Exercise participants at sea can conduct air strike sorties to Pohakuloa Training Area, and an ESG can conduct amphibious landings on DoD beaches, both while simultaneously conducting ASW. Finally, the presence of submarines homeported at Pearl Harbor provides access to these submarines, which can then serve as an opposition force during USWEX without having to transit to participate in the exercise training events. Sites outside of Hawaii do not provide a reasonable alternative for satisfying the Navy's required training purposes or its obligations under the Quadrennial Defense Review (QDR) to increase its presence in the Pacific.

The QDR sets forth a specific series of recommendations for implementing the goals and objectives of national defense and security strategies. The 2001 QDR noted that the Pacific and Asian regions have become increasingly important to regional and U.S. security in recent years. In response, the DoD's new planning construct calls for maintaining regionally tailored forces, forward stationed and deployed in the Pacific and Asian theaters. It requires enhancing the future capability of forward deployed and stationed forces, coupled with global intelligence, strike, and information assets, in order to deter aggression or coercion with only modest reinforcement from outside the theater. The 2006 QDR continued to emphasize the need for the Navy to provide more flexible and sustainable locations from which to operate globally. Pursuant to the QDR, the naval fleet must have greater presence in the Pacific Ocean, consistent with the global shift of trade and transport. Accordingly, the Navy plans to adjust its force posture and basing to provide at least six operationally available and sustainable carriers and 60 percent of its submarines in the Pacific to support engagement, presence and deterrence. The HRC provides the geography, infrastructure, space, and location necessary to accomplish these 2001 and 2006 QDR requirements.

1.4 PURPOSE AND NEED FOR THE PROPOSED ACTION

Given the strategic importance of the HRC to the readiness of naval forces and the unique training environment provided by the HRC, the Navy proposes to take actions for the purposes of:

- Achieving and maintaining Fleet readiness using the HRC to support and conduct current, emerging, future training, assessment events[3], and RDT&E activities;
- Conducting missions supported by the HRC, consistent with the requirements of the FRTP, and;
- Upgrading/modernizing existing range capabilities to enhance and ensure the sustainability of Navy and other DoD training and testing.

The Proposed Action is needed to provide a training environment consisting of ranges, training areas, and range instrumentation with the capacity and capabilities to fully support required training tasks for operational units and military schools. To accomplish this purpose and need and execute its Title 10 responsibilities, the Navy must:

- Maintain current levels of military readiness by training in the HRC;
- Accommodate future increases in training tempo in the HRC and support the rapid deployment of naval units and/or Strike Groups;
- Achieve and sustain readiness of ships and squadrons consistent with the FRTP so that the Navy can rapidly increase significant combat power in the event of a crisis or contingency operation;
- Support the acquisition and implementation into the Fleet of advanced military technology. The HRC must adequately support the testing and training needed for new platforms and weapons systems (e.g., the Littoral Combat Ship and the MH-60R Seahawk helicopter); and,
- Maintain the long-term viability of the HRC while protecting human health and the environment (including the implementation of marine mammal mitigation measures), and enhancing the quality and communication capability and safety of the range complex.

Conduct of current and emerging training and RDT&E training events, and implementation of range capabilities enhancements, includes a collection of actions which will be evaluated in this EIS/OEIS.

1.5 THE ENVIRONMENTAL REVIEW PROCESS

1.5.1 SCOPE AND CONTENT OF THE EIS/OEIS

The scope (Study Area) for this EIS/OEIS is the HRC (Figure 1.2-3), which includes the open ocean, offshore, and onshore areas. This EIS/OEIS will address current and proposed activities associated with the following three categories: (1) Navy units (ships, submarines, aircraft, personnel) conducting unit-level activities on any military's range within the HRC; (2) any U.S. or foreign military unit conducting activities on Navy-operated ranges; and, (3) any U.S. or foreign

3 An assessment event is an assessment of a program to determine if systems and tactics are capable of addressing an estimated threat.

military unit conducting activities on any military's range in Hawaii as part of a Navy-sponsored exercise.

To assist the reader, Sections 3.1 and 4.1 of Chapters 3.0 and 4.0 present the affected open ocean environment and associated impact analysis relative to EO 12114. The remaining sections of Chapters 3.0 and 4.0 present the affected environment and impact analysis relative to NEPA for offshore and onshore areas. Chapters 3.0 and 4.0 are further arranged according to islands from west to east: Northwestern Hawaiian Islands, Kauai, Oahu, Maui, and Hawaii. For organizational purposes in this document, discussions about Niihau and Kaula are included under the Kauai heading, because although they are separate islands, they are part of Kauai County. In addition, discussions about Molokai are included under the Maui heading, because although it is a separate island, it is part of Maui County.

1.5.2 COOPERATING AGENCIES

The following Federal agencies are cooperating agencies in the preparation of this EIS/OEIS:

- U.S. Department of Energy
- Missile Defense Agency
- U.S. Army
- National Marine Fisheries Service

1.5.3 NATIONAL ENVIRONMENTAL POLICY ACT

In 1969, Congress enacted NEPA, which provides for the consideration of environmental issues in Federal agency planning and decision-making. Regulations for Federal agency implementation of the act were established by the President's CEQ. NEPA requires that Federal agencies prepare an EIS if an Environmental Assessment (EA) determines a proposed action might significantly affect the quality of the human environment. The EIS must disclose significant environmental impacts and inform decision makers and the public of the reasonable alternatives to the Proposed Action. Presidential Proclamation 5928, issued December 27, 1988, extended the exercise of United States sovereignty and jurisdiction under international law to 12 nm; however, the Proclamation expressly provides that it does not extend or otherwise alter existing Federal law or any associated jurisdiction, rights, legal interests, or obligations. As a result, the Navy analyzes environmental effects and actions within 12 nm under NEPA and those effects occurring beyond 12 nm under the provisions of EO 12114.

This EIS/OEIS provides an assessment of the potential environmental impacts associated with sustainable range usage and enhancements within the Navy's HRC. The Navy completed the Supplement to the 2002 Rim of the Pacific (RIMPAC) Programmatic Environmental Assessment in May 2006 and the Undersea Warfare Exercise (USWEX) Programmatic Environmental Assessment in January 2007. This EIS/OEIS analyzes the continuation of these exercises in the baseline analysis. It also analyzes Navy training that currently occurs or is proposed to occur in open ocean, offshore, and onshore areas of the HRC.

1.5.3.1 PUBLIC SCOPING PROCESS

The first step in the NEPA process is the publication of a Notice of Intent (NOI) to prepare an EIS. The NOI provides an overview of the proposed action and the scope of the EIS. The NOI for this project was published in the *Federal Register* on August 29, 2006, and in five local newspapers (i.e., the *Maui News*, the *Honolulu Star Bulletin*, the *Hawaii Tribune Herald*, the *Garden Island*, and the *Honolulu Advertiser*) on September 2, 4, and 5, 2006.

Scoping is an early and open process for developing the "scope" of issues to be addressed in the EIS and for identifying significant issues related to a proposed action. During scoping, the public helps define and prioritize issues and convey these issues to the agency through both oral and written comments. The scoping period for the HRC EIS/OEIS began with the publication of an NOI. The scoping period lasted 46 days, concluding on October 13, 2006. Four scoping meetings were held on September 13, 14, 16, and 18, 2006 on the islands of Maui, Oahu, Hawaii, and Kauai, respectively. The scoping meetings were held in an open house format, presenting informational posters and written information, and making Navy staff and project experts available to answer participants' questions. Additionally, a court reporter was available to record participants' oral comments. This format allowed the public to interact informally, one-on-one, with project representatives or comment formally, on the record, to representatives of the Navy. Table 1.5.3.1-1 lists location, date, and number of attendees at the scoping meetings.

Table 1.5.3.1-1. Meeting Locations, Dates, and Attendees–Scoping

Location	Date	Public Attendees
Maui Arts and Cultural Center, Kahului, Maui, Hawaii	13 September 2006	9
Disabled American Veterans Hall, Honolulu, Oahu, Hawaii	14 September 2006	31
Hilo Hawaiian Hotel, Hilo, Hawaii, Hawaii	16 September 2006	39
Kauai Civil Defense Agency, Lihue, Kauai, Hawaii	18 September 2006	47

In addition to the scoping meetings, the public could make comments through a toll-free telephone number, by sending an email, or by mailing a written comment. Issues identified by the public were provided to resource specialists working on the EIS/OEIS to ensure that all comments were considered during the preparation of the document. Table 1.5.3.1-2 presents a summary of the number of issues identified for each resource area.

1.5.3.2 PUBLIC REVIEW PROCESS

After scoping, the Draft EIS/OEIS was prepared to provide an assessment of the potential impacts of the Proposed Action and alternatives on the environment. It was then provided to U.S. Environmental Protection Agency for review and comment in accordance with their responsibilities under Section 309 of the Clean Air Act and to have a Notice of Availability published in the *Federal Register*. The Navy also placed notices in the aforementioned newspapers announcing the availability of the Draft EIS/OEIS. The Draft EIS/OEIS was circulated for review, and the comment period ended September 17, 2007. Table 1.5.3.2-1 lists location, date, and number of attendees at the public hearings.

Table 1.5.3.1-2. Number of Comments by Resource Area–Scoping

Resource Area	Number of Comments	Percent of Total
Program	114	32.1%
Policy/National Environmental Policy Act Process	47	13.2%
Cumulative Impacts	5	1.4%
Socioeconomics	14	3.9%
Cultural Resources	12	3.4%
Hazardous Materials & Hazardous Waste	2	0.6%
Biological Resources—Marine	83	23.4%
Air Quality	4	1.1%
Health and Safety	28	7.9%
Environmental Justice	2	0.6%

Noise	1	0.3%
Land Use	10	2.8%
Transportation	3	0.8%
Water Resources	1	0.3%
Airspace	7	2.0%
Total	**355**	

Table 1.5.3.2-1. Public Hearing Locations, Dates, and Attendees–HRC Draft EIS/OEIS

Location	Date	Public Attendees
Kauai War Memorial Convention Hall, Lihue, Kauai, Hawaii	21 August 2007	55
McKinley High School, Honolulu, Oahu, Hawaii	23 August 2007	29
Baldwin High School, Wailuku, Maui, Hawaii	27 August 2007	76
Waiakea High School, Hilo, Hawaii, Hawaii	29 August 2007	51

In addition to the public hearings, the public was able to provide comments through the Navy's NEPA Programs in Hawaii website, by sending an email, or by mailing a written comment. Table 1.5.3.2-2 presents a summary of the number of issues identified for each resource area. Chapter 13.0 provides a more-detailed summary of public comments on the Draft EIS/OEIS.

**Table 1.5.3.2-2. Number of Comments by Resource Area–
HRC Draft EIS/OEIS**

Resource Area	Number of Comments	Percent of Total
Air Quality	10	0.4%
Airspace	10	0.4%
Biological Resources - Marine	492	19.1%
Biological Resources - Terrestrial	69	2.7%
Cultural Resources	299	11.6%
Geology and Soils	2	0.1%
Hazardous Materials and Waste	372	14.4%
Health and Safety	26	1.0%
Land Use	20	0.8%
Noise	5	0.2%
Socioeconomics	29	1.1%
Transportation	3	0.1%
Utilities	8	0.3%
Water Resources	15	0.6%
Environmental Justice	24	0.9%
Alternatives	524	20.4%
Program	439	17.0%
Policy/NEPA Process	87	3.4%
Mitigation Measures - Marine Mammal	59	2.3%
Cumulative Impacts	36	1.4%
Miscellaneous	46	1.8%
Total	**2,575**	

The Draft EIS/OEIS distribution list is presented in Chapter 10.0. The Draft EIS/OEIS was made available for general review in public libraries and other publicly accessible locations to include those listed in Chapter 10.0. Public meetings were held to accept public comments. The locations of public meetings were announced in local newspapers.

The Draft EIS/OEIS analyzed potential impacts on marine mammals from Navy actions that involve the use of acoustic sources. Following publication of the Draft EIS/OEIS in July 2007, the Navy, in coordination with the NMFS, conducted a re-evaluation of the analysis in that document. This re-evaluation and subsequent identification of new information led the Navy to prepare a Supplement to the Draft EIS/OEIS which was released to the public in February 2008.

The NOI for the Supplement to the Draft EIS/OEIS was published in the *Federal Register* on January 17, 2008. The Supplement was filed with U.S. Environmental Protection Agency for release to the public on February 22, 2008 and a Notice of Public Meeting was published in the *Federal Register* on February 26, 2008. The Navy also placed notices in the aforementioned newspapers announcing the availability of the Supplement to the Draft EIS/OEIS. The Supplement to the Draft EIS/OEIS was circulated for public review, and the comment period ended April 7, 2008. Table 1.5.3.2-3 lists location, date, and number of attendees at the public hearings.

Table 1.5.3.2-3. Public Informational Sessions Locations, Dates, and Attendees– HRC Supplement to the Draft EIS/OEIS

Location	Date	Public Attendees
Kauai Community College, Lihue, Kauai, Hawaii	13 March 2008	40
Maui Waena Intermediate School, Kahului, Maui, Hawaii	14 March 2008	19
Disabled American Veterans Memorial Hall Honolulu, Oahu, Hawaii	17 March 2008	16
Hilo Hawaiian Hotel, Hilo, Hawaii, Hawaii	18 March 2008	24

Table 1.5.3.2-4 presents a summary of the number of issues identified for each resource area. Chapter 14.0 provides a more-detailed summary of public comments on the Supplement to the Draft EIS/OEIS.

Table 1.5.3.2-4. Number of Comments by Resource Area HRC Supplement to the Draft EIS/OEIS

Total	**1,595**	

There is a 30-day wait period following the publication of the NOA of the Final EIS/OEIS in the Federal Register. At the conclusion of this wait period, the Navy will make its Record of Decision (ROD), which will be published in the Federal Register. The ROD will summarize the final decision and identify the selected alternative, describe the public involvement and agency decision-making processes, and present commitments to specific mitigation measures. The selected alternative can then be implemented. The ROD will be published in the *Federal Register*.

1.5.4 EXECUTIVE ORDER 12114

EO 12114, *Environmental Effects Abroad of Major Federal Actions*, directs Federal agencies to provide for informed decision-making for major Federal actions outside the United States, including the global commons, the environment of a non-participating foreign nation, or impacts on protected global resources. An OEIS is required when an action has the potential to significantly harm the environment of the global commons. Global commons are defined as "geographical areas that are outside of the jurisdiction of any nation, and include the oceans outside territorial limits (outside 12 nm from the coast) and Antarctica. Global commons do not include contiguous zones and fisheries zones of foreign nations." (32 CFR Part 187.3)

Effects on areas within the HRC that lie outside 12 nm (shown as Open Ocean on Figure 1.2-2) are analyzed using the procedures set out in EO 12114 and associated implementing regulations.

1.5.5 MARINE MAMMAL PROTECTION ACT COMPLIANCE

The Marine Mammal Protection Act (MMPA) established, with limited exceptions, a moratorium on the "taking" of marine mammals in waters or on lands under U.S. jurisdiction (MMPA, 1972). The Act further regulates "takes" of marine mammals on the high seas by vessels or persons under U.S. jurisdiction. The term "take," as defined in Section 3 of the MMPA (16 U.S.C. 1362), means "to harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill any marine mammal." "Harassment" was further defined in the 1994 and 2004 amendments to the MMPA. The 1994 amendments provided two levels of harassment, Level A (potential injury) and Level B (potential disturbance).

As applied to military readiness activities, the National Defense Authorization Act for Fiscal Year 2004 (FY04 NDAA) (Public Law [PL] 108-136) amended the MMPA to (1) clarify the applicable definition of harassment; (2) exempt such activities from the "specified geographical region" and "small numbers" requirements of Section 101(1)(5)(A) of the Act; (3) require consideration of personnel safety, practicality of implementation, and impact on effectiveness of military readiness activities by NMFS in making its determination regarding least practicable adverse impact; and (4) establish a national defense exemption. PL 107-314, Section 315(f), defines "military readiness activities" to include "all training and operations of the Armed Forces that relate to combat; and the adequate and realistic testing of military equipment, vehicles, weapons and sensors for proper operation and suitability for combat use." The testing and training with active sonar constitutes a military readiness activity under this definition.

The definition of "harassment" as applied to military readiness activities is any act that:

- Injures or has the significant potential to injure a marine mammal or marine mammal stock in the wild ("Level A harassment"), or
- Disturbs or is likely to disturb a marine mammal or marine mammal stock in the wild by causing disruption of natural behavioral patterns including, but not limited to, migration, surfacing, nursing, breeding, feeding, or sheltering to a point where such behavioral patterns are abandoned or significantly altered ("Level B harassment") (16 U.S.C. 1362 [18][B][i],[ii]).

Section 101(a)(5) of the MMPA directs the Secretary of Commerce to allow, upon request, the incidental, but not intentional, taking of marine mammals by U.S. citizens who engage in a specified activity (exclusive of commercial fishing). These incidental takes are allowed only if NMFS issues regulations governing the permissible methods of taking. In order to issue regulations, NMFS must make a determination that (1) the taking will have a negligible impact on the species or stock, and (2) the taking will not have an unmitigable adverse impact on the availability of such species or stock for taking for subsistence uses.

In addition, the MMPA requires NMFS to develop regulations governing the issuance of a LOA and to publish these regulations in the Federal Register. Specifically, the regulations for each allowed activity establish:

- Permissible methods of taking, and other means of affecting the least practicable adverse impact on such species or stock and its habitat, and on the availability of such species or stock for subsistence (as clarified above).
- Requirements for monitoring and reporting of such taking. For military readiness activities (as described in the NDAA), a determination of "least practicable adverse impacts" on a species or stock includes consideration, in consultation with the DoD, of personnel safety, practicality of implementation, and impact on the effectiveness of the military readiness activity.

In support of the Proposed Action, the Navy applied for an authorization pursuant to Section 101(a) (5) (A) of the MMPA. After the application was reviewed by NMFS, a Notice of Receipt of Application was published in the Federal Register. Publication of the Notice of Receipt of Application initiated the 30-day public comment period, during which time anyone could obtain a copy of the application by contacting NMFS. NMFS intends to publish a proposed rule for public comment coincident with the publication of this EIS/OEIS. The public will be afforded 30 days to comment on this proposed rulemaking. NMFS will consider and address all comment received during the public comment period, and anticipates issuing the final rule, if appropriate, toward the end of Calendar Year (CY) 2008.

On January 23, 2007, the Deputy Secretary of Defense exempted all military readiness activities employing MFA sonar or Improved Extended Echo Ranging (IEER) sonobuoys from compliance with the requirements of the MMPA for a period of 2 years. This exemption is limited to Major Exercises or training and RDT&E activities within established operating areas or established DoD maritime ranges. This National Defense Exemption (NDE) remains in effect until January 23, 2009 or authorization under the MMPA, whichever is earliest.

The NDE will cover MFA sonar and IEER sonobuoy activities on the HRC until an MMPA authorization is issued for these activities or the NDE expires whichever is earliest. While the NDE remains applicable (until an MMPA authorization is issued), the Navy will continue to employ the marine mammal mitigation measures outlined in Chapter 6.0 of this EIS/OEIS to protect marine mammals while training with the use of MFA sonar. These measures include safety zones around ships and trained lookouts based on coordination of science-based measures with NMFS. Additional measures that may be required as a result of the MMPA authorization would be implemented once authorization is received.

1.5.6 ENDANGERED SPECIES ACT COMPLIANCE

The Endangered Species Act (ESA) (16 U.S.C. 1531 to 1543) applies to federal actions in two separate respects. First, the ESA requires that federal agencies, in consultation with the responsible wildlife agency (e.g., NMFS), ensure that proposed actions are not likely to jeopardize the continued existence of any endangered species or threatened species, or result in the destruction or adverse modification of a critical habitat (16 U.S.C. 1536 [a][2]). Regulations implementing the ESA consultation requirement also include those actions that “may affect” a listed species or adversely modify critical habitat.

If an agency’s Proposed Action would take a listed species, the agency must obtain an incidental take statement from the responsible wildlife agency. The ESA defines the term “take” to mean “harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt any such conduct” (16 U.S.C. 1532[19]).

As part of the environmental documentation for this EIS/OEIS, and as an MMPA permit applicant, the Navy entered into early consultation procedures with NMFS, endangered species division. The Navy has been actively engaged in consultation with NMFS regarding the potential effects on ESA-listed species from the conduct of the activities outlined in this EIS/OEIS. In accordance with 50 CFR §402.11, prior to the issuance of the ROD, NMFS will issue a Preliminary Biological Opinion documenting its determination as to whether the activities conducted in the HRC are likely to jeopardize the continued existence of ESA-listed species, or result in the destruction or adverse modification of critical habitat. Additionally, a preliminary Incidental Take Statement will accompany the preliminary Biological Opinion. Because the Section 7 consultation is simultaneously conducted internally to address NMFS” issuance of an MMPA authorization, an Incidental Take Statement for marine mammals cannot be issued until an MMPA authorization is issued.

The Preliminary Biological Opinion and Preliminary Incidental Take Statement do not exempt the Navy from the prohibitions of Section 9 of the Endangered Species Act. Further, the Navy has determined that activities occurring in the HRC prior to the issuance of an MMPA authorization (e.g., RIMPAC, USWEX, etc.) may affect endangered species in the HRC, and may incidentally take ESA-listed species, thus requiring consultation under the ESA and an associated Incidental Take Statement. As such, the Navy and NMFS are engaged in a separate Section 7 consultation on these specified activities. A separate Biological Opinion and Incidental Take Statement will be issued, as appropriate, for this subset of specified activities, which will occur prior to the issuance of the MMPA authorization and be covered by the NDE.

1.5.7 OTHER ENVIRONMENTAL REQUIREMENTS CONSIDERED

The Navy must comply with a variety of other Federal environmental laws, regulations, and EOs. These include (among other applicable laws and regulations):

- Migratory Bird Treaty Act;
- Coastal Zone Management Act;
- Rivers and Harbors Act;
- Magnuson-Stevens Fishery Conservation and Management Act;
- Clean Air Act;
- Federal Water Pollution Control Act (Clean Water Act);
- National Historic Preservation Act;
- EO 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations;*
- EO 13045, *Environmental Health and Safety Risks to Children*;
- EO 13423, *Strengthening Federal Environmental, Energy and Transportation Management;*
- EO 13089, *Coral Reef Protection;* and
- National Marine Sanctuaries Act.

In addition, laws and regulations of the State of Hawaii appropriate to Navy actions are identified and addressed in this EIS/OEIS. To the extent practicable, this document will be used as the basis for any required consultation and coordination. Appendix C includes a brief description of the laws, regulations, and EOs that apply to events and activities in the HRC.

1.6 RELATED ENVIRONMENTAL DOCUMENTS

Environmental documents for some of the programs, projects, and installations within the geographical scope of this EIS/OEIS that have undergone environmental review to ensure NEPA and EO 12114 compliance include:

- *Barking Sands Underwater Range Expansion (BSURE) Refurbishment Overseas Environmental Assessment,* March 2008
- *Flexible Target Family Environmental Assessment,* December 2007
- *Undersea Warfare Exercise (USWEX) Programmatic Environmental Assessment,* October 2007
- *Overseas Environmental Assessment for Valiant Shield,* July 2007

- *Construction of a Mock Airfield on Pohakuloa Training Area, Hawaii Environmental Assessment, July 2007*
- *Permanent Stationing of the 2/25th Stryker Brigade Combat Team Draft Environmental Impact Statement,* June 2007
- *Environmental Assessment (EA) for MK-48 Mod 6 Torpedo Exercises in Hawaiian Waters,* June 2007
- *Programmatic Overseas Environmental Assessment for MK-48 Advanced Capability Torpedo Service Weapons Test and Sinking Exercises in Four Pacific Ocean Locations,* May 2007
- *Supplemental Overseas Environmental Impact Statement and Environmental Impact Statement for Surveillance Towed Array Sensor System Low Frequency Active (SURTASS LFA) Sonar*, April 2007
- *Composite Training Unit Exercises and Joint Task Force Training Exercises Environmental Assessment/Overseas Environmental Assessment,* February 2007
- *Ballistic Missile Defense System Programmatic Final Environmental Impact Statement*, February, 2007
- *2006 Exercise Valiant Shield Overseas Environmental Assessment,* June 2006
- *2006 Supplement to the 2002 Rim of the Pacific (RIMPAC) Programmatic Environmental Assessment,* May 2006
- *Draft Environmental Impact Statement Military Training Activities at Makua Military Reservation, Hawaii*, May 2005
- *Final Environmental Assessment for Construction and Operation of a C-17 Short Austere Airfield (SAAF) Within the State of Hawaii,* November 2004
- *Mobile Sensors Environmental Assessment*, October 2004
- *Ballistic Missile Defense System Programmatic Draft Environmental Impact Statement*, September 2004
- *2004 Supplement to the 2002 Rim of the Pacific Programmatic Environmental Assessment,* June 2004
- *Mobile Launch Platform Environmental Assessment*, June 2004
- *Final Environmental Impact Statement Transformation of the 2nd Brigade, 25th Infantry Division (L) to a Stryker Brigade Combat Team in Hawaii*, May 2004
- *Hickam Air Force Base C-17 Globemaster III Beddown Environmental Assessment,* September 2003
- *Ground-Based Midcourse Defense (GMD) Extended Test Range (ETR) Environmental Impact Statement*, July 2003
- *Theater High Altitude Area Defense (THAAD) Pacific Test Flights Environmental Assessment*, December 2002
- *Development and Demonstration of the Long Range Air Launch Target System Environmental Assessment*, October 2002

- *Rim of the Pacific (RIMPAC) 2002 Programmatic Environmental Assessment*, June 2002
- *North Pacific Targets Program Environmental Assessment*, April 2001
- *Mountaintop Surveillance Sensor Test Integration Center (MSSTIC) Facility Kauai, Hawaii Environmental Assessment*, May 2000
- *Rim of the Pacific (RIMPAC) 2000 Environmental Assessment*, May 2000
- *Pacific Missile Range Facility Enhanced Capability Final Environmental Impact Statement,* December 1998
- *Hawaiian Islands Humpback Whale National Marine Sanctuary Final Environmental Impact Statement/Management Plan*, February 1997
- *Final Environmental Assessment for Temporary Hawaiian Area Tracking System*, June 1994
- *Advanced Radar Detection Laboratory Environmental Assessment (in process)*

2.0 Description of the Proposed Action and Alternatives

2.0 DESCRIPTION OF THE PROPOSED ACTION AND ALTERNATIVES

This chapter provides detailed information on the Proposed Action and alternatives analyzed in this Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) and incorporates changes from the Draft and Supplement to the Draft EIS/OEIS. The United States (U.S.) Department of the Navy (Navy) proposes to implement actions within the Hawaii Range Complex (HRC) to:

- Maintain current levels of military readiness by training in the HRC;
- Accommodate future increases in training tempo in the HRC and support the rapid deployment of naval units and/or Strike Groups;
- Achieve and sustain readiness of ships and squadrons consistent with the Fleet Response Training Plan (FRTP) so that the Navy can rapidly increase significant combat power in the event of a crisis or contingency operation;
- Support the acquisition and implementation into the Fleet of advanced military technology. The HRC must adequately support the testing and training needed for new platforms and weapons systems that will be introduced and used by the Fleet before the summer of 2013 (e.g., the Littoral Combat Ship and the MH-60R Seahawk helicopter); and,
- Maintain the long-term viability of the HRC while protecting human health and the environment, and enhancing the quality and communication capability and safety of the range complex.

Conducting current and emerging training and research, development, test, and evaluation (RDT&E) activities and implementation of HRC enhancements includes a collection of actions which will be evaluated in this EIS/OEIS. Alternative implementation scenarios (described in detail in this chapter) involve combinations of the following elements:

- Increase training to support the FRTP and necessary force structure changes;
- Support three transient Strike Group training and assessment exercises at the same time;
- Support an additional carrier during Rim of the Pacific (RIMPAC) Exercises;
- Operate a Portable Undersea Tracking Range;
- Construct and operate an Acoustic Test Facility;
- Enhance RDT&E activities and training at the Pacific Missile Range Facility (PMRF),
- Relocate and operate the simulated underwater minefield training area; and
- Use the 2.1-million square nautical miles (nm^2) Temporary Operating Area (TOA) to support RDT&E and training.

2.1 DESCRIPTION OF THE HAWAII RANGE COMPLEX

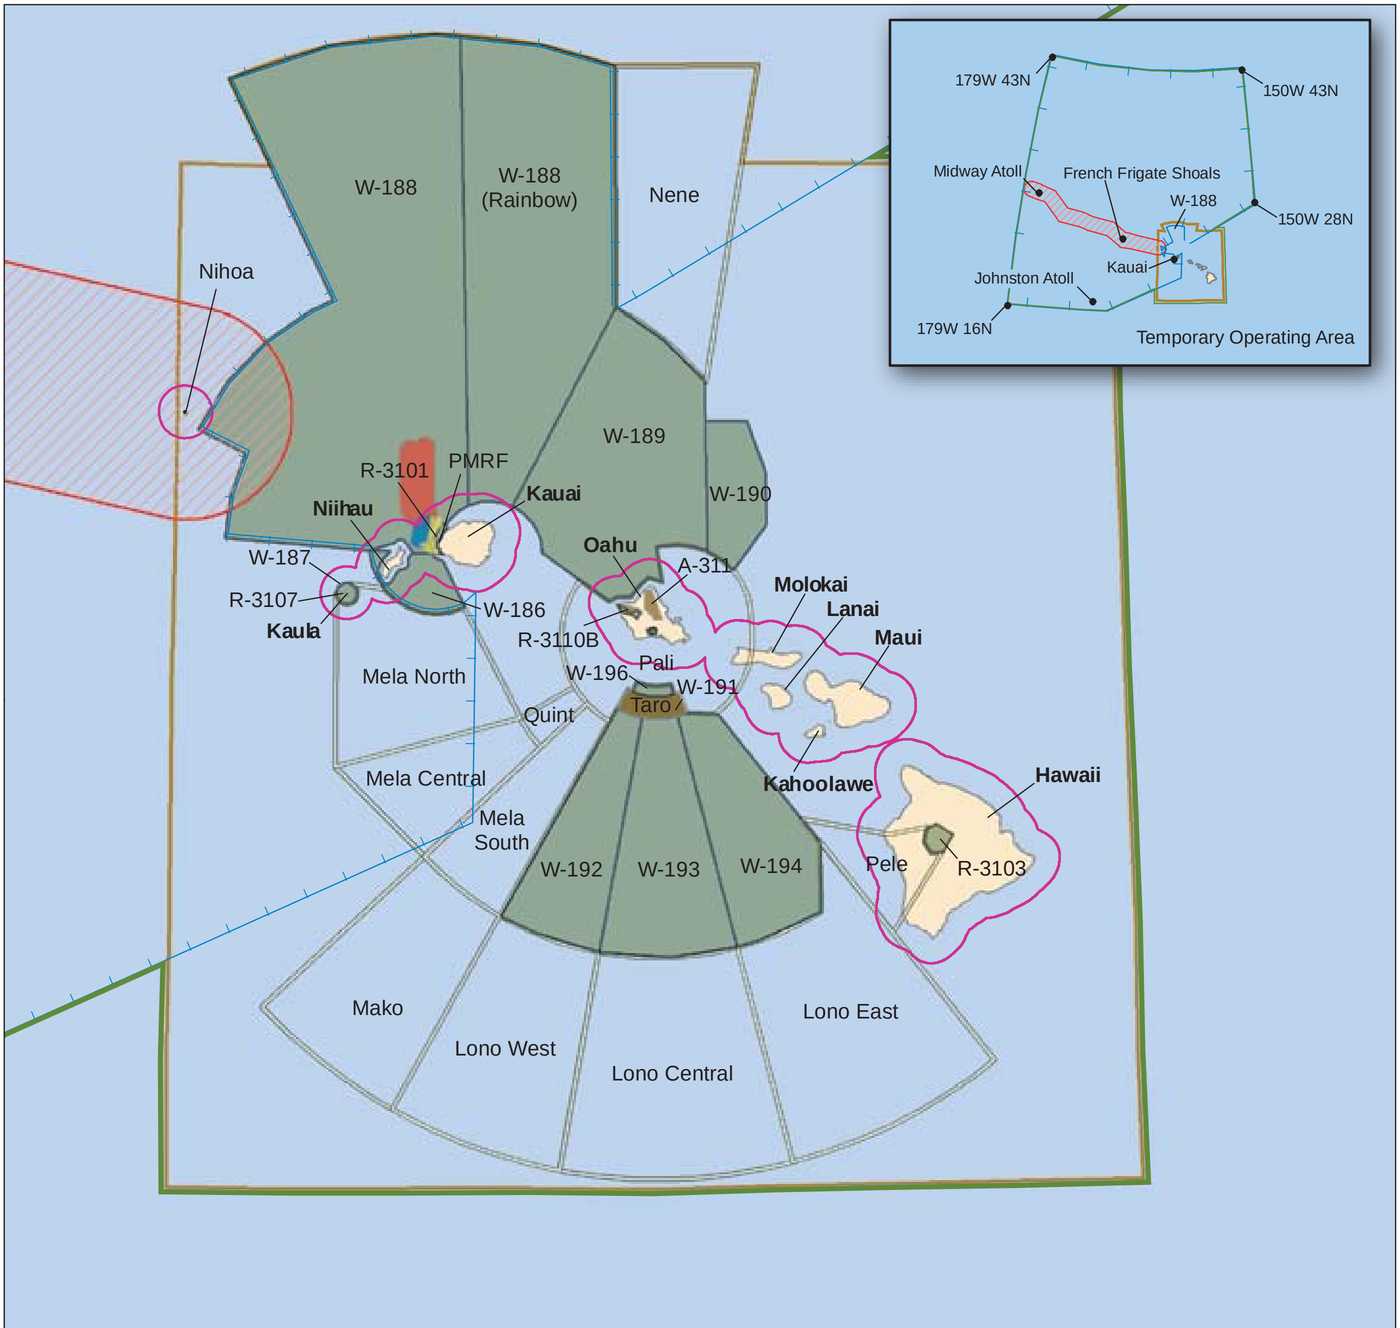
As described in Chapter 1.0, the HRC consists of open ocean areas (outside 12 nautical miles [nm] from land), offshore areas (within 12 nm from land), and onshore areas geographically situated on and around the Hawaiian Islands. The offshore areas extend from 16 degrees north latitude to 43 degrees north latitude and from 150 degrees west longitude to 179 degrees west longitude, forming an area approximately 1,700 nautical miles (nm) by 1,600 nm (Figure 1.2-3). The component areas of the HRC include:

- The Hawaii operating area (OPAREA) consisting of 235,000 square nautical miles [nm^2]) of surface and subsurface ocean areas and special use airspace for military training and RDT&E activities. In addition, various Navy land ranges and other Services' land for military training and RDT&E activities are also considered part of the Hawaii OPAREA (Figure 1.2-2) and
- The TOA consisting of 2.1 million nm^2 of sea and airspace for RDT&E activities (Figure 1.2-3).

Within the Hawaii OPAREA, there are a number of open ocean, offshore, and underwater ranges and training areas, Air Traffic Control Assigned Airspace (ATCAA), and Special Use Airspace (Figure 2.1-1).

The TOA was established to support missile defense testing and extends primarily north and west of Kauai (Figure 1.2-3). For safety purposes, PMRF requests use of the airspace within the TOA from the Federal Aviation Administration (FAA) during times of missile defense testing. During testing, PMRF will control the airspace and the FAA will temporarily restrict an area of airspace within the TOA (typically not the entire area) until testing is complete. Due to the range and speed of weapons and missiles, this large area is required to ensure a safety area in which debris and/or expended materials could fall with minimal risk of damage or injury to humans.

Onshore areas include air and land space associated with various Navy controlled land areas on Kauai, Niihau, Kaula, and Oahu where the Navy and other Department of Defense (DoD) services conduct military training and RDT&E activities. In addition, onshore areas include other military service's land and airspace on Oahu and Hawaii where Navy training is conducted (Figures 2.1-2 through 2.1-5 and Table 2.1-1).



Open Ocean = The air, surface, and subsurface areas of the HRC that lie 12 nautical miles or more from land.
Offshore Area = The air, surface, and subsurface areas within 12 nautical miles of the Hawaiian Islands.

Note: A description of the training events and RDT&E activities that occur at these locations is listed in Tables 2.2.2.3-1 and 2.2.2.5-1.

2.2 PROPOSED ACTION AND ALTERNATIVES

National Environmental Policy Act (NEPA) implementing regulations (40 Code of Federal Regulations [CFR] § 1502.14) and Navy procedures (32 CFR Part 775) provide direction on the consideration of alternatives in an EIS and promote rigorous exploration and objective evaluation of all reasonable alternatives. Alternatives were developed giving due consideration to the purpose and need of the Proposed Action, and factors such as the capability to support current and emerging Fleet tactical training and RDT&E requirements; the capability to support realistic, essential training at the level and frequency sufficient to support the FRTP and Tactical Training Theater Assessment and Planning (TAP) program recommendations; and the capability to support training requirements without impacting Navy guidelines governing the amount of time a unit may be deployed away from its homeport.

Guidance for the development of alternatives is provided in Council on Environmental Quality (CEQ) regulations (40 CFR § 1502.14) and Navy procedures described in 32 CFR § 775. The analysis of alternatives is the heart of an EIS and is intended to provide the decision-maker and the public with a clear understanding of relevant issues and the basis for choice among identified options. NEPA requires that an EIS be prepared to evaluate the environmental consequences of a range of reasonable alternatives. Reasonable alternatives must meet the stated purpose and need of the Proposed Action.

Alternatives that are outside the scope of what Congress has approved or funded must still be evaluated in the EIS/OEIS if they are reasonable, because the EIS/OEIS may serve as the basis for modifying congressional approval or funding in light of NEPA's goals and policies.

As described in the first paragraph, alternatives were selected based on their ability to meet the following criteria:

- Use existing Navy ranges and facilities in and around Hawaii;
- Be consistent with the stated current and emerging requirements for the range complex;
- Achieve training tempo requirements based on Fleet deployment schedules;
- Meet the requirements of DoD Directive 3200.15, Sustainment of Ranges and Operating Areas;
- Implement new training requirements and RDT&E activities; and
- Support realistic training that replicates expected operating environments for naval forces.

2.2.1 ALTERNATIVES ELIMINATED FROM FURTHER CONSIDERATION

2.2.1.1 REDUCTION OR ELIMINATION OF TRAINING IN THE HAWAII RANGE COMPLEX

During scoping the alternative to reduce the level of training or eliminate training in the HRC was suggested. A reduction in levels of or complete elimination of training within the HRC would not support the Navy's ability to meet United States Code (U.S.C.) Title 10 obligations, which at Section 5062 requires the Navy to be "organized, trained, and equipped primarily for prompt and sustained combat incident to operations at sea." Reduced or eliminated training would jeopardize the ability of specialty forces, transient units, and Strike Groups using the HRC for training purposes to be ready and qualified for deployment. Lastly, a reduction or termination of training in the HRC would require local units/users to routinely travel to other range complexes to fulfill training requirements and result in an unacceptable increase in time away from the homeport (that is, time away from home and families). For these reasons, an alternative that would decrease military training from current levels or eliminate training altogether would not meet the purpose and need of the Proposed Action. The CEQ requires an EIS to include an alternative of No-action. The CEQ defines "No-action" as no change from current activities. This alternative has been eliminated from further consideration in the EIS/OEIS.

2.2.1.2 ALTERNATIVE LOCATIONS FOR TRAINING CONDUCTED IN THE HAWAII RANGE COMPLEX

The HRC has the infrastructure to support a large number of forces, has extensive existing range assets, and accommodates Navy training and testing responsibilities both geographically and strategically, in a location under U.S. control. The strategic importance of the HRC is discussed in Section 1.3.5. The Navy's physical presence and training capabilities are critical in providing stability to the Pacific region. Centrally located in the North Pacific, the HRC is co-located with the naval command units of Commander U.S. Pacific Fleet; Commander Submarine Force, U.S. Pacific Fleet; and the U.S. Marine Corps Forces, Pacific. The HRC is also home to the joint armed services command units of U.S. Pacific Command, U.S. Army Pacific, and Commander, Pacific Air Forces. With a unified presence of Army, Marine Corps, Navy, Air Force, National Guard, and Coast Guard elements, the HRC provides the training area for large multi-force (air, land, and sea components) and multinational training exercises. One example of this is the biennial RIMPAC Exercise. The HRC is the only central location in the Pacific for numerous allied nations from North America, South America, and Asia to converge for valuable training that help strengthen ties with our many allies, partners, and friends. Other critical HRC capabilities include:

- The relative isolation of the HRC's broad open ocean area offers an invaluable facility on which to conduct missile testing and training.
- The HRC provides a superior joint training environment for all the services as well as advanced missile testing capability because of its ability to utilize the Army's Pohakuloa Training Area, Air Force, and Marine Corps bases where aircraft basing and amphibious training may occur.
- The open ocean of the HRC presents a realistic environment for strike warfare training, including amphibious, offshore, and Anti-submarine Warfare (ASW). There is room and space to operate within proximity of land but at safe distances from other simultaneous training. This allows both training of local units and the necessary build-up of capability through training that culminates in multi-force training in Hawaii as naval forces transit the Pacific. Training may be conducted that takes advantage of the proximity of the islands and military facilities/ranges to create realistic battle problems. The relatively large area of the HRC coupled with different islands and military facilities/ranges provides a safe, flexible, and diverse training environment for Multiple Strike Groups or units to operate simultaneously.
- The HRC is the most capable and time-efficient en route training location in the eastern pacific for U.S. west coast naval forces and units deploying to or returning from regions in the western Pacific and Indian Ocean from homeports on the U.S. west coast. Recent changes in the Navy's FRTP require ships and squadrons returning from overseas deployment to remain fully trained and ready to redeploy on short notice. The HRC is the training location for those units returning to homeports on the west coast of the United States after operational deployments.
- One of the HRC's premier capabilities is PMRF. PMRF is the world's largest military test and training range capable of supporting subsurface, surface, air, and space training. It consists of underwater ranges, controlled airspace, and a TOA covering 2.1 million nm^2 of ocean. PMRF provides major range services for training, tactics

development, and RDT&E of air, surface, and subsurface weapons systems for the Navy, other DoD agencies, allies, and private industry.

The specific value of the HRC and its superiority to alternative ranges is defined by its location in the Pacific Ocean, its proximity to Hawaii-based forces, its presence on the route of transiting forces, and its central location for nations around the rim of the Pacific. The HRC contains distinctive individual capabilities that require the continuation of specific in-place training and RDT&E activities. Further, the HRC is just one of many naval ranges in current operation that will require separate environmental analyses for mandated achievement of sustainable on-site training and testing. For the above reasons and those discussed in Section 1.3.5, it is neither reasonable, practicable, nor appropriate to seek alternative locations for training conducted in the HRC. Therefore, this alternative has been eliminated from further consideration in the EIS/OEIS.

2.2.1.3 COMPUTER SIMULATION TRAINING

Navy and Marine Corps training includes extensive use of computer-simulated virtual training environments, and conducts command and control exercises without operational forces (constructive training) where possible. These training methods have substantial value in achieving limited training objectives. Computer technologies provide excellent tools for implementing a successful, integrated training program while reducing the risk and expense typically associated with live military training. However, virtual and constructive training are an adjunct to, not a substitute for, live training, including live-fire training. Unlike live training, these methods do not provide the requisite level of realism necessary to attain combat readiness, and cannot replicate the high-stress environment encountered during an actual contingency situation.

The Navy and Marine Corps continue to research new ways to provide realistic training through simulation, but there are limits to realism that simulation can provide, most notably in dynamic environments involving numerous forces, and where the training media is too complex to accurately model, such as sound behavior in the ocean.

Current simulation technology does not permit ASW training with the degree of fidelity required to maintain proficiency. Basic training of sonar technicians does take place using simulators, but beyond basic levels, simulation is of limited utility. A simulator cannot match the dynamic nature of the environment, either in bathymetry, sound propagation properties, or oceanography. Specifically, coordinated unit-level and Strike Group Training activities require multiple crews to interact in a variety of acoustic environments that cannot be simulated. Moreover, it is a training imperative that crews actually utilize the equipment they will be called upon to operate. In addition, the majority of RDT&E activities also must be conducted in a variety of acoustic environments to ensure the safe and effective use of the active sonar system.

Sonar operators and crews must train regularly and frequently to develop the skills necessary to master the process of identifying underwater threats in the complex subsurface environment. They cannot reliably simulate this training through current computer technology because the actual marine environment is too complex. Sole reliance on simulation would deny Navy Strike

Groups the training benefit and opportunity to derive critical lessons learned in the employment of active sonar in the following specific areas:

- Bottom bounce and other environmental conditions;
- Mutual sonar interference;
- Interplay between ship and submarine target; and
- Interplay between ASW teams in the Strike Group.

Currently, these factors cannot be adequately simulated to provide the fidelity and level of training necessary in the employment of active sonar. Further, like any combat skill, employment of active sonar is a perishable skill that must be exercised—in a realistic and integrated manner—in order to maintain proficiency. Eliminating the use of active sonar during the training cycle would cause ASW skills to atrophy and thus put Navy forces at risk during real world operations.

Consequently, conducting all naval training by simulation is deemed inadequate and fails to meet the purpose and need of the Proposed Action. Therefore, this alternative has been eliminated from further consideration in the EIS/OEIS.

2.2.2 NO-ACTION ALTERNATIVE

The purpose of including a No-action Alternative in environmental impact analyses is to ensure that agencies compare the potential impacts of the proposed Federal action to the known impacts of maintaining the status quo. The No-action Alternative presented here comprises a baseline of current, ongoing training and RDT&E activities and support of existing range capabilities. This alternative represents what is in essence a continuation of the Navy's present course of action, that is, the regular and historic level of activity present within the HRC. The analysis of this alternative is a snapshot of the status quo, a description of the continuing and current use of the HRC. The Navy considered a reduced level of training and the elimination of training in the HRC as alternatives. However, as discussed in Section 2.2.1.1, these alternatives were eliminated and not carried forward for evaluation. As a part of the Navy's long-standing and ongoing commitment to the environment, and as a part of the No-action Alternative, the Navy will ensure compliance with applicable environmental laws and regulations. An integral part of this EIS/OEIS process is to take a hard look at all applicable environmental laws and regulations and to ensure that actions associated with each proposed alternative are in compliance with applicable laws and regulations.

The No-action Alternative stands as no change from current levels of training usage. The existing level of activity is used as a benchmark with which to compare the outputs and effects of differing alternatives. If the No-action Alternative is selected, the Navy would continue its current activities at the HRC. Alternatives 1, 2, and 3 analyze greater use of range assets to support training by combining activities together to maximize training opportunities. By using the status quo as the No-action Alternative, the Navy compares the impacts of current training and RDT&E activities to the impacts of enhanced training and RDT&E activities presented in Alternatives 1, 2, and 3.

Under the No-action Alternative, the current baseline of training and RDT&E activities includes over 9,300 events and activities being conducted in the HRC annually. Training, including Major Exercises (such as RIMPAC and Undersea Warfare Exercise [USWEX]), and RDT&E activities will continue at the baseline levels. The No-action Alternative includes the training and RDT&E activities discussed in the following sections as well as those described in the 1998 PMRF Enhanced Capability Final EIS, the additional PMRF programs analyzed since December 1998, the training described in the RIMPAC 2002 Programmatic Environmental Assessment (EA) and the supplements to that document in 2004 and 2006, and training described in the 2007 USWEX Programmatic EA.

Some confusion involving terminology is possible given that individual training events traditionally have names that include the word "exercise," but these events are very different in scale from a Major Exercise such as RIMPAC. For example, a "Torpedo Exercise" in this EIS/OEIS refers to an event that can take place as a stand-alone training event (exercising use of the weapon by a ship to meet qualifications) or as an event taking place in coordination with other events as part of an exercise such as RIMPAC. In short and as used in this document, an exercise (e.g., RIMPAC, USWEX) involves more than one participant and consists of a series of events that might include a Tracking Exercise (TRACKEX),Torpedo Exercise (TORPEX), and ASW.

2.2.2.1 HAWAII RANGE COMPLEX TRAINING FOR THE NO-ACTION ALTERNATIVE

Table 2.2.2.1-1 includes a brief description of current Navy training events within the HRC (Figure 1.2-3), and Appendix D includes a detailed description. Training events occur throughout the year based on training schedules. Section 2.2.2.3 presents the number of training events that occur within the HRC on an annual basis.

Table 2.2.2.1-1. Current Navy Training Events in the HRC

Mission Area	Training Event	Training Event Description
Anti-air Warfare (AAW)	Air Combat Maneuver (ACM)	Two to eight fighter aircraft engage in aerial combat, typically at high altitudes, far from land. No live ordnance used, only chaff and flares.
	Air-to-Air Missile Exercise (A-A MISSILEX)	In scripted scenarios, aircraft fire air-to-air guided missiles at aerial targets. Live and inert missiles fired.
	Surface-to-Air Gunnery Exercise (S-A GUNEX)	Surface ships fire guns at an aircraft towed target. Live and inert missiles fired.
	Surface-to-Air Missile Exercise (S-A MISSILEX)	Surface ships fire missiles at target drones. Live missiles fired at target.
	Chaff Exercise (CHAFFEX)	Ship and aircraft crews practice defensive maneuvering while expending chaff to evade radar targeting by a simulated missile threat. Chaff consists of thin metallic strips that reflect radio frequency energy, confusing radar. No ordnance used, only chaff.
Amphibious Warfare (AMW)	Naval Surface Fire Support (NSFS) Exercise	Navy ships fire main guns at a simulated target located west of Kauai. Live gunnery rounds fired into ocean.
	Expeditionary Assault	Ship, aircraft, and boat crews; and Marine expeditionary forces train to launch from ships at sea and safely move ashore. No ordnance used.

Table 2.2.2.1-1. Current Navy Training Events in the HRC (Continued)

Mission Area	Training Event	Training Event Description
Anti-Surface Warfare (ASUW)	Visit, Board, Search, and Seizure (VBSS)	Helicopter and boat crews train to transport teams to board vessels and inspect the ship's cargo and personnel. No ordnance used.
	Surface-to-Surface Gunnery Exercise (S-S GUNEX)	Surface ships fire guns against stationary or moving targets for live fire target practice. Live gunnery rounds fired at surface targets.
	Surface-to-Surface Missile Exercise (S-S MISSILEX)	Surface ships fire missiles against moving or stationary surface targets. Live and inert missiles fired against surface targets.
	Air-to-Surface Gunnery Exercise (A-S GUNEX)	Helicopter crews fire guns against stationary or moving targets for live fire target practice. Live gunnery rounds fired at surface targets.
	Air-to-Surface Missile Exercise (A-S MISSILEX)	Helicopter crews fire guided missiles or simulate firing missiles at stationary or moving targets. Inert Hellfire missiles fired at targets.
	Bombing Exercise (BOMBEX) (Sea)	Fixed-wing aircraft drop bombs against a stationary target on the surface of the ocean. Live and inert bombs dropped on surface targets.
	Sinking Exercise (SINKEX)	Multiple aircraft, ships, and submarines fire live weapons at a hulk (a surface ship, usually a former Navy ship that has been decommissioned). Multiple types of live ordnance fired on hulk.
	Anti-Surface Warfare Torpedo Exercise (ASUW TORPEX) (Submarine-Surface)	A submarine fires an inert exercise torpedo at a surface target. Target could be a Navy ship or a range support boat. Inert exercise torpedoes fired.
	Flare Exercise	Aircraft crews practice defensive maneuvering while expending flares to evade infrared (IR) targeting by a simulated surface-to-air missile (SAM) system.
Anti-Submarine Warfare (ASW)	Anti-Submarine Warfare Tracking Exercise (ASW TRACKEX)	Aircraft, ship and submarine crews train in locating and tracking a maneuvering submerged target using active or passive sonar. No ordnance. Sonobuoys are released from aircraft. Active and passive sonar used.
	Anti-Submarine Warfare Torpedo Exercise (ASW TORPEX)	Aircraft, ship and submarine crews track and fire an inert practice torpedo against a maneuvering submerged target. Inert exercise torpedoes fired. Active and passive sonar used.
	Major Exercise (Rim of the Pacific [RIMPAC], Undersea Warfare Exercise [USWEX], Three Strike Groups)	Elements of the ASW Tracking Exercise combine in this exercise of multiple air, surface and subsurface units, over a period of several days. No ordnance. Sonobuoys released from aircraft. Active and passive sonar used.
	Extended Echo Ranging/Improved Extended Echo Ranging (EER/IEER) Training Exercise	The EER/IEER Systems are airborne ASW systems used in conducting searches for submarines in large areas. Sonobuoys are released from aircraft. Active and passive sonar used.
Electronic Combat (EC)	Electronic Combat (EC) Operations	Air and land based systems emit electronic signals, designed to simulate threat radars. Ship and aircraft crews train to respond to these signals as appropriate. No ordnance used.

Table 2.2.2.1-1. Current Navy Training Events in the HRC (Continued)

Mission Area	Training Event	Training Event Description
Mine Warfare (MIW)	Mine Countermeasures (MCM) Exercise	Aircraft, ships, and submarines train to detect, then avoid or disable in-water mines. Active sonar used. No ordnance used.
	Mine Neutralization	Personnel train to detect and destroy or disable in-water mines. Underwater detonations occur.
	Mine Laying	Offensive mining where aircraft and submarines deploy mines into the water. Inert mine shapes released into the ocean.
	Land Demolitions	Explosive Ordnance Disposal personnel train to locate, excavate, identify and render land mines and other unexploded ordnance safe, which typically involves destroying the ordnance with an explosive charge. Land detonations occur.
Naval Special Warfare (NSW)	Swimmer Insertion/Extraction	Underwater training involving a Sea, Air, and Land (SEAL) Delivery Vehicle that transports SEALs between a submerged submarine and shore. No ordnance or sonar used.
	Special Warfare Operations (SPECWAROPS)	SPECWAROPS are performed by Navy SEALs and U.S. Marines. Activities include special reconnaissance, reconnaissance and surveillance, combat search and rescue, and direct action. No ordnance or sonar used.
Strike Warfare (STW)	Bombing Exercise (BOMBEX) (Land)	Fixed-wing aircraft drop inert bombs against a land target. Inert and live bombs dropped from aircraft.
	Air-to-Ground Gunnery Exercise (A-G GUNEX)	Helicopter crews fire guns at stationary land targets. Live gunnery rounds fired at land targets.
Other	Salvage Operations	Navy divers train to tow disabled ships, repair damaged ships, remove sunken ships, and conduct deep ocean recovery. No ordnance or sonar used.
	Live Fire Exercise (LFX)	Ground forces conduct live fire weapons training while maneuvering. Live fire includes small arms, artillery, and aerial gunnery. Live rounds fired at Pohakuloa Training Area; inert rounds (blanks) fired at Makua Military Reservation.
	Humanitarian Assistance Operations/Non-combatant Evacuation Operations (HAO/NEO)	HAO/NEO training events involve approximately 150 personnel and troops and specialists who initially provide assistance to civilians and then evacuate the civilians when necessary. No ordnance used.
	Humanitarian Assistance / Disaster Relief Operations (HA/DR)	HA/DR training events involve approximately 125 to 250 military personnel and 125 to 200 simulated refugees. The training event consists of military forces providing critical services (water, food, etc.) to refugees. No ordnance used.

2.2.2.2 HAWAII RANGE COMPLEX SUPPORT EVENTS FOR THE NO-ACTION ALTERNATIVE

Numerous support events take place as an integral part of training occurring in the HRC. These support events can generally be described as either supporting the command and control (C2) events, or supporting ships, submarines, aircraft, or personnel.

Command and Control

The purpose of the C2 events is to provide continuous C2 support for Major Exercises. Each activity is monitored and coordinated for safety and on-time performance, to ensure training objectives are accomplished, and to identify lessons learned for future training and exercises. Overall command functions can be performed from a command ship or from land facilities at Pearl Harbor or PMRF. C2 is achieved through a network of communication devices, or nodes, strategically located at selected DoD installations around the islands (e.g., at range control offices and air traffic centers) to ensure positive communication with the training and exercise participants. Existing C2 nodes are located on the following islands:

- Kauai (Makaha Ridge, Kokee, and Mt. Kahili)
- Oahu (Kaena Point, Mt. Kaala, Wheeler Network Segment Control, Mauna Kapu Communication Site, and Makua Radio/Repeater/Cable Head)
- Molokai (Molokai Mobile Transmitter Site)
- Maui (Maui Space Surveillance System, Maui High Performance Computing Center, and Sandia Maui Haleakala Facility)
- Hawaii (Big Island Mobile Transmitter Site)

In-port Ship Support Operations

The purpose of the In-port Ship Operations is to provide major support for Navy ships and submarines. In-port support includes the typical activities that are carried out when foreign and U.S. warships and submarines are berthed at Pearl Harbor. This includes in-port briefings and debriefings and in-port training activities, including oil spill response training. Once berthed, ships would re-supply, plan for refueling, load ammunition, and conduct other maintenance activities, including the off loading of solid wastes and wastewater (black and gray water). In addition, the Fleet and Industrial Supply Center at Pearl Harbor processes non-typical orders to acquire country unique items that are not normally handled by the U.S. Fleet.

Shore facilities management activities include berthing space and utility hookups, harbor coordination and control, and space management for equipment and personnel. Pearl Harbor has contained more than 60 warships during Major Exercises and on other occasions.

Pearl Harbor is a restricted area. No vessels are allowed into Pearl Harbor without permission of Commander Navy Region Hawaii. The restricted area extends outward from the mouth of the harbor and is defined by a rectangular boundary known as the Pearl Harbor Naval Defensive Sea Area.

Aircraft Support Operations

Aircraft Support Operations are necessary to ensure safe air activities. Aircraft support includes space for the various types of aircraft, equipment for refueling and maintenance.

U.S. and foreign aircraft (fixed wing, rotary, and airship) are supported from Hickam Air Force Base (AFB), Marine Corps Base Hawaii (MCBH), U.S. Coast Guard Air Station Barbers Point/Kalaeloa Airport, and Wheeler Army Airfield on Oahu; Bradshaw Army Airfield on Hawaii; and PMRF (Main Base) airfield on Kauai.

Personnel Support Operations

The purpose of the Personnel Support Operations is to meet the housing and facilities needs of the personnel that support range activities. This includes in-port briefings and debriefings and in-port training activities. In addition, some exercises conclude with receptions, athletic events, and other social activities.

Housing is provided both on and off installation as necessary to house transient aircraft crews and temporary support personnel. Off-installation housing requirements can range from 700 to 1,500 units.

Air Operations

Air Operations are a part of daily activities and Major Exercises. Air Operations are supported at the following facilities: Hickam AFB, MCBH, U.S. Coast Guard Air Station Barbers Point/Kalaeloa Airport, and Wheeler Army Airfield on Oahu; Bradshaw Army Airfield on Hawaii; and PMRF (Main Base) airfield on Kauai.

2.2.2.3 CURRENT TRAINING EVENTS WITHIN THE HAWAII RANGE COMPLEX FOR THE NO-ACTION ALTERNATIVE

Table 2.2.2.3-1 presents current Navy training events (No-action Alternative) that are conducted per year within the HRC. For purpose of comparison, Table 2.2.2.3-1 also presents proposed Navy training events under Alternative 1, Alternative 2, and Alternative 3. Detailed descriptions of these alternatives are described in Sections 2.2.3, 2.2.4, and 2.2.5, respectively. Appendix D provides additional description of these events.

Table 2.2.2.3-1. No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 Proposed Navy Training

Mission Area	Training Event	Area	Open Ocean	Offshore	Onshore	Training Events Per Year			
						No-action Alternative	Alternative 1	Alternative 2	Alternative 3
Anti-Air Warfare (AAW)	Air Combat Maneuver (ACM)	W-188, 189, 190, 192, 193, 194	X			738	774	814	814
	Air-to-Air Missile Exercise (A-A MISSILEX)	W-188	X			12	16	24	24
	Surface-to-Air Gunnery Exercise (S-A GUNEX)	W-188, 192, Mela South	X			86	108	108	108
	Surface-to-Air Missile Exercise (S-A MISSILEX)	W-188	X			17	26	26	26
	Chaff Exercise (CHAFFEX)	Hawaii Operating Area (OPAREA)	X			34	34	37	37
Amphibious Warfare) (AMW)	Naval Surface Fire Support (NSFS) Exercise	W-188 (including Barking Sands Underwater Range Expansion [BSURE], Barking Sands Tactical Underwater Range [BARSTUR])	X	X		22	28	28	28
	Expeditionary Assault	Pacific Missile Range Facility (PMRF) (Main Base), Marine Corps Base Hawaii (MCBH), Marine Corps Training Area–Bellows (MCTAB), Kawaihae Pier		X	X	11	11	12	12
Anti-Surface Warfare (ASUW)	Visit, Board, Search, and Seizure (VBSS)	Hawaii OPAREA	X			60	60	66	66
	Surface-to-Surface Gunnery Exercise (S-S GUNEX)	W-188, 191, 192, 193, 194, 196, Mela South	X			69	91	91	91
	Surface-to-Surface Missile Exercise (S-S MISSILEX)	W-188	X			7	12	12	12
	Flare Exercise	W-188 (PMRF [Main Base], Niihau)		X		6	6	7	7
	Air-to-Surface Gunnery Exercise (A-S GUNEX)	Hawaii OPAREA	X			128	152	152	152
	Air-to-Surface Missile Exercise (A-S MISSILEX)	W-188	X			36	50	50	50

Table 2.2.2.3-1. No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 Proposed Navy Training (Continued)

Mission Area	Training Event	Area	Open Ocean	Offshore	Onshore	Training Events Per Year			
						No-action Alternative	Alternative 1(1)	Alternative 2(1)	Alternative 3(1)
	Bombing Exercise (BOMBEX) (Sea)	Hawaii OPAREA	X			35	35	38	38
	Sinking Exercise (SINKEX)	Hawaii OPAREA	X			6	6	6	6
	Anti-Surface Warfare Torpedo Exercise (Submarine-Surface) (ASUW TORPEX)	Hawaii OPAREA	X			35	35	38	35
Anti-submarine Warfare (ASW)	Anti-Submarine Warfare Tracking Exercise (ASW TRACKEX)	Hawaii OPAREA (including BSURE, BARSTUR, Shallow Water Training Range [SWTR])	X	X		372	372	414	372
	Anti-submarine Warfare Torpedo Exercise (ASW TORPEX)	Hawaii OPAREA (including BSURE, BARSTUR, SWTR)	X	X		500	500	650	500
	Major Exercise	Hawaii OPAREA (including BSURE, BARSTUR, SWTR)	X	X		5	6	6	5

Notes:
Open Ocean includes the air, surface and subsurface ocean areas of the HRC that lie outside 12 nautical miles (nm) of land.
Offshore includes the air, surface, and subsurface ocean areas of the HRC within 12 nm of land.
Onshore includes the air and land areas of the HRC that are shoreward of the high-water mark.
(1)Alternative 1 training is discussed in Section 2.2.3, Alternative 2 training is discussed in Section 2.2.4, and Alternative 3 training is discussed in Section 2.2.5

2.2.2.4 MID-FREQUENCY ACTIVE/HIGH-FREQUENCY ACTIVE SONAR USAGE FOR THE NO-ACTION ALTERNATIVE

Mid-frequency active (MFA) sonar operates between 1 and 10 kilohertz (kHz). MFA sonar hours are based on data available from the Sonar Positional Reporting System (SPORTS). SPORTS is a database tool established by Commander, U.S. Fleet Forces Command in mid-2006. All commands employing MFA sonar and sonobuoys are required to populate the SPORTS database by reporting MFA sonar use. A review by senior officers determined that SPORTS data would be used in this EIS/OEIS in conjunction with previous planning data to assist in determining the amount of MFA sonar use for purposes of modeling potential effects on marine mammals.

The type of sonar sources used as part of ASW activities within the HRC are listed below. Table 2.2.2.4-1 lists MFA and HFA sonar usage analyzed for the No-action Alternative:

- Surface ship sonar (AN/SQS-53 and AN/SQS-56)
- Helicopter dipping sonar (AN/AQS-22)
- Aircraft deployed sonobuoys (AN/SSQ-62)

- Submarine sonar (BQQ-10, BQQ-5, BSY-1)
- MK-48 torpedo (HFA)

Table 2.2.2.4-1. Sonar Usage for the No-action Alternative

Supplement to the Draft EIS/OEIS Hours/Events Modeled		
Other HRC ASW Training		
	Source	**Modeled**
	53	360 hours
	56	75 hours
	Dipping	110 dips
	Sonobuoy	1,278 buoys
	MK-48	309 runs
	Submarine	200 hours

	Dipping	1,010 dips
	Sonobuoy	2,423 buoys
	MK-48	313 runs
	Submarine	200 hours

2.2.2.5 HAWAII RANGE COMPLEX RDT&E ACTIVITIES FOR THE NO-ACTION ALTERNATIVE

Navy RDT&E activities occur primarily at one of two locations in Hawaii: PMRF and the Naval Undersea Warfare Center (NUWC) Detachment Pacific ranges. The current RDT&E activities (No-action Alternative) conducted in the HRC are described below and summarized in Table 2.2.2.5-1. For purpose of comparison, Table 2.2.2.5-1 also presents proposed RDT&E events under Alternative 1, Alternative 2, and Alternative 3. Detailed descriptions of these alternatives are described in Sections 2.2.3, 2.2.4, and 2.2.5, respectively.

Table 2.2.2.5-1. No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 Proposed RDT&E Activities

Notes:
Open Ocean includes the air, surface and subsurface ocean areas of the HRC that lie outside 12 nm of land.
Offshore includes the air, surface, and subsurface ocean areas of the HRC within 12 nm of land.
Onshore includes the air and land areas of the HRC that are shoreward of the high-water mark.
Upgrade indicates that existing facilities and/or equipment would be modified
Construction indicates that additional facilities or infrastructure would be required
(1)Alternative 1 RDT&E activities are discussed in Section 2.2.3, Alternative 2 RDT&E activities are discussed in Section 2.2.4, and Alternative 3 RDT&E activities are discussed in Section 2.2.5

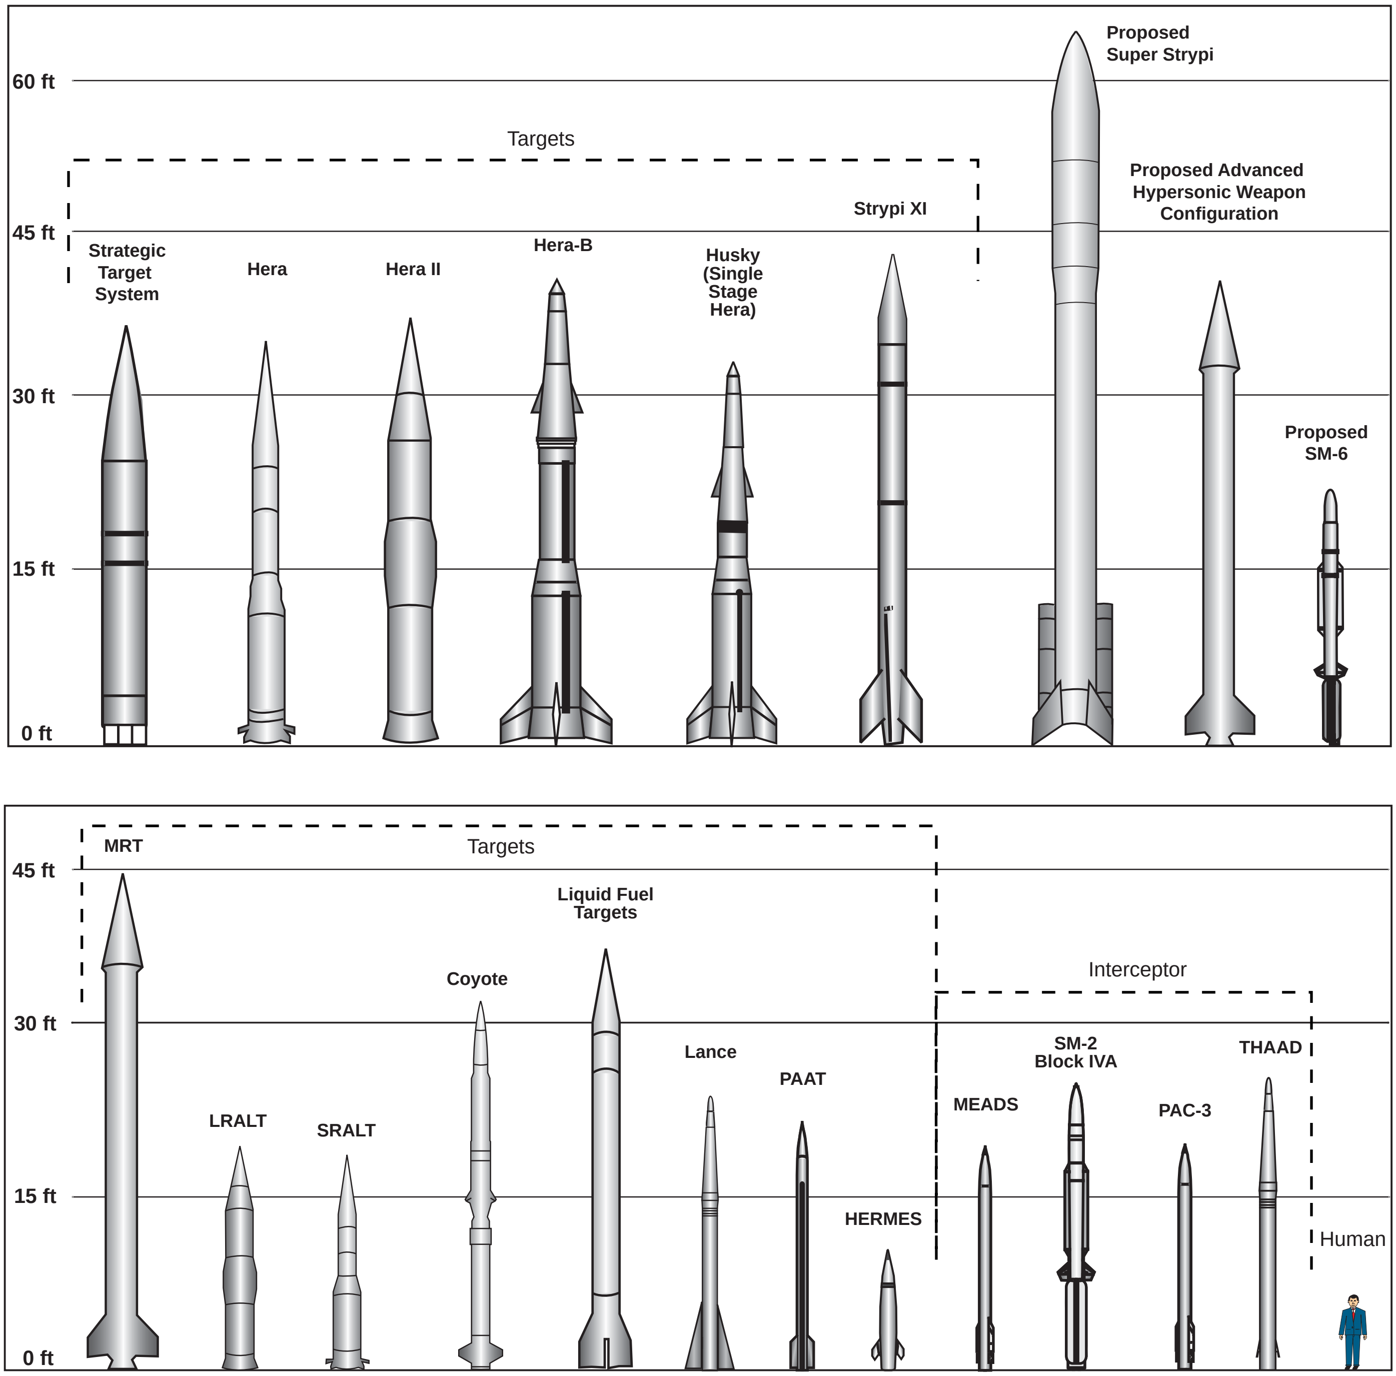
2.2.2.5.1 Pacific Missile Range Facility

PMRF is the world's largest military test range capable of supporting subsurface, surface, air, and space activities (Figure 2.1-2). PMRF consists of 1,000 nm^2 of underwater ranges, 42,000 nm^2 of controlled airspace, and a TOA covering 2.1-million nm^2 of ocean area. PMRF provides major range services for training, tactics development, and evaluation of air, surface, and subsurface weapons systems for the Navy, other DoD agencies, foreign military forces, and private industry. It also maintains facilities and provides services to support naval operations, and other activities and units designated by the Chief of Naval Operations (CNO).

PMRF's additional mission is supporting RDT&E projects. Current ongoing programs at PMRF include CNO designated activities, torpedo, torpedo defense, submarine and periscope detection, ship-defense systems, missile defense, and other miscellaneous programs (such as gunnery/special weapons tests). These programs involve the testing and evaluation of enhancements on systems already used in training conducted at PMRF. These are described briefly below:

- Navy projects are usually related to test and evaluation research, some involving tactical responses to potential underwater, surface, airborne, and ballistic missile threats. Other Navy projects study proposed or new hardware and software designs.
- Torpedo RDT&E programs include a torpedo development testing program involving deep and shallow-water testing of aircraft, helicopter, and surface ship-launched Anti-submarine torpedo sensors to enhance their operational performance.
- Torpedo defense RDT&E programs include a surface-ship torpedo-defense program, involving the testing of new systems to counter incoming torpedoes.
- Submarine detection RDT&E programs include an advanced sensor application program for locating submarines. Periscope detection programs include radar, optical, and laser testing from airborne, ground, and surface ship platforms.
- Ship defense system RDT&E programs include chaff and flare countermeasures testing.
- Missile defense RDT&E programs include missile launches from PMRF and offshore platforms and ships, with intercepts over the broad ocean area within the TOA and operation of radars at PMRF.
- Gunnery/special weapons tests include the usually one-of-a-kind adaptation of an existing weapon to meet a unique threat situation. The weapon is either mounted to or fired from a boat offshore of PMRF/Main Base or set up west of the PMRF launch facility. Targets include surface targets and small radio-controlled planes.

Missile training events conducted at PMRF include general Air-to-Air, Air-to-Surface, Surface-to-Air, and Surface-to-Surface Missile Exercises; specific Anti-surface Missile Exercises; and Anti-air Warfare (AAW) exercises. Each missile training activity must obtain PMRF safety approval before proceeding, covering the type of weapon, type of target, speed, altitude, debris corridor, ground hazard area, and water surface and undersea hazard areas. Figure 2.2.2.5.1-1 shows relative heights of missiles launched as part of PMRF activities. Appendix E lists the existing



EXPLANATION

SM - Standard Missile
MRT - Medium-Range Target
LRALT - Long-Range Air Launched Target
SRALT - Short-Range Air Launched Target
PAAT - Patriot as a Target
PAC-3 - Patriot Advanced Capability-3
THAAD - Terminal High Altitude Area Defense
MEADS - Medium Extended Air Defense System

Relative Missile Heights

Figure 2.2.2.5.1-1

missile defense systems at PMRF. These systems use both solid and liquid propellants. Defensive missile payloads may be equipped with divert and attitude control propulsion systems that control the payload after separation from the launch vehicle. Divert and attitude control systems may use small liquid hypergolic propellant systems or consist of miniature solid-propellant rocket motors.

Anti-Air Warfare RDT&E

AAW RDT&E activities involve testing and training on Aegis-capable ships after refurbishment or overhaul. Aegis Ballistic Missile Defense (BMD) activities involve testing and evaluating the ship's missile system and associated hardware in support of the ship's missile defense mission. An additional RDT&E activity for Aegis ships is the waterfront integration test (WIT), which simulates events that take place during the on range Aegis BMD activities. WIT ensures that all shipboard systems are operable. AAW RDT&E activities may include missile and gunnery ordnance and active sonar.

Anti-Submarine Warfare Test and Evaluation

ASW test and evaluation activities at PMRF include sensor, fire control, and weapon testing. PMRF Submarine Tracking Systems involve using this system to evaluate MK-30 system upgrades. The MK-30 target is a self-propelled underwater vehicle capable of simulating the dynamic, acoustic, and magnetic characteristics of a submarine. The Navy uses in-water submarine simulators such as the MK-30 ASW target. The MK-30 target fulfills the need for a convenient, cost-effective means for operational training of Fleet units. Submarine system evaluation activities conducted in submarine training areas near Maui are also part of ASW test and evaluation activities. The submarine's main active sonar system is not used; however, tracking pingers are a source of underwater sound during ASW test and evaluation activities.

Combat System Ship Qualification Trial

Combat System Ship Qualification Trial (CSSQT) activities are performed at PMRF and are categorized as test and evaluation activities. CSSQT is an at-sea test conducted for new ships and for ships that have undergone modification and/or overhaul of their combat systems. Although CSSQT can vary from ship to ship as requirements dictate, the primary goals are to ensure that the ship's equipment and combat systems are in top operational condition, and that the ship's crew is proficient at operating these systems. Therefore, CSSQT can include operating any or all of a ship's combat systems and may include firing missiles and conducting gunnery exercises.

Electronic Combat/Electronic Warfare

Electronic Combat/Electronic Warfare (EC/EW) activities include tests designed to assess how well EC/EW training events are performed. The EC/EW activities, which occur typically in W-188, are monitored at PMRF shore sites. No ordnance is used during these RDT&E activities.

High-Frequency Radio Signals

High-frequency test and evaluation activities include the use of high-frequency radio signals and the evaluation of their effectiveness. High frequency in the radio spectrum refers to frequencies between 3 megahertz (MHz) and 30 MHz. This frequency range is commonly used for maritime and amateur short-wave radio transmissions. These activities can take place both at PMRF shore sites and within W-188. No ordnance is used during these test and evaluation activities.

Joint Task Force Wide Area Relay Network

Joint Task Force Wide Area Relay Network (JTF WARNET) is a demonstration of advanced Command, Control and Communications (C3) technologies in a highly mobile, wireless, wide-area relay network in support of tactical forces. The objective of a network of this type is to link tactical forces, providing a common operating picture. Although similar in function to a common internet setting, JTF WARNET demonstrates this capability in a very austere battlefield environment, without the luxury of existing communication systems. In addition, the network must be capable of transmitting classified information. JTF WARNET testing evaluates joint and allied C3 decision-making, planning and execution, and tactical capability. These tests are monitored at PMRF shore facilities. No ordnance is used.

Missile Defense

Figure 2.2.2.5.1-2 shows the existing launch facilities at PMRF and the Kauai Test Facility (KTF). Figure 2.2.2.5.1-3 shows the existing missile flight corridors. Aerial targets are launched from PMRF, mobile sea-based platforms, or military cargo aircraft. During missile defense RDT&E activities, a ballistic missile target vehicle is launched from PMRF and intercepted by a ship-launched missile (Figure 2.2.2.5.1-4). No ordnance is used during these events. The test activities can involve:

- Aegis equipped classes of ships (destroyers and cruisers)
- Use of the mobile and airborne range safety systems
- On-load and off-load of aircraft
- Long-Range and Short-Range Air Launched Targets
- Smart Test Vehicle
- Light Detection and Ranging
- Mobile At-Sea Sensor System
- Use of the Battle Management Interoperability Center
- Transportation of liquid propellants to PMRF
- Flight Termination System preparations for an operation
- Dry runs and dress rehearsals for specific missile defense activities

The Army's Terminal High Altitude Area Defense (THAAD) is part of the DoD Ballistic Missile Defense System. THAAD is the antimissile system designed to intercept and destroy missiles in the final phase of their trajectories. THAAD PMRF test activities include midcourse tracking of ballistic missiles using the THAAD radar (two THAAD radars may be operated concurrently at PMRF during interceptor testing), Coherent Signal Processing radar, telemetry, C-Band precision radars, and Mobile At-Sea Sensor System. THAAD differs from other missile defense testing in that THAAD scenarios involve the target vehicle being launched outside of PMRF from a mobile launch platform, with the THAAD interceptor launched from an existing launch pad at PMRF (Figure 2.2.2.5.1-2). The intercept occurs in the TOA.

Other RDT&E associated missile defense activities include preparing security, range instrumentation and communications checks, radar calibrations, and range surveillance/ clearance.

As part of the required clearance before an activity, the target area must be inspected visually and determined to be clear. Range Control is charged with hazard area surveillance and clearance and the control of all range operational areas. Figures 2.2.2.5.1-4 and 2.2.2.5.1-5 depict the range areas associated with two conceptual missile defense scenarios. The PMRF Range Control Officer is solely responsible for determining range status and setting RED (no firing) and GREEN (range is clear and support units are ready to begin the event) range firing conditions. The Range Control Officer coordinates the control of PMRF airspace, with the FAA and other military users, often on a real-time basis.

The Range Control Officer communicates with the training events conductors and all participants entering and leaving the range areas. The Range Control Officer also communicates with other agencies such as the FAA Air Route Traffic Control Center in Honolulu, the PMRF/Main Base airfield control tower, the 154th Air Control Squadron at Kokee, and the Fleet Area Control and Surveillance Facility at Ford Island, Pearl Harbor.

2.2.2.5.2 Naval Undersea Warfare Center Ranges

RDT&E activities take place at the NUWC ranges in Hawaii (Figure 2.2.2.5.2-1). The Shipboard Electronic Systems Evaluation Facilities (SESEF) range, located off Barbers Point on Oahu, provides state-of-the-art test and evaluation of combat systems that radiate or receive electromagnetic energy. The SESEF range includes land based test facilities established to provide electromagnetic system test and evaluation services to afloat and shore commands. SESEF services can be used for the development of new and upgraded systems, and provide a real-time evaluation of a system in an operational environment.

The Fleet Operational Readiness Accuracy Check Site (FORACS) range control is located near Nanakuli, Oahu. The electronic equipment at this site checks range and bearing accuracy for Navy and Coast Guard ships to ensure equipment function and calibration.

SESEF Tests

SESEF tests are conducted to evaluate ship, shore, and aircraft systems that emit or detect electronic emissions. These systems include those used for radio communications, data transfer, navigation, radar, and systems that identify friend and foe. Depending on the system being evaluated, either the tested site, the SESEF, or both will transmit electronic signals in or near the radio frequency band of the electromagnetic spectrum. Specific frequencies and power settings are dependent on the type of test being conducted. The test equipment operated by SESEF allows for a performance evaluation of the ship, shore, or aircraft system. Tests conducted by SESEF fall into one of two broad categories: Quick Look and System Performance tests. Neither SESEF test uses ordnance or sonar.

Figure 2.2.2.5.2-1

Quick Look tests are generally conducted during transit to and from port, or while pier side at Pearl Harbor. These tests provide the ship a quick operational evaluation of the system(s) being tested with a simple “SAT or UNSAT” grade along with any detected system anomalies or problems. An example is a radio check that confirms that a ship’s radio can both transmit and receive voice communications. Quick Look tests have the following characteristics:

- Generally short in duration
- Require little or no advance scheduling
- Require little or no shipboard maneuvering
- May be accomplished pier side (Communications, LINK-4A and LINK-11 only)
- Require minimal internal shipboard coordination

System performance testing provides the ship with a more-detailed analysis and evaluation of the system(s) under test. The testing requirements and the desired measurement precision dictate a higher degree of control on the ship and coordination of its personnel. System performance tests are characterized as tests which:

- Generally require longer periods of dedicated testing
- Require advance scheduling and coordination with SESEF
- Require the ship to maneuver in pre-defined geometries within a certain geographic area; and
- Require internal shipboard coordination

FORACS Tests

The purpose of the FORACS tests is to provide accuracy checks of ship and submarine sonar, both in active and passive modes, and to evaluate the accuracy of a ship’s radar. The ship will conduct a series of “runs” on the range, each taking approximately 1.5 hours. Both active and passive sonar can be checked on a single run. During a run, the ship will approach the target, a stationary underwater acoustic transducer located offshore, making a slow turn to eventually track outbound from the target, establishing a bearing to the target in use. This information is compared with the known bearing by FORACS range technicians stationed onboard the ship. During active sonar testing, range-to-target information is also evaluated. No ordnance is used. Active sonar is used. Examples of specific FORACS tests are:

- Surface Weapons System Accuracy Trial (SURFSAT)—both an acoustic and a Radio Frequency accuracy evaluation for a surface ship’s radar.
- At-Sea Bearing Accuracy Test—a test of a ship’s radar alone.
- Submarine Warfare System Assessment (SWSA)—an assessment of a submarine’s radar and sonar. The SWSA is similar to the SURFSAT, but is only for submarines.
- Undersea Warfare Readiness Evaluation Facility (USWREF)—a test of a ship’s radar and sonar. The USWREF is similar to, but less involved than, the SURFSAT or SWSA.

2.2.2.6 MAJOR EXERCISES FOR THE NO-ACTION ALTERNATIVE

Types of Major Exercises that occur within the HRC include RIMPAC and USWEX. Table 2.2.2.6-1 shows the matrix of individual training events and RDT&E activities that could be included in a Major Exercise. Figure 2.2.2.6-1 shows the HRC OPAREA where these training events occur. The training and RDT&E activities that make up a Major Exercise are typically unit-level training, conducted under the umbrella of a large, coordinated event. These are the same training and RDT&E activities conducted throughout the year in Hawaii. During a Major Exercise, an additional C2 element is introduced which requires that units conduct and demonstrate multiple warfare capabilities (e.g., ASW).

Each of these exercises has at least one Strike Group at its center. A Strike Group is a naval force comprising one or more capital ships, such as an aircraft carrier. Several surface combatant ships such as cruisers, frigates, and destroyers; and one or more attack submarines, usually accompany the capital ship to complete the Strike Group.

Although multiple ships and aircraft may be participating in a simultaneous event, they commonly operate at significant distances from one another, usually not in sight of other participants. The vastness of the HRC allows multiple ships to operate, without creating a high density footprint in any discrete area.

ASW training conducted during RIMPAC and USWEX utilizes ships, submarines, aircraft, non-explosive exercise weapons, and other training systems and devices. The ASW training described here and in Table 2.2.2.1-1 includes both passive and active sonar use. This EIS/OEIS includes an acoustic exposure effects-analysis on marine mammals that may be affected by the RIMPAC and USWEX ASW training events and use of MFA tactical sonar.

Nearly all ASW training would occur in the eight sonar modeling areas delineated in Figure 2.2.2.6-1. ASW events could occur throughout the approximate 235,000 nm^2 of the Hawaii OPAREA; however, the approximately 55,000 nm^2 of these eight areas, were used for analysis as being representative of the marine mammal habitats and the bathymetric, seabed, wind speed, and sound velocity profile conditions within the entire Hawaiian Islands OPAREA. Sonar modeling included the AN/SQS-53 and AN/SQS-56 surface ship sonar, the AN/AQS-22 helicopter dipping sonar, the AN/SSQ-62 sonobuoy sonar, and the MK-48 torpedo sonar. Submarine sonar was not modeled for RIMPAC and USWEX because it is not used during these events.

2.2.2.6.1 Rim of the Pacific

The RIMPAC Exercise, dating back to 1968, is conducted biennially in the Hawaiian OPAREA. Consisting of the Navy, Army, Marine Corps and Air Force with Pacific Rim armed forces, RIMPAC enhances the ability of Pacific Rim armed forces to communicate effectively, understand the capabilities and limitations of each others' forces, and be able to execute the employment of forces quickly and precisely. This promotes stability in the region to the benefit of all participating nations.

■ Locations where training can occur

Training Events:

A-A MISSILEX	Air-to-Air Missile Exercise (formerly AAMEX)
AAW[1]	Anti-air Warfare
AIROPS	Aircraft Operations
AMPHIBEX	Amphibious Landing Exercise (now Expeditionary Assault)
Air MIWEX	Air Mine Warfare Exercise (formerly AMWEX)
A-S MISSILEX	Air-to-Surface Missile Exercise (formerly ASMEX)
ASUW[2]/ASW[3]	Anti-Surface Warfare/ Anti-Submarine Warfare Exercise
ASW	Anti-Submarine Warfare Exercise (formerly ASWEX)
CASEX	Close Air Support
C2	Command and Control
DEMO	Demolition Exercise
GUNEX	Gunnery Exercise
HA/DR	Humanitarian Assistance/Disaster Relief
HAO/NEO	Humanitarian Assistance Operation/ Non-Combatant Evacuation Operation
IN-PORT	In-port Briefings and Operations
LFX	Live Fire Exercise
MCM	Mine Countermeasures
MINEX	Mine Exercise
MIW[4]	Mine Warfare
SALVAGE OPS	Salvage Operations
S-A MISSILEX	Surface-to-Air Missile Exercise (formerly SAMEX)
SINKEX	Sinking Exercise
SMWEX	Ship Mine Warfare Exercise
SPECWAROPS	Special Warfare Operations (NSW Operations)
S-S MISSILEX	Surface-to-Surface Missile (formerly SSMEX)
STW	Strike Warfare Exercise (formerly STWEX)
SUBOPS	Submarine Operations
SUPPORTEX	In-Port Support Exercise
UMWEX	Underwater Mine Warfare Exercise

Note: Since the publication of the RIMPAC PEA, new terminology and/or categories of exercises have come into use. They are as follows:

[1] AAW includes AIROPS, S-A MISSILEX, A-A MISSILEX, and A-S MISSILEX

[2] ASUW includes GUNEX, S-S MISSILEX, and ASW

[3] ASW includes S-S MISSILEX and ASW

[4] MIW encompasses two subsets, MINEX and MCM. MINEX is the act of laying mines. MCM is the act of locating and countering mining by others and includes SMWEX, AMWEX, and UMWEX.

Existing Exercise Area for Rim of the Pacific and Undersea Warfare Exercise

Hawaiian Islands

Figure 2.2.2.6-1

Conducted on existing Army, Marine Corps, Army PMRF ranges, open ocean, and offshore, the month-long RIMPAC Exercise is different from exercises conducted offshore of southern California in several important ways. RIMPAC's focus on multi-national training is very different from other exercises conducted to certify U.S. Strike Groups for deployment. RIMPAC offers the only opportunity for military forces from both the Western and Eastern Pacific to train together in scripted, but realistic, scenarios, and in that regard is a vital training exercise.

A Programmatic EA for RIMPAC was completed in 2002, and supplemental EAs were prepared in 2004 and 2006. The 2004 Supplement to the RIMPAC Programmatic EA was prepared to evaluate the additional RIMPAC training proposed for 2004 not covered by the RIMPAC Programmatic EA. The 2004 Supplement examined new installations or facilities proposed for use, whether significantly different training levels or types of equipment were proposed, and whether environmental conditions had changed. The following events were evaluated in the 2004 Supplement:

- Gunnery Exercises (GUNEX) at PMRF Barking Sands Tactical Underwater Range (BARSTUR)
- Mine Countermeasures (MCM) at Marine Corps Training Area/Bellows (MCTAB), Oahu; Open Ocean Areas, Hawaiian Islands between Molokai, Lanai, and Maui, (including Penguin Bank and the Navy's shallow water training area south of Maui)
- Demolition at Land/Underwater Demolition Range, Naval Magazine Pearl Harbor, West Loch Branch, Oahu; Naval Inactive Ship Maintenance Facility, Middle Loch, Pearl Harbor, Oahu

The 2006 Supplement to the RIMPAC Programmatic EA also included an assessment of a Non-combatant Evacuation Operation (NEO) training event at PMRF and on Niihau and additional analysis related to MFA sonar. The training analyzed was the same as previously analyzed and had taken place with no significant changes over the previous 19 RIMPAC Exercises. Appendix D shows the matrix of training events used during previous RIMPAC Exercises by location.

For RIMPAC under the No-action Alternative, the marine mammal exposure modeling included 532 hours of AN/SQS-53 and AN/SQS-56 surface ship sonar and associated dipping sonar, sonobuoys, and MK-48 torpedoes.

2.2.2.6.2 Undersea Warfare Exercise

The USWEX is an assessment-based ASW exercise conducted by the Strike Groups while in transit from the west coast of the United States to the Western Pacific Ocean. USWEX is considered a "graduate" level assessment focused on ASW warfare and composed of more complex ASW scenarios that can be magnified in scale by adding increased numbers of adversary submarine threats to the training scenario. USWEX is invaluable to Strike Groups as they prepare to execute existing war plans, if necessary. In preparing for these missions, USWEX provides an extremely valuable opportunity to conduct ASW in a very realistic environment, against the level of threat expected in order to effect changes in both training and capabilities, such as tactics, equipment, size and manning of the Strike Group. Since the ability to operate MFA sonar as part of ASW is a highly perishable skill, losing the opportunities a USWEX provides will cause ASW personnel to suffer in the proficiency level and skills they have acquired right before they face real world events on deployment. USWEXs are designed to enable a Strike Group to maintain proficiency of its ASW skills during deployment. USWEX also allows the Navy to separately "assess" the ASW capabilities of a fully ready Strike Group to improve all future ASW training exercises.

A Programmatic Environmental Assessment/Overseas Environmental Assessment (EA/OEA) for USWEX in Hawaii was completed in January 2007.

For USWEX under the No-action Alternative, the marine mammal exposure modeling included 700 hours of AN/SQS-53 and AN/SQS-56 surface ship sonar plus associated dipping sonar, and sonobuoys.

2.2.2.7 MITIGATION MEASURES FOR THE NO-ACTION ALTERNATIVE

Under the No-action Alternative, the Navy's marine mammal mitigation measures will continue to be implemented. Chapter 6.0 presents these mitigation measures, outlining steps that are currently implemented to protect marine mammals and federally-listed species.

2.2.3 ALTERNATIVE 1

2.2.3.1 TRAINING EVENTS FOR ALTERNATIVE 1

Alternative 1 includes all ongoing Navy training associated with the No-action Alternative (as described in Section 2.2.2), and proposes an increased number of such training events. Table 2.2.2.3-1 includes the number of Navy training events associated with the No-action Alternative and the proposed number of events under Alternative 1.

2.2.3.2 MFA/HFA SONAR USAGE FOR ALTERNATIVE 1

Table 2.2.3.2-1 lists MFA/HFA sonar usage analyzed for Alternative 1. Sonar usage is based on SPORTS data and operator input.

	Submarine	200 hours

2.2.3.3 INCREASED TEMPO AND FREQUENCY OF TRAINING AND NEW TRAINING FOR ALTERNATIVE 1

Under Alternative 1, the Navy proposes to increase the tempo and frequency of training in the HRC (Table 2.2.2.3-1). In this setting, tempo means intensity and could include more forces or shorter/longer duration of activities. An increase in frequency means the number of training events in a given period would increase.

New Training: Field Carrier Landing Practice

Under Alternative 1, the Navy is also proposing to conduct Field Carrier Landing Practice (FCLP) for three pilots each year in Hawaii. An FCLP is a series of touch-and-go landings conducted to train and field qualify pilots for aircraft carrier landings. Only carrier-based, fixed-wing aircraft pilots (both jet and propeller aircraft) are required to conduct FCLPs. FCLPs involve pilots from an aircraft carrier air wing using carrier planes to practice at a land runway. For each pilot, the FCLP would include 8 to 10 touch-and-go landings at the PMRF runway during both daytime and at night (see Table 2.2.2.3-1). FCLPs would occur in association with transiting Strike Groups participating in Major Exercises. The landings will take place on airport runways at PMRF airfield on Kauai and Marine Corps Base Hawaii (MCBH) on Oahu.

2.2.3.4 ENHANCED RDT&E ACTIVITIES FOR ALTERNATIVE 1

The Navy proposes to enhance its RDT&E activities from current levels as necessary as shown in Table 2.2.2.5-1. Enhanced RDT&E could include activities such as additional AAW RDT&E activities involving Aegis-capable ships, EC/EW activities, and SESEF tests to evaluate ship, shore, and aircraft systems.

2.2.3.5 FUTURE RDT&E ACTIVITIES FOR ALTERNATIVE 1

Additional Chemical Simulant

The purpose of using chemical simulants in ballistic missile target vehicles is to assess the effectiveness of defensive missiles against threat missiles carrying chemical agents as payloads. To adequately emulate this threat in testing, it is necessary to use materials that are similar to the physical characteristics of actual chemical agents, but without the toxic effects. Use of actual chemical agents in testing would present the potential for unacceptable hazards, thus the need for simulants.

Target launches from PMRF would incorporate additional chemical simulants to include larger quantities of tributyl phosphate (TBP) and various glycols. The list of potential glycols would include glyceryl tributyrate, propylene glycol, diethyl phthalate, polyethylene glycol, triethylene glycol, diethyl decanedioate, dibenzyl ether, dibutyl phthalate, di(2-ethylhexyl) phthalate, diethylene glycol, and polypropylene glycol 425. The top three preferred simulants would be TBP, glyceryl tributyrate, and propylene glycol. TBP is typically used as a solvent for lacquers and natural gums, as a primary plasticizer in the manufacture of plastics and vinyl resins and as an antifoam agent. Primary uses for glyceryl tributyrate are a synthetic flavoring substance and a plasticizer. Propylene glycol is a substance used in foods, cosmetic products, and pharmaceutical creams to help retain moisture.

Approximately 120 gallons (gal) of simulant would be used in target vehicles launched from PMRF. The simulant would be transported from the continental United States to PMRF with the target vehicle and would be loaded into the target vehicle payload as part of the payload processing activities.

Intercept Targets Launched Into the TOA

Individual launches from Wake Island, the Reagan Test Site at U.S. Army Kwajalein Atoll, or Vandenberg AFB would be intercepted in the TOA (Figure 2.2.3.5-1). PMRF Range Control would manage these interceptor activities. Launches from those sites would be from existing launch facilities, and no new boosters from these sites are proposed. Targets would also continue to be launched from sea-based and air-based platforms as analyzed in previous environmental documents.

Proposed Target Flight Corridors into the Temporary Operating Area

Open Ocean

Figure 2.2.3.5-1

Launch SM-6 from Sea-Based Platform

Under Alternative 1, PMRF would also develop the capability to launch the Extended Range Active Missile, tentatively designated SM-6, from a sea-based platform. This testing would be similar to ongoing launches of the current version of the Standard Missile from Aegis ships. The SM-6 would consist of the SM-2 Block IV booster system and an active Advanced Medium Range Air-to-Air Missile seeker to provide enhanced capabilities. Testing would occur in the TOA.

Micro-Satellites Launch

The Super Strypi system is proposed as a joint venture between PMRF, the Department of Energy at KTF, and the University of Hawaii to launch micro-satellites into space. The 50K launcher (i.e. a 50,000-pound [lb] maximum design load) at Launch Area 2 would be modified with a 25-foot (ft) extension.

The Super Strypi system consists of three stages. The proposed first stage boosters would be a Graphite Epoxy Motor (GEM)-46 and two Terrier MK-70 strap-on boosters. The GEM-46 consists of 37,180 lb of solid propellant and each Terrier booster consists of 1,500 lb of solid propellant. The proposed second stage would be an Orbus-7 booster with a propellant weight of 7,290 lb. A STAR-30 rocket motor would be used to insert the satellite into orbit. The STAR-30 contains 1,114 lb of solid propellant.

The Super Strypi would require a 1,500-ft radius circle ground hazard area around the launcher. The launch hazard area would be within the existing launch hazard areas for PMRF. Launch azimuths would be within the existing launch azimuths for Launch Area 2.

Test Unmanned Surface Vehicles

Future testing of Unmanned Surface Vehicles (USVs) is proposed to occur within the HRC, and would be similar to current, ongoing training. These remote-controlled boats could be equipped with modular packages to potentially support surveillance and reconnaissance activities, mine warfare, anti-terrorism/force protection, port protection, Special Forces training, and possibly ASW.

USVs generally represent small boats up to approximately 40 ft in length, with either rigid hulls and/or inflatable pontoons. Inboard or outboard diesel or gasoline engines up to several hundred horsepower would likely be used for propulsion. Test packages carried on the USVs may include radars; HFA sonar; multi-functional camera suites; autonomous equipment packages; and required communications, testing, and support equipment. HFA sonar associated with USVs does not represent a significant sound source and its minimal use would not affect marine mammals. Onboard electrical power for equipment operations and engine starting would come from a series of batteries (lead-acid, lithium, etc.), and possibly an electrical generator run off the main engine.

For testing just off the coast of PMRF, the USV would be launched from either Port Allen or the Kikiaola Small Boat Harbor. For safety purposes, the USV would be towed by a manned vessel out of the harbor and up the coast to PMRF before operating remotely under its own power. Testing would only occur in areas cleared of non-mission essential vessels. Using computers, personnel would remotely operate the USV from a transportable command post in a trailer or located within an existing building at PMRF. The types of tests may include low-speed surveillance activities using cameras, radar, and/or sonar; maneuvering through obstacles; and high-speed runs in excess of 40 knots. Individual test activities could occur day or night and last for up to 24 hours, depending on test requirements. Following each test, the USV would be towed back to harbor. Depending on test schedules, the USV might be temporarily docked, or taken out of the water on a trailer for storage at the harbor or at PMRF. No new storage or docking facilities would be required.

The testing of USVs could also occur in open waters within the TOA. In this case, the USV would be towed out to sea or launched directly from a surface ship. Remote control of the USV would occur from a command center on a vessel. Again, testing would only occur in areas cleared of non-mission essential vessels.

Test Unmanned Aerial Vehicles

A variety of Unmanned Aerial Vehicles (UAVs) may also be tested in the future at PMRF and would be similar to current, ongoing training. UAVs are remotely piloted or self-piloted aircraft that include fixed-wing, rotary-wing, and other vertical takeoff vehicles. They can carry cameras, sensors, communications equipment, weapons, or other payloads. At PMRF, UAV testing could support one or more of the following mission areas: intelligence, surveillance, and reconnaissance; suppression of enemy air defenses; electronic attack; anti-surface ship and ASW; mine warfare; communications relay; and derivations of these themes.

UAVs can vary in size up to approximately 45 ft in length, with gross vehicle weights ranging from several hundred pounds to approximately 45,000 lb. Forms of propulsion for UAVs can range from traditional turbofans, turboprops, and piston engine-driven propellers; to electric motor-driven propellers powered by rechargeable batteries (lead-acid, nickel-cadmium, lithium ion), photovoltaic cells, and/or hydrogen fuel cells.

Prior to testing at PMRF, each UAV would be ground-checked at existing facilities to ensure proper system operations. Depending on engine propulsion, the vehicle would be fueled most likely with gasoline or diesel fuel (approximately 50 to 700 lb); or jet fuel (approximately 50 to 17,000 lb of JP-5 or JP-8). Takeoff procedures would vary by UAV system, using a traditional runway takeoff, small solid rocket-assisted takeoff, or a portable catapult launcher. Personnel would use computers to remotely operate the UAV from a transportable command post in a trailer or located within an existing building at PMRF.

Depending on the UAV system being tested, individual flights could extend just a few nautical miles off the PMRF coast, or well over 100 nm into the TOA. Maximum altitudes for flights could range from a few thousand feet for the smallest UAVs to over 30,000 ft for the largest jet-powered vehicles. Maximum velocities attained would range from approximately 100 to 500 knots. Testing would only occur in areas cleared of non-mission essential aircraft and away from populated areas. The types of tests conducted could include demonstration of aircraft flight worthiness and endurance, surveillance activities using onboard cameras and other sensors, and over-the-horizon targeting. Individual test flights could last from a few hours to more than a day. At the completion of each flight test, vehicle landing would occur via traditional runway landing or using retrieval nets for smaller UAVs. The storage and ground-support for UAVs would occur within existing facilities at PMRF. No new facilities are planned.

In some cases, UAV flight tests, including takeoff and landing procedures, may be conducted from surface ships in the TOA. Remote control of the UAV would occur from a command center on a vessel. Again, testing would only occur in areas cleared of non-mission essential aircraft.

Test Hypersonic Vehicles

The Navy and the DoD are working toward development of air-breathing hypersonic vehicles that are capable of maximum sustainable cruising speeds in excess of Mach 4. As potential ordnance delivery systems, such vehicles could significantly decrease the launch to target engagement timeline.

Hypersonic vehicles, such as those being developed under the Hypersonic Flight Demonstration program, could be flight-tested at PMRF from within and beyond the TOA. The missile-like test vehicle would be fueled at PMRF using JP-10 (exo-tetrahydrocyclo-pentadiene) or a similar turbine liquid fuel. On-board fuel weights are currently undetermined, but are expected to not exceed 500 lb. Because the hypersonic vehicles use a scramjet technology, engine operation requires a high-speed boost on a rocket or from a jet aircraft.

Rocket launching a hypersonic test vehicle could occur from the Vandal launch site at PMRF and follow a similar flight trajectory as other missiles launched from PMRF. For example, a two-stage Terrier-Orion sounding rocket could be used to boost the hypersonic vehicle. Following launch and booster motor separation, the spent motor casings would impact in the open ocean. Upon reaching hypersonic velocities at altitudes in excess of 50,000 ft, the test vehicle would continue on a pre-designated flight trajectory under its own scramjet power, before making a controlled splashdown into the open ocean.

For flight insertion using a jet aircraft, such as an F-15, the test vehicle would be attached under the aircraft at PMRF. Following takeoff, and upon reaching an appropriate altitude and velocity over the TOA, the test vehicle would be released from the aircraft. With engine ignition, the hypersonic test vehicle would climb to an appropriate cruising altitude before making a controlled splashdown into the open ocean.

The hypersonic vehicle flight tests would demonstrate flight performance and flight worthiness. Testing would only occur in areas cleared of non-mission essential aircraft and vessels, and away from populated areas. In support of test activities at PMRF, no new facilities would be needed.

2.2.3.6 HAWAII RANGE COMPLEX ENHANCEMENTS FOR ALTERNATIVE 1

As part of the Tactical Training Theater Assessment and Planning (TAP) Program, specific enhancements and recommendations to optimize range capabilities to adequately support training for all missions and roles were identified for the HRC (U.S. Department of Defense, 2006).

2.2.3.6.1 EOD Range Enhancements

Naval Special Warfare and Explosive Ordnance Disposal (EOD) Targets

Hawaii-based Sea, Air, and Land (SEAL) and EOD forces have target requirements not currently met in Hawaii. The Navy proposes to develop targets and support target maintenance for exposed beach obstacles and fortified beach or offshore defenses, at least some of which must be cleared for live Naval Special Warfare (NSW) weapons and explosives. NSW targets are steel frames and shapes that can be lowered into the water to simulate hulls of ships, or amphibious obstacles. EOD targets would be inert mine and bomb shapes. Some targets would be removed following the training. Others, including NSW obstacles and EOD targets, would be destroyed in place and are not recoverable. All the targets would be used at the EOD Land Range (Figure 2.2.3.6.1-1) or the Puuloa Underwater Range (Figure 2.1-3).

2.2.3.6.2 Pearl Harbor Enhancements

MK-84/MK-72 Pinger Acoustic Test Facility

MK-84 and MK-72 acoustic pingers are critical to the underwater tracking of targets on ASW ranges throughout the HRC. Each of these two models of pingers is a small acoustic transmitter that emits HFA sonar at regular intervals at low power. The pinger is attached internally or externally to submarines, simulated submarine targets, and exercise torpedoes. Undersea tracking ranges, such as the BARSTUR and Barking Sands Underwater Range Expansion (BSURE) at PMRF rely on this signal to track these underwater objects during training on the range. MK-84 and MK-72 pingers are serviced and tested in an in-ground tank at NUWC Detachment Pacific’s Acoustic Test Facility at the Lualualei location. However, due to Base Realignment and Closure, NUWC is vacating the Lualualei location, and there are no plans to move or rebuild the testing tank at the Acoustic Test Facility.

The Navy proposes to install new equipment to support a new open-water Acoustic Test Facility capability near NUWC’s Ford Island facility in Pearl Harbor, shown in Figure 2.2.3.6.2-1. Testing would take place in the water to the west of Ford Island, between Middle Loch and East Loch. The pinger (noise source) could be located in one of several sites. Possible locations include pier S291 on Ford Island, Beckoning Point piers, or a mobile test site that could operate within the test area. Pinger training events typically run for an 8-hour period once a week. Development of the Acoustic Test Facility would require minor modification to the pier to provide electrical cabling and pinger attach points.

Mobile Diving and Salvage Unit Training Area

The Navy would establish an underwater training area in which Mobile Diving and Salvage Unit ONE can conduct military diving and salvage training, including submerging a 100-ft by 50-ft vessel. Figure 2.2.3.6.2-2 shows three proposed locations (Sites A, B, and C) with Site B being the preferred location. The vessel would be placed within a 328- by 328-ft area. The type of training to be conducted would consist of various underwater projects designed to develop mission critical skills, such as hot tapping, welding, cutting, patching, plugging, drilling, tapping, and grinding.

2.2.3.6.3 Offshore Enhancements

Portable Undersea Tracking Range

The Portable Undersea Tracking Range would be developed to support ASW training and provide submarine training in areas where the ocean depth is between 300 ft and 12,000 ft and at least 3 nm from land. This proposed project would temporarily instrument 25-square-mile or smaller areas on the seafloor within the area depicted on Figure 2.2.3.6.3-1. Flat areas with no known coral concentration would be selected when possible. In areas that have not been mapped for coral presence, the Navy would develop appropriate habitat data and any necessary mitigations in coordination with the National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS). When training is complete, the Portable Undersea Tracking Range equipment would be recovered and moved to another location. This tracking system is a modification of the previously used Portable Acoustic Range system. All of these areas have been used for submarine training since World War II. This project allows for better crew feedback and scoring of crew performance during the time allocated for training.

No on-shore construction would take place. Seven electronics packages, each approximately 3 ft long by 2 ft in diameter, would be temporarily installed on the seafloor by a range boat, in water depths greater than 600 ft. The anchors used to keep the electronics packages on the seafloor would be either concrete or sand bags, which would be approximately 1.5 ft-by-1.5 ft and would weigh approximately 300 pounds. Operation of this range requires that underwater participants transmit their locations via pingers. Each package consists of a hydrophone that receives pinger signals, and a transducer that sends an acoustic “uplink” of locating data to the range boat. The uplink signal is transmitted at 8.8 kilohertz (kHz), 17 kHz, or 40 kHz, at a source level of 190 decibels (dB). The Portable Undersea Tracking Range system also incorporates an underwater voice capability that transmits at 8-11 kHz and a source level of 190 dB. Each of these packages is powered by a D cell alkaline battery. After the end of the battery life, the electronic packages would be recovered and the anchors with 25 ft of 0.25-inch stainless steel wire (depending on the environmental and seabed data) would remain on the

seafloor. The Navy proposes to use this portable instrumentation system for only 2 days per month in an area beyond 3 nm from shore. Fishermen would not be denied use of this area. Prior to training in the area, the Coast Guard would be notified and a Notice to Mariners would be issued. If fishermen, boaters, or whales are observed in the area, training involving weapons training would be stopped or moved to another area. The Notice to Mariners would also advise fishermen of the underwater buoys and cables and the risk they could pose to fishing gear entanglement. If necessary, additional environmental documentation and coordination with USFWS and NMFS would be completed prior to use of the Portable Undersea Tracking Range.

2.2.3.6.4 PMRF Enhancements

Large Area Tracking Range Upgrade

The Large Area Tracking Range (LATR) provides high fidelity time, space, and position information capability at PMRF (see Figure 2.2.3.6.4-1). Ground antenna stations detect participating ships and aircraft, relaying this information to PMRF. Each ground station comprises a Global Positioning System-based beacon and associated hardware, and a whip antenna. The stations transmit an ultra-high-frequency signal at approximately 150 watts of

Hawaiian Islands

Figure 2.2.3.6.4-1

power. Currently, only a small portion of the HRC is within range of the existing system. This capability is proposed to be upgraded with ground relay stations to cover training throughout much of the HRC. This upgrade would include Pohakuloa Training Area and the Warning Areas south of Oahu to provide seamless tracking within all Warning Areas, the Island of Hawaii, and surrounding each of the main islands (out to 75 nm). Under Alternative 1, three ground relay stations are proposed in order to enhance LATR capabilities. Proposed relay stations would consist of antennas placed on existing facilities, and no new construction is proposed. By establishing new ground relay stations, LATR detection capabilities would be enhanced by providing expanded relay capabilities to PMRF for training purposes.

Kingfisher Underwater Training Area

PMRF would also locate a new simulated underwater minefield to exercise the Kingfisher mine detection system closer to Niihau (Figure 2.2.3.6.4-2). This underwater training area would be approximately 2 miles (mi) off the southeast coast of Niihau at a depth of between 300 and 1,200 ft in flat areas that are typically covered by sand and silt and free of high-relief features such as cliffs. This training area had previously been located off the southwest coast of Kauai.

The Kingfisher system would consist of fewer than 20 steel sphere-shaped buoys that are approximately 37 inches in diameter. The buoys would be anchored to the ocean floor by a clump of welded chains weighing approximately 2,000 lb. A wire rope would be woven through the chain to attach to each buoy, suspending it between 60 and 120 ft from the ocean surface. The clump of chain would occupy an area of approximately 3 ft by 3 ft wide and 1.5 ft high. The chain may eventually bury itself, depending on the current and the softness of the ocean floor. Each buoy would be deployed from a ship in a grid determined by the Navy. There would be no electronics and no emitters on the buoys. If necessary, additional environmental documentation and coordination with USFWS and NMFS would be completed prior to establishment of the new Kingfisher underwater training area.

FORCEnet Antenna

An existing site would be chosen at Makaha Ridge (Figure 2.2.3.6.4-3) or Kokee (Figure 2.2.3.6.4-4) to be the location of a FORCEnet integration laboratory. FORCEnet is an effort to integrate military personnel, sensors, networks, command and control, platforms, and weapons into a fully netted, combat force. The site chosen would be an existing building or portable trailer. This new laboratory would bring a Cooperative Engagement Capability to PMRF and would consist primarily of software and minimal hardware upgrades. The purpose of the laboratory would be to demonstrate, experiment with, and evaluate emerging hardware and software technologies that support the FORCEnet architecture and standards as part of the Navy's SEA POWER 21, enhancing the United States' ability to project offensive power, defensive assurance, and operational independence around the globe. No ground disturbance or vegetation clearing would be required.

Enhanced Electronic Warfare Training

The PMRF capability for EW training would be enhanced to include sites on other islands (e.g., Maui and Hawaii). Pohakuloa Training Area will receive two Joint Threat Emitters and PMRF will upgrade from its present Mobile Remote Emitter Simulator system. EW training is accomplished when EW emitters transmit signals that replicate hostile radars and weapon systems. Ship and aircraft crews attempt to identify the electronic signals, and react defensively

if appropriate. Transmitters could be antennas or mobile vehicles. Where possible, existing towers would be chosen to incorporate new equipment with minimal modifications needed. The new equipment would primarily include software and minimal hardware upgrades. If new towers were to be built and operated, locations would be selected by personnel familiar with local environmental constraints, including the presence of threatened or endangered species and follow-on environmental analyses beyond this EIS/OEIS would be required before such activities could occur.

Expanded Training Capability for Transient Strike Groups

As part of the Joint National Training Capability, PMRF would provide dedicated equipment to enable deployed mid-Pacific forces, transiting Strike Groups, and vessels in-port at various locations to train in a virtual environment. The dedicated equipment would consist of a new communications node in an existing building at PMRF to enhance the capabilities of existing command and control facilities.

Enhanced Automatic Identification System and Force Protection Capability

The Automatic Identification System (AIS), (recommended by the Navy in 2001 for Homeland Security) is similar to Identification Friend or Foe that aircraft use, except that AIS is designed for use on commercial vessels for Force Protection purposes. These systems automatically report identification, origin, destination, current location, course and speed, intermediate stops, and cargo. AIS equipment would be installed on each island so each ship would have sensor connectivity and communication connections. Antennas would be added to existing structures, building 720 on Makaha Ridge and to building 282 on PMRF/Main Base as part of Alternative 1. No ground disturbance or vegetation clearing would be required.

Construct Range Operations Control Building

PMRF would build a new range operations building to consolidate the activities currently in 13 buildings. The facility would be almost 90,000 square feet (ft^2), and its proposed location on PMRF Main Base, shown in Figure 2.2.3.6.4-5, is within the previously disturbed administrative area. The proposed building height is 36 to 42 ft above finish grade. Roof-mounted antennas would be installed to replace those currently installed on buildings to be demolished. Full cutoff exterior lighting would be installed to protect the Newell's shearwater and Laysan albatross. The existing beacon (bore site) tower that is approximately 85 ft tall would be raised to approximately 105 ft above the surrounding existing grade in accordance with all applicable rules and regulations.

The project also would include the following:

- Construction of a 4,200 ft^2 dehumidified warehouse to replace building 106, which would be displaced by the proposed Range Operations building
- Construction of a new bore site tower for the Q-1 radar
- Conversion of building 105 annex into an electrical and electronic system laboratory
- Demolition of 13 buildings (some are trailers) with a combined floor area of over 55,000 ft^2, as shown in Figure 2.2.3.6.4-5
- Construction of antenna supports
- Installation of utilities and parking lots

Improve Fiber Optics Infrastructure

To improve communications and data transmission, PMRF would install fiber optic cable between the Main Base and the sites at Kokee, shown in Figure 2.1-2. This project would involve the installation of approximately 23 mi of fiber optic cable, which would be hung on existing Kauai Island Utility Cooperative poles between PMRF/Main Base and Kokee. The existing poles run from Kekaha Mill, up a ridge, and intersect Kokee Road at an existing substation. If exceptionally long spans are encountered, additional poles might need to be installed in some areas. It is expected that all equipment and installation activities would occur along existing public and Kauai Island Utility Cooperative access roads. Prior to implementation, PMRF would coordinate with Kauai Island Utility Cooperative and the local Department of Transportation for approvals.

2.2.3.7 MAJOR EXERCISES FOR ALTERNATIVE 1

The Navy proposes to continue Major Exercises such as RIMPAC and USWEX described in the No-action Alternative. Under Alternative 1, RIMPAC would include two Strike Groups (which could include up to two carriers), and FCLPs would occur in association with transiting Strike Groups participating in Major Exercises. The training events associated with Major Exercises would be chosen from the appropriate matrix of training events in Appendix D.

For RIMPAC under Alternative 1, the marine mammal exposure modeling included 1,064 hours of AN/SQS-53 and AN/SQS-56 surface ship sonar and associated dipping sonar, sonobuoys, and MK-48 torpedoes. For USWEX under Alternative 1, the marine mammal exposure modeling included six USWEXs for a total of 840 hours of AN/SQS-53 and AN/SQS-56 surface ship sonar and associated dipping sonar, sonobuoys, and MK-48 torpedoes (Table 2.2.3.2-1).

2.2.3.8 MITIGATION MEASURES FOR ALTERNATIVE 1

Under Alternative 1, the Navy's marine mammal mitigation measures would continue to be implemented. Chapter 6.0 presents these mitigation measures, outlining steps that are currently implemented to protect marine mammals and federally-listed species.

2.2.4 ALTERNATIVE 2

2.2.4.1 TRAINING EVENTS FOR ALTERNATIVE 2

Alternative 2 would include all of the training described in Alternative 1 plus a further increased tempo and frequency of training events, future RDT&E programs at PMRF and the addition of Major Exercises, such as supporting three carrier Strike Groups training at the same time. Table 2.2.2.3-1 shows the number of Navy training events proposed for Alternative 2, compared to No-action Alternative and the number of events proposed under Alternative 1.

For RIMPAC under Alternative 2, the marine mammal exposure modeling included 1,064 hours of AN/SQS-53 and AN/SQS-56 surface ship sonar and associated dipping sonar, sonobuoys, and MK-48 torpedoes. For USWEX under Alternative 2, the marine mammal exposure modeling included six USWEXs for a total of 840 hours of AN/SQS-53 and AN/SQS-56 surface ship sonar and associated dipping sonar, and sonobuoys (refer to Section 2.2.4.2).

2.2.4.2 MFA/HFA SONAR USAGE FOR ALTERNATIVE 2

Table 2.2.4.2-1 lists MFA/HFA sonar usage analyzed for Alternative 2. Sonar usage is based on SPORTS data and operator input.

Table 2.2.4.2-1. Sonar Usage for Alternative 2

	MK-48	374 runs
	Submarine	200 hours

2.2.4.3 INCREASED TEMPO AND FREQUENCY OF TRAINING FOR ALTERNATIVE 2

Under Alternative 2, the Navy proposes to increase the tempo and frequency of training events (above Alternative 1 levels) and compress the tempo of training events in the HRC. In this setting, tempo means intensity and could include more forces or shorter/longer duration of activities. For example, instead of a training event lasting 5 days, the same training events would be completed in 3 days. The frequency of training would also be increased. An increase in frequency means the number of training events in a given time period would increase.

2.2.4.4 ENHANCED RDT&E ACTIVITIES FOR ALTERNATIVE 2

The Navy proposes to enhance RDT&E activities from Alternative 1 levels as shown in Table 2.2.2.5-1. Enhanced RDT&E could include activities such as additional missile defense RDT&E (including an increase in THAAD interceptor activities), CSSQT at-sea tests, and FORACS accuracy checks.

2.2.4.5 FUTURE RDT&E ACTIVITIES FOR ALTERNATIVE 2

PMRF would develop the capability to support the Directed Energy and Advanced Hypersonic Weapon programs.

Directed Energy

The Navy proposes to establish a long-term support facility, the Maritime Directed Energy Test Center, at PMRF for directed energy programs, such as the High-Energy Laser.

The high-energy laser would require a permanent operations building with approximately 25,000 ft^2. Figure 2.2.4.5-1 shows the proposed location. The actual footprint of the proposed center would be smaller than the circles shown on Figure 2.2.4.5-1 and would avoid designated critical habitat. During testing, the range would need to be cleared. Up to four air targets and up to four surface targets would be used for testing. The laser would require 30 megawatts of power. Up to 100 personnel would support this program. Construction of the Maritime Directed Energy Test Center would require separate/additional environmental documentation.

PMRF would develop the necessary standard operating procedures and range safety requirements necessary to provide safe operations associated with future high-energy laser tests.

PMRF would add the capability to test non-eye-safe lasers. The range could also be used to support Airborne Laser program testing. The Airborne Laser aircraft would stage out of Hickam AFB on Oahu. The chemicals for operating the laser onboard the aircraft would be transported to Oahu by ship and would be stored at Hickam AFB. Should the Airborne Laser program decide to perform testing at PMRF, separate environmental documentation would be required to analyze potential impacts.

Proposed Directed Energy Facilities at Pacific Missile Range Facility

Kauai, Hawaii

Figure 2.2.4.5-1

The following PMRF assets would be used to support any future laser testing:

- Numerous tracking sensors at Makaha Ridge
- Fleet assets (air, surface, subsurface, strategic) for open range testing
- Hawaiian Surveillance Network programs on Kauai, Maui, Hawaii, and Niihau
- Supercomputer center at Kihei, Maui, to support operational analyses

Advanced Hypersonic Weapon

The Advanced Hypersonic Weapon is a U.S. Army Space and Missile Defense Command RDT&E program that would eventually involve launches of long range (greater than 3,400 mi) missiles deploying an unpowered payload. This is proposed to be a four-missile launch program, with the first two tests using a Strategic Target System booster launched from KTF at PMRF (Figure 2.2.2.5.1-2). The payload would travel a distance of approximately 2,500 mi from PMRF to Illeginni Island in U.S. Army Kwajalein Atoll. The first test is scheduled in the spring of 2010, and the second test would occur between 6 and 12 months later, again using a Strategic Target System following the same flight path. The third test would be approximately 1 year later and would use a two-stage system containing approximately 42,000 lb of solid propellant launched from the same pad. The fourth test from the same launch site would again use the same two-stage system. Launches would average one per year. There are no fuels or oxidizers on the payloads themselves, and they would all impact on land. The modified 10,000-ft ground hazard area would be used for both systems.

2.2.4.6 HAWAII RANGE COMPLEX ENHANCEMENTS FOR ALTERNATIVE 2

Under Alternative 2, all HRC enhancements would be the same as those described under Alternative 1, Section 2.2.3.6.

2.2.4.7 ADDITIONAL MAJOR EXERCISES—MULTIPLE STRIKE GROUP TRAINING FOR ALTERNATIVE 2

Up to three Strike Groups would conduct training exercises simultaneously in the HRC (Figure 1.2-3). The Strike Groups would not be homeported in Hawaii, but would stop in Hawaii en route to a final destination. The Strike Groups would be in Hawaii for up to 10 days per exercise.

The exercise would involve Navy assets engaging in a “free play” battle scenario, with U.S. forces pitted against a replicated opposition force. The exercise provides realistic training on in-theater training. Proposed training would be similar to current training for the RIMPAC and USWEX Exercises. Also included in the training events would be FCLP conducted at the following airfields: Marine Corps Base Hawaii and PMRF. With the increased Strike Group training required of this alternative, the potential for requiring FCLPs increases. Therefore, this alternative includes FCLPs for an additional Strike Group each year, increasing the total number of FCLPs to 16 per year.

The proposed exercise would provide Navy personnel realistic maritime training in a complex scenario that replicates the types of challenges that could be faced during real-world operations. Training would be provided to submarine, ship, and aircraft crews in tactics, techniques, and procedures for ASW, Defensive Counter Air, Maritime Interdiction, and operational level C2 of maritime forces. The three Strike Group marine mammal exposure modeling included 944 hours of AN/SQS-53 and AN/SQS-56 surface ship sonar and associated dipping sonar, sonobuoys, and MK-48 torpedoes (refer to Section 2.2.4.2).

2.2.4.8 MITIGATION MEASURES FOR ALTERNATIVE 2

Under Alternative 2, the Navy's marine mammal mitigation measures would continue to be implemented. Chapter 6.0 presents these mitigation measures, outlining steps that are currently implemented to protect marine mammals and federally-listed species.

2.2.5 ALTERNATIVE 3 (PREFERRED)

The only difference between Alternative 2 and Alternative 3 is the amount of MFA/HFA sonar usage. Alternative 3 would include all of the training and RDT&E activities associated with Alternative 2 (as described in Sections 2.2.4.1 and 2.2.4.3 through 2.2.4.7). As described under Alternative 2, Alternative 3 would provide increased flexibility in training activities by increasing the tempo and frequency of training events (Table 2.2.2.3-1), future and enhanced RDT& E activities (Table 2.2.2.5-1), and the addition of Major Exercises. Alternative 3 would consist of the MFA/HFA sonar usage as analyzed under the No-action Alternative. Sonar hours for Alternative 3 and effects associated with ASW training would be identical to that presented under the No-action Alternative. Table 2.2.5-1 lists MFA/HFA sonar usage analyzed for the No-action Alternative and Alternative 3. Sonar usage is based on SPORTS data and operator input.

	56	383 hours
	Dipping	1,010 dips
	Sonobuoy	2,423 buoys
	MK-48	313 runs
	Submarine	200 hours

Alternative 3 is the preferred alternative because it allows the Navy to meet its future non-ASW training and RDT&E mission objectives while maintaining historic levels of ASW training to avoid increases in potential effects on marine species in the HRC. At this time, the Navy believes that its ASW requirements will be met on the No-action Alternative sonar hours.

2.2.5.1 MITIGATION MEASURES FOR ALTERNATIVE 3

Under Alternative 3, the Navy's marine mammal mitigation measures would continue to be implemented. Chapter 6.0 presents these mitigation measures, outlining steps that are currently implemented to protect marine mammals and federally-listed species.

3.0 Affected Environment

3.0 AFFECTED ENVIRONMENT

This chapter describes the environmental characteristics that may be affected by the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3. Points of reference for understanding any potential impacts are based on the activities that have been historically conducted in the Hawaii Range Complex (HRC). Available reference materials including prior Environmental Assessments (EAs) and Environmental Impact Statements (EISs) were reviewed. Questions were directed to installation and facility personnel, and private individuals. Site visits were also conducted where necessary to gather the baseline data presented herein.

Environmental characteristics are discussed according to location; the Open Ocean Area (outside 12 nautical miles [nm] from land) is discussed first, followed by offshore (within 12 nm from land) and onshore discussion organized by island location from west to east: Northwestern Hawaiian Islands, Kauai, Oahu, Maui, and Hawaii. For organizational purposes, discussions about Niihau and Kaula are included under the Kauai heading, because although they are separate islands, they are part of Kauai County. In addition, discussions about Molokai, Lanai, and Kahoolawe are included under the Maui heading, because although they are separate islands, they are part of Maui County. The last section discusses the Hawaiian Islands Humpback Whale National Marine Sanctuary. The page headers in this chapter identify which location is discussed.

Thirteen environmental resource areas were evaluated to provide a context for understanding the potential effects of ongoing and proposed activities. These areas include air quality, airspace, biological resources, cultural resources, geology and soils, hazardous materials and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources. Each resource area is discussed for each proposed location unless the proposed activities at that location would not foreseeably result in an impact, as explained for each location in Chapter 4.0. Table 3-1 lists each location and the section number within this chapter where each of the resources is addressed.

3.1 OPEN OCEAN AREA

The Open Ocean Area is the area within the HRC that is greater than 12 nm offshore of the Hawaiian Islands. The Open Ocean Area also includes the Pacific Missile Range Facility (PMRF) Warning Areas, Oahu Warning Areas (Figure 2.1-1), and the Temporary Operating Area (Figure 1.2-3). The Open Ocean Area, as part of the high seas (outside 12 nm from land), is subject to Executive Order (EO) 12114. Both sea and air operations are covered in this section. Of the 13 environmental resources considered for analysis, air quality, geology and soils, land use, socioeconomics, transportation, and utilities are not addressed.

*A review of the 13 environmental resources against program activities determined there would be no impacts from site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3.

3.1.1 AIRSPACE—OPEN OCEAN AREA

Airspace, or that space which lies above a nation and comes under its jurisdiction, is generally viewed as being unlimited. However, it is a finite resource that can be defined vertically and horizontally, as well as temporally, when describing its use for aviation purposes. The time dimension is a very important factor in airspace management and air traffic control.

Under Public Law (PL) 85-725, *Federal Aviation Act of 1958*, the Federal Aviation Administration (FAA) is charged with the safe and efficient use of our nation's airspace, and has established certain criteria for and limits to its use. The method used to provide this service is the National Airspace System. This system is "…a common network of U.S. airspace; air navigation facilities, equipment and services, airports or landing areas; aeronautical charts, information and services; rules, regulations and procedures, technical information and manpower and material." Appendix C includes a detailed definition of airspace.

Region of Influence

For this EIS/Overseas EIS (OEIS), the region of influence for the Open Ocean Area airspace is defined as those areas beyond the territorial limit which is otherwise known as international airspace.

Affected Environment

The affected airspace environment in the Open Ocean Area region of influence is described below in terms of its principal attributes: controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, airports and airfields, and air traffic control. There are no military training routes in the region of influence.

Controlled and Uncontrolled Airspace

Most of the airspace within the region of influence is in international airspace, and air traffic is managed by the Hawaii Combined Facility. The Honolulu Combined Facility includes the Air Route Traffic Control Center (ARTCC), the Honolulu Control Tower, and the Combined Radar Approach Control collocated in a single facility. Airspace outside that managed by the Hawaii Combined Facility is managed by the Oakland ARTCC.

Special Use Airspace

The special use airspace in the region of influence (Figure 3.1.1-1) consists of Warning Area W-188 north of Kauai, and Warning Area W-186 southwest of Kauai, controlled by PMRF. Warning Areas W-188 Rainbow, W-189 and W-190 north of Oahu, W-187 surrounding Kaula, and W-191, W-192, W-193, W-194, and W-196 south of Oahu are scheduled through the Navy Fleet Area Control and Surveillance Facility (FACSFAC) Pearl Harbor which then coordinates with the Honolulu Combined Facility. There are also 12 Air Traffic Control Assigned Airspace (ATCAA) areas within the region of influence. These ATCAA areas provide additional controlled airspace adjacent to and between the Warning Areas.

Table 3.1.1-1 lists the affected Warning Areas and ATCAA areas and their effective altitudes, times used, and their manager or scheduler. There are no prohibited or alert special use airspace areas in the Open Ocean Area airspace use region of influence.

HCF = Honolulu Combined Facility (Air Route Traffic Control Center, Combined Radar Approach Control, and Honolulu Control Tower)
PMRF = Pacific Missile Range Facility

En Route Airways and Jet Routes

The Open Ocean Area airspace use region of influence has several en route high-altitude jet routes, as shown on Figure 3.1.1-1. Most of the oceanic routes enter the region of influence from the northeast and southwest and are generally outside the special use airspace warning areas described above. The Air Traffic Services routes are concentrated along the Hawaiian Islands chain. Most of the Open Ocean Area region of influence is well-removed from the jet routes that crisscross the North Pacific Ocean.

As an alternative to aircraft flying above 29,000 feet (ft) following published, preferred Instrument Flight Rules (IFR) routes (shown in Figure 3.1.1-1), the FAA is gradually permitting aircraft to select their own routes. This “Free Flight” program is an innovative concept designed to enhance the safety and efficiency of the National Airspace System. The concept moves the National Airspace System from a centralized command-and-control system between pilots and air traffic controllers to a distributed system that allows pilots, whenever practical, to choose their own route and file a flight plan that follows the most efficient and economical route.

The Central Pacific Oceanic Program is one of the Free Flight programs underway. In the airspace over the Central Pacific Ocean, advanced satellite voice and data communications are being used to provide faster and more reliable transmission to enable reductions in vertical, lateral, and longitudinal separation, more direct flights and tracks, and faster altitude clearances. With the full implementation of this program, the amount of airspace in the region of influence that is likely to be clear of traffic may decrease as pilots, whenever practical, choose their own route and file a flight plan that follows the most efficient and economical route.

Airports and Airfields

There are no airports or airfields in the Open Ocean Area airspace use region of influence. However, a small portion of the Honolulu Class B airspace extends beyond the territorial limit into the region of influence.

Air Traffic Control

Air traffic in the region of influence is managed by the Oakland and Honolulu ARTCCs (see Figure 3.1.1-2).

3.1.2 BIOLOGICAL RESOURCES—OPEN OCEAN AREA

Native or naturalized vegetation, wildlife, and the habitats in which they occur are collectively referred to as biological resources. Existing information on plant and animal species and habitat types in the vicinity of the proposed sites was reviewed, with special emphasis on the presence of any species listed as threatened or endangered by Federal or State agencies, to assess their sensitivity to the effects of the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. Appendix C includes a definition of biological resources and the main regulations and laws that govern their protection.

Region of Influence

The region of influence for open ocean species includes the areas of the Pacific Ocean within the HRC beyond 12 nm from the shore.

Affected Environment

The affected biological resources environment in the Open Ocean Area region of influence is described below.

3.1.2.1 CORAL

The Hawaiian Islands have 6,764.5 square miles (mi^2) of coral reef area, representing 84 percent of the coral reef area in the United States (Maragos, 1977). Due to the motion of the Pacific Plate, the Hawaiian Islands have been transported in a north to northwest direction away from their original location of formation over the hot spot at a rate of about 4 inches per year (Grigg, 1988; 1997b). The youngest island in the archipelago is Hawaii, where the youngest fringing reefs and barrier reefs are found. Fringing reefs on the western coast of Hawaii are from 100 to 1,000 years old.

Precious coral are corals of the genus Corallium and the pink, gold, bamboo and black corals. Precious coral resources in Hawaii and the Western Pacific are managed by the State of Hawaii and the U.S. Federal government per regulation. The State has jurisdiction over coral resources out to 3 nm but also claims authority over inter-island waters the Makapuu Coral Bed, 6 mi off Makapuu in the channel between Oahu and Molokai. Federal jurisdiction extends from 3 nm beyond the coast of Hawaii to 200 nm and from the shoreline of all U.S. possessions in the Western Pacific to 200 nm. This area is defined as the U.S. Exclusive Economic Zone (EEZ). (Grigg, 1993; United Nations Convention On The Law Of The Sea, 1982)

To the degree authorized by law, black corals in Hawaiian waters are managed by the State of Hawaii. Fishermen are required to have commercial fishing licenses and report their catch monthly to the Hawaii Division of Aquatic Resources. A state regulation sets a minimum size of 48 inches in colony height or a minimum stem diameter of 1 inch for the harvest of live black coral (U.S. Fish and Wildlife Service, 2007b). Currently, black coral divers in Hawaii comply voluntarily with this draft regulation (Grigg, 1993).

Precious coral resources within the U.S. EEZ are managed by the Western Pacific Regional Fishery Management Council, under a Fishery Management Plan (FMP) for precious coral. The FMP allows for domestic and foreign fishing by regular or experimental permits and requires logbooks. Specific weight quotas and size limits have been determined based on estimates of maximum sustainable yields and optimum yields (Grigg, 1993).

The FMP and regulations outline and classify the known beds of precious corals within the Western Pacific Region, and designate harvesting method and the amount of corals that can be harvested. There are four bed classifications:

- Established Beds—history of harvest and optimum yields have been established on the basis of biological stock assessment techniques and selective harvesting gear is required. Makapuu is the only designated Established Bed.
- Conditional Beds—yields have been estimated on the basis of bed size relative to established beds assuming that ecological conditions at established beds are representative of conditions at all other beds. Keahole Point, Kaena Point, Brooks Banks, and 180 Fathom Bank are Conditional Beds. Nonselective harvesting is permitted only in the two conditional beds in the Northwestern Hawaiian Islands (Brooks and the 180 Fathom Banks).
- Refugia Beds—one set aside to serve as a baseline study area and possibly reproductive reserve. No harvesting of any kind is permitted in Refugia. The Western Pacific bed, between Nihoa and Necker Islands, is the only designated Refugia Bed.
- Exploratory Permit Areas—unexplored portions of the EEZ in which coral beds are almost certain to exist, but no beds have yet been located. There are four exploratory permit areas, including one surrounding the Hawaiian Islands. Either selective or nonselective harvest gear is permitted in exploratory permit areas except in the Hawaii exploratory area around the Main Hawaiian Islands (Grigg, 1993).

Deep-sea coral communities are prevalent throughout the Hawaiian archipelago (Figure 3.1.2.1-1). They often form offshore reefs that surround all of the Main Hawaiian Islands at depths between 27 and 109 fathoms (Maragos, 1998). Although light penetrates to these depths, it is normally insufficient for photosynthesis. The term “deep-sea corals” may be misleading because substrate (surface for growth), currents, temperature, salinity, and nutrient supply are more important factors in determining the distribution of growth rather than depth (Chave and Malahoff, 1998).

Deep-sea coral communities provide habitat, feeding grounds, recruitment, and nursery grounds for a range of deep-water organisms including epibenthic invertebrates (e.g., echinoderms, sponges, polychaetes, crustaceans, and mollusks), fishes, solitary precious corals (e.g., black corals), and marine mammals (e.g., monk seals) (Maragos, 1998; Midson, 1999; Coral Reef Information System, 2003; Roberts and Hirshfield, 2003; Freiwald et al., 2004). Deep-sea corals live in complete darkness, in temperatures as low as 39 degrees Fahrenheit (°F), and in waters as deep as 19,685 ft (Coral Reef Information System, 2003).

Distribution of Deep-Sea Corals and Hydrothermal Vents

Hawaiian Islands

Figure 3.1.2.1-1

Deep-sea corals can form large communities ranging in size from patches of small solitary colonies to massive reef structures (mounds, banks, and forests) spanning an estimated total spatial coverage of about of 772 square miles (mi^2) (Cairns, 1994; Freiwald et al., 2004). Much like shallow-water corals, deep-sea corals are fragile, slow growing, and can survive for hundreds of years (Roberts and Hirshfield, 2003). Deep-sea corals can be of two basic types: (1) the hard or stony corals which are related to those found on tropical coral reefs; and (2) the soft corals which include the familiar gorgonians of tropical shallow seas, as well as a broad diversity of other fleshy or tree-like forms. Some of the stony corals are small, but they can grow to be very massive. The soft corals may be small and delicate or very large and tree-like (Watling, 2003). In the Hawaiian Islands, gorgonians are the most common group of deep-sea corals. Of the gorgonians, primnoids are the most abundant group in the Hawaiian archipelago and are dominant off Molokai (Chave and Malahoff, 1998). Potential threats to deep-sea corals include fishing (e.g., bottom trawling), oil- and gas-related activities, cable laying, seabed aggregate extraction, shipping activities, the disposal of waste in deep waters, coral exploitation, other mineral exploration, and increased atmospheric carbon dioxide (Gass, 2003; Freiwald et al., 2004).

3.1.2.2 FISH

Distribution and abundance of fisheries, as well as the individual species, depend greatly on the physical and biological factors associated with an ecosystem. Physical parameters include habitat quality variables such as salinity, temperature, dissolved oxygen, and large-scale environmental disturbances (e.g., El Niño Southern Oscillation [ENSO]). Biological factors affecting distribution are complex and include variables such as population dynamics, predator/prey oscillations, seasonal movements, reproductive/life cycles, and recruitment success (Helfman et al., 1997). A single factor is rarely responsible for the distribution of fishery species; more often, a combination of factors is accountable. For example, pelagic or open ocean species optimize their growth, reproduction, and survival by tracking gradients of temperature, oxygen, or salinity (Helfman et al., 1997). Additionally, the spatial distribution of food resources is variable and changes with prevailing physical habitat parameters. Another major component in understanding species distribution is the location of highly productive regions such as frontal zones.

The prevailing oceanographic current in the Hawaiian archipelago is the westward flowing North Equatorial Current. Due to the origin of the North Equatorial Current (cool waters and distance from Hawaii), it is not likely to have had a major impact on fish species occurring in the Hawaiian Islands archipelago. Based on the present current system, most fish larvae would probably arrive at the Northwestern Hawaiian Islands via an eddy of the warm Kuroshio Current that bathes southern Japan and heads northeast where it becomes the North Pacific Current (Randall, 1998).

Environmental variations, such as ENSO events, change the normal characteristics of water temperature, thereby changing the patterns of water flow. In the northern hemisphere, El Niño events typically result in tropical, warm-water species moving north (extending species range), and cold-water species moving north or into deeper water (restricting their range). Surface-oriented, schooling fish often disperse and move into deeper waters. ENSO events alter normal current patterns, alter productivity, and have dramatic effects on distribution, habitat range, and movement of pelagic species (National Marine Fisheries Service, 2002b). Fishes that remain in an affected region experience reduced growth, reproduction, and survival (National Marine

Fisheries Service, 2002b). El Niño events have caused fisheries such as that of the skipjack tuna (*Katsuwonus pelamis*) to shift over 621 miles (mi) (National Marine Fisheries Service-Pacific Islands Region, 2001).

The Hawaiian archipelago distinguishes itself as a subprovince of the spacious tropical and subtropical Indo-Pacific region, which extends from the Red Sea and coast of East Africa to the easternmost islands of Oceania (Hawaii and Easter Island). The composition of the Hawaiian marine life varies enough from the rest of the Indo-Pacific to be treated as a distinct faunal subregion. Hawaii's unique fish fauna can be explained by its geographical and hydrographical isolation (Randall, 1998). Pelagic fishes such as the larger tunas, the billfishes, and some sharks are able to traverse the great distance that separates the Hawaiian Islands from other islands or continents in the Pacific Ocean; however, shore fishes are dependent on passive transport as larvae in ocean currents for distribution. As would be expected, the fish families that have a high percentage of species in the Hawaiian Islands compared to elsewhere tend to be those with a long larval life stage, such as the moray eels and surgeonfishes (*Acanthurus* spp.). Families that contain mainly species with short larval life stages, such as the gobies, blennies, and cardinal fishes, are not as well represented in Hawaii as in the rest of the Indo-Pacific region (Randall, 1995).

3.1.2.2.1 Essential Fish Habitat

Pursuant to the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA), the National Marine Fisheries Service (NMFS), eight regional fishery management councils (Councils), and other Federal agencies are mandated to identify and protect important marine and anadromous fish habitat. The Councils (with assistance from NMFS) are required to delineate Essential Fish Habitat (EFH) for all managed species. Federal agencies which fund, permit, or carry out activities that may adversely impact EFH are required to consult with NMFS regarding potential impacts on EFH.

The MSFCMA defines EFH means those waters and substrate necessary to fish for spawning, breeding, feeding or growth to maturity (16 U.S.C.§ 1802). These waters include aquatic areas and their associated physical, chemical, and biological properties used by fish, and may include areas historically used by fish. Substrate types include sediment, hard bottom, structures underlying the waters, and associated biological communities.

EFH can consist of both the water column and the underlying surface (e.g., seafloor) of a particular area. Areas designated as EFH contain habitat essential to the long-term survival and health of our nation's fisheries. Certain properties of the water column such as temperature, nutrients, or salinity are essential to various species. Some species may require certain bottom types such as sandy or rocky bottoms, vegetation such as sea grasses or kelp, or structurally complex coral or oyster reefs. EFH also includes those habitats that support the different life stages of each managed species, as a single species may use many different habitats throughout its life to support breeding, spawning, nursery, feeding, and protection functions.

The Western Pacific Regional Fishery Management Council (WPRFMC) manages major fisheries within the EEZ around Hawaii and the territories and possessions of the United States in the Pacific Ocean (Western Pacific Regional Fishery Management Council, 1998, 2001). The WPRFMC, in conjunction with the State of Hawaii, Division of Aquatic Resources (HDAR), manages the fishery resources in the study area. The WPRFMC focuses on the major fisheries in the study area that require regional management. EFH species, as designated by the WPRFMC (2004), have been divided into management units according to their ecological relationships and preferred habitats. Management units include bottom fish management unit species (BMUS), pelagic management unit species (PMUS), crustacean management unit species (CMUS), precious corals management unit species (PCMUS), and coral reef ecosystem management unit species. Currently, 22 species are managed as BMUS, 32 species and one genus are managed as PMUS, five species and one genus are managed as CMUS, and 13 species are managed under the PCMUS.

Specific information on EFH within the HRC can be found in a separate document, *Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

Additionally, a potential squid group consisting of three flying squids (neon flying squid [*Ommastrephes bartramii*], diamondback squid [*Thysanoteuthis rhombus*], and purpleback flying squid [*Sthenoteuthis oualaniensis*]) has been proposed by the WPRFMC for incorporation into the existing PMUS (National Marine Fisheries Service, 2004c). Currently, no data are available to determine if the pelagic species are approaching an overfished situation (National Marine Fisheries Service, 2004b), except for the bigeye tuna (*Thunnus obesus)*. The National Marine Fisheries Service (2004d) determined that overfishing was occurring Pacific-wide for this species. In addition, shark species are afforded protection under the *Shark Finning Prohibition Act* (National Marine Fisheries Service, 2002c).

The broadbill swordfish (*Xiphias gladius)*, albacore tuna (*Thunnus alalunga)*, common thresher shark (*Alopias vulpinus*), and salmon shark (*Lamna ditropis*) have been listed as data deficient on the International Union for Conservation of Nature and Natural Resources (IUCN) Red List due to inadequate information to make a direct, or indirect assessment of its risk of extinction based on its distribution and/or population status (Safina, 1996; Uozumi, 1996a; Goldman and Human, 2000; Goldman et al., 2001). The shortfin mako shark (*Isurus oxyrinchus*), oceanic whitetip shark (*Carcharhinus longimanus*), crocodile shark (*Pseudocarcharius kamoharai*), blacktip shark (*C. limbatus*), and blue shark (*Prionace glauca*) have been listed as near threatened (Compagno and Musick, 2000; Shark Specialist Group, 2000; Smale, 2000; Stevens, 2000a; 2000b). The bigeye tuna and the great white shark (*Carcharadon carcharias*) are listed as vulnerable on the IUCN Red List (Uozumi, 1996b; Fergusson et al., 2000).

3.1.2.2.2 Offshore Ocean or Pelagic Species

Pelagic species occur in tropical and temperate waters of the western Pacific Ocean (National Marine Fisheries Service-Pacific Islands Region, 2001). Geographical distribution among these species is governed by seasonal changes in ocean temperature. These species range from as far north as Japan, to as far south as New Zealand. Albacore tuna, striped marlin (*Tetrapurus audax*), and broadbill swordfish have broader ranges and occur from 50°N to 50°S (Western Pacific Regional Fishery Management Council, 1998). Some species of tuna may aggregate near sea mounts (Yasui, 1986; Itano and Holland, 2000). Temperate species includes those that are found in greater abundance outside tropical waters at higher latitudes (e.g., broadbill swordfish, bigeye tuna, northern bluefin tuna [*Thunnus thynnus*], and albacore tuna). Pelagic species are typically found in epipelagic to pelagic waters; however, shark species can be found in inshore benthic, neritic to epipelagic, and mesopelagic (ocean zone from 109.3 to 546.7 fathoms) waters. Factors such as gradients in temperature, oxygen, or salinity can affect the suitability of a habitat for pelagic fishes. Skipjack tuna, yellowfin tuna (*T. albacares*), and Indo-Pacific blue marlin (*Makaira nigricans*) prefer warm surface layers where the water is well-mixed and relatively uniform in temperature (Western Pacific Regional Fishery Management Council, 1998). Species such as albacore tuna, bigeye tuna, striped marlin, and broadbill swordfish prefer temperate waters associated with higher latitudes and greater depths (Western Pacific Regional Fishery Management Council, 1998). Certain species, such as broadbill swordfish and bigeye tuna, are known to aggregate near the surface at night. During the day broadbill swordfish can be found at depths of about 437 fathoms and bigeye tuna around 150 to 301 fathoms (Table 3.1.2.2.2-1; Western Pacific Regional Fishery Management Council, 1998). Juvenile albacore tuna generally concentrate above 49 fathoms, with adults found in deeper waters (about 49 to 150 fathoms) (Western Pacific Regional Fishery Management Council, 1998).

3.1.2.2.3 Fish Acoustics

Fishes, like other vertebrates, have a variety of different sensory systems that enable them to glean information from the world around them (see volumes by Atema et al., 1988 and by Collin and Marshall, 2003 for thorough reviews of fish sensory systems). While each of the sensory systems may have some overlap in providing a fish with information about a particular stimulus (e.g., an animal might see and hear a predator), different sensory systems may be most appropriate to serve an animal in a particular situation. Thus, vision is often most useful when a fish is close to the source of the signal, in daylight, and when the water is clear. However, vision does not work well at night, or in deep waters. Chemical signals can be highly specific (e.g., a particular pheromone used to indicate danger). However, chemical signals travel slowly in still water, and diffusion of the chemicals depends upon currents and so chemical signals are not directional and, in many cases, they may diffuse quickly to a non-detectable level. As a consequence, chemical signals may not be effective over long distances.

In contrast, acoustic signals in water travel very rapidly, travel great distances without substantially attenuating (declining in level) in open water, and they are highly directional. Thus, acoustic signals provide the potential for two animals that are some distance apart to communicate quickly (reviewed in Zelick et al., 1999; Popper et al., 2003).

Since sound is potentially such a good source of information, fishes have evolved two sensory systems to detect acoustic signals, and many species use sound for communication (e.g., mating, territorial behavior—see Zelick et al., 1999 for review). The two systems are the ear, for detection of sound above perhaps 20 hertz (Hz) to 1 kilohertz (kHz) or more, and the lateral line for detection of hydrodynamic signals (water motion) from less than 1 Hz to perhaps 100 or 200 Hz. The inner ear in fish functions very much like the ear found in all other vertebrates, including mammals. The lateral line, in contrast, is only found in fish and a few amphibian (frogs) species. It consists of a series of receptors along the body of the fish. Together, the ear and lateral line are often referred to as the octavolateralis system.

Table 3.1.2.2.2-1. Summary of Pelagic or Open Water Species and Depth Distribution

Species	Depth Distribution
Temperate Species	
Striped marlin, *Tetrapurus audax*	Governed by temperature stratification
Broadbill swordfish, *Xiphias gladius*	Surface to 547 fathoms
Northern bluefin tuna, *Thunnus thynnus*	No data
Albacore tuna, *Thunnus alalunga*	Surface to 208 fathoms
Bigeye tuna, *Thunnus obesus*	Surface to 328 fathoms
Mackerel, *Scomber* spp.	No data
Sickle pomfret, *Tatactichthys steindachneri*	Surface to 164 fathoms
Lustrous pomfret, *Eumegistus illustris*	Surface to 300 fathoms
Tropical Species	
Yellowfin tuna, *Thunnus albacares*	Upper 55 fathoms with marked oxyclines
Kawakawa, *Euthynnus affinis*	20 to 109 fathoms
Skipjack tuna, *Katsuwonus pelamis*	Surface to 144 fathoms
Frigate tuna, *Auxis thazard*	No data
Bullet tuna, *Auxis rochei*	No data
Indo-Pacific blue marlin, *Makaira nigricans*	44 to 55 fathoms
Black marlin, *Makaira indica*	250 to 500 fathoms
Shortbill spearfish, *Tetrapturus angustirostris*	22 to 1,000 fathoms
Sailfish, *Istiophorus platypterus*	6-11 to 109-137 fathoms
Dolphinfish, *Coryphaena hippurus*	No data
Pompano dolphinfish, *Coryphaena equiselas*	No data
Wahoo, *Acanthocybium solandri*	Adult depth <109 fathoms
Moonfish, *Lampris guttatus*	Surface to 273 fathoms
Escolar, *Lepidocybium flavobrunneum*	Surface to 109 fathoms
Oilfish, *Ruvettus pretiosus*	Surface to 383 fathoms
Shark Species	
Crocodile shark, *Pseudocarcharias kamoharai*	Surface to 164 fathoms
Common thresher shark, *Alopias vulpinus*	Surface to 200 fathoms
Pelagic thresher shark, *Alopias pelagicus*	Surface to 83 fathoms
Bigeye thresher shark, *Alopias superciliosus*	Surface to 273 fathoms
Shortfin mako shark, *Isurus oxyrinchus*	Surface to 273 fathoms
Longfin mako shark, *Isurus paucus*	No data
Salmon shark, *Lamna ditropis*	Surface to 83 fathoms
Silky shark, *Carcharhinus falcirormis*	Adult depth of 10 to 273 fathoms
Oceanic whitetip shark, *Carcharhinus longimanus*	Adult depth of 20 to 83 fathoms
Blue shark, *Prionace glauca*	Surface to 83 fathoms

3.1.2.2.3.1 Sound in Water

The basic physical principles of sound in water are the same as sound in air (see Rogers and Cox, 1988; Kalmijn, 1988; 1989). Any sound source produces both pressure waves and actual motion of the medium particles. However, whereas in air the actual particle motion attenuates very rapidly and is often inconsequential even a few centimeters from a sound source, particle motion travels (propagates) much further in water due to the much greater density of water than air. One therefore often sees reference to the "acoustic near field" and the "acoustic far field" in the literature on fish hearing. Acoustic near field refers to the particle motion component of the sound and acoustic far field refers to the pressure. Acoustic near field is often misconstrued as only present close to the source. Indeed, all propagating sound in water has both pressure and particle motion components, but after some distance, often defined as the point at a distance of wavelength of the sound divided by 2 pi ($\lambda/2\pi$), the pressure component of the signal dominates, though particle motion is still present and potentially important for fish (e.g., Rogers and Cox, 1988; Kalmijn, 1988; Kalmijn, 1989). For a 500 Hz signal, this point is about 0.5 m from the source.

Fish detect both pressure and particle motion, whereas terrestrial vertebrates generally only detect pressure. Fish directly detect particle motion using the inner ear (see below). Pressure signals, however, are initially detected by the gas-filled swim bladder or other bubble of air in the body. The air bubble then vibrates and serves as a small sound source which "reradiates" (or resends) the signal to the inner ear as a near field particle motion. The ear can only detect particle motion directly, and it needs the air bubble to produce particle motion from the pressure component of the signal.

If a fish is able to only detect particle motion, it is most sensitive to sounds when the source is nearby due to the substantial attenuation of the particle motion signal as it propagates away from the sound source. As the signal level gets lower (further from the source), the signal ultimately gets below the minimum level detectable by the ear (the threshold). Fish that detect both particle motion and pressure generally are more sensitive to sound than are fish that only detect particle motion. This is the case because the pressure component of the signal attenuates much less over distance than does the particle motion, although both particle motion and pressure are always present in the signal as it propagates from the source.

One very critical difference between particle motion and pressure is that fish pressure signals are not directional. Thus, for fish, as to any observer with a single pressure detector, pressure does not appear to come from any direction (e.g., Popper et al., 2003; Fay, 2005). In contrast, particle motion is highly directional, and this is detectable by the ear itself. Accordingly, fish appear to use the particle motion component of a sound field to glean information about sound source direction. This makes particle motion an extremely important signal to fish.

Since both pressure and particle motion are important to fish, it becomes critical that in design of experiments to test the effects of sound on fish (and fish hearing in general), the signal must be understood not only in terms of its pressure levels, but also in terms of the particle motion component. This has not been done in most experiments on effects of human-generated sound to date, with the exception of one study on effects of seismic airguns on fish (Popper et al., 2005).

3.1.2.2.3.1.1 What Do Fish Hear?

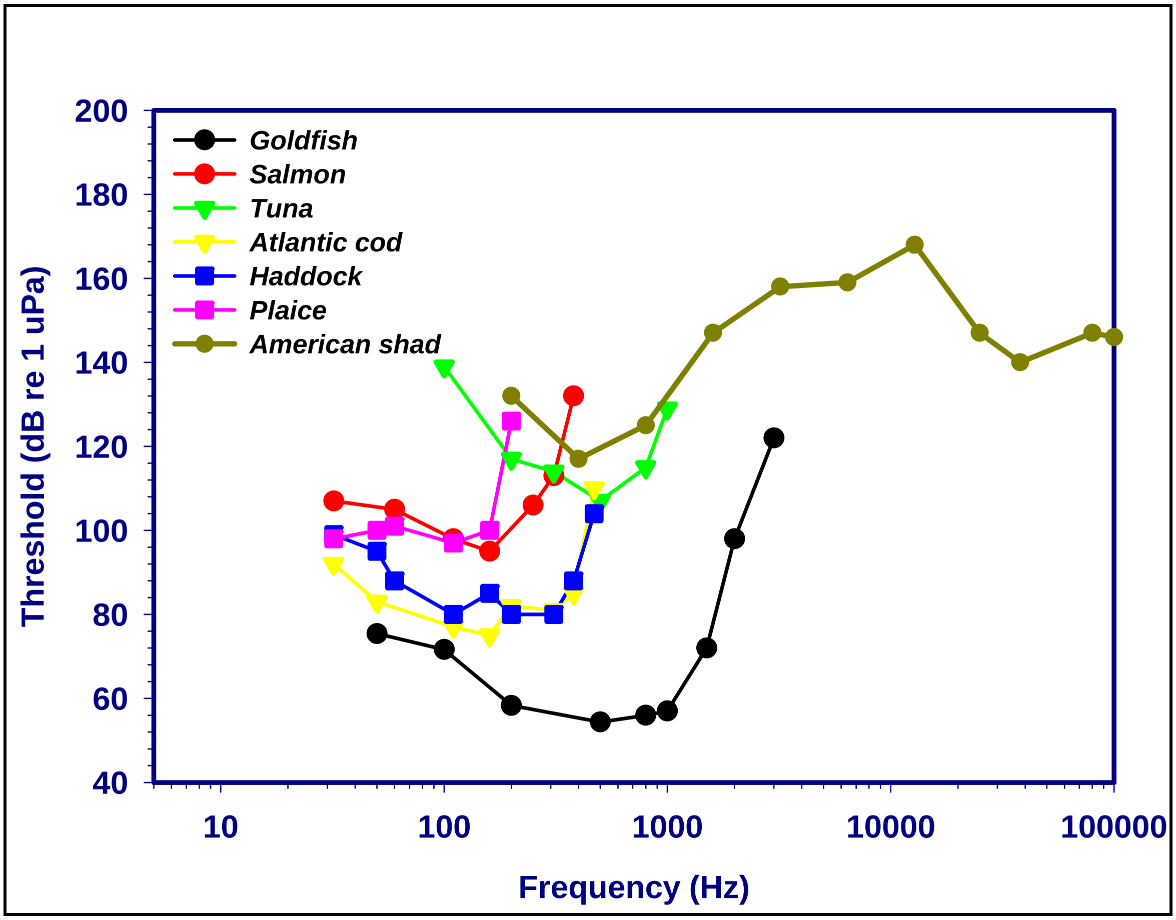
Basic data on hearing provides information about the range of frequencies that a fish can detect, and the lowest sound level that an animal is able to detect at a particular frequency. This level is often called the "threshold." Sounds that are above threshold are detectable by fish. It therefore follows that if a fish can hear a biologically irrelevant human-generated sound (e.g., sonar, ship noise), such sound might interfere with the ability of fish to detect other biologically relevant signals. In effect, anthropogenic sounds and explosions may affect behavior, and result in short and long-term tissue damage, but only at significantly high levels. Importantly, to date there has been not any experimental determination of an association of such effects from military mid-frequency active and high-frequency active (MFA/HFA) sonars.

Hearing thresholds have been determined for perhaps 100 of the more than 29,000 living fish species (Figure 3.1.2.2.3.1-1) (see Fay, 1988; Popper et al., 2003; Ladich and Popper, 2004; and Nedwell et al.; 2004 for data on hearing thresholds). These studies show that, with few exceptions, fish cannot hear sounds above about 3 to 4 kHz, and that the majority of species are only able to detect sounds to 1 kHz or even below. In contrast, a healthy young human can detect sounds to about 20 kHz, and dolphins and bats can detect sounds to well over 100 kHz. There have also been studies on a few species of cartilaginous fish, with results suggesting that they detect sounds to no more than 600 or 800 Hz (e.g., Fay, 1988; Casper et al., 2003).

Besides being able to detect sounds, a critical role for hearing is to be able to discriminate between different sounds (e.g., frequency and intensity), detect biologically relevant sounds in the presence of background noises, and determine the direction and location of a sound source in the space around the animal. While data are available on these tasks for only a few fish species, all species studied appear to be able to discriminate sounds of different intensities and frequencies (reviewed in Fay and Megela-Simmons, 1999; Popper et al., 2003) and perform sound source localization (reviewed in Popper et al., 2003; Fay, 2005).

Fish are also able to detect signals in the presence of background noise (reviewed in Fay and Megela-Simmons, 1999; Popper et al., 2003). The results of these studies show that fish hearing is affected by the presence of background noise that is in the same general frequency band as the biologically relevant signal. In other words, if a fish has a particular threshold for a biologically relevant sound in a quiet environment, and a background noise that contains energy in the same frequency range is introduced, this will decrease the ability of the fish to detect the biologically relevant signal. In effect, the threshold for the biologically relevant signal will become poorer.

The significance of this finding is that if background noise is increased, such as a result of human-generated sources, it may be harder for a fish to detect the biologically relevant sounds that it needs to survive.



Source: (see Fay, 1988 and Nedwell et al., 2004 for data)

Note: Goldfish and American shad are species with specializations that enhance hearing sensitivity and/or increase the range of sounds detectable by the animal. The other species are hearing generalists. Most of these data were obtained using methods where fish were conditioned to respond to a sound when it was present. Each data point represents the lowest sound level (threshold) the species could detect at a particular frequency. Data for American shad are truncated at 100 kHz to keep the size of the graph reasonable, but it should be noted that this species can hear sounds to at least 180 kHz (Mann et al., 1997). Note that these data represent pressure thresholds, despite the fact that some of the species (e.g., salmon, tuna) are primarily sensitive to the particle motion component of a sound field, something that was not generally measured at the time of the studies.

Figure 3.1.2.2.3.1-1. Hearing Curves (Audiograms) for Select Teleost Fishes

3.1.2.2.3.1.2 Sound Detection Mechanisms

While bony and cartilaginous fish have no external structures for hearing, such as the human pinna (outer ear), they do have an inner ear which is similar in structure and function to the inner ear of terrestrial vertebrates. The outer and middle ears of terrestrial vertebrates serve to change the impedance of sound traveling in air to that of the fluids of the inner ear. However, since fishes already live in a fluid environment, there is no need for impedance matching to stimulate the inner ear. At the same time, since the fish ear and body are the same density as water, they will move along with the sound field. While this might result in the fish not detecting the sound, the ear also contains very dense calcareous structures, the otoliths, which move at a different amplitude and phase from the rest of the body. This provides the mechanism by which fish hear.

The ear of a fish has three semicircular canals that are involved in determining the angular movements of the fish. The ear also has three otolith organs, the saccule, lagena, and utricle, that are involved in both determining the position of the fish relative to gravity and detection of sound and information about such sounds. Each of the otolith organs contains an otolith that lies in close proximity to a sensory epithelium.

The sensory epithelium (or macula) in each otolith organ of fish contains mechanoreceptive sensory hair cells that are virtually the same as found in the mechanoreceptive cells of the lateral line and in the inner ear of terrestrial vertebrates. All parts of the ear have the same kind of cell to detect movement, whether it be movement caused by sound or movements of the head relative to gravity.

3.1.2.2.3.1.3 Hearing Generalists and Specialists

Very often, fish are referred to as “hearing generalists” (or non-specialists) or “hearing specialists” (e.g., Fay, 1988; Popper et al., 2003; Ladich and Popper, 2004). Hearing generalists generally detect sound to no more than 1 to 1.5 kHz, whereas specialists are generally able to detect sounds to above 1.5 kHz (see Figure 3.1.2.2.3.1-1). And, in the frequency range of hearing that the specialists and generalists overlap, the specialists generally have lower thresholds than generalists, meaning that they can detect quieter (lower intensity) sounds. Furthermore, it has often been suggested that generalists only detect the particle motion component of the sound field, whereas the specialists detect both particle motion and pressure (see Popper et al., 2003).

However, while the terms hearing generalist and specialist have been useful, it is now becoming clear that the dichotomy between generalists and specialists is not very distinct. Instead, investigators are now coming to the realization that many species that do not hear particularly well still detect pressure as well as particle motion and pressure. However, these species often have poorer pressure detection than those fishes that have a wider hearing bandwidth and greater sensitivity (see Popper and Schilt, 2008).

It is important to note that hearing specialization is not limited to just a few fish taxa. Instead, there are hearing specialists that have evolved in many very diverse fish groups. Moreover, there are instances where one species hears very well while a very closely related species does not hear well. The only “generalizations” that one can make is that all cartilaginous fish are likely to be hearing generalists, while all otophysan fishes (goldfish, catfish, and relatives) are hearing specialists. It is also likely that bony fish without an air bubble such as a swim bladder (see below) are, like cartilaginous fishes, hearing generalists. These fish include all flatfish, some tuna, and a variety of other taxonomically diverse species.

3.1.2.2.3.1.4 Ancillary Structures for Hearing Specializations

All species of fish respond to sound by detecting relative motion between the otoliths and the sensory hair cells. However, many species, and most effectively the hearing specialists, also detect sounds using the air-filled swim bladder in the abdominal cavity. The swim bladder is used for a variety of different functions in fish. It probably evolved as a mechanism to maintain buoyancy in the water column, but later evolved to have multiple functions.

The other two roles of the swim bladder are in sound production and hearing (e.g., Zelick et al., 1999; Popper et al., 2003). In sound production, the air in the swim bladder is vibrated by the sound producing structures (often muscles that are integral to the swim bladder wall) and serves as a radiator of the sound into the water (see Zelick et al., 1999).

For hearing, the swim bladder serves to re-radiate sound energy to the ear. This happens since the air in the swim bladder is of a very different density than the rest of the fish body. Thus, in the presence of sound the air starts to vibrate. The vibrating gas re-radiates energy which then stimulates the inner ear by moving the otolith relative to the sensory epithelium. However, in species that have the swim bladder some distance from the ear, any re-radiated sound attenuates a great deal before it reaches the ear. Thus, these species probably do not detect the pressure component of the sound field as well as fish where the swim bladder comes closer to the ear.

In contrast, hearing specialists always have some kind of acoustic coupling between the swim bladder and the inner ear to reduce attenuation and ensure that the signal from the swim bladder gets to the ear. In the goldfish and its relatives, the otophysan fishes, there is a series of bones, the Weberian ossicles, which connect the swim bladder to the ear. When the walls of the swim bladder vibrate in a sound field, the ossicles move and carry the sound directly to the inner ear. Removal of the swim bladder in these fish results in a drastic loss of hearing range and sensitivity (reviewed in Popper et al., 2003).

Besides species with Weberian ossicles, other fishes have evolved a number of different strategies to enhance hearing. For example, the swim bladder may have one or two anterior projections that actually contact one of the otolith organs. In this way, the motion of the swim bladder walls directly couples to the inner ear of these species (see discussion in Popper et al., 2003).

3.1.2.2.3.1.5 Lateral Line

The lateral line system is a specialized sensory receptor found on the body that enables detection of the hydrodynamic component of a sound field or other water motions relative to the fish (reviewed in Coombs and Montgomery, 1999, Webb et al., 2008). The lateral line is most sensitive to stimuli that occur within a few body lengths of the animal and to signals that are from below 1 Hz to a few hundred hertz (Coombs and Montgomery, 1999; Webb et al., 2008). The lateral line is involved with schooling behavior, where fish swim in a cohesive formation with many other fish, and it is also involved with detecting the presence of near-by moving objects, such as food. Finally, the lateral line is an important determinant of current speed and direction, providing useful information to fishes that live in streams or where tidal flows dominate.

The only study on the effect of exposure to sound on the lateral line system suggests no effect on these sensory cells by very intense pure tone signals (Hastings et al., 1996). However, since this study was limited to one (freshwater) species and only to pure tones, extrapolation to other sounds is not warranted, and further work needs to be done on any potential lateral line effects on other species and with other types of sounds.

3.1.2.2.3.2 Overview of Fish Hearing Capabilities

Determination of hearing capability has only been done for fewer than 100 of the more than 29,000 fish species (Fay, 1988; Popper et al., 2003; Ladich and Popper, 2004; Nedwell et al., 2004). Much of this data is summarized in Table 3.1.2.2.3.2-1 for species of marine fish that have been studied and that could potentially be in areas where sonar or other Navy sound sources might be used. This data set, while very limited, suggests that the majority of marine species are hearing generalists, although it must be kept in mind that there are virtually no data for species that live at great ocean depths and it is possible that such species, living in a lightless environment, may have evolved excellent hearing to help them get an auditory “image” of their environment (e.g., Popper, 1980).

While it is hard to generalize as to which fish taxa are hearing generalists or specialists since specialists have evolved in a wide range of fish taxa (see, for example, Holocentridae and Sciaenidae in Table 3.1.2.2.3.2-1), there may be some broad generalizations as to hearing capabilities of different groups. For example, it is likely that all, or the vast majority of species in the following groups would have hearing capabilities that would include them as hearing generalists. These include cartilaginous fishes (Casper et al., 2003; Casper and Mann, 2006; Myrberg, 2001), scorpaeniforms (i.e., scorpionfishes, searobins, sculpins) (Tavolga and Wodinsky, 1963), scombrids (i.e., albacores, bonitos, mackerels, tunas) (Iversen, 1967, 1969; Song et al., 2006), and more specifically, midshipman fish (*Porichthys notatus*) (Sisneros and Bass, 2003), Atlantic salmon (*Salmo salar*) (Hawkins and Johnstone, 1978) and other salmonids (e.g., Popper et al., 2007), and all toadfish in the family Batrachoididae (see Table 3.1.2.2.3.2-1 for species).

Marine hearing specialists include some Holocentridae (“soldierfish” and “squirrelfish”) (Coombs and Popper, 1979) and some Sciaenidae (drums and croakers) (reviewed in Ramcharitar et al., 2006b) (see Table 3.1.2.2.3.2-1). In addition, all of the clupeids (herrings, shads, alewives, anchovies) are able to detect sounds to over 3 kHz. And, more specifically, members of the clupeid family Alosinae, which includes menhaden and shad, are able to detect sounds to well over 100 kHz (e.g., Enger, 1967; Mann et al., 2001; Mann et al., 2005).

3.1.2.2.3.2.1 Variability in Hearing Among Groups of Fish

Hearing capabilities vary considerably between different fish species (Figure 3.1.2.2.3.1-1), and there is no clear correlation between hearing capability and environment, even though some investigators (e.g., Amoser and Ladich, 2005) have argued that the level of ambient noise in a particular environment might have some impact on hearing capabilities of a species. However, the evidence for this suggestion is very limited, and there are species that live in close proximity to one another, and which are closely related taxonomically, that have different hearing capabilities. This is widely seen within the family Sciaenidae, where there is broad diversity in hearing capabilities and hearing structures (data reviewed in Ramcharitar et al., 2006b). This is also seen in the family Holocentridae. In this group, the shoulderbar soldierfish (*Myripristis kuntee*) and the Hawaiian squirrelfish (*Sargocentron xantherythrum*) live near one another on the same reefs, yet *Sargocentron* detects sounds from below 100 Hz to about 800 Hz, whereas *Myripristis* is able to detect sounds from 100 Hz to over 3 kHz, and it can hear much lower intensity sounds than can *Sargocentron* (Coombs and Popper, 1979; see also Tavolga and Wodinsky, 1963).

Table 3.1.2.2.3.2-1. Marine Fish Hearing Sensitivities

Family	Description of Family	Common Name	Scientific Name	Hearing Range (Hz) Low	Hearing Range (Hz) High	Best Sensitivity (Hz)	Reference
Albulidae	Bonefishes	Bonefish	*Albula vulpes*	100	700	300	Tavolga, 1974a
Anguillidae	Eels	European eel	*Anguilla anguilla*	10	300	40-100	Jerkø et al., 1989
Ariidae	Catfish	Hardhead sea catfish	*Ariopsis felis* [1]	50	1,000	100	Popper and Tavolga, 1981
Batrachoididae	Toadfishes	Midshipman[2]	*Porichthys notatus*	65	385		Sisneros, 2007

Triglidae	Scorpionfishes, searobins, sculpins	Leopard searobin	*Prionotus scitulus*	100	~800	390	Tavolga and Wodinsky, 1963

Among all fishes studied to date, perhaps the greatest variability has been found within the economically important family Sciaenidae (i.e., drumfish, weakfish, croaker) where there is extensive diversity in inner ear structure and the relationship between the swim bladder and the inner ear (all data on hearing and sound production in Sciaenidae is reviewed in Ramcharitar et al., 2006b) (see Table 3.1.2.2.3.2-1). Specifically, the Atlantic croaker's (*Micropogonias undulatus*) swim bladder comes near the ear but does not actually touch it. However, the swim bladders in the spot (*Leiostomus xanthurus*) and black drum (*Pogonias cromis*) are further from the ear and lack anterior horns or diverticulae. These differences are associated with variation in both sound production and hearing capabilities (Ramcharitar et al., 2006b). Ramcharitar and Popper (2004) found that the black drum detects sounds from 0.1 to 0.8 kHz and was most sensitive between 0.1 and 0.5 kHz, while the Atlantic croaker detects sounds from 0.1 to 1.0

kHz and was most sensitive at 0.3 kHz. Additionally, Ramcharitar et al. (2006a) found that weakfish (*Cynoscion regalis*) is able to detect frequencies up to 2.0 kHz, while spot can hear only up to 0.7 kHz.

The sciaenid with the greatest hearing sensitivity discovered thus far is the silver perch (*Bairdiella chrysoura*), a species which has auditory thresholds similar to goldfish and which is able to respond to sounds up to 4.0 kHz (Ramcharitar et al., 2004). Silver perch swim bladders have anterior horns that terminate close to the ear.

3.1.2.2.3.2.2 Marine Hearing Specialists

The majority of marine fish studied to date are hearing generalists. However, a few species have been shown to have a broad hearing range suggesting that they are specialists. These include some holocentrids and sciaenids, as discussed above. There is also evidence, based on structure of the ear and the relationship between the ear and the swim bladder that at least some deep-sea species, including myctophids, may be hearing specialists (Popper, 1977; Popper, 1980), although it has not been possible to do actual measures of hearing on these fish from great depths.

The most significant studies have shown that all herring like fishes (order Clupeiformes) are hearing specialists and able to detect sounds to at least 3 to 4 kHz, and that some members of this order, in the sub-family Alosinae, are able to detect sounds to over 180 kHz (Figure 3.1.2.2.3.1-1) (Mann et al., 1997, 1998, 2001, 2005; Gregory and Clabburn, 2003). Significantly, there is evidence that detection of ultrasound (defined by the investigators as sounds over 20 kHz) in these species is mediated through one of the otolithic organs of the inner ear, the utricle (Higgs et al., 2004, Plachta et al., 2004). While there is no evidence from field studies, laboratory data leads to the suggestion that detection of ultrasound probably arose to enable these fish to hear the echolocation sounds of odontocete predators and avoid capture (Mann et al., 1998; Plachta and Popper, 2003). This is supported by field studies showing that several Alosinae clupeids avoid ultrasonic sources. These include the alewife (*Alosa pseudoharengus*) (Dunning et al. 1992, Ross et al. 1996), blueback herring (*A. aestivalis*) (Nestler et al., 2002), Gulf menhaden (*Brevoortia patronus*) (Mann et al., 2001), and American shad (*A. sapidissima*) (Mann et al., 1997, 1998, 2001). Thus, masking of ultrasound by mid- or high-frequency sonar could potentially affect the ability of these species to avoid predation.

Although few non-clupeid species have been tested for ultrasound (Mann et al., 2001), the only non-clupeid species shown to possibly be able to detect ultrasound is the cod (*Gadus morhua*) (Astrup and Møhl, 1993). However, in Astrup and Møhl's (1993) study it is feasible that the cod was detecting the stimulus using touch receptors that were over driven by very intense fish-finding sonar emissions (Astrup, 1999; Ladich and Popper, 2004). Nevertheless, Astrup and Møhl (1993) indicated that cod have ultrasound thresholds of up to 38 kHz at 185 to 200 dB re 1 micropascal-meter (µPa-m), which likely only allows for detection of odontocete's clicks at distances no greater than 10 to 30 meters (m) (33 to 98 ft) (Astrup 1999).

Finally, while most otophysan species are freshwater, a few species inhabit marine waters. In the one study of such species, Popper and Tavolga (1981) determined that the hardhead sea catfish (*Ariopsis felis*) was able to detect sounds from 0.05 to 1.0 kHz, which is a narrower frequency range than that common to freshwater otophysans (i.e., above 3.0 kHz) (Popper et al., 2003). However, hearing sensitivity below about 500 Hz was much better in the hardhead sea catfish than in virtually all other hearing specialists studied to date (Table 3.1.2.2.3.2-1, Fay, 1988; Popper et al., 2003).

3.1.2.2.3.2.3 Marine Hearing Generalists

As mentioned above, investigations into the hearing ability of marine bony fishes have most often yielded results exhibiting a narrower hearing range and less sensitive hearing than specialists. This was first demonstrated in a variety of marine fishes by Tavolga and Wodinsky (1963), and later demonstrated in taxonomically and ecologically diverse marine species (reviews in Fay, 1988; Popper et al., 2003; Ladich and Popper, 2004).

By examining the morphology of the inner ear of bluefin tuna (*Thunnus thynnus*), Song et al. (2006) hypothesized that this species probably does not detect sounds to much over 1 kHz (if that high). This research concurred with the few other studies conducted on tuna species. Iversen (1967) found that yellowfin tuna (*T. albacares*) can detect sounds from 0.05 to 1.1 kHz, with best sensitivity of 89 dB (re 1 µPa) at 0.5 kHz. Kawakawa (*Euthynnus affinis*) appear to be able to detect sounds from 0.1 to 1.1 kHz but with best sensitivity of 107 dB (re 1 µPa) at 0.5 kHz (Iversen, 1969). Additionally, Popper (1981) looked at the inner ear structure of a skipjack tuna (*Katsuwonus pelamis*) and found it to be typical of a hearing generalist. While only a few species of tuna have been studied, and in a number of fish groups both generalists and specialists exist, it is reasonable to suggest that unless bluefin tuna are exposed to very high intensity sounds from which they cannot swim away, short- and long-term effects may be minimal or non-existent (Song et al., 2006).

Some damselfish have been shown to be able to hear frequencies of up to 2 kHz, with best sensitivity well below 1 kHz. Egner and Mann (2005) found that juvenile sergeant major damselfish (*Abudefduf saxatilis*) were most sensitive to lower frequencies (0.1 to 0.4 kHz); however, larger fish (greater than 50 millimeters) responded to sounds up to 1.6 kHz. Still, the sergeant major damselfish is considered to have poor sensitivity in comparison even to other hearing generalists (Egner and Mann, 2005). Kenyon (1996) studied another marine generalist, the bicolor damselfish (*Stegastes partitus*), and found responses to sounds up to 1.6 kHz with the most sensitive frequency at 0.5 kHz. Further, larval and juvenile Nagasaki damselfish (*Pomacentrus nagasakiensis*) have been found to hear at frequencies between 0.1 and 2 kHz; however, they are most sensitive to frequencies below 0.3 kHz (Wright et al., 2005, 2007). Thus, damselfish appear to be primarily generalists.

Female oyster toadfish (*Opsanus tau*) apparently use the auditory sense to detect and locate vocalizing males during the breeding season (e.g., Winn; 1967). Interestingly, female midshipman fish (*Porichthys notatus*) (in the same family as the oyster toadfish) go through a shift in hearing sensitivity depending on their reproductive status. Reproductive females showed temporal encoding up to 0.34 kHz, while non-reproductive females showed comparable encoding only up to 0.1 kHz (Sisneros and Bass, 2003).

The hearing capability of Atlantic salmon (*Salmo salar*) indicates relatively poor sensitivity to sound (Hawkins and Johnstone, 1978). Laboratory experiments yielded responses only to 580 Hz and only at high sound levels. The Atlantic salmon is considered to be a hearing generalist, and this is probably the case for all other salmonids studied to date based on studies of hearing (e.g., Popper et al., 2007, Wysocki et al., 2007) and inner ear morphology (e.g., Popper, 1976, 1977).

Furthermore, investigations into the inner ear structure of the long-spined bullhead (*Taurulus bubalis*, order Scorpaeniformes) have suggested that these fishes have generalist hearing abilities, and this is supported by their lack of a swim bladder (Lovell et al., 2005). While it is impossible to extrapolate from this species to all members of this large group of taxonomically diverse fishes, studies of hearing in another species in this group, the leopard robin (*Prionotus scitulus*), suggest that it is probably not able to detect sound to much above 800 Hz, indicating that it would be a hearing generalist (Tavolga and Wodinsky, 1963). However, since the leopard sea robin has a swim bladder, and the long-spined bullhead does not, this illustrates the diversity of species in this order and makes extrapolation on hearing from these two fishes to all members of the group very difficult to do.

A number of hearing generalists can detect very low frequencies of sound. Detection of very low frequencies, or infrasound, was not investigated until fairly recently since most laboratory sound sources were unable to produce undistorted tones below 20 to 30 Hz. In addition, most earlier measures of fish hearing indicated a steadily declining sensitivity towards lower frequencies (Fay, 1988), suggesting that fish would not detect low frequencies. However, as has been pointed out in the literature, often the problem with measuring lower frequency hearing (e.g., below 50 or 100 Hz) was simply that the sound sources available (underwater loud speakers) were not capable of producing lower frequency sounds, or the acoustics of the tanks in which the studies were conducted prevented lower frequency sounds from being effectively used.

Infrasound sensitivity in fish was first demonstrated in the Atlantic cod (*Gadus morhua*) (Sand and Karlsen, 1986). This species can detect sounds down to about 10 Hz and is sensitive to particle motion of the sound field and not to pressure. Other species shown to detect infrasound include the plaice flatfish (*Pleuronectes platessa*) (Karlsen, 1992), and the European eel (*Anguilla anguilla*) (Sand et al., 2000).

The sensitivity of at least some species of fish to infrasound may theoretically provide the animals with a wide range of information about the environment than detection of somewhat higher frequencies. An obvious potential use for this sensitivity is detection of moving objects in the surroundings, where infrasound could be important in, for instance, courtship and prey-predator interactions. Juvenile salmonids display strong avoidance reactions to near-by infrasound (Knudsen et al., 1992, 1994), and it is reasonable to suggest that such behavior has evolved as a protection against predators.

More recently, Sand and Karlsen (2000) proposed the hypothesis that fish may also use the ambient infrasounds in the ocean, which are produced by things like waves, tides, and other large scale motions, for orientation during migration. This would be in the form of an inertial guidance system where the fish detect surface waves and other large scale infrasound motions as part of their system to detect linear acceleration, and in this way migrate long distances.

An important issue with respect to infrasound relates to the distance at which such signals are detected. It is clear that fish can detect such sounds. However, behavioral responses only seem to occur when fish are well within the acoustic near field of the sound source. Thus, it is likely that the responses are to the particle motion component of the infrasound.

3.1.2.2.3.2.4 Hearing Capabilities of Elasmobranchs and Other "Fish"

Bony fishes are not the only species that may be impacted by environmental sounds. The two other groups to consider are the jawless fish (Agnatha – lamprey) and the cartilaginous fishes (i.e., elasmobranchs; the sharks and rays). While there are some lamprey in the marine environment, virtually nothing is known as to whether they hear or not. They do have ears, but these are relatively primitive compared to the ears of other vertebrates. No one has investigated whether the ear can detect sound (reviewed in Popper and Hoxter, 1987).

The cartilaginous fishes are important parts of the marine ecosystem, and many species are top predators. While there have been some studies on their hearing, these have not been extensive. However, available data suggests detection of sounds from 0.02 to 1 kHz, with best sensitivity at lower ranges (Myrberg, 2001; Casper et al., 2003, Casper and Mann, 2006). Though fewer than 10 elasmobranch species have been tested for hearing thresholds (reviewed in Fay, 1988), it is likely that all elasmobranchs only detect low frequency sounds because they lack a swim bladder or other pressure detector. At the same time, the ear in a number of elasmobranch species whose hearing has not been tested is very large with numerous sensory hair cells (e.g., Corwin, 1981, 1989). Thus, it is possible that future studies will demonstrate somewhat better hearing in those species than is now known.

There is also evidence that elasmobranchs can detect and respond to human-generated sounds. Myrberg and colleagues did experiments in which they played back sounds and attracted a number of different shark species to the sound source (e.g., Myrberg et al., 1969, 1972, 1976; Nelson and Johnson, 1972). The results of these studies showed that sharks were attracted to pulsed low-frequency sounds (below several hundred Hz), in the same frequency range of sounds that might be produced by struggling prey (or divers in the water). However, sharks are not known to be attracted by continuous signals or higher frequencies (which they cannot hear).

3.1.2.2.3.2.5 Data on Fish Hearing

Table 3.1.2.2.3.2-1 provides data on the hearing capabilities of all of the marine fish species that have been studied to date. However, before examining the data in the table, a number of important points must be made.

- In order to conform to the most recent taxonomic studies of the species, the table uses current scientific names for a number of species rather than the scientific names used at the time that the research paper was written (Fishbase, 2008).
- The data in the table were primarily compiled by two sources, Fay (1988) and Nedwell et al. (2004). Since the Nedwell et al. (2004) study was not published, the data were checked, where possible, against Fay (1988) or original sources.
- The data in the table for "best sensitivity" is only provided to give a sense of where the best hearing was for that species. However, since thresholds are often variable, this information should be used with utmost caution.
- It may generally be said that fish with a hearing range that only extends to 1.5 kHz are more likely to be hearing generalists, whereas fish with higher frequency hearing would be considered specialists.

- It is critical to note that comparison of the data in the table between species must be done with considerable caution. Most importantly, data were obtained in very different ways for the various species, and it is highly likely that different experimental methods yield different results in terms of range of hearing and in hearing sensitivity. Thus, data obtained using behavioral measures, such as those done by Tavolga and Wodinksy (1963) for a variety of marine fishes provide data in terms of what animals actually detected since the animals were required to do a behavioral task whenever they detected a sound.
- In contrast, studies performed using auditory evoked potentials (AEP), often called auditory brainstem response (ABR), a very effective general measure of hearing that is being widely used today, tends, in fishes, to generally provide results that indicate a somewhat narrower hearing range and possibly different sensitivity (thresholds) than obtained using behavioral methods. The difference is that ABR is a measure that does not involve any response on the part of the fish. Instead, ABR is a measure of the brainstem response and does not measure the integrated output of the auditory system (e.g. cortical process, decision-making, etc.). Examples of data from ABR studies include the work of Casper et al. (2003) and Ramcharitar et al. (2004, 2006a).
- Many of the species, as shown, are hearing generalists, and these species respond best primarily to particle motion rather than pressure, as discussed earlier. However, the vast majority of the species were tested with pressure signals, and the particle motion signal was not calibrated. Thus, hearing sensitivity data, and hearing range, may be somewhat different if particle motion had been calibrated. Accordingly, while the table gives a general sense of hearing of different species, caution must be taken in extrapolation to other species, and in interpretation of the data.

  Data were compiled from reviews in Fay (1988) and Nedwell et al. (2004). See the very important caveats about the data in the text. For a number of additional species, we can only surmise about hearing capabilities from morphological data. These data are shown in gray, with a suggestion as to hearing capabilities based only on morphology. Scientific names marked with an asterisk have a different name in the literature. (Fishbase, 2008).

As a consequence of these differences in techniques, as well as differences in sound fields used and differences in experimental paradigms, one must be extremely cautious in comparing data between different species when they were tested in different ways and/or in different laboratories. While general comparisons are possible (e.g., which species are generalists and which are specialists), more-detailed comparisons, such as of thresholds, should be done with utmost caution since one investigator may have been measuring pressure and another particle motion. At the same time, it should be noted that when different species were tested in the same lab, using the same experimental approach, it is possible to make comparative statements about hearing among the species used since all would have been subject to the same sound field.

3.1.2.3 SEA TURTLES

Sea turtles are long lived reptiles that can be found throughout the world's tropical, subtropical, and temperate seas (Caribbean Conservation Corporation and Sea Turtle Survival League, 2003). There are seven living species of sea turtles from two distinct families, the Cheloniidae (hard-shelled sea turtles; six species) and the Dermochelyidae (leatherback turtle [*Dermochelys* *coriacea]*; one species). These two families can be distinguished from one another on the basis of their carapace (upper shell) and other morphological features. Sea turtles are an important marine resource in that they provide economic, arid existence (non-use) value to humans (Witherington and Frazer, 2003). Over the last few centuries, sea turtle populations have declined dramatically due to anthropogenic (human-related) activities such as coastal development, oil exploration, commercial fishing, marine-based recreation, pollution, and over-harvesting (Natural Research Council, 1990; Eckert, 1995). As a result, all six species of sea turtles found in U.S. waters are currently listed as either threatened or endangered under the Endangered Species Act (ESA). Five of the seven living species of sea turtles are known to occur in the HRC: the green (*Chelonia mydas*), hawksbill (*Eretmochelys imbricata*), loggerhead (*Caretta caretta*), olive ridley (*Lepidochelys olivacea*), and leatherback turtles.

Sea turtles are highly adapted for life in the marine environment. Unlike terrestrial and freshwater turtles, sea turtles possess powerful, modified forelimbs (or flippers) that enable them to swim continuously for extended periods of time (Wyneken, 1997). They also have compact and streamlined bodies that help to reduce drag. Additionally, sea turtles are among the longest and deepest diving of the air-breathing vertebrates, spending as little as 3 to 6 percent of their time at the water's surface (Lutcavage and Lutz, 1997). Sea turtles often travel thousands of miles between their nesting beaches and feeding grounds, which makes the aforementioned suite of adaptations very important (Ernst et al., 1994; Meylan, 1995). Sea turtle traits and behaviors also help protect them from predation. Sea turtles have a tough outer shell and grow to a large size as adults; mature leatherback turtles can weigh up to 2,091 pounds (lb) (Eckert and Luginbuhl, 1988). Sea turtles cannot withdraw their head or limbs into their shell, so growing to a large size as adults is important.

Although they are specialized for life at sea, sea turtles begin their lives on land. Aside from this brief terrestrial period, which lasts approximately 2 months as eggs and an additional few minutes to a few hours as hatchlings scrambling to the surf, most sea turtles are rarely encountered out of the water. Sexually mature females return to land in order to nest, while certain species in the Hawaiian Islands, Australia, and the Galapagos Islands haul out on land in order to bask (Carr, 1995; Spotila et al., 1997). Sea turtles bask to thermoregulate, elude predators, avoid harmful mating encounters, and possibly to accelerate the development of their eggs, accelerate their metabolism, and destroy aquatic algae growth on their carapaces (Whittow and Balazs, 1982; Spotila et al., 1997). On occasion, sea turtles can unintentionally end up on land if they are dead, sick, injured, or cold-stunned. These events, also known as strandings, can be caused by either biotic (e.g., predation and disease) or abiotic (e.g., water temperature) factors.

Female sea turtles nest in tropical, subtropical, and warm-temperate latitudes, often in the same region or on the same beach where they hatched (Miller, 1997). Upon selecting a suitable nesting beach, most sea turtles tend to re-nest in close proximity during subsequent nesting attempts. The leatherback turtle is a notable divergence from this pattern. This species nests primarily on beaches with little reef or rock offshore. On these types of beaches erosion reduces the probability of nest survival. To compensate, leatherbacks scatter their nests over larger geographic areas and lay on average two times as many clutches as other species (Eckert, 1987).

At times, sea turtles may fail to nest after emerging from the ocean. These non-nesting emergences, known as false crawls, can occur if sea turtles are obstructed from laying their eggs (by debris, rocks, roots, or other obstacles), are distracted by surrounding conditions (by noise, lighting, or human presence), or are uncomfortable with the consistency or moisture of the sand on the nesting beach. Turtles that are successful at nesting usually lay several clutches of eggs during a nesting season with each clutch containing between 50 and 200 eggs, depending on the species (Witzell, 1983; Dodd, 1988; Hirth, 1997). Most sea turtles, with the possible exception of Kemp's ridley turtles (*Lepidochelys kempii*), do not nest in consecutive years; instead, they will often skip 2 or 3 years before returning to the nesting grounds (Márquez-M., 1990; Ehrhart, 1995). Nesting success is vital to the long-term existence of sea turtles since it is estimated that only 1 out of every 1,000 hatchlings survives long enough to reproduce (Frazer, 1986).

During the nesting season, daytime temperatures can be lethal on tropical, subtropical, and warm-temperate beaches. As a result, adult sea turtles most often nest and hatchlings most often emerge from their nest at night (Miller, 1997). After emerging from the nest, sea turtle hatchlings use visual cues (e.g., light intensity or wavelengths) to orient themselves toward the sea (Lohmann et al., 1997).

Hatchlings that make it into the water will spend the first few years of their lives in offshore waters, drifting in convergence zones or amidst floating vegetation, where they find food (mostly pelagic invertebrates) and refuge in flotsam that accumulates in surface circulation features (Carr, 1987). Originally labeled the lost year, this stage in a sea turtle's life history is now known to be much longer in duration, possibly lasting a decade or more (Chaloupka and Musick, 1997; Bjorndal et al., 2000). Sea turtles will spend several years growing in the early juvenile "nursery habitat," which is usually pelagic and oceanic, before migrating to distant feeding grounds that comprise the later juvenile "developmental habitat," which is usually demersal and neritic (in shallow water) (Musick and Limpus, 1997; Frazier, 2001). Hard-shelled sea turtles most often utilize shallow offshore and inshore waters as later juvenile developmental habitats; whereas leatherback turtles, depending on the season, can utilize either coastal feeding areas in temperate waters or offshore feeding areas in tropical waters (Frazier, 2001).

Once in the later juvenile developmental habitat, most sea turtles change from surface to benthic feeding and begin to feed on larger items such as crustaceans, mollusks, sponges, coelenterates, fishes, macroalgae, and seagrasses (Bjorndal, 1997). A sea turtle's diet varies according to its feeding habitat and its preferred prey. Upon moving from the later juvenile developmental habitat to the adult foraging habitat, sea turtles may demonstrate further changes in prey preference, dietary composition, and feeding behavior (Bjorndal, 1997; Musick and Limpus, 1997).

Throughout their life cycles, sea turtles undergo complex seasonal movements. Sea turtle movement patterns are influenced by changes in ocean currents, turbidity, salinity, and food availability. In addition to these factors, the distribution of many sea turtle species is dependent upon and often restricted by water temperature (Epperly et al., 1995; Davenport, 1997; Coles and Musick, 2000). Most sea turtles become lethargic at temperatures below 50°F and above 104°F (Spotila et al., 1997).

Sea turtles do not have an auditory meatus or pinna that channels sound to the middle ear, nor do they have a specialized tympanum (eardrum). Instead, they have a cutaneous layer and underlying subcutaneous fatty layer that function as a tympanic membrane. The subcutaneous fatty layer receives and transmits sound to the extracolumella, a cartilaginous disk, located at the entrance to the columella, a long, thin bone that extends from the middle ear cavity to the entrance of the inner ear or otic cavity (Ridgway et al., 1969a). Sound arriving at the inner ear via the columella is transduced by the bones of the middle ear. Sound also arrives by bone conduction through the skull.

Sea turtle auditory sensitivity is not well studied, though a few preliminary investigations suggest that it is limited to low-frequency bandwidths, such as the sounds of waves breaking on a beach. The role of underwater low-frequency hearing in sea turtles is unclear. It has been suggested that sea turtles may use acoustic signals from their environment as guideposts during migration and as a cue to identify their natal beaches (Lenhardt et al., 1983). The range of maximum sensitivity for sea turtles is 100 to 800 Hz, with an upper limit of about 2,000 Hz (Lenhardt, 1994). Hearing below 80 Hz is less sensitive but still potentially usable to the animal (Lenhardt, 1994). Ridgway et al. (1969a) used aerial and mechanical stimulation to measure the cochlea in three specimens of green turtle, and concluded that they have a useful hearing span of perhaps 60 to 1,000 Hz, but hear best from about 200 Hz up to 700 Hz, with their sensitivity falling off considerably below 200 Hz. The maximum sensitivity for one animal was at 300 Hz, and for another was at 400 Hz. At the 400 Hz frequency, the turtle's hearing threshold was about 64 dB in air. At 70 Hz, it was about 70 dB in air. Bartol et al. (1999) reported that juvenile loggerhead sea turtles hear sounds between 250 and 1,000 Hz. Lenhardt et al. (1983) applied audio-frequency vibrations at 250 Hz and 500 Hz to the heads of loggerheads and Kemp's ridleys submerged in salt water to observe their behavior, measure the attenuation of the vibrations, and assess any neural-evoked response. These stimuli (250 Hz, 500 Hz) were chosen as representative of the lowest sensitivity area of marine turtle hearing (Wever, 1978). At the maximum upper limit of the vibratory delivery system, the turtles exhibited abrupt movements, slight retraction of the head, and extension of the limbs in the process of swimming. Lenhardt et al. (1983) concluded that bone-conducted hearing appears to be a reception mechanism for at least some of the sea turtle species, with the skull and shell acting as receiving surfaces. Finally, sensitivity even within the optimal hearing range is apparently low as threshold detection levels in water are relatively high at 160 to 200 dB re 1 µPa-m (Lenhardt, 1994).

Five of the seven living species of sea turtles are known to occur in the HRC: the green, hawksbill, loggerhead, olive ridley, and leatherback turtles. Each of these species is protected under the ESA. However, critical habitat has not yet been designated for any of these species in the U.S. Pacific. A draft proposed rule was prepared in 1980 to designate critical habitat for the green turtle in the Hawaiian Islands, American Samoa, and the Trust Territories of the United States, but it was never approved by the U.S. Fish and Wildlife Service (USFWS) (Eckert, 1993).

Green, hawksbill, loggerhead, olive ridley, and leatherback turtles are all regular inhabitants of the HRC (i.e., they occur as a regular or normal part of the fauna in the HRC, regardless of how abundant or common they are). Green and hawksbill turtles are most common in offshore waters around the Main Hawaiian Islands and Nihoa, as they prefer to reside in reef-type environments that are less than about 55 fathoms in depth (U.S. Department of the Navy, 2005b). The green turtle is by far the most common species occurring in the offshore waters around the Hawaiian Islands; this is highly evidenced by the available stranding data for the Main Hawaiian Islands. More than 90 percent of all green turtle breeding and nesting activity in Hawaiian waters occurs at French Frigate Shoals in the Northwestern Hawaiian Islands, yet a substantial foraging population resides in and returns to the shallow, coastal waters surrounding the Main Hawaiian Islands (especially around Maui and Kauai). Hawksbill turtles are the second most common species in the offshore waters of the Hawaiian Islands, as also reflected by the stranding records, yet they are far less abundant than green turtles. Hawksbills occur around and nest on several of the Main Hawaiian Islands. Hawksbill nesting occurs primarily on the southeastern end of Hawaii and on the eastern end of Molokai (Aki et al., 1994).

Further offshore (in waters beyond the 55-fathom isobath), juvenile loggerheads forage in or migrate through the HRC as they move between North American developmental habitats and Japan. The highest densities of loggerheads can be found just north of the HRC within the North Pacific transition zone (Polovina et al., 2000). The highest densities of olive ridleys, on the other hand, are likely found just south of the HRC. The distribution of the olive ridley in the central Pacific Ocean is primarily tropical; as a result, they are often found in warmer waters than loggerheads (Polovina et al., 2004). The primary migration corridor for leatherbacks moving west from U.S. west coast foraging areas to western Pacific nesting and foraging areas lies along the southern edge of the HRC, while an eastward return corridor appears to pass through the northern portion of the HRC (U.S. Department of the Navy, 2005b).

Due to the offshore habitat preferences of the green and hawksbill turtles and the oceanic habitat preferences of the loggerhead, olive ridley, and leatherback turtles, the entire HRC is recognized as an area of primary occurrence for sea turtles. Since the Hawaiian Islands are situated in tropical waters that are warm year-round, the area of primary occurrence is the same in fall and winter as it is in spring and summer. Sea turtles are also known to come ashore at several locations throughout the Main Hawaiian Islands, for terrestrial basking (green turtles only) or nesting (primarily green and hawksbill turtles). Nesting/basking sites for sea turtles occur on all eight of the Main Hawaiian Islands. Of note are green turtle nesting/basking beaches located at PMRF Barking Sands on Kauai and a green turtle basking beach located along Kiholo Bay off the northwestern shore of Hawaii (National Ocean Service, 2001; U.S. Department of the Navy, 2004a). These beaches are located in areas where the HRC runs right up to the shoreline.

3.1.2.3.1 Green Turtle (*Chelonia mydas*)

Status. Green turtles are listed as threatened under the ESA, except for breeding populations found in Florida and the Pacific coast of Mexico, which are both listed as endangered. Commercial exploitation and uncontrolled subsistence harvest of nesters and eggs has resulted in a dramatic decline of nesting females at the two main nesting beaches in Michoacan, Mexico. A conservative estimate of the total number of adult females at these locations is 4,238. This population is considered to be stable for now, and estimated extinction probabilities indicate very low risks of quasi-extinction over the next 100 years (Snover, 2005). Green turtle populations are in serious decline throughout most of the rest of the Pacific Ocean, except for the Hawaiian population. The Hawaiian population of green turtles is its own distinct genetic haplotype.

The Hawaiian population of green turtles appears to have increased gradually over the past 30 years and currently has population sizes sufficient to warrant a status review (Balazs, 1995; Balazs and Chaloupka, 2004). This is presumably due to effective protection at primary nesting areas in the Northwestern Hawaiian Islands and better enforcement of regulations prohibiting take of the species.

A herpes virus is involved in a complex etiology of sea turtle fibropapilloma that affects the skin with large tumors (Herbst, 1994; Herbst et al., 1995; Quackenbush et al., 1998). Fibropapilloma may be caused by exposure to marine areas impacted by pollution such as runoff from agricultural, industrial, or urban sources (Aguirre and Lutz, 2004). Growth rates of green turtles were significantly lower in those with fibropapilloma tumors (Chaloupka and Balazs, 2005). Despite the occurrence of fibropapillomatosis, and spirochidiasis, both of which are major causes of stranding of this species, nester abundance has continued to increase (Balazs and Chaloupka 2004). The size of the green turtle population in the Pacific Ocean was estimated at about 21,000 adults in 2001 (National Marine Fisheries Service, 2005b; Seminoff, 2004).

Abundance and Distribution. Green turtles occur in the coastal waters surrounding the Main Hawaiian Islands throughout the year and also migrate seasonally to the Northwestern Hawaiian Islands to reproduce. Genetic analyses conducted by NMFS suggest that about 57 percent of the green turtles that have been captured in the Hawaii-based longline fisheries have been members of the endangered Mexican (Pacific coast) nesting aggregation, while 43 percent have represented the threatened Hawaiian (French Frigate Shoals) nesting aggregations. This EIS/OEIS assumes that these results are generally representative of the relative abundance of green turtles found in open ocean areas off the Main Hawaiian Islands.

Adult green turtles that breed in the Northwestern Hawaiian Islands make regular reproductive migrations from their foraging grounds either around the Main Hawaiian Islands or around the westernmost atolls in the Northwestern Hawaiian Islands. This has been evidenced by mark-recapture and satellite-tracking studies on both adult male and female green turtles (Balazs, 1976; 1983; Balazs and Ellis, 1998; Balazs et al., 1994). Juvenile green turtles can also make long-range movements throughout the Hawaiian archipelago. From June 2002 to March 2003, a captive-reared green turtle released off northwestern Hawaii traveled over 2,983 mi around the Hawaiian Islands, swimming as far west as the waters between Nihoa and Necker Islands before turning around and heading back to the Main Hawaiian Islands (Thompson, 2003).

The largest nesting colony in the central Pacific Ocean occurs at French Frigate Shoals in the Northwestern Hawaiian Islands, where about 200 to 700 females nest each year. On occasion, green turtles also nest in the Main Hawaiian Islands. The most famous nesting green turtle in the Main Hawaiian Islands is turtle 5690, known by sea turtle biologists as “Maui Girl.” This turtle, which was raised to a year old at Oahu’s Sea Life Park and then tagged and released, has nested on beaches near Lahaina, Maui in 2000, 2002, and 2004 (Leone, 2004). Other sporadic nesting events in the Main Hawaiian Islands have occurred along the north shore of Molokai, the northwest shore of Lanai, and the south, northeast, and southwest shores of Kauai (U.S. Department of the Navy, 2001a, 2002a; National Ocean Service, 2001).

The area of year-round primary occurrence for green turtles is located in waters inshore of the 55-fathom isobath (bathymetric contour of equal depth) around all of the Main Hawaiian Islands and Nihoa. It is in these areas where reefs, their preferred habitats for foraging and resting, are most abundant. The area of secondary occurrence encompasses an oceanic zone surrounding the Hawaiian Islands. This area is frequently inhabited by adults that are migrating to the Northwestern Hawaiian Islands to reproduce and by pelagic stage individuals that have yet to settle into coastal feeding grounds of the Main Hawaiian Islands. Further offshore of this seasonal use zone, green turtles occur in much lower numbers and densities. The occurrence of East Pacific green turtles in this oceanic habitat is documented through by-catch in the Hawaii-based longline fishery. These turtles may represent late stage pelagic juveniles from this population, but the reasons for their presence are otherwise not well understood.

3.1.2.3.2 Hawksbill Turtle (*Eretmochelys imbricata*)

Status. The hawksbill turtle is listed as endangered under the ESA. A lack of regular quantitative surveys for hawksbill turtles in the Pacific Ocean and the discrete nature of this species' nesting have made it extremely difficult for scientists to assess the distribution and population status of hawksbills in the region (National Marine Fisheries Service and U.S. Fish and Wildlife Service, 1998a; Seminoff et al., 2003).

Abundance and Distribution. Around the Hawaiian Islands, hawksbills are only known to occur in the coastal waters of the eight main and inhabited islands of the archipelago. Hawksbills forage throughout the Main Hawaiian Islands, although in much fewer numbers than green turtles. Hawksbills have been captured at several locations including Kiholo Bay and Kau (Hawaii), Palaau (Molokai), and Makaha (Oahu) (Hawaii Department of Land and Natural Resources, 2002). Strandings have been reported in Kaneohe and Kahana Bays (Oahu) as well as in other locations throughout the Main Hawaiian Islands (Eckert, 1993; National Marine Fisheries Service and U.S. Fish and Wildlife Service, 1998a). No reliable reports are known from Niihau (U.S. Department of the Navy, 2001a). Hawksbills are much more abundant in the shallow, offshore waters of the Hawaiian Islands than they are in deeper, offshore waters of the central Pacific Ocean.

Throughout the year, the area of primary occurrence for hawksbill turtles can be found in HRC waters shoreward of the 55-fathom isobath. Beyond the 55-fathom isobath, hawksbill occurrence is apparently rare year-round. Pelagic stage individuals may occur in oceanic waters off the Main Hawaiian Islands and Nihoa, but these life stages are nearly impossible to sight during surveys and rarely, if ever, interact with the pelagic longline fishery. Of the five sea turtle species known to occur in the HRC, the hawksbill is the only one that is not taken by Hawaiian longliners (Kobayashi and Polovina, 2005).

Since 1991, 81 nesting female hawksbills have been tagged on the Island of Hawaii at various locations, 22 tagged in the last 3 years. These do not include nesting females from Maui or Molokai which would add a small number to the total. While this appears to be an encouraging trend, Seitz and Kagimoto (2007) report that there are insufficient data to confirm an increasing population as yet.

3.1.2.3.3 Leatherback Turtle (*Dermochelys coriacea*)

Status. Leatherback turtles are listed as endangered under the ESA and are critically endangered with extinction in the Pacific Ocean. There are few quantitative data available concerning the seasonality, abundance, or distribution of leatherbacks in the central North Pacific Ocean. The leatherback is not typically associated with insular habitats, such as those characterized by coral reefs, yet individuals are occasionally encountered in deep ocean waters near prominent archipelagos such as the Hawaiian Islands (Eckert, 1993).

Abundance and Distribution. Based on the genetic sampling of 18 leatherback turtles in Hawaiian waters, about 94 percent of the leatherback turtles sampled originated from western Pacific nesting beaches (National Marine Fisheries Service, 2004b, 2005b). These turtles could represent individuals from Indonesia (Jamursba-Medi or War-Mon), Papua New Guinea (Kamiali or other areas of the Huon Gulf), Malaysia (Terrenganu), the Solomon Islands, or Fiji, although satellite tracks from leatherback turtles tagged in Papua New Guinea suggest that leatherback turtles from these islands tend to migrate south instead of north, which would take them away from the action area. The remaining 6 percent of the leatherback turtles found off the Main Hawaiian Islands represent nesting aggregations from the eastern tropical Pacific Ocean (Mexico and Costa Rica).

Leatherback turtles are regularly sighted by fishermen in offshore waters surrounding the Hawaiian Islands, generally beyond the 647-fathom contour, and especially at the southeastern end of the island chain and off the north coast of Oahu (Nitta and Henderson, 1993; Balazs, 1995; 1998). Leatherbacks encountered in these waters, including those caught incidental to fishing operations, may represent individuals in transit from one part of the Pacific Ocean to another (National Marine Fisheries Service and U.S. Fish and Wildlife Service, 1998b). Leatherbacks apparently have a wide geographic distribution throughout the region where the Hawaiian longline fishery operates, with sightings and reported interactions commonly occurring around seamount habitats located above the Northwestern Hawaiian Islands (from 35° to 45°N and 175° to 180°W) (Skillman and Balazs, 1992; Skillman and Kleiber, 1998).

McCracken (2000) has also documented incidental captures of leatherbacks at several offshore locations around the Main Hawaiian Islands. Although leatherback bycatch events are common occurrences off the archipelago, leatherback stranding events on its beaches are not. Since 1982, only five leatherbacks have stranded in the Hawaiian Islands (National Marine Fisheries Service, 2004c).

Satellite-tracking studies, a lack of Hawaiian stranding records, and occasional incidental captures of the species in the Hawaii-based longline fishery indicate that deep, oceanic waters are the most preferred habitats of leatherback turtles in the central Pacific Ocean. As a result, the area of year-round primary occurrence for the leatherback turtle encompasses all HRC waters beyond the 55-fathom isobath. Inshore of the 55-fathom isobath is the area of rare leatherback occurrence, which is the same year-round. Leatherbacks were not sighted during any of the aerial surveys for which data were collected, all of which took place over waters lying close to the Hawaiian shoreline. Leatherbacks were not sighted during any of the NMFS shipboard surveys either, although their deep diving capabilities and long submergence times lessen the probability that observers would be able to spot them during marine surveys.

3.1.2.3.4 Loggerhead Turtle (*Caretta caretta*)

Status. The loggerhead turtle is listed as threatened under the ESA. On July 16, 2007, NMFS received a petition from the Center for Biological Diversity and the Turtle Island Restoration Network requesting that loggerhead turtles in the North Pacific Ocean be reclassified as a Distinct Population Segment with endangered status and that critical habitat be designated. In a Federal Register Notice dated November 16, 2007 (National Marine Fisheries Service, 2007q) NMFS initiated a review of the status of the species to determine whether the petitioned action is warranted and to determine whether any additional changes to the current listing of the loggerhead turtle are warranted. NMFS requested information and comments which were due by January 15, 2008.

Abundance and Distribution. Loggerhead turtles found off the Main Hawaiian Islands represent turtles that nest on beaches in southern Japan, which includes about 1,500 adult females. According to the 2005 status review conducted by NMFS and USFWS (National Marine Fisheries Service and Fish and Wildlife Service 2007) it is probable that fewer than 1,000 females breed annually in Japan (Kamezaki *et al*., 2003). While annual nest numbers increased gradually from 1998 through 2004, these data are insufficient to conclude a trend. Based on a review of census data collected from most of the Japanese beaches from the 1950s through the 1990s, Kamezaki *et al*. (2003) concluded that a substantial decline (50-90 percent) occurred in the annual loggerhead nesting population in Japan in recent decades.

National Marine Fisheries Service and U.S. Fish and Wildlife Service (1998b) listed four records of this species for the Hawaiian Islands: two from the southeastern end of the archipelago, one from Kure Atoll (recovered from the stomach of a tiger shark [*Galeocerdo cuvier*]), and a fourth from the coast of Oahu (seen just offshore of the Sheraton Waikiki hotel). All four individuals were identified as juvenile loggerheads and most likely drifted or traveled to the region from either Mexico or Japan. A single male loggerhead turtle has also been reported to visit Lehua Channel and Keamano Bay (located off the north coast of Niihau) every June through July (U.S. Department of the Navy, 2001a; National Ocean Service, 2001). Only one loggerhead stranding has been recorded in the Hawaiian Islands since researchers began documenting them in 1982. This event, which was recorded along the shores of Kaneohe Bay, Oahu, was determined to be the result of a shark attack (National Marine Fisheries Service, , 2004c).

Genetic analyses indicate that nearly all of the loggerheads found in the North Pacific Ocean are born on nesting beaches in Japan (Bowen et al., 1995; Resendiz et al., 1998). Pacific loggerheads appear to utilize the entire North Pacific Ocean during the course of development, much like Atlantic loggerheads use the North Atlantic Ocean. There is substantial evidence that both stocks make two separate transoceanic crossings. The first crossing (west to east) is made immediately after hatching from the nesting beach, while the second (east to west) is made upon reaching either the late juvenile or adult life stage.

The area of primary occurrence for the loggerhead turtle spans all ocean waters off the Main Hawaiian Islands and Nihoa beyond the 55-fathom isobath. Incidental catches of loggerheads in the Hawaii-based longline fishery provided evidence of their presence and use of these waters for migrations and development (Polovina, et al., 2000). This area, like the area of rare occurrence, which can be found between the Hawaiian Islands shoreline and the 55-fathom isobath, is the same throughout the year. Occurrence in offshore waters is believed to be rare due to a lack of sighting and stranding records in those waters. Except for the four sighting and one stranding records listed previously, loggerheads have not been recorded at all on the Hawaiian shelf.

3.1.2.3.5 Olive Ridley Turtle (*Lepidochelys olivacea*)

Status. Olive ridley turtles are listed as threatened under the ESA, except for the Mexican nesting population, which is listed as endangered. Until the advent of commercial exploitation, the olive ridley was highly abundant in the eastern tropical Pacific Ocean, probably outnumbering all other sea turtle species combined in the area (National Marine Fisheries Service and U.S. Fish and Wildlife Service, 1998d). Clifton et al. (1995) estimated that a minimum of 10 million olive ridleys were present in ocean waters off the Pacific coast of Mexico prior to 1950. Even though there are no current estimates of worldwide abundance, the olive ridley is still considered the most abundant of the world's sea turtles. However, the number of olive ridley turtles occurring in U.S. territorial waters is believed to be small (National Marine Fisheries Service and U.S. Fish and Wildlife Service, 1998c).

The largest nesting aggregation in the world now occurs in the Indian Ocean along the northeast coast of India (Orissa), where in 1991 over 600,000 turtles nested in a single week (Mrosovsky, 1993). The second most important nesting area occurs in the eastern Pacific, along the west coast of Mexico and Central America (National Marine Fisheries Service and U.S. Fish and Wildlife Service, 1998d). Although increasing numbers of nests and nesting females have been observed in Mexico in recent years, the decline of the species continues in the eastern Pacific countries of Costa Rica, Guatemala, and Nicaragua. Egg loss has occurred from both legal and illegal collection, as well as natural loss due to nesting turtles inadvertently digging up previously laid nests. Population growth rate parameters calculated for the primary nesting site of Escobilla Beach, Oaxaca, Mexico indicate a negligible risk of extinction over the next several decades, given that current conservation practices are continued (Snover, 2005).

Abundance and Distribution. Genetic analyses of 44 olive ridleys captured in the Hawaii-based longline fishery concluded that 75 percent of these turtles (n=33) originated from the eastern Pacific (Mexico and Costa Rica) and 25 percent of the turtles (n=11) were from the Indian and western Pacific rookeries (National Marine Fisheries Service, 2005h).

About 61 percent of the sea turtles that interact (that are captured, killed, or both) with Hawaii-based longline fisheries are olive ridley turtles; more olive ridley turtles have been captured in these fisheries than all other sea turtles combined (National Marine Fisheries Service, 2005h). In addition, about 26 olive ridley turtles have stranded in the Hawaiian Islands since 1982, making it the third most common species to strand after greens and hawksbills (Hawaii Department of Land and Natural Resources, 2002). Available information suggests that olive ridleys traverse through the oceanic waters surrounding the Hawaiian Islands during foraging and developmental migrations (Nitta and Henderson, 1993).

In the Hawaiian Islands, a single olive ridley nest was recorded along Paia Bay, Maui in September 1985; however, there was no successful hatching associated with this event (Balazs and Hau, 1986; National Ocean Service, 2001). Since there are no other known nesting records for the central Pacific Ocean, the above nesting attempt should be considered an anomaly (National Marine Fisheries Service and U.S. Fish and Wildlife Service, 1998c).

3.1.2.4 MARINE MAMMALS

Marine mammals addressed within this EIS/OEIS include members of two orders: Cetacea, which includes whales, dolphins, and porpoises; and Carnivora, which includes true seals (family Phocidae) and sea lions (family Otariidae). Cetaceans spend their lives entirely at sea. Pinnipeds (seals and sea lions) hunt and feed exclusively in the ocean, and one of the species occurring in the areas addressed in this EIS/OEIS comes ashore to rest, mate, and bear young. There are 27 species of marine mammals that occur in the Hawaiian Islands area (Table 3.1.2.4-1). Most of the marine mammal species found in the Hawaiian Islands area are cetaceans, including 7 mysticetes (baleen whales) and 18 odonocetes (tooth whales and dolphins) with 2 pinniped species, both phocids (true seals). No otariids (sea lions and fur seals) or sirenians (dugongs and manatees) are found in the Hawaiian Islands area. Of the 27 marine mammal species, 7 species are considered endangered under the ESA and are considered a depleted and strategic stock under the 1972 Marine Mammal Protection Act (MMPA).

Information on the density of marine mammals used for the acoustic exposures modeling for MFA/HFA sonar and underwater detonations was primarily collected from Barlow (2006) and Mobley (2004). Information from the Hawaii Marine Resource Assessment (U.S. Department of the Navy, 2005a; Barlow, 2003; and Carretta, et al., 2006) was also used in the analysis. Barlow (2006) did not give a density estimate for fin (*Balaenoptera physalus*) and sei (*Balaenoptera borealis*) whales in Hawaii because the survey (originally analyzed in Barlow 2003) was not conducted during the peak period of abundance. Therefore, for the analysis undertaken in support of this EIS/OEIS, it was assumed that the number and density of fin and sei whales did not exceed that of the small population of false killer whales (*Pseudorca crassidens*) (236 false killer whales in Hawaii). Marine mammals inhabit most marine environments from deep ocean canyons to shallow estuarine waters. They are not randomly distributed. Marine mammal distribution is affected by demographic, evolutionary, ecological, habitat-related, and anthropogenic factors (Bowen et al., 2002; Bjørge, 2002; Forcada, 2002; Stevick et al., 2002). Marine mammal movements are often related to feeding or breeding activity (Stevick et al., 2002). A migration is the periodic movement of all, or significant components of, an animal population from one habitat to one or more other habitats and back again. Some baleen whale species, such as humpback whales (*Megaptera novaeangliae*), make extensive annual migrations to low-latitude mating and calving grounds in the winter and to high-latitude feeding grounds in the summer (Corkeron and Connor, 1999).

The oceanic waters surrounding the Hawaiian Islands do not contain a true continental shelf, and therefore no true shelf break—the region in which there is a sharp break in the slope of the island shelf (Kennett, 1982; Thurman, 1997). Rather, the HRC and vicinity is composed of a series of volcanic seamounts, several of which have broken the surface to form the Hawaiian Islands. Seamount topography has been previously correlated with enhanced production due to the formation of vortices capable of mixing nutrients to the surface and entraining phytoplankton in the overlying waters (Rogers, 1994).

Table 3.1.2.4-1. Summary of Hawaiian Islands Stock or Population of Marine Mammals

Order Cetacea	Scientific Name	Status	Occurs[1]	Group Size[2]	Detection Probability[3] Group 1-20	Group >20	Hawaii Abundance
MYSTICETES (baleen whales)							
Family Balaenidae (right whales)							
North Pacific right whale	*Eubalaena japonica*	E	Rare				UNK
Family Balaenopteridae (rorquals)							
Humpback whale	*Megaptera novaeangliae*	E	Regular	1.7			4,491
Minke whale	*Balaenoptera acutorostrata*		Regular				UNK
Sei whale	*Balaenoptera borealis*	E	Rare	3.4	0.90	0.90	236 [6]
Fin whale	*Balaenoptera physalus*	E	Rare	2.6	0.90	0.90	236 [6]

E = Endangered UNK = Unknown

In addition, the passage of the North Equatorial Current through the Hawaiian archipelago is capable of creating regions of enhanced turbulence. Passage of the current of the North Equatorial Current can initiate the formation of eddies on the lee side of the islands (Wolanski et al., 2003); these are capable of entraining phytoplankton and creating localized regions of enhanced primary production. In addition, passage of currents through a narrow channel (as found in the Alenuehaha Channel between Hawaii and Maui) can create localized zones of turbulent flow capable of mixing nutrients into the surface layer to fuel primary production (Gilmartin and Revelante, 1974; Simpson et al., 1982).

3.1.2.4.1 Marine Mammal Occurrence

Information on the abundance, behavior, distribution, and diving behavior of marine mammal species in the Hawaiian waters is based on peer reviewed literature including the most recent publications, the Navy Marine Resource Assessment, NMFS Stock Assessment Reports, marine mammals surveys using acoustics or visual observations from aircraft or ships, and previous environmental documents such as the Rim of the Pacific (RIMPAC) EA and supplements and the Undersea Warfare Exercise EA/Overseas EA and Incidental Harassment Authorization applications. Some specific definitions for terms used within this section of the document are required as they are not the same as used in other sections of the document. Information on each species is given relative to a specific definition of onshore (within 25 nm of shore) and offshore (beyond 25 nm from shore) habitats. A regular occurrence species is defined as a species that occurs as a regular or normal part of the fauna of the area, regardless of how abundant or common it is; a rare occurrence is a species that only occurs in the area sporadically; and an extralimital occurrence is a species that does not normally occur in the area, but for which there are one or more records that are considered beyond the normal range of the species. In this section, mysticetes are listed first, followed by odontocetes, then pinniped species (Table 3.1.2.4-1).

The acoustic abilities of marine mammals are important to their ability to communicate with conspecifics (offspring, mates, or competitors), navigation, foraging, and avoidance of predators. Little is known of the hearing abilities of mysticete whales, but generally they vocalize in low frequencies under 3 kHz, which may aid in long-range communication but do not echolocate (Review by Richardson et al., 1995a). The exception is the humpback whale, which may have a range up to 24 kHz (Au et al., 2006), and the north Atlantic right whale which may hear up to 22 kHz (Parks et al., 2004, 2007). It had been assumed that their hearing range was also under 3 kHz (Ketten, 1997) but from studies of vocalizations and anatomy, it may extend up to 24 kHz (Parks et al., 2004; Au et al., 2006; review by Southall et al., 2007). Odontocetes vocalize and echolocate over a much higher range of frequencies, ranging from below 1 kHz to 200 kHz (Review by Richardson et al., 1995a). Phocid seals, such as the Hawaiian monk seal (*Monachus schauinslandi*), hear underwater in the range of 2 to 40 kHz, with best hearing from 16 to 24 kHz (Thomas et al., 1990).

3.1.2.4.1.1 Mysticetes

North Pacific Right Whale (*Eubalaena japonica*)

Status. The North Pacific right whale is listed as endangered under the ESA and as a depleted and strategic stock under the MMPA (Carretta et al., 2005). Until recently, right whales in the North Atlantic and North Pacific were classified together as a single species, referred to as the "northern right whale." Genetic data indicate that these two populations represent separate species: the North Atlantic right whale (*Eubalaena glacialis*) and the North Pacific right whale (*Eubalaena japonica*) (Rosenbaum et al., 2000; Proposed in National Oceanic and Atmospheric Administration, 2006a).

The North Pacific right whale is perhaps the world's most endangered large whale species (Perry et al., 1999; International Whaling Commission, 2001). North Pacific right whales are classified as endangered both under the ESA and on the IUCN Red List (Reeves et al., 2003). There are insufficient genetic or resighting data to address whether there is support for the traditional separation into eastern and western stocks (Brownell et al., 2001); however, Clapham et al. (2004) noted that north–south migratory movements support the hypothesis of two largely discrete populations of right whales in the eastern and western North Pacific. No reliable population estimate presently exists for this species; the population in the eastern North Pacific is considered to be very small, perhaps only in the tens of animals (National Marine Fisheries Service, 2002a; Clapham et al., 2004), while in the western North Pacific, the population may number at least in the low hundreds (Brownell et al., 2001; Clapham et al., 2004). There is no proposed or designated critical habitat for the North Pacific right whale in the HRC.

Abundance and Distribution. Right whales occur in sub-polar to temperate waters. The North Pacific right whale historically occurred across the Pacific Ocean north of 35°N, with concentrations in the Gulf of Alaska, eastern Aleutian Islands, south-central Bering Sea, Sea of Okhotsk, and the Sea of Japan (Omura et al., 1969; Scarff, 1986; Clapham et al., 2004). Presently, sightings are extremely rare, occurring primarily in the Okhotsk Sea and the eastern Bering Sea (Brownell et al., 2001; Shelden et al., 2005). Prior to 1996, right whale sightings were very rare in the eastern North Pacific (Scarff, 1986; Brownell et al., 2001). Recent summer sightings of right whales in the eastern Bering Sea represent the first reliable consistent observations in this area since the 1960s (Tynan et al., 2001; LeDuc, 2001).

Neither the west coast of North America nor the Hawaiian Islands constituted a major calving ground for right whales within the last 200 years (Scarff, 1986). No coastal calving grounds for right whales have been found in the western North Pacific either (Scarff, 1986). Mid-ocean whaling records of right whales in the winter suggest that right whales may have wintered and calved far offshore in the Pacific (Scarff, 1986; 1991; Clapham et al., 2004). Such pelagic calving would appear to be inconsistent with the records of offshore calving grounds in other locales for the other right whale species.

There are very few recorded sightings from the Hawaiian Islands; they are from both shallow and deep waters (Herman et al., 1980; Rowntree et al., 1980; Salden and Mickelsen, 1999). Secondary occurrence is expected from the coastline to seaward of the HRC boundaries. Right whales are not expected to make their way into lagoons or busy harbors; therefore, occurrence in Pearl Harbor is expected to be rare to nonexistent (U.S. Department of the Navy, 2005b). Right whale occurrence patterns are assumed to be similar throughout the year. Based on migration patterns and whaling data, the Hawaiian Islands may have been a breeding ground for North Pacific right whales in the past (Clapham et al., 2004).

Reproduction/Breeding. Calving primarily occurs from December through March (Best, 1994).

Diving Behavior. Dives of 5 to 15 min or even longer have been reported (Winn et al., 1995; Mate et al., 1997; Baumgartner and Mate, 2003). Baumgartner and Mate (2003) found that the average depth of a North Atlantic right whale dive was strongly correlated with both the average depth of peak copepod abundance and the average depth of the bottom mixed layer's upper surface. North Atlantic right whale feeding dives are characterized by a rapid descent from the surface to a particular depth between 262 and 574 ft, remarkable fidelity to that depth for 5 to 14 min, and then rapid ascent back to the surface (Baumgartner and Mate, 2003). Longer surface intervals have been observed for reproductively active females and their calves (Baumgartner and Mate, 2003).

Acoustics. North Pacific right whale calls are classified into five categories: (1) up; (2) down-up; (3) down; (4) constant; and (5) unclassified (McDonald and Moore, 2002). The "up" call is the predominant type (McDonald and Moore, 2002; Mellinger et al., 2004). Typically, the "up" call is a signal sweeping from about 90 to 150 Hz in 0.7 sec and could be detected out to 13.5 nm (McDonald and Moore, 2002). Wiggins et al. (2004) recorded upsweeping low frequency (90 to 160 kHz) calls of North Pacific right whales in the Bering Sea. Right whales commonly produce calls in a series of 10 to 15 calls lasting 5 to 10 min, followed by silence lasting an hour or more; some individuals do not call for periods of at least 4 hours (McDonald and Moore, 2002). This calling pattern is similar to the "moan cluster" reported for North Atlantic right whales by Matthews et al. (2001). Vocalization rates of North Atlantic right whales are also highly variable, and individuals have been known to remain silent for hours (Gillespie and Leaper, 2001).

Frequencies of these vocalizations are between 50 and 500 Hz (Matthews et al., 2001; Laurinolli et al., 2003); typical sounds are in the 300 to 600 Hz range with up- and down-sweeping modulations (Vanderlaan et al., 2003). Vanderlaan et al. (2003) found that lower (<200 Hz) and higher (>900 Hz) frequency sounds are relatively rare. Source levels have been estimated only for pulsive calls of North Atlantic right whales, which are 172 to 187 dB re 1 µPa-m (Richardson et al., 1995a).

Morphometric analyses of the inner ear of right whales resulted in an estimated hearing frequency range of approximately 10 Hz to 22 kHz, based on established marine mammal models (Parks et al., 2004; 2007). Research by Nowacek et al. (2004) on North Atlantic right whales suggests that received sound levels of only 133 to 148 dB re 1 µPa at 500 Hz to 4.5 kHz for the duration of the sound exposure (three signals of 2 min each played over 18 min) are likely to disrupt feeding behavior. The authors did note, however, that a return to normal behavior within minutes of when the source is turned off would be expected. While some of the upper frequencies approach those of MFA sonar, the signals were not similar because they were either too low in frequency range or longer and contain a down sweep signal 4,500 to 500 Hz.

Humpback Whale (*Megaptera novaeangliae*)

Status. The humpback whale is listed as endangered under the ESA and as a depleted and strategic stock under the MMPA (Carretta et al., 2005). There is no designated critical habitat for this species in the North Pacific. Humpback whales and other marine mammals are of interest from a cultural perspective to some Native Hawaiians and other people (National Oceanic and Atmospheric Administration, 2003).

Abundance and Distribution. The best available estimate of abundance for the Central West Pacific stock of the humpback whales is 4,491 individuals (Mobley, 2004). Humpback whales use Hawaiian waters as a major breeding ground during winter and spring (November through April). Evidence suggests that some humpback whales may move between the waters of Japan in the Western North Pacific (Darling and Cerchio, 1993; Salden, et al., 1999; Calambokidis et al., 2001; Witteveen et al., 2004). Calambokidis et al. (1997) estimated that up to half of the North Pacific populations of humpback whales migrate to the Hawaiian Islands during the winter. Peak abundance around the Hawaiian Islands is from late February through early April (Mobley et al., 2001a; Carretta et al., 2005). During the fall–winter period, primary occurrence is expected from the coast to 50 nm offshore, which takes into consideration both the available sighting data and the preferred breeding habitat (shallow waters) (Herman and Antinoja, 1977; Mobley et al., 1999, 2000, 2001a). The greatest densities of humpback whales (including calves) are in the four-island region consisting of Maui, Molokai, Kahoolawe, and Lanai, as well as Penguin Bank (Baker and Herman, 1981; Mobley et al., 1999; Maldini, 2003) and around Kauai (Mobley, 2005). Secondary occurrence is expected from seaward of this area, past the HRC boundaries. Humpback whales are not expected to be in Pearl Harbor, though an anomalous sighting of an adult and calf was reported during 1998 and 2003 (U.S. Department of the Navy, 2005b). The occurrence of humpback whales in deeper waters is based on work in the Caribbean (the breeding ground for humpback whales in the North Atlantic), where humpback whale calls were acoustically detected over deep water, far from any banks or islands (Swartz et al., 2002; Frankel et al., 1995).

During the spring–summer period, secondary occurrence is expected offshore out to 50 nm, mainly to account for the possible occurrence of humpback whales during the end of the breeding season (April). Humpback whales return to the feeding grounds of near northern California to the Aleutian Islands as determined by comparing songs (McSweeney et al., 1989) and recording the migration path of animals with satellite tags (Mate et al., 1998). Occurrence further offshore, as well as in Pearl Harbor, is expected to be rare.

The Hawaiian Islands Humpback Whale National Marine Sanctuary was signed into law in November 1992. The Final EIS/Management Plan was released in March 1997, and the final rule was published in November 1999. Activities allowed within the Sanctuary are all classes of military activities, internal or external to the Sanctuary, that were being or had been conducted before the effective date of the regulations, as identified in the Final EIS/Management Plan. The sanctuary includes specific areas from the coast of the Hawaiian Islands seaward to the 100-fathom isobath.

Reproduction/Breeding. Most of the central north Pacific stock of humpback whales migrate south to Hawaii in winter for breeding and calving from December through April (Clapham and Mead, 1999; Mobley et al., 2001a).

Diving Behavior. Humpback whale diving behavior depends on the time of year (Clapham and Mead, 1999). In summer, most dives last less than 5 min; those exceeding 10 min are atypical. In winter (December through March), dives average 10 to 15 min; but dives of greater than 30 min have also been recorded (Clapham and Mead, 1999). Although humpback whales have been recorded to dive as deep as about 273 fathoms (Dietz et al., 2002), on the feeding grounds they spend the majority of their time in the upper 66 fathoms of the water column (Dolphin, 1987; Dietz et al., 2002). Humpback whales on the wintering grounds do dive deeply; Baird et al. (2000) recorded dives are to a maximum of 577 ft.

Acoustics. Humpback whales are known to produce three classes of vocalizations: (1) “songs” in the late fall, winter, and spring by solitary males; (2) sounds made within groups on the wintering (calving) grounds; and (3) social sounds made on the feeding grounds (Richardson et al., 1995a). The best-known types of sounds produced by humpback whales are songs, which are thought to be breeding displays used only by adult males (Helweg et al., 1992). Singing is most common on breeding grounds during the winter and spring months, but is occasionally heard outside breeding areas and out of season (Matilla et al., 1987; Clark and Clapham, 2004). There is geographical variation in humpback whale song, with different populations singing different songs, and all members of a population using the same basic song. However, the song evolves over the course of a breeding season, but remains nearly unchanged from the end of one season to the start of the next (Payne et al., 1983). Social calls are from 50 Hz to over 10 kHz, with the highest energy below 3 kHz (Silber, 1986). Female vocalizations appear to be simple; Simão and Moreira (2005) noted little complexity. The male song, however, is complex and changes between seasons. Components of the song range from under 20 Hz to 4 kHz and occasionally 8 kHz, with source levels of 144 to 174 dB re 1 µPa-m, with a mean of 155 dB re 1 µPa-m. Au et al. (2001) recorded high-frequency harmonics (out to 13.5 kHz) and source level (between 171 and 189 dB re 1 µPa-m) of humpback whale songs. (Au et al., 2001) Songs have also been recorded on feeding grounds (Mattila et al., 1987; Clark and Clapham, 2004). Zoidis et al. (2008) recorded humpback whale calves in Hawaii and reported that they produced simple structured vocalizations that were mostly low frequency (140 to 4,000 Hz with a mean of 220 Hz).

The main energy of the song lies between 0.2 and 3.0 kHz, with frequency peaks at 4.7 kHz. Feeding calls, unlike song and social sounds, are highly stereotyped series of narrow-band trumpeting calls. They are 20 Hz to 2 kHz, less than 1 sec in duration, and have source levels of 175 to 192 dB re 1 µPa-m. The fundamental frequency of feeding calls is approximately 500 Hz (D'Vincent et al., 1985).

No tests on humpback whale hearing have been made. Houser et al. (2001) constructed a humpback audiogram using a mathematical model based on the internal structure of the ear. The predicted audiogram indicates sensitivity to frequencies from 700 Hz to 10 kHz, with maximum relative sensitivity between 2 and 6 kHz. Maybaum (1989) reported that humpback whales showed a mild response to a hand held sonar marine mammal detection and location device (frequency of 3.3 kHz at 219 dB re 1 µPa at 1 meter or frequency sweep of 3.1 to 3.6 kHz), although this system is very different from the Navy's hull mounted sonars. In addition, the system had some low frequency components (below 1 kHz), which may be an artifact of the acoustic equipment. This may have affected the response of the whales to both the control and sonar playbacks. Humpback whales also stop singing in response to playbacks of the singing or social sounds of conspecifics (Tyack, 1983). Miller et al. (2000) reported that humpback whales sang longer during playbacks of low-frequency active sonar, which is much lower in frequency than the MFA sonar described in this EIS/OEIS. Recent information on the songs of humpback whales suggests that their hearing may extend to frequencies of at least 24 kHz (Au et al., 2006).

Minke Whale (*Balaenoptera acutorostrata*)

<u>Status</u>. The minke whale is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al*.,* 2005). The International Whaling Commission (IWC) recognizes three stocks of minke whales in the North Pacific: one in the Sea of Japan/East China Sea, one in the rest of the western Pacific west of 180°N, and one in the remainder of the Pacific (Donovan, 1991). For the National Oceanic and Atmospheric Administration (NOAA) stock assessment report, there are three stocks of minke whales within the U.S. Pacific EEZ: (1) a Hawaiian stock; (2) a California/Oregon/ Washington stock; and

(3) an Alaskan stock (Carretta et al*.,* 2005). There currently is no abundance estimate for the Hawaiian stock of minke whales, which appears to occur seasonally (approximately November through March) around the Hawaiian Islands (Carretta et al*.,* 2005).

Abundance and Distribution. There currently is no abundance estimate for the Hawaiian stock of minke whales, which appears to occur seasonally (approximately November through March) around the Hawaiian Islands (Carretta et al*.,* 2005). Mating is thought to occur in winter or early spring (Stewart and Leatherwood, 1985).

Minke whales are distributed in polar, temperate, and tropical waters (Jefferson et al*.,* 1993); they are less common in the tropics than in cooler waters. Minke whales are present in the North Pacific from near the equator to the Arctic (Horwood, 1990). The summer range extends to the Chukchi Sea (Perrin and Brownell, 2002). In the winter, minke whales are found south to within 2° of the equator (Perrin and Brownell, 2002). The distribution of minke whale vocalizations (specifically, “boings”) suggests that the winter breeding grounds are the offshore tropical waters of the North Pacific Ocean (Rankin and Barlow, 2003). There is no obvious migration from low-latitude, winter breeding grounds to high-latitude, summer feeding locations in the western North Pacific, as there is in the North Atlantic (Horwood, 1990); however, there are some monthly changes in densities in both high and low latitudes (Okamura et al*.,* 2001). In the northern part of their range, minke whales are believed to be migratory, whereas they appear to establish home ranges in the inland waters of Washington and along central California (Dorsey*,* 1983) and exhibit site fidelity to these areas between years (Borggaard et al*.,* 1999).

The minke whale is expected to occur seasonally in the HRC (Barlow, 2003). Abundance is expected to be higher between November and March (Carretta et al*.,* 2005). Therefore, an area of secondary occurrence is seaward of the shoreline during the fall–winter period. Both visual and acoustic detections of minke whales have been reported for this area (Balcomb, 1987; Thompson and Friedl, 1982; Barlow et al*.,* 2004; Carretta et al*.,* 2005; Norris et al*.,* 2005). The occurrence pattern takes into account both sightings in shallow waters in some locales globally as well as the anticipated oceanic occurrence of this species (U.S. Department of the Navy 2005b). “Boings” were recorded in waters with a bottom depth of approximately 700 to 2,100 fathoms (Norris et al*.,* 2005). Norris et al. *(*2005) reported sighting a minke whale 58 mi southwest of Kauai, in waters with a bottom depth of approximately 1,400 fathoms (U.S. Department of the Navy, 2005b). During the spring–summer period, there is a rare occurrence for the minke whale throughout the entire HRC although recent evidence from passive acoustic monitoring suggests that there may be more minke whales in the HRC than previously thought (Rankin and Barlow, 2005; Barlow 2006).

Reproduction/Breeding. Stewart and Leatherwood (1985) suggested that mating occurs in winter or early spring although it had never been observed. No breeding or calving areas for Hawaii have been described.

Diving Behavior. Stern (1992) described a general surfacing pattern of minke whales consisting of about four surfacings, interspersed by short-duration dives averaging 38 sec. After the fourth surfacing, there was a longer duration dive ranging from approximately 2 to 6 min. Minke whales are “gulpers,” like the other rorquals (baleen whales) (Pivorunas, 1979). Hoelzel et al. (1989) reported on different feeding strategies used by minke whales. In the North Pacific, major food items include krill, Japanese anchovy (*Engraulis japonicus)*, Pacific saury (*Cololabis saira)*, and walleye pollock (*Theragra chalcogramma*) (Perrin and Brownell, 2002).

Acoustics. Recordings in the presence of minke whales have included both high-and low-frequency sounds (Beamish and Mitchell, 1973; Winn and Perkins, 1976; Mellinger et al., 2000). Mellinger et al. (2000) described two basic forms of pulse trains that were attributed to minke whales: a “speed up” pulse train with energy in the 200 to 400 Hz band, with individual pulses lasting 40 to 60 milliseconds, and a less-common “slow-down” pulse train characterized by a decelerating series of pulses with energy in the 250 to 350 Hz band. Recorded vocalizations from minke whales have dominant frequencies of 60 Hz to greater than 12,000 Hz, depending on vocalization type (Richardson et al., 1995a). Recorded source levels, depending on vocalization type, range from 151 to 175 dB re 1 µPa-m (Ketten, 1998). Gedamke et al. (2001) recorded a complex and stereotyped sound sequence (“star-wars vocalization”) in the Southern Hemisphere that spanned a frequency range of 50 Hz to 9.4 kHz. Broadband source levels between 150 and 165 dB re 1 µPa-m were calculated. “Boings,” recently confirmed to be produced by minke whales and suggested to be a breeding call, consist of a brief pulse at 1.3 kHz, followed by an amplitude-modulated call with greatest energy at 1.4 kHz, with slight frequency modulation over a duration of 2.5 sec (Anonymous, 2002; Rankin and Barlow, 2003). While no data on hearing ability for this species are available, Ketten (1997) hypothesized that mysticetes have acute infrasonic hearing.

Sei Whale (*Balaenoptera borealis*)

Status. The sei whale is listed as endangered under the ESA and as a depleted and strategic stock under the MMPA (Carretta et al*.,* 2005). The IWC designates the entire North Pacific Ocean as one sei whale stock unit (Donovan, 1991), although some evidence exists for multiple stocks (National Marine Fisheries Service, 1998; Carretta et al*.,* 2005). For the NOAA stock assessment reports, sei whales within the Pacific EEZ are divided into three discrete, non-contiguous areas: (1) the Hawaiian stock; (2) California/Oregon/Washington stock; and (3) the Eastern North Pacific (Alaska) stock (Carretta et al*.,* 2005).

The taxonomy of the baleen whale group formerly known as sei and Bryde’s whales is currently confused and highly controversial (see Reeves et al*.,* 2004 for a recent review, also see the Bryde’s whale species account below for further explanation).

Abundance and Distribution. Barlow (2006) did not give a density estimate for sei whales in Hawaii because the survey (originally analyzed in Barlow, 2003) was not conducted during the peak period of abundance. Therefore, for the analysis undertaken in support of this EIS/OEIS, it was assumed that the number and density of sei whales did not exceed that of the small population of false killer whales (236 false killer whales in Hawaii). There is no information on the population trend of sei whales. Sei whales have a worldwide distribution, but are found primarily in cold temperate to subpolar latitudes, rather than in the tropics or near the poles (Horwood, 1987). Sei whales are also known for occasional irruptive occurrences in areas followed by disappearances for sometimes decades (Horwood, 1987; Schilling et al*.,* 1992; Clapham et al*.,* 1997).

Sei whales spend the summer months feeding in the subpolar higher latitudes and return to the lower latitudes to calve in winter. There is some evidence from whaling catch data of differential migration patterns by reproductive class, with females arriving at and departing from feeding areas earlier than males (Horwood, 1987; Perry et al., 1999). For the most part, the location of winter breeding areas remains a mystery (Rice, 1998; Perry et al., 1999). In the North Pacific, sei whales are thought to occur mainly south of the Aleutian Islands. They are present all across the temperate North Pacific north of 40°N (National Marine Fisheries Service, 1998) and are seen at least as far south as 20°N (Horwood, 1987). In the east, they range as far south as Baja California, Mexico, and in the west, to Japan and Korea (Reeves et al., 1999). As noted by Reeves et al. (1999), reports in the literature from any time before the mid-1970s are suspect, because of the frequent failure to distinguish sei from Bryde's whales, particularly in tropical to warm temperate waters where Bryde's whales are generally more common than sei whales.

The sei whale is considered to be rare in Hawaiian waters based on reported sighting data and the species' preference for cool, temperate waters. Secondary occurrence is expected seaward of the 1,640-fathom isobath on the north side of the islands only. This pattern was based on sightings made during the NMFS–Southwest Fisheries Science Center shipboard survey assessment of Hawaiian cetaceans (Barlow et al., 2004). Sei whales are expected to be rare throughout the remainder of the HRC. Occurrence patterns are expected to be the same throughout the year.

<u>Reproduction/Breeding</u>. No breeding areas have been determined but calving is thought to occur from September to March (Rice 1977). No breeding or calving areas for Hawaii have been described.

<u>Diving Behavior</u>. There are no reported diving depths or durations for sei whales.

<u>Acoustics</u>. Sei whale vocalizations have been recorded only on a few occasions. They consist of paired sequences (0.5 to 0.8 sec, separated by 0.4 to 1.0 sec) of 7 to 20 short (4 milliseconds) frequency modulated sweeps between 1.5 and 3.5 kHz; source level is not known (Richardson et al., 1995a). Sei whales in the Antarctic produced broadband "growls" and "whooshes" at a frequency of 433 ±192 kHz and source level of 156 ±3.6 dB re 1 µPa at 1 meter (Mc Donald et al., 2005).

Although no data on hearing ability for this species are available, Ketten (1997) hypothesized that mysticetes have acute infrasonic hearing.

Fin Whale (*Balaenoptera physalus*)

<u>Status</u>. The fin whale is listed as endangered under the ESA and as a depleted and strategic stock under the MMPA. There is no designated critical habitat for this species in the North Pacific. The IWC recognizes two management stocks in the North Pacific: a single widespread stock in the North Pacific and a smaller stock in the East China Sea (Donovan, 1991). The NOAA stock assessment report recognizes three stocks of fin whales in the North Pacific: (1) the Hawaii stock; (2) the California/Oregon/Washington stock; and (3) the Alaska stock (Carretta et al., 2005). There is no information on the population trend of fin whales.

<u>Abundance and Distribution</u>. Barlow (2006) did not give a density estimate for fin whales in Hawaii because the survey (originally analyzed in Barlow 2003) was not conducted during the peak period of abundance. Therefore, for the analysis undertaken in support of this EIS/OEIS, it was assumed that the number and density of fin whales did not exceed that of the small population of false killer whales (236 false killer whales in Hawaii). There is no information on

the population trend of fin whales. Fin whales are broadly distributed throughout the world's oceans, usually in temperate to polar latitudes, and less commonly in the tropics (Reeves et al., 2002). Fin whales are distributed across the North Pacific during the summer (May through October) from the southern Chukchi Sea (69°N) south to the Subarctic Boundary (approximately 42°N) and to 30°N in the California Current (Mizroch et al., 1999). They have been observed during the summer in the central Bering Sea (Moore et al., 2000).

Fin whales are not common in the Hawaiian Islands. Sightings were reported north of Oahu in May 1976, the Kauai Channel in February 1979, and north of Kauai in February 1994 (Shallenberger, 1981; Mobley et al., 1996). Thompson and Friedl (1982) suggested that fin whales migrate into Hawaiian waters mainly during fall and winter, based on acoustic recordings off the island of Oahu and the Midway Atoll (Northrop et al., 1971; McDonald and Fox, 1999). Primary occurrence is expected seaward of the 330-ft isobath during the fall-winter period to account for possible stragglers migrating through the area. There is a rare occurrence for the fin whale from the shore to the 55-fathom isobath. There is a rare occurrence of fin whales throughout the Hawaiian Islands during the spring–summer period.

<u>Reproduction/Breeding</u>. Reproductive activities for fin whales occur primarily in low latitude areas in the winter (Reeves 1998; Carretta et al. 2007). No breeding or calving areas for Hawaii have been described.

<u>Diving Behavior</u>. Fin whales typically dive for 5 to 15 min, separated by sequences of 4 to 5 blows at 10 to 20 sec intervals (Cetacean and Turtle Assessment Program, 1982; Stone et al., 1992; Lafortuna et al., 2003). Kopelman and Sadove (1995) found significant differences in blow intervals, dive times, and blows per hour between surface feeding and non-surface feeding fin whales. Croll et al. (2001) determined that fin whales dived to 321 ft ± 106.8 ft) with a duration of 6.3 min (standard deviation = ±1.53 min) when foraging and to 194 ft (standard deviation = ±97 ft) with a duration of 4.2 min (standard deviation = ±1.67 min) when not foraging. Goldbogen et al. (2006) reported that fin whales in California made foraging dives to a maximum of 748 to 889 ft and dive durations of 6.2 to 7.0 min. Fin whale dives exceeding 492 ft and coinciding with the diel migration of krill were reported by Panigada et al. (1999).

<u>Acoustics</u>. Fin whales produce calls with the lowest frequency and highest source levels of all cetaceans. Infrasonic, pattern sounds have been documented for fin whales (Watkins et al., 1987; Clark and Fristrup, 1997; McDonald and Fox, 1999). Fin whales produce a variety of sounds with a frequency range up to 750 Hz. The long, patterned 15 to 30-Hz vocal sequence is most typically recorded; only males are known to produce these (Croll et al., 2002). The most typical fin whale sound is a 20-Hz infrasonic pulse call (actually an FM sweep from about 23 to 18 Hz) with durations of about 1 sec and can reach source levels of 184 to 186 dB re 1 µPa-m (maximum up to 200) (Richardson et al., 1995a; Charif et al., 2002). Croll et al. (2002) recently suggested that these long, patterned vocalizations might function as male breeding displays, much like those that male humpback whales sing. The source depth, or depth of calling fin whales, has been reported to be about 27 fathoms (Watkins et al., 1987). While no data on hearing ability for this species are available, Ketten (1997) hypothesized that mysticetes have acute infrasonic hearing.

Blue Whale (*Balaenoptera musculus*)

Status. The blue whale is listed as endangered under the ESA and as a depleted and strategic stock under the MMPA. The NMFS considers blue whales found in Hawaii as part of the Western North Pacific stock (Carretta et al., 2005) due to differences in call types with the Eastern North Pacific stock (Stafford et al., 2001; Stafford, 2003). The blue whale was severely depleted by commercial whaling in the twentieth century (National Marine Fisheries Service, 1998). There is no designated critical habitat for this species in the North Pacific. There is no information on the population trend of blue whales.

Abundance and Distribution. Blue whales are distributed from the ice edges to the tropics in both hemispheres (Jefferson et al., 1993). Blue whales summer in high latitudes and move into the subtropics and tropics during the winter calving period (Yochem and Leatherwood, 1985). Data from both the Pacific and Indian Oceans, however, indicate that some individuals may remain in low latitudes year-round, such as over the Costa Rican Dome (Wade and Friedrichsen, 1979; Reilly and Thayer, 1990). The productivity of the Costa Rican Dome may allow blue whales to feed during their winter calving/breeding season and not fast, like humpback whales (Mate et al., 1999).

The only reliable sighting report of this species in the central North Pacific was a sighting made from a scientific research vessel about 216 nm northeast of Hawaii in January 1964 (National Marine Fisheries Service, 1998). There is a rare occurrence for the blue whale throughout the entire HRC. Blue whale calls have been recorded off the Midway Atoll and Oahu (Northrop et al., 1971; Thompson and Friedl, 1982; McDonald and Fox, 1999); these provide evidence of blue whales occurring within several hundred miles of these islands (National Marine Fisheries Service, 1998). The recordings made off Oahu showed bimodal peaks throughout the year, suggesting that the animals were migrating into the area during summer and winter (Thompson and Friedl, 1982; McDonald and Fox, 1999). The greatest likelihood of encountering blue whales would be in waters deeper than 55 fathoms, based on observations in locales where blue whales are seen regularly (Schoenherr, 1991).

Reproduction/Breeding. Calving occurs primarily during the winter (Yochem and Leatherwood, 1985). No breeding or calving areas for Hawaii have been described.

Diving Behavior. Blue whales spend more than 94 percent of their time below the water's surface (Lagerquist et al., 2000). Croll et al. (2001) determined that blue whales dive to an average of 462 ft for 7.8 min when foraging and to 222 ft for 4.9 min when not foraging. Calambokidis et al. (2003) deployed tags on blue whales and collected data on dives as deep as about 164 fathoms.

Acoustics. Blue whales produce calls with the lowest frequency and highest source levels of all cetaceans. Blue whale vocalizations are long, patterned low-frequency sounds with durations up to 36 sec (Richardson et al., 1995a) repeated every 1 to 2 min (Mellinger and Clark, 2003). Their frequency range is 12 to 400 Hz, with dominant energy in the infrasonic range at 12 to 25 Hz (Ketten, 1998; Mellinger and Clark, 2003). Source levels are up to 188 dB re 1 µPa-m over a frequency of 10 to 110 Hz (Ketten, 1998; McDonald et al., 2001). During the Magellan II Sea Test (at sea exercises designed to test systems for anti-submarine warfare) off the coast of California in 1994, blue whale vocalization source levels at 17 Hz were estimated in the range of 195 dB re 1 µPa-m (Aburto et al., 1997).

Vocalizations of blue whales appear to vary among geographic areas (Rivers, 1997), with clear differences in call structure suggestive of separate populations for the western and eastern regions of the North Pacific (Stafford et al., 2001). Stafford et al. (2005) recorded the highest calling rates when blue whale prey was closest to the surface during its vertical migration. Wiggins et al. (2005) reported the same trend of reduced vocalization during daytime foraging and then an increase in vocalizations at dusk as prey move up into the water column and disperse. Blue whales make seasonal migrations to areas of high productivity to feed and vocalize less in the feeding grounds than during the migration (Burtenshaw et al., 2004). Oleson et al. (2007) reported higher calling rates in shallow diving (<16 fathoms) whales while deeper diving (>27 fathoms) whales were likely feeding and calling less. Although no data on hearing ability for this species are available, Ketten (1997) hypothesized that mysticetes have acute infrasonic hearing.

Bryde's Whale (*Balaenoptera edeni*)

<u>Status</u>. The Bryde's whale is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). Bryde's whales can be easily confused with sei whales. It is not clear how many species of Bryde's whales there are, but genetic analyses suggest the existence of at least two species (Rice, 1998; Kato, 2002). The taxonomy of the baleen whale group formerly known as sei and Bryde's whales is currently confused and highly controversial (see Reeves et al., 2004 for a recent review).

The IWC recognizes three management stocks of Bryde's whales in the North Pacific: western North Pacific, eastern North Pacific, and East China Sea (Donovan, 1991). There is currently no biological basis for defining separate stocks of Bryde's whales in the central North Pacific (Carretta et al., 2005). For the NOAA stock assessment reports, Bryde's whales within the U.S. Pacific EEZ are divided into two areas: (1) Hawaiian waters, and (2) the eastern tropical Pacific (east of 150°W and including the Gulf of California and waters off California) (Carretta et al., 2005).

<u>Abundance and Distribution</u>. The best available estimate of abundance for the Hawaiian stock of the Bryde's whale is 469 (Coefficient of Variation [CV] = 0.45) individuals (Barlow, 2006). The Bryde's whale is found in tropical and subtropical waters, generally not moving poleward of 40° in either hemisphere (Jefferson et al., 1993). Long migrations are not typical of Bryde's whales, though limited shifts in distribution toward and away from the equator, in winter and summer, respectively, have been observed (Cummings, 1985). In summer, the distribution of Bryde's whales in the western North Pacific extends as far north as 40°N, but many individuals remain in lower latitudes, as far south as about 5°N. Data also suggest that winter and summer grounds partially overlap in the central North Pacific (Kishiro, 1996; Ohizumi et al., 2002). Bryde's whales are also distributed in the central North Pacific in summer; the southernmost summer distribution of Bryde's whales inhabiting the central North Pacific is about 20°N (Kishiro, 1996). Some whales remain in higher latitudes (around 25°N) in both winter and summer (Kishiro, 1996).

Bryde's whales are seen year-round throughout tropical and subtropical waters (Kato, 2002) and are also expected in the HRC year-round (U.S. Department of the Navy 2005b). It should be noted that more sightings are reported for the Northwest Hawaiian Islands than in the Main Hawaiian Islands (Barlow et al., 2004; Carretta et al., 2005). Bryde's whales have been reported to occur in both deep and shallow waters globally. There is a secondary occurrence of Bryde's whales seaward of the 27-fathom isobath in the HRC. Bryde's whales are sometimes seen very close to shore and even inside enclosed bays (Best et al., 1984). Occurrence is expected to be rare inshore of this area.

Reproduction/Breeding. Breeding and calving occur in warm temperate and tropical areas.

Diving Behavior. Bryde's whales are lunge-feeders, feeding on fish and krill (Nemoto and Kawamura, 1977). Cummings (1985) reported that Bryde's whales might dive as long as 20 min.

Acoustics. Bryde's whales produce low frequency tonal and swept calls similar to those of other rorquals (Oleson et al., 2003). Calls vary regionally, yet all but one of the call types has a fundamental frequency below 60 Hz; they last from 0.25 sec to several seconds; and they are produced in extended sequences (Oleson et al., 2003). Heimlich et al. (2005) recently described five tone types. While no data on hearing ability for this species are available, Ketten (1997) hypothesized that mysticetes have acute infrasonic hearing.

3.1.2.4.1.2 Odontocetes

Sperm Whale (*Physeter macrocephalus*)

Status. The sperm whale is listed as endangered under the ESA and as a depleted and strategic stock under the MMPA (Carretta et al., 2005). There is no designated critical habitat for this species in the North Pacific. Although many sperm whale populations have been depleted to varying degrees by past whaling activities, sperm whales remain one of the more globally common great whale species. In fact, in some areas, they are actually quite abundant. For example, there are estimated to be about 21,200 to 22,700 sperm whales in the eastern tropical Pacific Ocean (Wade and Gerrodette, 1993).

For management purposes, the IWC has divided the North Pacific into two management regions defined by a zig-zag line which starts at 150°W at the equator, is at 160°W between 40° to 50°N, and ends up at 180°W north of 50°N (Donovan, 1991). Preliminary genetic analyses reveal significant differences between sperm whales off the coast of California, Oregon, and Washington and those sampled offshore to the Hawaiian Islands (Mesnick et al., 1999; Carretta et al., 2005). The NOAA stock assessment report divides sperm whales within the U.S. Pacific EEZ into three discrete, noncontiguous areas: (1) waters around the Hawaiian Islands; (2) California, Oregon, and Washington waters; and (3) Alaskan waters (Carretta et al., 2005).

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the sperm whale is 6,919 (CV = 0.81) individuals (Barlow, 2006). Sperm whales are found from tropical to polar waters in all oceans of the world between approximately 70°N and 70°S (Rice, 1998). Females use a subset of the waters where males are regularly found. Females are normally restricted to areas with sea surface temperatures greater than approximately 15°C; whereas males, especially the largest males, can be found in waters as far poleward as the pack ice within approximately to the 40° parallels (50° in the North Pacific) (Whitehead, 2003). Sperm whale abundance in the eastern temperate North Pacific is estimated to be 32,100 individuals and 26,300 individuals by acoustic and visual detection methods, respectively (Barlow and Taylor, 2005).

Sperm whales are widely distributed throughout the Hawaiian Islands year-round (Rice, 1960; Shallenberger, 1981; Lee, 1993; and Mobley et al., 2000). Sperm whale clicks recorded from hydrophones off Oahu confirm the presence of sperm whales near the Hawaiian Islands throughout the year (Thompson and Friedl, 1982). Globally, sperm whales are typically distributed in waters over the shelf break and continental slope. The primary area of occurrence for the sperm whale is seaward of the shelf break in the HRC. There is a rare occurrence of sperm whales from the shore to the shelf break. This occurrence prediction is based on the possibility of this typically deepwater species being found in insular shelf waters that are in such close proximity to deep water. Mating behavior occurs from winter through summer and calving from spring through fall (U.S. Department of the Navy, 2005a). Occurrence patterns are assumed to be similar throughout the year.

<u>Reproduction/Breeding</u>. Breeding occurs from winter through summer and calving generally occurs in the summer through fall at lower latitudes and the tropics (U.S. Department of the Navy, 2005a). No breeding or calving areas for Hawaii have been described.

<u>Diving Behavior</u>. Sperm whales forage during deep dives that routinely exceed a depth of 219 fathoms and 30 min duration (Watkins et al., 2002). Sperm whales are capable of diving to depths of over 1,094 fathoms with durations of over 60 min (Watkins et al., 1993). Sperm whales spend up to 83 percent of daylight hours underwater (Jaquet et al., 2000; Amano and Yoshioka, 2003). Males do not spend extensive periods of time at the surface (Jaquet et al., 2000). In contrast, females spend prolonged periods of time at the surface (1 to 5 hours daily) without foraging (Whitehead and Weilgart, 1991; Amano and Yoshioka, 2003). The average swimming speed is estimated to be 2.3 ft per second (ft/sec) (Watkins et al., 2002). Dive descents averaged 11 min at a rate of 5 ft/sec, and ascents averaged 11.8 min at a rate of 4.6 ft/sec (Watkins et al., 2002).

<u>Acoustics</u>. Sperm whales produce short-duration (generally less than 3 sec), broadband clicks, (100 Hz to 30 kHz), with dominant energy in two bands (2 to 4 kHz and 10 to 16 kHz). Generally, most of the acoustic energy is present at frequencies below 4 kHz, although diffuse energy up to past 20 kHz has been reported (Thode et al., 2002). The source levels can be up to 236 dB re 1 µPa-m (Møhl et al., 2003). Thode et al. (2002) suggested that the acoustic directivity (angular beam pattern) from sperm whales must range between 10 and 30 dB in the 5 to 20 kHz region. The clicks of neonate sperm whales are very different from usual clicks of adults in that they are of low directionality, long duration, and low-frequency (centroid frequency between 300 and 1,700 Hz) with estimated source levels between 140 and 162 dB re 1 µPa-m (Madsen et al., 2003). Clicks are heard most frequently when sperm whales are engaged in diving/foraging behavior (Whitehead and Weilgart, 1991; Miller et al., 2004; Zimmer et al., 2005). These may be echolocation clicks used in feeding, contact calls (for communication), and orientation during dives. When sperm whales are socializing, they tend to repeat series of clicks (codas), which follow a precise rhythm and may last for hours (Watkins and Schevill, 1977). Codas are shared between individuals of a social unit and are considered to be primarily for intragroup communication (Weilgart and Whitehead, 1997; Rendell and Whitehead, 2004).

The anatomy of the sperm whale's ear indicates that it hears high-frequency sounds (Ketten 1992). Anatomical studies also suggest that the sperm whale has some ultrasonic hearing, but at a lower maximum frequency than many other odontocetes (Ketten, 1992). The sperm whale may also possess better low-frequency hearing than some other odontocetes, although not as extraordinarily low as many baleen whales (Ketten, 1992). Auditory brainstem response in a neonatal sperm whale indicated highest sensitivity to frequencies between 5 and 20 kHz (Ridgway and Carder, 2001).

Pygmy Sperm Whale (*Kogia breviceps*) and Dwarf Sperm Whale (*Kogia sima*)

Status. Neither species of *Kogia* is listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of pygmy sperm whales.

The difficulty in identifying pygmy and dwarf sperm whales is exacerbated by their avoidance reaction towards ships and change in behavior towards approaching survey aircraft (Würsig et al., 1998). Based on the cryptic behavior of these species and their small group sizes (much like that of beaked whales), as well as similarity in appearance, it is difficult to identify these species in sightings at sea.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the pygmy sperm whale is 7,138 (CV = 1.12) individuals (Barlow 2006). Both *Kogia* species have a worldwide distribution in tropical and temperate waters (Jefferson et al., 1993).

Pygmy and dwarf sperm whales within the U.S. Pacific EEZ are each divided into two discrete, non-contiguous areas: (1) Hawaiian waters, and (2) waters off California, Oregon, and Washington (Carretta et al., 2005). The best available estimate of abundance for the Hawaiian stock of the dwarf sperm whale is 19,172 individuals (Barlow, 2003; Carretta et al., 2005).

Both species of *Kogia* generally occur in waters along the continental shelf break and over the continental slope (Baumgartner et al., 2001; McAlpine, 2002; Baird, 2005b). The primary occurrence for *Kogia* is seaward of the shelf break in the HRC and in deep water with a mean depth of 779 fathoms (Baird, 2005b). This takes into account their preference for deep waters. There is a rare occurrence for *Kogia* inshore of the area of primary occurrence. Occurrence is expected to be the same throughout the year. Dwarf sperm whales showed a high degree of site fidelity, determined from photo identification over several years, in areas west of the island of Hawaii (Baird et al., 2006a).

Reproduction/Breeding. There is no information on the breeding behavior in this area. No breeding or calving areas for Hawaii have been described.

Diving Behavior. *Kogia* feed on cephalopods and, less often, on deep-sea fishes and shrimps (Caldwell and Caldwell, 1989; Baird et al., 1996; Willis and Baird, 1998; Wang et al., 2002). Willis and Baird (1998) reported that *Kogia* make dives of up to 25 min. Median dive times of around 11 min have been documented for *Kogia* (Barlow, 1999). A satellite-tagged pygmy sperm whale released off Florida was found to make long nighttime dives, presumably indicating foraging on squid in the deep scattering layer (Scott et al., 2001). Most sightings of *Kogia* are brief; these whales are often difficult to approach, and they actively avoid aircraft and vessels (Würsig et al., 1998).

Acoustics. Pygmy sperm whale clicks range from 60 to 200 kHz, with a dominant frequency of 120 kHz (Richardson et al., 1995a). There is no information available on dwarf sperm whale vocalizations or hearing capabilities. An auditory brainstem response study indicates that pygmy sperm whales have their best hearing between 90 and 150 kHz (Ridgway and Carder, 2001).

Cuvier's Beaked Whale (*Ziphius cavirostris*)

Status. The Cuvier's beaked whale is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of Cuvier's beaked whales.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the Cuvier's beaked whale is 15,242 (CV = 1.43) individuals (Barlow, 2006). Recent information collected from photo identification studies of Cuvier's beaked whale shows a degree of site fidelity near the island of Hawaii (Baird et al., 2006a). The same individuals had been observed multiple times off of the west coast of the island of Hawaii during a 15-year period, suggesting an island associated population (McSweeney et al., 1989). Mobley (2006a) report the presence of a Cuvier's beaked whale in the Alenuihaha Channel area between the islands of Maui and Hawaii during the RIMPAC 06 Exercise. There is no information on the population trend of Cuvier's beaked whales. Previously proposed definition of beaked whale habitat may be too narrow, and beaked whales may be found from the continental slope to the abyssal plain, in waters ranging from well-mixed to highly stratified. There was no geographic pattern in the data (Ferguson et al., 2006).

Reproduction/Breeding. Little is known of beaked whale reproductive behavior. No breeding or calving areas for Hawaii have been described.

Diving Behavior. Cuvier's beaked whales are generally sighted in waters with a bottom depth greater than about 109 fathoms and are frequently recorded at depths of 547 fathoms or more (Gannier, 2000; MacLeod, et al., 2004). They are commonly sighted around seamounts, escarpments, and canyons. In the eastern tropical Pacific Ocean, the mean bottom depth for Cuvier's beaked whales is approximately 1,859 fathoms, with a maximum depth of over 16,732 ft (Ferguson, 2005). Recent studies by Baird et al. (2006b) show that Cuvier's beaked whales dive deeply (maximum of 793 fathoms) and for long periods (maximum dive duration of 68.7 min) but also spent time at shallow depths. Gouge marks were observed on mud volcanoes on the sea floor at 930 to 1,094 fathoms, and Woodside et al. (2006) speculated that they were caused by Cuvier's beaked whales foraging on benthic prey.

Acoustics. There is no acoustic information on Longman's beaked whales but it is likely that they are similar to other beaked whales. MacLeod (1999) suggested that beaked whales use frequencies of between 300 Hz and 129 kHz for pulse sounds, and between 2 and 10 kHz, and possibly up to 16 kHz, for social communication. Cuvier's beaked whales echolocation clicks were recorded at frequencies from 20 to 70 kHz (Zimmer et al., 2005). Cook et al. (2006) reported that the Gervais beaked whale (*Mesoplodon europeus*) could hear in the range of 5 to 80 kHz although no measurements were attempted above 80 kHz). The Gervais beaked whale was most sensitive from 40 to 80 kHz (Cook et al., 2006).

Blainville's Beaked Whale (*Mesoplodon densirostris*)

Status. The Blainville's beaked whale is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005).

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the Blainville's beaked whale is 2,872 individuals (CV = 1.25) (Barlow, 2006). There is no information on the population trend of Blainville's beaked whales.

The Blainville's beaked whale occurs in temperate and tropical waters of all oceans (Jefferson et al., 1993). The distribution of *Mesoplodon* species in the western North Atlantic may relate to water temperature (Mead, 1989; MacLeod, 2000), with Blainville's beaked whale generally occurring in warmer southern waters (MacLeod 2000). In the eastern Pacific, where there are about a half-dozen *Mesoplodon* species known, the Blainville's beaked whale is second only to the pygmy beaked whale (*Mesoplodon peruvianus*) in abundance in tropical waters (Wade and Gerrodette, 1993). Mobley (2006a) reported the presence of a Blainville's beaked whale at the northern edge of the Kaulakahi Channel between the islands of Kauai and Niihau. Mobley (2006a) also reported the presence of a Blainville's beaked whale in the Alenuihaha Channel area between the islands or Maui and Hawaii during the RIMPAC 06 Exercise. The same individuals had been observed multiple times off the west coast of the island of Hawaii during a 15-year period, suggesting an island associated population (McSweeney et al., 2007). Previously proposed definition of beaked whale habitat may be too narrow and beaked whales may be found from the continental slope to the abyssal plain, in waters ranging from well-mixed to highly stratified. There was no geographic pattern in the data (Ferguson et al., 2006).

Reproduction/Breeding. Little is known of beaked whale reproductive behavior. No breeding or calving areas for Hawaii have been described.

Diving Behavior. Analysis of stomach contents from captured and stranded individuals suggests that beaked whales are deep-diving animals, feeding by suction (Heyning and Mead, 1996). Another species of beaked whales, the Baird's beaked whale (*Berardius bairdii*), feeds mainly on benthic fishes and cephalopods, but occasionally on pelagic fish such as mackerel, sardine, and saury (Kasuya, 2002; Walker et al., 2002; Ohizumi et al., 2003). Baird et al. (2006a) reported on the diving behavior of four Blainville's beaked whales off the west coast of Hawaii. The four beaked whales foraged in deep ocean areas (378 to 1,643 fathoms) with a maximum dive to 770 fathoms. Dives ranged from at least 13 min (lost dive recorder during the dive) to a maximum of 68 min (Baird et al., 2006a).

Acoustics. MacLeod (1999) suggested that beaked whales use frequencies of between 300 Hz and 129 kHz for echolocation, and between 2 and 10 kHz, and possibly up to 16 kHz, for social communication. Blainville's beaked whales echolocation clicks were recorded at frequencies from 20 to 40 kHz (Johnson et al., 2004).

Recent information on the hearing abilities of beaked whales (Gervais' beaked whales) shows that they are most sensitive from 40 to 80 kHz with an overall range of 5 to 80 kHz, although no measurements were attempted above 80 kHz (Cook et al., 2006).

Longman's Beaked Whale (*Indopacetus pacificus*)

Status. The Longman's beaked whale is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of Longman's beaked whale.

Abundance and Distribution. Beaked whales may be expected to occur in the area including around seaward of the shelf break. There is a low or unknown occurrence of beaked whales on the shelf between the 27-fathom isobath and the shelf break, which takes into account that deep waters come very close to the shore in this area. In some locales, beaked whales can be found in waters over the shelf, so it is possible that beaked whales have similar habitat preferences here. Occurrence patterns are expected to be the same throughout the year (U.S. Department of the Navy, 2005b). The best available estimate for the Hawaiian stock of the Longman's beaked whale is 1,007 (CV 1.26) individuals (Barlow, 2006).

Longman's beaked whale is not as rare as previously thought. However, the frequency with which it has been sighted in the eastern and western tropical Pacific oceans (MacLeod et al., 2004) suggests that it is probably not as common as the Cuvier's and *Mesoplodon* beaked whales (Ferguson and Barlow, 2001). Previously proposed definition of beaked whale habitat may be too narrow and beaked whales may be found from the continental slope to the abyssal plain, in waters ranging from well-mixed to highly stratified. There was no geographic pattern in the data (Ferguson et al., 2006).

Reproduction/Breeding. Little is known of beaked whale reproductive behavior. No breeding or calving areas for Hawaii have been described.

Diving Behavior. Analysis of stomach contents from captured and stranded individuals suggests that beaked whales are deep-diving animals, feeding by suction (Heyning and Mead 1996). Prolonged dives by the Baird's beaked whales for periods of up to 67 min have been reported (Kasuya, 2002), though dives of about 14 to 19 fathoms are typical, and dives of 45 min are not unusual (Balcomb, 1989; Von Saunder and Barlow, 1999).

Acoustics. There is no acoustic information on Longman's beaked whales, but it is likely that they are similar to other beaked whales. MacLeod (1999) suggested that beaked whales use frequencies of between 300 Hz and 129 kHz for echolocation, and between 2 and 10 kHz, and possibly up to 16 kHz, for social communication. Blainville's beaked whales echolocation clicks were recorded at frequencies from 20 to 40 kHz (Johnson et al., 2004) and Cuvier's beaked whales at frequencies from 20 to 70 kHz (Zimmer et al., 2005).

Recent information on the hearing abilities of beaked whales (Gervais' beaked whales) shows that they are most sensitive from 40 to 80 kHz with an overall range of 5 to 80 kHz, although no measurements were attempted above 80 kHz (Cook et al., 2006).

Rough-Toothed Dolphin (*Steno bredanensis*)

Status. The rough-toothed dolphin is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of rough-toothed dolphins. Nothing is known about stock structure for the rough-toothed dolphin in the North Pacific (Carretta et al., 2005).

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the rough-toothed dolphin is 8,709 (CV = 0.45) individuals (Barlow, 2006).

Rough-toothed dolphins are found in tropical to warm-temperate waters globally, rarely ranging north of 40°N or south of 35° (Miyazaki and Perrin, 1994). In the Main Hawaiian Islands, this species appears to demonstrate site fidelity to specific islands (Baird, R.W., 2005a).

Primary occurrence for the rough-toothed dolphin is from the shelf break to seaward of the HRC boundaries. There is also an area of rare occurrence of rough-toothed dolphins from the shore to the shelf break. Baird et al. *(*2003) noted that rough-toothed dolphins are rarely seen in offshore waters of the Main Hawaiian Islands. Occurrence patterns are expected to be the same throughout the year.

Reproduction/Breeding. Little is known of rough-toothed dolphin reproductive behavior. No breeding or calving areas for Hawaii have been described.

Diving Behavior. They are deep divers, and can dive for up to 15 min (Reeves et al., 2002). They usually inhabit deep waters (Davis et al., 1998), where they prey on fish and cephalopods (Reeves et al., 2002). Rough-toothed dolphins may stay submerged for up to 15 min and are known to dive as deep as 38 fathoms, but can probably dive much deeper (Miyazaki and Perrin, 1994).

Acoustics. The vocal repertoire of the rough-toothed dolphin includes broad-band clicks, barks, and whistles (Yu et al., 2003). Echolocation clicks of rough-toothed dolphins are in the frequency range of 0.1 to 200 kHz, with a peak of about 25 kHz (Miyazaki and Perrin, 1994; Yu et al., 2003). Whistles show a wide frequency range: 0.3 to >24 kHz (Yu et al., 2003). There is no published information on hearing ability of this species.

Bottlenose Dolphin (*Tursiops truncatus*)

Status. The bottlenose dolphin is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of bottlenose dolphins.

Genetic analyses of biopsied bottlenose dolphins in the Main Hawaiian Islands suggested the possibility of two species of bottlenose dolphins in Hawaiian waters (U.S. Department of the Navy, Command Third Fleet, 2006). In the meantime, however, information is presented on the one confirmed *Tursiops* species for this HRC.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the bottlenose dolphin is 3,215 (CV = 0.59) individuals (Barlow, 2006).

The overall range of *Tursiops* is worldwide in tropical to temperate waters. *Tursiops* generally do not range poleward of 45°, except around the United Kingdom and northern Europe (Jefferson et al., 1993).

Bottlenose dolphins found in offshore waters around the Main Hawaiian Islands are island-associated, with all sightings occurring in relatively offshore and shallow waters (<109 fathoms), and no apparent movement between the islands (Baird et al., 2002, 2003). Baird et al. (2003) noted the possibility of a second population of bottlenose dolphins in the Hawaiian Islands, based on sighting data, with a preference for deeper (bottom depth of 219 to 492 fathoms) waters.

Bottlenose dolphins are regularly found around the Main Hawaiian Islands in both onshore and offshore waters (Rice, 1960; Shallenberger, 1981; Mobley et al., 2000; Baird et al., 2003). Based on photo-identification studies and sighting data, there is a possibility of separate island populations with different preferences for shallow (<109 fathoms) and deep (about 219 to 492 fathoms) waters (Baird et al., 2003; 2006b). Therefore, an area of primary occurrence is expected from the shore to the 547-fathom isobath in the HRC, excluding Nihoa due to no survey effort. This area is continuous between Niihau and Kauai and between Oahu, Molokai, Lanai, Maui, and Kahoolawe to account for possible movements between islands. There is a secondary occurrence seaward of the 547-fathom isobath and seaward from the shoreline of Nihoa. Mead and Potter (1990) suggested that the Atlantic species has a calving period of spring through fall with a peak in the spring. Occurrence patterns are expected to be the same throughout the year.

Reproduction/Breeding. Hohn (1980) reported a calving season of spring season with possible summer and fall seasons on the east coast of the United States, but Mead and Potter (1990) suggested a prolonged calving season with a peak in spring. No specific breeding or calving areas for Hawaii have been described.

Diving Behavior. Pacific coast bottlenose dolphins feed primarily on surf perches (Family Embiotocidae) and croakers (Family Sciaendae) (Norris and Prescott, 1961; Walker, 1981; Schwartz et al., 1992; Hanson and Defran, 1993), and also consume squid (*Loligo opalescens*) (Schwartz et al., 1992). Navy bottlenose dolphins have been trained to reach maximum diving depths of about 164 fathoms (Ridgway et al., 1969b). Reeves et al. (2002) noted that the presence of deep-sea fish in the stomachs of some offshore individual bottlenose dolphins suggests that they dive to depths of more than 273 fathoms. Dive durations up to 15 min have been recorded for trained individuals (Ridgway et al., 1969b). Typical dives, however, are more shallow and of a much shorter duration.

Acoustics. Sounds emitted by bottlenose dolphins have been classified into two broad categories: pulsed sounds (including clicks and burst-pulses) and narrow-band continuous sounds (whistles), which usually are FM. Clicks and whistles have a dominant frequency range of 110 to 130 kHz and a peak to peak source level of 218 to 228 dB re 1 μPa-m (Au, 1993) and 3.5 to 14.5 kHz and 125 to 173 dB re 1 μPa-m, respectively (Ketten, 1998). Generally, whistles range in frequency from 0.8 to 24 kHz (Richardson et al., 1995a).

The bottlenose dolphin has a functional high-frequency hearing limit of 160 kHz (Au, 1993) and can hear sounds at frequencies as low as 40 to 125 Hz (Turl, 1993). Inner ear anatomy of this species has been described (Ketten, 1992). Electrophysiological experiments suggest that the bottlenose dolphin brain has a dual analysis system: one specialized for ultrasonic clicks and the other for lower-frequency sounds, such as whistles (Ridgway, 2000). The audiogram of the bottlenose dolphin shows that the lowest thresholds occurred near 50 kHz at a level around 45 dB re 1 μPa (Nachtigall et al., 2000). Below the maximum sensitivity, thresholds increased continuously up to a level of 137 dB at 75 Hz. Above 50 kHz, thresholds increased slowly up to a level of 55 dB at 100 kHz, then increased rapidly above this to about 135 dB at 150 kHz. Scientists have reported a range of best sensitivity between 25 and 70 kHz, with peaks in sensitivity occurring at 25 and 50 kHz at levels of 47 and 46 dB re 1 µPa-m (Nachtigall et al., 2000).

Temporary threshold shifts (TTS) in hearing have been experimentally induced in captive bottlenose dolphins (Ridgway et al., 1997; Finneran et al., 2000; 2005, 2007; Schlundt et al., 2000; Nachtigall et al., 2003). Ridgway et al. (1997) observed changes in behavior at the following minimum levels for 1 sec tones: 186 dB at 3 kHz, 181 dB at 20 kHz, and 178 dB at 75 kHz (all re 1 µPa). TTS levels were 194 to 201 dB at 3 kHz, 193 to 196 dB at 20 kHz, and 192 to 194 dB at 75 kHz (all re 1 µPa). Schlundt et al. (2000) exposed bottlenose dolphins to intense tones (0.4, 3, 10, 20, and 75 kHz); the animals demonstrated altered behavior at source levels of 178 to 193 dB re 1 µPa, with TTS after exposures generally between 192 and 201 dB re 1 µPa (though one dolphin exhibited TTS after exposure at 182 dB re 1 µPa). Nachtigall et al. (2003) determined threshold for a 7.5 kHz pure tone stimulus. No shifts were observed at 165 or 171 dB re 1 µPa, but when the noise level reached 179 dB re 1 µPa, the animal showed the first sign of TTS. Recovery apparently occurred rapidly, with full recovery apparently within 45 min following noise exposure. TTS measured between 8 and 16 kHz (negligible or absent at higher frequencies) after 30 min of noise exposure (4 to 11 kHz) at 160 dB re 1 µPa (Nachtigall et al., 2004). Finneran et al. (2005) reported the onset of TTS in bottlenose dolphins at 197 dB re 1 µPa^2-s for 1-sec pulse sounds at 3.0 and 4.5 kHz. For further discussion of TTS in marine mammals, see Section 4.1.2.

Pantropical Spotted Dolphin (*Stenella attenuata*)

Status. The pantropical spotted dolphin is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of pantropical spotted dolphins.

Abundance and Distribution. The best available estimate of abundance for the pantropical spotted dolphin within the Hawaiian Islands EEZ is 8,978 (CV = 0.48) individuals (Barlow, 2003; Carretta et al., 2005).

The pantropical spotted dolphin is distributed in tropical and subtropical waters worldwide (Perrin and Hohn, 1994). Range in the central Pacific is from the Hawaiian Islands in the north to at least the Marquesas in the south (Perrin and Hohn, 1994).

Based on known habitat preferences and sighting data, the primary occurrence for the pantropical spotted dolphin is between the 330-ft and 13,122-ft isobaths throughout the HRC. This area of primary occurrence also includes a continuous band connecting all the Main Hawaiian Islands, Nihoa, and Kaula, taking into account possible inter-island movements. Secondary occurrence is expected from the shore to 330 ft, as well as seaward of 13,122 ft. Pantropical spotted dolphins are expected to be rare in Pearl Harbor. In the Eastern Tropical Pacific there are two calving periods, one in the spring and one in the fall (Perrin and Hohn, 1994). Occurrence patterns are the same throughout the year.

Reproduction/Breeding. In the Eastern Tropical Pacific there are two calving peaks in the spring and fall (Perrin and Hohn, 1994). No breeding or calving areas for Hawaii have been described.

Diving Behavior. Results from various tracking and food habit studies suggest that pantropical spotted dolphins in the Eastern Tropical Pacific and off Hawaii feed primarily at night on epipelagic species and on mesopelagic species which rise towards the water's surface after dark (Robertson and Chivers, 1997; Scott and Cattanach, 1998; Baird et al., 2001). Dives during the day generally are shorter and shallower than dives at night; rates of descent and ascent are higher at night than during the day (Baird et al., 2001). Similar mean dive durations and depths have been obtained for tagged pantropical spotted dolphins in the Eastern Tropical Pacific and off Hawaii (Baird et al., 2001).

Acoustics. Pantropical spotted dolphin whistles have a dominant frequency range of 6.7 to 17.8 kHz (Ketten, 1998). Click source levels between 197 and 220 dB re 1 μPa-m (peak to peak), in the range of 40 to 140 kHz, have been recorded for pantropical spotted dolphins (Schotten et al., 2004). Data from Atlantic spotted dolphins are provided to fill in the gaps of acoustic information for pantropical spotted dolphins. Echolocation clicks measured in wild Atlantic spotted dolphins showed bimodal ranges of 40 and 50 kHz and a high-frequency peak between 110 and 130 kHz, with a source level of 210 dB re 1 μPa (Au and Herzing, 2003).

There is no information on the hearing abilities of pantropical spotted dolphins.

Spinner Dolphin (*Stenella longirostris*)

Status. The spinner dolphin is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of spinner dolphins.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the spinner dolphin is 3,351 (CV = 0.74) individuals (Barlow, 2006).

The spinner dolphin is found in tropical and subtropical waters worldwide. Limits are near 40°N and 40°S (Jefferson et al., 1993). These dolphins occur near islands such as the Hawaiian Islands, the Mariana Islands, the South Pacific, the Caribbean, and Fernando de Noronha Island off Brazil. Spinner dolphins have been documented to travel distances of about 25 mi between the Main Hawaiian Islands (Maldini, 2003). In the Hawaiian Islands, spinner dolphins occur along the leeward coasts of all the major islands and around several of the atolls northwest of the main island chain. Long-term site fidelity has been noted for spinner dolphins along the Kona coast of Hawaii, along Oahu, and off the island of Moorea in the Society Islands (Norris et al., 1994; Östman 1994; Poole, 1995; Marten and Psarakos, 1999), with some individuals being sighted for up to 12 years at Moorea (Poole, 1995). Recent data suggests that spinner dolphins do not readily move between islands as determined by genetic analysis (Andrews et al., 2006). Monitoring for RIMPAC 2006 showed that spinner dolphins are seen daily in the offshore area of Kekaha Beach, Kauai (near PMRF) and this despite being regularly accompanied by tour boats (U.S. Department of the Navy, 2006a).

Spinner dolphins occur year-round throughout the HRC, with primary occurrence from the shore to the 13,122-ft isobath. This takes into account offshore resting habitat and offshore feeding areas. Spinner dolphins are expected to occur in shallow water (about 162 ft or less) resting areas throughout the middle of the day, moving into deep waters offshore during the night to feed. Primary resting areas are along the west side of Hawaii, including Makako Bay, Honokohau Bay, Kailua Bay, Kealakekua Bay, Honaunau Bay, Kauhako Bay, and off Kahena on the southeast side of the island (Östman-Lind et al., 2004). Along the Waianae coast of

Oahu, spinner dolphins rest along Makua Beach, Kahe Point, and Pokai Bay during the day (Lammers, 2004). Kilauea Bay in Kauai is also a popular resting bay for Hawaiian spinner dolphins (U.S. Department of the Navy, Commander Third Fleet, 2006). There is an area of secondary occurrence seaward of 2,187 fathoms. Although sightings have been recorded around the mouth of Pearl Harbor (Lammers, 2004), spinner dolphin occurrence is expected to be rare. Occurrence patterns are assumed to be the same throughout the year. It is currently not known whether individuals move between islands or island groups (Carretta et al., 2005) but recent data on the genetic comparison of animals from each suggest there is little movement between the islands (Andrews et al., 2006). Spinner dolphins in Tahiti showed a pattern of being present a higher percentage of time on the weekend compared to weekdays despite the higher tourist traffic and encounter rate (Gannier and Petiau, 2007).

Reproduction/Breeding. Spinner dolphins have island specific populations and breeding may occur throughout the year (Östman-Lind et al., 2004).

Diving Behavior. Spinner dolphins feed primarily on small mesopelagic fishes, squids, and sergestid shrimp and they dive to at least 109 to 164 fathoms (Perrin and Gilpatrick, 1994). Foraging can begin in the late afternoon (Lammers, 2004), but takes place primarily at night when the mesopelagic prey migrates vertically towards the surface and also horizontally towards the shore (Benoit-Bird et al., 2001; Benoit-Bird and Au, 2004; Dollar and Grigg, 2003)

Acoustics. There is little information on the acoustic abilities of the spinner dolphin. They produce whistles in the range of 1 to 22.5 kHz with the dominant frequency being 6.8 to 17.9 kHz, above that of the active sonar frequencies. Whistles may have harmonics that may extend past 50 kHz and sometimes as high as 100 kHz (Lammers et al., 2003). The full range of hearing may extend down to 1 kHz or below as reported for other small odontocetes (Richardson et al., 1995a; Nedwell et al., 2004; Bazúa-Durán, C. and W.W.L. Au, 2002). They also display pulse burst sounds in the range of 5 to 60 kHz. Their echolocation clicks range up to at least 65 kHz (Richardson et al., 1995a). Whistles of spinner dolphins have harmonics that may extend past 50 kHz and sometimes as high as 100 kHz (Lammers et al., 2003). Spinner dolphins are island specific residents, but all island pods share about 48 percent of the parameters of their whistles (Bazua-Durana and Au, 2004).

Striped Dolphin (*Stenella coeruleoalba*)

Status. The striped dolphin is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of striped dolphins.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the striped dolphin is 13,143 (CV = 0.46) individuals (Barlow, 2003; Carretta et al., 2005). The striped dolphin has a worldwide distribution in cool-temperate to tropical waters. This species is well documented in both the western and eastern Pacific off the coasts of Japan and North America (Perrin et al., 1994a); the northern limits are the Sea of Japan, Hokkaido, Washington State, and along roughly 40°N across the western and central Pacific (Reeves et al., 2002). Scattered records exist from the South Pacific as well (Perrin et al., 1994a).

The striped dolphin regularly occurs throughout the HRC. There is a primary occurrence for the striped dolphin seaward of 547 fathoms based on sighting records and the species' known preference for deep waters. Striped dolphins are occasionally sighted closer to shore (Mobley et al., 2000); therefore, an area of secondary occurrence is expected from 55 fathoms to 547 fathoms. Occurrence patterns are assumed to be the same throughout the year.

Reproduction/Breeding. Off of Japan there are two calving peaks, one in summer and one in winter (Perrin et al., 1994a). No specific breeding or calving areas for Hawaii have been described.

Diving Behavior. Striped dolphins often feed in pelagic or benthopelagic zones along the continental slope or just beyond oceanic waters. A majority of the prey possess luminescent organs, suggesting that striped dolphins may be feeding at great depths, possibly diving to about 109 to 383 fathoms to reach potential prey (Archer and Perrin, 1999). Striped dolphins may feed at night, in order to take advantage of the deep scattering layer's diurnal vertical movements. Small, mid-water fishes (in particular, myctophids or lanternfish) and squids are the dominant prey (Perrin et al., 1994a).

Acoustics. Striped dolphin whistles range from 6 to 24+ kHz, with dominant frequencies ranging from 8 to 12.5 kHz (Richardson et al., 1995a). The striped dolphin's range of most sensitive hearing (defined as the frequency range with sensitivities within 10 dB of maximum sensitivity) was determined to be 29 to 123 kHz using standard psycho-acoustic techniques; maximum sensitivity occurred at 64 kHz (Kastelein et al., 2003).

Risso's Dolphin (*Grampus griseus*)

Status. The Risso's dolphin is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of Risso's dolphins.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the Risso's dolphin is 2,372 (CV = 0.65) individuals (Barlow, 2006). The Risso's dolphin is distributed worldwide in tropical to warm-temperate waters, roughly between 60°N and 60°S, where surface water temperature is usually greater than 50°F (Kruse et al., 1999). Water temperature appears to be a factor that affects the distribution of Risso's dolphins in the Pacific (Kruse et al., 1999). Changes in local distribution and abundance along the California coast are probably in response to protracted or unseasonal warm-water events, such as El Niño events (Shane, 1994).

There is an area of secondary occurrence between the 330-ft and 16,400-ft isobaths based on the known habitat preferences of this species, as well as the paucity of sightings, even though there is extensive aerial and boat-based survey coverage near the islands. There is a narrow band of rare occurrence from the shore to the 55-fathom isobath, including Pearl Harbor, which takes into consideration the possibility that this species, with a preference for waters with steep bottom topography, might swim into areas where deep water is close to shore. Risso's dolphins are expected to be rare seaward of the 16,400-ft isobath. Occurrence patterns are assumed to be the same throughout the year.

Reproduction/Breeding. There is no information on the breeding behavior in this area. No breeding or calving areas for Hawaii have been described.

Diving Behavior. They may remain submerged on dives for up to 30 min (Kruse et al., 1999). Cephalopods are the primary prey (Clarke, 1996).

Acoustics. Risso's dolphin vocalizations include broadband clicks, barks, buzzes, grunts, chirps, whistles, and simultaneous whistle and burst-pulse sounds (Corkeron and Van Parijs, 2001). The combined whistle and burst pulse sound appears to be unique to Risso's dolphin (Corkeron and Van Parijs, 2001). Corkeron and Van Parijs (2001) recorded five different whistle types, ranging in frequency from 4 to 22 kHz. Broadband clicks had a frequency range of 6 to greater than 22 kHz. Low-frequency narrowband grunt vocalizations had a frequency range of 0.4 to 0.8 kHz. A recent study established empirically that Risso's dolphins echolocate; estimated source levels were up to 216 dB re 1 µPa-m (peak to peak levels) with two prominent peaks in the range of 30 to 50 kHz and 80 to 100 kHz (Philips et al., 2003).

The range of hearing in Risso's dolphins is 1.6 to 122.9 kHz with maximum sensitivity occurring between 8 and 64 kHz (Nachtigall et al., 1995). The range of hearing in an infant Risso's dolphin was 4 to 150 kHz and showed more sensitive hearing at higher frequencies than adults (Nachtigall et al., 2005).

Melon-headed Whale (*Peponocephala electra*)

Status. The melon headed whale is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of melon headed whales.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the melon-headed whale is 2,950 (CV = 1.17) individuals (Barlow, 2006). Melon-headed whales are found worldwide in tropical and subtropical waters. They have occasionally been reported from higher latitudes, but these sightings are often associated with incursions of warm water currents (Perryman et al., 1994). Preliminary results from photo-identification work in the Main Hawaiian Islands suggest inter-island movements by some individuals (e.g., between the islands of Kauai and Hawaii) as well as some residency by other individuals (e.g., at the island of Hawaii) (U.S. Department of the Navy 2005b).

The melon-headed whale is an oceanic species. Melon-headed whales are primarily expected to occur from the shelf break to seaward of the HRC and vicinity. There is a rare sighting occurrence from the shore to the shelf break. Occurrence patterns are assumed to be the same throughout the year.

Reproduction/Breeding. There is no information on the breeding behavior in this area. No breeding or calving areas for Hawaii have been described.

Diving Behavior. There is no information on the diving behavior of melon headed whales.

Acoustics. Watkins et al. (1997) reported melon-headed whale whistles in the range of 8 to 12 kHz (source level of 155 dB re 1µPa-m) and clicks in the range of 20 to 40 kHz (165 dB re 1µPa-m). There are no data on the hearing abilities of melon-headed whales.

Fraser's Dolphin (*Lagenodelphis hosei*)

Status. The Fraser's dolphin is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of Fraser's dolphins.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the Fraser's dolphin is 10,226 (CV = 1.16) individuals (Barlow, 2006).

Fraser's dolphins have only recently been documented in Hawaiian waters (Carretta et al., 2005). Sightings have been recorded in the Northwestern Hawaiian Islands but not within the Main Hawaiian Islands (Barlow, 2003). There is a rare occurrence of the Fraser's dolphin from the shore to seaward of the HRC that takes into account that this is an oceanic species that can be found closer to the coast, particularly in locations where the shelf is narrow and deep waters are nearby. There is no evidence of a seasonal calving season (U.S. Department of the Navy, 2005a). Occurrence patterns are assumed to be the same throughout the year.

Reproduction/Breeding. There is little information on the breeding behavior in this area and there appears to be no seasonality to calving (Jefferson et al, 1994). No breeding or calving areas for Hawaii have been described.

Diving Behavior. There is no information available on their diving behavior.

Acoustics. Little is known of the acoustic abilities of Fraser's dolphins. Whistles have been reported in the range of 7.6 to 13.4 kHz (Leatherwood et al., 1993). Nothing is known of their hearing abilities.

Pygmy Killer Whale (*Feresa attenuata*)

Status. The pygmy killer whale is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of pygmy killer whales.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the pygmy killer whale is 956 (CV = 0.83) individuals (Barlow, 2006). This species has a worldwide distribution in deep tropical and subtropical oceans. Pygmy killer whales generally do not range north of 40°N or south of 35°S (Jefferson et al., 1993). Reported sightings suggest that this species primarily occurs in equatorial waters, at least in the eastern tropical Pacific (Perryman et al., 1994). Most of the records outside the tropics are associated with strong, warm western boundary currents that effectively extend tropical conditions into higher latitudes (Ross and Leatherwood, 1994).

Pygmy killer whales regularly occur in the HRC. Pygmy killer whales are easily confused with false killer whales and melon-headed whales, which are two species that also have expected occurrence in the HRC. The pygmy killer whale is primarily expected to occur from the shelf break to seaward of the HRC boundaries. There is a rare sighting occurrence from the shore to the shelf break. Occurrence patterns are assumed to be the same throughout the year. Pygmy killer whales off the island of Hawaii demonstrate tremendous site fidelity to the island (U.S. Department of the Navy, 2005b).

Reproduction/Breeding. There is no information on the breeding behavior in this area.

Diving Behavior. There is no information on the diving behavior of pygmy killer whales.

Acoustics. The pygmy killer whale produces clicks in the range of 45 to 117 kHz, with the main energy in the range of 70 to 85 kHz (Madsen et al., 2004). Peak to peak source levels were 197 to 223 dB re 1 µPa. There is no information on the hearing of pygmy killer whales.

False Killer Whale (*Pseudorca crassidens*)

Status. This stock is listed as a strategic stock by NMFS because the estimated level of serious injury and mortality from the Hawaii-based tuna and swordfish longline fishery is greater than the potential biological removal (Carretta et al., 2005). Genetic evidence suggests that the Hawaiian stock might be a reproductively isolated population from false killer whales in the eastern tropical Pacific (Chivers et al., 2003). Baird et al. (2005) noted that more work was needed to determine whether false killer whales using coastal waters might even be a discrete population from those in offshore waters and waters off the Northwestern Hawaiian Islands.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the false killer whale is 236 (CV = 1.13) individuals (Barlow, 2006). False killer whales are found in tropical and temperate waters, generally between 50°S and 50°N latitude with a few records north of 50°N in the Pacific and the Atlantic (Odell and McClune, 1999). Seasonal movements in the western North Pacific may be related to prey distribution (Odell and McClune, 1999). Baird et al. (2005) noted considerable inter-island movements of individuals in the Hawaiian Islands.

False killer whales are commonly sighted in offshore waters from small boats and aircraft, as well as offshore from longline fishing vessels (Mobley et al., 2000; Baird et al., 2003; Walsh and Kobayashi, 2004). Baird et al. (2005) reported that false killer whales in the Hawaiian Islands occur in waters from about 22 to 2,187 fathoms. There is an area of primary occurrence for the false killer whale from the shore to 1,094 fathoms, with the exception of Pearl Harbor, where there is a rare occurrence for this species. There is an additional area of primary occurrence seaward of 2,187 fathoms on the south side of the islands, which takes into account false killer whale sighting and incidental catch data in the southwestern portion of the HRC (Forney, 2004; Walsh and Kobayashi, 2004; Carretta et al., 2005). The area of secondary occurrence includes a narrow band between 1,094 fathoms and 2,187 fathoms south of the islands and the entire area north of the islands seaward of 1,094 fathoms. It has been suggested that false killer whales using coastal waters might be a discrete population from those in offshore waters and waters off the Northwestern Hawaiian Islands (Baird et al., 2005; Carretta et al., 2005). The area of secondary occurrence takes into account the possibility of two different stocks, with a possible hiatus in their distribution (U.S. Department of the Navy, Commander Third Fleet, 2006). There is no evidence of a seasonal calving period (Jefferson et al., 1993). Occurrence patterns are assumed to be the same throughout the year.

Reproduction/Breeding. There is no information on the breeding behavior in this area.

Diving Behavior. False killer whales primarily eat deep-sea cephalopods and fish (Odell and McClune, 1999), but they have been known to attack other cetaceans, including dolphins (Perryman and Foster, 1980; Stacey and Baird, 1991), sperm whales (Palacios and Mate, 1996), and baleen whales.

Acoustics. The dominant frequencies of false killer whale whistles are 4 to 9.5 kHz; those of their clicks are 25 to 30 kHz and 95 to 130 kHz (Thomas et al., 1990; Richardson et al., 1995a). The source level for clicks is 220 to 228 dB re 1 µPa-m (Ketten, 1998). Best hearing sensitivity measured for a false killer whale was around 16 to 64 kHz (Thomas et al., 1988, 1990). Yuen et al. (2005) tested a stranded false killer whale using auditory evoke potentials to produce an audiogram in the range of 4 to 44 kHz and with best sensitivity at 16 to 24 kHz, but it may have had age related hearing loss.

Killer Whale (*Orcinus orca*)

Status. The killer whale is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005). There is no information on the population trend of killer whales.

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the killer whale is 349 (CV = 0.98) individuals (Barlow, 2006). Genetic analysis of a biopsy sample taken from a killer whale in Hawaii (during the NMFS Hawaiian Islands Cetacean and Ecosystem Assessment Survey) was most closely related to mammal-eating killer whales in Alaska (Baird et al., 2003).

The killer whale is a cosmopolitan species found throughout all oceans and contiguous seas, from equatorial regions to the polar pack-ice zones. This species has sporadic occurrence in most regions (Ford, 2002). Though found in tropical waters and the open ocean, killer whales as a species are most numerous in coastal waters and at higher latitudes (Mitchell, 1975; Miyazaki and Wada, 1978; Dahlheim et al., 1982). Sightings in most tropical waters, although not common, are widespread (Visser and Bonoccorso, 2003).

Killer whales in general are uncommon in most tropical areas (U.S. Department of Defense, 2005). The distinctiveness of this species would lead it to be reported more than any other member of the dolphin family, if it occurs in a certain locale. Killer whales are infrequently sighted and found stranded around the Hawaiian Islands (Shallenberger, 1981; Tomich, 1986; Mobley et al., 2001b; Baird et al., 2003), though with increasing numbers of boaters, sightings each year could be expected (Baird et al., 2006c). Because the killer whale has a sporadic occurrence in tropical waters and can be found in both coastal areas and the open ocean, there is a rare occurrence of this species in the HRC from the shoreline to seaward of the HRC boundaries. Occurrence patterns are assumed to be the same throughout the year.

Reproduction/Breeding. There is no information on the breeding behavior in this area.

Diving Behavior. The maximum depth recorded for free-ranging killer whales diving off British Columbia is about 144 fathoms (Baird et al., 2005). On average, however, for seven tagged individuals, less than 1 percent of all dives examined were to depths greater than about 16 fathoms (Baird et al., 2003). The longest duration of a recorded dive from a radio-tagged killer whale was 17 min (Dahlheim and Heyning, 1999).

Acoustics. The killer whale produces a wide variety of clicks and whistles from 1.5 to 25 kHz, but most of its sounds are pulsed with dominant frequencies of 1 to 6 kHz (Richardson et al., 1995a). The peak-to-peak source levels of echolocation signals range between 195 and 224 dB re 1 μPa-m (Au et al., 2004). The source level of social vocalizations ranges between 137 to 157 dB re 1 μPa-m (Veirs, 2004). Acoustic studies of resident killer whales in British Columbia have found that there are dialects, in their highly stereotyped, repetitive discrete calls, which are group-specific and shared by all group members (Ford, 2002). These dialects likely are used to maintain group identity and cohesion, and may serve as indicators of relatedness that help in the avoidance of inbreeding between closely related whales (Ford, 2002). Dialects also have been documented in killer whales occurring in northern Norway, and likely occur in other locales as well (Ford, 2002). The killer whale has the lowest frequency of maximum sensitivity and one of the lowest high-frequency hearing limits known among toothed whales (Szymanski et al., 1999). The upper limit of hearing is 100 kHz for this species. The most sensitive frequency, in both behavioral and in auditory brainstem response audiograms, has been determined to be 20 kHz (Szymanski et al., 1999).

Short-finned Pilot Whale (*Globicephala macrorhynchus*)

Status. Stock structure of short-finned pilot whales has not been well-studied in the North Pacific Ocean, except in Japanese waters (Carretta et al., 2005). Two stocks have been identified in Japan based on pigmentation patterns and differences in the head shape of adult males (Kasuya et al., 1988). Pilot whales in Hawaiian waters are similar morphologically to the Japanese southern form (Carretta et al., 2005). Genetic analyses of tissue samples collected near the Main Hawaiian Islands indicate that the Hawaiian population is reproductively isolated from short-finned pilot whales found in the eastern North Pacific Ocean (Carretta et al., 2005).

Abundance and Distribution. The best available estimate of abundance for the Hawaiian stock of the short-finned pilot whale is 8,870 (CV = 0.38) individuals (Barlow, 2006). The short-finned pilot whale is found worldwide in tropical to warm-temperate seas, generally in deep offshore areas. The short-finned pilot whale usually does not range north of 50°N or south of 40°S (Jefferson et al., 1993). The long-finned pilot whale is not known to presently occur in the North Pacific (Kasuya, 1975); the range of the short-finned pilot whale appears to be expanding to fill the former range of the long-finned pilot whale (Bernard and Reilly, 1999). Pilot whales are sighted throughout the Hawaiian Islands (Shallenberger, 1981).

Short-finned pilot whales are expected to occur year-round throughout the HRC. They are commonly found in deep waters with steep bottom topography, including deepwater channels between the Main Hawaiian Islands, such as the Alenuihaha Channel between Maui and Hawaii (Balcomb, 1987). The area of primary occurrence for this species is between 109 fathoms and 2,187 fathoms. Considering the narrow insular shelf and deep waters in proximity to the shore, secondary occurrence is between 27 fathoms and 109 fathoms. Another area of secondary occurrence extends from 2,187 fathoms to seaward of the HRC boundaries. Short-finned pilot whales are expected to be rare between the shore and 27 fathoms. Occurrence patterns are assumed to be the same throughout the year. Photo-identification work suggests a high degree of site fidelity around the island of Hawaii (Shane and McSweeney, 1990).

Reproduction/Breeding. There is no information on the breeding behavior in this area.

Diving Behavior. Pilot whales are deep divers; the maximum dive depth measured is about 531 fathoms (Baird et al., 2002). Pilot whales feed primarily on squid, but also take fish (Bernard and Reilly, 1999). Pilot whales are not generally known to prey on other marine mammals; however, records from the Eastern Tropical Pacific suggest that the short-finned pilot whale does occasionally chase, attack, and may eat dolphins during fishery operations (Perryman and Foster, 1980), and they have been observed harassing sperm whales in the Gulf of Mexico (Weller et al., 1996).

Acoustics. Short-finned pilot whale whistles have a dominant frequency range of 2 to 14 kHz and clicks have frequency range of 30 to 60 kHz, both with source levels of 180 dB re 1 μPa-m (Fish and Turl, 1976; Ketten, 1998). There are no published hearing data available for this species.

3.1.2.4.1.3 Pinnipeds

Hawaiian Monk Seal (*Monachus schauinslandi*)

Status. The Hawaiian monk seal is listed as endangered under the ESA and as a depleted and strategic stock under the MMPA (Ragen and Lavigne, 1999; Carretta et al., 2005). Hawaiian monk seals are managed as a single stock, although there are six main reproductive subpopulations at French Frigate Shoals, Laysan Island, Lisianski Island, Pearl and Hermes Reef, Midway Atoll, and Kure Atoll (Ragen and Lavigne, 1999; Carretta et al., 2005). Genetic comparisons between the Northwestern and Main Hawaiian Islands seals have not yet been conducted, but observed interchange of individuals among the regions is extremely rare, suggesting that these may be more appropriately designated as separate stocks; further research is needed (Carretta et al., 2005).

Critical habitat for the Hawaiian monk seal is designated from the shore out to 20 fathoms in 10 areas of the Northwestern Hawaiian Islands (National Marine Fisheries Service, 1988). The eastern-most island is located on the northwestern edge of the HRC. A revised recovery plan, which included species status, threats to the population and recommendations to prevent extinction, was issued in 2007 (National Marine Fisheries Service, 2007e). Hawaiian monk seals were given the Hawaiian name `ilio holo i ka uaua, which translates literally as “dog walking on water.”

Abundance and Distribution. The best estimate of the total population size is 1,252 individuals in the Hawaiian Islands Archipelago (Carretta et al., 2006). There are an estimated 77 seals in the Main Hawaiian Islands (National Marine Fisheries Services, 2007e). The vast majority of the population is present in the Northwestern Hawaiian Islands. The trend in abundance for the population over the past 20 years has mostly been negative (Baker and Johanos, 2004; Carretta et al., 2005). A self-sustaining subpopulation in the Main Hawaiian Islands may improve the monk seal’s long-term prospects for recovery (Marine Mammal Commission, 2003; Baker and Johanos, 2004; Carretta et al., 2005).

The Hawaiian monk seal occurs only in the central North Pacific. Until recently, this species occurred almost exclusively at remote atolls in the Northwestern Hawaiian Islands where six major breeding colonies are located: French Frigate Shoals, Laysan and Lisianski Islands, Pearl and Hermes Reef, Midway Atoll, and Kure Atoll. In the last decade, however, sightings of Hawaiian monk seals in the Main Hawaiian Islands have increased considerably (Baker and Johanos, 2004; Carretta et al., 2005). Most monk seal haulout events in the Main Hawaiian Islands have been on the western islands of Niihau and Kauai (Baker and Johanos, 2004; Carretta et al., 2005), although sightings or births have now been reported for all of the Main Hawaiian Islands, including Lehua and Kaula (Marine Mammal Commission, 2003; Baker and Johanos, 2004). Births of Hawaiian monk seal pups have been recorded in the Main Hawaiian Islands including Kauai, Niihau (Baker and Johanos, 2004), Oahu, and Molokai (National Marine Fisheries Service, 2007e) Hawaiian monk seals wander to Maro Reef and Gardner Pinnacles and have occasionally been sighted on nearby island groups such as Johnston Atoll, Wake Island, and Palmyra Atoll (Rice, 1998).

Hawaiian monk seals may give birth throughout the year, but most births occur between February to August with a peak from March to June (Gilmartin and Forcada, 2002). Hawaiian monk seals show very high site fidelity to natal (birthing) islands, with only about 10 percent of individuals moving to another island in their lifetime (Gilmartin and Forcada, 2002). While monk seals do move between islands, long-distance movements are not common. Seals move distances of up to 135 nm on a regular basis, but longer distances have been recorded (e.g from Laysan to Molokai) (Johanos and Baker, 2005). Primary occurrence of monk seals within the HRC is expected in a continuous band between Nihoa, Kaula, Niihau, and Kauai. This band extends from the shore to around 273 fathoms and is based on the large number of sightings and births recorded in this area (Westlake and Gilmartin, 1990; Ragen and Finn, 1996; Marine Mammal Commission, 2003; Baker and Johanos, 2004). An area of secondary occurrence is expected from 273 fathoms to 547 fathoms around Nihoa, Kaula, Niihau, and Kauai. A continuous area of secondary occurrence is also expected from the shore to 547 fathoms around the other Main Hawaiian Islands, taking into account sighting records, the location of deep sea corals, and the ability of monk seals to forage in water deeper than about 273 fathoms (Parrish et al., 2002; Severns and Fiene Severns, 2002; Kona Blue Water Farms, 2003; Kubota, 2004; Anonymous 2005 [from Honolulu Star Bulletin]; Fujimori, 2005). The Pearl Harbor entrance is included in the area of secondary occurrence based on sightings of this species near the entrance of the harbor (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a). There is a rare occurrence of the monk seal seaward of the 3,281-ft isobath. Occurrence patterns are expected to be the same throughout the year.

<u>Reproduction/Breeding</u>. Pupping can occur year round but generally occurs from February to August with a peak in March (Johanos et al., 1994; Gilmartin and Forcada, 2002). Most pupping occurs on the Northwestern Hawaii Islands.

<u>Diving Behavior</u>. Monk seals feed on a variety of benthic and mid-water fish and invertebrates (Goodman-Lowe, 1998; Parrish et al., 2000). Adult seals at French Frigate Shoals forage at depths of 164 to 273 fathoms in coral beds, and juveniles forage at depths of about 5.5 to 16 fathoms and to 27 to 55 fathoms at underwater sand fields (Parrish et al., 2002; 2005).

In a study conducted by NMFS and Hubbs-Sea World Research Institute, movements of 11 tagged seals were monitored in the MHI for 32 to 167 days. Most locations for all seals were in nearshore, neritic, marine habitats and within the 200-m depth contours surrounding the MHI or nearby banks. Several seals moved between islands in the Main Hawaiian Islands. One juvenile male seal instrumented on Kauai traveled to the northwest and southwest coasts of Oahu. The adult males that were tagged on the south coast of Kauai ranged extensively along the south and west coasts of Kauai and also traveled to Niihau (Littnan et al., 2006).

Acoustics. The range of underwater hearing in monk seals is 2 to 48 kHz, with best hearing from 16 to 30 kHz (Thomas et al., 1990). This audiogram was from only one animal and may not be indicative of the species.

There is no information on underwater sounds. In-air sounds are low frequency sounds (below 1,000 Hz) such as "soft liquid bubble," short duration guttural expiration, a roar and belching/coughing sound (Miller and Job, 1992). A pup produces a higher frequency call (1.4 kHz) that presumably is used to call its mother.

Northern Elephant Seal (*Mirounga angustirostris*)

Status. The northern elephant seal is not listed as endangered under the ESA and is not a depleted or strategic stock under the MMPA (Carretta et al., 2005).

Abundance and Distribution. The northern elephant seal population has recovered dramatically after being reduced to several dozen to perhaps no more than a few animals in the 1890s (Bartholomew and Hubbs, 1960; Stewart et al., 1994). Although movement and genetic exchange continues between rookeries, most elephant seals return to their natal rookeries when they start breeding (Huber et al., 1991). The population size has to be estimated since all age classes are not ashore at any one time of the year (Carretta et al., 2005). There is a conservative minimum population estimate of 60,547 elephant seals in the California stock (Carretta et al., 2005). Based on trends in pup counts, abundance in California is increasing by around 6 percent annually, but the Mexican stock is evidently decreasing slowly (Stewart et al., 1994; Carretta et al., 2005).

Breeding and molting habitat for northern elephant seals is characterized by sandy beaches, mostly on offshore islands, but also in some mainland locations along the coast (Stewart et al., 1994). When on shore, seals will also use small coves and sand dunes behind and adjacent to breeding beaches. They rarely enter the water during the breeding season, but some seals will spend short periods in tide pools and alongshore; these are most commonly weaned pups that are learning to swim (Le Boeuf et al., 1972).

The northern elephant seal is endemic to the North Pacific Ocean, occurring almost exclusively in the eastern and central North Pacific. However, vagrant individuals do sometimes range to the western North Pacific. Northern elephant seals occur in Hawaiian waters only rarely as extralimital vagrants. The most far-ranging individual appeared on Nijima Island off the Pacific coast of Japan in 1989 (Kiyota et al., 1992). This demonstrates the great distances that these animals are capable of covering.

There is a rare occurrence of northern elephant seals throughout the HRC year-round. There are several unconfirmed reports of elephant seals at Midway Atoll, Pearl and Hermes Reef, and Kure Atoll (U.S. Department of the Navy, 2005b). The first confirmed sighting of a northern elephant seal in the Hawaiian Islands was a female found on Midway Atoll in 1978 that had been tagged earlier at San Miguel Island (off the coast of southern California) (Northwest and Alaska Fisheries Center, 1978). The first sighting of an elephant seal in the Main Hawaiian

Islands occurred on the Kona coast of Hawaii in January 2002; a juvenile male was sighted hauled out at Kawaihae Beach and later at the Kona Village Resort (Fujimori, 2002;). Based on these sightings and documented long-distance movements as far west as Japan (Northwest and Alaska Fisheries Center, 1978; Antonelis and Fiscus, 1980; Tomich, 1986; Kiyota et al., 1992; Fujimori, 2002), rare encounters with northern elephant seals in the HRC are possible.

Reproduction/Breeding. Northern elephant seals haul out on land exclusively in Baja California, Mexico and California, to give birth and breed from December through March, and pups remain on shore or in the shallow waters adjacent to the rookery through May.

Diving Behavior. Feeding habitat is mostly in deep, offshore waters of warm temperate to subpolar zones (Stewart and DeLong, 1995; Stewart, 1997; Le Boeuf et al., 2000). Some seals will move into subtropical or tropical waters while foraging (Stewart and DeLong, 1995).

Both sexes routinely dive deep (82 to 437.5 fathoms) (Le Boeuf et al., 2000); dives average 15–25 min, depending on time of year, and surface intervals between dives are 2 to 3 min. The deepest dives recorded for both sexes are over 833 fathoms (e.g., Le Boeuf et al., 2000; Schreer et al., 2001). Females remain submerged about 86 to 92 percent of the time and males about 88 to 90 percent (Le Boeuf et al., 1989; Stewart and Delong, 1995). Feeding juvenile northern elephant seals dive for slightly shorter periods (13 to 18 min), but they dive to similar depths (163 to 250 fathoms) and spend a similar proportion (86 to 92 percent) of their time submerged (Le Boeuf et al., 1996).

Acoustics. The northern elephant seal produces loud, low-frequency in-air vocalizations (Bartholomew and Collias, 1962). The mean fundamental frequencies are in the range of 147 to 334 Hz for adult males (Le Bouef and Petrinovich, 1974). The mean source level of the male-produced vocalizations during the breeding season is 110 dB re 20 μPa 1 m (Sanvito and Galimberti, 2003). In-air calls made by aggressive males include: (1) snoring, which is a low intensity threat; (2) a snort (0.2 to 0.6 kHz) made by a dominant male when approached by a subdominant male; and (3) a clap threat (<2.5 kHz) which may contain signature information at the individual level (Richardson et al., 1995a). These sounds appear to be important social cues (Shipley et al., 1992). The mean fundamental frequency of airborne calls for adult females is 500 to 1,000 Hz (Bartholomew and Collias, 1962). In-air sounds produced by females include a <0.7 kHz belch roar used in aggressive situations and a 0.5 to 1 kHz bark used to attract the pup (Bartholomew and Collias, 1962). As noted by Kastak and Schusterman (1999), evidence for underwater sound production by this species is scant. Except for one unsubstantiated report, none have been definitively identified (Fletcher et al., 1996; Burgess et al., 1998). Burgess et al. (1998) detected possible vocalizations in the form of click trains that resembled those used by males for communication in air.

The audiogram of the northern elephant seal indicates that this species is well-adapted for underwater hearing; sensitivity is best between 3.2 and 45 kHz, with greatest sensitivity at 6.4 kHz and an upper frequency cutoff of approximately 55 kHz (Kastak and Schusterman, 1999).

3.1.3 CULTURAL RESOURCES—OPEN OCEAN AREA

Cultural resources include prehistoric and historic sites, structures, objects, districts, artifacts or any other physical evidence of human activity considered important to a culture, subculture, or community for scientific, traditional, religious, or any other reasons. For ease of discussion, cultural resources have been divided into archaeological resources (prehistoric and historic), historic buildings and structures, and traditional resources. Traditional resources include, but are not limited to, topographical areas, natural features, plants/trees, minerals, water sources, or archaeological sites that contemporary cultures value presently (or did so in the past) and consider essential for the persistence of their traditional culture. Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

For all locations analyzed in this EIS/OEIS, the region of influence for cultural resources (both terrestrial and underwater) is synonymous with the Area of Potential Effect as defined under the National Historic Preservation Act. In general, the region of influence includes any area where ground disturbance from the proposed activities described in Chapter 2.0 could occur. The region of influence also encompasses any identified historic buildings or structures that could be affected by demolition, renovation, or other major alteration.

The region of influence for cultural resources within the Open Ocean Area and offshore areas includes any locations where underwater demolition; trenching; or placement of new systems, infrastructure, or equipment might affect submerged sites, features, wrecks, or ruins. Humpback whales and other marine mammals of cultural value to some Native Hawaiians and other people (National Oceanic and Atmospheric Administration, 2003) are also known to transit these areas.

Affected Environment

Open Ocean Area Archaeological Resources

In the waters surrounding the Hawaiian Islands, there are thousands of submerged cultural resources. Among the typical deep water resources are wrecks of World War II submarines and ships, commercial fishing vessels and tankers, and aircraft. There is no definitive count of the number of shipwrecks surrounding the Hawaiian Islands, as Pacific Ocean currents are quick to destroy wrecks. In addition, identifying older wrecks can be problematic, as islands are periodically subjected to large storms, powerful seas, and occasional tsunamis. The types of shipwrecks most likely to occur around the Hawaiian Islands are 19th century cargo ships, submarines, old whaling and merchant ships, fishing boats, or 20th century U.S. Warships, recreational craft, and land vehicles.

The State of Hawaii's Geographic Information System and the *Marine Resources Assessment for the Hawaiian Islands Operating Area, Final Report* (U.S. Department of the Navy, 2005b) were reviewed to determine the potential for shipwrecks to exist within the waters surrounding the Hawaiian Islands, as well as the specific proposed regions of influence. Figures 3.1.3-1 through 3.1.3-3 show the distribution of shipwrecks identified.

A discussion of offshore submerged resources (e.g., fishponds) is provided in Section 3.3.1.1.2.

3.1.4 HAZARDOUS MATERIALS AND WASTE—OPEN OCEAN AREA

Appendix C includes a discussion of hazardous materials and waste resource regulations.

Region of Influence

The hazardous materials and wastes region of influence for the Open Ocean Area includes the Navy's sea ranges and immediately adjacent waters.

Affected Environment

Hazardous Materials and Hazardous Constituents

Hazardous materials can be broadly defined as those materials with clearly hazardous properties that are in general use in commercial and industrial applications. Hazardous materials include, but are not limited to, petroleum products, coolants, paints, adhesives, solvents, corrosion inhibitors, cleaning compounds, photographic materials and chemicals, and batteries. Hazardous materials are required for maintenance and operation of vessels, machinery, and equipment used by the Navy in training activities.

Hazardous constituents can generally be defined as hazardous materials present at low concentrations in a generally non-hazardous matrix, such that their hazardous properties do not produce acute effects. Navy vessels conducting training do not intentionally release hazardous constituents into the water. U.S. Environmental Protection Agency (USEPA) and the Department of Defense (DoD), however, have identified numerous waste streams from Navy vessels that do or may contain hazardous constituents. Waste streams from Navy vessels that may contain hazardous constituents include hull coating leachate and:

- Bilgewater/oil water separator discharges,
- Gray water,
- Cooling water,
- Weather deck runoff
- Chain locker effluent,
- Elevator pit effluent, and
- Photographic laboratory drains.

In addition, small boat engines discharge petroleum products in their wet exhaust (U.S. Environmental Protection Agency, 2004).

Table 3.1.4-1 lists the hazardous constituents of common Navy training munitions. Hazardous materials associated with training are described below.

Table 3.1.4-1. Hazardous Constituents of Training Materials

Training Application/ Munitions Element	Hazardous Constituent
Pyrotechnics Tracers Spotting Charges	Barium chromate Potassium perchlorate
Oxidizers	Lead oxide
Delay Elements	Barium chromate Potassium perchlorate Lead chromate
Propellants	Ammonium perchlorate
Fuses	Potassium perchlorate
Detonators	Fulminate of mercury Potassium perchlorate
Primers	Lead azide

Hazardous Constituents of Concern

Missiles

The single largest hazardous constituent of missiles is solid propellant, but numerous hazardous constituents are used in igniters, explosive bolts, batteries, and warheads. Most of the missiles fired carry inert warheads that contain no hazardous constituents. Exterior surfaces may be coated, however, with anti-corrosion compounds containing chromium or cadmium.

Aerial Targets

Aerial targets are used for testing and training purposes. Most air targets contain jet fuels, oils, hydraulic fluid, batteries, and explosive cartridges as part of their operating systems. Fuel is shut off by an electronic signal, the engine stops, and the target begins to descend. A parachute is activated and the target descends to the ocean surface where range personnel retrieve it. Some targets are actually hit by missiles, however, and those targets fall into the Range unrecovered.

Surface Targets

Surface targets are used during Missile and Bombing Exercises. Surface targets are stripped of unnecessary hazardous constituents, and made environmentally clean; therefore, only minimal amounts of hazardous constituents are onboard.

Each Sinking Exercise (SINKEX) uses as a target an excess vessel hulk that is eventually sunk during the course of the training event. The target is an empty, cleaned, and environmentally remediated target vessel that is towed to a designated location where various ships, submarines, or aircraft use multiple types of weapons to fire shots at the target vessel. The vessels used as targets are selected from a list of USEPA-approved destroyers, tenders, cutters, frigates, cruisers, tugs, and transports (See Appendix D). Weapons can include missiles, precision and non-precision bombs, gunfire, and torpedoes. If none of the shots sinks the target vessel, either a submarine shot or placed explosive charges are used to sink the ship. If sunk by explosives, charges ranging from 100 to 200 lb, depending on the size of the ship, are placed on or in the target vessel.

USEPA granted the U.S. Department of the Navy a general permit through the Marine Protection, Research, and Sanctuaries Act to transport vessels "for the purpose of sinking such vessels in ocean waters…" (40 Code of Federal Regulations [CFR] Part 229.2). Subparagraph (a)(3) of this regulation states "All such vessel sinkings shall be conducted in water at least 1,000 fathoms (6,000 ft) deep and at least 50 nm from land." In Hawaii, SINKEX events take place in Warning Area W-188 (see Figure 3.1.1-1) at least 50 nm from shore and in water deeper than 1,000 fathoms.

Other Ordnance

Other ordnance includes bombs and gunnery rounds. Most of this ordnance is inert (non-explosive) and consists of non-hazardous constituents. Inert ordnance includes steel shapes or replicas containing concrete, vermiculite (clay), or other non-hazardous constituents similar in appearance, size, and weight to explosive ordnance.

Explosives

Trinitrotoluene (TNT), used since 1912 by the Navy, is a nitroaromatic compound that continues to be a component of modern military munitions. Modern explosives in military ordnance, however, are generally solid-cast explosive fills formed by melting the constituents and pouring them into casings (usually steel). Most new Navy formulations contain plastic-bonded explosives (PBX), with plastic or other polymer binders added to increase their stability (Jane's Information Group, 2005; 2006). Royal Demolition Explosive (RDX)/High Melting Explosive (HMX) blends have generally replaced TNT in plastic-bonded formulations.

Explosives become an environmental concern when expended ordnance fails to function as designed (dud), and explosive compounds in the unexploded ordnance (UXO) are released into the environment. Munitions constituents of concern include nitroaromatics—principally TNT, its degradation products, and related compounds—and cyclonitramines, including RDX, HMX, and their degradation products. TNT degrades to dinitrotoluene (DNT) and subsequent degradation products from exposure to sunlight (photolysis) or bacteria (biodegradation). RDX also is subject to photolysis and biodegradation once exposed to the environment. As a group, military-grade explosives have low water solubility (see Table 3.1.4-2), and are relatively immobile in water. The physical structure and composition of blended explosives containing multiple chemical compounds, often with additional binding agents, may further slow the degradation and dissolution of these materials (see Table 3.1.4-3).

Table 3.1.4-2. Water Solubility and Degradation Products of Common Explosives

Compound	Water Solubility, milligrams/liter (mg/L) (at 20°C)
Salt (sodium chloride) [for comparison]	357,000
Ammonium perchlorate	249,000
Picric acid	12,820
Nitrobenzene	1,900
Dinitrobenzene	500
Trinitrobenzene	335
Dinitrotoluene (DNT)	160-161
Trinitrotouene (TNT)	130
Tetryl	51
Pentaerythritol tetranitrate (PETN)	43
Royal Demolition Explosive (RDX)	38
High Melting Explosive (HMX)	7
White phosphorus	4

Table 3.1.4-3. Explosive Components of Munitions

Name	Composition	Use
Composition A	91% Royal Demolition Explosive (RDX)	Grenades, projectiles
Composition B	60% RDX, 39% trinitrotoluene (TNT)	Projectiles, grenades, shells, bombs
Composition C-4	91% RDX, 9% plasticizer	Demolition explosive
Explosive D	Picric acid, ammonium picrate	Bombs, projectiles
Octol	70-75% High Melting Explosive (HMX), 25-30% TNT	Shaped and bursting charges
TNT	Not Applicable	Projectiles, shells
Tritonal	80% TNT, 20% aluminum	Bombs, projectiles
H6	80% Composition B, 20% aluminum	Bombs, projectiles

Source: U.S. Environmental Protection Agency, 2006.

Other Munitions Constituents. Other munitions constituents of concern include pyrotechnic (illumination and smoke) compounds, propellants, primers, and metals (iron, manganese, copper, lead, zinc, antimony, mercury) released from both initiation primers and ordnance casing corrosion. Nitrocellulose, nitroglycerin, perchlorate, nitroguanidine, and pentaerythritol tetranitrate (PETN) are commonly used in artillery, mortar, and rocket propellants. Common primers include lead azide, lead styphnate, and mercury fulminate. PETN is a major component of detonation cord and blasting caps. Phosphorus, potassium perchlorate, and metal nitrates are common ingredients of pyrotechnics, flares, and smokes. In particular, the heavy metals tend to accumulate in the biosphere because of their generally low solubility and their elemental nature—they may oxidize or corrode, but do not break down in the manner of organic compounds.

Explosive Byproducts. The explosive byproducts generated when ordnance does function as designed (high order detonation), or experiences a low-order detonation, also generate constituents of concern. The major explosive byproducts of organic nitrated compounds such as TNT and RDX include water, carbon dioxide, carbon monoxide, and nitrogen (Department of Health and Human Services, Agency for Toxic Substance and Disease Registry, 2003); Renner and Short, 1980; Cook and Spillman, 2000). Residues of high-order detonations are primarily micron-sized and submicron-sized particles that are spread over hundreds of square meters. High-order detonations result in almost complete conversion of explosives (99.997% or more [U.S. Army Corps of Engineers, 2003]) into such inorganic compounds, whereas low-order detonations result in incomplete conversion (i.e., a mixture of the original explosive and its byproducts). For example, Table 3.1.4-4 lists the calculated chemical byproducts of high-order underwater detonation of TNT, RDX, and related materials. Table 3.1.4-5 lists the measured residues of high-order detonations of selected common military munitions.

Table 3.1.4-4. Chemical Byproducts of Underwater Detonations

Byproduct	Percent by Weight, by Explosive Compound			
	Trinitrotoluene (TNT)	Royal Demolition Explosive (RDX)	Composition B	Plastic-Bonded Explosive (PBX)
Nitrogen	18.2	37.0	29.3	33.2
Carbon dioxide	27.0	24.9	34.3	32.0
Water	5.0	16.4	8.4	13.2
Carbon monoxide	31.3	18.4	17.5	7.1
Carbon (elemental)	10.6	-	2.3	3.2
Ethane	5.2	1.6	5.4	7.1
Hydrogen	0.2	0.3	0.1	0.1
Propane	1.6	0.2	1.8	2.8
Ammonia	0.3	0.9	0.6	1
Methane	0.2	0.2	0.2	0.1
Hydrogen cyanide	<0.0	<0.0	<0.0	<0.0
Methyl alcohol	<0.0	<0.0	-	-
Formaldehyde	<0.0	<0.0	<0.0	<0.0
Other compounds	<0.0	<0.0	<0.0	<0.0

Source: Renner and Short, 1980

Munitions constituents are deposited on the surface of the ocean during training and testing in amounts similar to those identified on land ranges. Laboratory studies have determined that TNT exhibits toxicity in the marine environment at concentrations of 0.9 to 11.5 milligrams per liter (mg/L), while RDX generally showed limited toxicity. In marine sediments, TNT exhibits toxicity at concentrations of 159 to 320 parts per million (ppm). RDX exhibits no sediment toxicity at the concentrations tested (Lotufo and Ludy, 2005; Rosen and Lotufo, 2005; Rosen and Lotufo 2007a, 2007b). In a series of tests mimicking a natural environment, Ek et al. (2006) determined that, under environmental conditions typical of in-water UXO, no substantial toxicity or bioaccumulation of TNT munitions occurred. In general, munitions constituents in the marine environment appear to pose little risk to the environment.

Table 3.1.4-5. Per-Round Residues of Live Fire Detonations

Munition	Plume Area (square meters)	Residue (milligrams)				Total Residue (%)
		RDX	HMX	TNT	Total	
60-mm mortar	214	0.076	ND	ND	0.076	2.0×10^{-5}
81-mm mortar	230	8.3	ND	1.1	9.4	1.0×10^{-3}
120-mm mortar	450	17.0	1.3	2.8	21.0	7.0×10^{-4}
105-mm howitzer	530	0.095	ND	0.17	0.27	1.3×10^{-5}
155-mm howitzer	938	0.3	ND	0.009	0.31	4.4×10^{-6}

Notes:
HMX = High Melting Explosive
mm = millimeter
ND = not detected
RDX = Royal Demolition Explosive
TNT = trinitrotoluene

UXO and Low-Order Detonations

UXO is ordnance that fails to function as designed. This ordnance may remain capable of detonation, posing a physical risk to individuals in its vicinity. On ranges controlled by the Navy, this risk is limited to military personnel, who are trained in UXO avoidance. UXO poses a risk to the public when ordnance lands off-range and is not immediately recovered, or when Navy training activities occur in areas accessible to the public.

The failure rate, or percentage of ordnance that fails to properly function, varies widely by ordnance type and by the circumstances under which the ordnance is used. Quality control testing of Army ordnance identified failure rates by ordnance type (see Table 3.1.4-6). These rates were determined under controlled conditions; average failure rates under field conditions were estimated to be about 10 percent. The authors stated, however, that they had observed failure rates of up to 25 percent and low-order detonation rates of up to 5 percent for mortars (U.S. Army Corps of Engineers, 2007). These higher observed failure rates take into account operator error, missing the target, and other field conditions not present during the tests.

UXO and low-order detonations also account for much of the explosives residues on military ranges. Ordnance that does not detonate may break open on impact, or the casings may be compromised later by corrosion, releasing raw explosives into the environment. In low-order detonations, as much as 40 percent of the explosive material may remain, compared with about 0.003 percent for high-order detonations. For purposes of assessing impacts on the environment, a failure rate of 5 percent and a low-order detonation rate of 0.2 percent are assumed, and are considered to be sufficiently conservative.

Table 3.1.4-6. Failure and Low-Order Detonation Rates of Military Munitions

Munition	Failure Rate (%)	Low-Order Rate (%)
Gun/artillery	4.68	0.16
Hand grenade	1.78	NA
High explosive munitions	3.37	0.09
Howitzer	3.75	NA
Mortars	2.91	0.08
Rocket	3.84	NA
Submunition	8.23	NA

NA = Not available

Expended Training Materials

Various types of small, expendable training items are shot, thrown, dropped, or placed within the training areas. These items include smoke grenades, flares, and sonobuoys of various types. They are used in relatively small quantities for selected training activities, and are scattered over a large area. Items that are expended on the water, and fragments that are not recognizable as training materials (e.g., flare residue, or candle mix) are not collected.

Sonobuoys and residues of flares, smoke grenades, and other pyrotechnic devices that fall in the water may release small amounts of toxic substances as they degrade and decompose. The items degrade very slowly, so the volume of decomposing training materials within the training areas—and the amounts of toxic substances being released to the environment—gradually increases over the period of military use. Concentrations of some substances in sediments surrounding the disposed items increase over time. Sediment movements in response to tidal surge and longshore currents, and sediment disturbance from ship traffic and other sources, eventually disperse some of the contaminants outside of the training areas.

Sonobuoys. Approximately 6,300 sonobuoys are deployed annually as part of the training events. Sonobuoys are electro-mechanical devices used for a variety of ocean sensing and monitoring tasks. Sonobuoys contain lead solder, lead weights, and copper anodes. Sonobuoys also may contain fluorocarbons and lithium sulfur dioxide, lithium, or thermal batteries.

During operation, a sonobuoy's seawater batteries may release copper, silver, lithium, or other metals to the surrounding marine environment, depending on the type of battery used. They also may release fluorocarbons. Marine organisms are exposed to battery effluents for up to 8 hours, which is about the maximum life of seawater batteries. The batteries cease operating when their chemical constituents have been consumed. Once expended and scuttled, the sonobuoys sink to the ocean floor.

Various types of sonobuoys are used, so the exact amounts of materials that are generated are not known. Table 3.1.4-7 provides estimates of sonobuoy wastes, based on the types of sonobuoys typically used for current Navy training activities.

Table 3.1.4-7. Sonobuoy Hazardous Constituents

Constituent	Amount / Sonobuoy (lb)	Total Constituent Amount / Year[a]	
		Pounds	Kilograms
Copper thiocyanate	1.59	19,900	9,030
Fluorocarbons	0.02	250	114
Copper	0.34	4,250	1,930
Lead	0.94	11,800	5,340
Steel, tin/lead plated	0.06	750	341
TOTAL	2.95	37,000	16,800

Source: U.S. Department of the Navy, San Clemente Island Ordnance Database [No Date]

Notes: (a) values based on 12,500 sonobuoys discarded in the HRC, and rounded to three significant digits. Based on average amounts of constituents per sonobuoy.

Pyrotechnic Residues. About 760 smoke grenades and over 2,210 flares are used under baseline conditions. Solid flare and pyrotechnic residues may contain, depending on their purpose and color, aluminum, magnesium, zinc, strontium, barium, cadmium, nickel, and perchlorates. At an average weight of about 0.85 lb per item, about 1.3 tons per year of these wastes would be generated. Although pyrotechnic residues typically include hazardous constituents, most of them are present in small amounts or low concentrations, and are bound up in relatively insoluble compounds. As inert, incombustible solids with low concentrations of leachable metals, these materials typically do not meet the criteria for characteristic hazardous wastes. The perchlorate compounds present in the residues are relatively soluble.

Chaff. Chaff is a thin, non-toxic polymer with a metallic (aluminum) coating used to decoy enemy radars. The chaff is shot out of launchers using a propellant charge. The fine, neutrally buoyant chaff streamers act like particulates in the water, temporarily increasing the turbidity of the ocean's surface, but they quickly disperse. The Air Force has studied chaff and has determined that chaff has no adverse environmental impacts (U.S. Air Force, Air Combat Command, 1997).

At present, about 34 Chaff Exercises are held per year, releasing about 255 packages of chaff over the Open Ocean Area. In addition, Air Combat Maneuvers release more than 4,400 packages of chaff per year. The chaff disperses quickly, and the widely spaced exercises have no discernable effect on the marine environment.

Baseline Conditions

Open ocean areas are typically considered to be relatively pristine with regard to hazardous materials and hazardous wastes. Hazardous materials are present on the ocean, however, as cargoes and as fuel, lubricants, and cleaning and maintenance materials for marine vessels and aircraft. Infrequently, large hazardous materials leaks and spills—especially of petroleum products—have fouled the marine environment and adversely affected marine life. No quantitative information is available on the overall types and quantities of hazardous materials present on the sea ranges at a given time, nor on their distribution among the various categories of vessels.

Navy vessels present on the Hawaii sea ranges represent a small fraction of the overall commercial and recreational boat traffic and, correspondingly, account for only a small fraction of the potentially hazardous materials present in the Open Ocean Area around Hawaii. As described earlier, Navy training activities in open ocean areas involve the use of fuel, lubricants, explosives, propellants, batteries, oxidizers, and other hazardous substances. The Navy makes every effort to minimize its use of hazardous materials during training, and recovers and reuses unexpended training materials to the extent practicable.

Hazardous Wastes

Management

Environmental compliance policies and procedures applicable to training and RDT&E activities on shore are defined in Naval Operations Instruction (OPNAVINST) 5090.1C (2007), while environmental compliance policies and procedures applicable to shipboard operations afloat are defined in OPNAVINST 5090.1C (2007). The Consolidated Hazardous Materials Reutilization and Inventory Management Program (CHRIMP) also provides information on management of hazardous materials for both afloat and ashore. These documents provide a comprehensive compilation of procedures and requirements that are mandated by law, directive, or regulation. These documents have a compliance orientation to ensure safe and efficient control, use, transport, and disposal of hazardous waste. Hazardous wastes generated afloat are stored in approved containers. The waste is offloaded for proper disposal within 5 working days of arrival at a Navy port.

Generation

Environmental compliance policies and procedures applicable to shipboard operations afloat are defined in OPNAVINST 5090.1C (2007). Munitions containing or comprising hazardous materials expended during training exercises that are irretrievable from the ocean are not considered a hazardous waste in accordance with the Military Munitions Rule.

Storage

Navy ships may not discharge overboard untreated used or excess hazardous materials generated onboard the ship within 200 nm of shore. Ships retain used and excess hazardous material on board for shore disposal. Ships offload used hazardous materials within 5 working days of arrival at a Navy port.

Disposal

Hawaii lacks permitted hazardous waste disposal facilities; therefore, hazardous waste generated by the Navy is shipped to the mainland for disposal. Limited facilities for treatment and processing of recycled materials exist on Oahu.

Baseline Conditions

Commercial, scientific, and military vessels generate small quantities of hazardous wastes during their operations. These materials typically are accumulated while at sea, and then offloaded and transported to land disposal facilities when in port. No quantitative information is available on the overall types and quantities of hazardous wastes present on the sea ranges at a given time, nor on their distribution among the various categories of vessels.

3.1.5 HEALTH AND SAFETY—OPEN OCEAN AREA

Public health and safety issues include potential hazards inherent in flight operations, weapons firings, vessel operations, and target activities. This section also addresses public proximity and access, effects of electromagnetic radiation (EMR), potential ordnance hazards, and potential fuel hazards. The safety policy of the Navy is to observe every reasonable precaution in planning and executing its range operations to prevent injuries to or adverse health effects on its personnel or the public. Appendix C includes a discussion of health and safety resource regulations.

Region of Influence

The region of influence for public health and safety includes the sea ranges themselves, and ocean areas adjacent to the sea ranges.

Affected Environment

The ocean in the vicinity of the main Hawaiian Islands is used for a variety of recreational, commercial, scientific, transportation, cultural, and institutional purposes. The intensity of use generally declines with increasing distance from the shoreline, although specific resources in the Open Ocean Area may result in a concentration of use (e.g., sea mounts are preferred fishing locations). Areas that are shielded by land masses from the full force of wind and waves, such as the channels between Maui and adjacent islands, are preferred recreational areas. The HDAR is conducting a Hawaii Marine Recreational Fishing Survey Project to determine the quantity of recreational fishing in Hawaii.

Activities in the Open Ocean Area have no influence on public health. These areas are widely used for recreation, commerce, and scientific, educational, and cultural activities, however, surface vessel transits, aircraft operations, and weapons firing have the potential to affect public safety. The Navy has developed extensive protocols and procedures for the safe operation of its vessels and the safe execution of its training events.

3.1.6 NOISE—OPEN OCEAN AREA

Appendix C includes a definition of noise and the main regulations and laws that govern them. Wildlife receptors and their acoustic characteristic and sensitivities are described in Section 3.1.2, Biological Resources.

Region of Influence

Noise sources in the HRC are transitory and widely dispersed. The region of influence for noise includes all areas of the HRC where air operations or live weapons firings take place.

Affected Environment

Table 3.1.6-1 lists typical noise sources and their effects on the corresponding noise environments. Note that each of the sound levels indicated is for a single event. Such events are discrete, and the resulting noise is not additive.

Airborne Noise Sources

Airborne noise sources include civilian and military aircraft (both types of which fly at altitudes ranging from hundreds of feet to tens of thousands of feet above the surface), bombs, naval gunfire, missiles, rockets, and small arms. Noise levels may be significant in the vicinity of these activities, but the noise intensity decreases rapidly with increasing distance from the source, especially for impulsive noise from the discrete noise events characteristic of military training. Additionally, these activities take place miles at sea, where few or no human receptors are exposed to the noise. Open Ocean Area noise events are widely dispersed, temporally and geographically, with little or no overlap or additive effects.

Airborne Noise Levels

As shown on Table 3.1.6-1, at the lower end of the threshold, human hearing begins at 0 dB. At the upper end of the hearing range, sounds become uncomfortable, and even painful at approximately 140 dB. At or above approximately 140 dB, permanent damage and hearing loss can occur, even with brief exposure to the noise. The noise levels shown are measured at the receiver, not the source. For example, the vacuum cleaner level of 70 dB is measured 10 ft from the vacuum cleaner itself. In general, sound levels decrease by 6 dB as you double the distance to the source. At 20 ft from the same vacuum cleaner, a person would receive approximately 64 dB of noise. Therefore, both the source level and the distance from the source are important to gauge the impact of a noise on a human receptor.

Underwater Noise

Underwater sources on the HRC may be categorized in terms of their time-related characteristics. The categories are continuous or slowly varying, pulse (tonal), impulse (broadband), and explosive sources. The continuous or slowly varying source category includes submarine simulators, and torpedoes. Noise radiated into water from slower, low-flying fixed-wing aircraft and helicopters is also included in this category. The pulse category includes active sonar, beacons, transponders, fathometers, underwater telephones, and various pingers. The broadband impulse category includes noise made by fast, low-flying aircraft, naval surface gunfire, and objects impacting the water (e.g., sonobuoys, intact missiles, bombs, aerial targets, mine shapes, and various projectiles). Underwater noise sources include bombs and other projectiles that explode underwater and demolition activities. These sources are distinguished from the broadband impulse category by shock wave propagation near the source with high peak pressures and short durations. See Appendix G for additional details.

Table 3.1.6-1. Sound Levels of Typical Airborne Noise Sources and Environments

COMMON SOUNDS	SOUND LEVEL dB		LOUDNESS (Compared to 70 dB)
	130		
Oxygen Torch	120	UNCOMFORTABLE	32 Times as Loud
Discotheque	110		16 Times as Loud
Textile Mill	100	VERY LOUD	
Heavy Truck at 50 Feet	90		4 Times as Loud
Garbage Disposal	80	MODERATE	
Vacuum Cleaner at 10 Feet	70		
Automobile at 100 Feet	60		
Air Conditioner at 100 Feet	50		
Quiet Urban Daytime	40	QUIET	1/4 as Loud
Quiet Urban Nighttime	30		
Bedroom at Night	20		1/16 as Loud
Recording Studio	10	JUST AUDIBLE	
	0	Threshold of Hearing

3.1.7 WATER RESOURCES—OPEN OCEAN AREA

Appendix C describes the primary laws and regulations regarding water resources.

Region of Influence

The region of influence for water resources includes open ocean waters within the HRC.

Affected Environment

The Open Ocean Area off the Hawaiian Islands is a dynamic, tropical marine environment. Average water temperatures vary from 71° F in March to 81°F in September. Wave height varies from occasional flat seas to over 40 ft during high winter winds. Average swells commonly range from 3.3 to 9.8 ft in height. Water quality in the Open Ocean Area is excellent, with high clarity, low concentrations of suspended particles, high levels of dissolved oxygen, and low levels of contamination from trace metals or hydrocarbons (components of petroleum-based fuels) (U.S. Department of the Navy, 2000).

Physical and Chemical Properties

The general composition of the ocean includes water, salts, dissolved gases, minerals, and nutrients. The characteristics of seawater determine, in part, the interactions between the ocean and its inhabitants. The most important physical and chemical properties of seawater are temperature, salinity, density, alkalinity (pH), and dissolved gases.

Salinity

Salinity refers to the salt (sodium chloride) content of seawater. For oceanic waters, the salinity is approximately 35 parts of salt per 1,000 parts of seawater. Variations in the salinity of ocean water are linked primarily to climatic conditions. Salinity variations are at their highest at the surface of the water. The salinity of surface water is increased by the removal of water through evaporation. Alternately, it decreases through dilution from the addition of fresh water (e.g., rain, runoff from fresh water sources such as streams).

Seawater salinity has a profound effect on the concentration of salts in the tissues and body fluids of organisms. Slight shifts of salt concentrations in the bodies of animals can have stressful or even fatal consequences. Therefore, animals have either evolved mechanisms to control body salt levels, or they let them rise and fall with the levels of the seawater around them. (Waller, 1996)

In addition to the direct effects on marine biota, salinity also has an effect on the ocean's physical properties. For example, salinity helps maintain a constant temperature throughout the ocean depths. A high salt content in water slightly increases its density, which makes it resistant to drastic temperature fluctuations.

Density

Density (mass per unit volume) of seawater depends on its composition, and is affected by temperature. The dissolved salt and other dissolved substances contribute to the higher density of seawater versus fresh water. As temperatures increase, density decreases. Accordingly, water that is denser will sink, while water which is less dense will rise. Therefore, oceans can be thought of as having a three-layered system of water masses. The three layers of the ocean include: the surface layer, from 0 to 92 fathoms; an intermediate layer, from 92 to 250 fathoms; and a deepwater layer, from 250 fathoms to the sea floor. (Waller, 1996)

Temperature

Water temperature is one of the most important physical factors of the marine environment. Temperature controls the rate at which chemical reactions and biological processes occur (Waller, 1996). In addition, most organisms have a distinct range of temperatures in which they may thrive. A greater number of species live within the moderate temperature zones with fewer species tolerant of extremes in temperature. Typically, the vast majority of organisms cannot survive dramatic temperature fluctuations.

Temperature gradients are created when warmer, lighter water floats above the cold, denser water. The warm and cold layers of water are separated by a thin, narrow band of stable water called a thermocline. In tropical latitudes, the thermocline is present as a permanent feature and is located approximately 33 to 167 fathoms below the surface. The temperature below the thermocline remains relatively constant, with most areas of the Pacific Ocean maintaining a temperature of 39.2ºF. The thermocline acts as a depth barrier to many plants and animals and often represents the boundary between hospitable and inhospitable water masses for many species of organisms. (Waller, 1996)

pH

The measure of the acidity or alkalinity of a substance, known as the pH, is based on a scale ranging from 1 (highly acidic) to 14 (highly basic). A pH of 7 is considered neutral. Surface seawater often has a pH between 8.1 and 8.3 (slightly basic), but generally the acidity of ocean water is very stable with a neutral pH. In shallow seas and coastal areas, the pH can be altered by plant and animal activities, by pollution, and interaction with fresh water. (Waller, 1996)

Dissolved Gases

Oxygen is not readily soluble in seawater. The amount of oxygen present in seawater will vary with the rate of production by plants, consumption by animals and plants, bacterial decomposition, and by surface interactions with the atmosphere. Most organisms require oxygen for their life processes. When surface water sinks to deeper levels, it retains its store of oxygen. (Waller, 1996) Carbon dioxide is a gas required by plants for photosynthetic production of new organic matter. Carbon dioxide is 60 times more concentrated in seawater than it is in the atmosphere. Seawater in tropical regions has lower levels of dissolved gas in a given volume of water compared to seawater in high latitudes (Waller, 1996).

Marine Pollutants

Ocean waters and sediments are chemically complex solutions that contain numerous natural and manmade substances, including all of the heavy metals and manmade organic compounds such as polychlorinated biphenyls (PCBs). Depending upon their concentrations and other factors, such as the concentrations of other substances or the alkalinity, salinity, or temperature of the water, some of these substances could be toxic to marine plants or animals. NOAA has established pollutant thresholds (i.e., screening concentrations of potential contaminants) for marine waters and sediments (see Table 3.1.7-1). These thresholds (for acute exposures) are not intended to indicate observable effects on marine biota in general, but rather to trigger a more-detailed evaluation of their potential effects on specific target organisms. NOAA's screening thresholds are based, in part, on USEPA water quality criteria and sediment quality guidelines, as well as other relevant studies and recommendations (National Oceanic and Atmospheric Administration, 2006f).

Table 3.1.7-1. Threshold Marine Pollutant Concentrations

Constituent	Concentration (ppb)	
	Water Column	Sediment*
Antimony	1,500	9,300
Arsenic	69	70,000
Cadmium	40	9,600
Chromium	10,300	370,000
Copper	4.8	270,000
Lead	210	218,000
Mercury	1.8	710
Nickel	74	51,600
Zinc	90	410,000
Benzene	5,100	ns
Phenol	5,800	130
Polychlorinated biphenyls (PCBs)	10	180
Polycyclic aromatic hydrocarbons	300	44,792
Toluene	6,300	ns

Source: National Oceanic and Atmospheric Administration, 2006f.

Notes: ppb - parts per billion; ns - no standard; * - Effects Range - Median (median value), except for the values for antimony and phenol, which are their Apparent Effects Thresholds.

THIS PAGE INTENTIONALLY LEFT BLANK

3.2 NORTHWESTERN HAWAIIAN ISLANDS

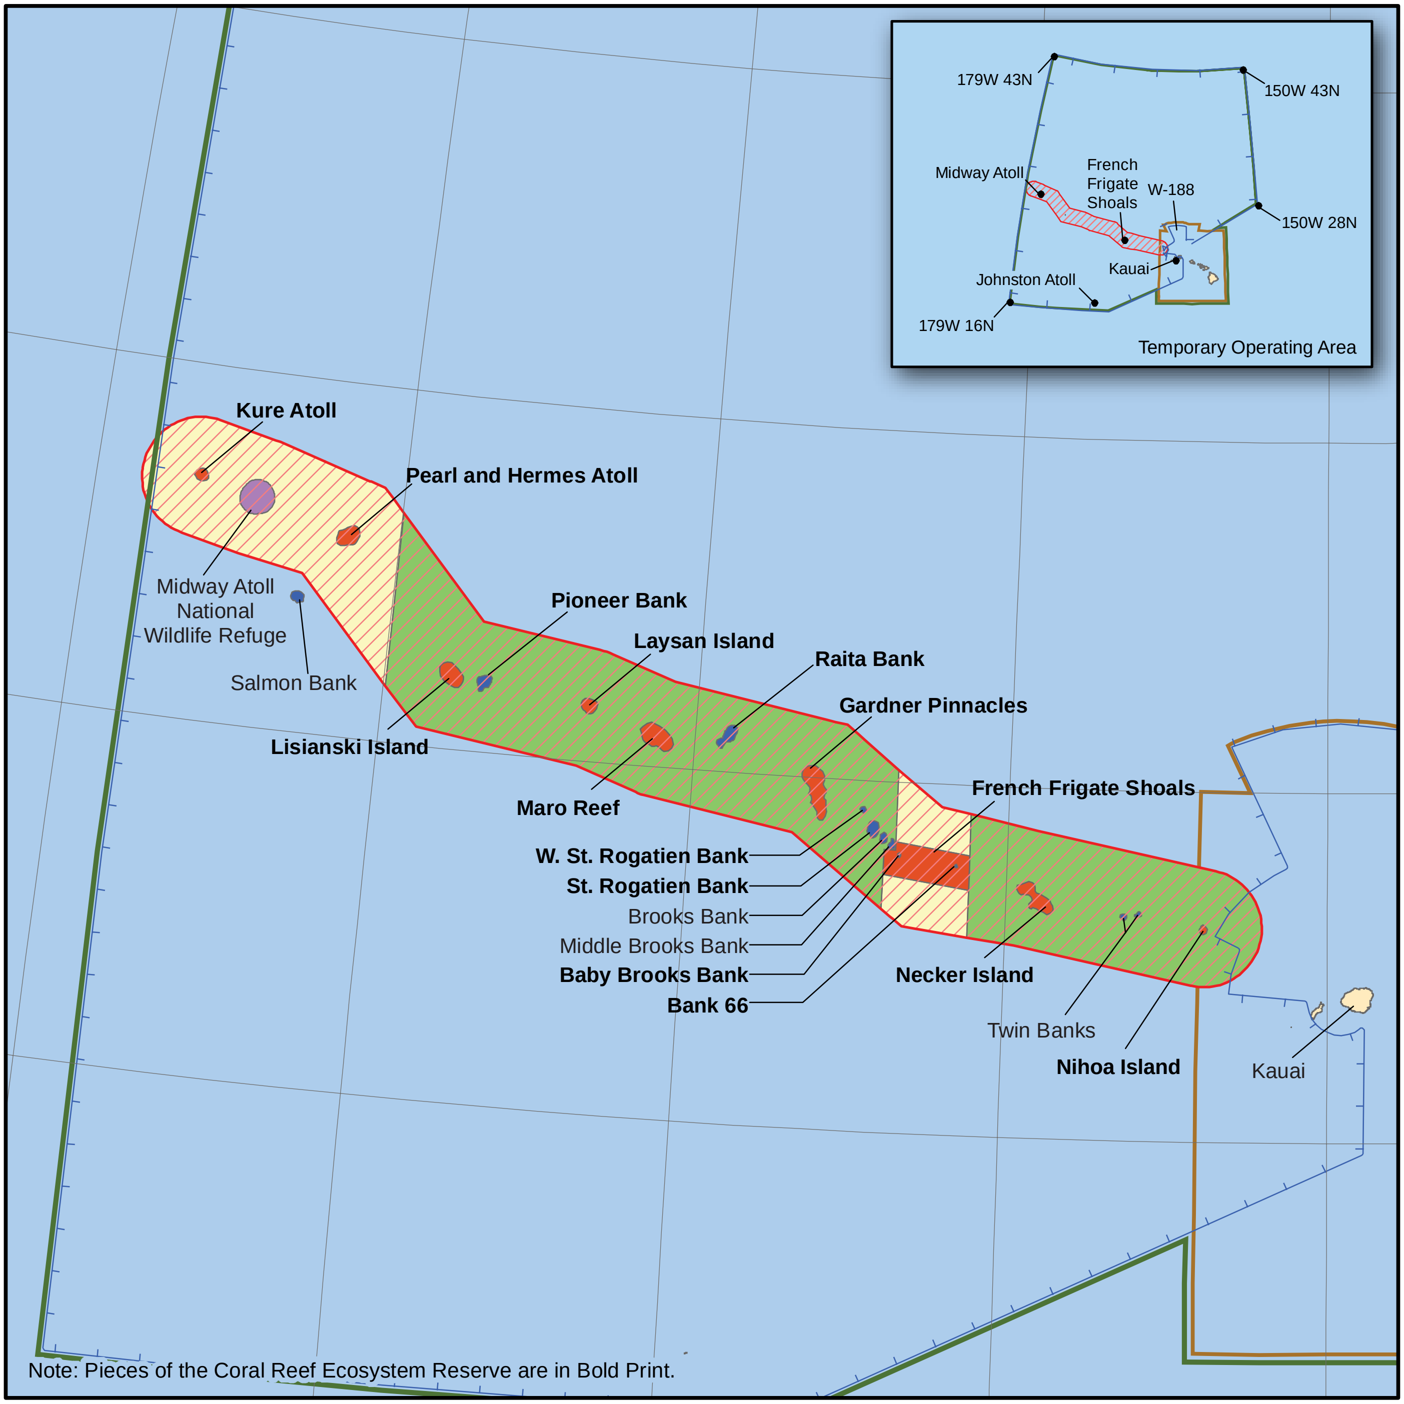
The Northwestern Hawaiian Islands are a chain of small islands, atolls, submerged banks, and reefs stretching for more than 1,000 miles (mi) northwest of the Main Hawaiian Islands. According to Friedlander et al. (2004), the coral reef fauna from the Northwestern Hawaiian Islands is rich, with over 1,000 identified species. Fifty-seven stony coral species have been identified in the shallow, subtropical waters of the Northwestern Hawaiian Islands (Friedlander et al., 2004). Only 12 species of alien marine algae, invertebrates, and fish have been recorded in the Northwestern Hawaiian Islands. *Hypnea musciformis*, an invasive algal species, is not yet established in the Northwestern Hawaiian Islands. It is located in drift only at Maro Reef. (National Oceanic and Atmospheric Administration, 2006c)

Depending on the trajectory, missiles launched from the Pacific Missile Range Facility (PMRF) have the potential to overfly portions of the Papahānaumokuākea Marine National Monument. Of particular concern is the potential for missile debris on or offshore of Nihoa and Necker, which are the islands closest to the Main Hawaiian Islands. Thus, these two islands are described in greater detail. Nihoa is located at the southeastern end of the Northwestern Hawaiian Islands and is 240 nautical miles (nm) northwest of Oahu.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for the Northwestern Hawaiian Islands. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

Papahānaumokuākea (Northwestern Hawaiian Islands) Marine National Monument

The Northwestern Hawaiian Islands Marine National Monument was established in June 2006 by Presidential Proclamation 8031 (Presidential Document, 2006), under the authority of the Antiquities Act (16 United States Code section 431). The Monument is nearly 140,000-square-mile (mi^2) area, 100 mi wide, established to protect marine resources in the area including coral reefs, the endangered Hawaiian monk seal (*Monachus schauinslandi*), the threatened Hawaiian green turtle (*Chelonia mydas*), and the endangered leatherback and hawksbill turtles (*Dermochelys coriacea* and *Eretmochelys imbricata*). The Monument includes the Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve, the Hawaiian Islands National Wildlife Refuge, the Midway Atoll National Wildlife Refuge, and the Battle of Midway National Memorial, which are briefly described below (National Oceanic and Atmospheric Administration, 2006b). The Monument was given the name Papahānaumokuākea Marine National Monument in 2007. Only a fraction of the Monument is within the Hawaiian Islands Operating Area on its western boundary near the northern border (Figure 3.2-1). The Temporary Operating Area encompasses the entire Monument.



EXPLANATION

- Hawaii Range Complex (HRC)
- Hawaii Operating Area (OPAREA)
- Temporary Operating Area (TOA)
- Papahānaumokuākea Marine National Monument
- Hawaiian Islands National Wildlife Refuge
- Midway Atoll National Wildlife Refuge
- Bank
- Ecological Reserve
- Commercial Fishing Phase-Out Area
- Land

NORTH

0 100 200 400 Nautical Miles

Papahānaumokuākea (Northwestern Hawaiian Islands) Marine National Monument

Hawaiian Islands

Figure 3.2-1

The Monument is situated in the Pacific Ocean northwest of the Main Hawaiian Islands and is an approximately 1,200-nm stretch of coral islands, seamounts, banks, and shoals (Figure 3.2-1). The Monument has been established for the protection of natural resources, including one of the last intact marine ecosystems in the world, home to sharks, whales, extensive coral reefs, and the endangered Hawaiian monk seal. The Presidential Proclamation establishing the Monument includes the following language regarding military activities in the area:

“1. The prohibitions required by this proclamation shall not apply to activities and exercises of the Armed Forces (including those carried out by the United States Coast Guard) that are consistent with applicable laws.
2. Nothing in this proclamation shall limit agency actions to respond to emergencies posing an unacceptable threat to human health or safety or to the marine environment and admitting of no other feasible solution.
3. All activities and exercises of the Armed Forces shall be carried out in a manner that avoids, to the extent practicable and consistent with operational requirements, adverse impacts on monument resources and qualities.
4. In the event of threatened or actual destruction of, loss of, or injury to a monument resource or quality resulting from an incident, including but not limited to spills and groundings, caused by a component of the Department of Defense or the USCG [U.S. Coast Guard], the cognizant component shall promptly coordinate with the Secretaries for the purpose of taking appropriate actions to respond to and mitigate the harm and, if possible, restore or replace the monument resource or quality.” (U.S. Government, The White House, 2006)

In April 2007, the Departments of Commerce and Interior issued a notice in the Federal Register (U.S. Fish and Wildlife Service, 2007c) advising the public that the National Oceanic and Atmospheric Administration, the U.S. Fish and Wildlife Service (USFWS) and the Department of Land and Natural Resources (DLNR), State of Hawaii intend to prepare a Monument Management Plan as well as an associated Environmental Assessment for the Papahānaumokuākea Marine National Monument in the Northwestern Hawaiian Islands and the surrounding marine areas. The Monument Plan will modify the existing Northwestern Hawaiian Islands Proposed National Marine Sanctuary Draft Management Plan and incorporate USFWS refuge comprehensive conservation planning requirements, DLNR planning needs, and other elements to reflect the area’s new status as a national monument.

The Departments of Commerce and Interior solicited comments from the public and other agencies. In September 2007, the agencies issued a Scoping Report that summarized the public comments and responses to those comments. Currently, the public review draft of the Monument Management Plan is planned for release in spring of 2008 with a final Plan to be issued in July 2008.

The Draft Management Plan’s Scoping Report indicates that the Management Plan and Environmental Assessment will address current military activities, with the understanding that “activities of the Armed Forces that could occur within the Monument are beyond the scope of [Monument Management Board] management activities,” wording in keeping with the Presidential Proclamation’s statement that required prohibitions are not applicable to activities and exercises of the Armed Forces.

The Monument's large geographic area is vitally important to strategic interests and international commerce. The Navy expects that the final Monument Plan will continue to recognize the need to preserve the operational flexibility of the military services and combatant commanders in this strategically important region.

Nihoa lies 130 mi northwest of Niihau and is the closest of the Northwestern Hawaiian Islands to the Main Hawaiian Islands. It is the largest volcanic island in the northwestern chain, with approximately 170 acres of land. The submerged coral reef habitat associated with Nihoa is approximately 142,000 acres.

The next closest island is Necker. This is a dry, volcanic island shaped like a fish hook that includes about 45 acres of land. More than 380,000 acres of coral reef habitat are associated with Necker (Hawaii Department of Land and Natural Resources, no date[b]). Because Nihoa and Necker are more likely to be impacted by program activities, they are discussed in more detail at the end of this section.

French Frigate Shoals is an 18-mi wide, crescent-shaped atoll. Its lagoon contains two exposed volcanic rocks and 11 low, sandy islets. Ninety to 95 percent of green turtle nesting and breeding occurs at French Frigate Shoals. Tern Island is a part of French Frigate Shoals. Approximately 67 acres of land and 230,000 acres of coral reef habitat are associated with French Frigate Shoals. Gardner Pinnacles consists of two peaks of volcanic rock that total 5 acres. Gardner Pinnacles is an important roosting site and breeding habitat for 12 species of tropical seabirds and is surrounded by approximately 600,000 acres of coral reef habitat (Hawaii Department of Land and Natural Resources, no date[b]).

Maro Reef is a largely submerged atoll, with only approximately 1 acre of emergent land but about 475,000 acres of submerged coral reef habitat. Laysan is the largest island in the chain, with about 1,000 acres of land. It is well vegetated and contains a hypersaline lake that is one of only five natural lakes in the State of Hawaii. Approximately 145,000 acres of coral reef habitat are associated with this island (Hawaii Department of Land and Natural Resources, no date[b]). Approximately 2 million birds nest on the island (National Oceanic and Atmospheric Administration, 2006c).

Lisianski Island is a low sand and coral island, with approximately 400 acres of land. It lies at the northern end of a large reef bank that spans about 65 mi^2, and totals about 310,000 acres. Pearl and Hermes Reef is a large atoll with several small islets forming about 80 acres of land with approximately 200,000 acres of coral reef habitat. The islets are periodically washed over during winter storms (Hawaii Department of Land and Natural Resources, no date[b]).

Midway Atoll measures 5 mi across and includes three small islands located at the southeastern end of the lagoon totaling 1,550 acres. The protective reef around the lagoon is submerged in some places and 4 to 5 feet (ft) above sea level in others. Approximately 55,000 acres of reef habitat are associated with Midway Atoll (Hawaii Department of Land and Natural Resources, no date[b]).

Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve

Executive Order (EO) 13178, *Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve*, created the Reserve. EO 13196, *Final Northwestern Hawaiian Islands Coral Reef Ecosystem*

Reserve, amended EO 13178 by finalizing several of its provisions. The principal purpose of the Reserve is the long-term conservation and protection of the coral reef ecosystem and related marine resources and species of the Northwestern Hawaiian Islands in their natural character.

The Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve lies to the northwest of the main islands of the Hawaiian chain. The Reserve includes submerged lands and waters of the Northwestern Hawaiian Islands, extending approximately 1,200 nm long and 100 nm wide. The Reserve is adjacent to and seaward of the seaward boundaries of the State of Hawaii and the Midway Atoll National Wildlife Refuge, and overlies the Hawaiian Islands National Wildlife Refuge to the extent that it extends beyond the seaward boundaries of the State of Hawaii (Presidential Document, 2000).

Midway Atoll National Wildlife Refuge

The Midway Atoll National Wildlife Refuge was created by EO 13022 in 1996. It is administered by the Secretary of the Interior through the USFWS in part to maintain and restore natural biological diversity and to provide for the conservation and management of fish and wildlife and their habitat. Fifteen species of seabirds nest on islands within the refuge, including the world's largest colony of Laysan albatross (*Phoebastria immutabilis*) and the largest colonies of red-tailed tropicbirds (*Phaethon rubricauda rothschildi*), black noddies (*Anous minutus*), and white terns (*Gygis alba*) in the Hawaiian archipelago. (U.S. Fish and Wildlife Service, 2006b)

Over 250 species of fish and a large diversity of marine invertebrates inhabit the lagoon and surrounding waters. Approximately 50 to 65 Hawaiian monk seals are located within the area offshore of the refuge. Midway's beaches provide critically important habitat where monk seals raise their pups. Threatened green turtles are most common offshore of Sand Island's beaches, but they are seen throughout the lagoon and surrounding offshore waters. A population of about 300 spinner dolphins (*Stenella longirostris*) also inhabit Midway's lagoon during daylight hours. (U.S. Fish and Wildlife Service, 2006b)

As part of the base closure process for Naval Air Facility Midway Island, the Navy was obligated to consider the effects of the closure process on historic sites and structures. The Navy determined that 78 structures, buildings, or objects were eligible for inclusion in the National Register of Historic Places, including the structures associated with the Battle of Midway National Historic Landmark, designated in 1986. (U.S. Fish and Wildlife Service, 2006b)

To guide the historic preservation process during the transition, the Navy entered into a Programmatic Agreement with the USFWS, the Hawaii State Historic Preservation Office and the Advisory Council on Historic Preservation. The Programmatic Agreement recommended specific types of treatment for the 78 historic sites or structures. (U.S. Fish and Wildlife Service, 2006a)

Hawaiian Islands National Wildlife Refuge

The Hawaiian Islands National Wildlife Refuge was designated by President Theodore Roosevelt in 1909. It consists of a chain of islands, atolls, and reefs extending approximately 800 mi northwest from the Main Hawaiian Islands. The refuge consists of Nihoa, Necker, French Frigate Shoals, Gardner Pinnacles, Maro Reef, Laysan, Lisianski, and Pearl and

Hermes Reef. Millions of seabirds, such as the sooty tern (*Sterna fuscata*) and albatross, live within the refuge, which also provides a rich habitat for marine life (U.S. Fish and Wildlife Service, Pacific Islands, 2002).

Kure Atoll State Wildlife Sanctuary

Kure is the northernmost coral atoll in the world. The island has a 6-mi diameter that encloses approximately 200 acres of emergent land. The outer reef almost completely encircles the lagoon except for passages to the southwest. The only permanent land in the atoll is Green Island, located near the fringing reef in the southeastern part of the lagoon. Almost 80,000 acres of coral reef habitat are associated with Kure Atoll. (Hawaii Department of Land and Natural Resources, no date[b]) Kure Atoll is a State wildlife refuge/sanctuary under the jurisdiction of the Hawaii Division of Forestry and Wildlife, DLNR. Jurisdiction of the USFWS and National Marine Fisheries Service (NMFS) applies to the enforcement of the Marine Mammal Protection Act and Endangered Species Act, although Kure Atoll is not part of the Hawaiian Islands National Wildlife Refuge.

3.2.1 NORTHWESTERN HAWAIIAN ISLANDS OFFSHORE

3.2.1.1 BIOLOGICAL RESOURCES—NORTHWESTERN HAWAIIAN ISLANDS OFFSHORE

Appendix C includes a definition of biological resources and the main regulations and laws that govern their protection. The 12- to 50-nm portion of the Papahānaumokuākea Marine National Monument is discussed in Section 3.2. As earlier noted, Nihoa and Necker islands are more likely to be affected by program activities. Their biological resources are addressed in greater detail below.

3.2.1.1.1 Nihoa—Biological Resources—Northwestern Hawaiian Islands Offshore

Region of Influence

The region of influence for biological resources offshore of Nihoa is the ocean surrounding the island from the shoreline out to 12 nm.

Affected Environment

A description of the coral reef area associated with the Hawaiian Islands and its management by both the State of Hawaii and the Federal government is provided in Section 3.1.2.1. Pink coralline, red, brown, and green algae are present offshore of Nihoa. The amount of shallow reef habitat immediately surrounding Nihoa is small due to the lack of suitable habitats, and fewer fish and other species have colonized there and been able to survive (Coral Reef Information System, 2007). Only submerged reefs are located around Nihoa. Most of the coral present only survives at depths greater than 40 ft, and coral cover is not greater than 25 percent. Seventeen species of stony coral have been identified offshore of Nihoa. Small lobe coral (*Porites lobata*) and rose coral colonies (*Pocillopora meandrina*) are the most common. The soft corals *Palythoa* sp. and *Sinularia abrupta* and the wire coral *Cirrhipathes* sp. are also present (National Oceanic and Atmospheric Administration, 2001). The most common invertebrates are small encrusting species such as sponges, bryozoans, and tunicates. (Coral Reef Information System, 2007; U.S. Fish and Wildlife Service and Hawaii Department of Land and Natural Resources, Division of Aquatic Resources, 2002; National Oceanic and Atmospheric Administration, 2006c)

No age data are available for coral communities off Nihoa; however, marine surveys indicate that the rocky bottoms around Nihoa are scoured by powerful surf and have limited coral growth, suggesting that coral communities are composed of relatively young colonies. High-wave energy coral communities appear to be most common and are dominated by cauliflower coral (*Pocillopora* spp.) and lobe coral (*Porites* spp.).

Reef sharks (*Carcharhinus* spp.) and jacks are common to the waters offshore of the island. The spotted knifejaw (*Oplegnathus punctatus*), which is uncommon in the Main Hawaiian Islands, is often seen. (Coral Reef Information System, 2007)

Nihoa supports a small population of endangered Hawaiian monk seals (Table 3.2.1.1.1-1) with limited reproduction, which is possibly maintained by immigration from other breeding colonies (National Oceanic and Atmospheric Administration, 2006c). The NMFS Southwest Fisheries Science Center (1999) estimated the population of monk seals to be approximately 35 to 77. Green turtles and leatherback turtles are located in the waters surrounding the Northwestern Hawaiian Islands, including Nihoa (Coral Reef Information System, 2007).

Table 3.2.1.1.1-1. Listed Species Known or Expected to Occur Offshore of Nihoa and Necker

Scientific Name	Common Name	Federal Status
Reptiles		
Chelonia mydas	Green turtle	T
Dermochelys coriacea	Leatherback turtle	E
Eretmochelys imbricata	Hawksbill turtle	E
Mammals		
Monachus schauinslandi	Hawaiian monk seal	E

Source: U.S. Fish and Wildlife Service, 2003b; 2007a; National Oceanic and Atmospheric Administration, 2006c

Key to Federal Status:
T = Threatened
E = Endangered

3.2.1.1.2 Necker—Biological Resources—Northwestern Hawaiian Islands Offshore

Region of Influence

The region of influence for biological resources offshore of Necker is the ocean surrounding the island from the shoreline out to 12 nm.

Affected Environment

A description of the coral reef area associated with the Hawaiian Islands and its management by both the State of Hawaii and the Federal government is provided in Section 3.1.2.1. A broad reef shelf surrounds the island, but is not shallow enough to protect the island from wave action. However, the number of coral species is comparable to that of Nihoa, fewer than 20. Reef growth is minimal (National Oceanic and Atmospheric Administration, 2006c). Most coral is found in habitats that are somewhat protected from wave scour, such as caves, overhangs, and trenches. The most commonly observed stony corals are small lobe coral and rose coral. Corals found at Necker that are not reported from Nihoa are finger coral (*Porites compressa*), cauliflower coral (*Pocillopora ligulata*), and corrugated coral (*Pavona varians*). (Coral Reef Information System, 2007)

Grey reef sharks (*Carcharhinus amblyrhynchos*), giant Trevally jacks (*Caranx ignobilis*), and gray snappers (*Lutjanus griseus*) are common. Large manta rays (*Manta birostris*) have been observed along the island's rocky surf zone.

Necker supports a small population of Hawaiian monk seals (Table 3.2.1.1.1-1) with limited reproduction that is possibly maintained by immigration from other breeding colonies. Green turtles occasionally are observed off the coast (National Oceanic and Atmospheric Administration, 2006c). Leatherback turtles are located in the waters surrounding the Northwestern Hawaiian Islands, including Necker (Coral Reef Information System, 2007).

3.2.2 NORTHWESTERN HAWAIIAN ISLANDS ONSHORE

3.2.2.1 BIOLOGICAL RESOURCES—NORTHWESTERN HAWAIIAN ISLANDS ONSHORE

Appendix C includes a definition of biological resources and the main regulations and laws that govern their protection.

3.2.2.1.1 Nihoa—Biological Resources—Northwestern Hawaiian Islands Onshore

Region of Influence

The region of influence for biological resources of Nihoa is the entire island.

Affected Environment

Vegetation

Most of the ridges on Nihoa are covered by grass: Kawelu (*Eragrostis variabilis*) and torrid panicgrass or kakonakona (*Panicum torridum*). The valleys are covered with dense shrubs, mainly goosefoot shrub or `aheahea (*Chenopodium oahuense*) and popolo (*Solanum nelsoni*). (U.S. Forest Service, undated; Resture, 2002)

Threatened and Endangered Plant Species

Nihoa is the home of three endemic, endangered plants (Table 3.2.2.1.1-1) located in what is reported to be an intact example of a Hawaiian coastal scrub community (U.S. Fish and Wildlife Service and Hawaii Department of Land and Natural Resources, Division of Aquatic Resources, 2002).

Table 3.2.2.1.1-1. Listed Species Known or Expected to Occur on Nihoa and Necker

Scientific Name	Common Name	Federal Status
Plants[1]		
Amaranthus brownii	No common name	E
Pritchardia remota	Loulu (Nihoa fan palm)	E
Schiedea verticillata	No common name	E
Sesbania tomentosa	`Ohai	E
Birds		
Acrocephalus familiaris kingi	Nihoa Millerbird	E
Telespyza ultima	Nihoa finch	E
Mammals		
Monachus schauinslandi	Hawaiian monk seal	E

Source: U.S. Fish and Wildlife Service, 2003b; National Oceanic and Atmospheric Administration, 2006c

1 Note: The entire island of Nihoa other than manmade features has been designated as critical habitat for these plants.

Key to Federal Status:
E = Endangered

The three endemic endangered plants on Nihoa are the loulu (Nihoa fan palm) (*Pritchardia remota), Amaranthus brownii* (no common name, last observed in 1983)*,* and *Schiedea verticillata* (no common name). The endangered `ohai (*Sesbania tomentosa*) is also found on Nihoa. The loulu relies on the isolation and protection from invasive species and disturbance that the Hawaiian Islands provide (U.S. Fish and Wildlife Service and Hawaii Department of Land and Natural Resources, Division of Aquatic Resources, 2002). The entire island other than manmade features has been designated as critical habitat for these plants (U.S. Fish and Wildlife Service, 2003b).

Wildlife

For many years the only regular inhabitants of Nihoa have been vast numbers of birds, including black-footed albatross (*Phoebastria nigripes*), Tristram's storm-petrel (*Oceanodroma tristrami*), Bulwer's petrel (*Bulweria bulwerii*), wedge-tailed shearwaters (*Puffinus pacificus chlororhynchus*), blue-gray noddies (*Procelsterna cerulea*), red-tailed tropic birds, great frigate birds or `iwa (*Fregata minor palmerstoni*), three kinds of boobies (*Sula* spp.), and terns such as the gray-backed tern or pakalakala (*Sterna lunata*), white (fairy) tern or manu-o-ku, and sooty tern or `ewa`ewa. Birds nest in a variety of places, from the ground to the crowns of the loulu palms. (State of Hawaii, 2005a)

Several species of migratory birds covered by the Migratory Bird Treaty Act (MBTA) are present during some portion of the year including, but not limited to boobies, wedge-tailed shearwaters, and albatross.

<u>Threatened and Endangered Wildlife Species</u>

In addition to the seabirds mentioned above, there are two species of native land birds: the Nihoa finch (*Telespyza ultima*) and the Nihoa Millerbird (*Acrocephalus familiaris kingi*), both endangered, endemic species found only on Nihoa (Table 3.2.2.1.1-1), but related to species on Laysan (Resture, 2002). Nihoa supports a small population of Hawaiian monk seals with limited reproduction, which is possibly maintained by immigration from other breeding colonies (National Oceanic and Atmospheric Administration, 2006c).

The current estimate of 300 to 700 Nihoa Millerbirds and 2,000 to 4,000 Nihoa finches rely on the isolation and protection from invasive species and disturbance that the Hawaiian Islands provide (State of Hawaii, 2005b; U.S. Fish and Wildlife Service and Hawaii Department of Land and Natural Resources, Division of Aquatic Resources, 2002). While critical habitat has not been designated for either species on Nihoa, the area nevertheless contains important habitat for both birds, and protection afforded by the Endangered Species Act still applies.

3.2.2.1.2 Necker—Biological Resources—Northwestern Hawaiian Islands Onshore

Region of Influence

The region of influence for biological resources of Necker is the entire island.

Affected Environment

Vegetation

Although Necker appears from a distance to be devoid of vegetation, its rounded crest and narrow terraces are actually sparsely covered with five species of plants: `aheahea, also common throughout the main Hawaiian Islands; kakonakona; purslane or ihi (*Portulaca lutea*); pickle weed or akulikuli kai (*Batis maritima*); and a few `ohai shrub. None of the plants reach more than 2 ft high. (Resture, 2004; Coral Reef Information System, 2007)

Threatened and Endangered Plant Species

The endangered `ohai shrub is present on the island (Table 3.2.2.1.1-1) (Coral Reef Information System, 2007).

Wildlife

The only wildlife other than land snails, spiders, and several endemic insects, are seabirds. Brown noddies (*Anous stolidus*) are year-round residents; egg laying has been documented throughout the year (Megyesi and Griffin, 1996). Great frigate birds or `iwa, blue-gray noddies, and masked boobies (*Sula dactylatra*) are also present. These birds are covered under the MBTA.

Threatened and Endangered Wildlife Species

Green turtles (Table 3.2.2.1.1-1) occasionally bask along the coast (National Oceanic and Atmospheric Administration, 2006c). Necker also supports a small population of endangered Hawaiian monk seals (Table 3.2.2.1.1-1) with limited reproduction that is possibly maintained by immigration from other breeding colonies (Coral Reef Information System, 2007).

3.2.2.2 CULTURAL RESOURCES—NORTHWESTERN HAWAIIAN ISLANDS ONSHORE

Appendix C includes a definition of cultural resources and the main regulations and laws that govern their protection.

Region of Influence

The region of influence for cultural resources encompasses portions of the Papahānaumokuākea Marine National Monument, particularly in the vicinity of Nihoa or Necker (Mokumanamana).

Affected Environment

Archaeological Resources (Prehistoric and Historic)

The Northwestern Hawaiian Islands were explored, colonized, and in some cases, semi-permanently settled by Native Hawaiians in pre-contact times. Nihoa and Necker (Mokumanamana), the islands that are closest to the Main Hawaiian Islands (approximately 150 mi apart), are listed in the National and Hawaii State Registers of Historic Places and are protected by the USFWS.

Several archaeological surveys of Nihoa and Necker have been conducted beginning with a survey by the Bishop Museum (the Tanager Expedition in 1923) (Emory, 1928). Between the two islands more than 140 archaeological sites have been documented. Though barren and seemingly inhospitable to humans, the number of cultural sites they support is testimony to their occupation and use prior to European discovery, and demonstrates how human colonization and settlement can occur even in seemingly marginal environments (U.S. Department of Commerce, The Under Secretary of Commerce for Oceans and Atmosphere, 2007).

All of the documented prehistoric archaeological sites within Papahānaumokuākea are on either Nihoa or Necker (Mokumanamana). The other islands within Papahānaumokuākea have been less investigated for these types of sites, but may contain cultural sites that have either not yet been discovered or properly interpreted. Archaeologists suspect that Hawaiians did not leave artifacts that they wished to preserve on such low-lying islets because they knew that the elements would soon reclaim them. Several underwater ko`a have been found in the main Hawaiian Islands, however, and burials are not unknown; therefore, it is possible that additional cultural sites may be discovered in Papahānaumokuākea (U.S. Department of Commerce, The Under Secretary of Commerce for Oceans and Atmosphere, 2007).

In addition to the prehistoric features within Papahānaumokuākea, there are World War II-era sites of national significance. These include the Battle of Midway National Memorial and nine defensive positions on Midway Atoll; each designated a National Historic Landmark under the theme of World War II Pacific battlefields (U.S. Department of Commerce, The Under Secretary of Commerce for Oceans and Atmosphere, 2007).

Nihoa

On Nihoa, 89 cultural sites have been recorded. The sites date from before the 13th century and include 25 to 35 house terraces, 15 ceremonial structures, burial caves, bluff shelters, and agricultural terraces. Numerous artifacts found on Nihoa establish a close relationship with Native Hawaiian culture in the Main Hawaiian Islands, and to the first settlers of Hawaii who sailed through the Pacific on large voyaging canoes. Because the island had sufficient soil and water for limited agriculture, Nihoa was a good place for voyagers to stop and resupply their canoes. This is evidenced by the remains of stone terraces that suggest an investment in agricultural food production (U.S. Department of Commerce, The Under Secretary of Commerce for Oceans and Atmosphere, 2007).

In 1789, Captain Douglas of the *Iphegenia* was the first Westerner to visit Nihoa. Queen Kaahumanu visited and annexed the island for the Kingdom of Hawaii in 1822 and, in 1885, Queen Liliuokalani and her 200-person entourage landed on Nihoa. As many as 175 people are estimated to have lived on the island at one time, but a shortage of fresh water likely was a limiting factor (Emory, 1928).

Necker (Mokumanamana)

At least 52 cultural sites exist on Necker (Mokumanamana), including 33 ceremonial features, which is the highest concentration of religious sites found anywhere in the Hawaiian Archipelago. Like Nihoa, Necker (Mokumanamana) shows clear evidence of prehistoric Hawaiian occupation, although given the numerous religious sites, the island appears to have been used primarily for worship by visitors from other Hawaiian Islands, rather than having supported permanent inhabitants for any length of time. Many of the temple sites closely resemble those of Tahiti, possibly establishing a link between this site and early Polynesian culture. Carved basalt human figurines found there are of a style not seen elsewhere in Hawaii, showing instead similarities to those found in the Marquesas. Emory (1928) considered the sites of Necker (Mokumanamana) to be a "…pure sample of the culture prevailing in Hawaii before the thirteenth century" (U.S. Department of Commerce, The Under Secretary of Commerce for Oceans and Atmosphere, 2007).

The first European to document Necker (Mokumanamana) was Compte de La Perouse in 1786. Captain John Paty claimed the island for the Kingdom of Hawaii in 1857, though his claim was later contested until the island was formally annexed by Hawaii's Provisional Government in 1894 (U.S. Department of Commerce, The Under Secretary of Commerce for Oceans and Atmosphere, 2007).

There are no longer permanent inhabitants of Nihoa or Necker (Mokumanamana); however, research scientists and other educational expeditions occasionally visit the various islands of the island chain and camp for 1 to 12 weeks (Northwestern Hawaiian Islands Multi-Agency Education Project, 2006).

Historic Buildings and Structures

There are no modern historic buildings or structures on Nihoa or Necker (Mokumanamana); however, there are a number of pre-contact stone structures representing habitation, agricultural, and ceremonial features (Emory, 1928).

Traditional Resources (Including Burials)

Among the recorded sites on Nihoa and Necker (Mokumanamana) are religious and ceremonial features (cairns, terraces, stone platforms, upright stones, and burial sites) (Emory, 1928; TenBruggencate, 2005; U.S. Department of Commerce, The Under Secretary of Commerce for Oceans and Atmosphere, 2007).

3.3 KAUAI

Kauai is the oldest and fourth largest of the Main Hawaiian Islands. It covers approximately 550 square miles (mi^2) and was formed by the volcano Waialeale located at its center. The town of Lihue is Kauai's county seat and is home to the State and County buildings. The islands of Kauai, Niihau, and Kaula combine to form Kauai County. Current and proposed Hawaii Range Complex (HRC) training and research, development, test, and evaluation (RDT&E) activities on Kauai addressed in this Environmental Impact Statement (EIS)/Overseas EIS (OEIS) are located at Pacific Missile Range Facility (PMRF) (PMRF/Main Base) or facilities that support PMRF range operations (Kauai Test Facility [KTF], Makaha Ridge, Kokee, Hawaii Air National Guard Kokee, Kamokala Magazines, Port Allen, Kikiaola Small Boat Harbor, and Mt. Kahili). PMRF also conducts range operations on the nearby islands of Niihau and Kaula. PMRF plans to continue using all sites. For organizational purposes in this document, discussions about Niihau and Kaula are included under the Kauai heading, because they are part of Kauai County.

3.3.1 KAUAI OFFSHORE

Kauai Offshore addresses ocean areas within 12 nautical miles (nm) of Kauai, Niihau, and Kaula, including ranges and training areas where activities are performed by the Navy. Discussions include PMRF Offshore (the Barking Sands Tactical Underwater Range [BARSTUR], the Barking Sands Underwater Range Expansion [BSURE], Shallow Water Training Range [SWTR], and the Kingfisher Underwater Training Area [Kingfisher]), Niihau Offshore, and Kaula Offshore. These offshore areas are not within the Hawaiian Islands Humpback Whale National Marine Sanctuary.

3.3.1.1 PMRF OFFSHORE (BARSTUR, BSURE, SWTR, KINGFISHER)

PMRF Offshore includes HRC ranges and training areas 0 to 12 nm from PMRF/Main Base (Figure 2.1-2). Included in PMRF Offshore are BARSTUR and BSURE, which are within the 12-nm area from PMRF/Main Base; SWTR, which is within 3 nm and extends into the 12-nm area offshore of PMRF/Main Base; and Kingfisher, which is within 3 nm of PMRF/Main Base. BARSTUR is a 104-square nautical mile range used for anti-submarine training. BSURE provides the capability to support Anti-Submarine Warfare (ASW) training and over 80 percent of PMRF's underwater tracking capability. SWTR provides submarine forces with a shallow-water sonar training area to conduct shallow-water sonar proficiency training and readiness under realistic conditions. Kingfisher is a simulated underwater minefield used with the Kingfisher mine detection system.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for PMRF Offshore. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and waste, health and safety, land use, noise, and utilities resources are not addressed.

3.3.1.1.1 Biological Resources—PMRF—Offshore (BARSTUR, BSURE, SWTR, Kingfisher)

Region of Influence

The region of influence for offshore biological resources is the ocean area from the shoreline out to 12 nm.

Affected Environment

Vegetation

The substrates of Hawaiian rocky intertidal habitats are mostly consolidated basalts with some consolidated limestones (cemented beach rock or raised coral reefs). Common plants found in rocky intertidal habitats include sea lettuce (*Ulva*), Sargasso or kala (*Sargassum*), coralline red algae (*Hydrolithon*), red fleshy algae (*Melanamansia*, *Pterocladiella*, *Jania*), brown algae (*Padina*, *Turbinaria*, *Dictyota*), and fleshy green algae (*Neomeris*, *Halimeda*, and *Caulerpa*). (U.S. Department of the Navy, 2005c)

Algal species on the limestone bench fronting Nohili Point preferred by the green turtle (*Chelonia mydas*) include but are not limited to lipuupuu (*Dictyospheria versluysii*), kala-lau-nunui (*Sargassum echinocarpum*), pahalahala (*Ulva fasciatus*), and mane`one`o (*Laurencia nidifica*). The algal and macroinvertebrate survey in Majors Bay noted that four macroalgal and eight macroinvertebrate species were present. (Pacific Missile Range Facility, 2001; Commander, Navy Region Hawaii, 2007)

<u>Threatened and Endangered Vegetation</u>

No threatened or endangered vegetation is located in the offshore area.

Wildlife

A description of the coral reef area associated with the Hawaiian Islands and its management by both the State of Hawaii and the Federal government is provided in Section 3.1.2.1. North of Mana Point on Kauai, a narrow fringing reef follows the coastline up to Nohili Point and Barking Sands (Figure 3.3.1.1.1-1). Coral density is low and is dominated by lobe coral (*Porites lobata*) and small stands of arborescent (branched or tree shaped) corals. Broad uncolonized pavement (1,772 feet [ft] wide) and colonized pavement (2,297 ft wide) stretch along the coastline seaward of the fringing reef. North of Nohili Point, the uncolonized pavement ends and the colonized pavement continues along a northward heading; it turns gradually to the east to join the coastline north of Keawanui. (U.S. Department of the Navy, 2007a) Uncolonized pavement is flat, low relief, solid carbonate rock often covered by a thin sand veneer. The surface of the pavement often has sparse coverage of macroalgae, hard coral, and other sessile invertebrates that does not obscure the underlying surface. Colonized pavement is flat, low-relief, solid carbonate rock with coverage of macroalgae, hard coral, and other sessile invertebrates that are dense enough to begin to obscure the underlying surface. (Center for Coastal Monitoring and Assessment, 2006)

Offshore Hardbottom Habitats of Pacific Missile Range Facility

Kauai, Hawaii

Figure 3.3.1.1.1-1

Wave action is the main natural control on coral reef structure along the coastline of the Hawaiian Islands (Grigg, 1997a; Jokiel et al., 2001; 2004). Corals in wave-exposed areas die as fast as they can be replaced (Grigg, 1997a). The breaking, scouring, and abrading action caused by waves on corals yields high mortality. Hence, no coral accretion takes place in wave-exposed areas. Despite the fact that wave action limits the accretion of reef building corals, reefs are also found along the north coastline of Kauai. (Maragos, 2000)

The general marine topography of the nearshore region off of PMRF consists of four sectors separated by distinct physiographic and biotic structure. The first three of these sectors are (1) the Nohili Sector, which extends from the northern end of the property to approximately the location of Nohili Ditch; (2) the Mana Point Sector, which extends southward to the southern part of Mana Point; and (3) the Majors Bay Sector, which extends to the southern boundary of PMRF at Kokole Point extending from the shoreline to a depth of approximately 49 ft. The fourth sector is considered the Offshore Sector, and extends along most of the entire length of PMRF within the depth range of 49 to 66 ft. (Commander, Navy Region Hawaii, 2007)

Total coral cover in the Nohili Sector ranges from 32 to 39 percent of bottom cover. The most abundant coral species are lobe coral, rose or cauliflower coral (*Pocillopora meandrina*), and ringed rice coral (*Montipora patula*). Macroinvertebrates in this area include the rock oyster (*Spondylus tenebrosus*), cone shells (*Conus* spp.), sea urchins (*Echinometra mathaei*), and sea cucumbers (*Holothuria atra*). Along the central portion of PMRF in the Mana Sector, living coral is sparsely distributed, approximately one half of that found in the Nohili area. The dominant species is lobe coral. Coral cover in the Major's Bay Sector is less than 2 percent. The algal and macroinvertebrate survey in Majors Bay noted that eight macroinvertebrate species were present. (Pacific Missile Range Facility, 2001; Commander, Navy Region Hawaii, 2007)

The predominant coral found in the Offshore Sector is antler coral (*Pocillopora eydouxi*), which occurs as single large branching colonies. Other corals found on the platform are primarily smaller species which have a collective coverage of about 5 percent of bottom cover: rose or cauliflower coral, lobe coral, corrugated coral (*Pavona varians*), flat lobe coral (*P. duerdeni*), blue rice coral (*Montipora flabellata*), ringed rice coral, Verrill's ringed rice coral *(M. verrilli),* rice coral (*M. capitata*), crust coral (*Leptastrea purpurea*), and mushroom coral (*Fungia scutaria*). (Commander, Navy Region Hawaii, 2007)

Black coral (Family *Antipathidae*) is found south of Kauai outside the region of influence, closer to shore and in shallower water than black coral of other Hawaiian Islands (Western Pacific Regional Fishery Management Council, 2006).

Essential Fish Habitat (EFH) occurs and is incorporated within Kauai's Exclusive Economic Zone (EEZ), the 200-mile (mi) limit around the island. EFH and Habitat Areas of Particular Concern (HAPC) are described in Section 3.1.2.2.1 (Open Ocean), and a detailed description, including status, distribution, and habitat preference of managed fisheries is provided in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a). EFH for adult and juvenile bottomfish includes the water column and all bottom habitats extending from the shoreline to a depth of 219 fathoms, which encompasses important steep drop-offs and high relief habitats. Shallow-water (0 to 328 ft) bottomfish species include uku or grey snappers (*Aprion virescens*), thicklip trevallies (*Pseudocaranx dentex*), groupers (*Epinephelus quernus*), emperors (*Lethrinus* spp.), amberjacks (*Seriola dumerili*), and taape or bluestriped snappers (*Lutjanus kasmira*). Deep-water (328 to 1,312 ft) species, which are discussed in Section 3.1.2, include ehu or squirrelfish snapper (*Etelis carbunculus*), onaga or red snapper (*Pristipomoides zonatus)*, opapaka or pink snapper (*Pristipomoides filamentosus*), gindai or snapper (*Etelis coruscans)*, hapu`upu`u or Hawaiian grouper (*Epinephelus quernus*), and lehi or ironjaw snapper (*Aphareus rutilans*). (Western Pacific Regional Fishery Management Council, 2005)

Pelagic HAPC that include the offshore area are designated as the water column down to 3,280 ft from the shoreline to the EEZ that lies above all seamounts and banks shallower than 1,100 fathoms. Marketable pelagic species include striped marlin (*Tetrapturus audax*), bluefin tuna (*Thunnus thynnus*), swordfish (*Xiphias gladius*), albacore (*Thunnus alalunga*), skipjack (*Katsuwonus pelamis*), sailfish (*Istiophorus platypterus)*, kawakawa or tuna (*Euthynnus affinis*), and various sharks. Banks with summits less than 16.3 fathoms have been designated as HAPC for crustaceans. Crustacean species include spiny lobsters (*Panulirus marginatus*), slipper lobsters (*Scyllarides squammosus*), and Kona crabs (*Ranina ranina*). (Western Pacific Regional Fishery Management Council, 2005)

Common animals found in rocky intertidal habitats include limpets or `opihi (*Cellana exerata*), periwinkles (*Littorina* sp.), littorine snails (*Littorina*, *Nerita*), rock crabs or `a`ama (*Metapograpsus* sp.), gastropods (*Drupa*, *Morula*, *Cypraea*, *Strombus*), and rock urchins (*Colobocentrotus atratus*). Adjacent to rocky shoreline, offshore waters are possible feeding areas for the threatened green turtle. (U.S. Department of the Navy, 2005c)

Spinner dolphins (*Stenella longirostris*) are the most commonly recorded cetaceans observed within 12 nm of the PMRF coastline. The spinner dolphin inhabits bays and protected waters, often in waters less than 40 ft deep (Pacific Missile Range Facility, 2001). Monitoring for Rim of the Pacific (RIMPAC) Exercises in 2006 showed that spinner dolphins are seen daily in the offshore area of Kekaha Beach, Kauai (near PMRF/Main Base) despite being accompanied regularly by tour boats (U.S. Department of the Navy, 2006a). Spinner dolphins are expected to occur in shallow water resting areas (about 162 ft deep or less) throughout the middle of the day, moving into deep waters offshore during the night to feed. Additional information on spinner dolphins, including description, habitat, abundance, and distribution is provided in Section 3.1.2.

A small-boat based survey for odontocetes was undertaken off the islands of Kauai and Niihau in October and November 2005 to photo-identify individuals and collect genetic samples for examining stock structure. Survey coverage was from shallow coastal waters out to over 9,842 ft depth, though almost half was in waters less than 1,640 ft in depth. There were 56 sightings of five species of odontocetes: 30 spinner dolphins; 14 bottlenose dolphins (*Tursiops truncatus*); 6 short-finned pilot whales (*Globicephala macrorhynchus)*; 5 rough-toothed dolphins (*Steno bredanensis*); and 1 pantropical spotted dolphin (*Stenella attenuata*). (Baird et al., 2006a)

<u>Threatened and Endangered Wildlife Species</u>

Table 3.3.1.1.1-1 lists threatened and endangered species that are known or expected to occur in the offshore areas off PMRF/Main Base.

Table 3.3.1.1.1-1. Listed Species Known or Expected to Occur Offshore of PMRF/Main Base

Notes: *Considered for listing as endangered
** Observed in May 2000

Key to Federal Status:
T = Threatened
E = Endangered
P = Proposed for listing as threatened or endangered

Green and hawksbill (*Eretmochelys imbricata*) turtles are the most common sea turtles in offshore waters around the Main Hawaiian Islands, as they prefer reef-type environments that are less than about 55 fathoms in depth (U.S. Department of the Navy, 2005c). Additional information on sea turtles, including description, habitat, abundance, and distribution, is provided in Section 3.1.2. Green turtles have been observed offshore of Nohili Ditch, the only area where basking/haul-out activity on PMRF/Main Base is observed. The PMRF Natural Resources Manager monitors sea turtle activity at PMRF. Security patrol reports include a record of the presence and locations of turtles. Any records of green turtle sitings are maintained by the PMRF Environmental Office. (Pacific Missile Range Facility, 2001)

In March of 2000, a juvenile short-tailed albatross (*Phoebastria albatrus*) was observed at PMRF, resting in the grass on the mountain side of the PMRF runway (U.S. Fish and Wildlife Service, 2004). The black-footed albatross (*Phoebastria nigripes*), a seabird that has been observed on and offshore of PMRF, has been proposed for listing as threatened or endangered (U.S. Fish and Wildlife Service, 2007b). The Newell's shearwater (*Puffinus auricularis newelli*) or \`A\`o is a seabird that forages over deep open ocean and offshore waters near its breeding grounds from October to April when it returns to land to look for nest sites (State of Hawaii, Department of Land and Natural Resources, 2005). On Kauai, several grounded dark-rumped petrel (*Pterodroma phaeopygia sandwichensis*) fledglings have been collected in recent years as part of the Newell's shearwater recovery program. Most birds have been found near the mouth of Waimea Canyon, indicating that some birds still breed in the vicinity. Observations of the dark-rumped petrel at sea are scarce. (Virginia Tech Conservation Management Institute, 1996)

Of the marine mammals listed in Table 3.1.2.4-1, the Hawaiian monk seal (*Monachus schauinslandi*), humpback whale (*Megaptera noveangliae*), and spinner dolphin (discussed above) are the most likely species to be observed within 12 nm of the PMRF coastline. The endangered Hawaiian monk seal is an indigenous mammal that has been observed at PMRF. The primary occurrence of Hawaiian monk seals within the HRC is expected to be in a continuous band between Nihoa, Kaula, Niihau, and Kauai. This band extends from the shore to around 273 fathoms and is based on the large number of sightings and births recorded in this area (Westlake and Gilmartin, 1990; Ragen and Finn, 1996; Marine Mammal Commission, 2003; Baker and Johanos, 2004). Additional information on Hawaiian monk seals, including description, habitat, abundance, and distribution, is provided in Section 3.1.2.

The humpback whale peak abundance around the Hawaiian Islands is from late February through early April (Mobley et al., 2001b; Carretta et al., 2005). During the fall-winter period, primary occurrence is expected from the coast to 50 nm offshore, including the areas off PMRF. Additional information on humpback whales, including description, habitat, abundance, and distribution, is provided in Section 3.1.2.

Hawaiian Islands Humpback Whale National Marine Sanctuary

The Hawaiian Islands Humpback Whale National Marine Sanctuary (Figure 3.3.1.1.1-2) was created by Congress in 1992. The Sanctuary includes a portion of the ocean north of Kauai, but not within the PMRF vicinity or in the BSURE coverage area (Pacific Missile Range Facility 2001). Further discussion of the sanctuary is provided in Section 3.7. Humpback whales are endangered marine mammals and are therefore protected under provisions of the Endangered Species Act and the Marine Mammal Protection Act wherever they are found. Humpbacks are seen in the winter months in the shallow waters surrounding the Hawaiian Islands where they congregate to mate and calve. The humpback whale population is growing by an average of 7 percent annually. The best available estimate of abundance for the Central West Pacific stock of humpback whales is 4,491 individuals (Mobley, 2004). The whales travel more than 3,500 mi from Alaska to Hawaii's warm waters to mate, give birth, and care for their calves. The whales span more than a quarter-million square miles of ocean surrounding Hawaii. The first whales of the season usually arrive around October, with the greatest number seen around Hawaii between 1 December and 15 May. (National Oceanic and Atmospheric Administration, 2007; Mobley, 2002)

3.3.1.1.2 Cultural Resources—PMRF—Offshore (BARSTUR, BSURE, SWTR, Kingfisher)

Region of Influence

The underwater cultural resources region of influence for PMRF would include offshore areas in Majors Bay and areas offshore from PMRF/Main Base (including PMRF Warning Area 188). The training and RDT&E activities proposed for these areas include Expeditionary Assault and other amphibious landings; torpedo; torpedo defense; submarine detection; deep and shallow water testing of anti-submarine torpedo sensors and weapons systems; mine-laying and neutralization; over-water missile launches and intercepts; Gunnery Exercise (GUNEX); Bombing Exercise (BOMBEX); and movement of the simulated underwater minefield (Kingfisher).

Affected Environment

Underwater Cultural Resources

For a discussion of Open Ocean Area underwater cultural resources, see Section 3.1.3.

Offshore Area Archaeological Resources

Within the offshore waters surrounding each island, there are a variety of submerged resources. The most common of these are shipwrecks (Figure 3.1.3-1) and fishponds; however, junked motor vehicles, harbor features, and old shoreline structures are also present.

Historically, Native Hawaiians constructed four different types of fishponds—freshwater taro ponds, other freshwater ponds, brackish water ponds, and seawater ponds (Aquaculture in Hawaii, 2006). Aquaculture was employed to supplement their other fishing activities, and permanent fishponds guaranteed a stable food supply for populations in lean times. Tended ponds provided fish without requiring fishing expertise, and harvesting the pond, unlike fishing at sea, was not weather dependent. Village-owned fishponds also increased the wealth of the managing Hawaiian Chief. At the time of European contact, there were hundreds of fishponds along the coast of the Hawaiian Islands. Many of the fishponds remain, but few are actively used (Aquaculture in Hawaii, 2006). Saltwater fishponds constructed on shallow water coral reef platforms are unique to the Hawaiian Islands and are very important national and international historical assets. Evidence suggests that Hawaiian fishponds were constructed as early as A.D. 1000, if not earlier, and continued to be built until the 1820s. The operation of fishponds declined throughout the islands by the early 1900s; there are approximately 488 fishponds in varying states of repair scattered throughout the six main islands. A database of identified Hawaiian saltwater fishponds is managed by the University of Hawaii at Manoa to publicize research and restoration projects, and to raise awareness of their cultural value.

Figure 3.3.1.1.2-1 shows the distribution of fishponds in the waters surrounding the Hawaiian Islands (State of Hawaii Office of Planning, 2005).

Hawaiian Fishpond Locations in the Vicinity of Kauai and Niihau

Kauai and Niihau, Hawaii

Figure 3.3.1.1.2-1

The underwater environment surrounding Kauai encompasses a large number of shipwrecks and Hawaiian fishponds (see Figures 3.1.3-1 and 3.3.1.1.2-1). Among the wrecks is *Pele*, a freighter that sank on March 22, 1892. *Pele* rammed into an underwater pinnacle (tearing the hull) and sank a half-mile later in 14 fathoms of water. Very little of the wreck remains—the boiler, some hull plates, and a couple of anchors.

In 1824 the King of Hawaii used a vessel named *Ha`aheo o Hawaii (Pride of Hawaii)* as a private yacht, a cargo and passenger transport, and a diplomatic vehicle. The ship was also once used as a pirate ship. While the king was en route to England on a diplomatic mission, a Native Hawaiian crew sailed her to the northern shore of the island of Kauai and wrecked her in the southwestern corner of Hanalei Bay. The ship struck a 5-ft-deep reef just a hundred yards offshore and sank after an unsuccessful salvage attempt by the local population. (Johnston, 2005)

Within the specific offshore and open ocean underwater cultural resources region of influence for PMRF and KTF are a sparse distribution of shipwrecks and fishponds (see Figures 3.1.3-1 and 3.3.1.1.2-1).

3.3.1.1.3 Socioeconomics—PMRF—Offshore (BARSTUR, BSURE, SWTR, Kingfisher)

Region of Influence

The region of influence for offshore Socioeconomics is the ocean area from the shoreline out to 12 nm from PMRF/Main Base. This includes the Kingfisher, which is within 3 nm of PMRF/Main Base; SWTR, which is within 3 nm and extends into the 12 nm area offshore of PMRF/Main Base; and BARSTUR and BSURE, which are within 12 nm of PMRF/Main Base.

Affected Environment

There are activities that occur in the offshore area of PMRF/Main Base that contribute to the economy of Kauai. They can be categorized as shipping, recreation, subsistence fishing, and tourism related.

Shipping

There is no commercial shipping to PMRF/Main Base, although boat tours are conducted within the region of influence. A primary commercial shipping route exists approximately 50 mi north of Kauai (EDAW, Inc., 2005).

Hawaii's remote location in the mid-Pacific makes it economically dependent upon the local waterways and its inter-modal maritime transportation system. Hawaii's harbors and local waterways use vessel traffic separation schemes that are closely monitored and supervised by the U.S. Coast Guard to promote safe navigation and provide a secure system for shipping. Barges and ships navigate these waterways daily to transport goods and personnel, not just within the Hawaiian Islands and to and from the mainland of North America, but across the Pacific Ocean to all the major ports of Asia, Oceania, Central and South America, and the South Pacific.

The National Oceanic and Atmospheric Administration (NOAA) provides frequently updated electronic and paper navigation charts for all mariners depicting the current vessel traffic separation schemes for all of Hawaii's major harbors and inland waterways. While traffic separation schemes are demarcated on NOAA charts to maintain safe traffic flow, inter-modal shipping lanes are not. Outside of the traffic schemes and regulated waterways of the Hawaiian Islands, mariners are free to plot their own course; however, it is common practice for many shipping companies to use great circle routes with track adjustments made for navigational risks such as restricted waters, obstructions, depth of water, currents, weather, traffic, and environmental factors. Great circle routes are commonly used because they are the shortest distance between two points on the globe; therefore, it is more economical for companies to follow these routes.

Recreation

Recreational activities include surfing, fishing, and boating. The physical areas accessible for fishing/surfing/recreation and socializing run from Shenanigans (all-hands club) up to KiniKini Ditch (south end of runway). Under PMRF Instruction 5530.7, normal access is allowed 7 days a week from 6:00 a.m. to 30 minutes after sunset, except during heightened force protection conditions or PMRF range operational periods.

Offshore of PMRF/Main Base, fishing is also allowed up to 1,000 ft in the Special Use Fishing Area (Kawaiele Ditch northward to the windsock adjacent to the runway) on weekends and Federal holidays, except during heightened force protection conditions and PMRF range operational periods. Use of this area is limited to 25 fishermen at one time. Fish species of commercial and recreational interest seen in the Majors Bay area in surveys performed in 2000 and 2006 included weke (*Mulloidichthys samoensi)*, moano (*Parupeneus multifasciatus*), malu (*Parupeneus pleurostigma)*, palani (*Acanthurus dussumieri*), mai`i`i (*Acanthurus nigrofuscus*), and naenae (*Acanthurus olivaceus*). The 2006 survey also found a small school of bonefish (*Albula vulpes*)*,* uku, and juvenile ula (*Panulirus marginatus*). Discussions with fisherman familiar with the resources fronting PMRF indicate that those waters are well known for the commercial catches of akule or bigeye scad (*Selar crumenophthalmus*) which is done using nets, papios (members of the Jack family), threadfin or moi (*Polydactylus sexfilis*)*,* opelu (*Decapterus macarellus*), uku, goatfishes and surgeonfishes*,* all of which are caught by a variety of methods by both commercial and recreational fishers. Surfing is also permitted in front of the PMRF housing area. (Commander, Navy Region Hawaii, 2007)

Subsistence Fishing

Hawaii Revised Statutes (HRS) Section 188-22.6 defines subsistence fishing as the customary and traditional Native-Hawaiian uses of renewable ocean resources for direct personal or family consumption or sharing. HRS defines Native-Hawaiian as any descendant of the races inhabiting the Hawaiian Islands prior to 1778.

Fishing is still an extremely popular pastime for people in Hawaii (Western Pacific Regional Fishery Management Council, 1999). Recent data indicate that a quarter of Hawaii's population participates in some form of fishing at least once a year. Hawaii's annual fish consumption is about 90 pounds (lb) per capita, over twice the national average (Western Pacific Regional Fishery Management Council, National Oceanic and Atmospheric Administration, 2003).

The overall level of subsistence fishing activity is difficult to assess, due to a lack of detailed catch data. Under-reporting by commercial fishermen and the existence of a large number of recreational and subsistence fishermen without licensing or reporting requirements have resulted in uncertainty in actual fisheries catch statistics for the state. Consequently, in the past no formal attempt to assess the subsistence fishing contribution to island economies has been made, but the value of fishing for subsistence by contemporary Native Hawaiians is known to be an important component of some communities, particularly rural communities (Pooley, 1993). However, it is believed that offshore recreational and subsistence catch is likely equal to or greater than the offshore commercial fisheries catch, with more species taken using a wider range of fishing gear (Friedlander, et al., 2004).

The Pacific Islands Region has a special mandate under the Magnuson and Stevens Fishery Conservation and Management Act to promote the sustained participation of indigenous communities. In March of 2004, the "Strategic Plan for the Conservation and Management of Marine Resources in the Pacific Islands Region" was developed by three Federal agencies: the National Marine Fisheries Service (NMFS) Pacific Islands Fisheries Science Center, the Pacific Islands Regional Office, and the Western Pacific Regional Fishery Management Council. The plan discusses critical issues facing the region and provides plans for addressing the issues. The plan identifies five research projects which the offices have started: (1) developing a sociological baseline of the Hawaii longline fishery; (2) developing profiles of fishing communities and fishing ports; (3) compiling and analyzing historical fishing club and tournament records, studies concerning fishing capacity in Hawaii's commercial fisheries; (4) developing an economic evaluation of fishing tournaments; and (5) developing cost-earning studies for Hawaii fisheries.

Hawaii's coastal fisheries, as in other parts of the world, are facing unprecedented overexploitation and severe depletion. In heavily populated areas of the Main Hawaiian Islands, fishing demands for offshore resources appear to exceed the capacity for resource renewal (Friedlander, et al., 2004).

The Western Pacific Regional Fishery Management Council and NOAA worked together to prepare a *Supplemental EIS to the Final Environmental Impact Statement on the Fishery Management Plan for Bottomfish and Seamount Groundfish Fisheries of the Western Pacific Region* in May of 2005. The purpose of the Supplemental EIS was to implement measures which would end overfishing in the bottomfish complex in the Hawaiian Archipelago. The draft of this document was published in March 2006. The draft Supplemental EIS analyzed five alternatives: (1) no action; (2) area closures; (3) seasonal closures; (4) catch quotas; and (5) combination of alternatives two and three. The draft Supplemental EIS concluded that the most effective means of ending overfishing would be implementation of alternative three (seasonal closures). For seasonal closures to be effective, State and Federal regulations would need to be promulgated (Western Pacific Regional Fishery Management Council, National Oceanic and Atmospheric Administration, 2003).

State and Federal agencies have given protective status to a variety of marine areas in Hawaii in efforts to improve fisheries. These areas include Marine Life Conservation Districts, Fisheries Management Areas, Fisheries Replenishment Areas, Bottomfish Restricted Fishing Areas, Hawaii Marine Laboratory Refuge-Coconut Island, Kahoolawe Island Reserve, Paiko Lagoon Wildlife Sanctuary, Ahihi-Kinau Natural Area Reserve, South Kona opelu fishing area, the Hawaiian Islands Humpback Whale National Marine Sanctuary (Figure 3.3.1.1.1-2), and the

Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve (Figure 3.2-1) (Friedlander, et al., 2004).

In Hawaii, habitats with low spatial relief and limited shelter were found to be associated with low biomass and diversity of reef fishes, whereas highly complex habitats harbored high fish biomass and diversity. Ideally, EFH in the Main Hawaiian Islands should consist of an area with high rugosity (roughness) or relief and moderate wave exposure that has a high percentage of branching and/or lobate coral coupled with legal protection from fish pressure. Habitats with these optimal characteristics should possess fish assemblages with high species richness, abundance, biomass, and diversity. If protective areas are to be effective, they must include the diversity of habitats necessary to accommodate the wide range of fish species (Friedlander, et al., 2004).

Due to the shape of Kauai and the lack of any protective barrier reef structure, the shoreline region is nearly continually scoured by the force of breaking waves. The essentially “round” shape of Kauai results in exposure from swells emanating from both the north and the south Pacific, hence the nearly continual wave action. The entire region offshore of PMRF is directly exposed to long-period swells generated by storms in both the North (winter) and South (summer) Pacific. As a result of these physical processes, the offshore areas are subjected to extreme stress from wave impact and scouring of sediment from wave action. Consequently, there is minimal coral reef development in the offshore areas off the coast of PMRF (Commander, Navy Region Hawaii, 2007). Since the implementation of the Force Protection Restriction after September 11, 2001, there has been a decline in fishing activities in the waters fronting PMRF, and this has corresponded to increases in the abundance, mean size, and biodiversity of fish in the area (Commander, Navy Region Hawaii, 2007).

Tourism

The tourism industry has been the economic mainstay of the Hawaiian Islands since statehood in 1959. The industry accounts for 22.3 percent of all jobs in Hawaii (Kauai, County of, 2005). Kauai’s share of the Hawaii visitor market was 14.5 percent in 2005. Despite terrorism concerns and periodic economic slumps, the tourism industry on Kauai has remained robust, with the number of annual visitors consistently over 1 million a year in the past 5 years (Kauai, County of, 2005). Estimated visitor expenditure in 2005 was $11.9 billion, a 9.6 percent increase from 2004 (State of Hawaii, Department of Business, Economic Development & Tourism, 2006). Many island visitors enjoy participating in activities in the ocean areas within the HRC such as scuba diving, kayaking, sailing, and dinner cruises. There are many businesses that rent equipment, offer guided tours, operate charter boats, and supply other services to the tourists within the region of influence. The Super Ferry was just starting its operations at the same time this document was drafted.

3.3.1.1.4 Transportation—PMRF—Offshore (BARSTUR, BSURE, SWTR, Kingfisher)

Region of Influence

The region of influence for offshore transportation is the ocean area from the shoreline out to 12 nm. This area includes the Kingfisher Area, which is within 3 nm of PMRF/Main Base; SWTR, which is within 3 nm and extends into the 12 nm range of PMRF/Main Base; and BARSTUR and BSURE, which are within 12 nm of PMRF/Main Base.

Affected Environment

The affected environment is the area from the shoreline of PMRF/Main Base out to 12 nm.

Waterways

There is no commercial shipping to PMRF, although boat tours are conducted within the region of influence. A primary commercial shipping route exists approximately 50 mi north of Kauai (EDAW, Inc., 2005).

3.3.1.2 NIIHAU OFFSHORE

Niihau is a privately owned island located approximately 17 nm southwest of Kauai. It is about 8 mi wide by 18 mi long and comprises approximately 72 mi^2. PMRF leases 1,170 acres of land in the northeastern corner of the island and operates radar units, optics, and electronic warfare sites on Niihau. Niihau Offshore includes proposed HRC ranges and training areas 0 to 12 nm from Niihau (Figure 2.1-2).

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Niihau Offshore. Of the 13 resources considered for analysis, airspace, air quality, cultural resources, geology and soils, hazardous materials and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.3.1.2.1 Biological Resources—Niihau—Offshore

Region of Influence

The region of influence for offshore biological resources is the ocean area from the shoreline of Niihau out to 12 nm.

Affected Environment

Vegetation

Common plants found in Niihau's rocky intertidal habitats include sea lettuce (*Ulva lactuca*), Sargasso or *kala*, coralline red algae, red fleshy algae, brown algae, and fleshy green algae (U.S. Department of the Navy, 2005c). Common plants that inhabit the sandy beach intertidal habitat on Niihau include the beach morning glory (*Ipomoea imperati*), beach heliotrope (*Heliotropium anomalum*), milo (*Thespesia populnea*), and hau (*Hibiscus tiliaceus*) (Maragos, 1998).

Threatened and Endangered Vegetation

No threatened or endangered vegetation is located in the offshore area.

Wildlife

Common animals using and inhabiting the sandy beach intertidal habitat on Niihau include ghost crabs (*Ocypode ceratophthalma*), mitre and auger shells (*Terebra*), clams, and seabirds. (Maragos, 1998)

Reefs offshore of Niihau are poorly developed due to extreme wave energy from all directions. There are no substantial bays that could shelter coral development. Colonized and uncolonized hardbottom areas are located off the western coastline. High-wave energy coral communities appear to be most common and are dominated by cauliflower coral and lobe coral. Black coral (*Antipathes sp.*) occurs as shallow as 90 ft off the northern end of the island. (Hawaii Institute of Marine Biology, 2006)

Pelagic fish such as tuna swim close to steep vertical walls around the northwest portion of Niihau. Large kumu (white saddle goatfish) (*Parupeneus porphyreus*), u`u (squirrelfish) (*Myripristis* spp.), and uhu (parrotfish) (*Chlorurus sordidus*) are abundant. Sharks are also present off of Niihau, including the grey reef shark (*Carcharhinus amblyrhynchos*), sandbar shark (*C. plumbeus*), Galapagos (*C. galapagensis*), and tiger shark (*Galeorcerdo cuvier*). (Papastamatiou, et al., 2006; Hawaii Institute of Marine Biology, 2006)

EFH and HAPC are described in Section 3.1.2 (Open Ocean), and a detailed description, including status, distribution, and habitat preference of managed fisheries is provided in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

<u>Threatened and Endangered Wildlife</u>

The endangered Hawaiian monk seal and the threatened green turtle have been observed offshore of Niihau.

3.3.1.3 KAULA OFFSHORE

Kaula is approximately 108 acres of land used by the Navy for aircraft gunnery and inert ordnance target practice. No HRC training events are performed offshore (0 to 12 nm) of Kaula; however, onshore training events may affect offshore resources.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Kaula Offshore. Of the 13 resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.3.1.3.1 Biological Resources—Kaula—Offshore

Vegetation

Common plants found in rocky intertidal habitats include sea lettuce, coralline red algae, red fleshy algae, brown algae, and fleshy green algae (U.S. Department of the Navy, 2005c).

No threatened or endangered vegetation is located in the offshore area.

Wildlife

Kaula is surrounded by Kaula Bank, which supports some coral reefs. The entire bank has been identified as a HAPC in the Coral Reef Ecosystem Fisheries Management Plan. Several commercially important fish, such as tunas and jacks observed spawning in the area, have been reported. Another species seen in the area is the whale shark (*Rhincodon typus*), which is rarely sighted in the Main Hawaiian Islands. Gray reef and sandbar sharks have also been observed. Spinner dolphins are common in the water around Kaula. (Pacific Missile Range Facility, 2001)

<u>Threatened and Endangered Wildlife Species</u>

Coastal waters off Kaula are considered viable foraging habitat for green turtles, but no sightings of sea turtles have been documented (Pacific Missile Range Facility, 2001).

Four consecutive NMFS humpback whale surveys conducted between 1976 and 1979 established that humpback whales occur in the offshore waters of Kaula during the peak of the winter season on an annual basis (Pacific Missile Range Facility, 2001). Three Hawaiian monk seals were observed on a shelf off Kaula in a 2000 aerial survey (Baker and Johanos, 2004). Fifteen Hawaiian monk seals were counted during a 4-hour period hauled out on Kaula during a 2006 cruise (National Marine Fisheries Service, 2007b).

3.3.1.3.2 Cultural Resources—Kaula—Offshore

Region of Influence

The underwater cultural resources region of influence for Kaula would include areas offshore of the southwestern tip of the island where there is an existing, heavily disturbed ordnance impact area. Proposed or ongoing training with the potential to affect cultural resources on Kaula and within Warning Area W-187 include BOMBEX and GUNEX.

Affected Environment

Underwater Cultural Resources

There are no recorded underwater archaeological resources surrounding Kaula (e.g., shipwrecks) (see Figures 3.1.3-1 and 3.3.1.1.2-1).

3.3.2 KAUAI ONSHORE

3.3.2.1 PMRF/MAIN BASE

The Main Base portion of PMRF is located on the west side of Kauai, approximately 120 nm from Pearl Harbor. The majority of PMRF's facilities and equipment are at the Main Base, which occupies a land area of 1,925 acres and lies just south of Polihale State Park. PMRF/Main Base is generally flat and approximately 0.5 mi wide and 6.5 mi long with a nominal elevation of 15 ft above mean sea level except for the target launch pad areas. PMRF is a multi-environment range capable of supporting surface, subsurface, air, and space events and activities simultaneously. Training and RDT&E activities areas on PMRF/Main Base contain tracking and surveillance radars, data processing, and the communications network. Airfield facilities are located on PMRF/Main Base. Ordnance and launch areas are also located on PMRF/Main Base, the KTF launch area, northern launch area, and southern launch facility. Sandia National Laboratories operates the KTF for the Department of Energy and provides PMRF with rocket launch services for target systems and upper atmosphere measurements.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for PMRF/Main Base. All 13 environmental resources are addressed.

3.3.2.1.1 Air Quality—PMRF/Main Base

Air quality in Hawaii is defined with respect to compliance with primary and secondary National Ambient Air Quality Standards (NAAQS) (40 Code of Federal Regulations [CFR] §50) established by U.S. Environmental Protection Agency (USEPA) and adopted by the State of Hawaii. The Clean Air Act (42 United States Code [U.S.C.] 7401-7671q), as amended, gives USEPA the responsibility to set safe concentration levels for six criteria pollutants: particulate matter measuring less than 10 and 2.5 microns in diameter (PM-10 and PM-2.5), sulfur dioxide, carbon monoxide, nitrogen oxides, 8-hour ozone, and lead. Ozone is measured by emissions of volatile organic compounds (VOCs) and nitrogen oxides. The NAAQS and State Ambient Air Quality Standards (AAQS) are presented in Appendix C.

Region of Influence

For inert pollutants (all pollutants other than ozone and its precursors), the region of influence is generally limited to an area extending several miles downwind from the source. The region of influence for ozone may extend much farther downwind than the region of influence for inert pollutants. As the project area has no heavy industry and very few automobiles, ozone and its precursors are not of concern. Consequently, for the air quality analysis, the region of influence for project activities is the existing airshed (the geographic area responsible for emitting 75 percent of the air pollution reaching a body of water) surrounding the various sites, which encompasses the Mana Plain, including PMRF/Main Base.

Affected Environment

Climate

Weather is an important factor in the disbursement of air pollutants. PMRF/Main Base is located just south of the Tropic of Cancer and has a mild and semi-tropical climate. Typical temperatures for the area are 80 to 84 degrees Fahrenheit (°F) during the day and 65 to 68°F during the night. The trade winds are from the northeast and are typically light—mean trade winds between 16 to 18 knots. Precipitation in the area averages 41 inches annually. Most of the rain falls during the October through April wet season. Relative humidity is approximately 60 percent during the day throughout the year.

Regional Air Quality

Air quality data in Hawaii are collected by the Hawaii State Department of Health, Clean Air Branch. The most recent available data (for the years 2001–2005) from monitoring stations State-wide are used to describe the existing ambient air quality in Hawaii.

The only State air quality monitoring station on Kauai is located in Lihue and collects data on PM-10 levels. The monitored ambient air concentrations in Lihue are well below the corresponding State and Federal annual average AAQS (Hawaii State Department of Health, Clean Air Branch, 2005). Between 2001 and 2005, none of the monitored ambient air concentrations in the entire state exceeded the annual average AAQS. Areas that meet the NAAQS for a criteria pollutant are designated as being “in attainment”; areas exceeding NAAQS are “nonattainment.” The entire State of Hawaii is in attainment of the NAAQS and State AAQS established for all criteria pollutants. Consequently, Clean Air Act applicability analysis and conformity determination do not apply to Navy actions in Hawaii.

Existing Emission Sources

The only major stationary sources for pollution at PMRF/Main Base are the five diesel generators that serve as a backup to the utility power system. During power outages and some of the mission events and activities, these generators are run to provide back-up power to critical facilities at the Main Base area. All five units are normally cycled, so that two or three units are in service at any time. However, when electrical demand is high, three or more of these generators may be operated simultaneously. During the worst case emergency conditions, all five generators can be operated simultaneously.

These generators are covered under the PMRF Title V Covered Source Permit. By restricting the hours of use for each generator and limiting the sulfur content of the diesel fuel supplied for the generators to 0.5 percent by weight, the Title V permit controls the nitrogen dioxide emissions. Operational limitations for the three 320-kilowatt (kW) generators are 208,000 gallons (gal) of fuel annually at maximum fuel consumption rate of 23.2 gal/hour, and the limitations for the two 600-kW generators are 217,800 gal of fuel annually at 43.5 gal/hour (Hawaii Department of Health, 2003).

Stationary emissions sources at KTF include two electrical generators that are permitted for operation by the State of Hawaii under a Non-covered Source Permit through April 2009 (Sandia National Laboratories, 2006).

Mobile sources from PMRF-associated training include aircraft, rocket launches, diesel-fueled vehicles, and dust from vehicular traffic. Aircraft are operated and supported at PMRF Airfield. Records show that existing PMRF air operations in fiscal year (FY) 2004 consisted of 13,395 air operations (defined as a takeoff or landing of one aircraft) of which 8,129 were Navy. The C-26 “Metroliner” aircraft and UH-3H “Sea King” helicopter accounted for 67 percent of all Navy air operations at PMRF. Transient Navy H-60, C-20, and NP-3D aircraft combined for the remaining 33 percent of Navy air operations at PMRF. (U.S. Department of the Navy, Engineering Field Activity Chesapeake, 2006)

Rocket launches are another source of mobile emissions at PMRF. Currently, there are as many as 46 missile launches per year from PMRF. These systems use both solid and liquid propellants. Appendix E includes a detailed list of the typical weapon systems tested at PMRF. The most common exhaust components for typical missiles include aluminum oxide, carbon dioxide, carbon monoxide, hydrogen, hydrogen chloride, nitrogen, water, ferric chloride, ferric oxide, nitric oxide, chlorine, and sulfur dioxide.

3.3.2.1.2 Airspace—PMRF/Main Base

Airspace, or that space which lies above a nation and comes under its jurisdiction, is generally viewed as being unlimited. However, it is a finite resource that can be defined vertically and horizontally, as well as temporally, when describing its use for aviation purposes. The time dimension is a very important factor in airspace management and air traffic control.

Under Public Law (PL) 85-725, *Federal Aviation Act of 1958*, the Federal Aviation Administration (FAA) is charged with the safe and efficient use of our nation's airspace and has established certain criteria and limits to its use. The method used to provide this service is the National Airspace System. This system is "…a common network of U.S. airspace; air navigation facilities, equipment and services, airports or landing areas; aeronautical charts, information and services; rules, regulations and procedures, technical information and manpower and material." Appendix C includes a detailed description of airspace.

Region of Influence

The region of influence for airspace includes the airspace over and surrounding PMRF/Main Base. Figure 3.3.2.1.2-1 shows a view of the airspace within the PMRF/Main Base region of influence, it includes the PMRF Aircraft Operational Areas, the R-3101 Restricted Area, and surrounding airspace off the western and northwestern coast of Kauai. For airspace, the region of influence also includes KTF, Makaha Ridge, Kokee, Kaula, and Niihau.

Affected Environment

The affected airspace use environment in the PMRF region of influence is described below in terms of its principal attributes: controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, airports and airfields, and air traffic control. There are no military training routes in the region of influence.

Controlled and Uncontrolled Airspace

The airspace outside the special use airspace identified below is essentially international airspace controlled by Honolulu Air Route Traffic Control Center (ARTCC). Class D airspace (described in Appendix C) surrounds the PMRF/Main Base airfield with a ceiling of 2,500 ft. It is

surrounded to the north, south, and east by Class D airspace with a floor 700 ft above the surface (see Figure 3.3.2.1.2-1). Lihue Airport, located approximately 20 nm east of PMRF, includes Class D, surface Class E, and additional Class E airspace with a floor 700 ft above the surface.

No Class B (U.S. terminal control areas) airspace, which usually surrounds the nation's busiest airports, or Class C airspace, is found in the region of influence.

Special Use Airspace

A restricted area is airspace designated under Part 73 within which the flight of aircraft, while not wholly prohibited, is subject to restriction. A warning area is airspace of defined dimensions, extending from 3 nm outward from the coast of the United States that contains activity that may be hazardous to nonparticipating aircraft. The purpose of such warning areas is to warn nonparticipating pilots of the potential danger. A warning area may be located over domestic or international waters or both. (14 CFR Title 14 Part 1.1, 2006)

The special use airspace in the region of influence (see Figure 3.3.2.1.2-1) consists of Restricted Area R-3101, which lies immediately above PMRF/Main Base and to the west of Kauai, portions of Warning Area W-188 north of Kauai, and Warning Area W-186 southwest of Kauai, all controlled by PMRF. Restricted Area R-3107 over Kaula, a small uninhabited rocky islet 19 nm southwest of Niihau that is used for fixed- and rotary-wing aircraft gunnery practice, and which lies within the W-187 Warning Area, is also special use airspace within the region of influence. Restricted Area R-3107 and Warning Area W-187 are scheduled through the Navy Fleet and Area Control and Surveillance Facility Pearl Harbor (FACSFACPH). PMRF and FACSFACPH each coordinate with the FAA Hawaii Combined Facility regarding special use airspace. The Hawaii Combined Facility is the location in which the ARTCC, the Honolulu control tower, and the Combined Radar Approach Control are collocated.

Table 3.3.2.1.2-1 lists the affected Restricted Areas and Warning Areas and their effective altitudes, times used, and their manager or scheduler. There are no Prohibited or Alert special use airspace areas in the PMRF airspace use region of influence.

En Route Airways and Jet Routes

Although relatively remote from the majority of jet routes that crisscross the Pacific, the airspace use region of influence has two instrument flight rules (IFR) en route low altitude airways used by commercial air traffic that pass through the region of influence: V15, which passes east to west through the southernmost part of Warning Area W-188, and V16, which passes east to west through the northern part of Warning Area W-186 and over Niihau (see Figure 3.3.2.1.2-1). An accounting of the number of flights using each airway is not maintained.

The airspace use region of influence, located to the west, northwest, and north of Kauai, is far removed from the low altitude airways carrying commercial traffic between Kauai and Oahu and the other Hawaiian islands, all of which lie to the southeast of Kauai. There is a high volume of island helicopter sightseeing flights along the Na Pali coastline and over the Waimea Canyon, inland and to the east of PMRF, particularly out of Port Allen near Hanapepe on Kauai's southern coastline and other tourist and resort towns on the island. However, these do not fly over PMRF or into Restricted Area R-3101 (National Aeronautical Charting Office, 2007).

Table 3.3.2.1.2-1. Special Use Airspace in the PMRF/Main Base Airspace Use Region of Influence

Number	Location	Altitude (Ft)	Time of Use		Controlling Agency
			Days	Hours

Notes:
R = Restricted, W = Warning
FL = Flight Level (FL 180 = 18,000 ft)
PMRF = Pacific Missile Range Facility
HCF = Hawaii Combined Facility, the location in which the Air Route Traffic Control Center (ARTCC), the Honolulu control tower, and the Combined Radar Approach Control are collocated.
FACSFACPH = Navy Fleet and Area Control and Surveillance Facility Pearl Harbor

Airports and Airfields

With the exception of the airfield at PMRF/Main Base, and the Kekaha airstrip approximately 3 mi to the southeast of PMRF and 2 mi northwest of Kekaha, there are no airfields or airports in the airspace use region of influence. Lihue Airport is located 20 nm east of PMRF, outside the region of influence. In addition to helicopter and fixed-wing aircraft landings associated with PMRF's mission, the PMRF airfield serves as a training facility for landings and takeoffs. The overall number of air operations was 13,395 for 2004. (U.S. Department of the Navy, Engineering Field Activity Chesapeake, 2006)

There is a heliport, used by PMRF personnel, located at the Makaha Ridge Instrumentation Site, as well as a heliport at Kokee Park used by State Park personnel. The standard instrument approach and departure procedure tracks for Kauai's principal airport at Lihue are all to the east and southeast of the island itself, well removed from the airspace use region of influence. (National Aeronautical Charting Office, 2007)

Air Traffic Control

Use of the airspace by the FAA and PMRF is established by a Letter of Agreement between the two agencies. Under this agreement, PMRF is required to notify the FAA by 2:00 p.m. the day before range operations would infringe on the designated airspace. Range Control and the FAA are in direct real-time communication to ensure safety of all aircraft using the airways and jet routes and the special use airspace. Within the special use airspace, military activities in Warning Areas W-186 and W-188 are under PMRF control, and the PMRF Range Control Officer is solely authorized and responsible for administering range safety criteria, the surveillance and clearance of the range, and the issuance of range RED (no firing) and GREEN (clearance to fire) status (Pacific Missile Range Facility, Barking Sands, Hawaii, 1991). Warning Area W-187 is scheduled through the Fleet Area Control and Surveillance Facility.

As Warning Areas are located in international airspace, the procedures of the International Civil Aviation Organization (ICAO), outlined in ICAO Document 444, *Rules of the Air and Air Traffic Services*, are followed. ICAO Document 444 is the equivalent air traffic control manual to FAA Handbook 7110.65, *Air Traffic Control*. The FAA acts as the U.S. agent for aeronautical information to the ICAO, and air traffic in the region of influence is managed by the Honolulu ARTCCs.

3.3.2.1.3 Biological Resources—PMRF/Main Base

Native or naturalized vegetation, wildlife, and the habitats in which they occur are collectively referred to as biological resources. Existing information on plant and animal species and habitat types in the vicinity of the proposed sites was reviewed, with special emphasis on the presence of any species listed as threatened or endangered by Federal or State agencies, to assess their sensitivity to the effects of the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3. For the purpose of discussion, biological resources have been divided into the areas of vegetation, wildlife, threatened and endangered species, and environmentally sensitive habitat.

The main Federal Acts that provide guidance on avoiding or minimizing impacts on biological resources are detailed in Appendix C.

Region of Influence

The region of influence for biological resources includes the area within the PMRF/Main Base property boundary and offshore areas used for testing and training. Within the region of influence, human activities have altered most of the natural terrestrial environment. The land in PMRF/Main Base is used for military activities such as air operations, rocket launches, various training, and base maintenance operations. Most of the same terrestrial species discussed below for PMRF/Main Base could also occur within the adjacent Mana Plain area.

Affected Environment

Vegetation

There are six recognized vegetation types on the undeveloped portions of PMRF/Main Base: kiawe *(Prosopis pallida*)-koa haole (*Leucaena leucocephala*) scrub, a`ali`i (*Dodonaea viscosa*)-nama (*Nama sandwicensis*) scrub, pohinahina (*Vitex rotundifolia*), naupaka (*Scaevola sericea*) dune, strand, drainage-way wetlands, and ruderal vegetation. Kiawe/koa haole and a`ali`i-nama scrub are the dominant vegetation in the undeveloped portions of the PMRF/Main Base region of influence. A well-developed native strand community exists along the shoreline. (Pacific Missile Range Facility, 2001) Common plants that inhabit the sandy beach habitat on Kauai include the beach morning glory, beach heliotrope, milo, and hau (Maragos, 1998).

Drainage-way wetlands vegetation occupies only a small area on PMRF/Main Base. Ruderal (disturbed, weedy) vegetation is present along roadsides and other areas where man has disturbed the natural vegetation, and much of this vegetation is mowed on a regular basis. The broad, white, sandy beach that fronts Majors Bay supports only sparse littoral kiawe-koa haole thickets on the northern half and native a`ali`i-nama scrub on the southern half. (Pacific Missile Range Facility, 2001)

Golden crown beard (*Verbesina enceliodes*) is a new invasive species on the Nohili dunes since the 2000 survey. It has recently begun to take over areas that were previously dominated by native vegetation such as nama. Other alien species include ironwood (*Casuarina* spp.), sourbush (*Pluchea carolinensis*), and swollen fingergrass (*Chloris barbata*). (Pacific Missile Range Facility, 2006a)

The vegetation in the Mana Plain restrictive easement area was dominated by sugar cane (*Saccharum officinarum*), ruderal vegetation, and wetlands associated with agricultural ponds and drains. Sugar cane is being phased out, and more diversified agricultural crops are being grown (Hawaii Coral Reef Assessment and Monitoring Program, 2006). The non-native, non-agricultural vegetation is dominated by kiawe/koa haole. This vegetation type is the dominant type present on the relatively undisturbed areas of the sand dunes, associated with PMRF and Polihale State Park, as well as along the cliff face in the restrictive easement area. Because of the restrictions on off-highway vehicle activities, the sand dune related vegetation within the PMRF boundary is less disturbed than the vegetation in Polihale State Park. (Pacific Missile Range Facility, 2001)

At KTF, naupaka, beach morning glory, and \`a\`ali\`i are common. Coastal dune vegetation covers much of the dunes north of KTF, which is located in the northern portion of the base. Vegetation at the Kokole Point Launch Complex in the southern portion of the base is composed of a mixture of Bermuda grass (*Cynodon dactylon*), portulaca (*Portulaca lutea*), and buffelgrass (*Cenchrus ciliaris*). (Department of Energy, 1991; Pacific Missile Range Facility, 2001)

<u>Threatened and Endangered Plant Species</u>

Table 3.3.2.1.3-1 lists threatened and endangered species known or expected to occur within the PMRF/Main Base region of influence. There is no known plant species listed as threatened or endangered on PMRF/Main Base. (Pacific Missile Range Facility, 2001)

Two Federally listed plant species have been observed north of, but not on, PMRF/Main Base. Ohai (*Sesbania tomentosa*), a spreading shrub, is a Federally endangered species that has been observed in the sand dunes to the north of PMRF/Main Base in Polihale State Park and could potentially occur on the installation, including KTF. Lau\`ehu (*Panicum niihauense*), an endangered species of rare grass, has been observed near Queens Pond also north of PMRF/Main Base. (Pacific Missile Range Facility, 2001; U.S. Department of the Navy, 1998a)

Wildlife

Birds identified at PMRF/Main Base include non-native, migratory and species endemic to Hawaii. The pueo *(Asio flammeus sandwichensis),* or Hawaiian short-eared owl, is the only endemic non-migratory bird species that occurs in the region. Non-native bird species on Kauai are usually common field and urban birds such as the non-migratory zebra dove (*Geopelia striata*) and Japanese white-eye (*Zosterops japonicus*) and the migratory ring-necked pheasant (*Phasianus colchicus*), northern cardinal (*Cardinalis cardinalis*), northern mockingbird (*Mimus polyglottos*), and house finch (*Carpodacus mexicanus*). (Pacific Missile Range Facility, 2001; 2006b)

Table 3.3.2.1.3-1. Listed Species Known or Expected to Occur in the Vicinity of PMRF/Main Base

Scientific Name	Common Name	Federal Status
Plants[1]		
Panicum niihauense	Lau`ehu	E
Sesbania tomentosa	Ohai	E
Reptiles		
Chelonia mydas	Green turtle	T
Birds		
Anas wyvilliana	Koloa maoli (Hawaiian duck)	E
Branta sandvicensis	Nene (Hawaiian goose)	E
Fulica alai	`Alae ke`oke`o (Hawaiian coot)	E

Notes: [1] Critical habitat has been designated on the installation for these plants.

** Observed in May 2000

Key to Federal Status:
T = Threatened
E = Endangered
P = Proposed for listing as threatened or endangered

Several species of migratory seabirds and shorebirds covered by the Migratory Bird Treaty Act (MBTA) are present during some portion of the year. Brown boobies (*Sula leucogaster*), sanderlings (*Calidris alba*), wandering tattlers (*Heteroscelus incanus*), ruddy turnstones (*Arenaria interpres*), and Pacific golden plovers (*Pluvialis fulva*) are commonly observed at PMRF/Main Base. Wedge-tailed shearwaters (*Puffinus pacificus*) nest in the Nohili dunes area. A nesting colony of wedge-tailed shearwaters is also located near the beach cottages. Nesting colony restoration efforts begun in 2006 included removing non-native trees and planting naupaka seedlings and native beach vegetation (pohinahina), ilima (*Sida fallax*), and akiaki (*Sporobolus virginicus*) seeds. The Navy built a fenced-in, 1-acre compound near the middle of PMRF to foster wedge-tailed shearwater nesting and to keep out unwanted "guests." There were an estimated 276 breeding pairs in the compound in 2006 (U.S. Navy NAVFAC Pacific Environmental Planning, 2007). The Navy also installed PVC pipe segments into the compound to provide some artificial burrows that would not collapse. (Currents, 2007)

The Laysan albatross (*Phoebastria immutabilis*), also protected under the MBTA, uses ruderal vegetation areas on the base for courtship and nesting (Pacific Missile Range Facility, 2001; 2006b).

The Laysan albatross is being discouraged from nesting at PMRF to prevent interaction between the species and aircraft using the runway. Albatross on the airfield are tagged and released on the north portion of the base or returnees are relocated to Kilauea National Wildlife Refuge in order to prevent bird/aircraft strikes. This action is accomplished under a U.S. Fish and Wildlife (USFWS) permit. During the nesting season, PMRF staff in cooperation with the U.S. Department of Agriculture's Animal and Plant Health Inspection Service and the Kauai National Wildlife Refuge Complex relocates viable PMRF albatross eggs to Kilauea Point and other north shore nest sites to replace eggs that would never hatch. All of the resulting chicks were accepted by new surrogate parents and should now return to the north shore when old enough to mate. With no chicks to feed, the adult albatross returned to the open sea. This surrogate parenting program continues through the 2007/2008 nesting season and is anticipated to continue as long as viable eggs are available at PMRF/Main Base. Thirty-seven eggs were placed with surrogate parents during the 2007 season (Burger, 2007e). (Burger, 2007a; U.S. Fish and Wildlife Service, 2005b; U.S. Department of the Navy, 1998a; U.S. Army Space and Missile Defense Command, 2001)

Feral dogs (*Canis familiaris*) and cats (*Felis catus*) occur in the region and prey on native and introduced species of birds. Rodents including the Polynesian black rat (*Rattus exulans*), Norway or brown rat (*Rattus norvegicus*), and the house mouse (*Mus musculus*) are also known to occur in the region. (U.S. Department of the Navy, 1998a; U.S. Army Space and Missile Defense Command, 2001) PMRF has an ongoing feral animal-trapping program to protect the albatross as well as the wedge-tail shearwater and other birds on base (Burger, 2007a). Reptiles observed on PMRF/Main Base during recent surveys were the house gecko (*Hemidactylus frenatus*), mourning gecko (*Lepidodactylus lugubris*), and snake-eyed skink (*Cryptoblepharus poecilopleurus*). The only amphibian observed was the marine toad (*Bufo marinus)*. (Pacific Missile Range Facility, 2006c; U.S. Department of the Navy, 1998c; U.S. Army Space and Missile Defense Command, 2001)

Wildlife on KTF is similar to that described above for PMRF/Main Base. Birds on KTF include resident species such as the red junglefowl (*Gallus gallus*), ring-necked pheasant, and northern mockingbird. Non-resident species identified include the short-eared owl, brown noddy (*Anous stolidus*), and great frigate bird (*Fregata minor*). The Laysan albatross has also been observed in the KTF area. Feral dogs and cats occur in the region. Rodents including the roof rat (*Rattus rattus*), Norway or brown rat, and the house mouse are also expected to be present on KTF. (Pacific Missile Range Facility, 2001)

Threatened and Endangered Wildlife Species

Seven birds Federally listed as threatened or endangered are potentially present or confirmed in the PMRF area (Table 3.3.2.1.3-1). The black-footed albatross, a seabird that has recently been proposed for listing as threatened or endangered (U.S. Fish and Wildlife Service, 2007b), has also been observed on PMRF. According to the Navy and USFWS, the nene (*Branta sandvicensis*) is present on PMRF/Main Base (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007). Kauai provides the majority of Hawaii's habitat for the threatened Newell's shearwater. The Newell's shearwater nests from April to November in the interior mountains of Kauai. Fledglings leave the nesting grounds at night in October and November and head for the open ocean. They may become temporarily blinded by lights when flying near brightly lit urban areas or street lights, and some may collide with trees, utility lines and light poles, buildings, and automobiles. PMRF personnel have retrofitted their outdoor lighting with hoods that direct the lights downward to prevent confusing the seabirds, which can be disoriented by upward- and outward-shining lights (Honolulu Advertiser, 2006). (Audubon, 2006; Hawaii Department of Land and Natural Resources, no date[a])

The Hawaiian dark-rumped petrel, which is federally listed as endangered and protected by the MBTA, arrives in February and may traverse the area from its nesting grounds to the sea. On Kauai, several grounded dark-rumped petrel fledglings have been collected in recent years as part of the Newell's shearwater recovery program. Most birds have been found near the mouth of Waimea Canyon, indicating that some birds still breed in the vicinity. Dark-rumped petrels are nocturnal over land and are active from about 1 hour after sunset until about 1 hour before sunrise. Nesting occurs from April through May. Chicks begin hatching in late June and fledge in late October to November, slightly earlier than that of the Newell's Townsend's shearwater. (Audubon, 2006; Virginia Tech Conservation Management Institute, 1996)

The Hawaiian coot (*Fulica alai*), Hawaiian black-necked stilt (*Himantopus mexicanus knudseni*), Hawaiian common moorhen (*Gallinula chloropus sandvicensis*), and Hawaiian duck (*Anas wyvilliana*) are endangered waterbirds that have been observed in the drainage ditches and ponds on PMRF/Main Base. The Hawaiian coot, black-necked stilt, and common moorhen are listed as migratory species (U.S. Fish and Wildlife Service, 2006c), but nest year-round, May through September, and April through October respectively. (U.S. Department of the Navy, 1998a)

The Hawaiian hoary bat (*Lasiurus cinereus* spp. *semotus*) is listed as a Federal and State endangered species. It has been recorded at PMRF; a group of four was observed foraging around the sewage treatment ponds, and another group of five bats was seen just offshore of northern PMRF/Main Base. It has also been observed at the Polihale State Park north of the base. (Pacific Missile Range Facility, 2001)

The threatened Newell’s shearwater and endangered Hawaiian coot, Hawaiian black-necked stilt, Hawaiian common moorhen, and Hawaiian duck are potentially present or confirmed within or near the KTF area. The endangered Hawaiian hoary bat has been observed at the Polihale State Park north of KTF. (Pacific Missile Range Facility, 2001)

Two marine wildlife species Federally and State listed as threatened or endangered commonly occur on PMRF/Main Base. The endangered Hawaiian monk seal has been observed at PMRF. The first Hawaiian monk seal birth recorded on a Kauai beach since 1993 occurred on PMRF in 1999 (Marine Mammal Commission, 2003; Pacific Missile Range Facility, 1999). Two and three pups were born on Kauai beaches in 2003 and 2004 respectively (Kauai Monk Seal Watch Program, 2003; National Oceanic and Atmospheric Administration, 2006d; National Marine Fisheries Service, 2007e). Three pups were born on Kauai in 2005 and four pups were born in 2006 (National Oceanic and Atmospheric Administration, 2006d; National Marine Fisheries Service, 2007e). Pups are born between February and August. Sitings of Hawaiian monk seal haul outs are documented by the PMRF Environmental Office.

Green turtles have been observed basking on shore in the vicinity of Nohili Ditch; the only area where basking/haul-out activity on PMRF/Main Base is observed. The PMRF Natural Resources Manager monitors sea turtle activity at PMRF. Green turtles have not nested anywhere along the beachfront. In the past 3 years only one apparent “false nesting” has been observed. (Burger, 2007b) Security patrols reports include a record of the presence and locations of turtles. Any records of green turtle sitings are maintained by the PMRF Environmental Office. (Pacific Missile Range Facility, 2001)

Environmentally Sensitive Habitat

Wetlands

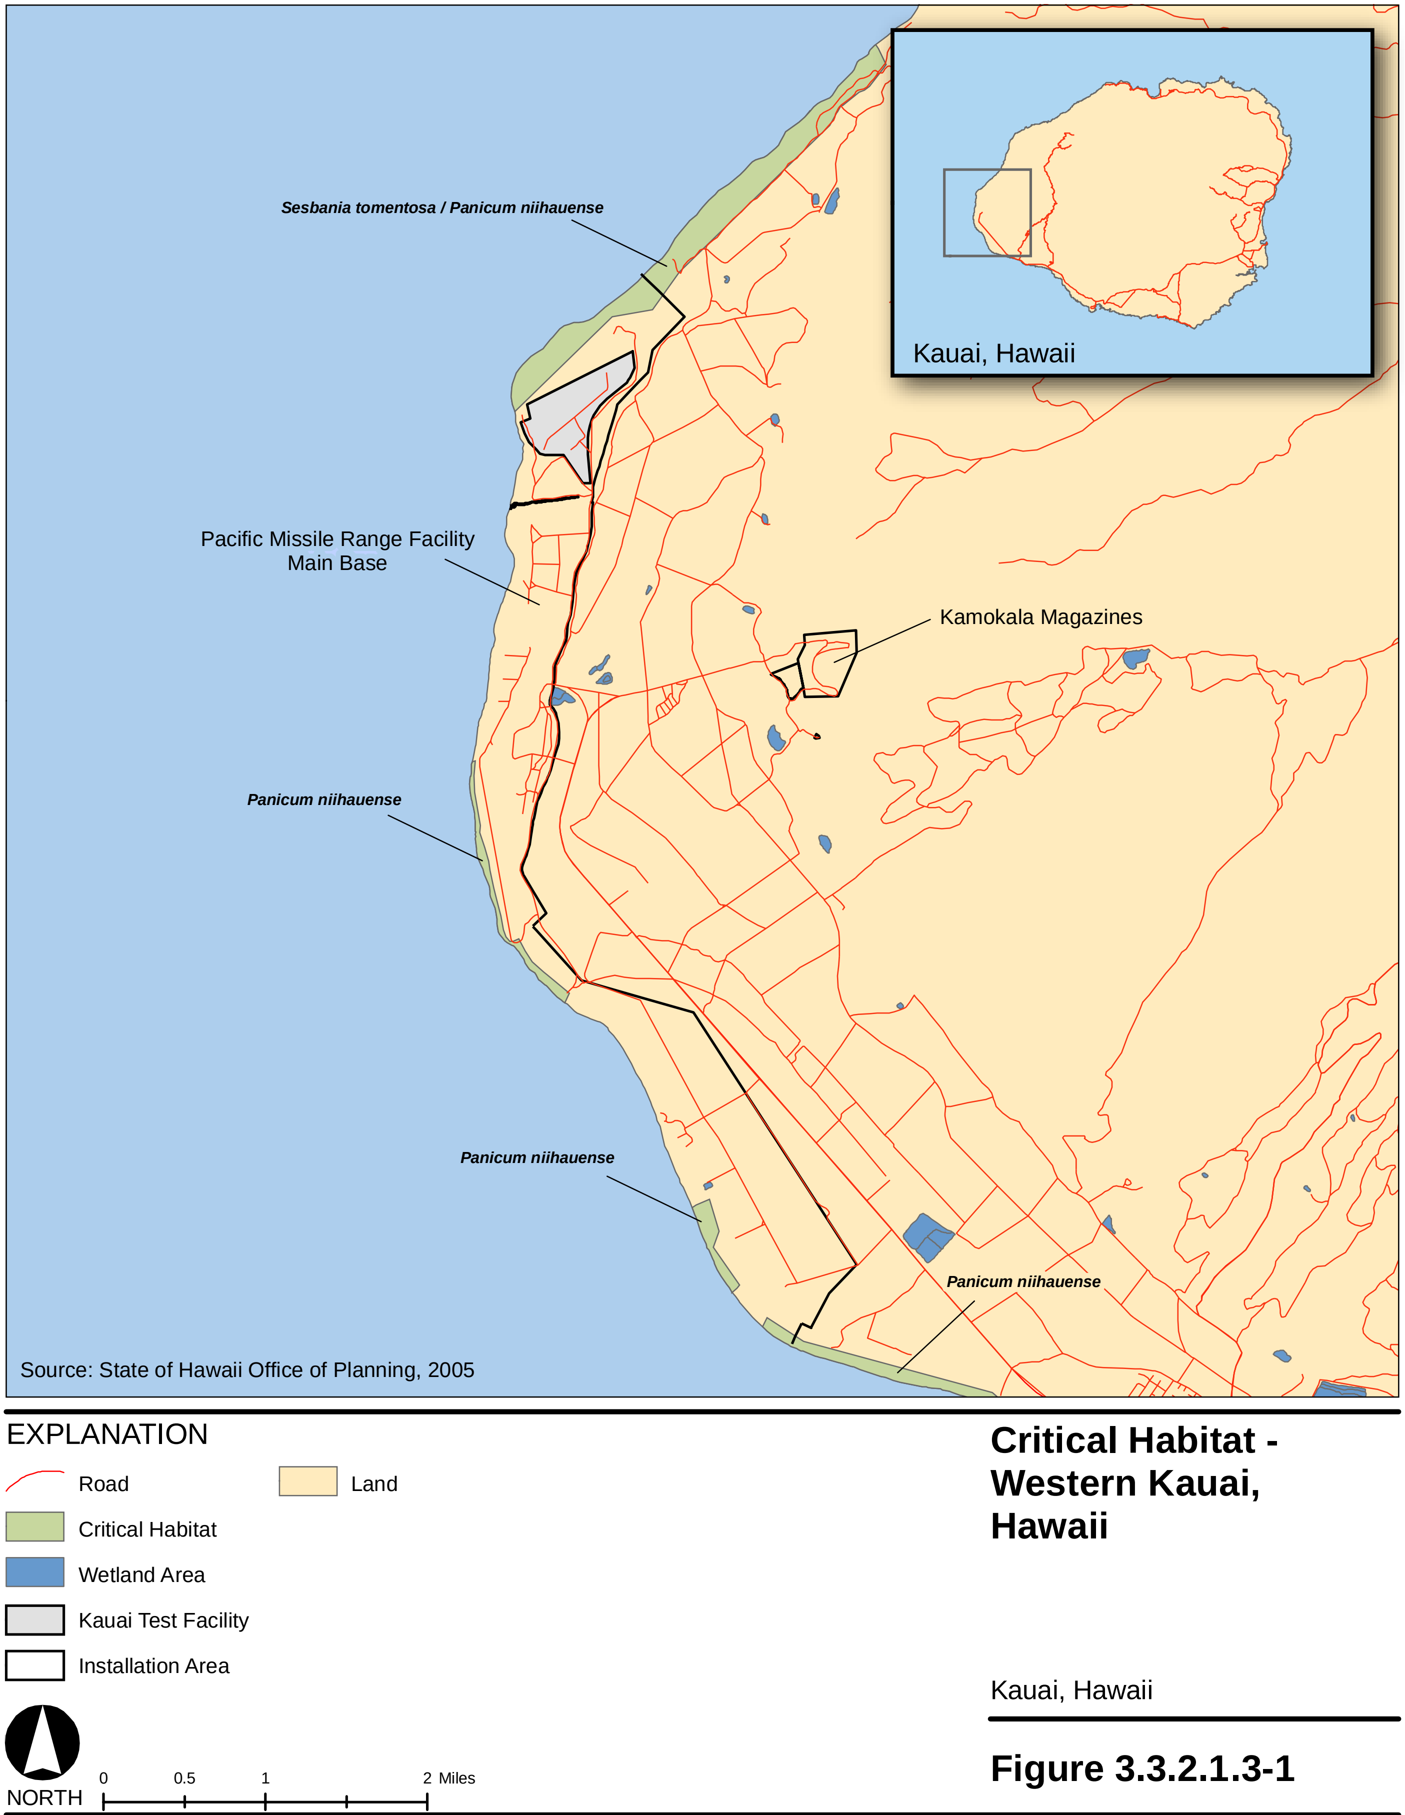
Wetlands are associated with (1) the Mana base pond located outside the industrial area of the facility boundaries; (2) Kawaiele wildlife sanctuaries that include a State Waterbird Refuge for Hawaii's four endangered waterbird species, created at Mana during a sand removal program; and (3) agricultural drains from the Nohili and Kawaiele ditches within PMRF/Main Base. (National Wetlands Inventory, 2007) The freshwater discharge at Nohili Ditch appears to be at least partially responsible for the preferred turtle foraging habitat since it stimulates filamentous algae growth on the nearshore reef bench (Commander, Navy Region Hawaii, 2007).

Two marine system, subtidal subsystem, reef class, coral subclass, subtidal wetlands exist along part of the coastline west of KTF. (Pacific Missile Range Facility, 2001)

Critical Habitat

A proposed rule to designate critical habitat for 76 listed plant species on the islands of Kauai and Niihau published in November 2000 (U.S. Fish and Wildlife Service, 2000) included land in the northwestern end of PMRF near Polihale Park as critical habitat for the endangered ohai and lau`ehu. In January 2002, the USFWS proposed critical habitat for additional plant species on Kauai and Niihau, revising the total number of plants to 83, which included additional land in the southern portion of PMRF for protection of lau`ehu. (U.S. Fish and Wildlife Service, Pacific Region, 2002; U.S. Fish and Wildlife Service, 2002) The USFWS reevaluated the dune habitat on PMRF and the habitat on Navy land at Makaha Ridge and determined that these lands were not essential for the conservation of ohai or dwarf iliau (*Wilkesia hobdyi*, found on Makaha Ridge). Although lau`ehu does not grow on PMRF/Main Base, the USFWS has determined that land on PMRF adjacent to Polihale State Park and dune areas along the southern portion of the range contain primary constituents necessary for the recovery of lau`ehu because not enough areas exist outside of PMRF (Figure 3.3.2.1.3-1). The USFWS designated these areas as unoccupied critical habitat because there are not enough other areas outside the base that contain the elements to achieve the USFWS's goal of 8 to 10 populations. (U.S. Fish and Wildlife Service, 2003a)

The areas of unoccupied critical habitat for the lau`ehu established along the coast of PMRF include the KTF coastal area and the area adjacent to Kokole Point. Lau`ehu has not been observed on KTF. (Pacific Missile Range Facility, 2001; U.S. Fish and Wildlife Service, 2003a)



Critical Habitat - Western Kauai, Hawaii

Kauai, Hawaii

Figure 3.3.2.1.3-1

3.3.2.1.4 Cultural Resources—PMRF/Main Base

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for terrestrial cultural resources at PMRF/Main Base/KTF consists of areas throughout the installation. These areas include existing launch pads and locations for the construction of new facilities and infrastructure features (e.g., Directed Energy facilities) (see Figures 2.2.2.5.1-2, 2.2.3.6.4-5, and 2.2.4.5-1). Survey data indicate that most of the proposed construction locations are surficially devoid of archaeological sites; however, subsurface archaeological and traditional cultural materials (particularly burials) could be present anywhere within the boundary of the installation. Locations for the proposed warehouse and consolidated Range Operations complex (see Figure 2.2.3.6.4-5) are located with an area of medium sensitivity for burials. Building 282, where a new Automatic Identification System antenna is planned, has not been recommended as a historic building (see Appendix H).

Affected Environment

Archaeological Resources (Prehistoric and Historic)

Brief Prehistory/Early History

PMRF/Main Base and KTF are situated in a region known as Mana. Throughout prehistory, large areas of the Mana Plain were covered by the great Mana swamp, allowing Native Hawaiians to canoe as far south as Waimea (Von Holt, 1985; State of Hawaii, 1993). It is believed that these wet conditions encouraged the independent invention of aquaculture on Kauai and the construction of stone and earthen ponds for growing staples such as taro, yam, and sweet potatoes (Kikuchi, 1987). After the arrival of Europeans to the island, aquaculture transitioned to agriculture through the eventual draining of the swamp and the cultivation of sugar cane and rice. The first successful sugar plantation to export from the islands was established at Koloa in 1835 (Hawaii Visitors Bureau, 1993), and by the 1930s, nearly all of the Mana swamp had been filled to produce this crop.

Brief Military History

In 1940, 549 acres in Mana were deeded to the U.S. War Department for an Army Air Corps flight training field. The Navy was given permission to use the facilities in 1944; however, after the Air Force was established (1947), it assumed control of the facility (redesignated Barking Sands Air Force Base), and continued operations through the Korean War years. In 1953, the base was re-named Bonham Air Force Base and in 1961, the U.S. Departments of the Air Force and Navy were operating the facility under a joint use agreement. In 1964, 1,884 acres of the Mana Plain were officially transferred to the Navy, and by 1966 the facility was renamed PMRF (International Archaeological Resources Institute, Inc., 2005).

Throughout the Cold War years (1946-1991), PMRF supported both offensive and defensive Cold War missions, including offensive weapons managed by the Navy, air defense weapons managed by the Hawaii Air National Guard, and research into ballistic missile defensive systems. PMRF also supported atmospheric nuclear testing by the Atomic Energy Commission, which led to the establishment of the KTF in the early 1960s. In 2007, PMRF is the largest instrumented multi-environment test range in the world. The range is unique in providing realistic testing environments for anti-submarine, air, surface, and subsurface weapons systems. The installation also provides services for training, tactics development, and evaluation of air, surface, and subsurface weapons systems for the Navy, other Department of Defense (DoD) agencies, foreign military forces, and private industry (International Archaeological Resources Institute, Inc., 2005).

Native Hawaiian (Traditional) Information

Mana is an area specifically referred to in Hawaiian literature and oral tradition as a leina-a-ka-uhane, a place (generally cliffs or seacoast promontories) where the spirits of men, after death, plunge into eternity and are divided into one of three spiritual realms: the realm of the wandering spirits; the realm of the ancestral spirits; or the realm of the endless night (Han, et al., 1986; Fornander, 1917). Typical of Native Hawaiian mortuary practices, burial sites believed to be associated with the Mana leina-a-ka-uhane have been identified throughout the area.

Large portions of PMRF have been systematically surface surveyed for archaeological resources; however, subsurface features may still be present (West and Desilets, 2005). Previous investigations have identified a variety of prehistoric and historic resources, including burial sites, heiaus (temples), campsites, house sites, lithic (stone) scatters, aquaculture ponds, and modern military-associated sites, any or all of which could be potentially eligible for inclusion in the National Register of Historic Places (NRHP). Appendix H includes a list of significant archaeological and traditional resources (International Archaeological Resources Institute, Inc., 2005).

Historic Buildings and Structures

Since 1991, several architectural evaluations have been conducted for PMRF, including PMRF/Main Base, Kamokala Ridge, and Port Allen (Drolet et al., 1996; Rechtman, et al., 1998). The evaluations covered pre-military facilities and features, as well as World War II and Cold War era resources. Appendix H includes a list of the buildings and structures recommended eligible for inclusion in the NRHP (International Archaeological Resources Institute, Inc., 2005).

Traditional Resources

Traditional resources can include archaeological sites, burial sites, ceremonial areas, natural features (e.g., caves, mountains, water sources, trails, plant habitat, or gathering areas), or any other natural area important to a culture for religious or heritage reasons. As such, many of the cultural materials identified within the region of influence could also be considered traditional resources. In addition to Native Hawaiians, several other cultures have also inhabited the island of Kauai. These include the Japanese, Korean, Portuguese, Chinese, and Filipino. A Japanese cemetery is located within the boundary of PMRF, and cemeteries associated with each of the other cultures are located near Kekaha, Hanapepe, and Waimea.

A comprehensive cultural study of the Mana Plain was carried out by Flores and Kaohi in 1992 as part of investigations related to the proposed Strategic Defense Command Energy Dispersive X-Ray Analysis project (U.S. Army Strategic Defense Command, 1990). This study included historical research, review of documented Hawaiian traditions, and oral history interviews with knowledgeable local residents.

Intensive historical research and a review of traditions were also undertaken by Maly and Wulzen (1997) as part of an extensive reconnaissance survey of PMRF Barking Sands and Makaha Ridge. Oral histories were collected by McGerty and Spear (1997) for a project that technically covered an area inland of PMRF Barking Sands. Oral history information, however, is pertinent to the Mana Plain in general and thus provides a cultural context for PMRF.

In 1999, traditional cultural properties on Navy lands in Hawaii were assessed. The PMRF research was conducted by Alitha Kachi and Kalani Flores, with some additional research by Tuggle and Tomonari-Tuggle. The assessment lists Kawaiele Ditch, Nohili Dune, and Elekuna Heiau as potential traditional cultural properties. Identified traditional Hawaiian sites under the jurisdiction of PMRF are listed in Appendix H. Traditional sites recommended as eligible for listing in the NRHP are listed in Appendix H.

Burials

Burials are the most significant cultural resources concern within the sandy soils of PMRF. There have been numerous inadvertent discoveries of human remains in both the coastal and back bay areas of the installation. The sites represent both traditional Hawaiian and Plantation-era periods (see Appendix H).

3.3.2.1.5 Geology and Soils—PMRF/Main Base

Geology and soils are considered earth resources that may be adversely affected by proposed training and RDT&E activities. This resource is described in terms of existing information on the land forms, geology, and associated soil development as it may be subject to erosion, flooding, mass wasting, mineral resource consumption, contamination, and alternative land uses resulting from proposed construction and launch activities. Appendix C includes a description of geology and soils.

Region of Influence

Geology and soils are considered resources that may be adversely affected by proposed training and RDT&E activities. These resources are described in terms of existing information on land forms, geology, and associated soil development.

Affected Environment

Physiography

PMRF/Main Base is situated on a strip of low-lying coastal terrace called the Mana Plain. The plain bounds the western flank of the island, forming gentle westerly slopes ranging from about 2 percent near the volcanic uplands to relatively flat over the coastal margin occupied by PMRF/Main Base. The plain does not form cliffs at the PMRF/Main Base shoreline. Local relief is formed by low beach barrier dunes, mildly undulating blanket sands, and the more prominent Nohili Dune located in the northern portion of PMRF/Main Base, adjacent to the northwestern side of KTF at Nohili Point. Ground elevations over the facility average between 10 ft to 20 ft, rising to 100 ft at Nohili Dune. PMRF/Main Base is not traversed by perennial or ephemeral streams. Surface runoff is controlled by manmade channels located at Nohili Ditch on northern PMRF/Main Base, Kawaiele Drainage in central PMRF/Main Base, and a drainage channel just south of Kawaiele Drainage.

Geology

Kauai is the result of a massive shield volcano, part of the chain of similar volcanoes that migrated northwest to southeast to form the Hawaiian archipelago. Kauai is the oldest of the eight main islands. Volcanic rocks exposed in the western half of the island are composed of Pliocene basaltic flows of the Waimea Volcanic Series (U.S. Army Strategic Defense Command, 1992). The volcanic terrain forms an abrupt, crescent-shaped scarp at the eastern boundary of the Mana Plain, the result of wave action from a higher sea stand. The surface of the volcanic basement complex plunges beneath the Mana Plain at approximately 5 degrees (U.S. Army Strategic Defense Command, 1992).

The Mana Plain is composed of alluvium, lagoon, beach, and dune deposits that overlie the volcanic basement. This sedimentary sequence forms a wedge that thickens east to west, attaining an approximate thickness of 200 ft at the eastern base boundary, increasing to about 400 ft at the coast (U.S. Army Strategic Defense Command, 1992). Older and younger terrestrial alluvium interfingers with gypsum-bearing clayey lagoonal deposits and marine offshore deposits at depth. Sediments are characteristically red and brown near volcanic outcrops, changing to tan and gray calcareous sand near the coast.

The surface of the Mana Plain typically consists of loose sand associated with younger (Modern) alluvium and flattened dunes with little relief (U.S. Army Strategic Defense Command, 1992). The dune sands can be of substantial thickness along the coastal margin where they have been reported to be in excess of 42 ft thick at the Kokole Point housing area (U.S. Army Strategic Defense Command, 1992). The dunes are composed of loose fine sand and silty sand that is weakly to strongly indurated (hardened) a few meters below ground surface. This indurated surface can form resistant remnants, or fossil dunes, fronting the beach along some reaches of the PMRF shoreline. The beach berm is about 10 ft high and is breached only where drainage canals have been excavated at Nohili and Kawaiele (U.S. Army Strategic Defense Command, 1992).

Coral reefs developed on the eroded platform around the island when the sea was about 5 ft above its current level (U.S. Army Strategic Defense Command, 1992). Wave action has eroded the coral surface, creating a primary source for beach sand which is actively being deposited and reworked along the shoreline. Coral reefs are also discussed in Section 3.3.1.1.1. Beach sand is generally medium to coarse grained.

Soil

The U.S. Department of Agriculture Soil Conservation Service published a soil survey that includes the surficial deposits of the Mana Plain (PMRF and Easement areas). The dominant soil within the PMRF area has been mapped as Jaucas loamy fine sand, 0 to 8 percent slopes (U.S. Army Strategic Defense Command, 1992). The U.S. Department of Agriculture describes this soil as occurring on old (inactive) beaches and on windblown sand deposits. It is pale brown to very pale brown sand, and in some cases it is more than 5 ft deep. In many places, the surface layer is dark brown as a result of accumulated organic matter and alluvium. The silt is neutral to moderately alkaline through its profile. It has an available water capacity of 0.05 to 0.07 inch per foot of soil (U.S. Army Strategic Defense Command, 1992). The soils are permeable, and infiltration is rapid. Wind erosion is severe where vegetation has been removed.

Along the ocean margin of PMRF/Main Base are areas of active dunes and beaches. Dune lands consist of hills and ridges of sand drifted and piled by the wind. The hills and ridges are actively shifting, or so recently stabilized that no soil horizons have developed. The sand is chiefly calcareous, derived from coral and seashells (U.S. Army Strategic Defense Command, 1992).

Soil samples at the Vandal launch site were obtained to determine if lead concentrations exceeded the 400 milligrams per kilogram (mg/kg) cleanup goal established by the Hawaii Department of Health for residential use. No site soil samples had lead concentrations exceeding 400 mg/kg prior to the 1994 Vandal launches. After five 1994 launches, two sites contained lead concentrations exceeding 400 mg/kg. Both of these sites were located within 50 ft of the launch site. Concentrations of lead 100 ft away in the same direction were only 30 and 75 mg/kg. None of the lead concentrations outside this 100-ft range were above the reporting limit. (U.S. Department of the Navy, Naval Facilities Engineering Command, Pearl Harbor, 1996)

Although the Vandal target missile is no longer used, past launches from PMRF appear to have caused elevated lead concentrations in soil only within 100 ft of the launch mechanism. The locations of these soil samples suggest that lead concentrations do not pose an immediate risk to human health because the launch pad is restricted from public access and that none of the apparently contaminated sand has been or will be transported to the beach.

A study was conducted by the Department of Energy to determine if elevated aluminum concentrations occur at PMRF/Main Base and/or KTF as a result of rocket emissions. Analysis of background aluminum levels from Mana Plain soils ranged from 0.2 to 1.1 ounces per pound (oz/lb). Kauai soil aluminum values range from 0.09 to 0.7 oz/lb. Deposits of gibbsite, the trihydrate of aluminum oxide, occur naturally in the high rainfall areas of windward Kauai (Land Study Bureau, 1967). The study suggested that if there has been an increase in the amount of aluminum in the soil at PMRF/Main Base as a result of rocket emissions, the total amount is still less than nearby soils.

KTF also tested for lead and found levels up to 270 mg/kg and indicated that these were not “actionable levels” (U.S. Army Strategic Defense Command, 1992). The KTF report described studies of lead poisoning in children, which found that levels of lead of 300 to 400 mg/kg (300 to 400 parts per million) are acceptable. An additional study of the soils of the Mana Plain and KTF area revealed that chloride and pH do not indicate residual effects from past missile launches at KTF.

3.3.2.1.6 Hazardous Materials and Waste—PMRF/Main Base

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and hazardous waste would be limited to areas of PMRF/Main Base, including KTF, to be used for launch preparation, launch, and post-launch activities and in areas where hazardous materials are stored and handled.

Affected Environment

Hazardous Materials

PMRF manages hazardous materials through the Navy's Consolidated Hazardous Materials Reutilization and Inventory Management Program (CHRIMP). CHRIMP mandates procedures to control, track, and reduce the variety and quantities of hazardous materials in use at facilities. The CHRIMP concept established Hazardous Materials Minimization Centers as the inventory controllers for Navy facilities. All departments, tenant commands, and work centers must order hazardous materials from the Hazardous Materials Minimization Centers, where all such transactions are recorded and tracked. The exception to this is KTF, which obtains its hazardous materials through Department of Energy channels. Hazardous materials on PMRF are managed by the operations and maintenance contractor through CHRIMP. Hazardous materials managed through the CHRIMP program other than fuels are stored in Building 338. Typical materials used on PMRF/Main Base and stored at Building 338 include cleaning agents, solvents, and lubricating oils.

PMRF has management plans for oil and hazardous materials outlined in the *PMRF Spill Prevention Control and Countermeasures Plan* and the *Installation Spill Contingency Plan.* These plans regulate both PMRF/Main Base as well associated sites and tenant organizations, including KTF, Makaha Ridge, Kokee, Kamokala Magazines, and Port Allen.

PMRF has developed programs to comply with the requirements of the Superfund Amendments and Reauthorization Act Title III and Emergency Planning and Community Right-to-Know Act. This effort has included submission to the State and local emergency planning committees of annual Tier II forms, which are an updated inventory of chemicals or extremely hazardous substances in excess of threshold limits. These chemicals at PMRF include jet fuel, diesel fuel, propane, gasoline, aqueous fire fighting foam, chlorine, used oil, paint/oils, and paint.

Hazardous Waste Management

PMRF/Main Base is a large-quantity hazardous waste generator with a USEPA identification number. Hazardous waste on PMRF is not stored beyond the 90-day collection period. In 2004, PMRF/Main Base generated 35,613 lb of hazardous waste.

PMRF/Main Base has two accumulation points on base for hazardous wastes: Building 392 and Building 419. Building 392 accumulates all base waste except for OTTO (torpedo) fuel, a liquid monopropellant. Building 419 is the torpedo repair shop. At present, both buildings are not used at their maximum hazardous waste storage capacity. KTF has one hazardous waste accumulation point. Makaha Ridge and Kokee generate only used oil, which is recycled. Port Allen activities generate used oil and oily bilge water, which are taken to PMRF/Main Base to be recycled and processed. The oily bilge water is processed through an oil/water separator and then is fed into the PMRF/Main Base sewage treatment plant.

PMRF outlines management and disposal procedures for used oils and fuels in the Hazardous Waste Management Plan. PMRF maintains a Used Oil transporter/Processor Permit through the Hawaii Department of Health. Additionally, degraded jet fuel is used in crash-fire training events. The majority of wastes are collected and containerized at PMRF/Main Base for direct offsite disposal through the Defense Reutilization and Marketing Office (DRMO) at Pearl Harbor within 90 days. The DRMO provides for the transportation and disposal of the wastes to the final disposal facility.

KTF is a small-quantity hazardous waste generator and has a USEPA identification number. There is one hazardous waste accumulation point on KTF; however, KTF has not generated enough hazardous waste for disposal since becoming a small quantity generator in 1994. (Sandia National Laboratories, 2006)

<u>Pollution Prevention/Recycling/Waste Minimization</u>

PMRF has a pollution prevention plan in place for the Main Base and all sites on Kauai, which follows CHRIMP procedures for controlling, tracking, and reducing hazardous materials use and waste generation. PMRF/Main Base currently has three hazardous waste elimination programs in place. These involve recycling toner cartridges, mercury from mercury lamps, and acid/lead batteries.

<u>Installation Restoration Program</u>

PMRF/Main Base has 19 Installation Restoration Program (IRP) sites. Two fire fighting training pits, the battery acid disposal, three former oil change pits, a battery acid neutralization unit and the torpedo post run facility require no further action based on the results of past investigations and approval by the Hawaii Department of Health. Three landfills (5, 6, and 7), tanker truck pod facility, former missile (Regulus) defueling pit, and the former oil/fuel pipeline are scheduled to be investigated in FY 2011. A site investigation of transformer sites (four) and the reclamite asphalt rejuvenation burial areas is complete. A recommendation for a No Further Action was sent to the Hawaii Department of Health for these sites.

KTF has no Environmental Restoration sites. Three Environmental Restoration sites were identified in 1995 and were given a No Further Action determination by USEPA in 1996 (Sandia National Laboratory, 2006).

<u>Underground and Aboveground Storage Tanks</u>

PMRF/Main Base has nine 50,000-gal field constructed underground storage tanks (USTs) located at the Fuel Farm, one 30,000-gal UST located at the Power Plant, two 5,000-gal USTs at the Navy Exchange, three 5,000-gal USTs at the gasoline station, and one 1,000-gal UST at the Calibration Lab. With the exception of the field constructed tanks, all tanks are double-walled, fiberglass-reinforced plastic. All USTs are equipped with a leak detection system. (Burger, 2006)

There are two 25,000-gal aboveground storage tanks (ASTs) at the Kokee Power Plant, two 6,000-gal diesel ASTs and one 1,000-gal AST at Makaha Ridge, three 200-gal ASTs near building 510 and one 1,000-gal AST near building 450. All tanks have proper capacity spill containment systems. (Burger, 2006)

There is one UST and one 10,000-gal aboveground fuel tank at KTF. KTF complies with PMRF's management plans for oil and hazardous materials outlined in the *PMRF Spill Prevention Control and Countermeasures Plan* and the *Installation Spill Contingency Plan.* (Sandia National Laboratories, 2006)

Asbestos, Lead-Based Paint, and Polychlorinated Biphenyls

PMRF manages asbestos in accordance with the base asbestos management plan. Prior to any construction projects, areas to be disturbed are surveyed for asbestos, and any asbestos is removed, before disturbance, by a certified asbestos contractor. The handling of hazardous materials and the potential generation and disposal of hazardous wastes follow ongoing, standard, and applicable regulations and procedures at PMRF.

All facilities associated with PMRF follow its lead-based paint management plan. The exception is KTF, which follows Department of Energy plans for the removal of lead-based paint wastes.

No known components at PMRF/Main Base contain polychlorinated biphenyl (PCBs). In the event that components containing PCBs are found at PMRF/Main Base and become waste, they would be labeled according to the Toxic Substances Control Act, 40 CFR 761, requirements for shipping, and disposed of through the DRMO or a contractor within 1 year of the waste's initial storage.

KTF follows the Department of Energy plans for the removal of any lead-based paint wastes. The transformers on the KTF site have been tested and are free of PCBs, and there are no asbestos issues at the site. (Sandia National Laboratory, 2006)

Liquid Fuels and Other Toxic Fuels

PMRF uses gasoline and diesel fuels to power range trucks and equipment. Aircraft at PMRF utilize jet fuel and Jet-A. Jet-A is available at the fuel farm near the airfield. Both aircraft fuels are delivered to the flight line in refuelers.

3.3.2.1.7 Health and Safety—PMRF/Main Base

Health and safety includes consideration of any activities, occurrences, or training and RDT&E activities that have the potential to affect one or more of the following:

The well-being, safety, or health of workers—Workers are considered to be persons directly involved with the training and RDT&E activities producing the effect or who are physically present at the site.

The well-being, safety, or health of members of the public—Members of the public are considered to be persons not physically present at the location of the training and RDT&E activities, including workers at nearby locations who are not involved in the training and RDT&E activities and the off-base population. Also included within this category are hazards to equipment, structures, plants, and wildlife.

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for potential impact related to the health and safety of workers includes work areas associated with range operations, training, and RDT&E activities. The population of concern includes the workers employed at PMRF/Main Base, including KTF, but also encompasses the contractor, military, and government civilian personnel directly involved with range operation, training, and RDT&E activities.

The region of influence for potential impact related to public health and safety includes the areas of Kauai County and the island of Kauai and Niihau affected by range operations, training, and RDT&E activities. These areas include the PMRF overwater training areas. The population of concern consists of visitors to Kauai and permanent residents living in Kauai County.

Affected Environment

PMRF takes every reasonable precaution during the planning and execution of the range operations, training, and RDT&E activities to prevent injury to human life or property. In addition to explosive, physical impact, and electromagnetic hazards, potential hazards from chemical contamination, ionizing and non-ionizing radiation, radioactive materials, and lasers are studied by PMRF Range Safety Office to determine safety restrictions. In addition, Appendix K includes a discussion in general terms of the potential health and safety hazards associated with missile launch activities and the corresponding procedures that are in place to protect people and assets.

Range Safety

Range Safety at PMRF is controlled by Range Control, which is responsible for hazard area surveillance and clearance and control of all PMRF operational areas. Range Control maintains real time surveillance, clearance, and safety at all PMRF areas including PMRF/Main Base. PMRF sets requirements for minimally acceptable risk criteria to occupational and non-occupational personnel, test facilities, and non-military assets during range operations. For all range operations at PMRF, the Range Control Officer requires a safety plan. A Range Safety Operation Plan (RSOP) is generated by PMRF Range Safety personnel prior to range operations.

The PMRF Range Safety Office is responsible for establishing Ground Hazard Areas and Launch Hazard Areas over water beyond which no debris from early flight termination is expected to fall. The Ground and Launch Hazard Areas for missile launches are determined by size and flight characteristics of the missile, as well as individual flight profiles of each flight test. Data processed by ground-based or onboard missile computer systems may be used to recognize malfunctions and terminate missile flight. Before a launch is allowed to proceed, the range is determined cleared using input from ship sensors, visual surveillance from aircraft and range safety boats, radar data, and acoustic information.

Other safety areas under PMRF's control include radars, explosives, and airspace. All range users must: (1) provide a list of project materials, items, or test conditions that could present hazards to personnel or material through toxicity, combustion, blast, acoustics, fragmentation, electromagnetic radiation (EMR), radioactivity, ionization, or other means; (2) describe radiation, toxic, explosive, or ionization problems that could accumulate as a result of their tests; (3) provide aerodynamic and flight control information, and destruct system information and parameters; (4) submit plans, specifications, and procedural or functional steps for events and activities involving explosives to conform to criteria in the PMRF instruction; and (5) provide complete operational specifications of any laser to be used and a detailed description of its planned use. (U.S. Department of the Navy, 1998a)

Missile Flight Analysis

PMRF conducts missile flight safety, which takes into account potential hazards from chemical contamination, ionizing and non-ionizing radiation, radioactive materials, and lasers in accordance with Naval Air Warfare Center Weapons Division Instruction. Missile flight safety includes analysis of missile performance capabilities and limitations, of hazards inherent in missile operations and destruct systems, and of the electronic characteristics of missiles and instrumentation. It also includes computation and review of missile trajectories, launch azimuths, kinetic energy intercept debris impact areas, and hazard area dimensions, review and approval of destruct systems proposals, and preparation of the RSOP required of all programs at PMRF. These plans are prepared by the PMRF Safety Office for each mission and must be approved by the Commanding Office prior to any launch. Launch is only allowed when the risk levels are less than the acceptable risk criteria in PMRF Instruction 8020.16, which are equivalent to the criteria developed by the Range Commanders Council (e.g., RCC 321).

Ground Safety

The Range Control Officer using PMRF assets is solely responsible for determining range status and setting RED (no firing – unsafe condition due to a fouled firing area) and GREEN (range is clear and support units are ready to begin the event) range firing conditions. The Range Safety Approval and the RSOP documents are required for all weapons systems using PMRF (U.S. Department of the Navy, 1998a). PMRF uses RCC 321, *Common Risk Criteria for National Test Ranges*. RCC 321 sets requirements for minimally-acceptable risk criteria to occupational and non-occupational personnel, test facilities, and non-military assets during range operations. Under RCC 321, the general public shall not be exposed to a probability of casualty greater than 1 in 10 million for each individual during any single mission and a total expectation of casualty must be less than 30 in 1 million. (Range Commanders Council, Range Safety Group, 2002) Figure 3.3.2.1.7-1 shows the PMRF health and safety areas including the Ground Hazard Areas associated with missile launch activities at PMRF/Main Base.

To ensure the protection of all persons and property, standard operating procedures (SOPs) have been established and implemented for the Ground Hazard Areas. These SOPs include establishing road control points and clearing the area using vehicles and helicopters (if necessary). Road control points are established 3 hours prior to launches. This allows security forces to monitor traffic that passes through the Ground Hazard Areas. At 20 minutes before a launch, the Ground Hazard Area is cleared of the public to ensure that, in the unlikely event of early flight termination, no injuries or damage to persons or property would occur. After the Range Safety Officer declares the area safe, the security force gives the all-clear signal, and the public is allowed to reenter the area. (U.S. Department of the Navy, 1998a) No inhabited structures are located within the off-base sections of the Ground Hazard Area. The potential for launch-associated hazards are further minimized through the use of the PMRF Missile Accident Emergency Team. This team is assembled for all launches from PMRF facilities and on-call for all PMRF launches in accordance with PMRF Instruction (PMRFINST) 5100.1F.

Ordnance Management and Safety

Ordnance safety includes procedures to prevent premature, unintentional, or unauthorized detonation of ordnance. Any program using a new type of ordnance device for which proven safety procedures have not been established requires an Explosive Safety Approval before the

ordnance is allowed on PMRF or used on a test range. This approval involves a detailed analysis of the explosives and of the proposed training and RDT&E activities, procedures, and facilities for surveillance and control, an adequacy analysis of movement and control procedures, and a design review of the facilities where the ordnance items will be handled.

Ordnance management procedures are found in PMRFINST 8020.5, *Explosive Safety Criteria for Range Users Ordnance Operation*s. The Range Control Branch of the Range Programs Division is responsible for: (1) providing detailed analysis of all proposals concerning missiles or explosives and their proposed operation on the range; (2) establishing procedures for surveillance and control of traffic within and entering hazard areas; (3) reviewing the design of facilities in which ordnance items are to be handled to ensure that safety protection meets the requirements of Naval Sea System Command Publication (NAVSEAOP) -5, *Ammunition and Explosives Ashore; Safety Regulations for Handling, Storing, Production, Renovation, and Shippin*g, Chapter 4; (4) training, certifying, and providing Launch Control Officers, Safety Monitors, and Ordnance personnel for training and RDT&E activities involving explosive ordnance; (5) assuming responsibility for the control of all emergency facilities, equipment, and personnel required in the event of a hazardous situation from a missile inadvertently impacting on a land area; (6) providing positive control of the ordering, receipt, issue, transport, and storage of all ordnance items; and (7) ensuring that only properly certified handling personnel are employed in any handling of ordnance.

Ordnance is either delivered to PMRF/Main Base by aircraft to the on-base airfield or by ship to Nawiliwili Harbor, then over land by truck transport along Highway 50 to the base (see Figure 2.1-2). The barges carrying explosives are met at Nawiliwili Harbor by trained ordnance personnel and special vehicles for transit to and delivery at PMRF/Main Base. All ordnance is transported in accordance with U.S. Department of Transportation regulations. Ordnance is stored in caves at the Kamokala Magazine area, except for the Strategic Target System, which is stored in a specially constructed facility on KTF. No mishaps involving the use or handling of ordnance have occurred at PMRF.

PMRF/Main Base has defined explosive safety-quantity distance (ESQD) arcs. The arcs are generated by launch pads, the Kamokala Magazine ordnance storage area, the Interim Ordnance Handling Pad, and the Missile Assembly/Test Buildings 573 and 685. Only the ESQD arcs generated by the Interim Ordnance Handling Pad and Building 573 are covered by a waiver or exemption. The Sandia Launcher site can accommodate a 1,250-ft ESQD arc.

A 1,250-ft ESQD Red Label Area, to handle incoming and outgoing ordnance items, is centered on the airfield taxiway, 1,250 ft from Building 412 (see Figure 3.3.2.1.7-1). A soft pad in the Red Label recovery area is used by helicopters for setting down targets and weapons recovered from the range. The 800-ft ESQD surrounding the soft pad falls totally within the Red Label ESQD area.

Ocean Area Clearance

Range Safety officials manage operational safety for projectiles, targets, missiles, and other hazardous activities into PMRF operational areas. The operational areas consist of two Warning Areas (W-186 and W-188) and one Restricted Area (R-3101) under the local control of PMRF. The Warning Areas are in international waters and are not restricted; however, the surface area of the Warning Areas is listed as “HOT” (actively in use) 24 hours a day. For special operations, multi-participant or hazardous weekend firings, PMRF publishes dedicated warning Notices to Mariners (NOTMARs) and Notices to Airmen (NOTAMs) 1 week before hazardous operations. In addition, a 24-hour recorded message is updated on the hotline daily by Range Operations to inform the public when and where hazardous operations will take place.

Prior to a hazardous operation proceeding, the range is determined to be cleared using inputs from ship sensors, visual surveillance of the range from aircraft and range safety boats, radar data, and acoustic information from a comprehensive system of sensors and surveillance from shore.

Transportation Safety

PMRF transports ordnance by truck from Nawiliwili Harbor to PMRF along Highway 50 (see Figure 2.1-2). The barges carrying explosives are met at Nawiliwili Harbor by trained ordnance personnel and special vehicles for transit to and delivery at PMRF. All ordnance is transported in accordance with U.S. Department of Transportation regulations. PMRF has established PMRFINST 8023.G, which covers the handling and transportation of ammunition, explosives, and hazardous materials on the facility.

In addition, liquid fuels (e.g., nitrogen tetroxide and unsymmetrical dimethylhydrazine) are transported to KTF. These fuels can be shipped to the site by truck, aircraft or barge, which do not affect transportation routes on the island of Kauai. Transportation of these materials is conducted in accordance with U.S. Department of Transportation regulations and specific safety procedures developed for the location.

Range Control and the FAA are in direct communication in real time to ensure the safety of all aircraft using the airways and the Warning Areas. Within the Special Use Airspace, military activities in Warning Areas W-186 and W-188 are under PMRF control. Warning Areas W-189, W-187, and W-190 are scheduled through the Fleet Area Control and Surveillance Facility. Section 3.3.2.1.2 provides further airspace details.

The Warning Areas are located in international airspace. Because they are in international airspace, the procedures of the ICAO are followed. The FAA acts as the U.S. agent for aeronautical information to the ICAO, and air traffic in the region of influence is managed by the Honolulu ARTCC.

Fire and Crash Safety

The Navy has developed standards that dictate the amount of fire/crash equipment and staffing that must be present based on the number and types of aircraft stationed on base, and the types and total square footage of base structures and housing. PMRF Crash/Fire is located in the base of the Air Traffic Control Tower, Building 300. Personnel are trained to respond to activities such as aircraft fire fighting and rescue in support of airfield operations, hazardous material incidents, confined space rescue, and hypergolic fuel releases, plus structure and brush fire fighting, fire prevention instruction and fire inspections.

Ambulance and Class II Emergency Medical Technician services are provided by Emergency Medical Technicians assigned to Crash/Fire. These contractor-operated services are available to military, civil service, and non-government personnel at PMRF, 24 hours a day, 7 days a week. More extensive emergency medical services are available from the West Kauai Medical Center in Waimea, 10 mi from the Main Gate at Barking Sands.

KTF

KTF is a launch facility operated by Sandia National Laboratories for the Department of Energy on PMRF/Main Base through Inter-Service Support Agreements (U.S. Department of the Navy, 1998a). KTF notifies PMRF Operations, Security, Fire Department, and Ordnance/Explosive Disposal as required prior to launch and other hazardous operations. (Sandia National Laboratories, 2006)

All hazardous operations at KTF are performed under strict adherence to SOPs. A site SOP provides general requirements and guidance for all range operations at KTF, including ordnance safety, pre-launch and hazardous operations control, ordnance handling and storage facilities, liquid fuels storage and handling, and launch pad operations.

KTF rocket motors and other ordnance components are stored in explosive storage magazines by PMRF, except when needed by KTF for processing, assembly, and launch. The movement of explosives and other hazardous materials between PMRF and KTF is conducted in accordance with PMRF procedures and DoD Explosives Safety Standards.

PMRF provides fire protection and fire fighting services to KTF, and enforces base safety regulations and programs on KTF.

3.3.2.1.8 Land Use—PMRF/Main Base

This section describes current land-based uses including recreational activities. The No-action Alternative will be a continuation of training and RDT&E activities which currently occur on PMRF/Main Base, and the Alternative Actions are incremental increases of training and RDT&E activities which already occur or have occurred. The Navy has no intention of expanding land ownership in the PMRF/Main Base area. Appendix C includes a definition of land use and laws and regulations that pertain to it. Additionally, Appendix I describes the circumstance by which the lands now known as PMRF came into Federal ownership.

Region of Influence

The region of influence for land use includes the Main Base Complex and adjacent areas on the Mana Plain. Because KTF resides entirely within PMRF/Main Base, all discussion regarding land use and recreation stated for PMRF/Main Base would apply to KTF.

Affected Environment

On-base Land Use

PMRF's land use is managed via the 2006 Comprehensive Infrastructure Plan. The plan promotes efficient, effective use of resources through a consolidation of like land uses and the minimization, recognition, and deconfliction of existing constraints. The plan supports the protection of essential range operations from encroachment and the protection of human and natural environments (U.S. Department of the Navy, 2006b, U.S. Department of the Navy, 1998a).

According to the State Land Use Classification, PMRF is located within a conservation district (Figure 3.3.2.1.8-1). The 2000 Kauai General Plan and the Waimea-Kekaha Region Development Plan classify PMRF as a Military Land Use area. Kauai County has designated the dune area from Nohili Point to the north boundary of PMRF as a scenic ecological area.

The Nohili and Kinikini Ditches act as natural dividers, separating PMRF into three zones: North, Central, and South (Figure 3.3.2.1.8-1). The North Zone is used for rocket launches and its associated support activities, administration, and services. This includes ESQD Arcs and Ground Hazard Areas. The Central Zone contains air operations, administration, supply, base services, range operations, ordnance maintenance, and fuel/supply. In addition, the runway has Clear Zones and Accident Potential Zones (I & II) as safety measures which are discussed further in Section 3.3.2.1.7. The South Zone contains housing, personnel support, recreational, communications and rocket launcher facilities (KTF). ESQDs and Ground Hazard Areas exist for the rocket launcher pad as well. Additionally, KTF, as shown in Figure 3.3.2.1.8-1 is located in the northern portion of PMRF/Main Base. Sandia National Laboratories operates KTF for the Department of Energy and provides testing, evaluation, research and development of rocket systems (Sandia National Laboratories, 2006; U.S. Department of Defense, 2006).

On-base Recreation

Recreational services available to military and civilian personnel include an auto hobby shop, a craft center, a 200-seat outdoor movie theater, a recreation center, a wood hobby shop, and a racquetball/handball court. Outdoor facilities include three tennis courts, a lighted golf driving range, a lighted softball field, a lighted multi-purpose playing court, a year-round swimming pool, and an 18-hole miniature golf course (U.S. Department of the Navy, 1998a).

Public access to the installation’s approximately 200 ft wide by 2 mi long coastline is outlined in PMRF Instruction 5530.7 (March 2004). Individuals who can demonstrate Kauai residency can obtain a PMRF-approved beach access pass, which allows them access to the beach recreation area of Majors Bay at PMRF/Main Base. PMRF Range Operations maintains a 24-hour hotline, which is updated daily in order to provide information on recreational area access. Recreational activities include surfing, fishing, and boating. The physical areas accessible for fishing/surfing/recreation/and socializing run from Shenanigans (All-hands club) up to KiniKini Ditch (south end of runway). Under PMRF Instruction 5530.7, normal access is allowed 7 days a week from 6:00 am to 30 minutes after sunset, except during heightened force protection conditions or range operational periods.

Off-base Land Use

Current land uses adjacent to PMRF are agricultural, recreational, and a landfill. No inhabited buildings are within these areas. The non-developed, open-type uses of these adjacent lands are compatible with range operations and safety requirements of PMRF. The State Land Use District Boundary Map classifies adjacent lands to the north of PMRF/Main Base (Polihale State Park) and adjacent lands to the South of PMRF/Main Base (Kekaha Landfill), as conservation (Figure 3.3.2.1.8-1). Adjacent lands to the east of PMRF/Main Base are classified as agricultural (formerly sugar cane fields). To the west of PMRF/Main Base is the Pacific Ocean (for Naval training and recreational activities). The County of Kauai classifies adjacent lands as open and agricultural. The State and County’s designations are compatible with base activities

and limits development that would conflict with current use. PMRF activities which affect off-base land uses include those within the ESQD arcs, EMR areas, aircraft noise contours, and missile Ground Hazard Areas. ESQD arcs that extend beyond the PMRF boundary include four areas in the northern area and one in the central portion of the base. The off-base land use within these State-owned lands has been designated by both the County and State as agricultural areas. Missile Ground Hazard Areas which are only used during launch events, and extend off-base, occur in northern PMRF and encompass agricultural and recreational uses. Specifically, adjacent areas to PMRF include Polihale State Park, the Agricultural Preservation Initiative (API) and the Kekaha Landfill.

Coastal Zone Management

All Federal development projects in a coastal zone and all Federal activities which directly affect a coastal zone must be consistent to the maximum extent practicable with the Coastal Zone Management Program as authorized by the Coastal Zone Management Act of 1972. The entire State of Hawaii is included in Hawaii's Coastal Program and Coastal Zone. Federally owned, leased, or controlled facilities and areas are excluded from the State's Coastal Zone Management Plan, and are thus outside of the Coastal Zone. The proposed action required a determination evaluating the consistence of the PMRF activities with the policies of the Hawaii Coastal Act. The proposed actions are incremental increases in activities that already occur at PMRF and which were previously found to be consistent to the maximum extent possible with the Hawaii Coastal Act in the 1998 PMRF Enhanced Capability Final EIS.

In December 2007 the Kauai County Council passed a science-based shoreline setback ordinance. The law mandates a 40-ft minimum setback plus 70 times the annual coastal erosion rate as recommended in the Hawaii Coastal Hazard Mitigation Guidebook. The law preserves beaches and protects property owner's coastal assets. (The Garden Island, 2007, Hawaii Revised Statutes (HRS), 2007) Federally owned, leased, or controlled facilities are not subject to such requirements, but the Navy will remain consistent to the maximum extent possible or practicable.

<u>Polihale State Park</u>

Polihale State Park, a small area just east of PMRF North Gate, and a parcel of land south of PMRF and south makai, from the Kekaha Landfill have been designated as special management areas (U.S. Department of the Navy, 1998a). Kauai County established guidelines for reviewing proposed developments in special management areas (Figure 3.3.2.1.8-1) as part of the Coastal Zone Management Act Program. Any development in these areas requires a special management use permit.

<u>The Agricultural Preservation Initiative (API)</u>

In May of 2004, by amendments, the State Board of Land and Natural Resources approved the API (U.S. Department of the Navy, 2006a). The purpose of the API is to ensure lands adjacent to PMRF (5,371 acres + 215 acres-leased = 5,586 acres), which are currently designated as agricultural by the State Land Use Commission, remain agricultural lands for the term of the agreement (the agreement expires December 31, 2030 [U.S. Department of the Navy, 1998a]). The use of this land requires activation of a restrictive easement. The initiative is consistent with the Kauai General Plan policy for agricultural lands, which states: "The primary intent of the Agriculture designation is to conserve land and water resources" (Kauai, County of, 2005.)

The agricultural land is owned by the State of Hawaii and is leased to the Agribusiness Development Corporation.

The API benefits to the Navy include: (1) land use remains compatible with PMRF activities, thus preventing encroachment issues; (2) able to maintain compliance with Anti-Terrorism Force Protection criteria (Unified Facilities Criteria 4-010-01); and (3) improved Homeland defense/physical security. The API includes 215 leased acres, which contain the pumping system for the Mana Plain. By placing the drainage pumps under a Navy lease, the Navy will be able to use Federal funds to maintain the pumps that help prevent flooding in the Mana Plain (U.S. Department of the Navy, 2006b). The lease agreement (S-3852) for the 215 acres was signed February 2007 with the State of Hawaii. The over 5,000 acres maintained in the API support the initiatives of the State Department of Agriculture in its charge to preserve important resources to ensure the viability of Hawaii's diversified agricultural industry. The API restrictive use easement was signed by the State of Hawaii, June 2007. Figure 3.3.2.1.8-2 shows the land use alignment of PMRF and the Agricultural Preservation Initiative/Mana Plan and Figure 3.3.2.1.7-1 shows the Restrictive Easement.

Kekaha Landfill

Kekaha Landfill sits on 64 acres of land, of which 32 acres make up the footprint of the lined Subtitle-D landfill itself. Kekaha averages 230 tons of trash per day and 88,000 tons of trash per year. The Landfill was opened in 1953 and was expected to close in 2004, but was recently given permission to operate until approximately 2012 (Kauai Island Utility Cooperative, 2006a).

Off-base Recreation

Off-base recreation within the region of influence is limited to range operations within the 140 acres of Polihale State Park (Figure 3.3.2.1.8-2). The park provides overnight camping and day use recreational activities (swimming, shore fishing, subsistence fishing, picnicking). It is operated by the Department of Land and Natural Resources, Division of State Parks, which estimates half a million people visit during the day, each year. Approximately 70 acres of the southern extent of the park is within the restrictive easement boundary (Figure 3.3.2.1.7-1). Use of the restrictive easement may be exercised up to 30 times per year during launches conducted by the U.S. Government. In order to launch missiles from PMRF and KTF, the U.S. Government must, in accordance with DoD policy, be able to exclude nonparticipants from a Ground Hazard Area (U.S. Army Space and Strategic Defense Command, 1993a). None of the developed campsites or picnic areas are within the restricted easement or the Ground Hazard Area (southern extent). The northern area, where picnicking and camping facilities are located, is accessible via a 5-mi dirt road from Highway 50 and is within a Ground Hazard Area.

The Division of State Parks plans to expand Polihale State Park, subject to the availability of funds. The expansion would include a portion of a sugar cane field and cliffs adjacent to the park’s boundary (Figure 3.3.2.1.8-2). The purpose is to encompass sensitive cultural resources and biological resources within the park boundary. No park development, other than interpretive trail signs, is expected within the expansion area (U.S. Department of the Navy, 1998a).

3.3.2.1.9 Noise—PMRF/Main Base

Appendix C includes a definition of noise and the main regulations and laws that govern it.

Region of Influence

The region of influence for noise analysis is the area within and surrounding PMRF/Main Base in which humans and wildlife may suffer annoyance or disturbance from noise sources at PMRF/Main Base. This would include all areas on the Mana Plain (PMRF, Polihale State Park, and sugar cane fields), KTF, and the city of Kekaha.

Affected Environment

Primary sources of noise on PMRF/Main Base include airfield and range operations and missile, rocket, and drone launches. Airfield operations include take-offs and landings of high-performance and cargo/passenger aircraft, as well as helicopter operations. Range operations include training and RDT&E activities support. Ambient noise levels from natural sources include wind, surf, and wildlife.

Noise generated at the PMRF airfield stem from one active runway, four helicopter operating spots, and maintenance operations. Noise levels produced by airfield operations tend to have a continuous impact on PMRF/Main Base. Existing noise levels near the runway may average as high as 75 A-weighted decibels (dBA). Buildings in this area are insulated to achieve a noise reduction of up to 35 dBA. Noise levels farther away from the runway are more characteristic of a commercial park, with levels not exceeding 65 dBA. Airfield noise zones have been established to safeguard the public and all station personnel from the effects of noise from air operations. Figure 3.3.2.1.9-1 depicts modeled noise contours based on 2004 airfield operations. The *Final Noise and Accident Potential Zone Study for the Pacific Missile Range Facility Barking Sands* determined that noise levels around the airfield are low due to the relatively few annual air operations, 13,395 for 2004. The noise study determined that 1 acre of land was affected by 75-decibel noise levels and that no housing units or populations are impacted. (U.S. Department of the Navy, Engineering Field Activity Chesapeake, 2006)

Range operations that may impact the sound environment include, but are not limited to, power generation, training and RDT&E activities support, maintenance operations, and construction or renovation. Table 3.3.2.1.9-1 lists typical construction noise levels.

The activity with the most noticeable sound events is the launch of missiles, rockets, and drones. These launches result in high-intensity, short-duration sound events. Typical launches at PMRF/Main Base (including KTF launch sites) include Strategic Target System, Terminal High Altitude Area Defense, and Strypi missile launches and have resulted in no public noise complaints. Table 3.3.2.1.9-2 lists the noise levels monitored for previous ZEST and Strategic Target System launches at PMRF/Main Base.

The nearest on-base housing area is located approximately 5 mi south of the northern KTF and PMRF launch areas and 1 mi from the southern launch site. The nearest off-base residential area is Kekaha, which is approximately 8 mi south of the northern launch areas and 2 mi from the southern launch sites.

Source: U.S. Army Strategic Defense Command, 1992

KTF supports a variety of sounding rocket missions; therefore, occasional rocket, missile, or drone launches produce high-intensity, short-duration sound events. Table 3.3.2.1.9-2 lists noise levels associated with these types of launches. Data collected in the nearest town of Kekaha indicated that levels were no louder than noise generated from passing vehicles on a nearby highway. No noise-sensitive land uses are affected by existing noise levels. (Sandia National Laboratories, 2006)

In addition to the noise of the rocket engine, sonic booms are possible. A sonic boom is a sound that resembles rolling thunder, and is produced by a shock wave that forms at the nose of a vehicle that is traveling faster than the speed of sound. Sonic booms from PMRF/Main Base launches do not occur over land. Offshore vessels impacted by sonic booms will be expected to experience sound resembling mild thunder. Sonic booms generated during launch activities will occur over the Pacific Ocean, and will not affect the public on Kauai or Niihau because the proposed missile trajectory will not include overflight of populated areas.

Wildlife receptors at the PMRF/Main Base area are discussed in Section 3.3.2.1.3, Biological Resources.

3.3.2.1.10 Socioeconomics—PMRF/Main Base

Socioeconomics describes the social and economic character of a community through the review of several metrics including population size, employment characteristics, income generated, and the type and cost of housing. This section presents a socioeconomic overview of the Kauai region. Appendix C includes a general definition of socioeconomics.

Region of Influence

The region of influence for socioeconomics is defined as the island of Kauai, which covers 552 mi^2. The entire island is designated as Kauai County.

Affected Environment

Population and Income

In 2000, the population of Kauai County was 58,463. The 2005 Bureau of Census Counties Profile estimates that the population for the County rose to 62,640 in 2005 (equal to 4.9 percent of the population of Hawaii), a change of approximately 7.1 percent over the 5-year period. The estimated population for 2006 is 63,004 (U.S. Census Bureau, 2007a). The projected population for 5 and 10 years out is 65,900 people in 2010 and 70,200 people in 2015 (Hawaii, State of, 2004). PMRF employs nearly 1,000 personnel, of which 54 are military personnel (Mossman, 2007). The 54 personnel account for 0.086 percent of the estimated 2006 population of Kauai. Table 3.3.2.1.10-1 summarizes the demographics of the population of Kauai in 2000. Table 3.3.2.1.10-2 illustrates the age profile of those living in Kauai County in 2000.

Personal income in Kauai was estimated by the Department of Business, Economic Development and Tourism to be $1.595 billion in 2005 (FY 2000 dollars). This represented 4 percent of the total personal income of Hawaii. In FY 2000 the annual average salary for Kauai County was $26,550, while the annual average income in 2005 for Kauai County was $29,650, which is an 11.6 percent increase.

Table 3.3.2.1.10–1. Demographics of the Population of Kauai in 2000

Persons		**58,463**
	Male	29,252

18 years-64 years	43,020	73.6	915,770	75.6
65 and over	8,067	13.8	160,601	13.3

Source: U.S. Census Bureau, 2000b.

In FY 2005 the total defense expenditures of Hawaii were $5.6 billion, an increase of 8.7 percent over FY 2004, and for this same time period, defense procurement contracts in Hawaii totaled $2.0 billion, an increase of 16.2 percent over FY 2004. Appropriations for FY 2006 defense projects in Hawaii totaled $767 million, which includes a military construction program of $354 million, and $413 million for defense related projects. Appropriations for FY 2007 defense projects total nearly $622 million (Chamber of Commerce of Hawaii, Military Affairs Council, 2007). Table 3.3.2.1.10-3 shows the economic impact of the military in Hawaii for 2006.

PMRF is a major contributor to the economy of Kauai County, particularly on the western side of the island. The installation employs nearly 1,000 military, civilian and contract personnel and has a $130 million impact annually on the local economy. In FY 2001, expenditures for PMRF and other defense initiatives on Kauai totaled about $144 million (Division of Economics, U.S. Fish and Wildlife Service, 2002). In 2004, it was estimated that FY 2005 expenditures for PMRF and other defense initiatives on Kauai would total about $113 million (Inouye, 2004).

Housing

In 1993, housing on Kauai was characterized as overcrowded, costly, and in short supply (U.S. Department of the Navy, 1998a). In December 2006 sales remained fairly steady at half sold for more than $592,500 and half for less, as the median price dropped 2 percent. In December 2005, the median price of a Kauai home was $605,000. At the market height of summer 2005, the median sales price on Kauai reached close to $700,000. Median home prices declined by 15.4 percent between the summer of 2005 and December 2006 and declined by 2.1 percent between December 2005 and December 2006 (Star Bulletin, 2007). Condominium prices on Kauai, on the other hand, increased to by 17.7 percent; up to $570,000 in December 2005 from $484,500 in December 2005 (Star Bulletin, 2007).

Table 3.3.2.1.10-3. 2006 Economic Impact of the Military in Hawaii

Employment

Government, tourism, and tourism-related services have been the main employment generators on Kauai since the 1992 hurricane (U.S. Department of the Navy, 1998a). In 2006, government and tourism were the main employment generators. In FY 2006 PMRF employed a total of 821 employees, which comprised 128 DoD civilian personnel, 54 military personnel, 512 ITT personnel (Prime Support Contractor), 97 other contractors personnel, and 30 Hawaii Island Air National Guard. Table 3.3.2.1.10-4 shows the number of individuals employed in the main sectors of the economy of Kauai and in Hawaii as a whole.

Unemployment in Kauai has steadily declined from 4.5 percent in 2000 to 2.7 percent in 2005. This is the lowest the rate has been in over 15 years, which is also significantly lower than the 1998 unemployment rate of 11.6 percent. During the same period, the total labor force has increased from 30,350 in 2000 to 32,350 in 2005, a 6.7 percent increase (Hawaii, State of, 2005a).

Table 3.3.2.1.10-4. Employment in Kauai and Hawaii

Employment Sector	Kauai Employees		Hawaii Employees	
	Number of Employees	Percent of Total	Number of Employees	Percent of Total
Agriculture, forestry, fishing, hunting, and mining	1,227	4.6	12,119	2.3
Construction	2,083	7.8	32,180	6.0
Manufacturing	652	2.4	18,979	3.5

Other Services (except public administration)	1,111	4.1	320,324	59.5
Total	**26,789**	**100**	**537,909**	**100**

Source: U.S. Census Bureau, 2000b.

Agriculture

Although the number of farms on Kauai increased from 450 in 1994 to 600 in 2004, and the number of self-employed farm operators and their unpaid family members stood at 350 persons in 2004, farm acreage declined by approximately 25 percent (Hawaii, State of, 2005b). Despite the decline in farmland, sales of all crops increased 14 percent from 2002 to 2004. Sugar cane had the highest sales in 2004 with 15.3 million dollars, approximately 32 percent of Kauai's total crop sales. However, the reduction of sugar cane farms (only two are left, one on Kauai and one on Maui) has led to the diversification of crops. This diversity includes the production of coffee, seed corn, vegetables, melons, fruits, macadamia nuts, taro, field crops, flowers, and nursery products. The Aquaculture industry is on the rise as well, increasing from 85 operations with $22 million in sales in 2000 to 100 operations with $28 million in sales in 2004.

Tourism

The tourism industry has been the economic mainstay of the Hawaiian Islands since statehood in 1959. The industry accounts for 22.3 percent of all jobs in Hawaii (Kauai, County of, 2005). Kauai's share of the Hawaii visitor market was 14.5 percent in 2005. Despite terrorism concerns and periodic economic slumps, the tourism industry on Kauai has remained robust, with the number of annual visitors consistently over 1 million/year in the past 5 years (Kauai, County of, 2005). Estimated visitor expenditure in 2005 was $11.9 billion, a 9.6 increase from 2004 (State of Hawaii, Department of Business, Economic Development & Tourism, 2006).

The accommodation inventory for Kauai rose 18 percent between 1998 and 2005, with 447 properties providing 8,081 rooms. This inventory is slightly less than the peak capacity in 2004 of 8,105 rooms. The capacity could increase by 6,225 units based on projects on file in the County of Kauai Planning and Permitting Department (Kauai, County of, 2005). Concurrently, the number of annual visitors is expected to rise to approximately 1.5 million (Kauai, County of, 2005). Table 3.3.2.1.10-5 shows the numbers of annual visitors to Kauai from 2000 through 2006.

Table 3.3.2.1.10-5. Visitors to Kauai (2000– 2006)

Year	Kauai Visitors	State of Hawaii Visitors
2000	1,074,821	6,948,594
2001	1,008,698	6,303,790
2002	1,005,897	6,389,058
2003	975,867	6,380,439
2004	1,022,442	6,917,166
2005	1,090,147	7,416,574
2006	1,203,264	7,461,299

Source: State of Hawaii, Department of Business, Economic Development & Tourism, 2006.

Education

Each year since FY 2000, the DoD has contributed $5 million to the Hawaiian public education system via the Joint Venture Education Forum. The Joint Venture Education Forum was started in 1998 as a cooperative effort between the Hawaii Department of Education and U.S. Pacific Command, and was formalized as an organization, via charter, in August of 2005. The organization is comprised of public school educators and leaders from military commands, business, government, and the community (Joint Venture Education Forum, 2005). In FY 2005-06, the federal education budget included $46 million in impact aid funding for Hawaii's public schools (Honolulu Advertiser, 2006). Additionally, in FY 2005-06, $5.5 million was provided to improve infrastructure for Hawaii's public schools with high enrollments of military children; more than $31 million has been given over the past 6 years (Chamber of Commerce of Hawaii, Military Affairs Council, 2006).

3.3.2.1.11 Transportation—PMRF/Main Base

Transportation is the movement within the area of study of all equipment, facilities, and resources (materials, manpower) by ground, water, and air. Transportation fluctuates depending on training, testing, and construction activities which occur throughout the year. Appendix C includes definition and general description of transportation.

Region of Influence

The region of influence for transportation includes ground transportation and waterways in the vicinity of PMRF expected to be utilized for training and RDT&E activities. There are no railways within the region of influence. See Section 3.3.2.1.2 for the discussion on PMRF/Main Base airways.

Affected Environment

Ground Transportation

Imiloa Road is a two-lane roadway that provides direct access to PMRF from the southwest through its intersection with State Highway 50 (Kaumualii Highway), a primary circulation route connecting the base with Kekaha and Lihue. Kaumualii Highway, in the vicinity of Imiloa Road, is a two-lane road with a posted speed limit of 50 mi per hour. On September 20 and 21, 2005, a Hawaii Department of Transportation traffic counter, located on Kaumualii Highway between Imiloa Road and Kao Road, measured 24-hour total volumes of 469 and 516 vehicles respectively. The average daily volume of 493 translates to Level of Service (LOS) B, which is a 50 to 75 percent volume-to-capacity of the roadway capacity. Another traffic counter between Imiloa Road and Kia Road on the same days counted 749 and 747 vehicles respectively in a 24-hr period, which again translates into LOS B (Hawaii Department of Transportation, 2005; Transportation Research Board, 2000; 2006). North Nohili Road, which branches off Imiloa Road, provides access to KTF.

3.3.2.1.12 Utilities—PMRF/Main Base

This section discusses utilities serving the existing and proposed project areas, which include water supply, wastewater treatment, electricity, and natural gas. Additionally, this section identifies utility providers and the major attributes of utility systems in these areas such as existing capacity and existing demand. The PMRF Public Works Office maintains base facilities and oversees the facility's environmental program (U.S. Army Space and Missile Defense Command, 2002). Appendix C includes a definition and general discussion of utilities.

Region of Influence

The utility systems that could potentially be affected include potable water distribution, wastewater collection, solid waste collection and disposal, and electrical lines within or servicing the project sites.

Affected Environment

Water

Potable water at PMRF is a blend of on-base and municipal sources, including both the State Department of Land and Natural Resources and the Waimea-Kekaha Service Area of the Kauai Department of Water. The water department of Kauai County supplies water to PMRF that originates from the Kekaha's Waipao Valley Well, Paua Valley Well, and Shaft 12, as well as Waimea wells A and B (County of Kauai, Department of Water, 2006 and Naval Facilities Engineering Command, Hawaii, 2007). PMRF's portion is stored in two 126,000-gal tanks at Kokole Point. These sources serve the southern portions of the base. The Department of Land and Natural Resources supply water originates from the Mana well (located approximately 1,000 ft south of the Kamokala Ridge magazine), which is pumped to PMRF and stored near the Main Hanger in one 100,000-gal tank and one 420,000-gal tank. This source serves the central and northern portions of the base (U.S. Army Space and Missile Defense Command, 2002). In 2006, PMRF's water consumption from the Mana well system was 78,533,000 gal and 10,817,909 gal from the Kauai County Department of Water. The monthly consumption from the Mana well ranged from as low as 3,753,000 gal in November 2006 to as high as 8,827,000 gal in July 2006. The monthly consumption from the Kauai County Department of Water ranged from as low as 215,147 gal in November 2006 to as high as 1,719,843 gal in May

2006 (Maintenance Logs and Records-PMRF, 2006). The Navy chlorinates and fluoridates all purchased water before distribution, except that provided by the State of Hawaii (Commerce Business Daily, 2000). The maximum delivery capacity of water from the State is 320,000 gal per day (GPD).

Wastewater

The PMRF wastewater system comprises two domestic sewage treatment facilities and a collection system. These facilities include a treatment plant located approximately one half-mile south of the Main Gate and an oxidation pond south of the family housing area (U.S. Army Space and Missile Defense Command, 2002). A package treatment plant located at PMRF/Main Base treats approximately 8,000 GPD, or 27.7 percent of its 30,000-GPD design capacity. On the southern end of the base, an oxidation pond receives 20,000 to 25,000 GPD of its 54,000-GPD capacity. Both sites discharge their effluent into leach fields. For the period of 6 June 1995 to 31 May 1996, the average flow into the leach field (situated between the runway and the coast) was 9,500 GPD, or 37 percent of its 26,000-GPD design capacity. PMRF also has approximately 22 septic tank/leachfield systems and cesspools serving individual buildings in the northern part of PMRF/Main Base (U.S. Army Space and Missile Defense Command, 2002; Commerce Business Daily, 2000).

Solid Waste

Kauai County's Kekaha Landfill sits on 64 acres of land, of which 32 acres make up the footprint of the lined Subtitle-D landfill itself. Kekaha averages 230 tons per day and 88,000 tons per year. The Landfill was opened in 1953 and was expected to close in 2004, but was recently given permission to operate until approximately 2012. The FY 2006 total for refuse deposited into the landfill from PMRF was 530.6 tons, and 252.32 tons were recycled by PMRF (Burger and Nizo, 2007). To minimize waste flow, PMRF maintains a recycling program for aluminum cans, glass, paper and cardboard, all of which are collected biweekly. Green waste is collected and chipped for composting and use on the base (U.S. Army Space and Missile Defense Command, 2002).

Electricity

Until recently, PMRF's municipal power was provided by Kauai Electric; however, in 2002 Kauai Electric was purchased by Kauai Island Utility Cooperative (Pacific Business News, 2002). The total firm electrical generating capacity on the island is 110 megawatts (MW), with an additional 4.1 MW provided by non-firm sources (Kauai County, 2005).

PMRF is located in Kauai County's West Side region. The West Side's main transmission line runs along Kaumualii Highway from Port Allen to Mana, and includes double circuits between Port Allen and Kekaha. There are switchyards in Kekaha and Port Allen, as well as substations in Mana and Kaumakani (Kauai County, 2005). Power to PMRF/Main Base and northern complex area is supplied via a 57-kilovolt (kV)/69-kV transmission line between the Kauai Island Utility Cooperative's Mana Substation and Kekaha Switchyard. This West Side transmission line's capacity is 7.6 MW at 95 percent power factor; the current peak load is 2.5 MW (U.S. Department of the Navy, Naval Sea Systems Command, 2005). A 12.47-kV feeder circuit system owned by Kauai Island Utility Cooperative supplies primary power to the base's southern area; this circuit has a capacity of 4.3 MW at 95 percent power factor (U.S. Department of the Navy, Naval Sea Systems Command, 2005). In the event of a power outage PMRF provides additional power, utilizing commercial power as a backup. The PMRF power plant contains two 600-kW and three 300-kW generator units (U.S. Army Space and Missile Defense Command, 2002).

By 2003, PMRF's energy consumption had been considerably reduced from its 1985 baseline; moreover, the base's energy consumption during peak hours had decreased by $100,000 annually, allowing the Kauai Island Utility Commission to redirect energy to other areas on the island (U.S. House of Representatives, 2003). PMRF has been recognized for these energy-saving efforts, as well as initiating innovative high-tech energy conservation projects, including using methane gas, by the County of Kauai's Kekaha landfill and using fuel cells to support range operations (U.S. House of Representatives, 2003). Since 2005, photovoltaic panels have been used to augment base requirements without increasing consumption from the island's commercial electric utility grid (Naval Facilities Engineering Command, Hawaii Public Affairs, 2005).

3.3.2.1.13 Water Resources—PMRF/Main Base

Water resources include those aspects of the natural environment related to the availability and characteristics of water. For the purposes of this document, water resources can be divided into three main sections: surface water, groundwater, and flood hazard areas.

Surface water includes discussions of runoff, changes to surface drainage, and general surface water quality. Groundwater discussions focus on aquifer characteristics, general groundwater quality, and water supply. Flood hazard area discussions center on floodplains.

Where practicable, water resources are described quantitatively (volume, mineral concentrations, salinity, etc.); otherwise they are described qualitatively (good, poor, etc.) when necessary. Appendix C includes a description of the primary laws and regulations regarding water resources.

Detailed descriptions of fresh water quality and well water supplies can be found in the Utilities section of this EIS/OEIS.

Region of Influence

The region of influence for PMRF/Main Base includes the area within and surrounding the PMRF property boundaries. The region of influence also includes KTF and the restrictive easement, including the Mana Plain and the Ground Hazard Area.

Affected Environment

Surface Water

The surface water within the PMRF boundary is in the canals that drain the agricultural areas east of PMRF. Apart from these drainages, no surface drainage has been established because the rain sinks into the permeable sand. There are numerous drains and several irrigation ponds in the agricultural land.

The waters in the irrigation ponds generally do not meet drinking water standards for chloride salts, but have near neutral to slightly alkaline pH. A surface water quality study for chloride was conducted in the Mana Plain/KTF area. The chloride levels do not indicate residual hydrochloric acid effects of the past launches at KTF (U.S. Army Program Executive Office, 1995). The surface waters on the southern half of PMRF/Main Base are expected to have similar chemical characteristics. Because the drainage ditches are designed to move water away from the agricultural fields during irrigation and rainfall, and to leach salts from the soil, no residual effects of past launches are expected. (U.S. Army Program Executive Office, 1995)

Surface water in the area of the restrictive easement on the Mana Plain is restricted to drains and agricultural irrigation ponds. Within the restrictive easement boundary, the surface water and storm water runoff drain onto Amfac Sugar-Kauai lands and agricultural ponds below the Mana cliffs. The Mana Plain is drained by canals that flow seaward. Typically, the water from the canals that drain from the sugar cane fields is brackish. (U.S. Army Space and Strategic Defense Command, 1993a)

The waters in the agricultural ponds along the Mana cliffs generally do not meet drinking water standards for chloride salts but are near neutral to slightly alkaline. The highest chloride salt levels, near those of seawater, were observed in water from the Mana Pond Wildlife Sanctuary near the north gate of PMRF. This may be due to the infiltration of brackish to saline groundwater into the pond basin or excessive evaporation to a low surface level. (U.S. Army Space and Strategic Defense Command, 1993a)

Water quality along the PMRF shoreline was within Department of Health standards, with the exception of two locations where sugar cane irrigation water, pumped from the sugar cane fields, is discharged to the ocean (Belt Collins Hawaii, 1994). In these areas, Department of Health water quality criteria are exceeded within 164 ft of the shoreline. Mixing processes are sufficient to dilute the drainage water to near background levels within 164 to 328 ft of the shoreline (Belt Collins Hawaii, 1994).

Groundwater

Bedrock, alluvium, and sand dunes make up hydraulically connected aquifers within the region of influence. The bedrock (basement volcanics, primarily basalt) is highly permeable, containing brackish water that floats on seawater. (U.S. Army Space and Strategic Defense Command, 1993a)

The overlying sediments act as a caprock because of their overall low permeability, although individual layers, such as buried fossil coral reefs, may be as permeable as the basalt. Although the sediments are saturated, they are not exploitable as an aquifer because of unfavorable hydraulic characteristics. The groundwater in the sediments originates as seepage from irrigation percolation and rainfall in the basalt aquifer, especially where the sediments are thin near the inland margin of the Mana Plain.

The dune sand aquifer on which PMRF/Main Base lies has a moderate hydraulic conductivity and moderate porosity of about 20 percent. It consists of a lens of brackish groundwater that floats on seawater and is recharged by rainfall and by seepage from the underlying sediments. The only record of an attempt to exploit this groundwater is of a well drilled for the Navy in 1974, 4 to 5 mi south of KTF. The well was drilled to a depth of 42 ft, and tested at 300 gal per minute. In 1992, the water was too brackish for plants and animals to consume; consequently, the well is not used. (U.S. Army Program Executive Office, 1995)

The nearest fresh groundwater sources are in the Napali formation at the inland edge of the coastal plain along the base of the Mana cliffs. Groundwater in the region is generally considered to be potable at the base of the cliffs, increasing in salinity closer to the coast. (U.S. Army Space and Strategic Defense Command, 1993a)

The groundwater beneath the restrictive easement increases in salinity from the base of the Mana cliffs to the Pacific Ocean. To keep the groundwater table below the root zone of the sugar cane, thousands of feet of canal have been excavated to drain excess water from the soil. The water is then pumped into canals such as the Nohili Ditch for release into the ocean. (U.S. Army Space and Strategic Defense Command, 1993a)

Sampling for perchlorate was initiated at PMRF in 2006. USEPA adopted an oral reference dose for perchlorate in 2005, following a National Academy of Sciences recommendation that it not exceed 24.5 parts per billion in drinking water. Until USEPA promulgates standards for perchlorate, the DoD has established 24 parts per billion as the current level of concern for managing perchlorate. This level has also been adopted in the Navy Perchlorate Sampling and Management Policy, 15 April 2006.

As part of the implementation of the Navy policy, perchlorate sampling has been conducted at two drinking water supply locations. One location is the "Mana well," which is the former Kekaha Sugar/AMFAC well from which PMRF obtains drinking water, referenced as "BS 335," and supplies the "north end" of PMRF. It is a hand-dug well, now concrete-lined, approximately 90 ft deep, and is located at the base of the ridge near the Kamokala Caves. The pumps and electric motors are down in the well. The other location is the water tank at the southern end of the base identified as reference code "BS 820." Water in the tank comes from the County of Kauai. The results are shown in Table 3.3.2.1.13-1.

Table 3.3.2.1.13-1. Water Tank Perchlorate Sampling

Sample Location	Sample date 1	Sample Date 2
BS 335	0.860 ppb	<4 ppb (specifics pending)
BS 820	3.500 ppb	<4 ppb (specifics pending)

Note: ppb = parts per billion

Perchlorate concentrations at both sites were less than the initial screening level of 4.0 parts per billion. Based on guidance PMRF received from Navy Region Hawaii, since the two consecutive samples were less than 4 parts per billion, no further analysis was required.

Flood Hazard Areas

The primary flood hazard is from overflow of the ditches that drain the Mana Plain. Extended periods of heavy rainfall have resulted in minor flooding of low-lying areas of PMRF/Main Base. In addition, most of PMRF/Main Base is within the tsunami evacuation area.

3.3.2.2 MAKAHA RIDGE

Makaha Ridge, a secondary range operation area for PMRF, is about 7 miles north of PMRF/Main Base. This 244.7-acre complex is located approximately at the 1,600-ft elevation of Makaha Ridge and is leased from the State of Hawaii. Its primary mission in support of PMRF is to provide facilities for range operations at PMRF. Makaha Ridge features tracking and surveillance radars, primary telemetry receivers and recorders, a Frequency Monitoring Station, and Electronic Warfare and networked communications systems.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Makaha Ridge. Of the 13 resources considered for analysis, airspace, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed. Any issues with these resources that are associated with Makaha Ridge are included within the PMRF/Main Base discussion.

3.3.2.2.1 Air Quality—Makaha Ridge

Appendix C includes a definition of air quality and the main regulations and laws governing its protection.

Region of Influence

For inert pollutants (all pollutants other than ozone and its precursors), the region of influence is generally limited to an area extending a few miles downwind from the source. The region of influence for ozone may extend much farther downwind than the region of influence for inert pollutants. However, as the project area has no heavy industry and very few automobiles, ozone and its precursors are not of concern. Consequently, for the air quality analysis, the region of influence for project activities is the existing airshed surrounding Makaha Ridge.

Affected Environment

Climate and Regional Air Quality

Section 3.3.2.1.1 describes climate and regional air quality on Kauai, which includes Makaha Ridge.

Existing Emission Sources

The primary air pollutant emissions at Makaha Ridge are from diesel generators. The two 600-kW and two 300-kW generators are permitted by the State of Hawaii under a non-covered source permit.

3.3.2.2.2 Biological Resources—Makaha Ridge

Appendix C includes a definition of biological resources and the main regulations and laws that govern their protection.

Region of Influence

The region of influence for biological resources encompasses Makaha Ridge and limited adjacent areas.

Affected Environment

Vegetation

Vegetation at the sites is dominated by introduced non-native, naturalized species. The most common native species that occur on the cliffs in the area are false sandalwood, or naio, (*Myoporum sandwicense*) and kawela, a bunch grass. Thirteen endemic species are represented within the boundaries of the Makaha Ridge facility: `ahinahina (*Artemisia australis*), ko`oko`olau (*Bidens sandwicensis*), *Carex wahuensis*, *Gahnia beecheyi, Pteridium aquilinum* var. *decompositum,* koa (*Acacia koa)*, naupaka kuahiwi (*Scaevola gaudichaudi)*, kawelu (*Eragrostis variabilis),* hakonakona (*Panicum torridum),* kumuniu (*Doryopteris decipiens),* lepelepe a moa (*Selaginella arbuscula*), the native herb (*Spermolepis hawaiiensis),* and dwarf iliau (*Wilkesia hobdyi*). The last two species are discussed below as endangered plant species. There are also 14 indigenous species on the property including naio (*Myoporum sandwicense)*, and `ilima (*Sida fallax).* (Pacific Missile Range Facility, 2006d) A few shrubs of naio and introduced lantana (*Lanatana camara*) occur along the makai (coastal) edge of the Makaha Ridge complex. Pine plantings and mixed scrub covers most of the area at the Makaha Ridge facility. Rows or scattered clumps of pine trees have been planted for erosion control. There are high levels of erosion at the ridge with many areas having less than 10 percent cover due most likely to ungulates (hoofed mammals). Silk oak trees (*Grevillea robusta)* are also abundant. Mixed scrub consisting mainly of lantana shrubs and molasses grass (*Melinis minutiflora)* with scattered guava shrubs (*Psidium* spp.) is located between the trees. Some native koa trees are located in the southern portion of the property. Well-maintained grassy lawns and landscape plantings are located around the existing buildings. (Pacific Missile Range Facility, 2001; U.S. Department of the Navy, 1998a)

<u>Threatened and Endangered Plant Species</u>

Table 3.3.2.2.2-1 lists threatened and endangered species known or expected to occur in the vicinity of the Makaha Ridge site. The endemic dwarf iliau, a shrub species Federally and State listed as endangered, occurs on cliffs overlooking the Makaha Valley along the northern boundary of the Makaha Ridge site. The Makaha Ridge population was estimated to be about 50 plants in 2000. A survey conducted in April 2006 documented an additional 11 colonies of dwarf iliau on cliffs within and adjacent to the Makaha Ridge boundary totaling 214 individuals (Pacific Missile Range Facility, 2006d). The plants are out of the reach of goats (*Capra hircus*) that frequent the area. (Center for Plant Conservation, 2006; U.S. Fish and Wildlife Service, 2002; Pacific Missile Range Facility, 2001)

Table 3.3.2.2.2-1. Listed Species Known or Expected to Occur in the Vicinity of Makaha Ridge

Scientific Name	Common Name	Federal Status
Plants		
Spermolepis hawaiiensis	No common name	E
Wilkesia hobdyi	Dwarf iliau	
Birds		
Branta sandvicensis	Nene (Hawaiian goose)	E
Pterodroma phaeopygia sandwichensis	\`Ua\`u (Hawaiian dark-rumped petrel)	E
Puffinus auricularis newelli	\`A\`o (Newell's Townsend's shearwater)	T
Mammals		
Lasiurus cinereus spp. *semotus*	Hawaiian hoary bat	E

Source: U.S. Fish and Wildlife Service, 2005a; b; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007

Key to Federal Status:
T = Threatened
E = Endangered

Also during the April survey, two large colonies (about 700 individual plants) of another endangered plant *(Spermolepis hawaiiensis*) were discovered. This herb is a member of the parsley family. It was previously thought to be extinct on Kauai, but including this new discovery, about 2,400 reproducing individuals have been documented on the island. (Pacific Missile Range Facility, 2006d)

Wildlife

Sixteen species of birds were observed during a wildlife survey conducted in 2000, including the indigenous white-tailed tropicbird (*Phaeton lepturus*) and the migratory Pacific golden plover. Species of introduced birds commonly found in this area of Kauai and observed during the survey included the spotted dove (*Streptopelia chinensis*), zebra dove, house finch, northern mockingbird, chukar (*Alectoris chukar*), and the common myna (*Acridotheres tristis*). (Pacific Missile Range Facility, 2001; 2006b) Another introduced species, the Japanese white-eye, is very abundant at the facility, as noted during a 2006 survey (Pacific Missile Range Facility, 2006b).

The green anole (*Anolis carolinensis*), house gecko, and mourning gecko were documented during a 2006 survey, as well as rats (Pacific Missile Range Facility, 2006c). Although no evidence of cats or rats was observed, it is likely that these mammals inhabit the Makaha Ridge area. Feral goats and pigs, and black-tailed deer (*Odocoileus hemionus columbianus*) are also seen in this general area. Goat densities on Makaha Ridge are likely higher than densities from other areas on the island because hunting is not allowed on base. (Pacific Missile Range Facility, 2001; 2006c)

Threatened and Endangered Wildlife Species

Table 3.3.2.2.2-1 lists threatened and endangered species known or expected to occur in the vicinity of the Makaha Ridge site. The threatened Newell's shearwater may fly over the site while on the way to its feeding grounds at sea. In addition, the endangered Hawaiian goose, or nene (*Branta sandvicensis*), occurs as a breeding population within the Makaha Ridge facility. The nene appears to still use the area, but may not nest due to the high density of goats. The endangered Hawaiian hoary bat is known to frequent the area and may forage or roost on the property or in surrounding forested areas. (Pacific Missile Range Facility, 2001)

Environmentally Sensitive Habitat

No critical habitat is located at the Makaha Ridge Facility (Figure 3.3.2.2.2-1).

3.3.2.2.3 Cultural Resources—Makaha Ridge

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for cultural resources at Makaha Ridge encompasses the location for a new laboratory, power plant, and fiber optic cable. There are no archaeological resources within the region of influence. Building 720, where a new Automatic Identification System antenna is planned (see Figure 2.2.3.6.4-3), has not been identified as a historic property.

Affected Environment

Archaeological Resources (Prehistoric and Historic)

Operated as a sub-installation of PMRF, Makaha Ridge encompasses 244 acres of a prominent ridgeline overlooking the Mana Plain. The area consists of range operations communications facilities (International Archaeological Resources Institute, Inc., 2005). Makaha Ridge has been surveyed for archaeological resources and found to contain no significant archaeological sites (International Archaeological Resources Institute, Inc., 2005).

Historic Buildings and Structures

There are no identified historic buildings or structures at Makaha Ridge (International Archaeological Resources Institute, Inc., 2005).

Traditional Resources

Makaha Ridge has been surveyed and found to contain no significant traditional Hawaiian sites (International Archaeological Resources Institute, Inc., 2005).

3.3.2.2.4 Hazardous Materials and Waste—Makaha Ridge

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and potential hazardous waste is limited to areas of Makaha Ridge where hazardous materials are stored, handled, and consumed.

Affected Environment

Hazardous materials and potential hazardous waste activities at Makaha Ridge are included in PMRF management plans for these types of materials. Daily activities are in accordance with those plans and similar range operations described in Section 3.3.2.1.6 for PMRF/Main Base.

Makaha Ridge follows PMRF's hazardous materials management plans as described under PMRFINST 5100.2C, *Hazardous Material Control and Management Program*. The hazardous materials used at Makaha Ridge consist of lubricating oils, low sulfur diesel fuel, and some minor amounts of solvents. Each hazardous material storage area has appropriate Material Safety Data Sheets.

Hazardous waste generated at Makaha Ridge has been eliminated through Best Management Practices for routine range operations. Small aerosol solvent requirements for electrical parts/radar maintenance do not generate hazardous waste, and empty containers are returned to the PMRF Hazardous Material Minimization Center for disposal. Corrosion control/painting activities do not generate hazardous waste. Generator overhauls, following 1,000 hours of operations, produce “on-specification used oil fuel” confirmed by routine laboratory testing.

There are two 600-kW and two 300-kW generators supplied by two 6,000-gal diesel tanks and four 300-gal day tanks. There is one 1,000-gal gasoline tank and one 55-gal drum of motor oil. All tanks are above ground with appropriate containment devices.

Pesticide use at Makaha Ridge is applied by the certified applicator from PMRF. There are no radon issues at the site, and ordnance is not stored at Makaha Ridge. No medical or radioactive wastes are generated, and there are no IRP sites at Makaha Ridge. Lead-based paint management and asbestos management at Makaha Ridge follow the same procedures as described for PMRF/Main Base.

3.3.2.2.5 Health and Safety—Makaha Ridge

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for health and safety of workers includes immediate work areas and EMR hazard areas. The region of influence for public safety includes areas bordering Makaha Ridge.

Affected Environment

Hazards to health and safety potentially occur as a result of EMR at the site. There are four tracking radars, two surveillance radars, and the primary PMRF telemetry station at Makaha Ridge. Frequency Interference Control, Electronic Warfare (EW) and Communication Facilities are also located at Makaha Ridge.

Hazards of EMR to personnel and fuel (called HERP and HERF, respectively) are the main concerns at Makaha Ridge. No ordnance is stored at the site, so there are no Hazards of Electromagnetic Radiation to Ordnance (HERO) issues. The helicopters that use the heliport at Makaha Ridge may have Electro-explosive Devices; however, the area is below HERO unsafe levels due to sector blanking (i.e., filtering) of the area. To ensure conditions are safe, the site is regularly surveyed for radiation hazards, and all systems have warning lights to inform personnel when radar units are operating. Because of Makaha Ridge’s location at the end of a ridge, there are no health and safety issues associated with the public. As discussed under airspace, aircraft are warned through aeronautical charts of the potential EMR hazards associated with Makaha Ridge.

3.3.2.3 KOKEE

Kokee is located at an altitude of 3,710 ft above mean sea level within Kokee State Park, which is owned by the State of Hawaii and managed by the Department of Land and Natural Resources, Division of State Parks. Kokee is operated jointly by PMRF and NASA. Kokee supports tracking radars, telemetry, Ultra-High Frequency/Very High Frequency (UHF/VHF) communications, and Command and Control (C2) systems.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Kokee. Of the 13 resources considered for analysis, air space, cultural resources, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed. Any issues with these resources that are associated with Kokee are included within the PMRF/Main Base discussion.

3.3.2.3.1 Air Quality—Kokee

Appendix C includes a definition of air quality and the main regulations and laws governing its protection.

Region of Influence

For inert pollutants (all pollutants other than ozone and its precursors), the region of influence is generally limited to an area extending a few miles downwind from the source. The region of influence for ozone may extend much farther downwind than the region of influence for inert pollutants; however, as the project area has no heavy industry and very few automobiles, ozone and its precursors are not of concern. Consequently, for the air quality analysis, the region of influence for project activities is the existing airshed surrounding Kokee.

Affected Environment

Climate and Regional Air Quality

Section 3.3.2.1.1 describes climate and regional air quality on Kauai, which includes Kokee.

Existing Emission Sources

The primary air pollutant emissions at Kokee are from backup diesel generators. The two 500-kW, two 350-kW, and one 250-kW generator sets are permitted by the State of Hawaii under a current non-covered source permit.

3.3.2.3.2 Biological Resources—Kokee

Appendix C includes a definition of biological resources and the main regulations and laws that govern their protection.

Region of Influence

The region of influence for biological resources is the area within the fence surrounding the site.

Affected Environment

Vegetation

A botanical assessment survey was conducted at Kokee in 2000. The vegetation on the site is dominated by non-native species. The site is surrounded by forested areas that are a mixture of exotic species and some native trees and shrubs. Kokee is composed of mainly intact koa-ohia mesic native forest that is contiguous with the surrounding State forest (Pacific Missile Range Facility, 2006e). Most of the areas around existing buildings and within the fenceline are paved or are grassy lawns (kikuyu grass [*Pennisetum clandestinum*]). Native plants observed include koa, \`ohi\`a, and \`a\`ali\`i. The areas outside the fence lines of the southern portion of Kokee are periodically maintained and consist of grassy lawn. Dense thickets of blackberry (*Rubus argutus*), mats of kikuyu grass, and scattered firetree and firethorn are located outside the common fence line surrounding the northern portion of Kokee. The northern portion of Kokee also contains large iliahi/sandalwood trees. A small patch of Asian melastome (*Melastoma septemnervium*), an invasive species targeted for removal in the Kokee area, was found near the roadside at northern Kokee. (Pacific Missile Range Facility, 2001; 2006e)

<u>Threatened and Endangered Plant Species</u>

No threatened or endangered plant species were identified on Navy property at Kokee during the surveys conducted as part of the Integrated Natural Resources Management Plan process.

Wildlife

A bird and feral mammal survey was conducted at Kokee in 2001. Native and migratory bird species observed at Kokee included the Pacific golden plover, the common amakihi (*Hemignathus kauaiensis*), short-eared owl, Kauai \`elepaio (*Chasiempis sandwichensis)*, \`i\`iwi (*Vestiaria coccinea*), and \`apapane (*Himatione sanguinea*). The \`apapane was the most abundant native bird observed in 2006, followed by the Kauai amakihi and \`elepaio. \`I\`iwi were not observed in 2006. Other birds observed at Kokee included the common myna, Japanese white-eye, red junglefowl, spotted dove, white-rumped shama (*Copsychus malabaricus*), northern cardinal, house finch, hwa-mei (*Garrulax canorus*), zebra dove, and nutmeg manikin (*Lonchura punctulata*). (Pacific Missile Range Facility, 2001; 2006b)

No evidence of cats or rats was noted at the facility, but these mammals likely do occur on or near the site. Roof and Norway rats were captured at Kokee during a 2006 survey. The metallic skink (*Lampropholis delicata*) was observed during the same survey. There was also evidence of dogs, black-tailed deer (*Odocoileus hemionus*), and feral pigs on the site. (Pacific Missile Range Facility, 2001; 2006c)

<u>Threatened and Endangered Wildlife Species</u>

Table 3.3.2.3.2-1 provides a list of threatened and endangered species at or adjacent to the Kokee facility. The threatened Newell's shearwater may fly over the Kokee site. Three endangered Hawaiian hoary bats were observed at Site 3, foraging above the forest. (Pacific Missile Range Facility, 2001)

Table 3.3.2.3.2-1. Listed Species Known or Expected to Occur in the Vicinity of Kokee

Scientific Name	Common Name	Federal Status
Plants[1]		
*Chamaesyce halemanui**	Akoko	E
Diellia pallida	No common name	E
*Dubautia latfolia**	Na ena e	E
Lipochaeta waimeaensis	No common name	E
*Nothocestrum peltatum**	Aiea	E

Source: U.S. Fish and Wildlife Service, 2005a; b; 2007a; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007

Notes: [1] Plants listed have not been observed on Navy property at Kokee, but may be on adjacent property.

* Critical habitat has been designated for these plants.

Critical habitat has also been designated for *Mariscus pennatiformis, Poa mannuum, and Poa siphonoglossa.*

Environmentally Sensitive Habitat

No environmentally sensitive habitat is located at the Kokee site (Figure 3.3.2.2.2-1).

3.3.2.3.3 Hazardous Materials and Waste—Kokee

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and potential hazardous waste would be limited to areas of Kokee where hazardous materials are stored, handled, and consumed.

Affected Environment

Hazardous materials and activities that may result in hazardous waste at Kokee are included in PMRF management plans for these types of materials. Daily activities are in accordance with those plans and similar range operations described in Section 3.3.2.1.6 for PMRF/Main Base.

Kokee follows PMRF's hazardous materials management plans as described under PMRFINST 5100 and the Navy's CHRIMP. The hazardous materials used at Kokee consist of lubricating oils, low sulfur diesel fuel, and some minor amounts of solvents. Each hazardous material storage area has appropriate Material Safety Data Sheets.

Best Management Practices for routine range operations have eliminated hazardous waste at Kokee. Small aerosol solvent requirements for electrical parts/radar maintenance do not generate hazardous waste, and empty containers are returned to PMRF Hazardous Material Minimization Center for disposal. Corrosion control/painting activities do not generate hazardous waste. Generator overhauls, following 1,000 hours of operations, produce "on-specification used oil fuel" confirmed by routine laboratory testing.

Hydrostatic oil associated with the radar units is replaced every 4 years and generates approximately 55 gal of used oil. There are five generators at Kokee, two 500-kW, two 350-kW, and one 250-kW, with associated fuel tanks. There are two 25,000-gal aboveground diesel tanks, and one 500-gal day tank. All tanks have appropriate containment devices.

Pesticide at Kokee is applied by the certified applicator from PMRF. There are no radon issues at the site, and ordnance is not stored at Kokee. No medical or radioactive wastes are generated, and there are no IRP sites at Kokee. Lead-based paint management and asbestos management at Kokee follow the same procedures as described for PMRF/Main Base.

There are no PCB-containing transformers at Kokee. Kokee radar facilities do have capacitors and other components that contain PCBs. When such an oil-containing part is no longer functional and requires disposal, the component is disposed according to PMRF's Hazardous Waste Management Plan. When a component suspected of containing PCBs needs to be disposed of, the manufacturer is called to determine if PCBs are actually present in the part. Disposal occurs according to the required procedures.

3.3.2.3.4 Health and Safety—Kokee

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for health and safety of workers includes immediate work areas and EMR hazard areas. The region of influence for public safety includes areas bordering Kokee.

Affected Environment

Kokee supports tracking radars, telemetry, UHF/VHF Communications, and C2 systems. Hazards to health and safety potentially occur as a result of EMR at the site. Hazards of electromagnetic radiation to personnel and fuel (called HERP and HERF, respectively) are the main concerns at Kokee. No ordnance is stored at the site, so there are no HERO issues. The only fuel stored at the site (low sulfur diesel fuel for the electrical generators) is located outside of any EMR generating areas, so there are no HERF issues at the site. Appropriate sector blanking and the elevation of the radar units above the ground have eliminated any potential HERP issues at Kokee. To ensure that conditions are safe, the site is regularly surveyed for radiation hazards, and all systems have warning lights to inform personnel when the radar units are operating. The public is not exposed to any unsafe EMR levels. As discussed under airspace, aircraft are warned through aeronautical charts of the potential EMR hazards associated with Kokee range operations.

3.3.2.4 HAWAII AIR NATIONAL GUARD KOKEE

The Hawaii Air National Guard provides operation and maintenance of the Hawaii Digital Microwave System. Hawaii Air National Guard Kokee is a radar site, and PMRF maintains an APS-134, X-band, surface search radar.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Hawaii Air National Guard Kokee. Of the 13 resources considered for analysis, air quality, airspace, cultural resources, geology and soils, hazardous materials and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.3.2.4.1 Biological Resources—Hawaii Air National Guard Kokee

Appendix C includes a definition of biological resources and the main regulations and laws that govern their protection.

Region of Influence

The region of influence includes the areas on and surrounding Kokee.

Affected Environment

Kokee Air Force Station is located on 11 acres of leased land operated by Hawaii Air National Guard 150th Aircraft Control and Warning Squadron.

Vegetation

Kokee Air Force Station lies within the Na Pali-Kona Forest Reserve. \`Ohi\`a and koa trees are present in the area as well as native dry-land shrubs pukiawe and \`a\`ali\`i.

<u>Threatened and Endangered Plant Species</u>

No rare, threatened, or endangered plants have been recorded at Kokee Air Force Station (Air Force Center for Environmental Excellence Environmental Services Office, 2003).

Wildlife

Wildlife present in the Kokee Air Force Station area is similar to that described above in Section 3.3.2.3.2, such as the birds Kauai elepaio, \`i\`iwi, and \`apapane. Feral pigs and goats are also located in the area.

<u>Threatened and Endangered Wildlife</u>

Table 3.3.2.4.1-1 provides a list of threatened and endangered species at the Kokee Air Force Station. Three endangered species have been recorded at Kokee Air Force Station: the Newell's shearwater, dark-rumped petrel, and the Hawaiian hoary bat. The Hawaiian hoary bat roosts and forages on the station property or in adjacent forested areas. The seabirds are known to nest near the installation. (Air Force Center for Environmental Excellence Environmental Services Office, 2003)

Table 3.3.2.4.1-1. Listed Species Known or Expected to Occur in the Vicinity of Kokee Air Force Station

Scientific Name	Common Name	Federal Status
Birds		
Branta sandvicensis	Nene (Hawaiian goose)	E
Pterodroma phaeopygia sandwichensis	\`Ua\`u (Hawaiian dark-rumped petrel)	E
Puffinus auricularis newelli	\`A\`o (Newell's Townsend's shearwater)	T
Mammals		
Lasiurus cinereus spp. *semotus*	Hawaiian hoary bat	E

Source: U.S. Fish and Wildlife Service, 2005a; b; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007

Key to Federal Status:
T = Threatened
E = Endangered

Environmentally Sensitive Habitat

There are three designated wetlands located in the immediate vicinity of Kokee Air Force Station. Kalalau Stream and Honopu Stream are directly downslope and north of the installation in the direction of its surface runoff. Alakai Swamp is approximately 1 mi east of the station. (Air Force Center for Environmental Excellence Environmental Services Office, 2003)

3.3.2.5 KAMOKALA MAGAZINES

Kamokala Magazines are located approximately 2 mi east of PMRF/Main Base. Kamokala Magazines are a secure explosive storage area consisting of 10 magazines.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Kamokala Magazines. Of the 13 resources considered for analysis, air quality, airspace, biological, cultural resources, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.3.2.5.1 Hazardous Materials and Waste—Kamokala Magazines

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and potential hazardous waste would be limited to areas of Kamokala Magazines where hazardous materials are stored, handled, and consumed. The only hazardous materials stored at the Kamokala Magazines are associated with the devices authorized for storage; specifically, hypergolic fuels, solid propellants, and other ordnance. These materials are contained in the devices that are required to be stored in the Kamokala Magazines with proper ventilation, marking, and placarding.

Affected Environment

No hazardous materials are used or hazardous waste generated from range operations at Kamokala Magazines. There are no storage tanks or known IRP sites at this location. The gunnite material lining the caves has not been tested for asbestos, and therefore, must be presumed to be an asbestos-containing material. The site does not have any PCB-containing material or radon issues.

The magazines are a secured area controlled by the PMRF Ordnance Office, Code 7331, and they are the storage sites for the ordnance and solid rocket motors used in training events at PMRF. When needed, they are transported to the launch or loading site. All explosive ordnance, including solid rocket motors, is handled in accordance with NAVSEA OP5, Volume 1.

3.3.2.5.2 Health and Safety—Kamokala Magazines

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for health and safety consists of the immediate work areas and ordnance hazard areas. The region of influence for public safety includes Kamokala Magazines, Mana Plain, and the ESQD not within the surrounding cliffs.

Affected Environment

Kamokala Magazines are an explosive storage area consisting of 10 magazines. The health and safety issues for Kamokala Magazines are associated with the transfer and storage of ordnance. No more than 30,000-lb net explosive weight can be stored at each magazine cave; this generates a safety area with a 2,350-ft radius in a 60-degree arc to the front of each 30,000-lb net explosive weight tunnel, diminishing in radius by 30-degree increments away from the front (see Figure 3.3.2.1.7-1). Ordnance is stored in accordance with DoD and Navy standards. In addition, PMRF has established instruction 8023.G, which details how the storage and handling of ordnance is conducted.

3.3.2.6 PORT ALLEN

Port Allen is a State of Hawaii harbor facility, located approximately 17 miles from PMRF/Main Base, on the southern coast of Kauai. The Navy leases office, storage, and berthing space at the Port Allen pier for range vessels and surface target support. Port Allen hosts PMRF's Range Support Boats and Seaborne Powered Target Boat site operations and maintenance facilities, and provides pier space, protected anchorage, and small-boat launch facilities. A review of the 13 resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from site operations at Port Allen.

3.3.2.7 KIKIAOLA SMALL BOAT HARBOR

Kikiaola Harbor is located on the southwest coast of the island of Kauai. The Harbor hosts Range Support Boats and small-boat launch facilities. PMRF's Seaborne Powered Targets are launched from Kikiaola. A review of the 13 resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from site operations at the Kikiaola Small Boat Harbor.

3.3.2.8 MT. KAHILI

Mt. Kahili is an existing Department of Energy/PMRF communication site required for line-of-sight transmissions that contains a repeater station. The Mt. Kahili electronic site is one of the most remote tower locations in the Hawaiian Islands. Frequency band information is listed in Appendix E, Table E-5 (Remote Sites). There is no lighting at the facility. Road access is limited, in good weather, to very high-clearance 4-wheel drive vehicles only, and one can only drive within about a mile below the tower. From the end of the road, there is a 1-hour hike up a steep ridge covered with wet Hawaiian ferns, and finally a 30 ft. rope leads to the summit and the electronic site. (Broadcast Engineering Services of Bonny Doon, 2007)

The endangered Newell's shearwater and Hawaiian petrel traverse the area, which may support breeding locations for these species. Hawaiian hoary bats are also likely to be using Mt. Kahili. (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007) A review of the 13 environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from site operations at Mt. Kahili.

3.3.2.9 NIIHAU

Niihau is a privately owned island located about 17 nm southwest of Kauai. It is about 8 mi wide by 18 mi long and comprises approximately 72 mi^2. PMRF leases 1,170 acres of land in the northeastern corner of the island and operates radar units, optics, and electronic warfare sites.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Niihau. Of the 13 resources considered for analysis, air quality, airspace, cultural resources, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources for Niihau are not addressed.

3.3.2.9.1 Biological Resources—Niihau

Appendix C includes a definition of biological resources and the main regulations and laws that govern their protection.

Region of Influence

The region of influence for biological resources is the island of Niihau and its offshore environment.

Affected Environment

Vegetation

The vegetation of the island is dominated by non-native plant species and plant communities. The dominant types of vegetation on Niihau are kiawe forest, grassland, and koa haole. On the northern lowland areas, the kiawe forest is more open and has a kiawe overstory with an extensive shrub understory of `ilima. A coastal dry herbland/grassland community is present along the northeastern coast of Niihau. A dry coastal community, koa haole shrubland, often dominated by pure stands of koa haole, occurs at scattered locations at higher elevations on the island. This vegetation community is often associated with abandoned pastures. In some locations the koa haole canopy is so thick and grazing pressure of feral sheep and pigs so intense that there is little, if any, herbaceous understory. Small mixed stands of eucalyptus (*Eucalyptus robusta*) and common ironwood occur in a few sheltered areas at higher elevations. Ironwood also occurs in coastal areas near the ocean. Scattered individuals of the endemic naio occur at higher elevations in a mixed kiawe/koa haole shrub association. (Pacific Missile Range Facility, 2001; U.S. Department of the Navy, 1998a)

<u>Threatened and Endangered Plant Species</u>

Table 3.3.2.9.1-1 lists threatened and endangered species known or expected to occur on Niihau. Alula (*Brighamia insignis*), Federally listed as endangered, was historically known on Niihau. A population occurred on the Kaali Cliff, but has not been observed since 1947. Other endangered plants that have been found in the area include pu`uka`a (*Cyperus trachysanthos)* and *Lobelia niihauensis* (no common name) (Hawaii Department of Land and Natural Resources, no date [c]). Threats to the species include loss of native pollinators, browsing by goats, and invertebrate pests. (Hawaii Department of Land and Natural Resources, 2006)

Table 3.3.2.9.1-1. Listed Species Known or Expected to Occur on Niihau

Scientific Name	Common Name	Federal Status
Plants		
Brighamia insignis	Alula	E
Cyperus trachysanthos	Pu`uka`a (Sticky flatsedge)	E
Lobelia niihauensis	No common name	E
Panicum niihauense	Lau`ehu	E
Pritchardia aylmer-robinsonii	Lo`ulu	E
Sesbania tomentosa	`Ohai	E
Reptiles		
Chelonia mydas	Green turtle	T
Birds		
Anas wyvilliana	Koloa maoli (Hawaiian duck)	E
Fulica alai	`Alae ke`oke`o (Hawaiian coot)	E
Hemignathus munroi	`Akiapola`au (Honeycreeper)	E
Himantopus mexicanus knudseni	Ae`o (Hawaiian black-necked stilt)	E
Mammals		
Lasiurus cinereus spp. *semotus*	Hawaiian hoary bat	E
Monachus schauinslandi	Hawaiian monk seal	E

Source: U.S. Fish and Wildlife Service, 2005a; b; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007

Key to Federal Status:
T = Threatened
E = Endangered

Wildlife

The wildlife on Niihau is dominated by non-native species. The terrestrial vertebrate animal community is dominated by feral pigs, sheep, cattle, horses, donkeys, turkeys (*Meleagris gallopavo*), quail, pheasants, and peacocks. Large numbers of pigs and sheep freely roam the island. The common bird species are introduced species such as the spotted dove, cardinal, and mynah. The migratory Laysan albatross nests on Niihau, but its success is limited by predation by feral pigs. (Pacific Missile Range Facility, 2001)

Threatened and Endangered Wildlife Species

Table 3.3.2.9.1-1 lists threatened and endangered species known or expected to occur on Niihau. The koloa maoli (Hawaiian duck), alae ula (common moorhen), ae`o (Hawaiian stilt), and the `alae ke`oke`o (Hawaiian coot) are found in and around the lakes (playas) on the southern part of Niihau.

The endangered Hawaiian monk seal uses most of the coastline on Niihau to haul out, bask, and occasionally pup. From 10 to 12 pups are born on Niihau annually (Hawaii Institute of Marine Biology, 2006). The threatened green turtle has been observed to come ashore on selected beaches and occasionally nests at some of these locations.

Environmentally Sensitive Habitat

An area of 357 acres in the northern portion of Niihau has been designated as critical habitat for the alula (Figure 3.3.2.9.1-1). This area is considered essential to the conservation of the taxon by the USFWS. (U.S. Fish and Wildlife Service, 2003a)

3.3.2.9.2 Hazardous Materials and Waste—Niihau

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and potential hazardous waste would be limited to areas of Niihau where hazardous materials are stored, handled, and consumed.

Affected Environment

Hazardous materials are used on Niihau during the minor maintenance activities associated with PMRF facilities, including some aerosol solvents, diesel fuel for generators, paint, and oil. These materials are used for the radar unit and EW site facilities. These materials are brought to Niihau when required for maintenance. General site maintenance is provided by Niihau Ranch. All hazardous materials used and waste generated are managed in accordance with PMRF procedures described in Section 3.3.2.1.6.

PMRF does maintain two aboveground diesel fuel storage tanks on Niihau to operate the electrical generators for the radar site and EW site. These fuel storage tanks consist of a 1,000-gal tank for the radar site and a 100-gal tank for the EW site. There are no radon issues associated with operation of range facilities on Niihau, and there are no IRP sites. There are no PCB-containing devices in any of the radar or power-related components at Niihau.

3.3.2.9.3 Health and Safety—Niihau

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for health and safety is Niihau.

Critical Habitat - Niihau, Hawaii

Niihau, Hawaii

Figure 3.3.2.9.1-1

Affected Environment

Niihau is a privately owned island, that through agreements with the owners, PMRF uses to support range operations. The primary health and safety concern for the residents of Niihau is the potential for a fire on the island. Due in part to the dry climate and kiawe vegetation that dominates the island, there is the potential for very large fires to occur. Currently, the island does not have any firefighting equipment. Emergency medical evacuation service can be provided by the helicopter owned by the Robinson family.

PMRF operates a radar at Paniau that is remotely operated from PMRF/Main Base. The radar unit, which is located on top of a facility, presents no HERP hazards at ground level where any island resident could be affected. PMRF/Main Base also operates the Niihau Perch site EW system, which has a HERP EMR hazard of 12 ft in front of where the system is pointing. A warning light and warning signs are placed in the area when the system is operating. In addition, PMRF flies AEGIS drone targets along the east coast of the island away from inhabited areas. Presently, helicopters are airborne with buckets during nearland/overland range operations occurring on or near Niihau to deal with potential fire hazards.

3.3.2.10 KAULA

Kaula is approximately 108 acres of federally owned and controlled land. The Navy uses a small portion of Kaula for aircraft gunnery and inert ordnance target practice. The ordnance impact area is limited to about 10 acres on the south end of the island. The island is not inhabited, and there are no structures. Access to the island is restricted.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Kaula. Of the 13 resources considered for analysis, air quality, noise, hazardous materials and waste, socioeconomics, transportation, utilities, and water resources are not addressed.

3.3.2.10.1 Airspace—Kaula

Appendix C includes a detailed description of airspace. Kaula is included in the region of influence for PMRF/Main Base. See Section 3.3.2.1.2 for the airspace affected environment that includes Kaula.

3.3.2.10.2 Biological Resources—Kaula

Kaula is located approximately 60 miles southwest of PMRF. It is approximately 1 mi long and 0.25 mi wide (an area of 0.25 mi^2 or 160 acres). The island is crescent shaped and generally comprised of steep cliffs on all sides ranging from 100 to 150 ft above mean sea level with no beaches. Kaula is covered by a sparse grass landscape and earthen/rock outcrops, and is reportedly underlain by a relatively thin soil layer with highly weathered limestone bedrock. The southern end of the island is used as a range for inert ordnance. The majority of the island is left undisturbed with a portion designated as a bird sanctuary. Kaula is used by the Navy for aircraft gunnery and inert ordnance target practice. Appendix C includes a definition of biological resources and the main regulations and laws that govern their protection.

Region of Influence

The region of influence for biological resources associated with Kaula includes the island and offshore area.

Affected Environment

Vegetation

Due to strong, dry, and continuous winds, the vegetation on Kaula is very sparse. The dominant vegetation is low-growing shrubs or herbs that belong to a semi-arid and strand flora. A small number of koa haole have been noted on the island. Common plants that inhabit the sandy beach intertidal habitat include beach morning glory, beach heliotrope, milo, and hau (Maragos, 1998). The vegetation composition includes 5 endemic Hawaiian species, 10 indigenous species, and 14 introduced (exotic) species. Native ilima and ihi are the most abundant species. (Pacific Missile Range Facility, 2001; Offshore Island Restoration Committee, undated)

Threatened and Endangered Plant Species

Endangered plants located on Kaula are listed in Table 3.3.2.10.2-1.

Table 3.3.2.10.2-1. Listed Species Known or Expected to Occur on Kaula

Scientific Name	Common Name	Federal Status
Plants		
Amaranthus brownii	No common name	E
Pritchardia aylmer-robinsonii	Lo`ulu	E
Schiedea verticellata	No common name	E
Sesbania tomentosa	`Ohai	E
Reptiles		
Chelonia mydas	Green turtle	T

Mammals		
Monachus schauinslandi	Hawaiian monk seal	E

Source: U.S. Fish and Wildlife Service, 2007a

Key to Federal Status:
T = Threatened
E = Endangered

Wildlife

Twenty-six different species of seabirds have been observed on Kaula. An estimated 18 species of seabirds currently nest on the island (Offshore Island Restoration Committee, undated). These species appear to be healthy and are reproducing normally. The species include three species of migratory shorebirds that occasionally stop on Kaula seasonally and small numbers of six species of exotic (introduced) land birds. The sooty tern (*Sterna fuscata*), brown noddy, red-footed booby, and masked booby are some of the more common species observed. No other terrestrial wildlife is known to occur on Kaula, and none is expected. (Pacific Missile Range Facility, 2001; Offshore Island Restoration Committee, undated)

Threatened and Endangered Wildlife Species

None of the species of birds Federally listed as threatened or endangered occur on Kaula. Coastal waters off Kaula are considered viable foraging habitat for green turtles, but no sightings of sea turtles have been documented. (Pacific Missile Range Facility, 2001)

Three Hawaiian monk seals were observed on a shelf off Kaula in a 2000 aerial survey (Baker and Johanos, 2004). Fifteen Hawaiian monk seals were counted during a 4-hour period hauled out on Kaula during a 2006 cruise (National Marine Fisheries Service, 2007b).

Environmentally Sensitive Habitat

According to the Hawaii Department of Land and Natural Resources, the Hawaii State Seabird Sanctuary consists of and includes 40 State-owned or controlled islands, islets, and rocks (Hawaii Department of Land and Natural Resources, 1981). Kaula was listed erroneously by the State as one of these islands; it remains Federally owned and controlled.

3.3.2.10.3 Cultural Resources—Kaula

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for cultural resources at Kaula encompasses the southwestern tip of the island where there is an existing, heavily disturbed ordnance impact area (see Figure 2.1-2). There are no known historic properties within the impact area; however, due to the presence of unexploded ordnance, only a portion has been surveyed (U.S. Department of Defense, 2006).

Proposed or ongoing training events with the potential to affect cultural resources on Kaula and within Warning Area W-187 include BOMBEX and GUNEX. Both BOMBEX and GUNEX (Air-to-Ground) involve the islet only and not the surrounding waters.

Affected Environment

Archaeological Resources (Prehistoric and Historic)

Kaula has no evidence of extensive human habitation, although six archaeological sites located in the northern portion of the islet indicate some level of visitation (U.S. Department of the Navy, Commander, Third Fleet, 2006).

Historic Buildings and Structures

Two stone features (possibly heiaus); a sea cave with a low man-made wall; and the remains of a small unmanned light station, derrick, and shelter constructed by the U.S. Lighthouse Service in 1932 are the only structures mentioned in the literature for Kaula (Resture, 2006; Columbia Gazetteer of North America, 2000).

Traditional Resources

References to Kaula have been noted in Hawaiian oral traditions; however, there are no recorded traditional Hawaiian sites on the islet.

3.3.2.10.4 Geology and Soils—Kaula

Region of Influence

The region of influence for geology and soils is the southern end of Kaula, specifically, the southernmost 10 acres, currently used by the Navy for airborne ordnance training.

Affected Environment

Physiography

Kaula is a small, crescent-shaped volcanic island located southwest of Niihau. The island is the remnant of a breached volcanic cone that has been heavily eroded. The island is fairly symmetrical, with the highest elevation achieved near the center of the island at slightly greater than 500 ft. Steep sea cliffs occur around the island perimeter; however, the remnants of a narrow wave-cut terrace, cut 8 to 10 ft above current sea level, are evident on the eastern shore. Near the northwest end of the convex (leeward) side of the island, slopes are the steepest, reaching approximately 140 percent and greater. In general, the sea cliffs are relatively smooth; however, in some areas, joints and fissures in the rock have promoted large blocks of ash to erode, making elongated sea caves (U.S. Department of the Navy, 1980). On the concave windward side, upland slopes generally range from 75 to 125 percent. Gullies on the leeward slopes are relatively few and small, whereas those on the windward slopes tend to be more numerous and larger (U.S. Department of the Navy, 1980).

Geology

The distance and water depth between Kaula and Niihau suggest that Kaula was an independent volcanic center (U.S. Department of the Navy, 1980). Earlier geologic surveys reported by Palmer (1927) indicate a geologic history typical of other islands in the Hawaiian chain. Kaula was raised to sea level, or near sea level, during a major period of Tertiary volcanism when large volumes of lava were deposited. An erosional unconformity ensued, during which coral reefs developed on the summit of the submerged volcano or the beveled base of the subaerial mountain. A second eruptive epoch followed, during which a tuff crater was formed. The crater was probably unsymmetrical, with the leeward side being the highest and the windward side considerably lower, possibly not above sea level. The tuff crater was subsequently eroded by wind, waves, and runoff, and a submarine terrace was cut around most of the island. The sea has since receded to about 15 ft below the wave cut terrace.

Volcanic rock on Kaula is reported as a light brownish-gray tuff (U.S. Department of the Navy, 1980). Embedded in the tuff are olivine nodules, which may be the same age as the tuff. Other inclusions encompass fragments of older lava and reef limestone, which suggest that the last phase of volcanic activity dislodged and incorporated these materials during violent eruptions (U.S. Department of the Navy, 1980).

Soils

Soil on Kaula is primarily composed of water-lain detritus, which mantles the wave cut terrace on the leeward side of the island. The detritus is fine- to coarse-grained tuffaceous material and has not been reworked; therefore, the grains are generally angular. The coarsest grains are composed of fresh to decomposed volcanic glass, fine grained basalt, and fragments of bird bones along with a few olivine fragments (U.S. Department of the Navy, 1980). The relicts in the finer-grained material suggest that the parent material was of basaltic composition. Augite and feldspar, common elements of Hawaiian basalts, however, have been weathered out (U.S. Department of the Navy, 1980).

3.3.2.10.5 Health and Safety—Kaula

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for health and safety is Kaula and the immediate surface danger zone around the island.

Affected Environment

The primary health and safety issue concern associated with Kaula is the aerial inert bombing/aircraft gunnery impact area; no other hazardous operations occur on the island. To minimize health and safety risks, a Surface Danger Zone surrounding Kaula was established for the primary purpose of ensuring an adequate margin of safety to both personnel and equipment during the conduct of gunnery training events by the military. In addition, because of the potential for unexploded ordnance to be present on and just below the surface of the island and adjacent waters, the island and tidal shoreline are closed to unauthorized personnel at all times. Prior to any bombing training events, an aircraft flies over the island and determines if it is safe to conduct the mission.

To allow some fishing use of the waters surrounding the island (excluding the tidal zone), the Navy does open the surface danger zone on weekends and holidays for fishing by notifying the appropriate State agency. The Commander Fleet Air Hawaii, as the controlling and scheduling agency for the military use of Kaula, is responsible for notifying the Hawaii Department of Land and Natural Resources, Division of Fish and Game, and Commander Fourteenth Coast Guard District, in writing, of the period of time the Surface Danger Zone will be opened for fishing.

3.3.2.10.6 Land Use—Kaula

Appendix C includes a definition of land use and laws and regulations that pertain to it.

Region of Influence

The region of influence is the southern end of Kaula, specifically, the southernmost 10 acres, currently used by the Navy for airborne ordnance training. The Navy has no intention of expanding land holdings at this location. Kaula is federally owned and controlled.

Affected Environment

Kaula is a 108-acre island southwest of Niihau and is part of Kauai County (Figure 2.1-2). There are no recreational activities associated with or occurring on Kaula. Ordnance delivery is limited to the southeastern tip of the island (U.S. Department of Defense, 2006). The State Land Use classification for Kaula is Conservation Land, and there is no County land use designation for Kaula.

THIS PAGE INTENTIONALLY LEFT BLANK

3.4 OAHU

Oahu serves as the main commerce port for all of Hawaii. It is the third largest of the Hawaiian Islands in size and the largest in population, with roughly 75 percent of the State's residents. Honolulu County encompasses the entire island of Oahu; its county seat is the city of Honolulu. Current and proposed Hawaii Range Complex (HRC) training and research, development, test, and evaluation (RDT&E) activities offshore or onshore of Oahu addressed in this Environmental Impact Statement (EIS)/Overseas EIS (OEIS) are located at Puuloa Underwater Range, Naval Defensive Sea Area, U.S. Coast Guard Air Station Barbers Point/Kalaeloa Airport, Marine Corps Base Hawaii (MCBH), Marine Corps Training Area–Bellows (MCTAB), Makua Military Reservation, Dillingham Military Reservation, Ewa Training Minefield, Barbers Point Underwater Range, Naval Undersea Warfare Center (NUWC) Range Shipboard Electronic Systems Evaluation Facility (SESEF), NUWC Fleet Operational Readiness Accuracy Check Site (FORACS), Naval Station Pearl Harbor, Ford Island, Naval Inactive Ship Maintenance Facility Pearl Harbor, Explosive Ordnance Disposal (EOD) Land Range–Naval Magazine (NAVMAG) Pearl Harbor West Loch, Lima Landing, Hickam Air Force Base (AFB), Wheeler Army Airfield, Kahuku Training Area, Keehi Lagoon, Kaena Point, Mt. Kaala, Wheeler Network Segment Control/Pacific Missile Range Facility (PMRF) Communication Sites, Mauna Kapu Communication Site, and Makua Radio/Repeater/Cable Head.

3.4.1 OAHU OFFSHORE

Oahu Offshore addresses ocean areas within 12 nautical miles (nm) of Oahu, including ranges and training areas where activities are performed by the Navy. Discussions include Puuloa Underwater Range, Naval Defensive Sea Area, MCBH, MCTAB, Makua Military Reservation, Dillingham Military Reservation, Ewa Training Minefield, Barbers Point Underwater Range, NUWC SESEF, and NUWC FORACS. These offshore areas are not within the Hawaiian Islands Humpback Whale National Marine Sanctuary.

3.4.1.1 PUULOA UNDERWATER RANGE—OFFSHORE

The Puuloa Underwater Range is 2 square nautical miles (nm^2) and oriented parallel to the shore at Ewa Beach, west of the mouth of Pearl Harbor. Water depths range from about 9 feet (ft) near shore to a maximum depth approaching 228 ft in the southwest corner. The majority of the range is less than 39 ft in depth. The Puuloa Underwater Range supports underwater demolition activities.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Puuloa Underwater Range Offshore. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.1.1 Biological Resources—Puuloa Underwater Range—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence includes the underwater range and adjacent waters.

Affected Environment

Vegetation

Several hundred species of marine algae (seaweed) have been collected in Hawaiian waters (MacCaughey, 1916). Seaweed, mainly alien forms such as *Acanthophora spicifera and Hypnea musciformis,* is still very abundant in the offshore areas of Oahu (U.S. Department of the Navy, 2002a). *A. spicifera* is the most widespread and successful alien alga in Hawaii. Its adaptability has enabled it to spread throughout the state where it is found in brackish water ponds, salty tidepools, on basalt ledges and in sandy bottomed habitats attached to coral rubble. It is now found on all of the Main Hawaiian Islands and is a common component of the intertidal environment throughout the state. Soon after the introduction of *H. musciformis*, it was identified as a food source for the green sea turtle. *H. musciformis* can make up a significant part of their diet, sometimes representing 99 to 100 percent of the seaweed found in their stomachs. *Avarainvillea amadelpha* can be found in abundance on the shallow reef flats on Oahu's south shore where it competes directly with the Islands' only native seagrass on sandy bottoms off south Oahu. Specimens have been collected from deeper water up to 90 meter (m) depth. It is not known if this alga has been introduced or is a native. (University of Hawaii, undated)

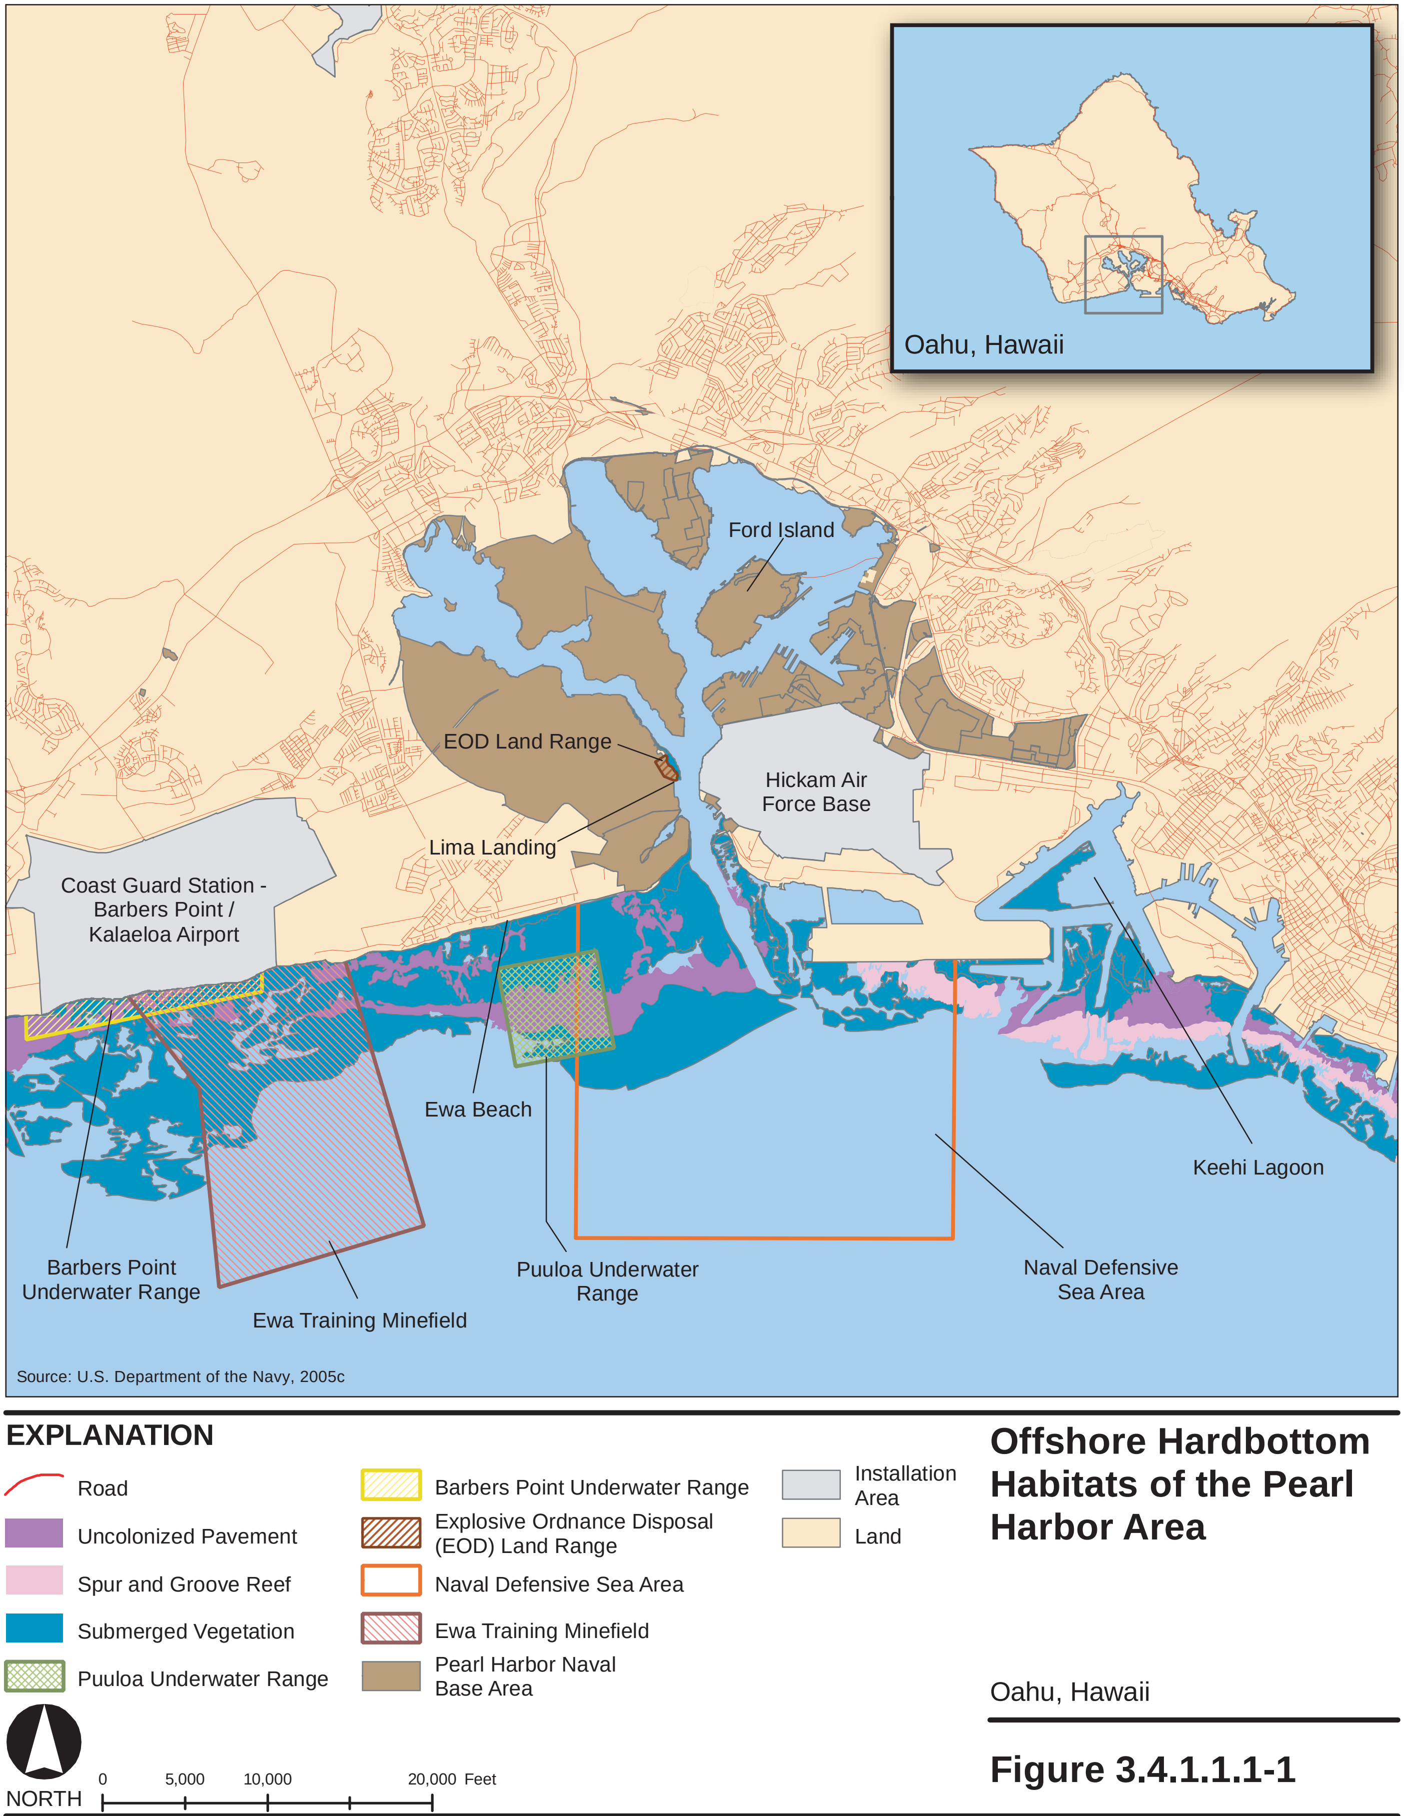
<u>Threatened and Endangered Plant Species</u>

No threatened or endangered plant species have been observed in the region of influence.

Wildlife

A description of coral reef area associated with the Hawaiian Islands and its management by both the State of Hawaii and the Federal government is provided in Section 3.1.2.1. A benthic survey conducted in 2001 close to and with a similar depth range to the Puuloa Underwater Range indicated that corals ranged from locally abundant on the northern inshore reef slope at Ewa Beach (Figure 3.4.1.1.1-1) to uncommon on the broad sandy slopes on the south (seaward) side of the surveyed area. Coral coverage ranged from 80 to 90 percent at depths between 9.7 and 13 fathoms to less than 1 percent in water depths from 13 to 20 fathoms. The coral community was dominated by rose or cauliflower coral (*Pocillopora meandrina*), lobe coral (*Porites lobata*)*,* and finger coral (*Porites compressa*)*.* (U.S. Department of the Navy, 2002a)

Coastal waters of the Ewa Plain receive nutrient rich water from springs below sea level. The nutrients in this water come from upland agricultural fertilization, leaching from cesspools and septic tanks, domestic waste injection wells, and urban application of fertilizers. These extra nutrients promote the growth of benthic algae (limu). A few species of reef fish are present in low numbers in the littoral waters. (U.S. Department of the Navy, 2002a)



Offshore Hardbottom Habitats of the Pearl Harbor Area

Oahu, Hawaii

Figure 3.4.1.1.1-1

Fish species are diverse and abundant and generally associated with the deeper (greater than 20 fathoms) areas containing coral coverage and vertical relief. This type of area has been designated by the National Oceanic and Atmospheric Administration (NOAA) as Habitat Areas of Particular Concern (HAPC). The most common families represented are surgeonfishes (acanthurids), butterflyfishes (chaetodontids), damselfishes (pomacentrids), wrasses (labrids), triggerfishes (balistids), and moorish idols (zanclids). (U.S. Department of the Navy, 2002a) Section 3.1.2.2.1 includes a description of Essential Fish Habitat (EFH); however, a detailed description, including status, distribution, and habitat preference of managed fisheries, is provided in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

A variety of whales and dolphins not listed as threatened or endangered are found around the Hawaiian Islands, including the minke whale (*Balaenoptera acutorostrata*) and Bryde's whale (*Balaenoptera edeni*). These whales have been identified both by visual sighting and by acoustic surveys. More than 20 species of toothed whales and dolphins are known to exist around the islands, including those most frequently seen: spinner dolphin (*Stenella longirostris*), spotted dolphin (*Stenella attenuata*), bottlenose dolphin (*Tursiops truncatus*), short finned pilot whale (*Globicephala macrorynchus*), and false killer whale (*Pseudorca crassidens*). The spinner dolphin is commonly seen on the leeward side of all of the Main Hawaiian Islands. Spotted dolphins are usually located near the spinners in deeper waters, while the bottlenose dolphins frequent both shallow and deep areas. (U.S. Department of the Navy, 2002a)

Threatened and Endangered Species

Table 3.4.1.1.1-1 provides a list of threatened and endangered species that are known or expected to occur in the vicinity of Puuloa Underwater Range. Transitory humpback whales (*Megaptera novaeangliae*) are occasionally reported in the area outside of the Pearl Harbor Entrance Channel but are not resident in the area (Smith et al., 2006). Hawaiian monk seals (*Monachus schauinslandi)* are resident on Oahu and have been sighted near the Pearl Harbor Entrance Channel. The green turtle (*Chelonia mydas*) is commonly sighted in this area (Smith et al., 2006).

Nine marine wildlife species listed as Federal and State threatened or endangered species are known or suspected to exist in Hawaiian waters. These species include the Hawaiian monk seal, blue whale (*Balaenoptera musculus*), fin whale (*Balaenoptera physalus*), humpback whale, sei whale (*Balaenoptera borealis*), sperm whale (*Physeter macrocephalus*), hawksbill turtle (*Eretmochelys imbricata*), green turtle, and loggerhead turtle (*Caretta caretta*). Section 3.1.2 includes a description of these listed species. (U.S. Department of the Navy, 2002a)

Environmentally Sensitive Habitat

No environmentally sensitive habitat has been identified.

Hawaiian Islands Humpback Whale National Marine Sanctuary

Hawaiian Islands Humpback Whale National Marine Sanctuary areas are located off the northern and southeastern coastlines of Oahu. No current HRC activities are being performed within portions of the Hawaiian Islands Humpback Whale National Marine Sanctuary offshore of Oahu, and none are being proposed.

Table 3.4.1.1.1-1. Listed Species Known or Expected to Occur in the Vicinity of Puuloa Underwater Range

Scientific Name	Common Name	Federal Status
Reptiles		
Caretta caretta	Loggerhead turtle	T
Chelonia mydas	Green turtle	T
Eretmochelys imbricata	Hawksbill turtle	E
Mammals		
Monachus schauinslandi	Hawaiian monk seal	E
Balaenoptera borealis	Sei whale	E
Balaenoptera musculus	Blue whale	E
Balaenoptera physalus	Fin whale	E
Megaptera novaeangliae	Humpback whale	E
Physeter macrocephalus	Sperm whale	E

Source: U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a; U.S. Department of the Navy, 2002a; U.S. Fish and Wildlife Service, 2006b.

Key to Federal Status:
E = Endangered
T = Threatened

3.4.1.1.2 Cultural Resources—Puuloa Underwater Range—Offshore

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for the Puuloa Underwater Range encompasses areas where EOD would occur.

Affected Environment

Underwater Cultural Resources

There are no known submerged archaeological resources within the Puuloa Underwater Range region of influence (e.g., fishponds or shipwrecks).

3.4.1.1.3 Hazardous Materials and Waste—Puuloa Underwater Range—Offshore

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and wastes includes the range and adjacent ocean waters.

Affected Environment

Hazardous Materials

Puuloa Underwater Range is used for underwater demolition training using small underwater detonations. Training on Puuloa Underwater Range involves transporting (by vehicle and boat), handling, and using small quantities of hazardous materials (e.g., explosives). Explosives charges up to 20 pounds (lb) (net explosive weight) may be detonated on this range.

Hazardous Waste

The detonations of explosives generate small quantities of explosives residues, metals, and inorganic salts. These hazardous constituents generally disperse into the water column, but some may remain in bottom sediments. The annual quantities of hazardous materials consumed on this range are very small, however, and have no known offsite effects.

3.4.1.1.4 Health and Safety—Puuloa Underwater Range—Offshore

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for public health and safety includes the footprint of the range and adjacent ocean areas.

Affected Environment

Puuloa Underwater Range is a 2 nm^2 area in the open ocean outside and to the west of the entrance to Naval Station Pearl Harbor. The range lies well offshore under the Surface Danger Zone of the Marine Corps' Puuloa Firing Range. The range is used for training in underwater demolition and Special Warfare Operations (SPECWAROPS).

Public health and safety risks associated with this training activity include the possible dispersal of hazardous explosives residues in ocean waters, re-suspension of bottom sediment contaminants, and possible public proximity to an underwater detonation.

Public uses are not permitted within the range. Procedures for approving an underwater detonation include filing a "Request for Detonation of Underwater Ordnance" with Commander, Naval Station Pearl Harbor to determine whether the proposed detonation would constitute any danger. Upon concurrence by appropriate commands, Commander, Naval Surface Force, Pacific grants permission to conduct the underwater detonations and concurrently requests issuance of a local Notice to Mariners by the appropriate U.S. Coast Guard District. Thus, current underwater EOD training at Puuloa Underwater Range poses no risk to public safety.

3.4.1.2 NAVAL DEFENSIVE SEA AREA—OFFSHORE

The Naval Defensive Sea Area is a restricted area at Naval Station Pearl Harbor established by Executive Order 8143 of May 26, 1939 and controlled by the Navy. The Naval Defensive Sea Area encompasses areas where underwater training for HRC training and RDT&E activities would occur. Access to the area is restricted.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for the Naval Defensive Sea Area. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.2.1 Biological Resources—Naval Defensive Sea Area—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence includes the Naval Defensive Sea Area offshore waters.

Affected Environment

Vegetation

Seaweed is very abundant in the offshore areas as described in Section 3.4.1.1.1 (U.S. Department of the Navy, 2002a).

<u>Threatened and Endangered Plant Species</u>

No threatened or endangered plant species have been observed in the region of influence.

Wildlife

A fairly large spur-and-groove reef is found adjacent to the runway of the Honolulu International Airport and on the insular shelf beyond the fore reef. The reef is oriented east-west and is approximately 9,190 ft long and 1,770 ft wide. This reef extends further eastward from the airport area toward Waikiki Beach covering an approximate distance of 5.4 miles. Contrary to earlier data, moderately developed spur and groove reefs do occur on either side of the Naval Station Pearl Harbor entrance channel, including Tripod Reef and Ahua Reef. (U.S. Department of the Navy, 2005b)

A visual inspection of two proposed positions outside the Pearl Harbor channel entrance was performed as part of a Pearl Harbor West Loch reconnaissance survey in 2007. The preferred location for the Mobile Diving and Salvage Unit Training Area (Site B) was observed to be 85 percent hard bottom, 10 percent coral, and 5 percent shallow sand patches. The topography is flat at a depth of 65 ft. Site C was observed to be 24 percent hard bottom, 75 percent sand, and 1 percent coral. The topography of the site is flat at a depth of 45 ft. (National Oceanic and Atmospheric Administration Pacific Islands Region, 2007)

Coastal waters of the Ewa Plain receive nutrient rich water from springs below sea level. The nutrients in this water come from upland agricultural fertilization, leaching from cesspools and septic tanks, domestic waste injection wells, and urban application of fertilizers. These extra nutrients promote the growth of benthic algae (limu). A few species of reef fish are present in low numbers in the littoral waters. (U.S. Department of the Navy, 2002a)

Fish species are diverse and abundant and generally associated with the deeper (greater than 20 fathoms) areas containing coral coverage and vertical relief. This type of area has been designated by NOAA as HAPC. The most common families represented are surgeonfishes, butterflyfishes, damselfishes, wrasses, triggerfishes, and moorish idols. (U.S. Department of the Navy, 2002a) Section 3.1.2.2.1 includes a description of EFH; however, a detailed description, including status, distribution, and habitat preference of managed fisheries is available in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

Threatened and Endangered Species

Nine marine wildlife species listed as Federal and State threatened or endangered species (Table 3.4.1.1.1-1) are known or suspected to exist in Hawaiian waters and could transit through the Naval Defensive Sea Area. These species include the Hawaiian monk seal, blue whale, fin whale, humpback whale, sei whale, sperm whale, hawksbill turtle, green turtle, and loggerhead turtle. Section 3.1.2 includes a description of these listed species. (U.S. Department of the Navy, 2002a)

Transitory humpback whales are occasionally reported in the area outside of the Pearl Harbor Entrance Channel but are not resident in the area (Smith et al., 2006). Hawaiian monk seals are resident on Oahu and have been sighted near the Pearl Harbor Entrance Channel.

Environmentally Sensitive Habitat

No environmentally sensitive habitat has been identified within the region of influence.

3.4.1.2.2 Cultural Resources—Naval Defensive Sea Area—Offshore

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The cultural resources region of influence for the Naval Defensive Sea Area encompasses an underwater training area where Mobile Diving and Salvage Unit ONE can conduct military diving and salvage training.

Affected Environment

Underwater Cultural Resources

There are no known submerged archaeological resources within the Naval Defensive Sea Area region of influence (e.g., fishponds or shipwrecks).

3.4.1.2.3 Health and Safety—Naval Defensive Sea Area—Offshore

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for public health and safety includes the footprint of the Naval Defensive Sea Area and adjacent ocean areas.

Affected Environment

Naval Station Pearl Harbor is a restricted area. No vessels are allowed into Naval Station Pearl Harbor without permission of Commander Naval Region Hawaii. The restricted area extends outward from the mouth of the harbor and is defined by a rectangular-shaped boundary known as the Naval Defensive Sea Area. The Navy regulates recreational fishing and boating in Pearl Harbor, and allows active duty and retired military personnel in specified areas of the harbor for such purposes. Fishing from boats is limited to permitted vessels and to non-prohibited areas within Naval Station Pearl Harbor. Permission to enter Naval Station Pearl Harbor must be obtained in advance from Commander, Naval Station Pearl Harbor, Hawaii.

3.4.1.3 MARINE CORPS BASE HAWAII (MCBH)—OFFSHORE

MCBH is a 2,951-acre reservation on Mokapu Peninsula on the northeast side of the island of Oahu. The base is bounded by water on three sides: Kaneohe Bay, the Pacific Ocean, and Kailua Bay. MCBH Offshore includes areas used for HRC training 0 to 12 nm from MCBH (Figure 2.1-3).

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for MCBH Offshore. Of the 13 environmental resources considered for analysis, airspace, air quality, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.3.1 Biological Resources—MCBH—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence consists of the MCBH offshore areas.

Affected Environment

Vegetation

Seagrass (*Halophila ovalis*) is located in the Hale Koa Beach/West field area. At Fort Hase Beach, the seafloor is composed of a flat limestone platform dominated by brown algae (*Distyopteris australis*). (U.S. Department of the Navy, 2002a)

<u>Threatened and Endangered Plant Species</u>

No threatened or endangered plants have been observed offshore of MCBH.

Wildlife

The offshore area at Pyramid Rock Beach is composed primarily of sand and exposed, barren basalt with limited coral coverage by small colonies of cauliflower coral (*Pocillopora meandrina*). The Expeditionary Assault landing site is within an area with a wide sand channel that extends several hundred yards offshore. Sparse colonies of live coral (less than 10 percent coverage) occur in deeper waters offshore. (U.S. Department of the Navy, 2002a)

The following information on corals is summarized from the more extensive data provided in the *Marine Resources Assessment for the Hawaiian Islands Operating Area* (U.S. Department of the Navy, 2005b). In Kaneohe Bay a narrow reef crest is located approximately 0.5 nm offshore that consists of uncolonized pavement (Figure 3.4.1.3.1-1). Seaward of the reef crest a fore reef and slope are covered by colonized pavement. The colonized pavement is approximately 3.8 nm long and 1 nm wide running more or less parallel to the shoreline in a northwest to southeast direction. Aggregated coral heads are located on the back reef, and isolated patch reefs occur on the reef flat shoreward of the back reef. The patch reefs range in size from 230

Oahu, Hawaii

Figure 3.4.1.3.1-1

ft in diameter to an area of 2,953 ft by 1,968.5 ft. Three of the patch reefs encircle Kapapa Island, Ahu o Laka Island, and Mokuoloe Island. The largest patch reef encircles Mokuoloe Island. At the southern end of Kaneohe Bay off of Kokokahi and Keaalu, there are three narrow reefs (each approximately 131 ft wide) made of aggregated coral heads. The lengths of these reefs range from 1,148 to 2,297 ft. The back reef zone to the northeast of the Kaneohe Marine Corps Airfield contains three reefs made of aggregated coral heads located approximately 2,297 to 3281 ft from the shore and the reef farthest north measures approximately 328 ft by 1,640 ft. The other two reefs are relatively narrow (less than 98 to 328 ft wide and up to 4,593 ft long).

In 1998, the most common coral species within the Kaneohe Bay was *Porites compressa*, a species that since it is not wave resistant occurs in protected embayments. Other common coral species of Kaneohe Bay are *Montipora verrucosa*, *Pocillopora damicornis*, *Cyphastrea ocellina*, *Pavona varians*, and *Fungia scutaria*. The most common coral species on the seaward side of the barrier reef of Kaneohe Bay are *Porites lobata* and *Pocillopora meandrina*. Both species are resistant to high-energy environments; mean coral cover on the barrier reef ranges from 5 to 10 percent. In 2002, the overall range of coral cover at six sites of Kaneohe Bay was 2.5 percent to 67.5 percent.

Seabirds, including the great frigate bird (`iwa) and brown noddy have been seen foraging offshore. (U.S. Department of the Navy, 2002a)

Threatened and Endangered Wildlife Species

Threatened and endangered species known or expected to occur offshore of Marine Corps Base Hawaii are listed in Table 3.4.1.3.1-1. Threatened green turtles frequent the inshore waters at all three landing beaches, and are especially abundant in the Hale Koa Beach/West field area where they forage on seagrass (*Halophila ovalis*). The endangered Hawaiian monk seal occurs in the area. Migrating endangered humpback whales occur in deeper offshore waters during winter months, often coming close to shore at Pyramid Rock Beach. (U.S. Department of the Navy, 2002a)

Table 3.4.1.3.1-1. Listed Species Known or Expected to Occur Offshore of Marine Corps Base Hawaii

3.4.1.3.2 Cultural Resources—MCBH—Offshore

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

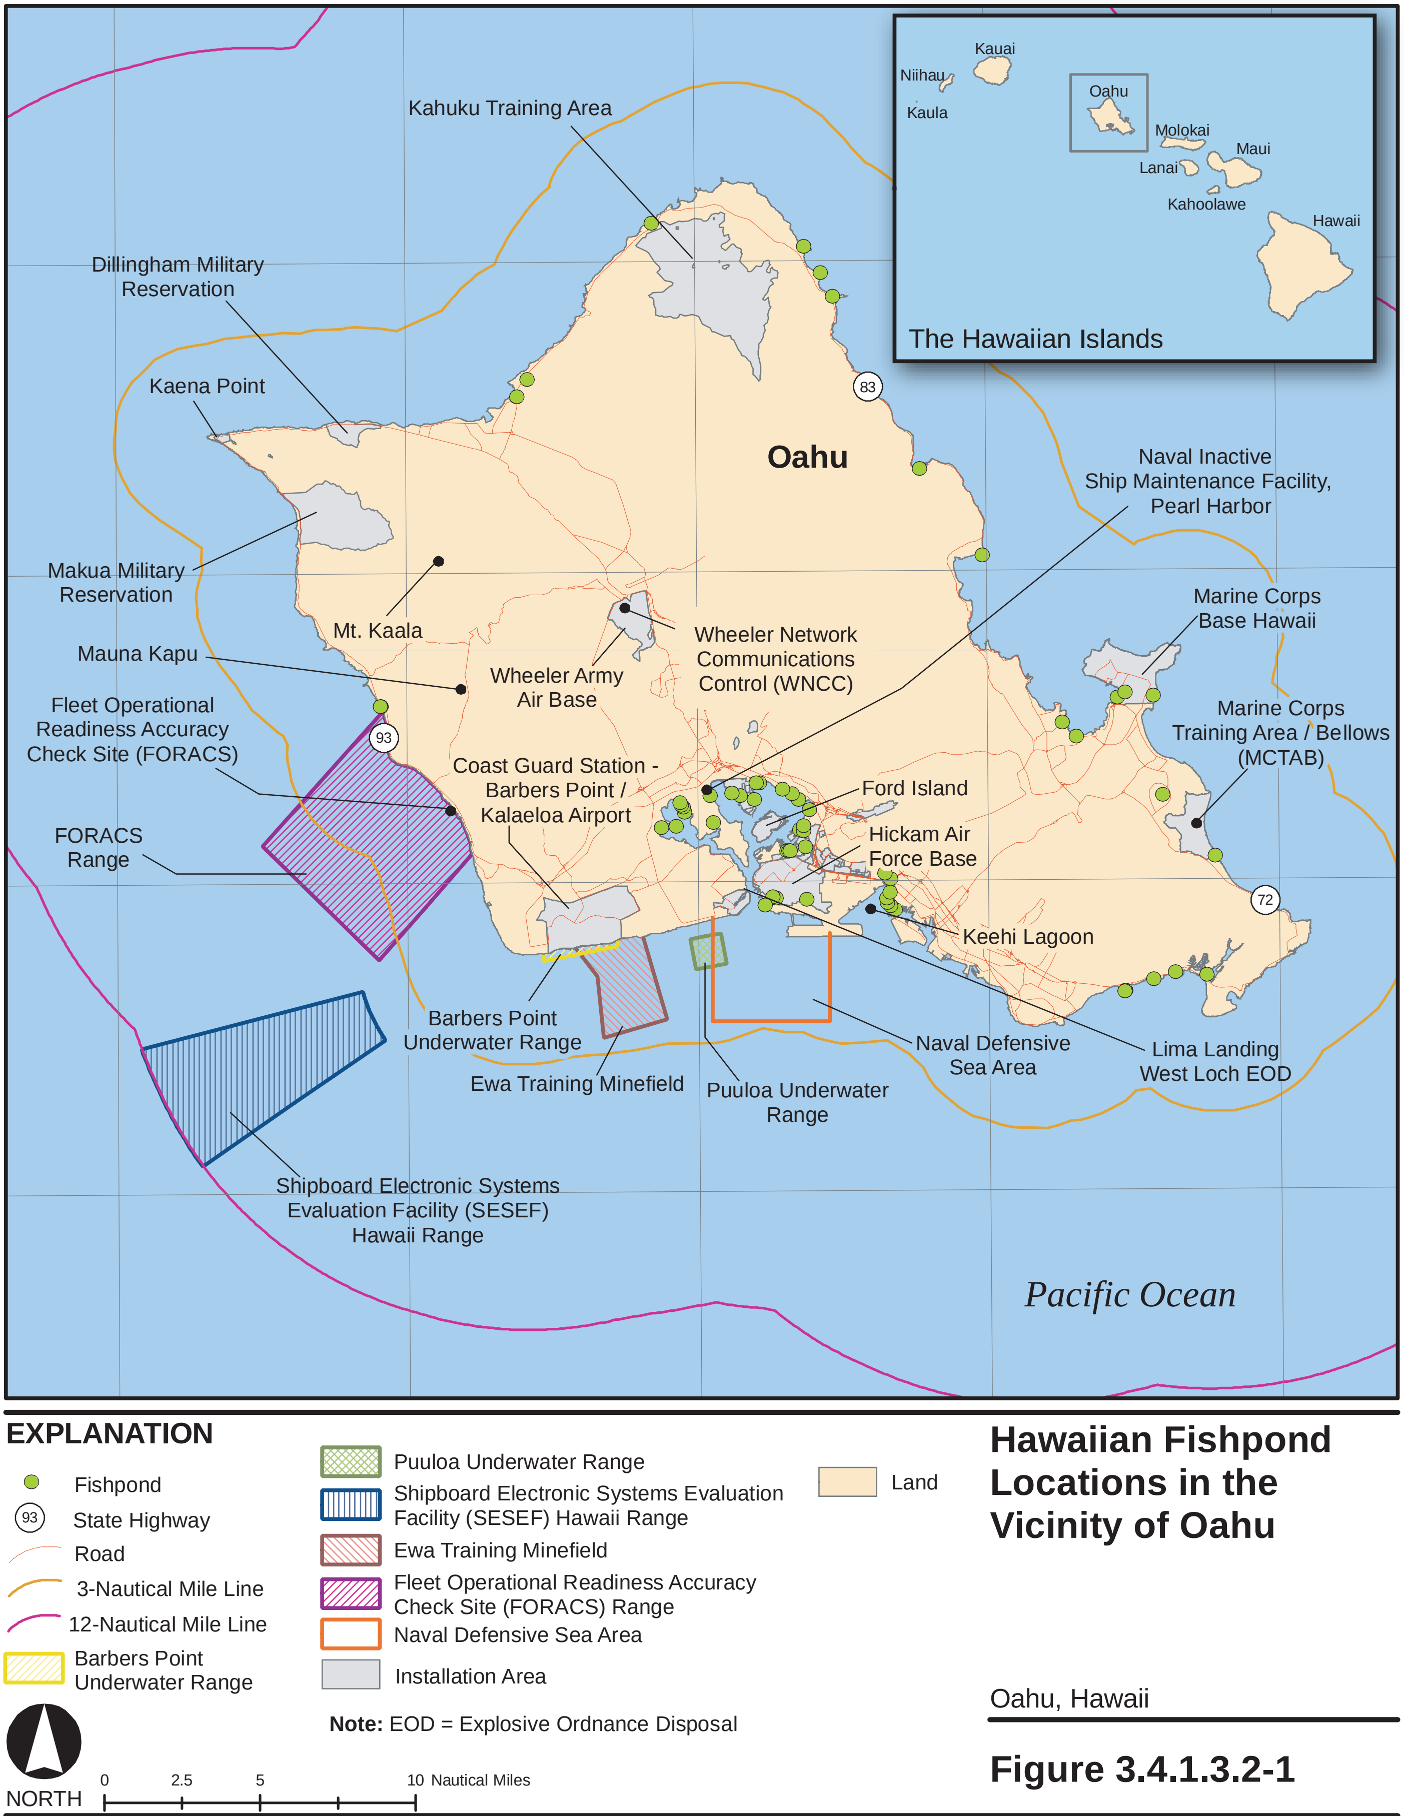
Region of Influence

The region of influence for cultural resources at MCBH encompasses locations where Humanitarian Assistance/Disaster Relief Operations will occur.

Affected Environment

Underwater Cultural Resources

Underwater archaeological resources within the offshore waters of MCBH include shipwrecks and several Hawaiian fishponds (see Figures 3.1.3-2 and 3.4.1.3.2-1).



Hawaiian Fishpond Locations in the Vicinity of Oahu

Oahu, Hawaii

Figure 3.4.1.3.2-1

3.4.1.4 MARINE CORPS TRAINING AREA/BELLOWS (MCTAB)—OFFSHORE

MCTAB covers 1,078 acres on the southeastern portion of Oahu. The inactive airfield in the center of the site is limited to rotary wing activity, and is occasionally used for U.S. Marine Corps helicopter training. MCTAB Offshore includes areas used for HRC training 0 to 12 nm from MCTAB (Figure 2.1-3).

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for MCTAB. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.4.1 Biological Resources—MCTAB—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence consists of the MCTAB offshore areas.

Affected Environment

Vegetation

Threatened and Endangered Plant Species

No threatened or endangered plants have been observed offshore of MCTAB.

Wildlife

There are no live coral colonies in the offshore areas as a result of redistribution of sand and scouring caused by wave action. The seafloor out to a distance of 492 ft from the beach consists of a sand flat, beyond which a low-relief fossil reef platform becomes interspersed with the sand. The outer barrier reef crest (see Figure 3.4.1.3.1-1) is an actively accreting coral reef habitat comprising predominantly the genera *Pocillopora, Porites, and Montipora*. There are two well-defined sand channels that extend from the shoreline through the barrier reef to the open ocean beyond. (U.S. Department of the Navy, 2002a) Section 3.1.2.2.1 includes a description of EFH; however, a detailed description, including status, distribution, and habitat preference of managed fisheries, is provided in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

Threatened and Endangered Wildlife Species

Threatened and endangered species known or expected to be in offshore MCTAB are the same as those listed in Table 3.4.1.3.1-1. Green turtles occur frequently in the offshore water. Also occasionally feeding in these waters are hawksbill turtles (U.S. Department of the Navy, 2005b). Hawaiian monk seals have been sighted in the area (U.S. Department of the Navy, 2005b). Waimanalo Bay is expected to be too shallow for whales, such as the humpback whale, which winters in the Hawaiian Islands. However, it is possible that an occasional humpback whale could use Waimanalo Bay. (U.S. Pacific Command, 1995)

3.4.1.4.2 Cultural Resources—MCTAB—Offshore

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for underwater cultural resources at MCTAB includes locations where Expeditionary Assault (amphibious training), Mine Neutralization, Swimmer Insertion/Extraction, and SPECWAROPS would occur (see Figure 2.1-3).

Affected Environment

Underwater Cultural Resources

Offshore features within the region of influence for MCTAB include a shoreline burial complex (Site 4854) and several Hawaiian fishponds (Figure 3.4.1.3.2-1) (U.S. Army Corps of Engineers, Honolulu Engineer District, 2005). As shown on NOAA maps, there are also several shipwrecks in the MCTAB vicinity (Figure 3.1.3-2).

3.4.1.5 MAKUA MILITARY RESERVATION—OFFSHORE

Makua Military Reservation is a Department of the Army reservation containing a total of 4,190 acres in the Makua Valley on the northwestern side of Oahu. Makua Military Reservation extends from the Farrington Highway along the west coast eastward to the ridgeline of the Waianae Mountains. Makua Military Reservation Offshore includes areas used for HRC training 0 to 12 nm from Makua Military Reservation (Figure 2.1-3).

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Makua Military Reservation. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.5.1 Biological Resources—Makua Military Reservation—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence consists of the Makua Military Reservation offshore areas.

Affected Environment

Vegetation

Threatened and Endangered Plant Species

No threatened or endangered plants have been observed offshore of Makua Military Reservation.

Wildlife

The National Centers for Coastal Ocean Science/NOAA benthic habitat maps show no coral reefs along the western side of Oahu from the Naval Reservation to the Makua Military Reservation. (U.S. Department of the Navy, 2005b)

Non-listed marine mammals present in the region of influence include the bottlenose dolphin, spotted dolphin, and spinner dolphin, which are common along the coastline (U.S. Department of the Navy, 2005b; U.S. Department of the Army, 2005). Spinner dolphins are regularly seen in Makua Bay where they use the sandy-bottom habitat for resting and socializing (National Marine Fisheries Service, 2007a).

Threatened and Endangered Wildlife Species

Threatened and endangered species known or expected to occur offshore of Makua Military Reservation are the same as those provided in Table 3.4.1.3.1-1, with the exception of the leatherback turtle. The only threatened and endangered marine mammals potentially present in the region of influence are the Hawaiian monk seal and the humpback whale (U.S. Department of the Navy, 2005b). Of the five species of sea turtles that occur in Hawaiian waters, only the green turtle, hawksbill turtle, and rarely the leatherback turtle (which prefers deep ocean water) are likely to be in the region of influence (U.S. Department of the Army, 2005).

3.4.1.5.2 Cultural Resources—Makua Military Reservation—Offshore

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The cultural resources region of influence for Makua Military Reservation encompasses all areas where Live Fire Exercise (LFX) events (including major ground troop and artillery movement and munitions detonation [e.g., mortars, heavy artillery]) could be conducted (see Figure 2.1-3).

Affected Environment

Underwater Cultural Resources

Underwater archaeological resources within the offshore Makua Military Reservation region of influence include several shipwrecks (see Figure 3.1.3-2).

3.4.1.6 DILLINGHAM MILITARY RESERVATION—OFFSHORE

Dillingham Military Reservation is a 664-acre training area with a beach and an airfield on the northwestern shore of Oahu. It is on a narrow, sloping plain between the Waianae Range and the sea. Dillingham Military Reservation Offshore includes areas used for HRC training 0 to 12 nm from Dillingham Military Reservation (Figure 2.1-3).

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Dillingham Military Reservation. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.6.1 Biological Resources—Dillingham Military Reservation—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence consists of the Dillingham Military Reservation offshore areas.

Affected Environment

Vegetation

Threatened and Endangered Plant Species

No threatened or endangered plants have been observed offshore of Dillingham Military Reservation.

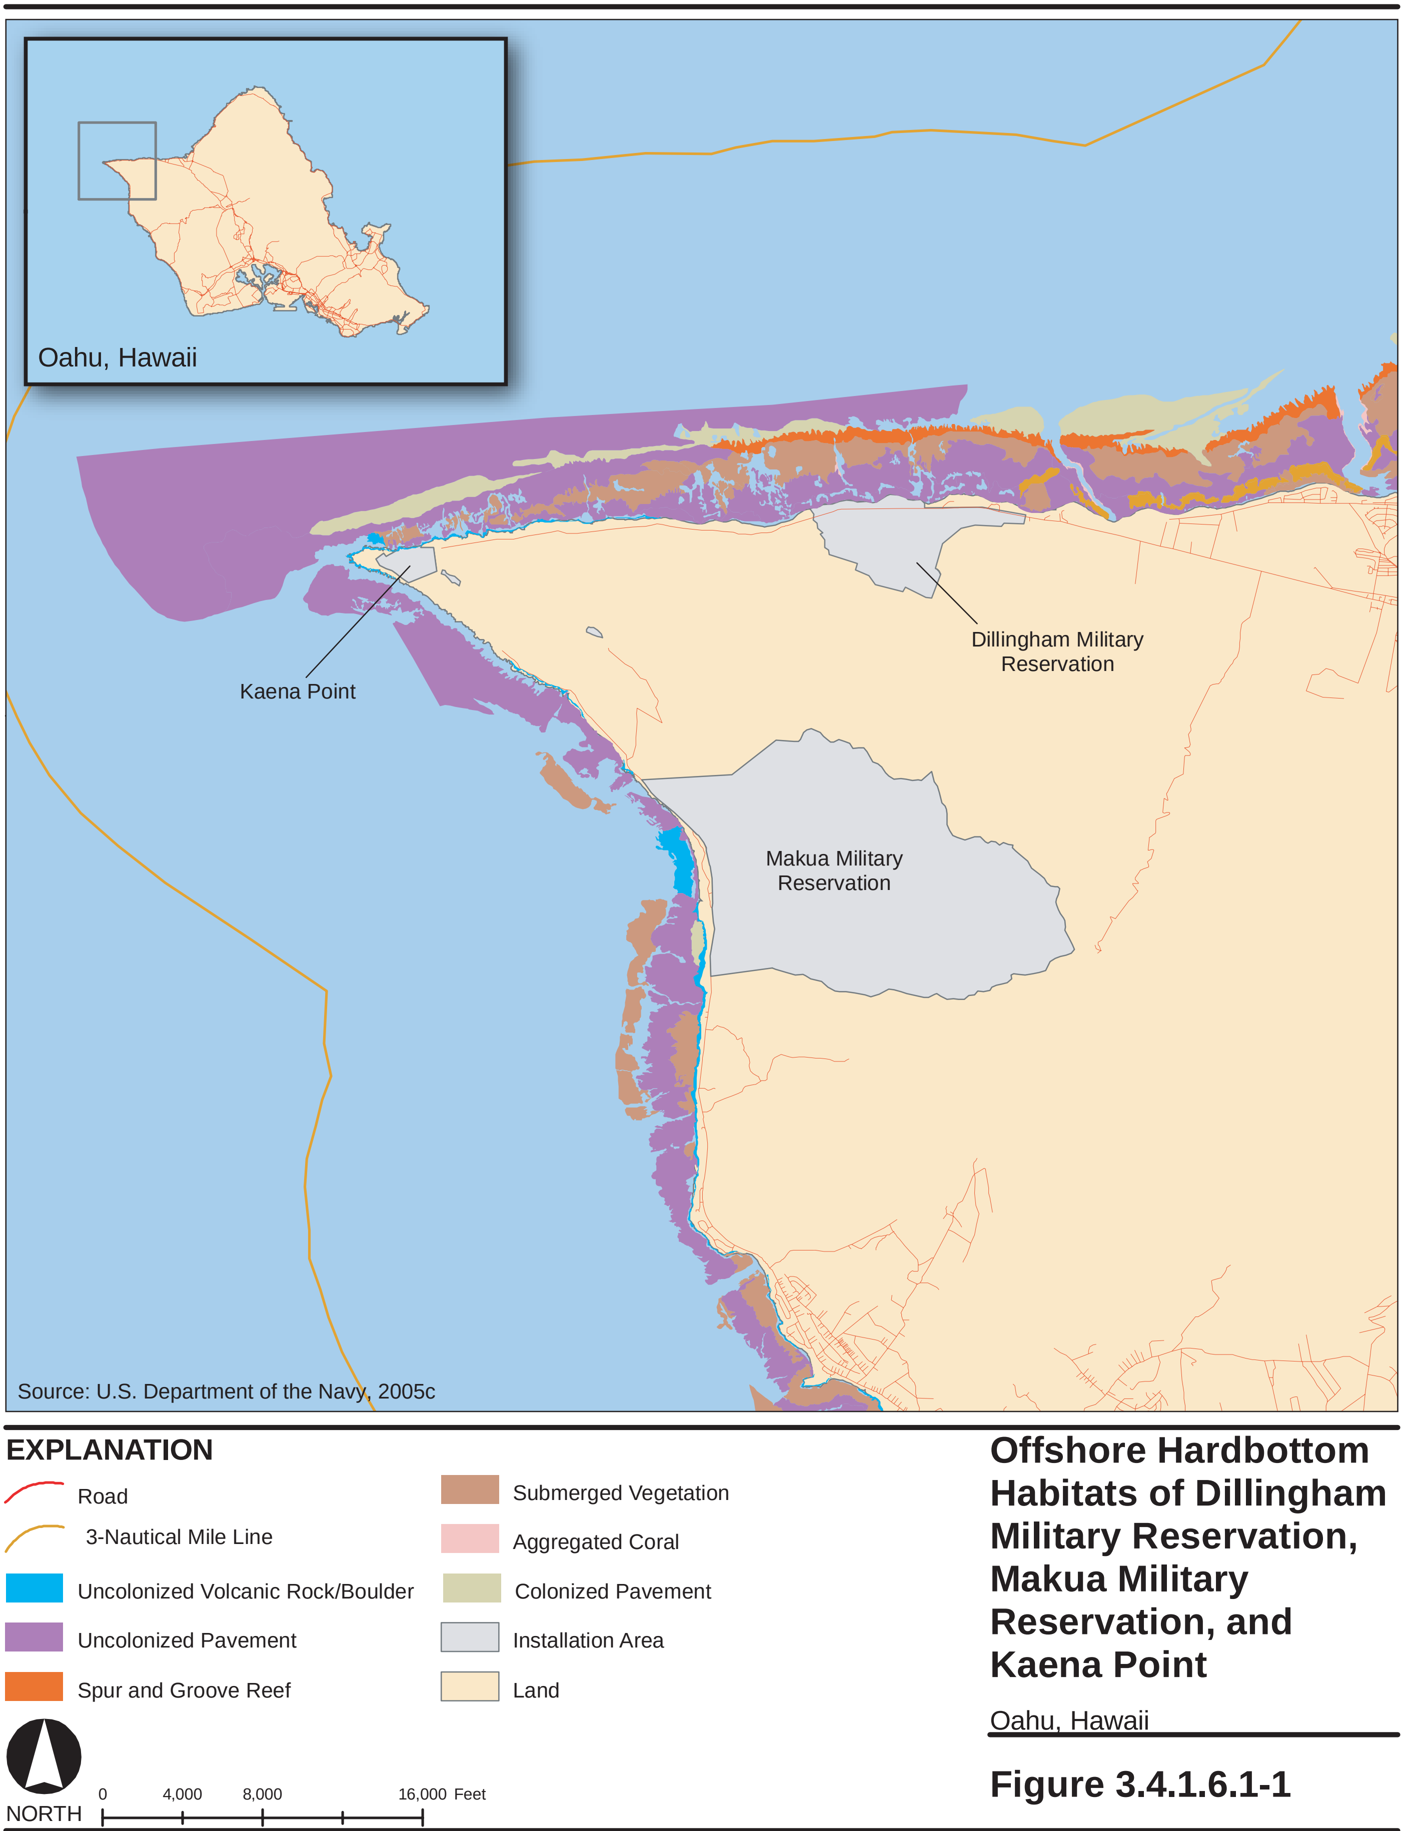
Wildlife

There are coral reefs within 0.5 mile (mi) of the shoreline. Spur-and-groove reefs are found along the northern shoreline of Oahu (from Dillingham Airfield to Kaena Point) (Figure 3.4.1.6.1-1). There are no specific coral reefs of management concern. (U.S. Department of the Army, 2004)

Non-listed marine mammals potentially present in the region of influence include the bottlenose dolphin, spotted dolphin, and spinner dolphin, which are common along the coastline (U.S. Department of the Army, 2004).

Threatened and Endangered Wildlife Species

Threatened and endangered species known or expected to occur offshore of Dillingham Military Reservation are the same as those listed in Table 3.4.1.3.1-1. Since Dillingham Military Reservation is adjacent to a small segment of beachfront, a portion of the region of influence extends to the offshore waters. This area is outside the Hawaiian Islands Humpback Whale National Marine Sanctuary. The humpback whale and several dolphin species are marine mammals most likely to be present in the region of influence (U.S. Department of the Navy, 2005b). The Hawaiian monk seal is likely to occur since the area of Kaena Point is used by monk seals to haul-out, pup, and rear young (National Marine Fisheries Service, 2007a). No



Offshore Hardbottom Habitats of Dillingham Military Reservation, Makua Military Reservation, and Kaena Point

Oahu, Hawaii

Figure 3.4.1.6.1-1

sea turtle nesting has been observed in the region of influence, although the green turtle is expected to occur in the region of influence. (U.S. Department of the Army, 2004)

3.4.1.6.2 Cultural Resources—Dillingham Military Reservation—Offshore

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The cultural resources region of influence for Dillingham Military Reservation encompasses areas where Navy and Marine Corps SPECWAROPS under the Rim of the Pacific (RIMPAC) Exercise and small unit maneuvers by the Army occur (e.g., reconnaissance insertions and search and rescue). (See Figure 2.1-3.)

Affected Environment

Underwater Cultural Resources

Underwater archaeological resources within the offshore Dillingham region of influence include scattered shipwrecks.

3.4.1.7 EWA TRAINING MINEFIELD—OFFSHORE

Ewa Training Minefield is an offshore area extending from Ewa Beach approximately 2 nm toward Barbers Point, and out to sea approximately 4 nm (Figure 2.1-3). This area is defined and restricted by 33 Code of Federal Regulations (CFR) 334.1400 and has been used for surface ship mine avoidance training.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Ewa Training Minefield. Of the 13 environmental resources considered for analysis, air quality, airspace, cultural resources, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.7.1 Biological Resources—Ewa Training Minefield—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence is the area that can be affected by mine avoidance training.

Affected Environment

Vegetation

The Ewa Beach area is a popular seaweed harvesting area on Oahu (U.S. Department of the Navy, 2002a).

Threatened and Endangered Plant Species

No threatened or endangered plant species have been identified in the region of influence.

Wildlife

Organisms offshore of Ewa Beach include corals, several species of sea cucumber, sea urchins, and colonial soft corals. A few species of reef fish are also present in low numbers in the littoral waters. A benthic survey conducted in 2001 indicated that corals were locally abundant on the northern inshore reef slope at Ewa Beach (Figure 3.4.1.1.1-1). (U.S. Department of the Navy, 2002a) Section 3.1.2.2.1 includes a description of EFH; however, a detailed description, including status, distribution, and habitat preference of managed fisheries is provided in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

Threatened and Endangered Wildlife Species

Green turtles are common in the region of influence. Threatened and endangered species potentially occurring in the region of influence would be the same as those listed in Table 3.4.1.1.1-1.

Environmentally Sensitive Habitat

No environmentally sensitive habitat has been identified.

3.4.1.7.2 Hazardous Materials and Waste—Ewa Training Minefield—Offshore

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and wastes includes the range and adjacent ocean waters.

Affected Environment

Ewa Training Minefield is an ocean area extending from Ewa Beach approximately 2 nm toward Barbers Point, and out to sea approximately 4 nm. This restricted area has been used in the past for surface ship mine avoidance training. Although the area is not used for this training mission, the Navy may use it in the future, and retains control over it. No hazardous materials are used on this range, and no hazardous wastes are normally generated. Bottom sediments within the range may harbor some residual contamination from past uses of the area.

3.4.1.7.3 Health and Safety—Ewa Training Minefield—Offshore

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for public health and safety includes the footprint of the range and adjacent ocean areas.

Affected Environment

Because there are no current public health and safety concerns, there are no restrictions on commercial or recreation activities at Ewa Beach. Ocean activities occurring at Ewa Beach include netting, fishing, tropical fish collecting, surfing, scuba diving, paddling, kayaking, and shelling. A commercial net pen cage aquaculture site is located near the western range boundary (U.S. Department of the Navy, 2000).

3.4.1.8 BARBERS POINT UNDERWATER RANGE—OFFSHORE

The Barbers Point Underwater Range is a restricted area established by 33 CFR 334. The range encompasses a narrow offshore strip water directly in front of the U.S. Coast Guard Air Station/Kalaeloa Airport. The Barbers Point Underwater Range includes areas used for HRC training (Figure 2.1-3).

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Barbers Point Underwater Range. Of the 13 environmental resources considered for analysis, air quality, airspace, cultural resources, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.8.1 Biological Resources—Barbers Point Underwater Range—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence includes the underwater range and adjacent waters.

Affected Environment

Vegetation

Seaweed is abundant in the offshore areas (U.S. Department of the Navy, 2002a).

Threatened and Endangered Plant Species

No threatened or endangered plant species have been observed in the region of influence.

Wildlife

Biological resources are similar to those described previously for the Puuloa Underwater Range (Section 3.4.1.1.1). A variety of whales and dolphins not listed as threatened or endangered are found around the Hawaiian Islands, including the minke whale and Bryde's whale. Spinner dolphin, spotted dolphin, bottlenose dolphin, short finned pilot whale, false killer whale, and sperm whale are seen in the area most frequently. (U.S. Department of the Navy, 2002a)

Coral coverage ranges from 80 to 90 percent at depths between 9.7 and 13 fathoms to less than 1 percent in water depths from 13 to 20 fathoms. The coral community (Figure 3.4.1.1.1-1) is dominated by *Pocillopora meandrina*, *Porites lobata,* and *Porites compressa*. (U.S. Department of the Navy, 2002a)

The most common fish families represented are surgeonfishes (acanthurids), butterflyfishes (chaetodontids), damselfishes (pomacentrids), wrasses (labrids), triggerfishes (balistids) and moorish idols (zanclids) (U.S. Department of the Navy, 2002a). Section 3.1.2.2.1 includes a description of EFH; however, a detailed description, including status, distribution, and habitat preference of managed fisheries, is provided in the Navy's *Final Essential Fish Habitat and*

Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS (U.S. Department of the Navy, 2007a).

Threatened and Endangered Species

Threatened and endangered species known or expected to occur in the vicinity of Barbers Point Underwater Range are the same as those listed in Table 3.4.1.1.1-1. Nine marine wildlife species listed as Federal and State threatened or endangered species are known or suspected to exist in Hawaiian waters, although the offshore environment may be too shallow for frequent use. These species include the Hawaiian monk seal, blue whale, fin whale, humpback whale, sei whale, sperm whale, hawksbill turtle, green turtle, and loggerhead turtle. A description of these listed species is provided in Section 3.1.2. (U.S. Department of the Navy, 2002a)

Environmentally Sensitive Habitat

No environmentally sensitive habitat has been identified.

3.4.1.8.2 Hazardous Materials and Waste—Barbers Point Underwater Range—Offshore

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and wastes includes the range and adjacent ocean waters and shoreline.

Affected Environment

Barbers Point Underwater Range comprises a narrow strip of offshore ocean that directly fronts the entire southern boundary of the former Naval Air Station Barbers Point. Naval Air Station Barbers Point was closed as part of the Base Realignment and Closure in July 1998 and renamed the Kalaeloa Airport. The northern range boundary is the high-water mark of the beach at Kalaeloa Airport. It aligns with what was once the station boundary of the closed Naval Air Station Barbers Point. The U.S. Coast Guard Air Station Barbers Point is across the street from the beach and covers a third of the shore of the original installation. No hazardous materials are used on this range, and no hazardous wastes are normally generated. Bottom sediments within the range may harbor some residual contamination from past uses of the area.

3.4.1.8.3 Health and Safety—Barbers Point Underwater Range—Offshore

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for public health and safety includes the range and adjacent shore and ocean areas.

Affected Environment

Currently there are no public health and safety concerns at Barbers Point Underwater Range. Therefore beach activities, including netting, fishing, topical fish collecting, surfing, scuba diving, paddling, kayaking, and shelling, are not constrained.

3.4.1.9 NAVAL UNDERSEA WARFARE CENTER (NUWC) SHIPBOARD ELECTRONIC SYSTEMS EVALUATION FACILITY (SESEF)—OFFSHORE

The NUWC SESEF range, located off Barbers Point on Oahu (Figure 2.1-3), provides state-of-the-art testing and evaluation of combat systems which emit or receive electromagnetic radiation (EMR). Ships operate and maneuver in this area as necessary to remain within electronic signal reception range of the Fleet Technical Evaluation Center onshore. Offshore RDT&E activities associated with SESEF include the SESEF Quick Look Tests and the SESEF System Performance Tests.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for SESEF. Of the 13 environmental resources considered for analysis, airspace, air quality, cultural resources, geology and soils, hazardous materials and hazardous waste, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.9.1 Biological Resources—SESEF—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence is the ocean area that could be affected by RDT&E activities.

Affected Environment

Wildlife

Wildlife in the SESEF range would be to the same as those discussed in Section 3.1.2, Biological Resources (Marine)—Open Ocean Area.

<u>Threatened and Endangered Wildlife Species</u>

Threatened and endangered species would be the same as those discussed in Section 3.1.2, Biological Resources (Marine)—Open Ocean Area.

Environmentally Sensitive Habitat

Environmentally sensitive habitat would be to the same as that discussed in Section 3.1.2, Biological Resources (Marine)—Open Ocean Area.

3.4.1.9.2 Health and Safety—SESEF—Offshore

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for public health and safety includes the footprints of the range and adjacent ocean areas.

Affected Environment

Land areas associated with NUWC ranges are minimal and are for range operations facilities only. NUWC's SESEF area provides state-of-the-art testing and evaluation of combat systems which emit or receive EMR. At present, an average of about 3,910 events—or about 15 per day—take place on the SESEF range.

The potential public health risks of these training events include public exposure to excessive densities of EMR. The potential public safety risks include conflicts between Navy vessels and other vessels on the range.

The sea space where SESEF tests are conducted is unrestricted and is not controlled by NUWC or the Navy. Ships underway for SESEF tests maintain safe separation from other vessels without direct control by SESEF operators.

Communications and electronic devices such as radar, electronic jammers, and other radio transmitters produce EMR. Equipment that produces an electromagnetic field has the potential to generate hazardous levels of EMR. An EMR hazard exists when transmitting equipment generates electromagnetic fields that induce currents or voltages great enough to trigger electro-explosive devices in ordnance, cause harmful effects on people or wildlife, or create sparks that can ignite flammable substances in the area.

EMR fields generally decrease rapidly in intensity with increasing distance from the source, so hazards are reduced or eliminated by establishing minimum distances from EMR emitters for people, ordnance, and fuels. Furthermore, ground-level EMR levels that are generally safe for military personnel aboard ship for long-term exposure are generally safe for transient exposure of individuals at greater distances from the source. Thus, EMR emissions from Navy vessels conducting RDT&E activities on the NUWC ranges are not a public health concern.

NUWC's SESEF area provides state-of-the-art testing and evaluation of combat systems which radiate or receive electromagnetic energy. The sea space where SESEF tests are conducted is unrestricted and is not controlled by NUWC or the Navy. Ships underway for SESEF tests maintain safe separation from other units without direct control by SESEF operators. If the range is fouled by non-participants, the NUWC Range Control Officer determines if and when range operations can continue.

3.4.1.10 NAVAL UNDERSEA WARFARE CENTER (NUWC) FLEET OPERATIONAL READINESS ACCURACY CHECK SITE (FORACS)—OFFSHORE

The offshore area where NUWC FORACS tests are conducted is unrestricted and is not controlled by NUWC or the Navy (Figure 2.1-3). The NUWC Range Control Officer conducts visual lookout and radar searches of the FORACS range to identify any transient, non-participating vessels.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for FORACS. Of the 13 environmental resources considered for analysis, air quality, airspace, cultural resources, geology and soils, hazardous materials and hazardous waste, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.1.10.1 Biological Resources—FORACS—Offshore

Section 3.1.2 provides a detailed description of marine biological resources.

Region of Influence

The region of influence is that area of the range that could be affected by current or proposed RDT&E activities.

Affected Environment

Vegetation

A filamentous green algae (*Neomeris annulata)* that grows upright is common over wide areas of sandy substrate at depths between about 12.5 and 15 fathoms (Commander in Chief Pacific Fleet, 2001).

<u>Threatened and Endangered Plant Species</u>

No threatened or endangered plants have been identified in the region of influence.

Wildlife

Inshore areas at depths of about 7 to 12 fathoms have a modestly diverse coral community. *Pocillopora meandrina*, *Porites lobata,* and *Porites compressa* are dominant species of coral. Coral coverage (Figure 3.4.1.10.1-1) declines markedly at depths below 12.5 fathoms with gently sloping sand flats. (Commander in Chief Pacific Fleet, 2001)

Fish are generally rare, except where a coral colony or ocean floor debris provides habitat. The Hawaiian dascyllus is often abundant in these areas. Small schools of pennantfish, Hawaiian cleaner wrasses, Moorish idols, damselfish, and surgeonfish are also present. Common invertebrates include black sea urchins and sea cucumbers. (Commander-in-Chief Pacific Fleet, 2001)

Offshore Hardbottom Habitats Near Fleet Operational Readiness Accuracy Check Site

Oahu, Hawaii

Figure 3.4.1.10.1-1

A detailed description, including status, distribution, and habitat preference of managed fisheries, is provided in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

A variety of whales and dolphins not listed as threatened or endangered are found around the Hawaiian Islands, including the minke whale and Bryde's whale. Spinner dolphin, spotted dolphin, bottlenose dolphin, short finned pilot whale, false killer whale, and sperm whale are seen in the area most frequently. (U.S. Department of the Navy, 2002a)

<u>Threatened and Endangered Wildlife Species</u>

Green turtles are abundant in the area and frequently use caves and ledges along the fringing reef as resting areas (Commander-in-Chief Pacific Fleet, 2001). Nine marine wildlife species listed as Federal and State threatened or endangered species are known or suspected to exist in Hawaiian waters. These species include the Hawaiian monk seal, blue whale, fin whale, humpback whale, sei whale, sperm whale, hawksbill turtle, green turtle, and loggerhead turtle. A description of these listed species is provided in Section 3.1.2. (U.S. Department of the Navy, 2002a)

Environmentally Sensitive Habitat

No environmentally sensitive habitat has been identified.

3.4.1.10.2 Health and Safety—FORACS—Offshore

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for public health and safety includes the footprints of the range and adjacent ocean areas.

Affected Environment

Land areas associated with Naval NUWC ranges are minimal and are for range operations facilities only. At present, an average of about five events per year take place on the FORACS range.

The sea space where FORACS tests are conducted is unrestricted and is not controlled by NUWC or the Navy. The NUWC Range Control Officer conducts visual lookout and radar searches of the FORACS range to identify any transient, non-participating vessels. If the range contains non-participants, the NUWC Range Control Officer determines if and when range operations can continue. These measures have proved adequate for safe operation of the ranges, and the potential for public safety effects from current training on the NUWC ranges is considered to be negligible.

The potential health risks of these training events include exposure to excessive densities of EMR. As discussed in Section 3.4.1.9.2, EMR emissions from Navy vessels conducting RDT&E activities on the NUWC ranges are not a public health concern.

3.4.2 OAHU ONSHORE

3.4.2.1 NAVAL STATION PEARL HARBOR

Naval Station Pearl Harbor, on the southern shore of the island of Oahu, is a natural water body divided into three lochs by the Waipio and Pearl City peninsulas: West Loch, Middle Loch, and East Loch. Naval Station Pearl Harbor (Figure 2.1-3) encompasses land along the eastern and southern shorelines of East Loch and Ford Island under the Navy's exclusive control. A major portion of the operational area at Naval Station Pearl Harbor is used for maintenance and supply/storage largely located adjacent to ship berthing and repair areas.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Naval Station Pearl Harbor. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, transportation, utilities, and water resources are not addressed.

3.4.2.1.1 Biological Resources—Naval Station Pearl Harbor

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes the land area and waters adjacent to Naval Station Pearl Harbor that could be affected by current and proposed training.

Affected Environment

Vegetation

Exotic imported grasses and trees maintained by intensive landscaping efforts make up the majority of the vegetative community at Naval Station Pearl Harbor. Native vegetation, including grasses, trees, and shrubs, is present only in small areas. These areas of native vegetation provide erosion control except during the heaviest rainfall.

Vegetation along the shoreline and the intertidal zone is dominated by pickleweed (*Batis maritima*) and the alien red mangrove (*Rhizophora mangle*) at the heads of the three lochs. Red mangrove has been successful because there are no mangrove predators, herbivores and insects, or diseases. (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a)

<u>Threatened and Endangered Plant Species</u>

No threatened and endangered plant species have been identified at Naval Station Pearl Harbor. Recently, three endangered plants, ko`oloa`ula (*Abutilon menziesii*), ohai (*Sesbania tomentosa*), and loulu (*Pritchardia kaalae*) were established as mitigation for past projects at the Honouliuli Unit of the Pearl Harbor National Wildlife Refuge. These three plants are at least 3 mi from the EOD Land Range and Lima Landing, the closest facilities along West Loch.

Wildlife

Fish and wildlife on and in the waters off of Naval Station Pearl Harbor are managed through its Integrated Natural Resources Management Plan in cooperation with the U.S. Fish and Wildlife Service (USFWS) and the State of Hawaii. Feral dogs (*Canis familiaris*) and cats (*Felis catus*), mongooses (*Herpestes javanicus*), and rodents are present throughout the region of influence. The majority of forest birds at Naval Station Pearl Harbor are exotic or introduced species. The common myna (*Acridotheres tristis*), red-vented bulbul (*Pycnonotus cafer*), Japanese white-eye (*Zosterops japonicus*), house finch (*Carpodacus mexicanus*), and zebra dove (*Geopelia striata*) are among the most common. The State-threatened white tern (*Gygis alba rothschildi*) and the State-endangered pueo *(Asio flammeus sandwichensis)* are occasionally found in the Naval Station Pearl Harbor vicinity. (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a)

One resident indigenous bird, the black-crowned night heron (`auku`u) (*Nycticorax nycticorax*), and 46 migratory species occur in the Naval Station Pearl Harbor area. The migratory birds are dominated by wading birds including the wandering tattler (*Heteroscelus incanus*), ruddy turnstone (*Arenaria interpes*), and Pacific golden plover (*Pluvialis fulva*). (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a)

Introduced species of crustaceans, insects, fish, amphibians, and birds dominate the wildlife of Naval Station Pearl Harbor's wetlands, estuaries, springs, and the lowest reaches of streams. The numbers of native *Megalagrion* damselflies and the native o`opu nakea (goby) (*Awaous guamensis*) have been declining. Approximately 90 percent of the sea floor of the harbor is considered soft bottom with a layer of terrigenous (derived primarily from erosive action on land) mud and/or calcareous (composed of, containing, or resembling calcium carbonate, calcite, or chalk) sand. The remaining 10 percent is considered hard bottom, the limestone platform (Figure 3.4.1.1.1-1). (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a)

The following information on corals is summarized from the more extensive data provided in the *Marine Resources Assessment for the Hawaiian Islands Operating Area* (U.S. Department of the Navy, 2005b). Considerable reef development occurs in embayments and sheltered areas on Oahu including Kaneohe Bay and Hanauma Bay (Figure 3.4.1.1.1-1). Sediment-laden runoff and polluted runoff have impacted reefs of Oahu, specifically Pearl Harbor and Kaneohe Bay.

No reefs are shown along the southeastern end of the island (Kaloko to Wailea Point) (Figure 3.4.1.1.1-1). Fringing reefs are well developed on the southern side of Oahu from the Wailupe Peninsula to Kawaihoa Point and Hanauma Bay, while west of Kawaihoa Point, fringing reefs as well as spur-and-groove reefs are well developed. Other spur-and-groove reefs are found along the southern coastline (Wailupe Peninsula to Honolulu International Airport). (U.S. Department of the Navy, 2005b)

According to the National Centers for Coastal Ocean Science/NOAA, no coral reefs occur to the west of the airport runway, along the shoreline of the Fort Kamehameha Military Reservation, Hickam AFB, the Naval Reservation, or within Naval Station Pearl Harbor (Figure 3.4.1.1.1-1). Contrary to the National Centers for Coastal Ocean Science data, moderately developed spur and groove reefs do occur on either side of the Pearl Harbor entrance channel, including Tripod Reef and Ahua Reef. Tripod Reef is a spur-and-groove system where average coral cover is approximately 40 percent, and live coral cover on Ahua Reef is 40 percent, but in some parts of the reef, coral cover reaches 80 percent. Five species of stony corals occur within Pearl

Harbor: *Pocillopora damicornis*, *P. meandrina*, *Porites compressa*, *Leptastrea purpurea*, and *Montipora patula*. In 1996, the most common coral in Pearl Harbor was *L. purpurea,* and corals were most abundant at the entrance of the West Loch Channel. (U.S. Department of the Navy, 2005b)

A detailed study in 1974 found 90 species of fish in Pearl Harbor (Evans, et al., 1974). Some of the commercially important species are ama`ama (grey mullet) (*Mugil cephalus*), awa (milkfish) (*Chanos chanos*), o`io (bonefish) (*Albula vulpes*), kaku (barracuda) (*Sphyraena barracuda*), nenue (chub) (*Kyphosus* sp.), menpachi (soldierfish) (*Myripristis* spp.), and papio (jacks) (*Carangoides* spp.). Pearl Harbor appears to be very important in the life cycle of the scalloped hammerhead shark (*Sphyrna lewini*). All waters around Naval Station Pearl Harbor have been designated as EFH for eggs and larvae of a number of species. The harbor has not been designated as a HAPC. (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a)

Threatened and Endangered Wildlife Species

Four Federally endangered waterbirds (Table 3.4.2.1.1-1) are recognized as occurring on Naval Station Pearl Harbor: koloa maoli (Hawaiian duck) (*Anas wyvilliana)*, `alae ke`ok`o (Hawaiian coot) (*Fulica alai)*, alae ula (Hawaiian common moorhen) (*Gallinula chloropus sandvicensis)*, and ae`o (Hawaiian black-necked stilt) (*Himantopus mexicanus knudseni)*.

Table 3.4.2.1.1-1. Listed Species Known or Expected to Occur at Naval Station Pearl Harbor

Scientific Name	Common Name (Hawaiian Name)	Federal Status
Reptiles/Mammals		
Chelonia mydas	Green turtle	T
Lasiurus cinereus semotus	Hawaiian hoary bat	E
Monachus schauinslandi	Hawaiian monk seal	E
Birds		
Anas wyvilliana	Koloa maoli (Hawaiian duck)	E
Fulica alai	`Alae ke`oke`o (Hawaiian coot)	E
Gallinula chloropus sandvicensis	Alae ula (Hawaiian common moorhen)	E
Himantopus mexicanus knudseni	Ae`o (Hawaiian black-necked stilt)	E
Pterodroma phaeopygia sandwichensis	`Ua`u (Hawaiian dark-rumped petrel)	E
Puffinus auricularis newelli	`A`o (Newell's Townsend’s shearwater)	T

Source: U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a; U.S. Department of the Navy, 2002a; U.S. Fish and Wildlife Service, 2006b; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007.
Key to Federal Status:
E = Endangered
T = Threatened

According to the USFWS, the Hawaiian hoary bat is located within the region of influence for Naval Station Pearl Harbor (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007). The green turtle has rarely been seen in Pearl Harbor, and no sandy beaches suitable for nesting exist inside the harbor. They have been seen routinely in the outer reaches of the Naval Station Pearl Harbor entrance channel (Smith et al., 2006). Although the Hawaiian monk seal has never been reported in the harbor, it has been recorded at Iroquois Point at the Naval Station Pearl Harbor entrance channel (Smith et al., 2006). An adult humpback and calf were once reported to have entered East Loch, but this was an unusual event. The pair left the harbor within 24 hours on their own volition. (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a)

Environmentally Sensitive Habitat

The Pearl Harbor National Wildlife Refuge (Figure 3.4.2.1.1-1) is comprised of the Honouliuli Unit (located on the northwestern tip of West Loch) and the Waiawa Unit (located on Pearl City Peninsula). The refuge provides primary wetland habitat for threatened and endangered waterbirds and other bird species in Naval Station Pearl Harbor. Mangrove wetlands are the most common type of wetland. (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a)

No critical habitat has been designated within Naval Station Pearl Harbor (Figure 3.4.2.1.1-1). Approximately 127 acres of jurisdictional wetlands are located on Navy properties in Naval Station Pearl Harbor. Wetland areas adjacent to Naval Station Pearl Harbor include mudflats, shallow ponds, small streams, pickleweed beds, kiawe forests, cattails (*Typha latifolia*), and watercress (*Rorippa microphylla*) and provide habitat for waterbirds. (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a)

3.4.2.1.2 Cultural Resources—Naval Station Pearl Harbor

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

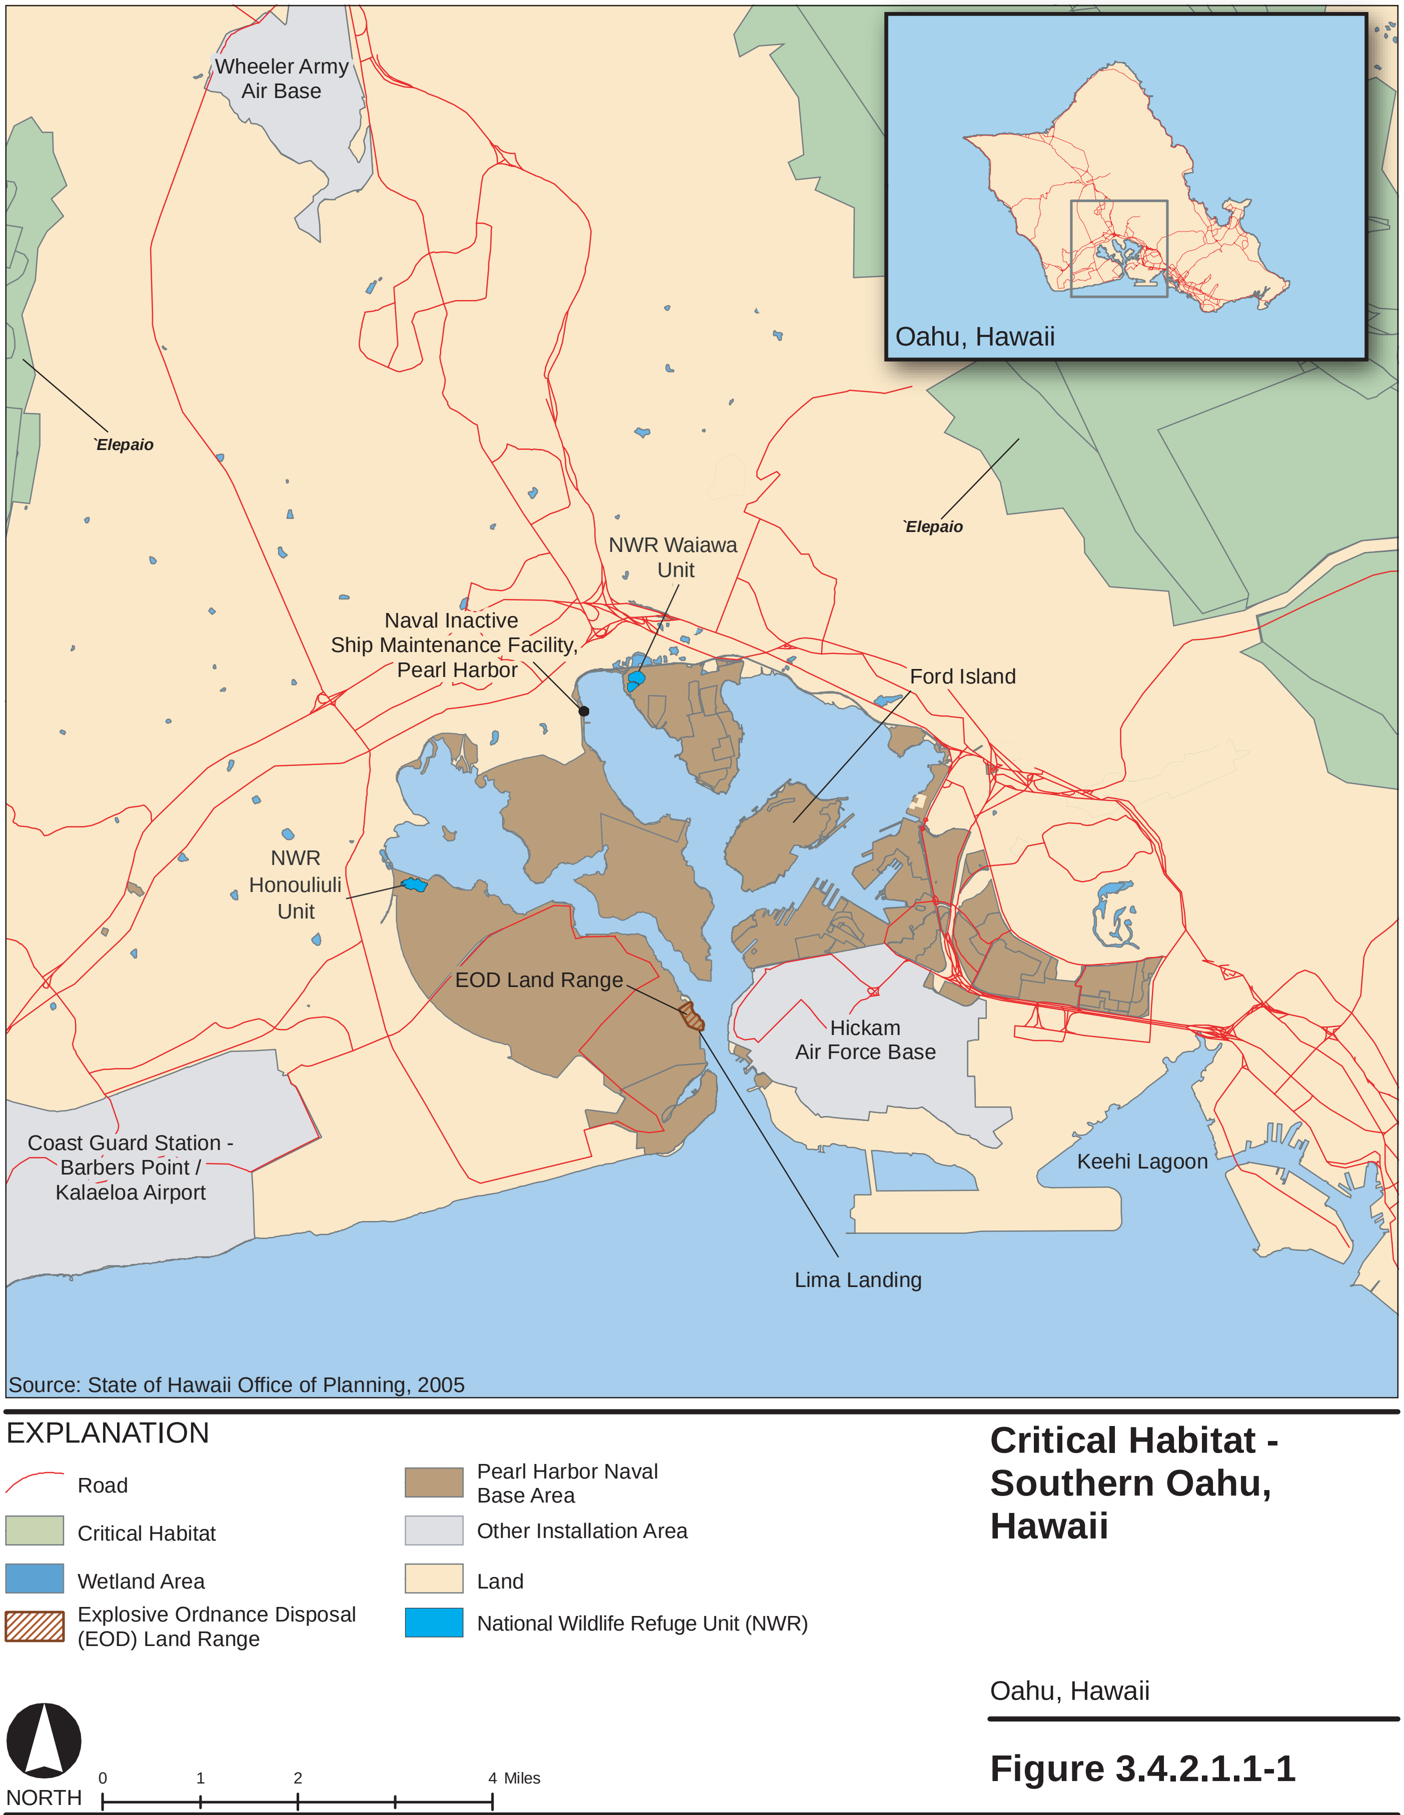
Region of Influence

The region of influence for proposed or ongoing training within Naval Station Pearl Harbor would include any location where Salvage Operations would occur.

Affected Environment

Underwater Cultural Resources

Submerged archaeological resources surrounding Oahu include numerous shipwrecks (see Figure 3.1.3-2), many of which, including *USS Arizona* and *USS Utah,* are within Naval Station Pearl Harbor and are National Historic Landmarks. *USS Arizona* lies in 40 ft of water and is the final resting place for many of the ship's 1,177 crewmen who lost their lives during the Japanese attack on December 7, 1941. The *USS Arizona* Memorial became a National Park Service unit in 1980, and the National Park Service conducts approximately 50 research and cultural preservation dives per year (National Park Service, 2006). *USS Utah* lies where she sank on the northern side of Ford Island. Naval Station Pearl Harbor contains the wrecks of other U.S. Warship remnant fields, Japanese midget submarines, and Japanese aircraft as well (Rosendahl, 2000).



Critical Habitat - Southern Oahu, Hawaii

Oahu, Hawaii

Figure 3.4.2.1.1-1

Other known wrecks surrounding Oahu include the largely intact wreck of the Sea Tiger, which was sunk in 1996 by a submarine company; a World War II-era Japanese midget submarine located in 2002; *Mahi*, a scuttled Navy minesweeper/cable layer located off the Waianae Coast, which now serves as an artificial reef; and the YO-257, which was a Navy yard oiler built in the 1940s and sunk off Waikiki in 1989 to create an artificial reef. There is also an aircraft crash site, which resulted from a Corsair ditching when it ran out of fuel along the south shore.

Only a few of the roughly 100 fishponds that once existed in the waters surrounding Oahu still remain (see Figure 3.4.1.3.2-1); however, four of them are located within Pearl Harbor. These include Loko Paaiau near McGrew Point in the East Loch; Loko Okiokiolepe, located northwest of the EOD Land Range; Loko Pamoku near the NAVMAG in West Loch, and Loko Laulaunui on Laulaunui Island in West Loch (see also Section 3.4.2.4.2) (U.S. Department of the Navy, Commander Navy Region Hawaii, 2002).

Loko Okiokiolepe Fishpond

The areas around the lochs of Naval Station Pearl Harbor were once used extensively for aquaculture. Historical maps and other sources indicate that there were as many as 25 fishponds, fish traps, and other kinds of aquacultural features along the shoreline of Pearl Harbor. Based on an overlay of historical maps with current facilities, 20 of these features were located wholly or partially within the boundaries of Naval Station Pearl Harbor. Although most of the original fishponds have been buried beneath fill and subsequently developed, archaeological and paleoenvironmental studies have shown that in some areas intact fishpond sediments are still present. Among the four extant fishponds listed above, Loko Okiokiolepe was officially listed in the National Register of Historic Places (NRHP) on March 14, 1973 (Hawaii State Historic Preservation Office, 2006; U.S. Department of the Navy, Commander Navy Region Hawaii, 2002). Most of the interior of the fishpond has been filled, but the seaward coral wall still remains intact (Naval Facilities Engineering Command, 2006).

3.4.2.1.3 Socioeconomics—Naval Station Pearl Harbor

Appendix C includes a general definition of socioeconomics.

Region of Influence

The region of influence for socioeconomic analysis is the island of Oahu. The County of Honolulu comprises the entire island of Oahu.

Affected Environment

Population and Income

In 2000, the population of Oahu was 876,156. The 2005 Bureau of Census Counties Profile estimates that the population of the county rose to 912,900 in 2005 (equal to 71 percent of the population of Hawaii), a change of almost 4.0 percent over the 5-year period. The estimated 2006 population for Oahu was 909,863 (U.S. Census Bureau, 2007b). The State of Hawaii Data Book 2006 indicates that the number of military personnel and dependence (Air Force, Army, Coast Guard, Marine Corps and Navy) is approximately 96,496. In 2006, military personnel and dependence accounted for 10.6 percent of the population of Oahu. The projected population for 5 and 10 years out is 952,650 people in 2010 and 995,550 people in 2015, which would be an increase of 4.5 percent (Hawaii, State of, 2004). Table 3.4.2.1.3-1 summarizes the demographics of the population of Oahu in 2006. Table 3.4.2.1.3-2 illustrates the age profile of those living in Honolulu County in 2006.

Table 3.4.2.1.3-1. Demographics of the Population of Oahu in 2006

Persons		**909,863**
	Male	455,051
	Female	454,812
Race	Asian	402,365
	White	201,795
	Native Hawaiian & Other Pacific Islander	72,053
	Hispanic/Latino	63,312
	Black/African American	25,103
	American Indian & Alaska Native	2,969
	Other	9,972

Source: U.S. Census Bureau, 2006a

Table 3.4.2.1.3-2. Age Profile of Honolulu County Residents in 2006

	Honolulu County		**Hawaii**	
Age group (years)	**Population**	**Percentage**	**Population**	**Percentage**
Under 5 years	63,084	6.9	87,179	6.8
18-64 years	700,359	77.0	988,265	76.9
65 and over	130,938	14.4	179,012	13.9

Source: U.S. Census Bureau 2006a & 2006b

The Department of Defense (DoD) is the second major source of revenue to the State of Hawaii; second only to tourism (Chamber of Commerce of Hawaii, Military Affairs Council, 2006). In fiscal year (FY) 2005 total defense expenditures and appropriations for Hawaii were $5.6 billion, an increase of 8.7 percent over FY 2004, and appropriations for FY 2006 defense projects totaled $767 million (Chamber of Commerce of Hawaii, Military Affairs Council, 2007). In January 2006, Congressman Neil Abercrombie announced that the Navy awarded $30 million to two Hawaii firms located on Oahu for repair, maintenance, and alterations to Navy ships. See Table 3.3.2.1.10-3 for the economic impact of the military in Hawaii.

Personal income in Oahu was estimated by the Department of Business, Economic Development and Tourism to be $30.4 billion in 2005, which represented 77 percent of the total personal income of Hawaii. The average per capita income in Honolulu County in 2004 was $34,911.00, while in the same year the average per capita income for the state was $32,625.00 (6.5 percent less) (Fedstats, 2007).

Housing

In the fall of 2006, housing supply was 2,005 single-family homes and 2,750 condominiums available. At the same time prices have remained fairly level with interest rates at a 6-month low (Honolulu Board of REALTORS®, 2006a). The number of owner-occupied homes has grown from 156,290 in 2000, to 173,182 in 2005 (Hawaii, State of, 2004, U.S. Census Bureau, 2000a). This change represents a 9.8 percent increase in the stock of owner-occupied homes, compared to a 6.7 percent growth in the State as a whole. Additionally, as shown in Table 3.4.2.1.3-3, renter-occupied homes increased 34.7 percent over a 6-year period.

Table 3.4.2.1.3-3. Renter Occupied Housing Units

Gross Monthly Rent	Number of Housing Units, 2000	Number of Housing Units, 2006
Less than $200	4,501	4,272
$200 to $299	3,324	4,423
$300 to $499	9,265	8,125
$500 to $749	30,991	17,505
$750 to $999	28,973	32,420
$1000 or more	33,801	91,348
No cash rent	19,052	16,940
Total	129,907	175,033
Median rent	$802	$1,116

Source: U.S. Census Bureau, 2000a and 2006c.

Employment

In 2001, the U.S. military employed 64,074 people in the State of Hawaii. The number employed by the Navy and Marine Corps was 24,654 (38 percent of military). Major locations for the active duty military and civilian personnel on Oahu in 2001 were: Schofield Barracks (12,699 jobs), Naval Station Pearl Harbor (12,407 jobs), Kaneohe (6,847 jobs), Hickam AFB (5,374 jobs), Tripler Army Medical Center (2,826 jobs), Fort Shafter (2,337 jobs), Honolulu (1,879 jobs), Wheeler AFB (1,816), Kunia (1,495 jobs) and Camp H.M. Smith (1,045). Naval Station Pearl Harbor is the largest industrial employer in Hawaii (Enterprise Honolulu, 2007). Table 3.4.2.1.3-4 shows the number of individuals employed in the main sectors of the economy of Oahu, and within Hawaii as a whole.

Tourism, tourism-related services, and government continue to be the main employment generators (U.S. Department of the Navy, 1998a). Natural resources and mining, mainly consisting of the agriculture, forestry, and fishing industry will add the fewest number of jobs and will continue to employ only 1 percent of the workforce (Department of Labor and Industrial Relations, 2006).

Unemployment on Oahu has fluctuated from a low of 2.0 percent in 1991 to a high of 4.9 percent in 1996 and 1998. In 2001, the rate was 4.1 and has steadily declined to 2.7 percent in 2005. This is the lowest the rate has been in over 12 years. During the same period, the total labor force has increased from 435,300 in 2001 to 445,150 in 2005—a 2.2 percent increase. In the last 5 years, Honolulu County's unemployment rate has been within 0.1 to 0.2 percentage points of the State-wide rate (Hawaii, State of, 2005a).

Table 3.4.2.1.3-4. Employment on Oahu and in Hawaii

Employment Sector	Oahu		State of Hawaii	
	Number of Employees	Percent of Total	Number of Employees	Percent of Total
Agriculture, forestry, fishing, hunting, and mining	3,456	0.83	9,864	1.6
Construction	30,583	7.4	51,174	8.4
Manufacturing	12,565	3.1	16,851	2.8
Transportation and warehousing and utilities	25,659	6.2	33,654	5.5
Wholesale trade	13,213	3.2	18232	3.0
Retail trade	45,952	11.1	72,383	11.9
Finance, insurance and real estate and rental and leasing	29,681	7.2	41089	6.7
Information	9,744	2.4	13,091	2.1
Professional, scientific, management, administrative and waste management services	42,990	10.4	62,291	10.2
Education services, health care, and social assistance	87,448	21.0	119,906	19.6
Arts, entertainment, recreation, accommodation and food services	50,090	12.0	90,241	14.8
Public Administration	44,531	10.8	54,046	8.9
Other services, except public administration	18,122	4.4	27572	4.5
Total	**414,034**	**100**	**610,394**	**100**

Source: U.S. Census Bureau, 2006d and 2006e.

Agriculture

The number of farms on Oahu has decreased from 900 in 1994 to 800 in 2004. Farm acreage has declined by about 28 percent over the same period. The number of self-employed farm operators and their unpaid family members stood at 2,300 persons in 2002. These operators and others employed 2,450 hired workers on Oahu (Hawaii, State of, 2005b).

Corresponding to the decline in farm land, sales of all crops decreased 10 percent from 2002 to 2004. Sugar cane (unprocessed cane) and pineapple accounted for 70.3 percent of all crop sales in 1994 at $84.3 million. By 2004, however, sugar cane was no longer a crop and pineapple only accounted for 37.6 percent of all crop sales, at $51.96 million. Livestock sales have declined by 38.4 percent over the 10-year period from 1994 to 2004. The reduction in sugar, pineapple, and livestock sales has been offset by increases in other crops with sales of $86.1 million in 2004, a 41 percent increase from 1994. The diversification of crops includes the production of coffee, seed corn, vegetables and melons, fruits, macadamia nuts, taro, field crops, and flowers and nursery products. This diversification of crops has been, and still is, a goal of Oahu in order to strengthen, sustain, and maintain the agricultural segment of the economy, thus making it less susceptible to short-term conditions which could negatively impact agriculture (Hawaii, State of, 2005b). Additionally, the aquaculture industry is on the rise as well, increasing from 40 operations with $4.67 million in sales in 2003 to 46 operations with $5.20 million in sales in 2004, which is an 11 percent increase (Hawaii, State of, 2005b).

Subsistence Fishing

The overall level of subsistence fishing activity on Oahu and all other islands is difficult to assess, due to a lack of detailed catch data. There has been no attempt to formally assess the subsistence fishing contribution to island economies, but the value to consumers is known to be substantial. In particular, subsistence fishing is an important supplement to cash income in many rural communities despite increasing commercialization of the catch in these areas (Western Pacific Regional Fishery Management Council, 1999). See Section 3.3.1.1.3 for a detailed discussion on subsistence fishing.

Tourism

The tourism industry has been the economic mainstay of the Hawaiian Islands since statehood in 1959. The industry accounts for 22.3 percent of all jobs in Hawaii (Kauai, County of, 2005). Oahu's share of the Hawaii visitor market was 64.6 percent in 2004. Despite terrorism threats and periodic economic slumps, the tourism industry on Oahu has remained strong, with the number of visitors consistently over 4 million per year over the past 5 years (State of Hawaii Department of Business, Economic Development & Tourism, 2006). Estimated visitor expenditures in 2005 were $11.9 billion, a 9.6 percent increase from 2004 (State of Hawaii Department of Business, Economic Development & Tourism, 2006). The numbers of visitors to Oahu from 2000 through 2006 are shown in Table 3.4.2.1.3-5.

Table 3.4.2.1.3-5. Visitors to Oahu (2000–2006)

Year	Oahu Visitors	State of Hawaii Visitors
2000	4,719,244	6,948,594
2001	4,257,536	6,303,790
2002	4,276,077	6,389,058
2003	4,090,483	6,380,439
2004	4,469,278	6,917,166
2005	4,731,843	7,416,574
2006	4,627,484	7,461,299

Source: State of Hawaii Department of Business, Economic Development & Tourism, 2006.

The accommodation inventory for Oahu declined 5.9 percent between 2000 and 2005, with 222 properties providing 34,167 rooms. This is 12 percent less than the peak capacity in 1986 of 39,010 rooms. Despite this short-term trend, the capacity is projected to increase 1.2 percent annually, which translates into 2,100 additional units by 2010 (Department of Planning and Permitting, 2006).

3.4.2.2 FORD ISLAND

Ford Island is a 450-acre site in the heart of Naval Station Pearl Harbor, about 1 mi long by 0.25-mi wide. It is connected to the main island by the Ford Island Bridge. The island houses several naval facilities.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Ford Island. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, and utilities are not addressed.

3.4.2.2.1 Biological Resources—Ford Island

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence is Ford Island and its adjacent waters.

Affected Environment

Vegetation

Vegetation on Ford Island consists mainly of non-native grasses, shrubs, and trees such as kiawe, mangrove, koa haole, Cuban jute (*Sida rhombifolia*), and pitted beardgrass (*Bothriochloa pertusa*). Non-native ornamental plants are used in housing area landscaping. There are a small number of native plants on the island such as \`ilima, milo (*Thespesia populnea*), and \`uhaloa (*Waltheria indica*). (National Oceanic and Atmospheric Administration, 2006d)

<u>Threatened and Endangered Plant Species</u>

No threatened and endangered plant species have been reported on Ford Island. (National Oceanic and Atmospheric Administration, 2006d)

Wildlife

Wildlife similar to that described at Naval Station Pearl Harbor is likely to be found on Ford Island. Two indigenous bird species are found on Ford Island: the black-crowned night heron (\`auku\`u) and the Pacific golden plover. (National Oceanic and Atmospheric Administration 2006d) Non-native birds such as the myna, house finch, and zebra dove are also found on the island. Mongoose and rodents are present in the region of influence.

Ghost shrimp (*Myrichthys maculosus*), mantis shrimp (*Odontodactylus scyllarus)*, Samoan crabs (*Scylla serrata*), and clams are members of the soft bottom community. These species are eaten by fish such as the weke pueo (bandtail goatfish) (*Upeneus arge*), hailepo (spotted eagle ray) (*Aetobatus narinari*), and pakii (panther flounder) (*Bothus pantherinus*). Piers and pilings around Ford Island are habitat for species such as pualo and manini (surgeonfish) *Acanthurus* spp.), butterflyfish (*Chaetodon* spp.*)*, and goby. The largest concentrations of fish are found around the seaplane ramps along the southeastern corner of the island and around

USS Utah. The region of influence contains EFH for juvenile, adult, egg, and larvae life stages for all pelagic and bottom fish and crustaceans. However, no HAPC has been designated. (National Oceanic and Atmospheric Administration, 2006d) Section 3.1.2.2.1 includes a description of EFH; however, a detailed description, including status, distribution, and habitat preference of managed fisheries, is provided in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

During surveys conducted in 1999 and 2000, colonies of *Montipora* spp., *Pocillopora damicornis,* and *Leptastrea purpurea* were found at a few scattered locations in the region of influence. While these corals do not constitute a coral reef, they are indicative of improved water quality within the harbor. (National Oceanic and Atmospheric Administration, 2006d)

Threatened and Endangered Wildlife Species

There are no threatened or endangered terrestrial wildlife on the island. In the past 10 years, there have been four documented green turtle sightings within Pearl Harbor and one hawksbill turtle carcass was collected from the island. There are no reported sightings of live hawksbill turtles and no suitable sea turtle nesting habitat within the region of influence (Smith et al., 2006). There has only been one case of humpback whales in the region of influence, which is mentioned in Section 3.4.2.1.1, Naval Station Pearl Harbor. (National Oceanic and Atmospheric Administration, 2006d)

Environmentally Sensitive Habitat

No critical habitat has been designated in the region of influence.

3.4.2.2.2 Cultural Resources—Ford Island

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The cultural resources region of influence for Ford Island encompasses the area where a new open-water Acoustic Test Facility would be constructed.

Affected Environment

Underwater Cultural Resources

Ford Island is one of Naval Station Pearl Harbor's Historic Management Zones. Historically, the development and use of Ford Island served one military purpose: aviation. The island is the only area at Naval Station Pearl Harbor specifically associated with that "theme" or activity. As a result, the Ford Island Management Zone encompasses all of Ford Island, including the shallow reef areas and coral islets at the northern end of the island, and the associated wharves and docks that are attached to the island. It also includes the mooring quays just offshore and the submerged resources near the island such as *USS Utah* and *USS Arizona*. (U.S. Department of the Navy, Commander Navy Region Hawaii, 2002)

Archaeological Resources

There is very little specific archival or archaeological information concerning traditional land use or pre-contact events on Ford Island, although some inferences can be made. Given the island's lack of water, there was probably little pre-contact habitation, except short-term occupation for fishing, collecting pili grass, and possible seasonal cultivation of dryland crops, such as gourd and sweet potato. Fisheries adjacent to the island were probably associated with land units on the island, which at the time of the Great Mahele, were divided between the ahupua`a of Waimalu and Kalauao (U.S. Department of the Navy, Commander Navy Region Hawaii, 2002).

Based on previous land use and/or historical information, three areas within Naval Station Pearl Harbor may contain intact subsurface deposits beneath historically deposited fill. Although the presence of intact deposits at these locations has not been confirmed through archaeological testing, the three areas include the original lands of Ford Island (including the area where the new Acoustic Test Facility would be constructed), the northwestern portion of Pearl City Peninsula, and the Navy's Bishop Point parcel (U.S. Department of the Navy, Commander Navy Region Hawaii, 2002).

Historic Buildings and Structures. Within the Ford Island Management Zone there are numerous historic buildings and structures. The facilities are associated with aviation, housing, and recreation. Subtypes include airfield facilities (e.g., control tower, hangars), Officer's Quarters, barracks, a theater, and a Plantation-era seawall in the vicinity of the planned Acoustic Test Facility.

Traditional Resources. Ethnographic information identifies the Pearl Harbor lagoon as a place that was rich in resources and a place associated with sharks; as deities, as a food source, and as a family `aumakua (family or personal god). Several contemporary Hawaiian sources characterize the lagoon as a "breadbasket" in ancient times, and one source describes Mokuumeume (Ford Island) as the piko or umbilical cord located in the middle of Ka-awa-lau-o-pu`uloa, transferring mana (supernatural or divine power) from one generation to the next. There is one historical reference to the use of the island as a burial place (U.S. Department of the Navy, Commander Navy Region Hawaii, 2002)

3.4.2.2.3 Water Resources—Ford Island

Appendix C includes a description of the primary laws and regulations regarding water resources.

Region of Influence

The region of influence for water resources includes Ford Island and the adjacent waters.

Affected Environment

Ford Island is located within Naval Station Pearl Harbor, which differs from most industrialized harbors in that the surface waters are entirely under the jurisdiction of the Navy, and are dominated by a significant homeport presence of surface ships, submarines, and inactive and reserve vessels. A large shore-based infrastructure has developed around the harbor in response to a historical build-up of the area as a major support base for fleet activities (U.S. Department of the Navy, 1998a).

Water temperatures in Pearl Harbor range from an average low of 76°F in the winter to 81°F in September and October (National Oceanic and Atmospheric Administration, 2006a). The mean tidal range in the harbor is 1.28 ft. The relatively high water temperatures and low volume of tidal exchange combine to result in low dissolved oxygen concentrations within the harbor.

The Department of Health has classified Pearl Harbor as a “Water Quality Limited Segment” due to its high levels of nutrients, suspended solids, and turbidity (Department of Health, 2001) and its chronic inability to meet the State’s Water Quality Standards.

3.4.2.3 NAVAL INACTIVE SHIP MAINTENANCE FACILITY, PEARL HARBOR

The Naval Inactive Ship Maintenance Facility, Pearl Harbor inactivates, performs custodial and maintenance duties, and disposes of Naval vessels in the Pacific. Its ship moorings are located in Middle Loch, Pearl Harbor. Figure 2.2.3.6.1-1 shows the location of Naval Inactive Ship Maintenance Facility, Pearl Harbor. The proposed demolition location in Middle Loch is approximately 1,100 ft from the nearest shoreline (Waipio Peninsula).

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for the Naval Inactive Ship Maintenance Facility, Pearl Harbor. Of the 13 environmental resources considered for analysis, air quality, airspace, cultural resources, geology and soils, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.3.1 Biological Resources—Naval Inactive Ship Maintenance Facility, Pearl Harbor

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes Naval Inactive Ship Maintenance Facility, Pearl Harbor and its adjacent waters.

Affected Environment

The Waiawa Unit of the Pearl Harbor National Wildlife Refuge is located on the western boundary of Pearl City Peninsula, adjacent to Middle Loch. The Waiawa Unit is located approximately 2,360 ft northeast of the demolition location. The Honouliuli Unit of the Pearl Harbor National Wildlife Refuge is located along the western shoreline of West Loch, over 2 mi from the location of the proposed demolition at Naval Inactive Ship Maintenance Facility, Pearl Harbor. Waipio Peninsula is located between the proposed demolition location and the Honouliuli Unit. Both the Waiawa and Honouliuli Units are managed under a cooperative use agreement between the USFWS and the Navy for enhancement of endangered waterbirds. The affected environment of the Naval Inactive Ship Maintenance Facility is similar to that described for Naval Station Pearl Harbor.

3.4.2.3.2 Hazardous Materials and Waste—Naval Inactive Ship Maintenance Facility, Pearl Harbor

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and wastes includes the Naval Inactive Ship Maintenance Facility, and the waters adjacent to the facility.

Affected Environment

Naval Inactive Ship Maintenance Facility, Pearl Harbor inactivates, performs custodial and maintenance duties, and disposes of U.S. Naval vessels in the Pacific. Its ship moorings are located in Middle Loch, Pearl Harbor. Navy ships brought to the Naval Inactive Ship Maintenance Facility, Pearl Harbor are defueled upon decommissioning and towed in. Residual fuels remain in the tanks of the ships, with the exception of those that are to be used in Sinking Exercises or artificial reefs. The residual fuel in the tanks and pipes of these ships are removed and disposed of in accordance with Naval Station Pearl Harbor Standard Operating Procedures. In addition, some decommissioned ships contain hazardous materials that are part of the structure of the ship. These materials are also removed and disposed of in accordance with Naval Station Pearl Harbor Standard Operating Procedures. The demolition location in Middle Loch is approximately 1,100 ft from the nearest shoreline (Waipio Peninsula).

3.4.2.3.3 Water Resources—Naval Inactive Ship Maintenance Facility, Pearl Harbor

Appendix C includes a description of the primary laws and regulations regarding water resources.

Region of Influence

The region of influence for water resources includes the Naval Inactive Ship Maintenance Facility, and the waters adjacent to the facility.

Affected Environment

Pearl Harbor is a natural marine water body located on the southern shore of the island of Oahu. It is divided into three lobes or bays, East Loch, Middle Loch, and West Loch. The Naval Inactive Ship Maintenance Facility is located in the Middle Loch, and the demolition location is approximately 1,100 ft from the nearest shoreline.

Pearl Harbor receives inflow from eight streams that enter the harbor from the highly urbanized areas of Honolulu and its suburban areas. The upstream reaches of these streams include multiple uses: agriculture, residential development, commercial and industrial, and storm water discharge. Each of these streams carries a load of sediment, nutrients, and pollutants, depending on the land use and storm water management activities that occur in the watershed. In addition, Pearl Harbor is affected by releases of partially treated sewage effluent.

The Department of Health has classified Pearl Harbor as a “Water Quality Limited Segment” due to its high levels of nutrients, suspended solids, and turbidity (Department of Health, 2001) and its chronic inability to meet the State’s Water Quality Standards. The Department of Health lists several locations within Pearl Harbor as impaired waters due to high concentrations of nutrients (nitrogen and phosphorus), turbidity (suspended sediment), and polychlorinated biphenyls. The Navy reported in 1998 and 2001 that copper and nutrient loading were of concern in the harbor, in addition to leachate from anti-fouling paint widely used on ship hulls. The presence of these pollutants can be directly linked to the Navy’s long-term use of the harbor and nearby shore facilities (U.S. Department of the Navy, 1998a, 2001a).

Groundwater

Groundwater aquifers on the island typically consist of deep lenses of fresh water within the basalt bedrock that float on top of a saltwater lens. The two layers remain separate due to the difference in density between fresh water and seawater. Aquifer recharge occurs through infiltration of precipitation, return of irrigation water, and exchange between the underground aquifers.

Groundwater accounts for about 90 percent of the water consumed on Oahu for municipal, industrial, agricultural, and military uses. The numerous hydrogeologic units and aquifer basins yield over 635 million gallons per day. Oahu is more dependent on groundwater than the other Hawaiian Islands (U.S. Department of the Army, 2004). There are no groundwater resources in Naval Station Pearl Harbor.

3.4.2.4 EXPLOSIVE ORDNANCE DISPOSAL (EOD) LAND RANGE—NAVAL MAGAZINE (NAVMAG) PEARL HARBOR WEST LOCH

The EOD Land Range is a 2.75-acre facility located within NAVMAG, West Loch, Pearl Harbor where land demolition of ordnance occurs.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for the EOD Land Range. Of the 13 environmental resources considered for analysis, air quality, airspace, hazardous materials and hazardous waste, land use, noise, socioeconomics, transportation, and utilities resources are not addressed.

3.4.2.4.1 Biological Resources—EOD Land Range—NAVMAG Pearl Harbor West Loch

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence is within and adjacent to the EOD Land Range.

Affected Environment

This flat, 2.75-acre tract of land is located at an elevation of about 0 to 10 ft above mean sea level, adjacent to Naval Station Pearl Harbor. Portions of the site are paved or disturbed.

Vegetation

The vegetation consists of an overstory primarily of non-native kiawe trees (*Prosopis pallida*) with an understory of non-native grasses, primarily buffelgrass (*Cenchrus ciliaris*). Other introduced species in this plant community include koa haole (*Leucaena leucocephala*), panic grasses (*Panicum* sp.), and other non-native grasses such as hurricane grass (*Dicanthium pertusum*) and natal redtop (*Melinus repens*). (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001b)

<u>Threatened and Endangered Plant Species</u>

The property has been well-surveyed, and no plants listed as threatened or endangered under the Federal Endangered Species Act have ever been reported for the site (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001b).

Wildlife

The wildlife community at West Loch is typical of disturbed vacant lands in Hawaii. A comprehensive bird survey in 1985 identified 21 species on the site, of which only two Pacific golden plover (Pluvialis fulva) and Hawaiian short-eared owl (Asio flammeus sandwichensis), or pueo, are native species. Mammals found on the property include the mongoose, rat, house mouse, feral dog, and feral cat, all of which are non-native pests. (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001b)

Threatened and Endangered Wildlife Species

No animal species listed as threatened or endangered under the Federal Endangered Species Act are known to inhabit the site. The Oahu population of pueo is listed by the State of Hawaii as endangered.

Environmentally Sensitive Habitat

No critical habitat has been designated in the region of influence (Figure 3.4.2.1.1-1).

3.4.2.4.2 Cultural Resources—EOD Land Range—NAVMAG Pearl Harbor West Loch

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for the EOD Land Range encompasses a 2.75-acre area where land demolition of ordnance occurs (see Figure 2.2.3.6.1-1). The range falls within the boundary of the Pearl Harbor National Historic Landmark Boundary (International Archaeological Resources Institute, Inc., 2005).

Affected Environment

Archaeological Resources (Prehistoric and Historic)

The EOD Land Range is situated within the greater NAVMAG, West Loch, Pearl Harbor area. The NAVMAG area was surveyed for archaeological resources in 1997 (Jensen, et al., 1997). Undeveloped lands at West Loch contain a wide range of archaeological sites including stone walls, enclosures, mounds, platforms, and modified outcrops and sinkholes; however, the area of the EOD Land Range was determined to be devoid of archaeological sites. (International Archaeological Resources Institute, Inc., 2005; Jensen, et al., 1997)

Historic Buildings and Structures

The EOD Land Range consists of two concrete blast chambers and one concrete safety bunker. Although historic buildings and structures have been identified within the greater NAVMAG area, which is managed as a Pearl Harbor World War II-era Historic Management Zone, the three EOD Land Range facilities are south of the Management Zone and are not among the identified historic properties (International Archaeological Resources Institute, Inc., 2005).

Traditional Resources

Archaeological, historical, and paleoenvironmental studies conducted within Naval Station Pearl Harbor have documented sites associated with traditional Hawaiian aquaculture, agriculture, and habitation-related activities; early historic land use activities; and historic military activities (International Archaeological Resources Institute, Inc., 2005). In addition to the types of archaeological sites described above (which could also be considered traditional Hawaiian resources), identified site types include fishponds and former taro/rice fields. The closest identified traditional Hawaiian site is the NRHP-listed Okiokiolepe fishpond located along the shoreline approximately 0.5 mi northwest of the EOD Land Range. (International Archaeological Resources Institute, Inc., 2005)

3.4.2.4.3 Geology and Soils—EOD Land Range—NAVMAG Pearl Harbor West Loch

Appendix C includes a description of geology and soils.

Region of Influence

The region of influence for the EOD Land Range includes the surface soils and subsurface geology of the site.

Affected Environment

The ground surface at West Loch is the top of a fossil reef, which has consolidated into limestone. The fossil reef is highly permeable and serves as an aquifer. Below the reef, caprock consisting of terrestrial and marine sediments extends to the top of the basement rock, Koolau basalt. The overall permeability of the caprock is very low, preventing upward seepage of groundwater. The Koolau basalt is composed of layered lava flows. The Hawaiian Agronomics' 1986 report identifies the predominant soils of the West Loch area as Mamala series, or Coral outcrop.

Surface soils on the EOD Land Range have not been tested. Soils within the EOD pit itself are assumed to be contaminated with detectable concentrations of typical explosives such as Royal Demolition Explosive (RDX) (cyclotrimethylenetrinitramine) and TNT (trinitrotoluene) (and their degradation products), and perhaps with other ordnance constituents or byproducts such as heavy metals or perchlorate. The surface topography is such that surface flows are unlikely to convey constituents of concern to nearby surface waters. The caprock under the site limits downward migration of contaminants, effectively containing any such materials in the surface soils.

3.4.2.4.4 Health and Safety—EOD Land Range—NAVMAG Pearl Harbor West Loch

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for public health and safety of the EOD Land Range includes the range and adjacent land and water (Pearl Harbor) areas.

Affected Environment

Navy training at the EOD Land Range could affect public health through releases to the environment (e.g., air, soil, or water) of hazardous constituents. EOD training could affect public safety through inappropriate public proximity to EOD events. The EOD Land Range is located within NAVMAG Pearl Harbor, West Loch; however, the public already is excluded due to larger safety concerns associated with the bulk storage of munitions. At present, about 85 training events are held per year on this range, or about one to two events per week.

Explosive Safety Quantity Distance Arcs and Explosives

The types and amounts of explosives materials that may be stored in an area are determined by the quantity-distance requirements established by the DoD Explosives Safety Board. Explosive safety quantity-distance (ESQD) arcs, defined by the Naval Sea Systems Command, are used to establish the minimum safe distance between munitions storage areas and habitable structures. To ensure safety, personnel movements are restricted in areas surrounding a magazine or group of magazines. ESQD arcs have been developed for the Navy's munitions storage facilities at NAVMAG Pearl Harbor.

Baseline Conditions

NAVMAG West Loch Branch constrains large land and water areas because its ordnance storage and transfer activities require large ESQD arcs. Land use and personnel occupancy of the lands encumbered by the arcs are strictly limited, particularly around West Loch (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a). During land training, gates are locked to secure the area, and warning flags are raised.

The EOD Land Range is within NAVMAG, West Loch. Land demolition training takes place on this range. Training materials, including small quantities of explosives, are brought to the facility as needed for each training session. The demolition pit consists of two concrete blast chambers and one concrete safety bunker. The safety arc for the demolition pit is contained entirely within the Land Range and adjacent, Navy-controlled waters of Pearl Harbor. Current EOD training thus has no effect on public safety in the nearest public use areas.

3.4.2.4.5 Water Resources—EOD Land Range—NAVMAG Pearl Harbor West Loch

Appendix C includes a description of the primary laws and regulations regarding water resources.

Region of Influence

The region of influence for water resources of the EOD Land Range includes the range and adjacent land and water (Pearl Harbor) areas.

Affected Environment

Water resources at the EOD Land Range consist primarily of storm water infiltration and runoff from the site. No streams or other surface water features are present at the site, no well-defined surface hydrology features (e.g., drainage swales) exist, and no potable groundwater aquifer is known to exist there. Rainfall in the Honolulu–Pearl Harbor area averages about 32 inches per year. In an average year, about 7.3 acre-ft of rain water (2.5 ft of rainfall x 2.75 acres) falls on the site. Surface water which does not evaporate or get taken up by vegetation either percolates into the soil or flows off the site into Pearl Harbor. Surface water flows from the site drain into Pearl Harbor. An impermeable capstone limits the downward movement of groundwater, so storm water entering the shallow aquifer under the site tends to move horizontally into Pearl Harbor.

3.4.2.5 LIMA LANDING

Lima Landing range is at the southernmost tip of the EOD Land Range and within the Naval Station Pearl Harbor. Lima Landing is a small underwater area used for underwater demolition training using small underwater detonations.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Lima Landing. Of the 13 environmental resources considered for analysis, airspace, air quality, geology and soils, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.5.1 Biological Resources—Lima Landing

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence for Lima Landing encompasses areas where EOD would occur.

Affected Environment

Vegetation

Exotic imported grasses and trees maintained by intensive landscaping efforts make up the majority of the vegetative community in the vicinity of Naval Station Pearl Harbor. Native vegetation, including grasses, trees, and shrubs are present only in small areas. These areas of native vegetation provide control for erosion except under the heaviest rainfall conditions. (U.S. Department of the Navy, 2002a)

Threatened and Endangered Plant Species

No threatened or endangered plant species have been identified in the region of influence.

Wildlife

A cooperative agreement for the conservation and management of terrestrial and aquatic resources within Naval Station Pearl Harbor has been developed with the Navy, USFWS, National Marine Fisheries Service, and the Hawaii Department of Land and Natural Resources. There are no HAPC in Naval Station Pearl Harbor. (U.S. Department of the Navy, 2002a) Section 3.1.2.2.1 includes a description of EFH; however, a detailed description, including status, distribution, and habitat preference of managed fisheries, is provided in the Navy's *Final Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007a).

Threatened and Endangered Wildlife Species

Green turtles have been seen in the entrance to Pearl Harbor (Smith et al., 2006). Monk seals have been reported hauled-out on the beach at Iroquois Point housing area. There was a report of a humpback whale and calf entering Pearl Harbor in 1998, which is mentioned in Section 3.4.2.1.1. (U.S. Department of the Navy, 2002a)

Threatened and endangered terrestrial species that may occur in the region are similar to those provided in Table 3.4.2.1.1-1.

Environmentally Sensitive Habitat

No environmentally sensitive habitat has been identified in the region of influence.

3.4.2.5.2 Cultural Resources—Lima Landing

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for Lima Landing encompasses areas where EOD would occur. The range is at the southernmost tip of the EOD Land Range (see Figure 2.2.3.6.1-1) and is within the Pearl Harbor National Historic Landmark Boundary.

Affected Environment

Underwater Cultural Resources

There are no known submerged cultural resources within the Lima Landing region of influence.

3.4.2.5.3 Hazardous Materials and Waste—Lima Landing

Appendix C includes a discussion of hazardous materials and waste resource laws and regulations.

Region of Influence

The region of influence for hazardous materials and wastes includes Lima Landing, and the waters adjacent to the range.

Affected Environment

Hazardous Materials

Lima Landing is a small underwater area used for underwater demolition training using small underwater detonations. Training at Lima Landing involve transporting (by vehicle and boat), handling, and using small quantities of hazardous materials (e.g., explosives). Explosives charges of up to 0.25 lb (net explosive weight) may be detonated on this range. Baseline training consists of about five training events per year, resulting in the detonation of about 1.25 lb per year.

Hazardous Waste

The detonations of explosives generate small quantities of explosives residues, metals, and inorganic salts. These hazardous constituents generally disperse into the water column, but some may remain in bottom sediments. The annual quantities of hazardous materials consumed on this range are minute, however, and have no known offsite effects.

3.4.2.5.4 Health and Safety—Lima Landing

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for Lima Landing for public health and safety includes the range and adjacent portions of Naval Station Pearl Harbor.

Affected Environment

Lima Landing is a small underwater area just off an abandoned concrete pier at the approach to Pearl Harbor near the entrance of West Loch. Access to the range is via small boats. Underwater demolition training on this range uses small underwater detonations. At present, about five training events per year occur on this range, or about one every other month.

Procedures for approving an underwater detonation include filing a “Request for Detonation of Underwater Ordnance” with Commander, Naval Station Pearl Harbor to determine whether the proposed detonation would constitute any danger. Upon concurrence by appropriate commands, Commander, Naval Surface Force, Pacific grants permission to conduct the underwater detonations and concurrently requests issuance of a local Notice to Mariners by the appropriate U.S. Coast Guard District.

Public health and safety risks associated with this training activity include the possible dispersal of hazardous explosives residues in the bay waters, re-suspension of bay sediment contaminants, and possible public proximity to an underwater detonation. The Navy regulates recreational fishing and boating in Pearl Harbor, and allows active duty and retired military personnel in specified areas of the harbor for such purposes. In addition, eligible DoD personnel may launch their own boats from Rainbow Bay, Iroquois Point, or Hickam Marinas, with a permit from the Navy's Pass and Identification office. The Navy permits shore fishing from Navy property by authorized personnel (military and civilian employees of the DoD and their dependents, relatives, and guests) from sunrise to sunset. Fishing from boats is limited to permitted vessels and to non-prohibited areas within Pearl Harbor. Prohibited areas identified in the instruction include West Loch (U.S. Department of the Navy, Commander Navy Region Hawaii, 2001a).

Current underwater EOD training events at Lima Landing thus pose no risk to public safety. Public uses are not permitted within or adjacent to the range, the proximity of authorized personnel is managed and restricted, and range activities are planned and executed so as to contain all effects within the boundaries of the range.

3.4.2.6 U.S. COAST GUARD AIR STATION BARBERS POINT/KALAELOA AIRPORT

U.S. Coast Guard Air Station Barbers Point is located on Kalaeloa Airport, which was formerly the active airfield portion of Naval Air Station Barbers Point. Kalaeloa Airport is a general aviation facility that uses 750 acres of the former Naval facility. The state operates the three runways at the airport, the control tower and support facilities. Aircraft Support Operations are associated with U.S. Coast Guard Air Station Barbers Point.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for the U.S. Coast Guard Air Station Barbers Point. Of the 13 environmental resources considered for analysis, air quality, cultural resources, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.6.1 Airspace—U.S. Coast Guard Air Station Barbers Point/Kalaeloa Airport

Appendix C includes a detailed description of airspace.

Region of Influence

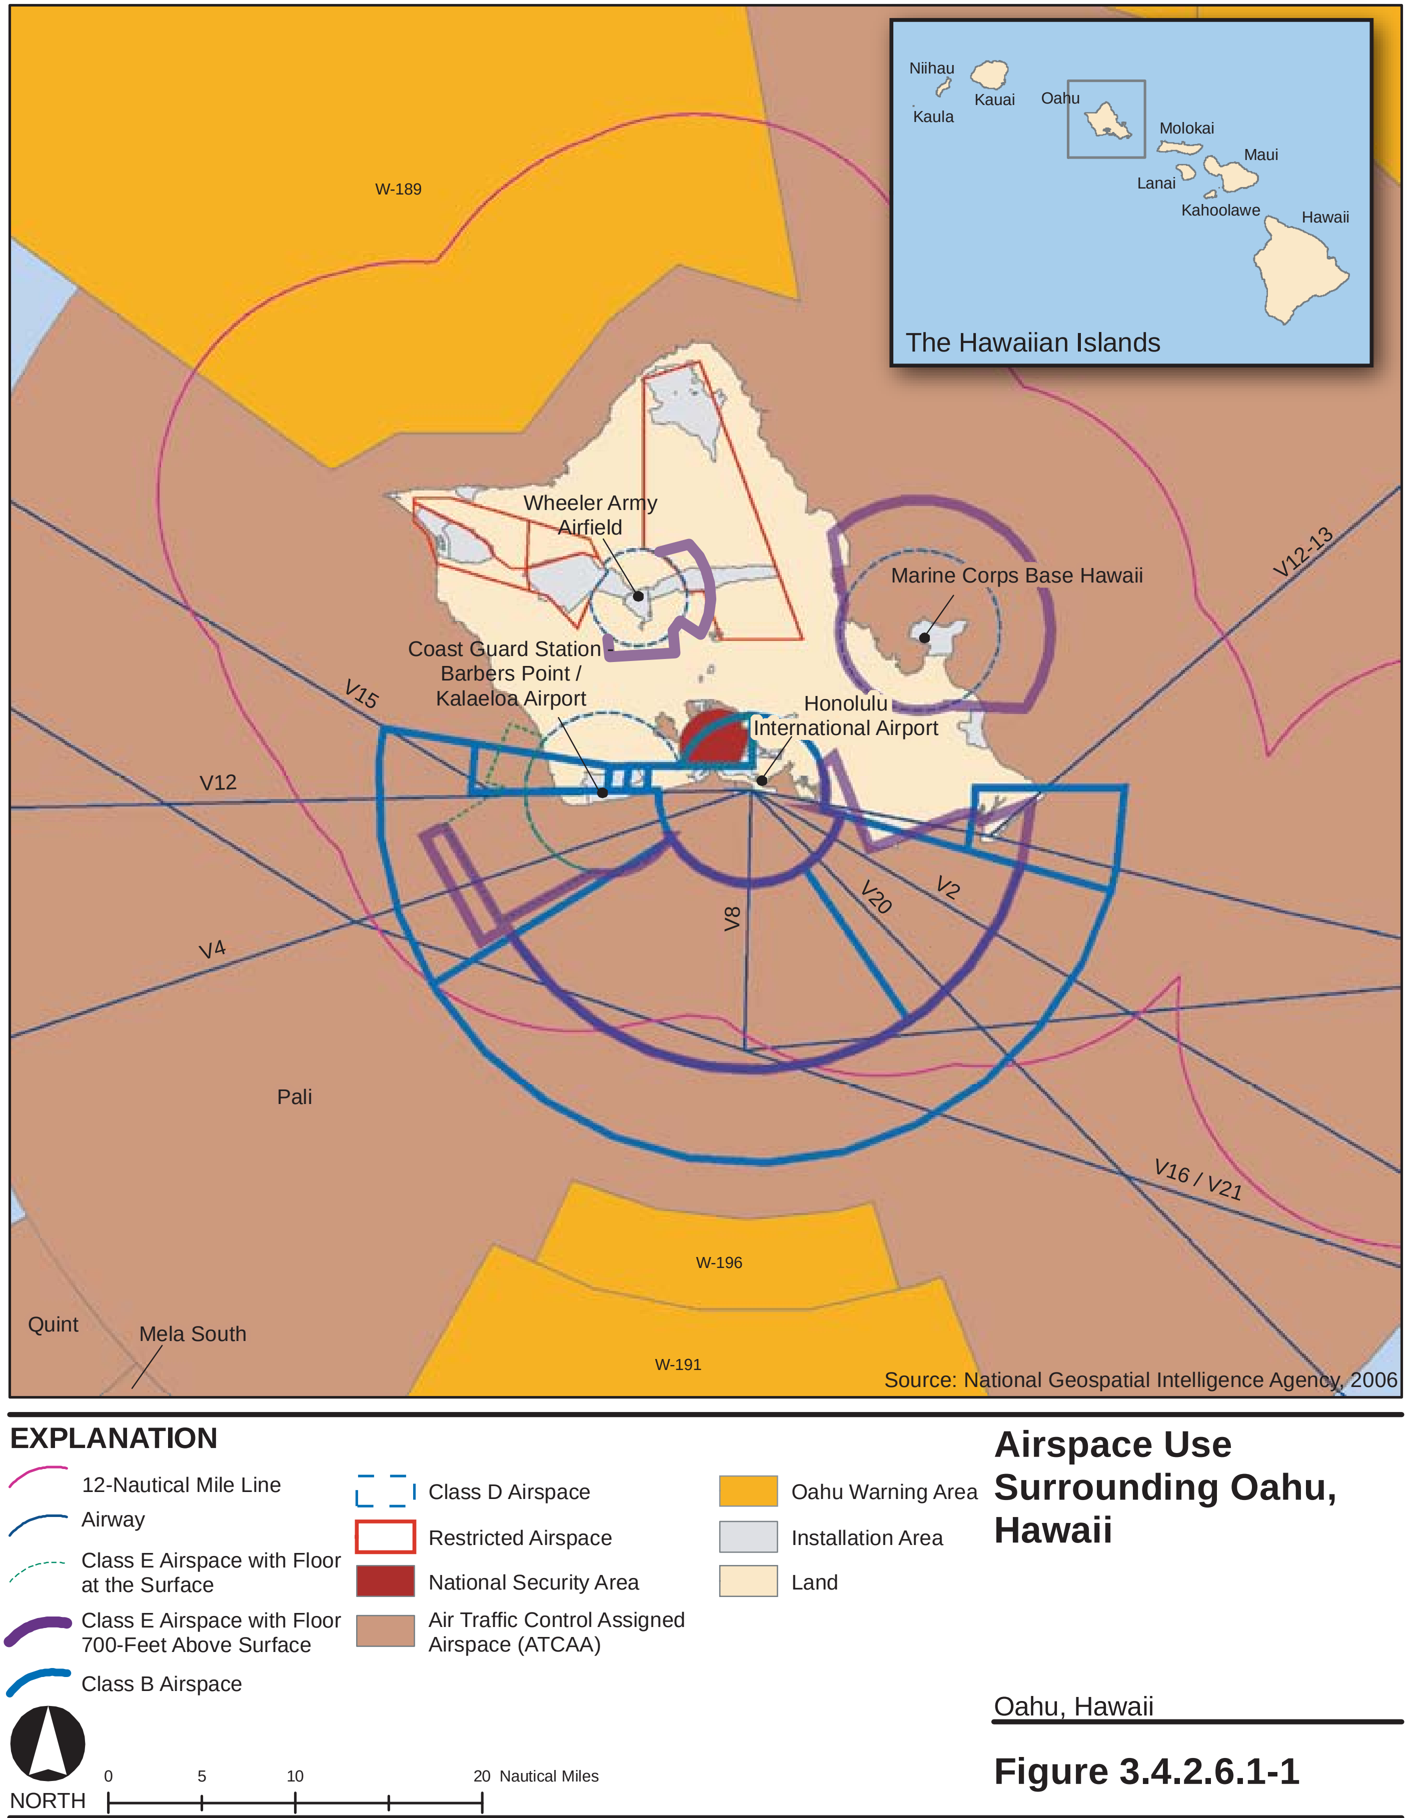
Based on the RIMPAC Exercise, air operations include space for the various types of aircraft and equipment for refueling and maintenance. The use of U.S. Coast Guard Air Station Barbers Point by aircraft during RIMPAC would be secondary and would fall within the day-to-day coordination for the movement of equipment and supplies.

The use of U.S. Coast Guard Air Station Barbers Point by aircraft during RIMPAC would be coordinated as part of the biennial planning process during three planning conferences leading up to the RIMPAC Exercise. Due to the level and extent of planning involved, and the minimal potential for significant impacts, airspace has not been evaluated under the RIMPAC Environmental Assessments (EAs) (U.S. Department of the Navy, 2006a; 2002a; 2000 and U.S. Department of the Navy, Commander Third Fleet, 2004).

The region of influence is the airspace above U.S. Coast Guard Air Station Barbers Point and Kalaeloa Airport. This area is within the area described for Hickam AFB. Figure 3.4.2.6.1-1 shows a view of the airspace above Oahu including U.S. Coast Guard Air Station Barbers Point/Kalaeloa Airport.

Affected Environment

Search and rescue is the primary mission of U.S. Coast Guard Air Station Barbers Point within the Pacific Maritime Region. As the sole U.S. Coast Guard Air unit in this area of the Pacific, U.S. Coast Guard Air Station Barbers Point is responsible for a vast area, including such island chains as the Hawaiian, Marianas, Caroline, and Marshalls. To accomplish its assigned missions, the U.S. Coast Guard uses four Aerospatiale HH-65A “Dolphin” short-range recovery helicopters and four Lockheed HC-130H “Hercules” long-range search aircraft.



Airspace Use Surrounding Oahu, Hawaii

Oahu, Hawaii

Figure 3.4.2.6.1-1

The affected airspace use environment in the U.S. Coast Guard Air Station Barbers Point region of influence is described below in terms of its principal attributes: controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields. There are no military training routes in the region of influence.

Controlled and Uncontrolled Airspace

The airspace within the region of influence consists of the airspace above Kalaeloa Airport which includes Class D, surface Class E, and Class E airspace with a floor 700 ft above the surface (see Figure 3.4.2.6.1-1). Honolulu International Airport Class B airspace is located partially within and above the Kalaeloa airport airspace.

Special Use Airspace

The only special use airspace in the region of influence (see Figure 3.4.2.6.1-1) is the Pali Air Traffic Control Assigned Airspace that is in effect above the entire Oahu area from flight level (FL) 250 (25,000 ft) to unlimited. The Pali airspace is scheduled through the Navy Fleet Area Control and Surveillance Facility (FACSFAC) Pearl Harbor who then coordinates with the Federal Aviation Administration (FAA) Honolulu Combined Facility.

En Route Airways and Jet Routes

The closest instrument flight rules (IFR) en route low altitude airways are V12 and V15, which pass directly over the airfield and V4, which passes above the Kalaeloa Class D and E airspace.

Airports and Airfields

Wheeler Army Airfield is located 10 nm to the north and Honolulu International Airport is located 8 nm to the east.

3.4.2.6.2 Biological Resources—U.S. Coast Guard Air Station Barbers Point/Kalaeloa Airport

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes the installation and its offshore waters.

Affected Environment

Vegetation

U.S. Coast Guard Air Station Barbers Point occupies a portion of the 750-acre Kalaeola Airport. As such, there are few biological resources associated directly with the facility. Open areas are grassed and maintained. Pua pilo (*Capparis sandwichiana* var. *zoharyi*), a Federal species of concern endemic shrub, is located in the southwestern corner of Kalaeloa on the USFWS Pearl Harbor National Wildlife Refuge, Kalaeloa Unit (State of Hawaii, 2006).

Threatened and Endangered Plant Species

The endemic, endangered `akoko shrub (*Chamaesysce skottsbergii var. kalaeloana*) (Table 3.4.2.6.2-1) occurs in at least three locations at the former Barbers Point Naval Air Station. The endangered round-leafed chaff-flower or ewa hina hina (*Achyranthes splendens* var. *rotundata*) is located in the southwestern corner of Kalaeloa. (State of Hawaii, 2006)

Table 3.4.2.6.2-1. Listed Species Known or Expected to Occur in the Vicinity of U.S. Coast Guard Air Station Barbers Point/Kalaeloa Airport

Scientific Name	Common Name	Federal Status
Plants		
Achyranthes splendens var. *rotundata*	Ewa hina hina (Round-leafed chaff-flower)	E
Chamaesysce skottsbergii var. kalaeloana	`Akoko (Coastal sandmat)	E
Birds		
Himantopus mexicanus knudseni	Ae`o (Hawaiian black-necked stilt)	E

Source: U.S. Fish and Wildlife Service, 2005a; b; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007

Key to Federal Status:
E = Endangered

Wildlife

The Kalaeloa Airport is used by birds, feral dogs and cats, rodents, and mongooses. Birds are the most common form of wildlife on the site and include the black-crowned night heron, great frigate bird, Pacific golden plover, sanderling (*Calidris alba*), wandering tattler, ruddy turnstone, zebra dove, Japanese white-eye, northern cardinal, red-crested cardinal (*Paroaria coronata*), and red-vented bulbul. (U.S. Department of the Navy, 2002a; State of Hawaii, 2001)

The State endangered Hawaiian short-eared owl, which is Federally listed as a Species of Concern, may transit through the region of influence (State of Hawaii, 2006).

Threatened and Endangered Wildlife Species

Ordy Pond, an anchialine (marine) pond east of the airfield; the coastal salt flats between Runway 4R-22L and Taxiway K; and also the western boundary of Kalaeloa are frequented by the endangered Hawaiian black-necked stilt and migratory birds. (State of Hawaii, 2006)

Environmentally Sensitive Habitat

The Kalaeloa Unit, which was once part of the former Barbers Point Naval Air Station, has been added to the Pearl Harbor National Wildlife Refuge. The Kalaeloa Unit supports the second largest population of endangered ewa hina hina. (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007)

3.4.2.7 MARINE CORPS BASE HAWAII (MCBH)

MCBH is a 2,951-acre reservation on Mokapu Peninsula on the northeast side of the Island of Oahu. The base is bounded by water on three sides: Kaneohe Bay, the Pacific Ocean, and Kailua Bay. The Nu`upia Pond Wildlife Management Area lies in the isthmus between the base and the mainland.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for MCBH. Of the 13 environmental resources considered for analysis, air quality, geology and soils, hazardous materials and hazardous waste, health and safety, land use, transportation, utilities, and water resources are not addressed.

3.4.2.7.1 Airspace—MCBH

Appendix C includes a detailed description of airspace.

Region of Influence

Based on RIMPAC, aircraft support includes space for the various types of aircraft and equipment for refueling and maintenance. U.S. and foreign aircraft (fixed wing, rotary, and airship) would be supported from several locations. For a typical RIMPAC, approximately 20 aircraft would be supported at MCBH. Housing would be provided at the installation.

The use of MCBH by aircraft during RIMPAC would be coordinated as part of the biennial planning process during three planning conferences leading up to the RIMPAC Exercise. Due to the level and extent of planning involved, and the minimal potential for significant impacts, airspace has not been evaluated under the RIMPAC EAs (U.S. Department of the Navy, 2006a; 2002a; 2000 and U.S. Department of the Navy, Commander Third Fleet, 2004).

The MCBH region of influence includes the Class D and Class E airspace (defined in Appendix C) above MCBH. Figure 3.4.2.6.1-1 shows a view of the airspace above Oahu including MCBH.

Affected Environment

The affected airspace use environment in the MCBH region of influence is described below in terms of its principal attributes: controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields. There are no military training routes in the region of influence.

Controlled and Uncontrolled Airspace

The airspace within the region of influence consists of the airspace above MCBH which includes Class D, and Class E airspace with a floor 700 ft above the surface. No Class B (U.S. terminal control areas) airspace, which usually surrounds the nation’s busiest airports, or Class C airspace is found in the MCBH region of influence.

Special Use Airspace

The only special use airspace in the region of influence (see Figure 3.4.2.6.1-1) is the Pali Air Traffic Control Assigned Airspace that is in effect above the entire Oahu area from FL 250 (25,000 ft) to unlimited. The Pali airspace is scheduled through the Navy FACSFAC Pearl Harbor, which then coordinates with the FAA Honolulu Combined Facility.

En Route Airways and Jet Routes

The closest IFR en route low altitude airways are V12-13 and V15, which pass outside the region of influence approximately 10 nm southeast of MCBH.

Airports and Airfields

MCBH is surrounded by Class D airspace that extends from the surface to 2,500 ft. The Class E airspace extension to the north and east has a floor 700 ft above the surface. Honolulu International Airport is located southeast of MCBH, outside the region of influence.

3.4.2.7.2 Biological Resources—MCBH

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes the installation and adjacent waters.

Affected Environment

Vegetation

Dune vegetation consists of naupaka (*Scaevola sericea*) thickets interspersed with clusters of sea grape. Along the seaward side of the naupaka is a mat of beach dropseed grass (aki`aki) (*Sporobolus virginicus*) and morning glory (pohuehue) (*Ipomoea pes-caprae*). Ironwood trees are also present at the Hale Koa/West Field landing area. The terrestrial habitat typically consists of sparse ground cover composed of indigenous grasses and shrubs. Most of the vegetation on MCBH is dominated by introduced species. (U.S. Department of the Navy, 2002a)

Threatened and Endangered Plant Species

No threatened or endangered plants have been observed at MCBH.

Wildlife

Migratory birds such as the Pacific golden-plover and ruddy turnstone have been observed foraging and resting on the landing beaches. Seabirds, including the great frigate bird (`iwa) and brown noddy have been seen foraging offshore. (U.S. Department of the Navy, 2002a)

A red-footed booby nesting colony consisting of over 3,000 birds is located on the cliffs of the 23-acre Ulupau Wildlife Management Area. Wedge-tailed shearwaters and black-crowned night herons (`auku`u) are also found in the area. (U.S. Fish and Wildlife Service, 2005a; Defense Environmental Network & Information eXchange, 2005; Sierra Club, not dated)

Threatened and Endangered Wildlife Species

Threatened and Endangered species in the MCBH region are listed in Table 3.4.2.7.2-1. The koloa maoli (Hawaiian duck), `alae ke`oke`o (Hawaiian coot), and `alae `ula (Hawaiian common moorhen) have been observed at the base wetlands. The ae`o (Hawaiian stilt) nests on mud mounds in the region of influence and feeds on insects, worms, and crustaceans uncovered by Marine amphibious assault vehicles. Marines of the amphibious-assault vehicle platoon churn up the mud of wetlands in the 482-acre Nuupia Ponds Wildlife Management Area once a year. These tracked vehicles flatten invasive pickleweed that threaten to choke off the ponds, creating the same terrain that is preferred by this endangered bird. (U.S. Department of the Air Force, 2003; Sierra Club, 2006)

Table 3.4.2.7.2-1. Listed Species Known or Expected to Occur in the MCBH Region

Scientific Name	Common Name	Federal Status
Reptiles		
Chelonia mydas	Green turtle	T
Eretmochelys imbricata	Hawksbill turtle	E
Birds		
Anas wyvilliana	Koloa maoli (Hawaiian duck)	E
Fulica alai	`Alae ke`oke`o (Hawaiian coot)	E
Gallinula chloropus sandvicensis	`Alae `ula (Hawaiian common moorhen)	E
Himantopus mexicanus knudseni	Ae`o (Hawaiian black-necked stilt)	E
Pterodroma phaeopygia sandwichensis	`Ua`u (Hawaiian dark-rumped petrel)	E
Puffinus auricularis newelli	`A`o (Newell's Townsend's shearwater)	T
Mammals		
Lasiurus cinereus semotus	Hawaiian hoary bat	E
Monachus schauinslandi	Hawaiian monk seal	E

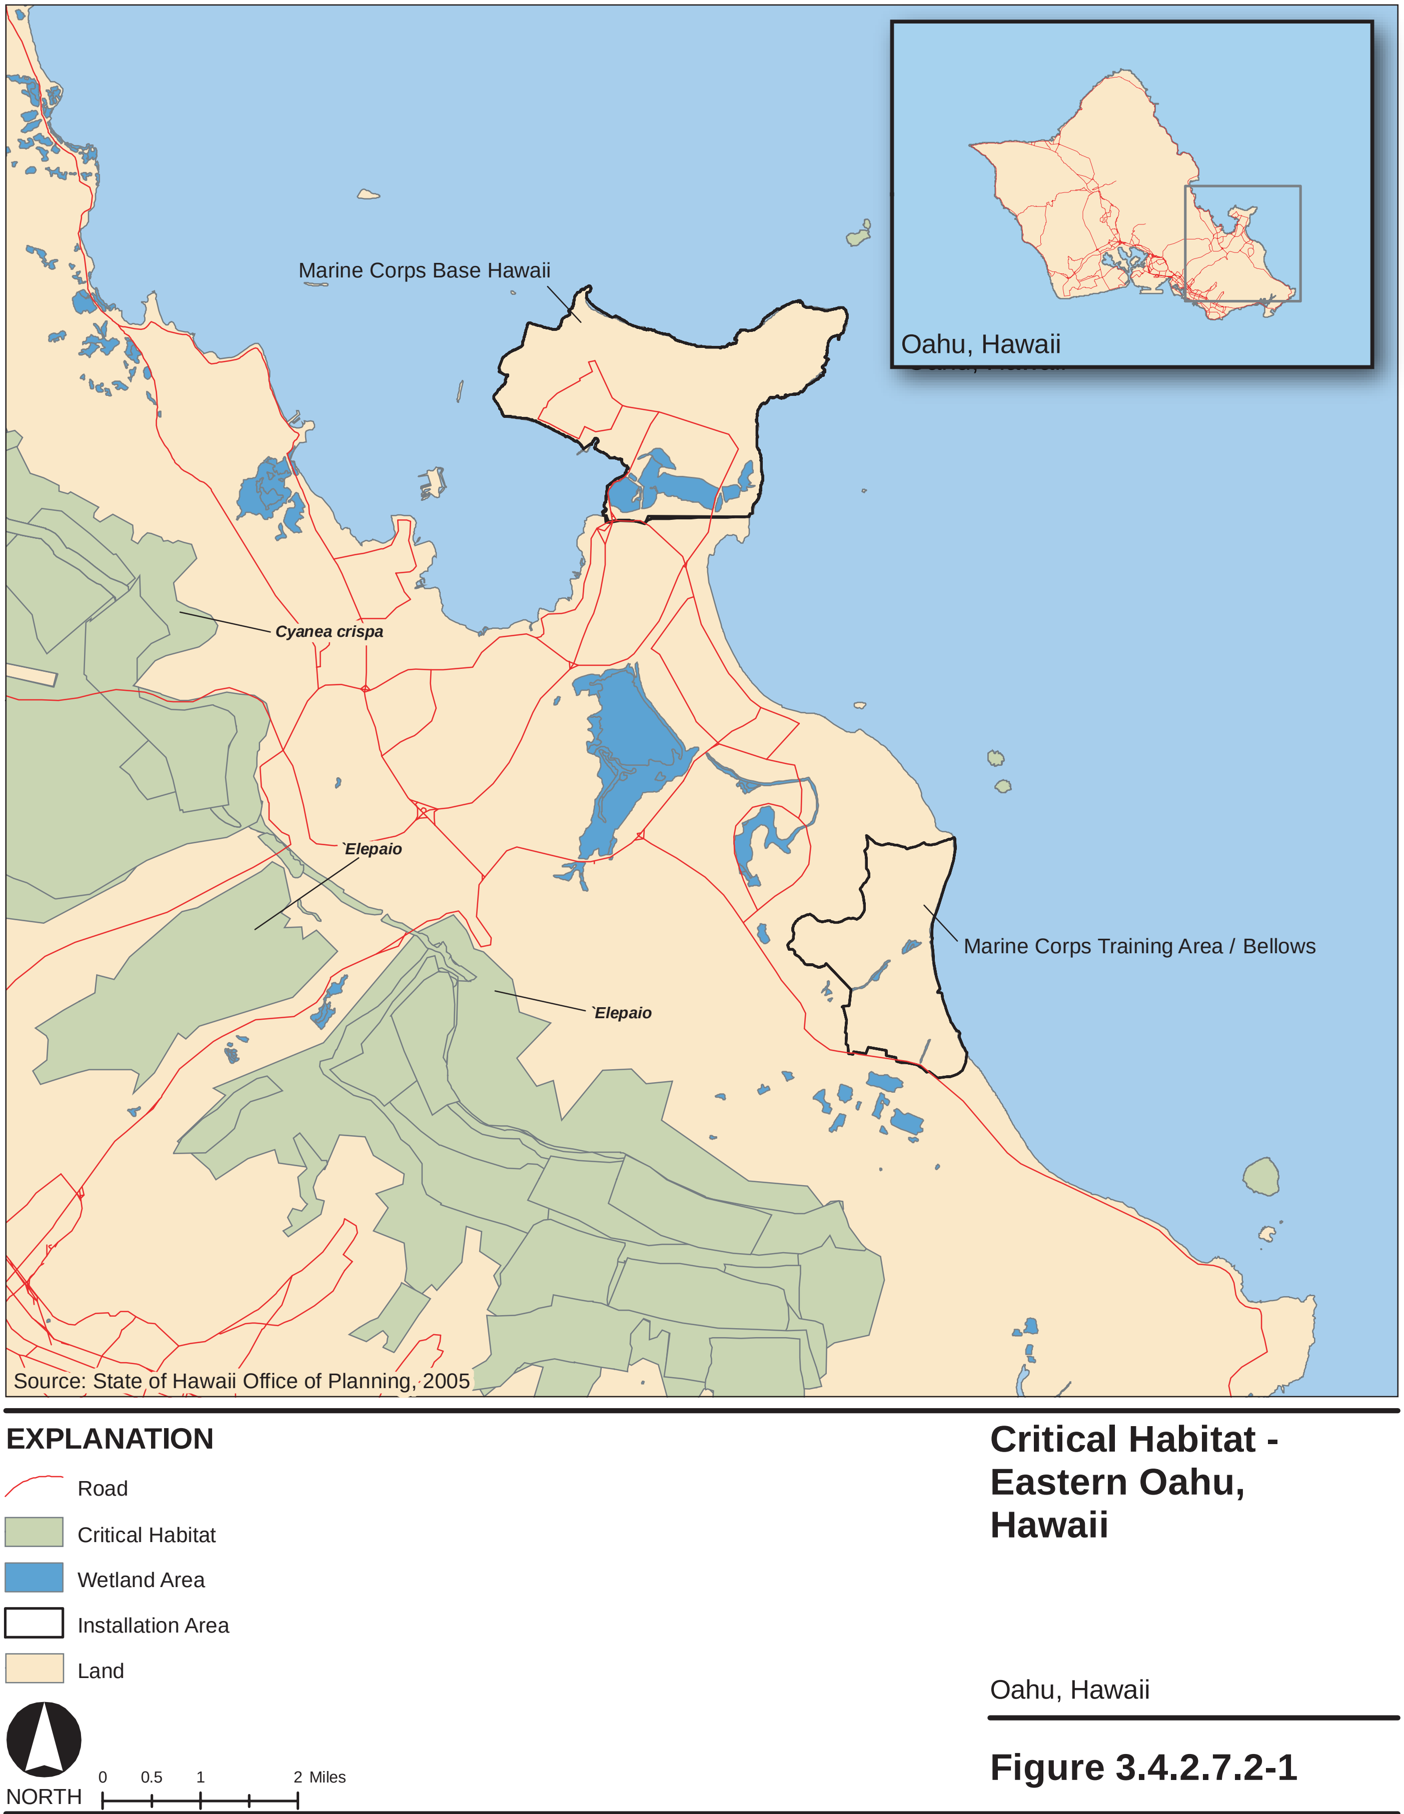
Source: U.S. Department of the Air Force, 2003; U.S. Fish and Wildlife Service, 2006b; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007

Key to Federal Status:
T = Threatened
E = Endangered

The endangered Hawaiian monk seal has occasionally hauled out on Pyramid Rock Beach. In 1996, a monk seal gave birth on a small beach near recreational cabins north of West Field. (U.S. Department of the Navy, 2002a)

Environmentally Sensitive Habitat

No critical habitat has been designated on MCBH (Figure 3.4.2.7.2-1). Wetlands include the Nuupia Ponds complex at the southern boundary of the base. Approximately 22 acres of invasive mangrove stands have been removed from Nuupia Pond since the early 1980s. There are also several ephemeral ponds and marshes that provide short-lived habitat for wildlife after rainfall. (U.S. Department of the Air Force, 2003)



Critical Habitat - Eastern Oahu, Hawaii

Oahu, Hawaii

Figure 3.4.2.7.2-1

3.4.2.7.3 Cultural Resources—MCBH

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for cultural resources at MCBH encompasses locations where Humanitarian Assistance/Disaster Relief Operations will occur. About 700 acres of MCBH's total properties are the focus of cultural resources management. Approximately 550 of the 700 acres are at Mokapu, including the Nuupia Ponds and Mokapu Burial Area (Defense Environmental Network and Information eXchange, 1999).

Affected Environment

Archaeological Resources (Prehistoric and Historic)

Baseline cultural resources surveys completed in 1981 and 1986 were updated, and the data were included in the Mokapu Cultural Resources Management Plan (1997). As part of the update, a Cultural Resources Assessment of the MCBH was performed in May 1997. The report indicated that Hale Koa/West Field Beach was created with dredged fill during World War II and contains no cultural resources or human remains. Hale Koa/West Field's additional runway was created with fill as part of the World War II base expansion and has no potential for cultural resources or the discovery of human remains. The Pyramid Rock Beach landing and staging areas contain no known cultural resources or human remains. The landing and staging areas at Fort Hase Beach are within a zone classified as having a low archaeological sensitivity. A ground-penetrating radar survey of the landing and staging areas detected no cultural deposits or burials and confirmed that the areas were previously disturbed (Yamada, 2002; U.S. Department of the Navy, 2002a).

Archaeological sites identified at MCBH include the Nuupia Ponds; the Mokapu Burial Area, which is listed in the NRHP; approximately 27 pre-contact or early-contact Hawaiian sites; and 45 post-contact sites that cover the period from early Hawaiian through World War II (Defense Environmental Network and Information eXchange, 1999).

Historic Buildings and Structures

Historic buildings, structures, and other features under the control of MCBH include the following (Defense Environmental Network and Information eXchange, 1999):

- Hangar 101 and Seaplane Ramps. Located on the Kaneohe Bay shoreline, Hangar 101 and its associated seaplane ramps are a designated National Historic Landmark. The facilities once supported the Navy's PBY Catalina patrol plane fleet and were bombed minutes before the December 7, 1941 attack on Naval Station Pearl Harbor.
- Aircraft Parts. Kaneohe Bay waters and Ulupau Crater ravines harbor the wreckage of aircraft downed during the December 7, 1941 attack on Naval Station Pearl Harbor.
- Battery Pennsylvania at Ulupau Crater Head. Battery Pennsylvania is a World War II fortification that has been determined to be eligible for inclusion in the NRHP. Seven stories deep, this massive reinforced concrete gun emplacement supported a turret with 14-inch guns from the sunken battleship, *USS Arizona*.

Traditional Resources

Archival research and oral histories verify Mokapu as inspiration for many Hawaiian stories, songs, dance, and religious ceremonies. The exact translation of the word Mokapu is not confirmed; however, it could be a contraction of moku (district or island) and kapu (sacred or forbidden).

3.4.2.7.4 Noise—MCBH

Appendix C includes a definition of noise and the main regulations and laws that govern it.

Region of Influence

The region of influence for MCBH is the area within and surrounding MCBH in which humans and wildlife may suffer annoyance or disturbance from noise levels from the proposed training at MCBH.

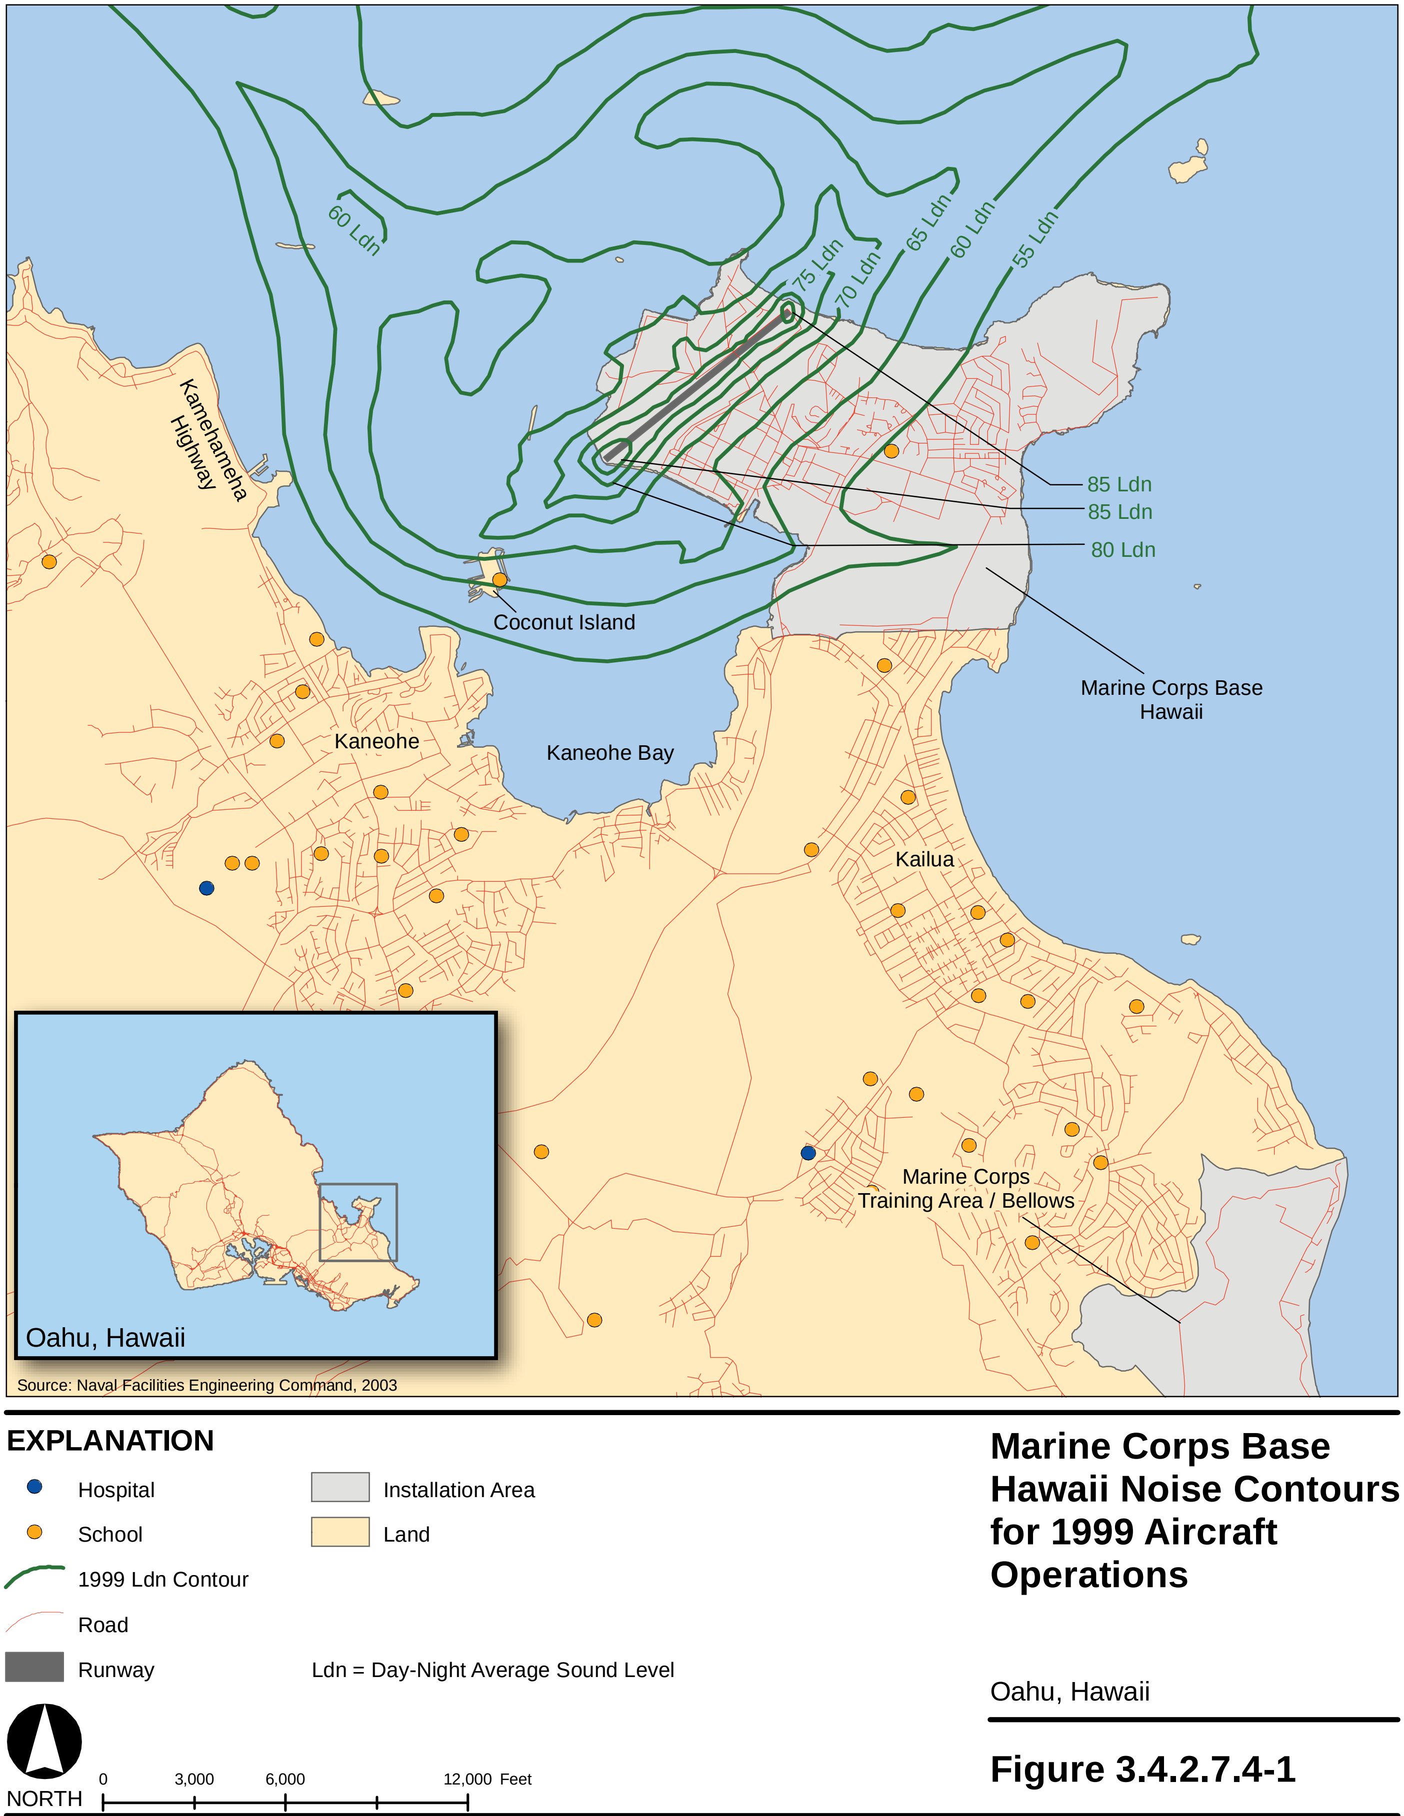
Affected Environment

The primary source of noise at MCBH is the neighboring military landing field that serves both fixed-wing and helicopter events. Helicopter and aircraft activities and amphibious training occur regularly at the landing field. During active runway use or amphibious training, noise levels typically range between 70 and 75 dBA. During periods of no runway use or training, the noise levels are equal to or less than 55 dBA during the day and fall to less than 45 dBA during the evening and night hours. The nearest sensitive noise receptor is Hale Koa Beach, approximately 328 ft southeast of helicopter landing areas and 2,198 ft northwest of an active runway. Noise levels at Hale Koa Beach are similar to the noise levels described at MCBH. (U.S. Department of the Navy, 2002a)

MCBH has established noise controls to protect base personnel and the community, including establishing flight patterns and airfield operation schedules that satisfy the community and support mission activities. In addition, a community notification plan for all short-term training that may increase noise levels is followed. (U.S. Department of the Navy, 2002a)

Figure 3.4.2.7.4-1 depicts noise contours based on annual events for MCBH in 1999, which includes 163,390 flight events during the day and 13,460 night flight events. Aircraft at MCBH include, but are not limited to P-3s, C-130s, C-17s, F/A-18s, CH-53Ds, SH-60s, and C-20Gs. The *MCBH Kaneohe Bay Air Installation Compatible Use Zones* (Naval Facilities Engineering Command, 2003) determined that the only off-base land areas that would be impacted by noise levels greater than Day-Night Level (DNL) 60 are Coconut Island and other small uninhabited islands. Land uses within the DNL 65 noise contour on-base include the industrial area near the runway, maintenance facilities, portions of the officers' family housing and bachelor enlisted quarters, a portion of the golf course, beach areas, operational and maintenance uses on both sides of the runway, and the runway itself. (Naval Facilities Engineering Command, 2003)

Wildlife receptors for the MCBH area are described in Section 3.4.2.7.2, Biological Resources.



Marine Corps Base Hawaii Noise Contours for 1999 Aircraft Operations

Oahu, Hawaii

Figure 3.4.2.7.4-1

3.4.2.7.5 Socioeconomics—MCBH

Appendix C includes a general definition of socioeconomics.

Region of Influence

The region of influence for socioeconomic analysis is MCBH. The County of Honolulu comprises the entire island of Oahu. The base is bounded by water on three sides: Kaneohe Bay, the Pacific Ocean, and Kailua Bay.

Affected Environment

The closest civilian community to MCBH is Kaneohe. Kaneohe is considered a single-family suburban "bedroom community" and is likely to be affected by MCBH airfield operations due to the nearby major flight tracks. In addition airfield operations are visible to Kaneohe residents. Kaneohe has a population of approximately 55,800, and the average household income is about $80,000 (American Dream Realty, 2006). In addition to residential land use, there are several other significant uses of the Kaneohe Bay area, including major commercial activities along Kamehameha Highway and several light industries. Kaneohe is a town and census-designated place included in the City and County of Honolulu and located in Hawaii, on the island of Oahu (Honolulu Board of Realtors, 2006b). Section 3.4.2.1.3 discusses the socioeconomic characteristic of Oahu, which encompasses the Kaneohe community.

There are several small islands within Kaneohe Bay. Coconut Island, the only inhabited island, comprises approximately 29 acres. Approximately half of this area is landfill formed by dredged materials form the main Kaneohe Bay channel, deposited on the perimeter of the island. The University of Hawaii Institute of Marine Biology, a research facility, is the primary activity on the island. The former privately owned area in the central area of the island is now owned by the University of Hawaii Foundation and leased to the University of Hawaii for the Hawaii Institute of Marine Biology's long-term use. Daytime staffing ranges from 50 to 100 personnel. There are about 17 full-time residents on the island, which include institute staff members and their families. There are also several temporary lodging facilities on the island that are used by visiting researchers. Three other small uninhabited islands are located near MCBH Kaneohe Bay. These islands are seabird sanctuaries managed by the State of Hawaii. (Naval Facilities Engineering Command, 2003)

3.4.2.8 MARINE CORPS TRAINING AREA/BELLOWS (MCTAB)

MCTAB covers 1,078 acres on the southeastern portion of Oahu. The inactive airfield in the center of the site is limited to rotary wing activity, and is occasionally used for Marine Corps helicopter training.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for MCTAB. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.8.1 Biological Resources—MCTAB

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes those areas on or adjacent to MCTAB that could be affected by existing or proposed training.

Affected Environment

Vegetation

Virtually all native vegetation on MCTAB has been replaced by exotic species. Extensive second-growth forest is dominated by koa haole, Christmas berry (*Schinus terebinthifolius*), and ironwood. (U.S. Air Force 15th Airlift Wing, 2005) Only 12 percent of the species recorded were native species (U.S. Department of the Navy, 2002a). However, sea cliffs and sand dunes at MCTAB support unique strand vegetation (Defense Environmental Network & Information eXchange, 2001).

<u>Threatened and Endangered Plant Species</u>

No rare, threatened, or endangered plant species are known to occur on or near MCTAB (U.S. Air Force 15th Airlift Wing, 2005).

Wildlife

Shorebirds observed in the vicinity of MCTAB include the Pacific golden plover, wandering tattler, ruddy turnstone, and sanderling. The Hawaiian short-eared owl has also been seen on the station's perimeter.

<u>Threatened and Endangered Wildlife Species</u>

Threatened and endangered species observed or potentially occurring at MCTAB (Table 3.4.2.8.1-1) include the endangered koloa maoli (Hawaiian duck), `alae ke`ok`o (Hawaiian coot), alae ula (Hawaiian common moorhen), and ae`o (Hawaiian black-necked stilt). Forty to sixty percent of the statewide population of the ae`o (Hawaiian black-necked stilt) is found on Oahu. According to the USFWS, the Hawaiian dark-rumped petrel and Newell's shearwater have the potential to occur on the base (U.S. Fish and Wildlife Service, 2007a). Oahu also has the largest population of `alae ke`ok`o (Hawaiian coot) in the islands. The endangered Hawaiian hoary bat may also use the habitat at MCTAB. (U.S. Air Force 15th Airlift Wing, 2005)

Table 3.4.2.8.1-1. Listed Species Known or Expected to Occur at Marine Corps Training Area/Bellows

Scientific Name	Common Name	Federal Status
Reptiles		
Chelonia mydas	Green turtle	T
Eretmochelys imbricata	Hawksbill turtle	E
Birds		
Anas wyvilliana	Koloa maoli (Hawaiian duck)	E
Fulica alai	`Alae ke`oke`o (Hawaiian coot)	E
Gallinula chloropus sandvicensis	Alae ula (Hawaiian common moorhen)	E
Himantopus mexicanus knudseni	Ae`o (Hawaiian black-necked stilt)	E
Pterodroma phaeopygia sandwichensis	`Ua`u (Hawaiian dark-rumped petrel)	E
Puffinus auricularis newelli	`A`o (Newell's Townsend's shearwater)	T
Mammals		
Lasiurus cinereus semotus	Hawaiian hoary bat	E
Monachus schauinslandi	Hawaiian monk seal	E

Source: U.S. Department of the Navy, 2002a; U.S. Fish and Wildlife Service, 2006b; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007

Key to Federal Status:

E = Endangered

T = Threatened

Environmentally Sensitive Habitat

Critical habitat for the endangered Oahu `elepaio (*Chasiempis sandwichensis ibidis*) is located approximately 2 mi west of MCTAB (Figure 3.4.2.7.2-1). No critical habitat has been designated on MCTAB. Wetland acreage on MCTAB is located along the Waimanalo stream, which provides habitat for native waterbirds and aquatic species (Defense Environmental Network & Information eXchange, 2001; National Wetlands Inventory, 2007).

3.4.2.8.2 Cultural Resources—MCTAB

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for terrestrial and underwater cultural resources at MCTAB includes locations where Expeditionary Assault (amphibious training), Swimmer Insertion/Extraction, Humanitarian Assistance Operations/Non-Combatant Evacuation Operations, SPECWAROPS, and Humanitarian Assistance/Disaster Relief Operations would occur (see Figure 2.1-3).

Affected Environment

Archaeological Resources (Prehistoric and Historic)

Located on the windward coast of Oahu, MCTAB has a long history of human occupation and exploitation. Archaeological studies reveal extensive prehistoric use of beach ridges and swales for campsites, tool making, and as burial areas and, in some locations (particularly along streams and near the coast), cultural deposits are relatively thick. (Desilets, 2002)

At the time of the Great Mahele (in 1848), most of the area now encompassed by MCTAB was in the ahupuaa of Waimanalo, which during the mid 1800s was part of the Crown Lands of Kamehameha III. In 1850, the area was leased for cattle, horse, and sheep ranching, but by the late 1870s, ranching had been replaced by sugar cane fields (in non-beach areas).

In 1917, the Waimanalo Military Reservation was established with boundaries nearly identical to those of present day MCTAB. Significant use of the area by the military did not occur until 1933 when the name of the installation was changed to Waimanalo Military Reservation, Bellows Field. At the time of the Japanese attack on Naval Station Pearl Harbor, new runways were already under construction. Along with many other facilities, the runways were completed during World War II and the installation was used as an airfield. After World War II, Bellows Field transitioned from an airfield to a training, recreation, and communications facility. A Nike/Hercules missile site was added to the facility during the Cold War era, and interior areas were leased for cattle ranching. (Desilets, 2002)

Approximately 20 archaeological sites have been identified at MCTAB, several of which are located within the runway complex. There is also a high probability for additional subsurface sites to exist, particularly along stream banks and in dune areas (U.S. Air Force, 15th Airlift Wing, 2005; U.S. Department of Defense, 2006). Most of the archaeological sites at MCTAB are subsurface, including both identified and potential burial sites at isolated locations. Many of the identified sites, including Site 4852 (Bellows Dune Site), are eligible for inclusion in the NRHP. (U.S. Pacific Command, 1995; U.S. Department of the Navy, 2002a; U.S. Army Corps of Engineers, Honolulu Engineer District, 2005) A list of archaeological and traditional resources sites at MCTAB is provided in Appendix H.

Historic Buildings and Structures

A complete inventory of potential historic buildings and structures was completed for MCTAB in 2002 (U.S. Army Corps of Engineers, Honolulu Engineer District, 2005). Properties were identified as eligible for inclusion in the NRHP, including World War II-era aircraft revetments for the B-17 aircraft and Pursuit Planes, runways, and taxiways. (U.S. Army Corps of Engineers, Honolulu Engineer District, 2005)

Traditional Resources

Although traditional Hawaiian resources information is scant for the MCTAB area, there are several associated legend sites that have been identified and determined to be eligible for inclusion in the NRHP as Traditional Cultural Properties. These include the area of the Battle of Kukui (a 2-day battle between Kalanikupule [the ruler of Oahu in 1794] and his Uncle Kaeokulani [ruler of Kauai]) (Archaeological Site No. 4858); the legend of *Haununaniho,* a small hill (puuhonua), which is said to have once been a place of refuge (Archaeological Site No. 383); and the legend of the black stone (Pohaku-paakiki), which is believed to have been a shrine built by sweet potato growers who used it to place offerings to their shark god, Kamohoalili. This same area is also associated with a legend about a stone watch tower and small house used to guard Oahu from approaching canoes. Archaeological Site No. 4852 (Bellows Dune Site) and three areas of nearby excavations have been listed in the NRHP. In addition, 49 burials have been recorded. (U.S. Army Corps of Engineers, Honolulu Engineer District, 2005)

3.4.2.9 HICKAM AIR FORCE BASE (AFB)

Hickam AFB is located on the south side of Oahu next to the Honolulu International Airport and consists of 2,850 acres of land and facilities. Hickam AFB, Hawaii is home to the 15th Airlift Wing and 67 partner units including Pacific Air Forces Headquarters and the Hawaii Air National Guard.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Hickam AFB. Of the 13 environmental resources considered for analysis, air quality, cultural resources, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.9.1 Airspace—Hickam AFB

Appendix C includes a detailed description of airspace.

Region of Influence

Based on RIMPAC, aircraft support includes space for the various types of aircraft and equipment for refueling and maintenance. U.S. and foreign aircraft (fixed wing, rotary, and airship) would be supported from several locations. For a typical RIMPAC, approximately 50 aircraft would be supported at Hickam AFB. Housing would be provided at the installation.

The use of Hickam AFB by aircraft during RIMPAC would be coordinated as part of the biennial planning process during three planning conferences leading up to the RIMPAC Exercise. Due to the level and extent of planning involved, and the minimal potential for significant impacts, airspace has not been evaluated under the RIMPAC EAs (U.S. Department of the Navy, 2006a;; 2002a; 2000 and U.S. Department of the Navy, Commander Third Fleet, 2004).

The Hickam AFB region of influence includes the airspace above and south of Honolulu International Airport. Figure 3.4.2.6.1-1 shows a view of the airspace above Oahu including Hickam AFB/Honolulu International Airport.

Affected Environment

The affected airspace use environment in the Hickam AFB region of influence is described below in terms of its principal attributes: controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields. There are no military training routes in the region of influence.

Controlled and Uncontrolled Airspace

The airspace within the region of influence consists of the airspace above Hickam AFB/Honolulu International Airport as shown on Figure 3.4.2.6.1-1. Hickam AFB shares its runways with the adjacent Honolulu International Airport. Hickam AFB and the Honolulu International Airport constitute a single airport complex operated under a joint-use agreement.

The Class B airspace that lies above Hickam AFB consists of a core surface area surrounded by several layers of varying floor altitudes (FL 10, 15, 20, 30, 40) but the same ceiling altitude of FL 90. Below the Class B layers is Class E airspace with a floor 700 ft above the surface. Honolulu Combined Facility, more specifically, the Honolulu Control Tower, controls the movement of aircraft within the region of influence.

Special Use Airspace

The Pali Air Traffic Control Assigned Airspace is in effect above the entire Oahu area from FL 250 (25,000 ft) to unlimited. The Pali airspace is scheduled through the Navy FACSFAC Pearl Harbor who then coordinates with the FAA Honolulu Combined Facility.

There is also a National Security Area above a portion of Naval Station Pearl Harbor as shown on Figure 3.4.2.6.1-1. For reasons of national security, pilots are requested not to fly below 5,000 ft in this area.

En Route Airways and Jet Routes

Several IFR en route low altitude airways enter or transect the region of influence. These airways are Class E airspace corridors with centerlines established by navigational aids.

Airports and Airfields

The Hickam AFB/Honolulu International is the primary airport within the region of influence. Kalealoa Airport is located approximately 8 nm west of Hickam AFB, Wheeler Army Airfield is located 12 nm northwest, and Kaneohe Bay Marine Corps Airfield at MCBH is located 12 nm northeast.

3.4.2.9.2 Biological Resources—Hickam AFB

Region of Influence

The region of influence includes the base and adjacent waters.

Affected Environment

Vegetation

Vegetation on Hickam AFB has been disturbed or removed, and there are no significant, naturally occurring, native plant communities. Native plants are occasionally used in landscaping. Managed vegetation consists of herbaceous ruderal vegetation. Unmanaged vegetation exists in the southern part of the base and includes buffelgrass/kiawe woodland, kiawe forest, pickleweed flats, and mangrove. (U.S. Department of the Air Force, 2003)

Threatened and Endangered Plant Species

No threatened or endangered plants have been identified on base.

Wildlife

Fish and wildlife on Hickam AFB are managed through its Integrated Natural Resources Management Plan in cooperation with the USFWS and the State of Hawaii. Terrestrial wildlife on the base includes feral cats and mongoose. Shoreline wetlands provide a limited amount of cover, nesting, and feeding habitat for songbirds. Wedge-tailed shearwaters have been downed by lights on the base. The State endangered pueo (Hawaiian short-eared owl) has been observed on base. (U.S. Department of the Air Force, 2003)

Threatened and Endangered Wildlife Species

Threatened and endangered wildlife species on or in the area of Hickam AFB are listed in Table 3.4.2.9.2-1. The ae`o (Hawaiian stilt) has been observed in the Reef Runway Lagoon, near the Manuwai Canal, and in ephemeral ponds on other parts of the base. Federally endangered Hawaiian waterbirds, primarily Hawaiian stilts, are regular visitors to Hickam AFB, having been observed foraging and nesting on base and adjacent to the runway. On March 2006, at least two separate stilt pairs nested adjacent to the runway where dewatering ponds were in place on Hickam AFB. (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007) Habitat for the `alae ke`oke`o (Hawaiian coot) and the `alae`ula (Hawaiian common moorhen) exists at the Manuwai Canal, but these birds have not been recorded at this location. The koloa maoli (Hawaiian duck) has been observed on the Waipio Peninsula, which is 2 to 3 mi from Hickam AFB. The Hawaiian hoary bat, which is usually found on Kauai and Hawaii, could use portions of Hickam AFB since a few scattered sightings on Oahu have been reported. (U.S. Department of the Air Force, 2003)

Green turtles, resting Hawaiian monk seals, and transitory humpback whales are known to occur or could occur in waters off Hickam AFB.

Table 3.4.2.9.2-1. Listed Species Known or Expected to Occur in the Hickam AFB Region

Scientific Name	Common Name	Federal Status
Reptiles		
Chelonia mydas	Green turtle	T
Birds		
Anas wyvilliana	Koloa maoli (Hawaiian duck)	E
Fulica alai	`Alae ke`oke`o (Hawaiian coot)	E
Gallinula chloropus sandvicensis	Alae ula (Hawaiian common moorhen)	E
Himantopus mexicanus knudseni	Ae`o (Hawaiian black-necked stilt)	E
Mammals		
Lasiurus cinereus semotus	Hawaiian hoary bat	E
Monachus schauinslandi	Hawaiian monk seal	E

Source: U.S. Department of the Air Force, 2003; U.S. Fish and Wildlife Service, 2006b; 2007

Key to Federal Status:
T = Threatened
E = Endangered

Environmentally Sensitive Habitat

Most of the wetlands on Hickam AFB are located in the southern part of the base in flat or depressed areas, along the coast, and along the edges of canals (National Wetlands Inventory, 2007). Most wetlands, except for the coastal mangrove shrubland and sand beaches, are disturbed by human activities and are of little value to wildlife.

3.4.2.10 WHEELER ARMY AIRFIELD

Wheeler Army Airfield consists of approximately 1,389 acres of land adjacent to Schofield Barracks. Wheeler Army Airfield is home to a variety of DoD activities including the Defense Communications Agency, the Air Force's 6010th Aerospace Defense Group, the Hawaii Army National Guard's Aviation Support Facility, and the 25th Infantry Division (Light) Aviation Brigade.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Wheeler Army Airfield. Of the 13 environmental resources considered for analysis, air quality, cultural resources, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.10.1 Airspace—Wheeler Army Airfield

Appendix C includes a detailed description of airspace.

Region of Influence

Based on RIMPAC, aircraft support includes space for the various types of aircraft and equipment for refueling and maintenance. The use of Wheeler Army Airfield by aircraft during RIMPAC is secondary and falls within the day-to-day coordination for the movement of equipment and supplies.

The use of Wheeler Army Airfield by aircraft during RIMPAC would be coordinated as part of the biennial planning process during three planning conferences leading up to the RIMPAC Exercise. Due to the level and extent of planning involved, and the minimal potential for significant impacts, airspace has not been evaluated under the RIMPAC EAs (U.S. Department of the Navy, 2006b;; 2002a; 2000 and U.S. Department of the Navy, Commander Third Fleet, 2004).

The region of influence is defined as the area affected by the ongoing No-action Alternative and the proposed training. Figure 3.4.2.6.1-1 shows a view of the airspace above Oahu, including Wheeler Army Airfield. The region of influence includes the Class D and Class E airspace above Wheeler Army Airfield.

Affected Environment

The affected airspace use environment in the Wheeler Army Airfield region of influence is described below in terms of its principal attributes: controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields. There are no military training routes in the region of influence.

Controlled and Uncontrolled Airspace

The airspace within the region of influence consists of the airspace above Wheeler Army Airfield which includes Class D airspace from the surface to FL 33, and Class E airspace with a floor 700 ft above the surface.

No Class B (U.S. terminal control areas) airspace, which usually surrounds the nation's busiest airports, or Class C airspace is found in the region of influence.

Special Use Airspace

Several restricted airspace areas (3109 A, B, C and 3110 A, B, C) are located immediately northwest of the Wheeler Army Airfield Class D airspace. These areas are outside the region of influence for Wheeler Army Airfield.

The Pali Air Traffic Control Assigned Airspace is in effect above the entire Oahu area from FL 250 (25,000 ft) to unlimited. The Pali airspace is scheduled through the Navy FACSFAC Pearl Harbor, which then coordinates with the FAA Honolulu Combined Facility.

En Route Airways and Jet Routes

The closest IFR en route low altitude airways are located outside the region of influence, south of Oahu.

Airports and Airfields

MCBH is located 15 nm to the east and Honolulu International Airport is located 12 nm to the southeast, both outside the region of influence.

3.4.2.10.2 Biological Resources—Wheeler Army Airfield

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes the installation and adjacent land.

Affected Environment

Vegetation

Wheeler Army Airfield is a developed area that contains mostly non-native urban vegetation (U.S. Department of the Army, 2004).

Threatened and Endangered Plant Species

No threatened or endangered plants have been identified on Wheeler Army Airfield.

Wildlife

There are no native terrestrial amphibians or reptiles on the Hawaiian Islands. Non-native amphibians and reptiles that have the potential to occur on Wheeler Army Airfield include the green and black poison dart frog, (*Dendrobates auratus*), bullfrog (*Rana catesbeiana*), giant toad (*Bufo marinus*), Cuban tree frog (*Osteopilus septentrionalis*), green anole (*Anolis carolinensis*), mourning gecko (*Lepidodactylus lugubris*), house gecko (*Hemidactylus frenatus*), metallic skink (*Lampropholis delicata*), and island blind snake (*Rhamphotyphlopys braminus*). (U.S. Department of the Army, 2004)

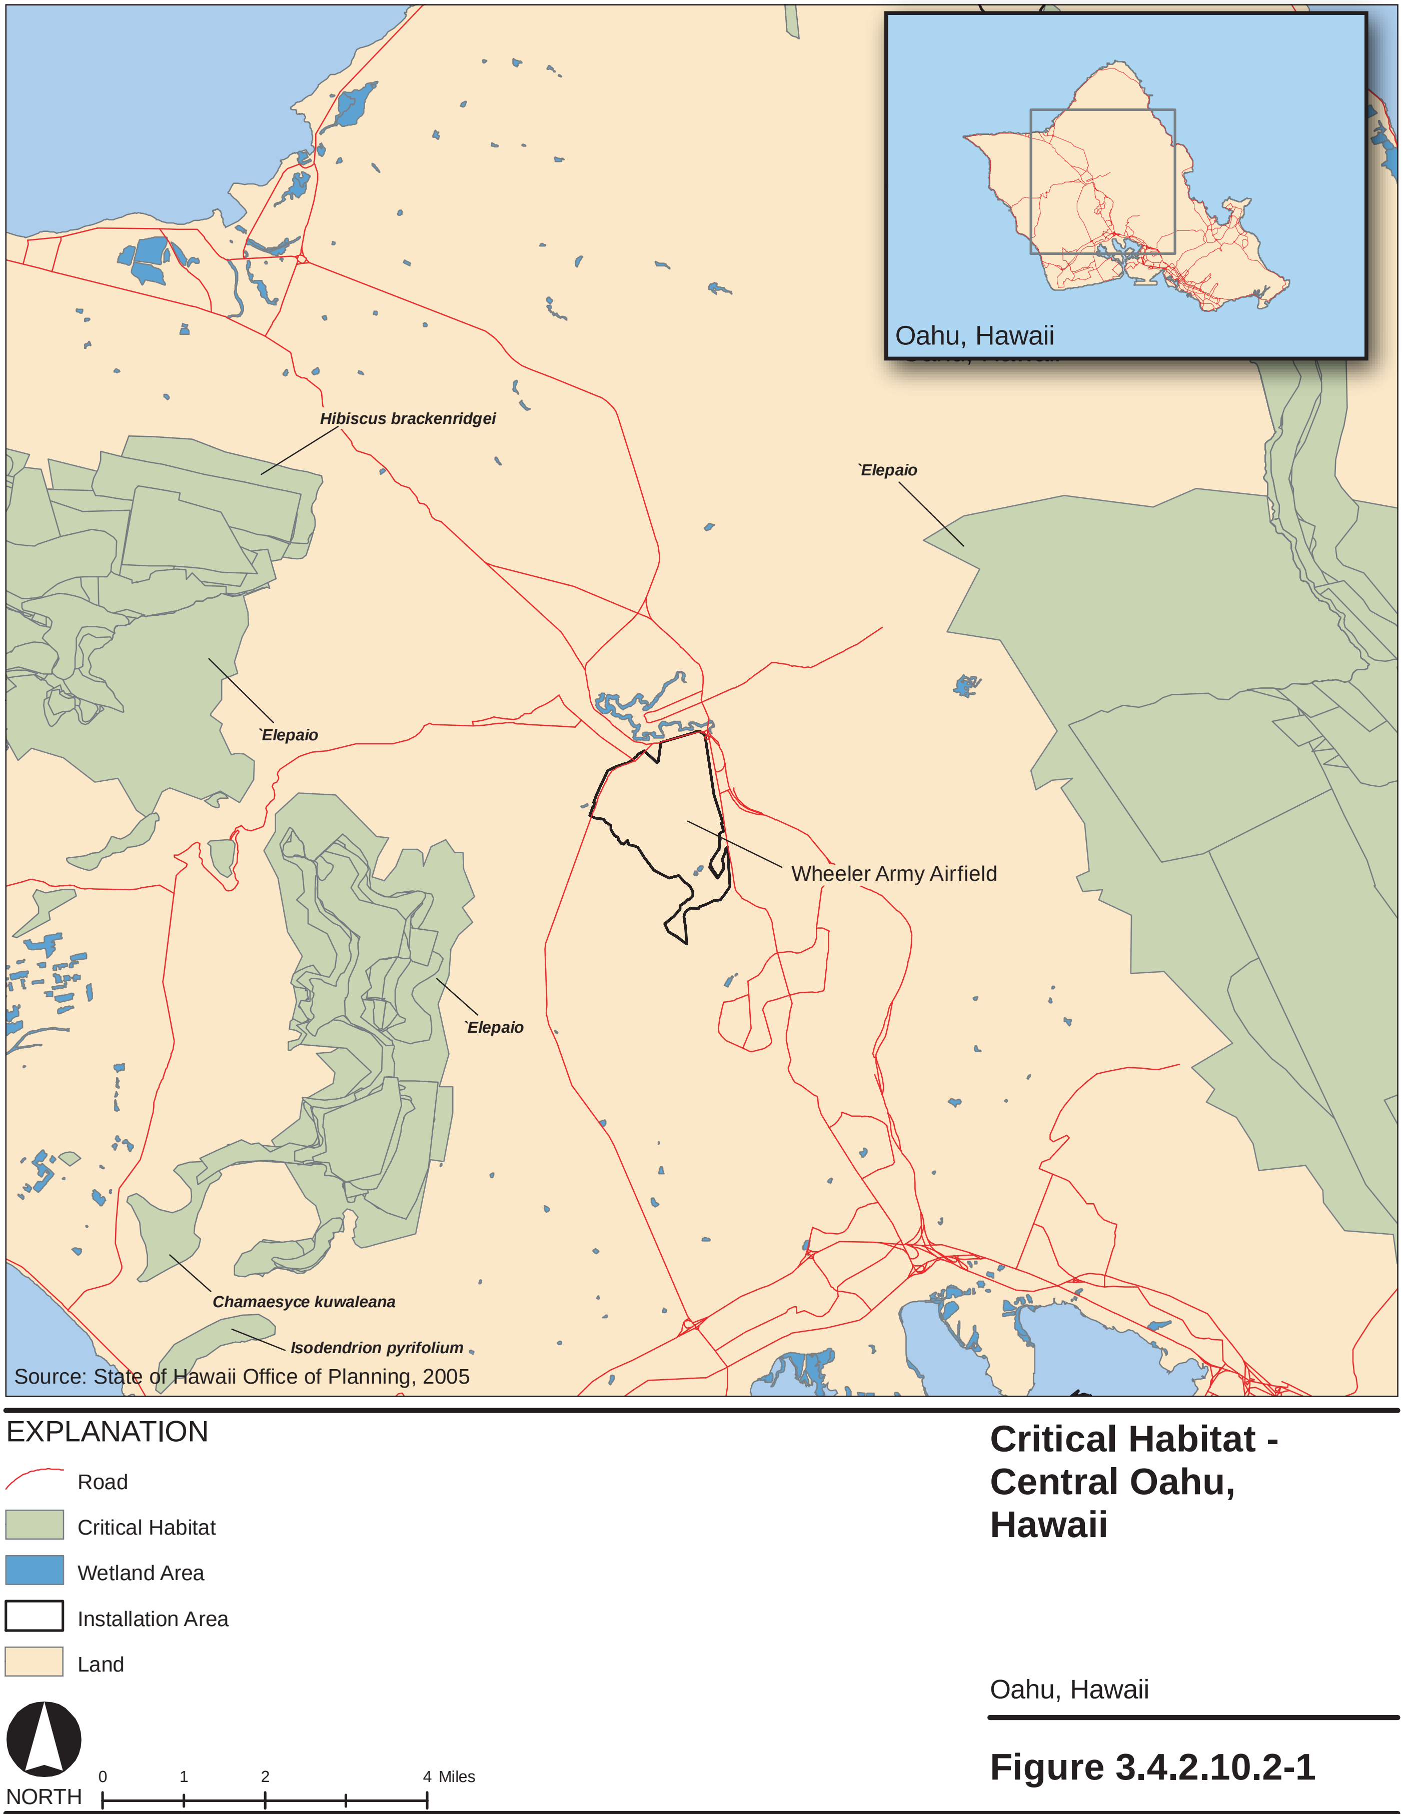
Several species of native and non-native birds are located in the region of influence. The black-crowned night heron, Pacific golden plover, and white-tailed tropicbird (*Phaethon lepturus*) are indigenous birds that are in the region of influence. Non-native birds in the region include, but are not limited to, the rock dove (*Columba livia*), zebra dove, common myna, and red-vented bulbul. (U.S. Department of the Army, 2004)

Threatened and Endangered Wildlife Species

The Hawaiian hoary bat may occur at or in the vicinity of the airfield.

Environmentally Sensitive Habitat

No critical habitat has been designated in the region of influence (Figure 3.4.2.10.2-1).



Critical Habitat - Central Oahu, Hawaii

Oahu, Hawaii

Figure 3.4.2.10.2-1

3.4.2.11 MAKUA MILITARY RESERVATION

Makua Military Reservation is a Department of the Army reservation containing a total of 4,190 acres in the Makua Valley on the northwestern side of Oahu. Makua Military Reservation extends from the Farrington Highway along the west coast eastward to the ridgeline of the Waianae Mountains. The Navy would only use the Makua Military Reservation if approved by the Army.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Makua Military Reservation. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, land use, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.11.1 Biological Resources—Makua Military Reservation

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes Makua Military Reservation and adjacent waters.

Affected Environment

Vegetation

Three ecological zones have been identified within Makua Military Reservation. The Army delineated these zones based on elevation, topography, and prevailing climatic conditions within the Reservation, resulting in three designations: Ridge Crest Vegetation Zone, Native Shrub on Cliff and Slope Zone, and Lowland Native Forest Zone. The ecological subzones and plant and animal biota within each of these have also been well documented. Guinea grass and molasses grass are two examples of alien plant species occurring on the installation. (U.S. Department of the Army, 2005)

<u>Threatened and Endangered Plant Species</u>

Records dating back to 1970 indicate that there are 32 endangered plants on Makua Military Reservation (Table 3.4.2.11.1-1). The majority of these plants are found along the southern and northeastern boundaries of the reservation. The removal of wild goats on the range has been beneficial to the management of the endangered plants. Another primary threat to the endangered plants on the range is fire. Recent fires have burned acreage containing some of these plants. (U.S. Department of the Army, 2005)

Wildlife

In addition to native species, introduced nuisance species such as pigs, rats, and goats adversely affect range habitat. The Army has implemented measures, including more than 7 mi of fencing, to control the movement of pigs and goats onto the Makua Military Reservation. (U.S. Department of the Army, 2005)

Table 3.4.2.11.1-1. Listed Species Known or Expected to Occur at Makua Military Reservation

Scientific Name	Common Name	Federal Status
Plants		
Abutilon sandwicense	Flowering maple	E

Key to Federal Status: U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007
E Endangered
T Threatened

Threatened and Endangered Wildlife Species

Records dating back to 1970 indicate that there are two endangered birds, one endangered terrestrial mammal, and one endangered snail (*Achatinella mustelina*, Oahu tree snail) on Makua Military Reservation (Table 3.4.2.11.1-1). (U.S. Department of the Army, 2005)

Section 7 consultation has been conducted with USFWS to determine if routine military training at Makua Military Reservation would jeopardize the continued existence of endangered species. In 1999, the USFWS issued a Biological Opinion concluding that the routine military training would not jeopardize the endangered species if certain conditions were met. These include restrictions to military training, and preparation and implementation of a Wildland Fire Management Plan. The *Integrated Wildland Fire Management Plan Oahu and Pohakaloa Training Areas* was completed in 2003 (U.S. Army, Hawaii and 25th Infantry Division [Light], 2003). The Army also completed an Implementation Plan in 2003 to stabilize the targeted plant and animal populations. An Addendum was submitted to the USFWS in 2005 that emphasized management of three population units per plant taxon. The consultation completed in 1999 for Makua Military Reservation has been reinitiated three times, most recently in June 2007. (U.S.

Department of the Navy, 2002a; U.S. Army Garrison, Hawaii, 2005; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007)

Environmentally Sensitive Habitat

The USFWS designated critical habitat on Makua Military Reservation in 2001 for the Oahu `elepaio (Figure 3.4.2.11.1-1). The USFWS determined that lands on Oahu that fall under Army jurisdiction do not meet the definition of critical habitat under the ESA for the listed plant species shown in Table 3.4.2.11.1-1, based on the Army's continuing commitment to management and stabilization of sensitive species through their Integrated Natural Resources Management Plan, Integrated Wildland Fire Management Plan, Ecosystem Management Plan, and Endangered Species Management Plan. These documents/plans outline specific strategies and programs in place to stabilize species and habitats on Army land. (U.S. Department of the Army, 2005) Critical plant habitat is however, located outside the boundaries of Makua Military Reservation.

Although potential estuarine wetlands have been observed on Makua Military Reservation, no formal identification or designation has been made (U.S. Department of the Navy, 2002a). According to the 2005 *Draft Environmental Impact Statement Military Training Activities at Makua Military Reservation,* aquatic natural communities on the installation include intermittent streams and gulches, such as Punapohaku Stream, Makua Stream, and Kalena Stream. Although potential estuarine wetlands (muliwai or small ponds) have been noted, there has been no formal identification or designation of them (U.S. Department of the Army, 2005). The intermittent Kalena Stream with head waters in Koiahi Gulch crosses through part of the proposed managed area on the south side of Makua Valley. Intermittent streams on the reservation fit the state definition of Class 2 Inland Freshwaters, which are waters used for recreational purposes, the support and propagation of aquatic life, agricultural and industrial water supplies, shipping, and navigation. (U.S. Department of the Army Headquarters, and U.S. Department of the Army, 2006)

3.4.2.11.2 Cultural Resources—Makua Military Reservation

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

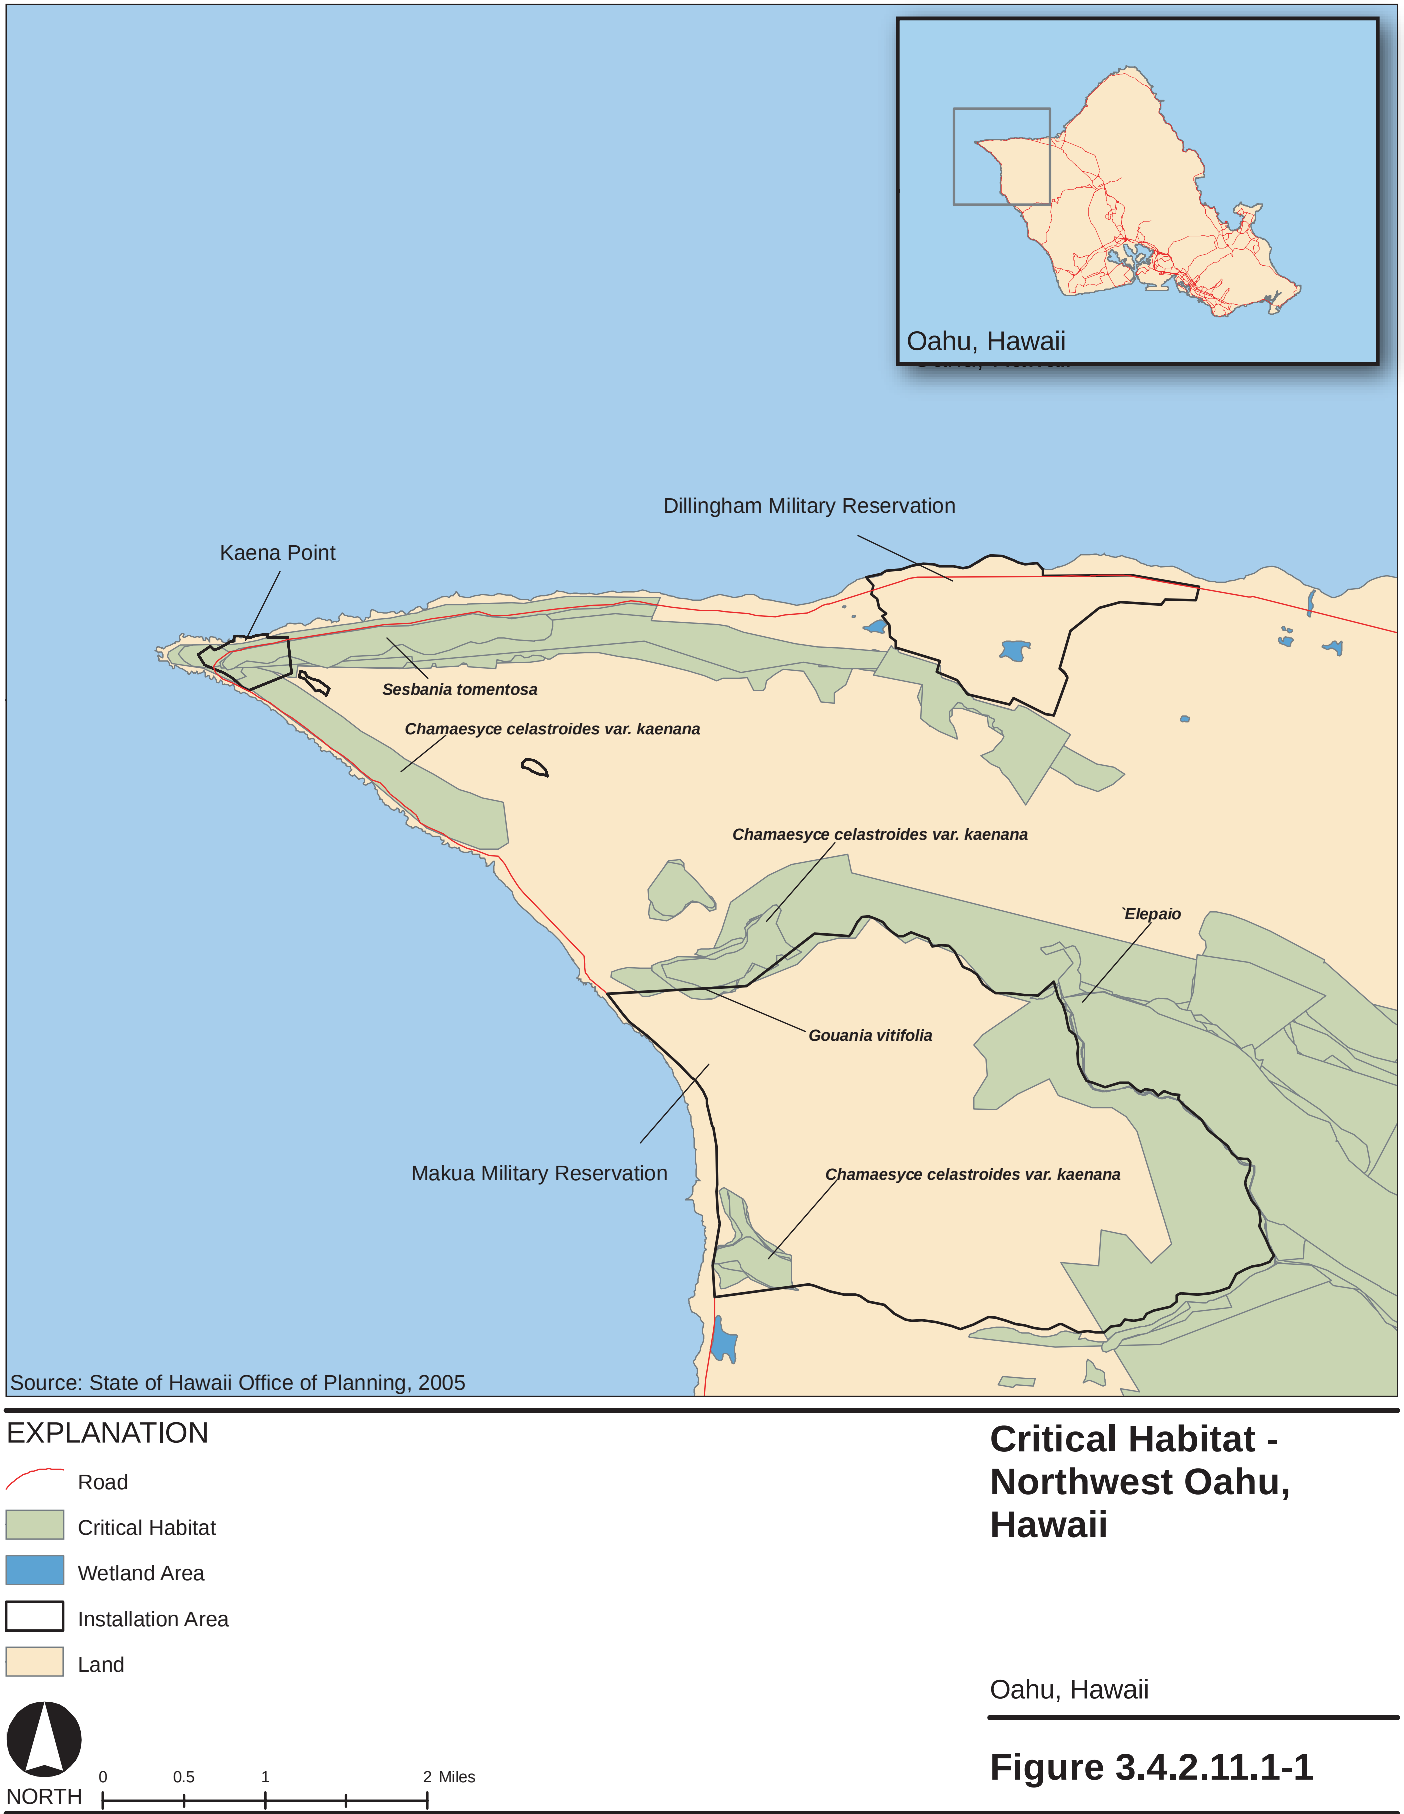
Region of Influence

The cultural resources region of influence for Makua Military Reservation (Figure 2.1-3) encompasses all areas where LFX events (including major ground troop and artillery movement and munitions detonation [e.g., mortars, heavy artillery]) could be conducted.

Affected Environment

Archaeological Resources (Prehistoric and Historic)

Archaeological evidence indicates that Makua Valley once supported both a coastal population (historically known as Makua Village), and permanent occupation in the middle and upper elevations. Archaeologists hypothesize that Makua has similar settlement patterns to the Makaha, Waianae, and Lualualei valleys, with more people living in the back of the valley, at the higher elevations where rainfall was more abundant. Data infer that by the mid-1800s, the middle area was claimed only as community kula (pasture) lands that had once been habitation



Critical Habitat - Northwest Oahu, Hawaii

Oahu, Hawaii

Figure 3.4.2.11.1-1

sites abandoned early in the post-contact period (Williams and Patolo, 2000). Early missionary accounts of Makua Valley note that there was a large school, suggesting more population than just the coastal village. (The Onyx Group, 2001)

Sandalwood harvesting began in Makua Valley as early as 1815, but as the wood was exhausted, ranching and agriculture (particularly sweet potatoes) became the more common land use practices. After the Great Mahele of 1848 (a system of private land division/ownership), land in Makua Valley was awarded to various claimants, including a large portion to the Hawaiian government. The lands remained under private or government ownership or lease until the Army's use of the land in 1941. (The Onyx Group, 2001)

Since the early 1900s, a number of archaeological surveys have been conducted in the Makua Valley. Among these are Thrum (1906); McAllister (1933); Rosendahl for the Bishop Museum (1977); and Williams and Patolo (2000). Additional surveys and subsurface testing were undertaken at Makua Military Reservation by archaeologists from the Environmental Division of the Department of Public Works in 2000 and 2007. Among the identified site types are heiaus, shrines, trails, stone walls, and enclosures, terraces, platforms, and habitation sites. One site, the Ukanipo Heiau, is listed in the NRHP and other sites may qualify (Pilia`au Range Complex and Makua Military Reservation, 2006). A list of recorded archaeological sites is provided in Appendix H (The Onyx Group, 2001; U.S. Department of the Navy, 2002a).

On September 18, 2000, a Section 106 Programmatic Agreement was finalized with the Hawaii State Historic Preservation Officer and the Advisory Council on Historic Preservation. The Programmatic Agreement was developed by the Army in consultation with Native Hawaiian groups and regulatory agencies over a period of 2 years. It contains specific programs and efforts to protect and mitigate impacts on cultural resources at Makua Military Reservation. (The Onyx Group, 2001) A copy of the Programmatic Agreement is provided as Appendix H.

Historic Buildings and Structures

Makua Military Reservation is a large training range. There are no identified historic buildings and structures.

Traditional Resources

Makua Military Reservation is associated with a number of legends and traditional Hawaiian deities, and has significant religious and social value to local inhabitants. Among other important resources, a comprehensive investigation of the traditional complexion and resources of Makua Military Reservation entitled *Cultural History Report of Makua Military Reservation, Makua Valley, Oahu, Hawaii*, was prepared in 1977 by Kelley and Quintal. The report presents the history, traditional accounts, and legends of Makua Valley. (The Onyx Group, 2001)

The 2000 Programmatic Agreement described above includes provisions for access for members of the Native Hawaiian community to Ukanipo Heiau. This access is independent of training in the valley. Access to other sites within the valley has been given on a case-by-case basis, as is consistent with training and safety concerns. The potential for increased access to other sites within Makua Military Reservation is being examined (see Appendix H). (The Onyx Group, 2001)

3.4.2.11.3 Health and Safety—Makua Military Reservation

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence for potential impact related to the health and safety of personnel and the public includes areas associated with training events at Makua Military Reservation and those off-base areas affected by training.

Affected Environment

Makua Military Reservation takes every precaution during planning and execution of training events to prevent injury to human life or property. Standard Operating Procedures for LFX outline assets, personnel, safety requirements, and procedures to be used during each event. Use of the range is scheduled through the Range Division—Hawaii Scheduling Office, and Makua Range Control monitors all communications during training.

For each training event, a detailed surface danger zone is determined, in accordance with Army Regulation 385-64, *Ammunition and Explosives Safety Standards.* A surface danger zone ensures a proper buffer zone to the range and ordnance impact area, which prevents accidental injury and exposure to live weapons outside the designated training area. Upon completion of the training event, every effort is made to restore the range to its condition prior to use, including explosive ordnance disposal specialists destroying all identifiable unexploded ordnance.

An additional concern at Makua Military Reservation is accidental wildfires due to military training. A majority of the fires that have started on Makua Military Reservation have been contained with the boundaries of the installation. However, some fires have burned onto the adjacent land of Albert Silva, the Kuaokala Game Management Area, and the Air Force Kaena Point Satellite Tracking Station. (U.S. Department of the Army, 2005)

Fire prevention at Makua Military Reservation includes planning, managing fuels, using prescribed fire, planning water resources, and training firefighters. Makua Military Reservation has a fire danger rating system that uses the following three colors to characterize fire threat conditions:

- Green (indicating normal caution during training). Weather conditions are favorable for all authorized munitions, and smoking is permitted.
- Yellow (indicating caution because fires will start easily). For this fire danger period, smoking is permitted only in designated areas, and only ball ammunition, mortar, artillery, hand grenades, and smoke grenades are allowed.
- Red (indicating extreme caution because a fire would be difficult to control). No smoking is permitted on the ranges and no munitions or pyrotechnics are allowed. In other words, no live fire training is allowed, and the ranges are closed. (U.S. Department of the Army, 2005)

3.4.2.11.4 Noise—Makua Military Reservation

Appendix C includes a definition of noise and the main regulations and laws that govern it.

Region of Influence

The region of influence for Makua Military Reservation is the area within and surrounding Makua Military Reservation in which humans and wildlife may suffer annoyance or disturbance from noise levels from proposed training at Makua Military Reservation and those off-base areas affected by training events.

Affected Environment

Noise is generated at the Makua Military Reservation from military activities, including infantry and helicopter gunnery training events. Other noise sources include low background noise levels from wind, surf, birds, insects, and light highway traffic. Ambient noise levels at Makua Beach are estimated to be between 40 and 50 dBA, with peaks reaching noise levels greater than 70 dBA during high tide and afternoon winds. Small arms, demolition, mortar, artillery, and aircraft gunnery events all generate noise at Makua Military Reservation. Noise level contributions from Makua Military Reservation training vary greatly, depending on whether LFX are in progress. Actual noise measurements in 1989, when the Army was conducting training, showed that noise levels at the reservation boundary would ordinarily not exceed the standards of the Oahu community noise rule. (U.S. Department of the Army, 2005; Tetra Tech, Inc., 2005)

The nearest housing is approximately 1,000 to 3,000 ft down the beach that is adjacent to the Makua Military Reservation. Most military training at the reservation occurs during early morning hours, when the number of beachgoers is small. There are no schools, day-care centers, hospitals, or nursing homes within 2 mi of Makua Military Reservation. When there are no training events in progress at Makua Military Reservation, noise conditions are dominated by wind, bird songs, and insects. Under these conditions, noise levels typically vary between approximately 25 dBA and 45 dBA. (U.S. Department of the Army, 2005)

Wildlife receptors in the Makua Military Reservation area are detailed in Section 3.4.2.11.1, Biological Resources.

3.4.2.12 KAHUKU TRAINING AREA

Kahuku Training Area consists of 9,355 acres of leased lands, most of which are in a state-designated conservation district. The Kahuku Training Area is one of the more widely used military training areas in Hawaii and fulfills a need for maneuver training on Oahu. Army Reserve, National Guard, and Marine Corps units also use this area.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Kahuku Training Area. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.12.1 Biological Resources—Kahuku Training Area

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes the training area and adjacent land.

Affected Environment

Vegetation

Parts of Kahuku Training Area contain valuable native vegetation communities. However, much of the lower-lying vegetation is composed of introduced and invasive plants such as Christmas berry, ironwood, and strawberry guava. Manuka (New Zealand tea tree) (*Leptospermum scoparium*) and moho (white moho) (*Heliocarpus popayanensis*) are two plants recently discovered in the region of influence that can be detrimental to the native communities of the Kahuku Training Area. (U.S. Department of the Army, 2004)

Montane wet, lowland wet, lowland forest, lowland moist, lowlands dry, and intermittent aquatic natural communities are the six general categories of native natural vegetation community types. (U.S. Department of the Army, 2004)

Makou (*Botrychium subbifoliatum*), `oha (*Cyanea lanceolata Ssp. calycina*), anini (*Eurya sandwicensis*), *Hedyotis fluviatilis*, *Lindsaea repens* var. *macraeana*, keahi (*Nesoluma polynesicum*), *Platydesma cornuta*, and kaulu (*Pteralyxia macrocarpa*) are species of concern that have been identified on the Kahuku Training Area. (U.S. Department of the Navy, 2002a)

<u>Threatened and Endangered Plant Species</u>

Eighteen rare plant types have been identified at Kahuku Training Area, of which 10 are Federally listed as endangered (Table 3.4.2.12.1-1). (U.S. Department of the Navy, 2002a)

Table 3.4.2.12.1-1. Listed Species Known or Expected to Occur at Kahuku Training Area

Scientific Name	Common Name	Federal Status
Plants		
Adenophorus periens	Pendant kihi fern	E
Chamaesyce rockii	`Akoko, koko, kokomalei	E

Source: U.S. Department of the Navy, 2002a; U.S. Fish and Wildlife Service, 2006b; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007.

Key to Federal Status:

E = Endangered

Wildlife

The bullfrog, wrinkled frog (*Rana rugosa*), coqui frog (*Eleutherodactylus coqui*), and poison dart frog are non-native amphibians found on Oahu and potentially on Kahuku Training Area. Reptiles such as the green anole, gecko, and metallic skink may be found in the region of influence. Feral pigs, Indian mongoose, feral dogs, rats, and house mice are terrestrial mammals that may occur on Kahuku Training Area. The great frigate bird, Pacific golden plover, pueo (Hawaiian short-eared owl), and Oahu `amakihi are indigenous birds that have been observed on the training area. Several non-native bird species such as the white-rumped shama, zebra dove, and house finch are also in the area. (U.S. Department of the Army, 2004)

Threatened and Endangered Wildlife Species

The Kahuku Training Area was addressed in the 2003 Biological Opinion for routine and transformation training conducted by the Army (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007). According to the USFWS, the Hawaiian hoary bat could be present on the installation (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007). Eight rare wildlife species have been identified at the Kahuku Training Area. These include six varieties of endangered tree snails (*Achatinella* sp.) and two rare birds, including the Oahu `elepaio and `alauahio (Oahu creeper), species Federally listed as endangered (Table 3.4.2.12.1-1). (U.S. Department of the Navy, 2002a; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007)

Environmentally Sensitive Habitat

Critical habitat was officially designated for the Oahu `elepaio on 10 December 2001 that encompasses areas in the Koolau and Waianae Mountain Ranges on Oahu south of Kahuku Training Area (Figure 3.4.2.12.1-1). Five biologically significant areas occur in the southern and midwestern portion of the training area. (U.S. Department of the Navy, 2002a)

3.4.2.12.2 Cultural Resources—Kahuku Training Area

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The cultural resources region of influence for Kahuku Training Area encompasses all areas where Humanitarian Assistance/Disaster Relief Operations or any other ground disturbing or amphibious events would occur. These areas would include beach landing areas and well established trails that lead to predetermined buildings or temporary tent areas (see Appendix D).

Affected Environment

Underwater Cultural Resources

Underwater cultural resources within the Kahuku offshore region of influence include scattered shipwrecks and at least one Hawaiian fishpond (see Figures 3.1.3-2 and 3.4.1.3.2-1).

Archaeological Resources (Prehistoric and Historic)

Kahuku Training Area was occupied at least seasonally from the 14th century on and was used for agriculture beginning in the 15th century. Evidence of occupation prior to European contact includes rock shelters, burial sites, irrigation complexes, and habitation sites. (U.S. Department of the Army, 2004)

In 1890 James Campbell, James Castle, and Benjamin Dillingham formed the Kahuku Plantation Company and sugar cane began to replace pastureland. A sugar mill was established at Kahuku and the area of Kahuku Training Area was operated as a sugar plantation until the 1930s. Just prior to World War II, an airfield and radar station was constructed; after the war, additional land was purchased to support the Kahuku Training Area. A Nike Hercules missile battery was constructed in 1959. (U.S. Department of the Army, 2004)

EXPLANATION

Road

Critical Habitat

Land

NORTH

0 0.5 1 2 Miles

Critical Habitat - Northern Oahu, Hawaii

Oahu, Hawaii

Figure 3.4.2.12.1-1

There have been several archaeological surveys of Kahuku Training Area (Anderson and Williams 1998; Davis 1981; Drolet 2000; McAllister 1933; Rosendahl 1977; Williams and Patolo 1998; and GANDA 2003) and the area has been divided into six separate archaeological management areas (U.S. Army Garrison, Hawaii, and U.S. Army Corps of Engineers 1998). Within the six areas approximately 100 archaeological sites have been identified, including prehistoric, historic, and military-era sites. Sites include the Hanakoae Heiau, which is listed in the NRHP; several rock shelters; a possible Plantation-period site; and hearth, dwelling, and agricultural sites. Historic sites include a house, irrigation features, foxholes, and bunkers (U.S. Department of the Army, 2004). Areas closest to the coast have the highest potential for archaeological resources (U.S. Department of the Navy, 2002a). A list of identified archaeological sites and historic buildings at Kahuku Training Area is provided in Appendix H.

Historic Buildings and Structures

Within the Kahuku Training Area, the World War II-era Opana Mobile Radar Station is listed in the NRHP and has been designated a National Historic Landmark. The site was operational on December 7, 1941, and is famous for its role in detecting the approaching Japanese aircraft just prior to the attack on Naval Station Pearl Harbor. (U.S. Department of the Army, 2004)

There are also 22 Cold War-era buildings and structures at Kahuku Training Area. The features are associated with the former Nike missile facility active in Hawaii between January 1961 and March 1970. The site is significant as an intact example of a Cold War Nike missile site and has been determined eligible for inclusion in the NRHP (International Archaeological Resources Institute, Inc, 2005). Preservation of the site was mandated as a result of consultation with the Hawaii State Historic Preservation Officer over the Nike site at Dillingham Military Reservation (U.S. Department of the Army, 2004).

Traditional Resources

The general area of Kahuku plays an important role in Hawaiian legends. Identified legend locations are in the off-shore and coastal areas but, to date, none of the legends have been tied to Kahuku Training Area land areas. There are, however, important Native Hawaiian sites within the Kahuku Training Area, including a terrace that may have been used for religious ceremonies and burials (Drolet, 2000).

In 1998, archival information concerning traditional cultural places in and around Kahuku Training Area was collected and reviewed (Anderson, 1998). Subsequently, the Army began a traditional cultural resources survey of Kahuku Training Area, which has resulted in the identification of several traditional sites.

3.4.2.13 DILLINGHAM MILITARY RESERVATION

Dillingham Military Reservation is a 664-acre training area with a beach and an airfield on the northwestern shore of Oahu. It is on a narrow, sloping plain between the Waianae Range and the sea.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Dillingham Military Reservation. Of the 13 environmental resources considered for analysis, air quality, airspace, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.4.2.13.1 Biological Resources—Dillingham Military Reservation

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence consists of the Dillingham Military Reservation land and offshore areas.

Affected Environment

Vegetation

Dillingham Military Reservation contains native natural communities that are considered rare and globally imperiled. The area is composed primarily of stands of native forest and shrubland vegetation on the cliffs and talus slopes. Ecological surveys have identified four rare plant species of concern associated with the cliff ecological zone: `ahakea (*Bobea sandwicensis*), koki`o `ula`ula (*Hibiscus kokio* ssp. *kokio*), `anaunau (*Lepidium bidentatum* var. *o-waihiense*), and nehe (*Lipochaeta remyi*).

Threatened and Endangered Plant Species

Ecological surveys have identified eight rare plants associated with the cliff ecological zone, including four with endangered status (Table 3.4.2.13.1-1) (U.S. Department of the Navy, 2002a).

Wildlife

Field surveys on Dillingham Military Reservation have been limited to special-status wildlife, due mainly to the rugged terrain. Non-native amphibians that have the potential to occur on Dillingham Military Reservation include bullfrogs, green and black poison dart frogs, giant toads, and coqui frogs. Non-native reptiles could include green anoles, mourning geckos, tree geckos, and metallic skinks. Feral pigs, cats, and dogs; rats and house mice are mammals that may be found on the installation. (U.S. Department of the Army, 2004)

Table 3.4.2.13.1-1. Listed Species Known or Expected to Occur at Dillingham Military Reservation

Scientific Name	Common Name	Federal Status
Plants		
Cyperus trachysanthos	Pu`uka`a (Sticky flatsedge)	E
Hibiscus brackenridgei ssp. *Mokuleianus*	Ma`o hau hele (Mokulei rosemallow)	E
Nototrichium humile	Kulu`i (Kaala rockwort)	E

Monachus schauinslandi	Hawaiian monk seal	E

Source: U.S. Department of the Navy, 2002a; U.S. Department of the Army, 2004; U.S. Fish and Wildlife Service, 2006b
Key to Federal Status:
E = Endangered
T = Threatened

Threatened and Endangered Wildlife Species

The Dillingham Military Reservation was addressed in the 2003 Biological Opinion for routine and transformation training conducted by the Army (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007). The endangered Hawaiian hoary bat has the potential to occur on Dillingham. The `alae ke`oke`o (Hawaiian coot), `alae`ula (Hawaiian moorhen), koloa maoli (Hawaiian duck), and ae`o (Hawaiian black-necked stilt) have been recorded on Dillingham Military Reservation. The Oahu `elepaio and `alauahio (Oahu creeper) are normally found in Native Hawaiian forest habitat. (U.S. Department of the Army, 2004)

Environmentally Sensitive Habitat

Army lands were excluded from the latest critical habitat for plants (Figure 3.4.2.11.1-1) since the Army has implemented a comprehensive program of endangered species management on its lands under the Integrated Natural Resources Management Plan process. A wetland delineated on the reservation is within the region of influence, but outside of the area used for maneuver training. (U.S. Department of the Army, 2004)

3.4.2.13.2 Cultural Resources—Dillingham Military Reservation

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The cultural resources region of influence for Dillingham Military Reservation (see Figure 2.1-3) encompasses areas where Navy and Marine Corps SPECWAROPS under RIMPAC and small unit maneuvers by the Army occur (e.g., reconnaissance insertions and search and rescue).

Affected Environment

Archaeological Resources (Prehistoric and Historic)

An extensive complex of agricultural and occupation features has been identified at Dillingham Military Reservation within the rocky sloping area between the airfield and the cliffs. Pre- and post-contact features have also been identified. These include platforms, boulder alignments, stone piles, walls, a ditch, and concrete foundations. There are three heiau temples also located within the Dillingham Military Reservation —two fishing shrines and “hidden waters” associated with Hawaiian legend (U.S. Army Garrison, Hawaii U.S. Army Corps of Engineers 1998; U.S. Department of the Navy, 2002a).

Historic Buildings and Structures

There are several World War II-era buildings at Dillingham Military Reservation; however, they have not been evaluated for eligibility for inclusion in the NRHP (U.S. Army Garrison, Hawaii, U.S. Army Corps of Engineers 1998; U.S. Department of the Navy, 2002a).

Traditional Resources

There are indications of pre-contact use of the coastal dune areas of Dillingham Military Reservation for burials. Burial remains in sand deposits would be considered significant as “properties of traditional religious and cultural importance” (U.S. Army Garrison, Hawaii, and U.S. Army Corps of Engineers 1998; U.S. Department of the Navy, 2002a).

3.4.2.14 KEEHI LAGOON

Keehi Lagoon is located on Oahu's southern shore, encompassing a triangular-shaped area between the Honolulu International Airport and Honolulu Harbor. Keehi Lagoon was originally a large shallow reef and subtidal area approximately 3 to 6.5 ft deep. The lagoon has changed over the passage of time into an almost completely artificial area. A review of the 13 environmental that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there were no impacts from HRC training at Keehi Lagoon.

3.4.2.15 KAENA POINT

The Kaena Point tracking radar used by PMRF and operated by the Air Force is on the island of Oahu within the Kaena Point Air Force Station. The radar used by PMRF is on a ridge overlooking the Pacific Ocean. Kaena Point tracking site has been in existence since 1959 (U.S. Department of the Air Force, 15th Airlift Wing, 2003). Kaena Point provides real-time telemetry data to PMRF. Metric and signature tracking data are also provided by the 30th Range Squadron located at Kaena Point. Training at this site consists of using an existing tracking radar operated by the Air Force. Kaena Point provides habitat for several listed plant species, nesting habitat for wedge-tailed shearwater (*Puffinus pacificus chlororhynchus)* and Laysan albatross (*Phoebastria immutabilis*), and resting areas for the endangered monk seal. A review of the 13 environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training at Kaena Point.

3.4.2.16 MT. KAALA

The Mt. Kaala site consists of leased building space only. Training at this site consists of radio frequency communication and radar tracking. A review of the 13 environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training Mt. Kaala.

3.4.2.17 WHEELER NETWORK SEGMENT CONTROL/PMRF COMMUNICATION SITES

Wheeler Network Communications Control is a major communications hub for PMRF located on Wheeler Army Auxiliary Airfield. Training at this site consists of support for the existing telemetry towers and communications. This facility—in conjunction with transceiver sites on Mount Kaala, Oahu, and Mount Kahili, Kauai, and computer/communication networks on Oahu and Maui—provides line-of-sight coverage of PMRF operational areas. In addition, PMRF utilizes data from a radar operated on Mount Kaala. A review of the 13 environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training at Wheeler Network Communications Control.

3.4.2.18 MAUNA KAPU COMMUNICATION SITE

The Mauna Kapu Communication Site, leased through the FAA by the Department of Energy, contains a repeater station. Training at this site consists of support for existing telemetry towers and communications. A review of the 13 environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training at the Mauna Kapu Communication Site.

3.4.2.19 MAKUA RADIO/REPEATER/CABLE HEAD

Makua Radio/Repeater/Cable Head is a Department of Energy communication site. Training at this site consists of existing telemetry towers and communications. A review of the 13 environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training at Makua Radio/Repeater/Cable Head.

3.5 MAUI

Maui is the second largest of the populated Hawaiian Islands. It covers approximately 700 square miles and was formed by two separate volcanoes: Mt. Haleakala, the world's largest dormant volcano, and Puu Kukui. Wailuku is the county seat. Maui County includes the islands of Maui, Lanai, Molokai (except Kalaupapa peninsula), and Kahoolawe. Current and proposed Hawaii Range Complex (HRC) training and research, development, test, and evaluation (RDT&E) activities on or offshore of Maui addressed in this Environmental Impact Statement /Overseas Environmental Impact Statement (EIS/OEIS) are located at the Maui Offshore area, Maui Space Surveillance Site, Maui High Performance Computing Center, Sandia Maui Haleakala Facility, and Molokai. For organizational purposes in this document, discussions about Molokai are included under the Maui heading, although it is a separate island and is not part of the island of Maui.

3.5.1 MAUI OFFSHORE

3.5.1.1 MAUI OFFSHORE

The Maui Offshore is an area situated around the islands of Maui, Kahoolawe, Lanai, and Molokai. The offshore area also includes the portion of Penguin Bank that is within 12 nautical miles (nm) of the islands' coastlines. The area is used as a submarine training area due to the unique characteristics of its acoustic environment and shallow depths of 50 and 100 fathoms. Multiple in-water runs of exercise MK-48 torpedoes (with no warheads) using one submarine as both target and launch platform occur in the Penguin Bank area as part of training and RDT&E activities.

Of the 13 environmental resources considered for analysis, air quality, airspace, cultural resources, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, visual and aesthetics, and water resources are not addressed.

3.5.1.1.1 Biological Resources—Maui Offshore

Appendix C includes a description of the primary laws and regulations regarding biological resources.

Region of Influence

The region of influence is the area within 12 nm around the islands of Maui, Kahoolawe, Lanai, and Molokai.

Affected Environment

Marine Habitats, Invertebrates

Detritus from nearby islands and calcareous sand and mud make up the bottom sediments in the region of influence. Sand, coral, and mud are all present in the area that formerly held hydrophones. Since black coral has been identified near the western end of Kahoolawe, additional coral patches are expected to be in the area. (Naval Undersea Warfare Center Detachment, 1994)

Fish

Bottomfish and pelagic fish occur at Penguin Bank. Bottomfish are fish species that live their lives on the ocean floor, whereas pelagic fish are species that live in the upper layers of the ocean. (Naval Undersea Warfare Center Division Newport, Rhode Island, 2007)

Lutjanid snapper (opakapaka) makes up the bulk of the bottomfish catch, although other fish, crabs, lobsters, and occasionally shrimp are present. The bottom fishery appears to be in decline or to have reached its maximum sustainable yield. A small commercial and recreational hand-line fishery for opakapaka is located in the region of influence. (Naval Undersea Warfare Center Detachment, 1994)

Pelagic fish that occur in Hawaiian waters include, but are not limited to, striped marlin (*Tetrapurus audax*), broadbill swordfish (*Xiphias gladius*), northern bluefin tuna (*Thunnus thynnus*), albacore (*Thunnus alalunga*), Bigeye tuna (*Thunnus obesus*), mackerel (*Scomber* spp.), sickle pomfret (*Tatactichthys steindachnen*), lustrous pomfret (*Eumegistus illustris*), yellowfin tuna (*Thunnus albacares*), kawakawa (*Euthynnus affinis*), and skipjack tuna (*Katsuwonus pelamis*). (Naval Undersea Warfare Center Division Newport, Rhode Island, 2007)

Marine Mammals

Spinner dolphins (*Stenella longirostris*) travel in pods of 10 to 300 dolphins throughout the Hawaiian Islands, but are found most frequently in deeper water. They prefer clear, calm water close to deep water where food is found, and rest in shallow bays during the day. Spotted dolphins (*Stenella attenuata*), which may be the most numerous Hawaiian cetacean, are found in large pods in offshore waters less than 100 fathoms. Bottlenose dolphins (*Tursiops truncatus*) inhabit offshore waters along the 50- to 100-fathom isobaths around the Hawaiian Islands. (Commander, Submarine Force U.S. Pacific Fleet, 1997)

At least 28 different marine mammal species have been observed in the Penguin Bank area. Of these, 26 species are whales and dolphins and 1 is a pinniped. At least seven species are generally found in the study area in moderate to high numbers either year-round or during annual migrations into or through the proposed test area. These include humpback whale (*Megaptera novaeangliae*), beaked whales (family *(Ziphiidae),* bottlenose dolphin, Pantropical spotted dolphin, spinner dolphin, false killer whale (*Pseudorca crassidens)*, and short-finned pilot whale (*Globicephala macrorhynchus*). Other cetacean species are present during part of the year based on occasional sightings, or stranding records. (Naval Undersea Warfare Center Division Newport, Rhode Island, 2007) Cetaceans are discussed in more detail in Section 3.1.2, Biological Resources—Open Ocean.

Rare, Threatened, and Endangered Species

Two species of sea turtles may occur at Penguin Bank: green turtle (*Chelonia mydas*) and hawksbill turtle (*Eretmochelys imbricata*) (Naval Undersea Warfare Center Division Newport, Rhode Island, 2007). Green turtles and hawksbill turtles are the most commonly seen marine turtles in the Main Hawaiian Islands. Most sightings of these species have been in shallow water. The green turtle prefers to forage and rest in waters less than about 27 fathoms deep, and migrate from the Four Island Area to French Frigate Shoals every 2 to 3 years. Numerous sightings have been reported for the water off Maui. Hawksbill turtles have been observed on Molokai and Maui. No critical habitat has been designated in the Pacific for any of these species of sea turtles. (Commander, Submarine Force U.S. Pacific Fleet, 1997) Sea turtles are discussed in more detail in Section 3.1.2, Biological Resources—Open Ocean.

The presence of the endangered humpback whale in the region of influence is seasonal, with peak concentrations in mid-February to mid-March. The whales seem to prefer areas within the 100-fathom contours such as the Molokai–Lanai–Maui–Kahoolawe channels and Penguin Bank. Humpback whale sightings in the region of influence are mainly concentrated north of Kahoolawe in protected channel areas. The Hawaiian monk seal (*Monachus schauinslandi*), is occasionally seen in the region of influence. The first monk seal birth on Maui was recorded in June 1997. (Commander, Submarine Force U.S. Pacific Fleet, 1997; Naval Undersea Warfare Center Division Newport, Rhode Island, 2007)

Hawaiian Islands Humpback Whale National Marine Sanctuary

Portions of the Maui Offshore area are included in the Hawaiian Islands Humpback Whale National Marine Sanctuary. According to the Hawaiian Islands Humpback Whale National Marine Sanctuary EIS (U.S. Department of Commerce, National Oceanic and Atmospheric Administration and State of Hawaii, Office of Planning, 1997), "… the waters adjacent to Maui, Molokai, and Lanai are important training areas for Navy ships homeported in Pearl Harbor. The channel between Maui, Lanai and Molokai is extensively used for biennial RIMPAC [Rim of the Pacific] exercises, EOD/MCM [Explosive Ordnance Disposal/Mine Countermeasures] exercises, and as well for shallow-water ASW [Anti-Submarine Warfare]… The areas inside the 100-fathom isobath surrounding Maui, Molokai and Lanai, and specifically the channel between these islands, are used for shallow-water ASW operations."

3.5.1.2 SHALLOW-WATER MINEFIELD SONAR TRAINING AREA-OFFSHORE

The Shallow-water Minefield Sonar Training Area provides Naval Station Pearl Harbor based submarines with the capability to conduct mine sonar training. A review of the 13 resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training and RDT&E activities at the Shallow-water Minefield Sonar Training Area. This training area, outside the Hawaiian Islands Humpback Whale National Marine Sanctuary, is utilized by submarines using high-frequency active sonar (not mid-frequency active sonar). Training in the Shallow-water Minefield Sonar Training Area can occur when humpback whales are present, as well as other marine species. During the years of use of this training area, there have been no reports of negative impacts. Section 4.1.2.4.12 includes a discussion of active acoustic devices, including submarines.

3.5.2 MAUI ONSHORE

3.5.2.1 MAUI SPACE SURVEILLANCE SYSTEM

The Maui Space Surveillance Site provides facilities that observe sub-orbital vehicles. Training and RDT&E activities at this site consist of an existing telemetry tower, communications, and tracking facilities. A review of the 13 resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training and RDT&E activities at the Maui Space Surveillance System site.

3.5.2.2 MAUI HIGH PERFORMANCE COMPUTING CENTER

The Maui High Performance Computing Center is an Air Force Research Laboratory managed by the University of Hawaii that provides state-of-the-art data processing. Training and RDT&E activities at this site consist of data processing. A review of the 13 resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training and RDT&E activities at the Maui High Performance Computing Center.

3.5.2.3 SANDIA MAUI HALEAKALA FACILITY

The Sandia Maui Haleakala Facility provides telemetry receiving and recording, flight following, command control and flight termination systems for high-altitude/exoatmospheric launches from the Pacific Missile Range Facility and for high-altitude training and RDT&E activities that traverse the Hawaiian Islands Chain. Training and RDT&E activities at this site consist of support for existing telemetry towers and communications. A review of the 13 resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training and RDT&E activities at the Sandia Maui Haleakala Facility.

3.5.2.4 MOLOKAI MOBILE TRANSMITTER SITE

A mobile command and control node is located at the Molokai Mobile Transmitter Site during Major Exercises. The transmitter site includes vehicles and portable equipment to generate low-power electronic signals that simulate various types of radar. A review of the 13 resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 determined there would be no impacts from HRC training and RDT&E activities at the Molokai Transmitter Site.

3.6 HAWAII

The island of Hawaii is the largest of the Hawaiian Islands. It covers approximately 4,028 square miles and is still growing because of continual eruptions of Kilauea. Resorts and most residential developments are located in coastal areas. Hilo, located on the east side of the island, is the county seat. Current and proposed Hawaii Range Complex (HRC) training and research, development, test, and evaluation (RDT&E) activities on the island of Hawaii addressed in this Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) are located at Pohakuloa Training Area (PTA), Bradshaw Army Airfield, and Kawaihae Pier.

3.6.1 HAWAII OFFSHORE

Hawaii Offshore addresses ocean areas within 12 nautical miles (nm) of the island of Hawaii, including ranges and training areas where activities are performed by the Navy. Discussions include the area offshore of the Kawaihae Pier. This offshore area is within the Hawaiian Islands Humpback Whale National Marine Sanctuary. The Kawaihae Pier itself is not part of the Hawaiian Islands Humpback Whale National Marine Sanctuary boundaries.

3.6.1.1 KAWAIHAE PIER—OFFSHORE

Kawaihae Pier is located within the Kawaihae Harbor on the northwestern corner of the island of Hawaii. Kawaihae Harbor is a deep-water port, one of two on the island of Hawaii. Expeditionary Assault events are conducted at Kawaihae Pier. Activities primary consist of offloading and loading vehicles and equipment from a landing ship at an existing boat ramp.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Kawaihae Pier Offshore. Of the 13 environmental resources considered for analysis, airspace, air quality, cultural resources, geology and soils, hazardous material and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.6.1.1.1 Biological Resources—Kawaihae Pier—Offshore

Region of Influence

The region of influence includes the area up to 12 nm offshore of the pier that may be affected by proposed training.

Affected Environment

Vegetation

A small beach area containing no vegetation is located immediately adjacent to the pier.

Threatened and Endangered Plant Species

No threatened or endangered plant species have been identified within the harbor area.

Wildlife

Habitat Areas of Particular Concern have not been identified within the harbor. A coral reef of management concern is located at Kawaihae Harbor. It is at risk from extensive development at the commercial harbor and from recent and continued development at the small boat harbor. Another coral reef, Puako Reef, is located approximately 3 to 4 miles (mi) from Kawaihae Harbor. (National Park Service, 2004)

A description of the coral reef area associated with the Hawaiian Islands and its management by both the State of Hawaii and the Federal government is provided in Section 3.1.2.1. The following coral information is summarized from the more extensive data provided in the *Marine Resources Assessment for the Hawaiian Islands Operating Area* (U.S. Department of the Navy, 2005b). Overall, coral communities of Hawaii are considered to be in good condition. The growth of coral reefs around the island of Hawaii is correlated to the intensity and frequency of wave disturbance. Coral reefs are primarily found on the western (leeward) side of the island, which includes the offshore area between Waikui and Mahukona (Figure 3.6.1.1.1-1). During summer, an occasional Kona storm generates storm swells of about 10 to 20 feet (ft) in height that can remove accreted reefs on the leeward side. (U.S. Department of the Navy, 2005b)

North of Waikui, there is a fairly large spur-and-groove reef system (1.3 nm long and 590 to 1,772 ft wide) off the Kawaihae Small Boat Harbor (Figure 3.6.1.1.1-1). This is the only spur-and-groove reef that the 2003 National Centers for Coastal Ocean Science/National Oceanic and Atmospheric Administration (U.S. Department of the Navy, 2007a) benthic habitat mapping program recorded for the island of Hawaii. From the Kawaihae Small Boat Harbor to Malae Point, the shoreline is flanked by a narrow intertidal area consisting of uncolonized volcanic rock (approximately 131 ft wide); just seaward there is a strip of colonized volcanic rock (131 to 459 ft wide) and aggregated coral heads (131 to 459 ft wide). Another 2.2 nm north of Malae Point, there is similar habitat zonation and sizes. From Malae Point to Makaohule Point the widths of colonized volcanic rock and aggregated coral head habitats range from 328 to 820 ft and 590 to 1,181 ft, respectively. (U.S. Department of the Navy, 2005b)

Threatened and Endangered Wildlife Species

No threatened or endangered species have been identified within the harbor. However, the water on this leeward side of the island provides good habitat for humpback whale (*Megaptera noveangliae*) mother and calf pods and for resting dolphin pods (National Park Service, 2004). No critical habitat is present (National Park Service, 2004).

Hawaiian Islands Humpback Whale National Marine Sanctuary

The Kawaihae Pier area is not part of the Hawaiian Islands Humpback Whale National Marine Sanctuary boundaries (National Oceanic and Atmospheric Administration, 2001).

EXPLANATION

Island of Hawaii

Figure 3.6.1.1.1-1

3.6.2 HAWAII ONSHORE

3.6.2.1 POHAKULOA TRAINING AREA (PTA)

PTA is a sub-installation of Schofield Barracks. It is located near the center of the island of Hawaii between three volcanoes: Mauna Kea, Mauna Loa, and Hualalai. The mission of Pohakuloa Training Area is to provide training of full-scale Live Fire Exercises (LFX) for the 25th Infantry Division (Light), U.S. Army Garrison, Hawaii. PTA also provides training facilities for other branches of the U.S. military and friendly foreign forces.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Pohakuloa Training Area. Of the 13 environmental resources considered for analysis, air quality, hazardous materials and hazardous waste, geology and soils, land use, socioeconomics, transportation, utilities, and water resources are not addressed.

There are no proposed activities in this EIS/OEIS that include Navy training at the Hilo Airport, and there are no plans to expand use of the airport by Navy aircraft. Air operations at the Hilo Airport are, therefore, not addressed in the following sections or analyzed within the EIS/OEIS.

3.6.2.1.1 Airspace—PTA

Appendix C includes a detailed description of airspace.

Region of Influence

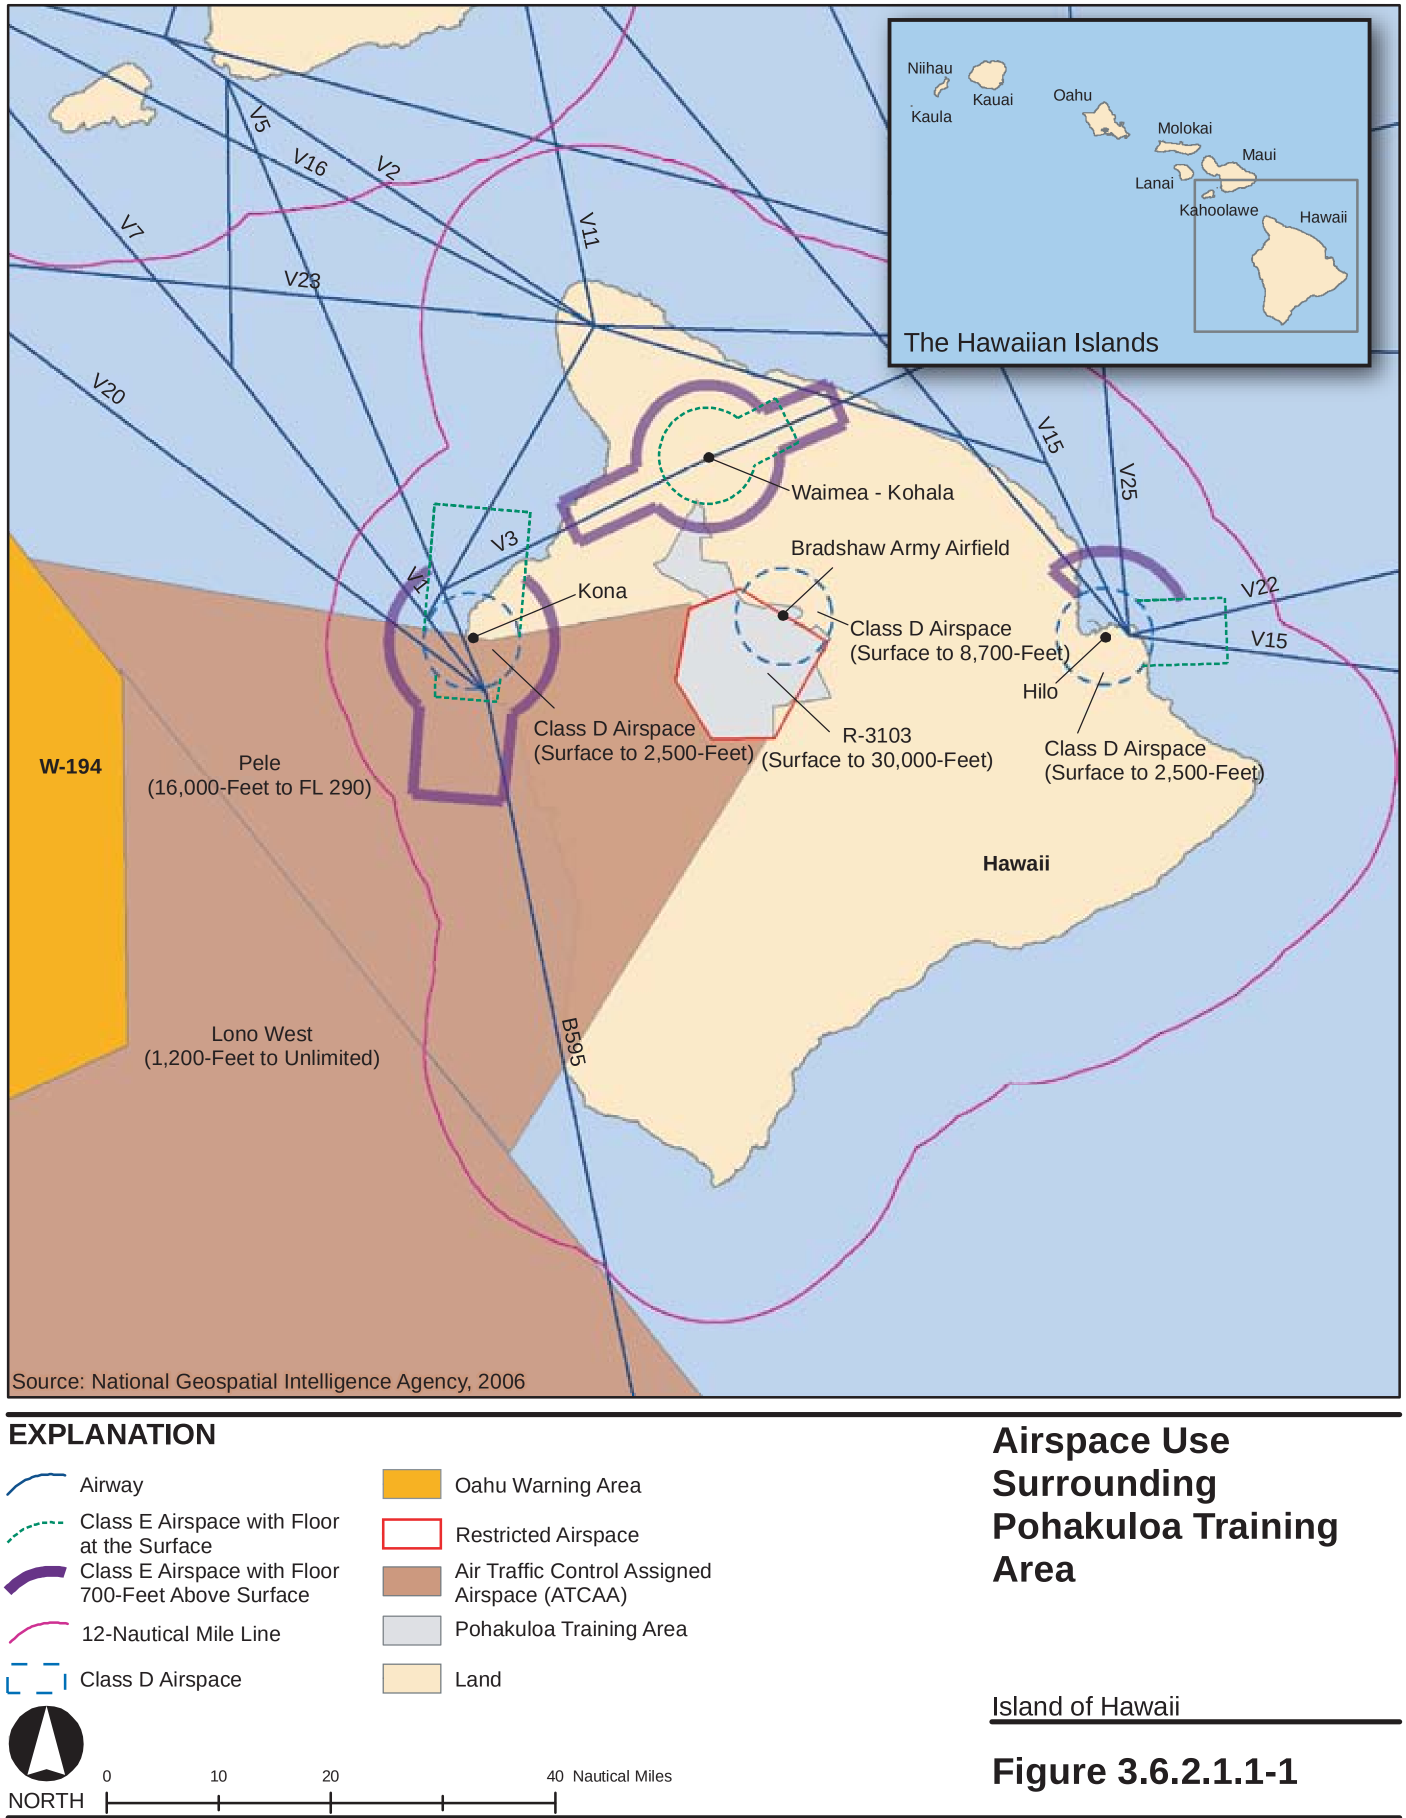
The PTA region of influence includes selected airspace within the territorial limits of the island of Hawaii as shown on Figure 3.6.2.1.1-1. The primary training and RDT&E activities occur above the PTA and within the Pele transition area between PTA and Warning Area W-194.

Affected Environment

The affected airspace in the PTA region of influence is described below in terms of its principal attributes: controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, airports and airfields, and air traffic control. There are no military training routes in the region of influence.

Controlled and Uncontrolled Airspace

The airspace in the PTA region of influence includes uncontrolled Class G airspace (see Appendix C), which extends from the surface to a ceiling of 1,200 ft, and controlled Class E airspace, which is airspace above 1,200 ft unless the special use airspace, discussed below, is activated. Bradshaw Army Airfield, located within PTA, is surrounded by Class D airspace extending from the surface to a ceiling of 8,700 ft. There is also class D airspace at the Kona and Hilo airports extending from the surface to 2,500 ft. (National Aeronautical Charting Office, 2007) However, because the PTA impact area and Bradshaw Army Airfield are located at an elevation approximately 6,000 ft above Hilo and Kona, those airports are typically not within the region of influence.



Airspace Use Surrounding Pohakuloa Training Area

Island of Hawaii

Figure 3.6.2.1.1-1

Special Use Airspace

The R-3103 restricted area (Figure 3.6.2.1.1-1) lies above PTA, extending from the surface to 30,000 ft (Table 3.6.2.1.1-1). The time of use is intermittent; notification is made by Notice to Airmen 12 hours in advance. The area is scheduled through the Navy Fleet Area Control and Surveillance Facility Pearl Harbor, which coordinates with the Honolulu Combined Facility. When R-3103 is active, Bradshaw Army Airfield Tower maintains control of a corridor of airspace for aircraft arriving or departing Bradshaw Army Airfield and PTA. Aircraft operating outside this corridor must coordinate with Range Control to enter or exit the airspace and to obtain specific routes for flights within Restricted Airspace R-3103 (U.S. Army Garrison, Hawaii, 1996). When the airspace is scheduled to be inactive, the agency releases it back to the Honolulu Combined Facility, and, in effect, the airspace is no longer restricted. (U.S. Department of the Army, 2004; National Aeronautical Charting Office, 2007)

Table 3.6.2.1.1-1. Special Use Airspace in the Island of Hawaii Region of Influence

Warning/ATCAA Number/Name	Location	Altitude (Ft)	Time of Use		Controlling Agency
			Days	Hours	
R-3103	Restricted Airspace	To 30,000	Intermittent	By Notice to Airmen	HCF
Pele	Between W-194 and R-3103	16,000 to FL290		By request	HCF

Source: National Aeronautical Charting Office, 2007
Notes:
W = Warning
ATCAA = Air Traffic Control Assigned Airspace
FL = Flight Level (FL 290 = 29,000 ft)
HCF = Honolulu Combined Facility

Although there are no formal, published military training routes on the island of Hawaii, the R-3103 restricted area is used for helicopter training, with an average of 900 aircraft movements per month, 99 percent of which involve helicopters. Typical training involves the use of 10 rotary-winged aircraft at any one time. During deployment training, one or two C-130s would be involved about twice a year. (U.S. Department of the Army, 2004)

Naval aircraft use of the R-3103 restricted area includes Navy and Marine Corps fighter and attack aircraft crews training during training. Strike Warfare Exercise training would typically involve a flight of 2 to 10 aircraft training in air-to-ground missile firing, conventional ordnance delivery, and precision-guided munitions firing. All Strike Warfare Exercise training at PTA uses inert munitions.

There is also one Air Traffic Control Assigned Airspace (ATCAA) area within the region of influence (Pele) that provides additional controlled airspace between R-3103 and Warning Area W-194 (Table 3.6.2.1.1-1).

En Route Airways and Jet Routes

As shown on Figure 3.6.2.1.1-1, there is one oceanic route (B595) located approximately 18 nm west of PTA, running along the eastern side of the island, terminating near Kona. Several low altitude Air Traffic Service (ATS) routes are located near Kona, and several others are located approximately 26 nm west of PTA at Hilo. One ATS route is located approximately 15 nm north of PTA.

Airports and Airfields

Bradshaw Army Airfield, located within PTA, is surrounded by Class D airspace extending from the surface to a ceiling of 8,700 ft. As described earlier, the Hilo and Kona airports and associated airspace are below the airspace typically utilized at PTA. Both Hilo and Kona are surrounded by Class D airspace. Both include surface Class E airspace extensions and additional Class E extensions, with a floor 700 ft above the surface. The Waimea airfield is located approximately 15 nm north of PTA at an altitude of 2,671 ft. It is surrounded by surface Class E airspace with additional Class E airspace extensions with a floor 700 ft above the surface. Air traffic in the region of influence is managed by the Honolulu Air Route Traffic Control Center.

3.6.2.1.2 Biological Resources—PTA

For the purpose of discussion, terrestrial biological resources have been divided into the areas of vegetation and wildlife (including threatened and endangered species) and environmentally sensitive habitat. Appendix C lists some of the regulations that govern biological resources.

Region of Influence

The region of influence is the area within or adjacent to PTA that could be affected by proposed training and RDT&E activities.

Affected Environment

Vegetation

Lava with little vegetative development covers approximately 25 percent of the installation. Treelands are dominated primarily by `ohia lehua (*Metrosideros polymorpha),* which is a member of the myrtle family and is the most abundant tree in Hawaii. Shrublands are the most diverse plant communities on the installation (14 different types). Dominant shrubs include *Myoporum sandwicense (*naio)*, Sophora chrysophylla* (mamane)*, Dodonaea viscosa (*a`ali`i), *Chenopodium oahuense* (`aweoweo)*,* and *Styphelia tameiameiae* (pukiawe)*.* Introduced plants are components of all habitats on PTA. (U.S. Department of Agriculture, 1990; U.S. Department of the Army, 2004; 2006)

<u>Threatened and Endangered Plant Species</u>

Fourteen Federally endangered plants and one threatened one, listed in Table 3.6.2.1.2-1, are known or expected to occur in the region of influence.

Table 3.6.2.1.2-1. Listed Species Known or Expected to Occur in the Vicinity of Pohakuloa Training Area

Scientific Name	Common Name	Federal Status
Plants		
*Asplenium fragile var. insulare**	Fragile fern	E
Haplostachys haplostachya	Honohono (Hawaiian mint)	E
*Hedyotis coriacea**	Kio`ele (leather-leaf sweet ear)	E
*Isodendrion hosakae**	Aupauka	E
Lipochaeta venosa	Nehe	E
*Neraudia ovata**	Big Island ma`oloa (spotted nettle brush)	E
*Portulaca sclerocarpa**	Po`e (purselane)	E
*Silene hawaiiensis**	Hawaii catchfly	T
*Silene lanceolata**	Lanceleaf catchfly	E
*Solanum incompletum**	Popolo ku mai (Hawaiian prickle leaf)	E
*Spermolepis hawaiiensis**	Hawaii scaleseed (Hawaiian parsley)	E
Stenogyne angustifolia	Ma`ohi`ohi (creeping mint)	E
Tetramolopium arenarium spp *arenarium**	Mauna Kea pamakani	E
*Vigna owahuensis**	Mohihihi	E
*Zanthoxylum hawaiiense**	A`e (Hawaiian yellow wood)	E
Birds		
Branta sandvicensis	Nene (Hawaiian goose)	E
Buteo solitarius	`Io (Hawaiian hawk)	E
Loxioides bailleui	Palila (finch-billed honeycreeper)	E
Pterodroma phaeopygia sandwichensis	`Ua`u (Hawaiian petrel)	E
Puffinus auricularis newelli	`A`o (Newell's Townsend's shearwater)	T
Mammals		
Lasiurus cinereus spp. *semotus*	Hawaiian hoary bat	E

Source: Shaw, 1997; U.S. Fish and Wildlife Service, 2006b; U.S. Department of the Army, 2004; 2006; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007

Notes:

* Critical habitat originally proposed for this plant, but later determined unnecessary by the U.S. Fish and Wildlife Service due to the management actions put forth in the Integrated Natural Resources Management Plan and Ecosystem Management Plan of the installation.

Key to Federal Status:

T Threatened
E Endangered

Wildlife

No reptiles have been documented on PTA. Wild pigs (*Sus scrofa*), goats (*Capra hircus*), sheep (*Ovis aries*), cats (*Felis catus*), and dogs (*Canis familiaris*) have been observed on PTA. U.S. Army Garrison Hawaii is proposing to construct and maintain fence units on PTA to protect threatened and endangered species and their habitats from the impact of introduced ungulates (hoofed mammals). The program would involve the removal of all ungulates from within the fence units. Without a physical barrier, sheep, pigs, and goats would continue to damage native natural communities and threatened and endangered species. (U.S. Department of the Army, 2006) Mouflon sheep, (*Ovis musimon*), cows, Norway rats (*Rattus norvegicus)*, and house mice (*Mus musculus*) are also present.

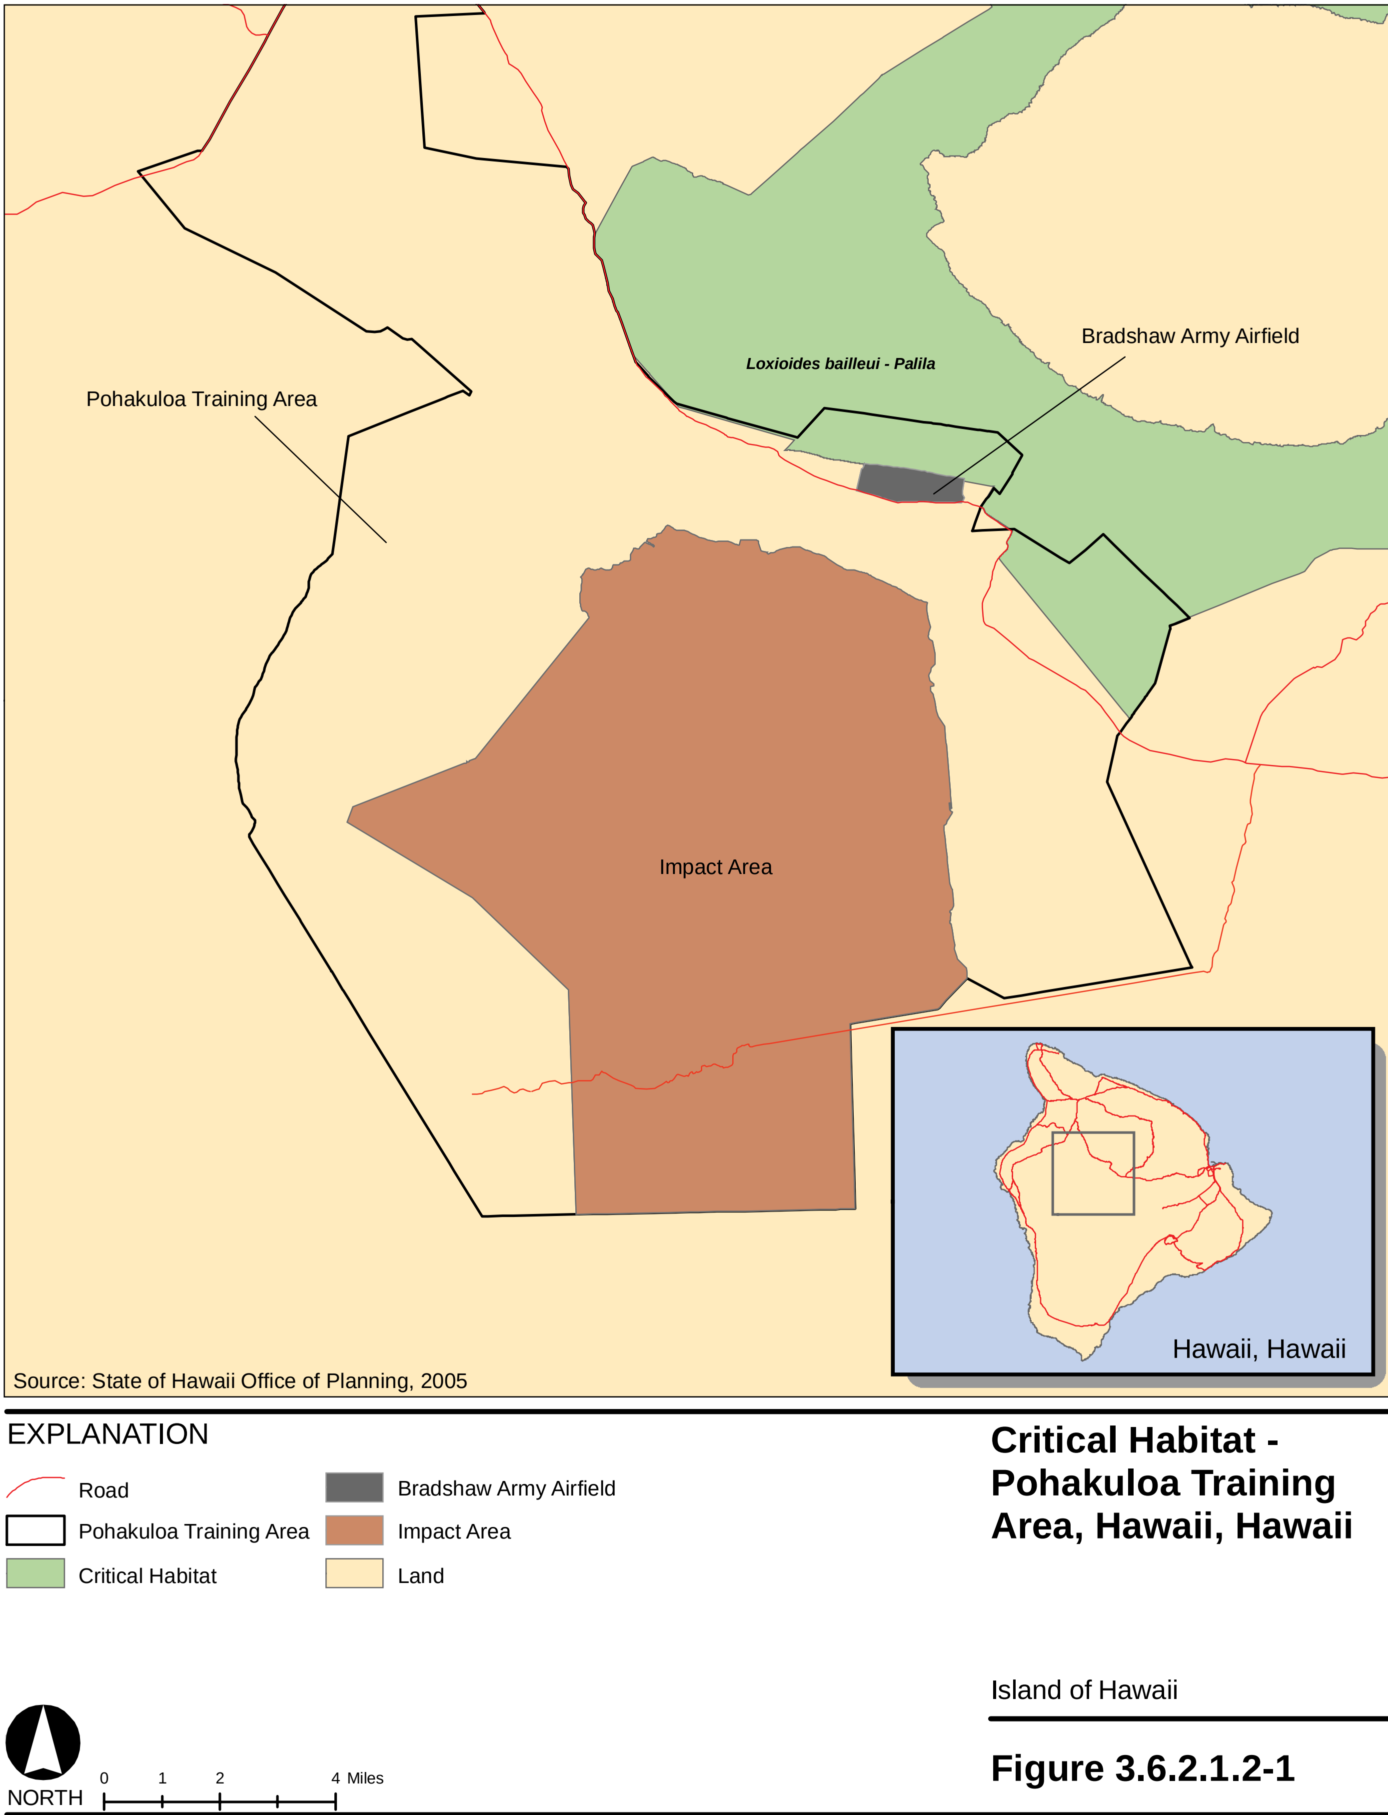
Endemic birds common to PTA are the `apapane (a honeycreeper) (*Himatione sanguinea*) and Hawaii `amakihi (a honeycreeper) (*Hemignathus virens*). The `i`iwi (a honeycreeper) (*Vestiaria coccinea*), Hawaii `elepaio (flycatcher) (*Chasiempis sandwichensis*), and ōma`o (Hawaiian thrush) (*Myadestes obscurus*) are present, but less common to PTA. The first `elepaio nest observed on PTA was discovered during a 2006 survey (U.S. Army Garrison, Hawaii, 2006). The pueo (Hawaiian owl) *(Asio flammeus sandwichensis)* is also present (U.S. Department of the Army, 2006). Nonnative bird species include Erckel's francolin (*Francolinus erckelii*), black francolin (*Francolinus francolinus*), California quail (*Callipepla californica*), and Japanese quail (*Coturnix japonica)*. (U.S. Department of the Army, 2004)

Threatened and Endangered Wildlife Species

Routine and transformation training actions at PTA were addressed in the 2003 biological opinion for PTA (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007). The only native terrestrial mammal in the Hawaiian Islands, the endangered Hawaiian hoary bat (*Lasiurus cinereus semotus*), is known to occur on PTA (Table 3.6.2.1.2-1). Of the four endangered forest birds listed in Table 3.6.2.1.2-1, only the `io (Hawaiian hawk) (*Buteo solitarius*) and nene (*Branta sandvicensis*) have been recorded in the past 5 years at PTA. The Federally endangered Hawaiian petrel (*Pterodroma phaeopygia sandwichensis*), a seabird, and the `a`o (Newell's Townsend's shearwater) (*Puffinus auricularis newelli)* have also been known to occur on PTA (Colorado State University, 2002). (U.S. Department of the Army, 2004; 2006; U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007)

Environmentally Sensitive Habitat

The U.S. Fish and Wildlife Service determined that critical habitat for 12 plants (see Table 3.6.2.1.2-1) was not necessary since the PTA Integrated Natural Resources Management Plan and Ecosystem Management Plan encompass management actions that will benefit the listed species for which critical habitat was originally proposed (U.S. Fish and Wildlife Service, 2003c). Critical habitat has been designated on the installation (Figure 3.6.2.1.2-1) for one of the larger Hawaiian honeycreepers, the palila (*Loxioides bailleui*), although this bird has not been observed in recent years. Up to 96 percent of the palila population and nearly all of the successful breeding occur on the southwestern slope of Mauna Kea (U.S. Fish and Wildlife Service, 2003d). The mamane-naio forest on the central plateau of Hawaii is the prime habitat of the palila, an endangered native bird (University of Hawaii Kapiolani Community College, undated).



Critical Habitat - Pohakuloa Training Area, Hawaii, Hawaii

Island of Hawaii

Figure 3.6.2.1.2-1

3.6.2.1.3 Cultural Resources—PTA

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for cultural resources at PTA encompasses existing, heavily disturbed impact and training areas, trails, and roads and PTA facilities where LFX would take place and Large Area Tracking Range (ground relay stations) would be added.

Affected Environment

Archaeological Resources (Prehistoric and Historic)

PTA is part of a large cultural landscape that includes Mauna Kea, Mauna Loa, and the Saddle area between them. Researchers of Hawaiian culture (Maly, 1999; McEldowney, 1979; and Langlas et al., 1997) indicate that this landscape is spiritually and historically one of the most important places in Hawaiian tradition and history. Evidence of the area's significance is confirmed by physical and archaeological remains and through the many oral histories that describe historical events and uses of the area (U.S. Department of the Army, 2004,). Site types encompass traditional activities such as bird hunting for feathers and meat, quarrying volcanic glass, and lithic workshop locations for manufacturing the adzes made from Mauna Kea basalt. The Saddle region also displays numerous trails used for movement both cross-island and to the Mauna Kea and Mauna Loa summits. The Umi heiau on the slopes of Hualalai (south of PTA) is believed to have been built by the legendary chief "Umi a Liloa" around 1600 and derives some of its importance from its location at the juncture of several of these trails. Cave shelters are abundant due to an extensive natural lava tube system in the area; historically they have been a source of limited water and have provided refuge from the elements.

In the late 1800s, cattle and sheep ranching was the primary activity within the PTA area. There were two primary land leases during those years—the John Parker lease (ca. 1876-1891) situated in the western portion of what is now the PTA, and the Waimea Grazing and Agricultural Company lease (ca. 1860-1891) situated in the eastern portion. The latter completed a wagon road from one of its remote sheep stations near the Saddle Road (at Humuula) to Waimea to transport wool to the harbor at Kawaihae, and a portion of that road is still visible. A number of stone walls were also constructed during the 1890s (U.S. Department of the Army, 2004).

Approximately 30 percent of the PTA has been surveyed for archaeological resources, and 291 prehistoric and historic archaeological sites and traditional resources sites have been recorded (U.S. Department of the Navy, Commander, Third Fleet 2004, and 2006 and U.S. Department of the Navy, 2002a; U.S. Department of the Army, 2004,); additional sites have been recorded within adjacent areas. Typical site types include lava tubes, walls, trails, shelters (including C-shape), lithic scatters, quarries, shrines, cairns (ahu), platforms, and pits of unclear origin. Appendix H contains a list of PTA sites recommended as eligible for inclusion in the National Register of Historic Places (NRHP). One site, the Bobcat Trail Habitation Cave, is already listed in the NRHP. (U.S. Department of the Army, 2004)

Historic Buildings and Structures

PTA's first use as a military installation began in 1938 with the building of the Kaumana Road for military access between Hilo and Waimea (i.e., the Saddle Road). The new road allowed development of the Saddle Training Area, which consisted of the Bradshaw Army Airfield and the PTA. Permanent and consistent use of PTA began in the 1950s (Hays, 2002). In 2002, a historic evaluation of 129 buildings and structures was conducted of the cantonments within the PTA and Bradshaw Army Airfield (Hays, 2002). Of the 129 facilities evaluated, 107 were recommended as historic with 20 recommended for retention; however, the report has not been submitted to the Hawaii State Historic Preservation Office for concurrence (Godby, 2007). Eleven of the 20 were recommended for indefinite maintenance (Buildings T-001, T-39, T-90, T-109, T-184, T-230, T-246, T-285, T-286, T-290, and T-293.) (Hays, 2002) (see Section 3.6.2.2.3).

Traditional Resources

An oral history survey of PTA that included both interviews and a field visit with eight of the informants was conducted by Social Research Pacific, Inc. in 2002. The survey focused on place names, trail systems, and known Native Hawaiian structures. The report from this survey includes information gleaned from previous works, including McEldowney (1982), which contains oral accounts and written evidence about the Mauna Kea summit area; other early accounts from western visitors passing through the area (Maly, 1999); and myth and legend material found in Elbert (1959) and Kamakau (1992). Specific types of traditional sites identified in the region include agricultural terraces and enclosures, habitation shelters, and rock art sites. Some of the archaeological sites described above may have traditional components or be considered traditional sites as well.

3.6.2.1.4 Health and Safety—PTA

Appendix C includes a detailed discussion of health and safety resources laws and regulations.

Region of Influence

The region of influence is the area of the PTA where proposed training and RDT&E activities are planned.

Affected Environment

The affected environment is in an isolated area in the center of PTA with restricted access and located away from the civilian population. Safety and health precautions are covered in *Pohakuloa Training Area External Standing Operating Procedures* and are briefed by the PTA Operations Center.

For missile and weapons systems, the Range Safety Office at PTA establishes criteria for the safe execution of the test activity in the form of Range Safety Approval and Range Safety Operational Plan documents. These plans are required for all weapon and target systems using PTA. The plans include the allowable launch and flight conditions and flight control methods necessary to contain the missile flight and impacts within the predetermined impact hazard areas. All hazard areas are checked and determined to be clear of nonessential personnel and aircraft prior to an exercise.

Ammunition is brought from Wheeler Army Airfield or Lualualei to PTA via boat or helicopter. If boats are used, the ammunition is driven from Kawaihae Harbor to PTA. Once ammunition is brought to PTA, it is temporarily stored in ammunition holding areas on PTA. At completion of training, unused ammunition is returned to the ammunition supply point on Wheeler Army Airfield. Permanent ammunition storage is not authorized on PTA. Ranges at PTA have designated surface danger zones, whose construction is based on information in Army Regulation 385-63 and the draft update of this regulation. There have been no accidents involving the transportation of ammunition in the last 5 years. (U.S. Department of the Army, 2004; 2008)

Depleted Uranium

Uranium is a naturally occurring, slightly radioactive heavy metal found in many parts of the world. Natural uranium becomes depleted uranium (DU) when the more radioactive isotopes are removed to create nuclear fuel, which is used in commercial nuclear power plants for production of electricity and in nuclear weapons. DU is 40 percent less radioactive than natural uranium and is not nuclear waste. People are routinely exposed to natural uranium through food, water, and air. It has been estimated that the average person ingests 1.3 micrograms (µg) of uranium per day and inhales 0.6 µg every year. Most (more than 95 percent) of uranium that enters the body is not absorbed, but is eliminated through waste within a few days and never reaches the blood stream. Approximately 67 percent of the uranium that is absorbed into the blood will be filtered by the kidney and excreted within 24 hours. (International Atomic Energy Agency, 2003, U.S. Army Center for Health Promotion and Preventive Medicine, 2002, and World Health Organization, 2001)

All uranium mixtures (natural, depleted, and enriched) have the same chemical effect on the human body. Large amounts of uranium can react with human tissues and damage the kidneys. The radiation damage from exposure to high levels of natural or depleted uranium is not known to cause cancer. The Occupational Safety and Health and Administration occupational exposure limits for uranium in breathing air over an 8-hour workday, 40-hour work week are 0.05 milligrams per cubic meter (mg/m^3). (U.S. Army Center for Health Promotion and Preventive Medicine, 2002)

Current military use of DU includes making armor-piercing ammunitions. In addition, DU is a very dense metal, making it suitable for several commercial uses, such as a counter weight to balance aircraft and boats. (International Atomic Energy Agency, 2003) Current U.S. Army policy prohibits the use of DU ammunition for training events (U.S. Department of the Army, 2008).

In August 2007 the Army confirmed the presence of DU on remote sections of PTA. The Army has begun a three-part process to assess DU on Army ranges in Hawaii, including PTA. First, a historical assessment was performed of all Hawaii Army ranges where DU ammunition could have been fired. Next, a scoping survey was conducted to determine the presence of DU on the ranges. Finally, a full characterization survey will be performed to determine the extent of contamination and the possible health hazards. Once the surveys are completed, a plan will be developed to fully address the issue of DU. Part of the Army's plan is to work with the State of Hawaii and the Nuclear Regulatory Commission to determine an appropriate response. (U.S. Army, Pacific Public Affairs, 2007) All Navy activities at PTA will follow existing standard operating procedures and will comply with future plans and regulations for DU.

3.6.2.1.5 Noise—PTA

Appendix C includes a definition of noise and the main regulations and laws that govern it.

Region of Influence

The region of influence for noise analysis is the area within and surrounding PTA in which humans and wildlife may suffer annoyance or disturbance from proposed training and RDT&E activities noise sources at PTA.

Affected Environment

The Army's noise evaluation program is known as the Installation Compatible Use Zone (ICUZ). The following three broad noise exposure zones are used as the basis for characterizing various land use compatibility conditions at PTA:

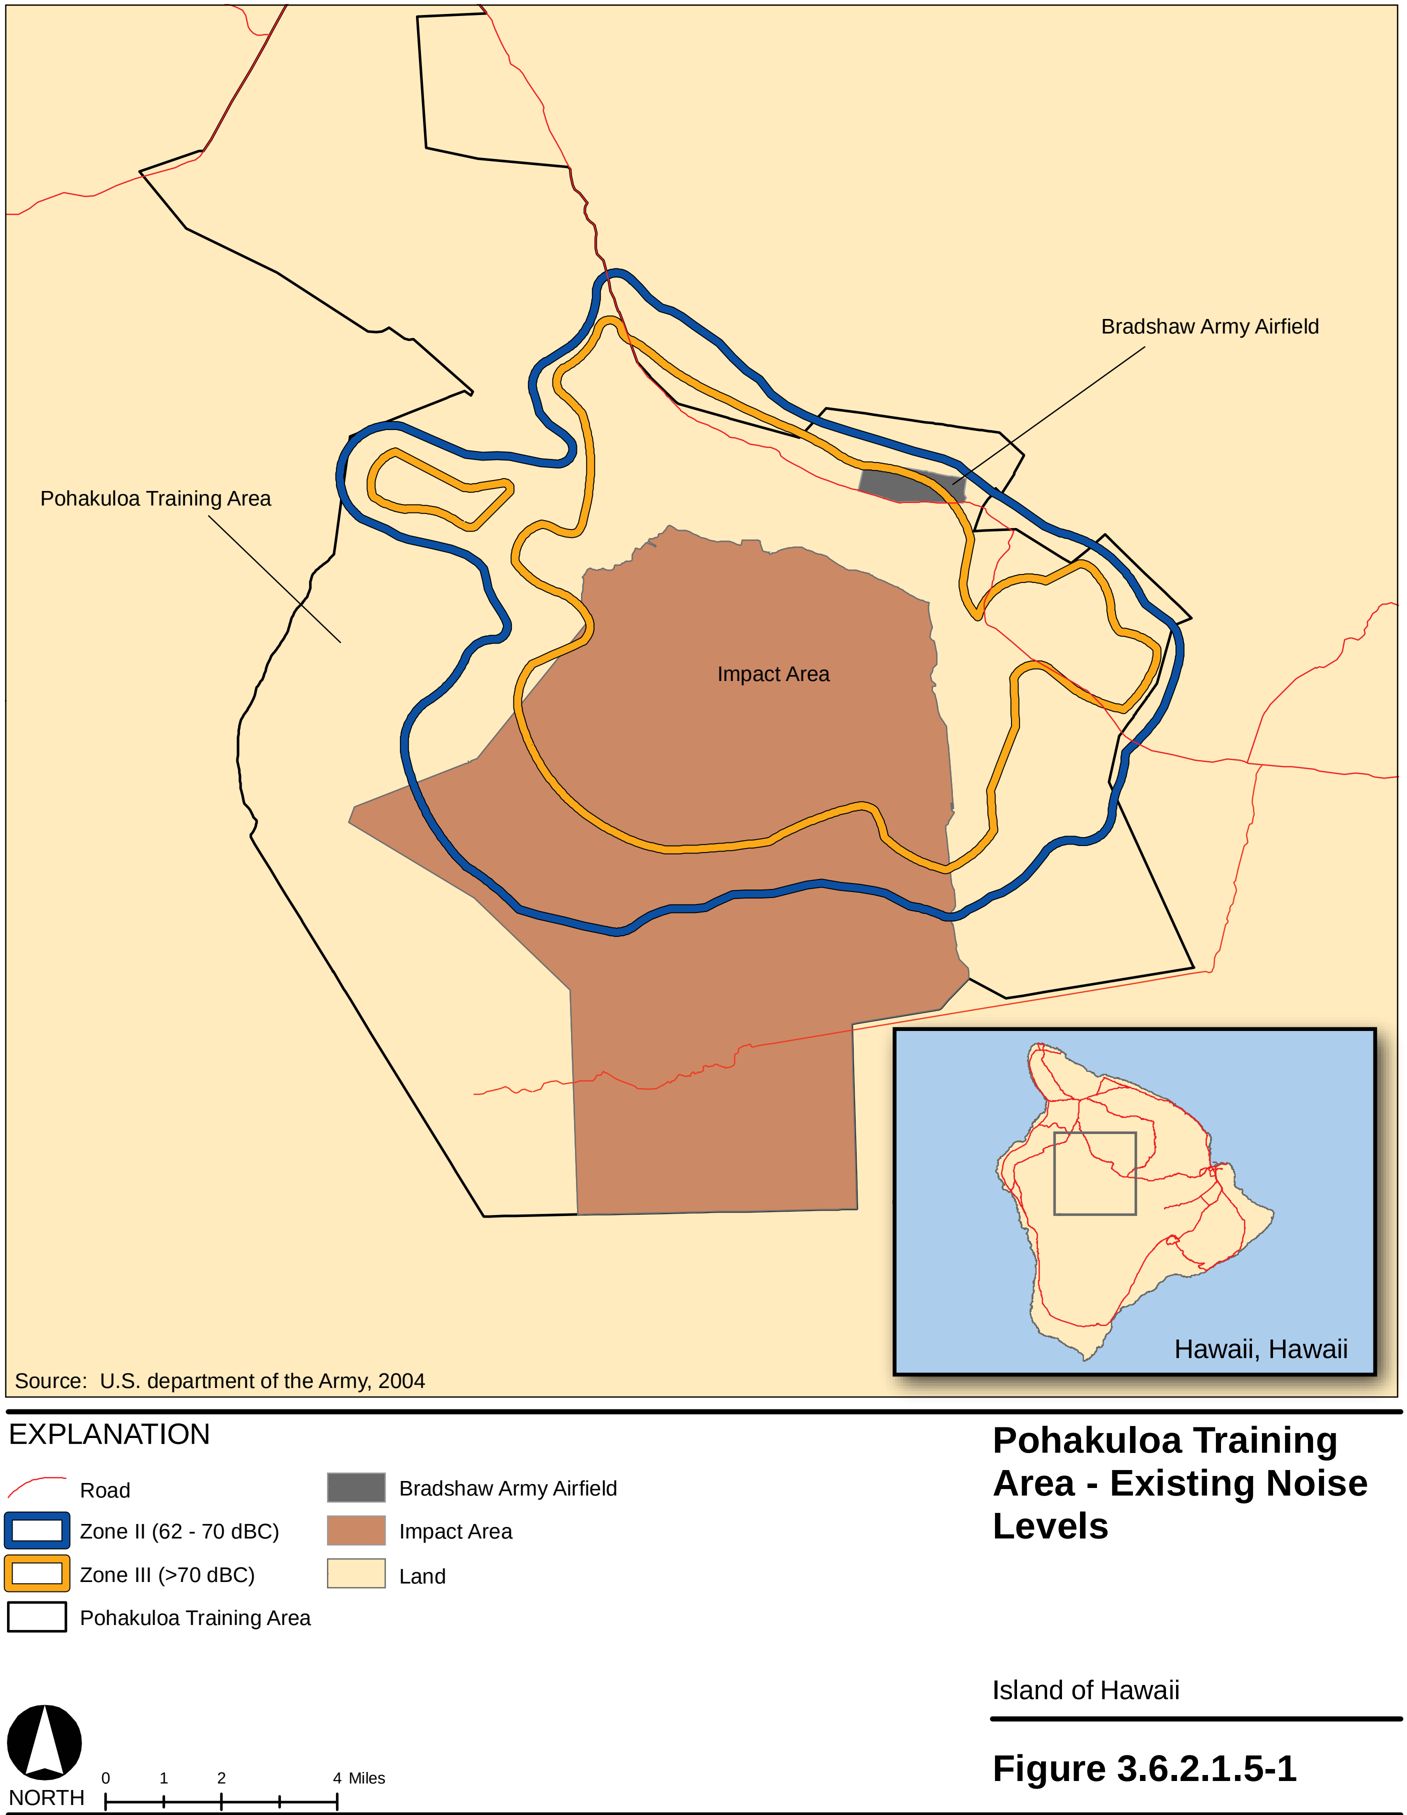
- Zone I – areas with day-night average sound level (L_{dn}) levels below 65 dBA;
- Zone II – areas with L_{dn} levels of 65 to 75 dBA; and
- Zone III – areas with L_{dn} levels above 75 dBA.

The ICUZ program states that all land uses are compatible with Zone I noise levels. Unless special acoustic designs or treatments are used to ensure acceptable interior noise levels, educational, medical, and residential land uses are not typically compatible with Zone II areas. Educational, medical, and residential areas are not compatible with Zone III noise levels; however, industrial, manufacturing, and office land uses may be acceptable in Zone II areas if special building designs or other measures are implemented. (U.S. Department of the Army, 2004; 2008)

Noise levels surrounding PTA are typically low due to the area having a low population and low volume of traffic on nearby roads. The noise levels within PTA can be high due to military training, such as military aircraft (primarily helicopters, but including jet fighters), military vehicle traffic, and ordnance used during LFX and other training events. Figure 3.6.2.1.5-1 depicts the existing Zone II and III noise levels at PTA. All Zone III noise levels occur within the boundaries of PTA. With the exception of the cantonment area, no noise-sensitive land uses are affected by existing Zone II noise levels. Because troops are not permanently based at PTA, all troop housing is used for troops who are visiting PTA to participate in training events. (U.S. Department of the Army, 2004; 2008)

The Army is developing an environmental noise management plan for PTA in accordance with the Army's Environmental Noise Management Program (described in Army Regulation 200-1). This plan is intended to improve land use compatibility and notification to surrounding communities about the scheduling and nature of military training events. (U.S. Department of the Army, 2004; 2008)

Wildlife receptors at PTA are described in Section 3.6.2.1.2, Biological Resources.



Pohakuloa Training Area - Existing Noise Levels

Island of Hawaii

Figure 3.6.2.1.5-1

3.6.2.2 BRADSHAW ARMY AIRFIELD

Bradshaw Army Airfield is located on the northern boundary of PTA and supports maneuver training. It has a 3,700-ft airstrip and a small cantonment area.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Bradshaw Army Airfield. Of the 13 environmental resources considered for analysis, air quality, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.6.2.2.1 Airspace—Bradshaw Army Airfield

Appendix C includes a detailed description of airspace.

Region of Influence

The region of influence for Bradshaw Army Airfield is similar to that described for airspace at PTA (Section 3.6.2.1.1).

Affected Environment

The affected airspace for Bradshaw Army Airfield is the same as that described in Section 3.6.2.1.1 for PTA.

3.6.2.2.2 Biological Resources—Bradshaw Army Airfield

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence is the area within or adjacent to Bradshaw Army Airfield that could be affected by proposed training.

Affected Environment

Since Bradshaw Army Airfield is located on the northern boundary of PTA, its affected environment is similar to that described in Section 3.6.2.1.2.

Vegetation

The majority of the open area is vegetated with native plants and is identified as Subalpine dryland.

Threatened and Endangered Plant Species

Plant species listed in Table 3.6.2.1.2-1 could also potentially be located on Bradshaw Army Airfield.

Wildlife

Since the area has been cleared for the runway, only small mammals and birds are likely to be in the region of influence. However, other wildlife species listed above at PTA could also potentially occur at Bradshaw Army Airfield.

Threatened and Endangered Wildlife Species

Routine and transformation training actions at Bradshaw Army Airfield were addressed in the 2003 biological opinion for PTA (U.S. Department of the Interior, Office of Environmental Policy and Compliance Pacific Southwest Region, 2007). The endangered Hawaiian hoary bat could pass through the area, as well as the `io and nene.

Environmentally Sensitive Habitat

Critical habitat for the endangered palila has been established both north and southeast of Bradshaw Army Airfield (see Figure 3.6.2.1.2-1), but none is located in the immediate vicinity of the airfield.

3.6.2.2.3 Cultural Resources—Bradshaw Army Airfield

Appendix C includes a description of cultural resources and the laws and regulations pertaining to them.

Region of Influence

The region of influence for cultural resources at Bradshaw Army Airfield encompasses the building where a new ground relay station will be added.

Affected Environment

Archaeological Resources (Prehistoric and Historic)

Bradshaw Army Airfield is located within PTA (see Figure 2.1-5); therefore, the prehistoric and historic context for the facility is the same as described for PTA. There are no known significant archaeological resources within Bradshaw Army Airfield; however, there are numerous archaeological sites identified within the adjacent PTA (see Section 3.6.2.1.3). (U.S. Department of the Navy, 2002a)

Historic Buildings and Structures

Identification of historic buildings and structures at Bradshaw Army Airfield is the same as described for PTA (see Section 3.6.2.1.3.)

Traditional Resources

Bradshaw Army Airfield is within the PTA; therefore, the traditional resources context for the facility is the same as described for PTA. There are no known traditional resources sites within Bradshaw Army Airfield (see Section 3.6.2.1.3). (U.S. Department of the Army, 2004)

3.6.2.3 KAWAIHAE PIER

Kawaihae Pier is located within the Kawaihae Harbor on the northwestern corner of the island of Hawaii. Kawaihae Harbor is a deep-water port, one of two on the island of Hawaii. Expeditionary Assault events are conducted at Kawaihae Pier. Activities primarily consist of offloading and loading vehicles and equipment from a landing ship at an existing boat ramp.

This section describes the environmental resources that would be affected by the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3 for Kawaihae Pier. Of the 13 environmental resources considered for analysis, airspace, air quality, cultural resources, geology and soils, hazardous material and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources are not addressed.

3.6.2.3.1 Biological Resources—Kawaihae Pier

Appendix C includes a detailed description of biological resources.

Region of Influence

The region of influence includes the beach and other areas adjacent to the pier that may be affected by proposed training.

Affected Environment

Vegetation

A small beach area containing no vegetation is located immediately adjacent to the pier.

Threatened and Endangered Plant Species

No threatened or endangered plant species have been identified within the harbor area.

Wildlife

Terrestrial wildlife at Kawaihae Pier is limited to transitory birds and small mammals.

Threatened and Endangered Wildlife Species

No threatened or endangered species have been identified within the harbor.

Environmentally Sensitive Habitat

No critical habitat is present (National Park Service, 2004).

3.7 HAWAIIAN ISLANDS HUMPBACK WHALE NATIONAL MARINE SANCTUARY (HIHWNMS)

The National Marine Sanctuaries Act (NMSA),16 United States Code § 1431 et seq., authorizes the Secretary of Commerce to designate areas of the marine environment that possess conservation, recreational, ecological, historical, research, and educational, or aesthetic resources and qualities of national significance as National Marine Sanctuaries, and to provide comprehensive management and protection of these areas. To protect the area designated, any Federal action that is likely to destroy, cause the loss of, or injure a sanctuary resource must consult with the Secretary of Commerce prior to commencement and adhere to reasonable and prudent alternatives set by the Secretary of Commerce. To the extent practicable, consultation may be consolidated with other consultation efforts under other Federal laws, such as the Endangered Species Act.

The Hawaiian Islands Humpback Whale National Marine Sanctuary (HIHWNMS) (Figure 3.3.1.1.1-2) is one of 14 established sanctuaries under the NMSA. It was established in 1992 by the Hawaiian Islands National Marine Sanctuary Act, Title II, subtitle C of the Oceans Act of 1992. At the inception of the HIHWNMS and by virtue of the *Hawaiian Islands Humpback Whale National Marine Sanctuary Final Environmental Impact Statement/Management Plan* (February 1997) and implementing regulations (15 CFR § 922.180), certain military activities were identified as exempt from the interagency consultation requirements and the prohibited activities designated under the NMSA.

Specifically, the HIHWNMS Final Environmental Impact Statement (EIS)/Management Plan identified 28 offshore training events and 20 open ocean training events as “classes of military activities” conducted in the Hawaiian waters. Offshore activities are conducted within the 100-fathom isobath demarcation of the HIHWNMS around the Hawaiian Islands. These classes of activities were noted to be conducted “by all the military services of the United States and, during combined exercises, by military units from cooperating foreign nations or the State of Hawaii Department of Defense/National Guard” (U.S. Department of Commerce, National Oceanic and Atmospheric Administration and State of Hawaii, Office of Planning, 1997). The HIHWNMS EIS described seven examples of “types” of Department of Defense (DoD) military activities that occur in or around the Sanctuary, then further described 31 “Other DoD Military Operations in the Hawaiian Islands”, noting whether each activity occurred within the 100 fathom isobath (the designated demarcation boundary of the HIHWNMS around the Hawaiian Islands). Included in the list of seven examples of types is “Anti-submarine Warfare (ASW) Exercises.” The example indicates that ASW exercises take place “usually two per year, lasting several days with surface ships and submarines and including the use of expendable equipment such as smoke floats and bathythermograph probes.” The bulleted types of activities and Appendix F of the HIHWNMS EIS/Management Plan (see Exhibit C-1 of Appendix C) more thoroughly list the ASW events as both within and outside the 100-fathom isobath, using sonar, sonobuoys, and mine countermeasures using sonar. Additionally, non-ASW activities such as air-to-surface gunnery exercises, air combat maneuvers, air-to-surface missile/bombing exercises, air-to-ground Strike Warfare Exercises, and Amphibious Exercises are listed as potential activities both outside and within the boundaries of the HIHWNMS. These types of activities can be combined into the Undersea Warfare Exercises (USWEX) or Rim of the Pacific (RIMPAC) exercise.

Under the HIHWNMS regulations, military activities are allowed within the HIHWNMS and are not subject to vessel/aircraft approach distances, discharge of materials prohibitions and consultation requirements if they are “classes of military activities, internal and external to the HIHWNMS, that are being or have been conducted before the effective date of these regulations, as identified in the Final Environmental Impact Statement/Management Plan.” If the military activity is proposed after the effective date of the regulations, then the activity is also allowable, but is subject to the prohibited activities provisions of 15 CFR § 922.184 unless the activity is not subject to consultation under NMSA (that is, not likely to destroy, cause the loss of, or injury to any sanctuary resource). Regulatory prohibition provisions include distance restrictions on vessel and aircraft approaches to humpback whales, prohibitions on depositing materials within or near the Sanctuary, and prohibitions on the taking or possessing of humpback whales. Finally, any military activity that is subsequently modified in a way that causes the activity to be “likely to destroy, cause the loss of, or injure a HIHWNMS resource in a manner significantly greater than was considered in previous consultation” is treated as a new military activity for which consultation may be necessary.

In April 1995, before the completion of the HIHWNMS Final EIS/Management Plan, the Department of the Navy provided the Department of Commerce with a “Report on Military Activities in Hawaiian Waters.” This document detailed to National Oceanic and Atmospheric Administration (NOAA) the varying military activities that occur around Hawaii, specifically explaining the nature of RIMPAC as well as other Major Exercises, unit-level training, and additional military activities. This document’s specificity aided NOAA in listing “classes” of activities for purposes of brevity in its EIS. (See Exhibit C-2 of Appendix C for the complete Report.)

In October 1995, the Department of Navy and the Department of Commerce entered into a Memorandum of Understanding regarding the military activities and the HIHWNMS. That Memorandum reflected the parties’ completion of consultation required by NMSA Section 304(d) regarding existing classes of military activities. The activities were found not likely to destroy, cause loss of, or injure a humpback whale. It was determined that the existing classes of military activities, therefore, were not subject to further consultation unless they became modified in a way that is likely to destroy, cause loss of, or injure a Sanctuary resource in a manner significantly greater than was considered in previous consultation. (See Exhibit C-3 of Appendix C for the complete Navy/NOAA Memorandum of Understanding Concerning Military Activities and the Hawaiian Islands Humpback Whale National Marine Sanctuary).

Humpback whales are seen in the winter months in the shallow waters surrounding the Hawaiian Islands where they congregate to mate and calve. The humpback whale population is growing by an average of 7 percent annually. The best available estimate of the central west pacific stock humpback whale abundance is 4,491 individuals. (Mobley et al., 2001) The whales travel more than 3,500 mi from Alaska to Hawaii's warm waters to mate, give birth, and care for their calves. The first whales of the season usually arrive around October, with the greatest number seen around Hawaii between 1 December and 15 May. (National Oceanic and Atmospheric Administration, 2007a; Mobley, 2002)

The following sections describe areas of the HIHWNMS, by island, that could be affected by proposed Hawaii Range Complex (HRC) training and research, development, test, and evaluation (RDT&E) activities.

3.7.1 BIOLOGICAL RESOURCES—HIHWNMS

3.7.1.1 KAUAI—BIOLOGICAL RESOURCES—HIHWNMS

The HIHWNMS (Figure 3.3.1.1.1-2) includes a portion of the ocean north of Kauai, but not within the Pacific Missile Range Facility vicinity or in the Barking Sands Tactical Underwater Range (BARSTUR) and the Barking Sands Underwater Ranges Expansion (BSURE) coverage areas (U.S. Department of the Navy, 2001a). (U.S. Department of Commerce, National Oceanic and Atmospheric Administration and State of Hawaii, Office of Planning, 1997)

No training or RDT&E activities are planned to occur in the area north of Kauai that is included in HIHWNMS. Warning Areas W-186 and W-188 airspace over the Open Ocean are outside the HIHWNMS boundary. The Warning Areas are used for missile, bomb, and gunnery exercises. Air, surface, and underwater exercises are conducted in the surface area of W-186 and W-188.

Instrumentation at BARSTUR provides the capability to conduct ASW and Anti-surface Underwater Warfare training. BSURE is also used for ASW and Anti-surface Underwater Warfare training and to track submarines and torpedo firing.

3.7.1.2 OAHU—BIOLOGICAL RESOURCES—HIHWNMS

HIHWNMS (Figure 3.3.1.1.1-2) areas are located off the northern and southeastern coastlines of Oahu. No current HRC activities are being performed within the HIHWNMS's boundaries, and none are being proposed.

3.7.1.3 MAUI—BIOLOGICAL RESOURCES—HIHWNMS

The Maui Offshore is an area situated around the islands of Maui, Kahoolawe, Lanai, and Molokai, portions of which are within the HIHWNMS (Figure 3.3.1.1.1-2). The waters adjacent to Maui, Molokai, and Lanai are important Navy training areas. The offshore area also includes the portion of Penguin Bank that is within 12 nautical miles (nm) of the islands' coastlines. The area is used as a submarine training area due to the unique characteristics of its acoustic environment and shallow depths of 50 and 100 fathoms. Multiple in-water runs of exercise MK-48 torpedoes (with no warheads) using one submarine as both target and launch platform also occur in the Penguin Bank area. According to the HIHWNMS EIS/Management Plan, submarines conduct post-overhaul shallow water dives and shallow water ASW events in the vicinity of Penguin Bank. Penguin Bank is the only shallow water area in Hawaiian waters suitable for initial submerged testing, which is necessary for crew rescue. Submarines also conduct mine warfare training at Penguin Bank.

According to the HIHWNMS EIS (U.S. Department of Commerce, National Oceanic and Atmospheric Administration and State of Hawaii, Office of Planning, 1997), "… the waters adjacent to Maui, Molokai, and Lanai are important training areas for Navy ships homeported in Pearl Harbor. The channel between Maui, Lanai and Molokai is extensively used for biennial RIMPAC [Rim of the Pacific] exercises, EOD/MCM [explosive ordnance disposal/mine countermeasures] exercises, and as well for shallow-water ASW [anti-submarine warfare]…

The areas inside the 100-fathom isobath surrounding Maui, Molokai and Lanai, and specifically the channel between these islands, are used for shallow-water ASW operations."

The presence of the endangered humpback whale in the region of influence is seasonal, with peak concentrations in mid-February to mid-March. The whales seem to prefer areas within the 100-fathom contours such as the Molokai–Lanai–Maui–Kahoolawe channels and Penguin Bank. Humpback whale sightings in the region of influence are mainly concentrated north of Kahoolawe in protected channel areas. (Commander, Submarine Force U.S. Pacific Fleet, 1997; Naval Undersea Warfare Center Division Newport, Rhode Island, 2007)

3.7.1.4 HAWAII—BIOLOGICAL RESOURCES—HIHWNMS

The Kawaihae Pier area is not included within the HIHWNMS (Figure 3.3.1.1.1-2), which is located off the northwestern shore of Hawaii. Other than transiting the HIHWNMS to reach Kawaihae Pier, no current HRC activities are being performed within the HIHWNMS's boundaries, and none are being proposed.

FINAL ENVIRONMENTAL IMPACT STATEMENT/
OVERSEAS ENVIRONMENTAL IMPACT STATEMENT
HAWAII RANGE COMPLEX (HRC)

Lead Agency for the EIS:	U.S. Department of the Navy
Title of the Proposed Action:	Hawaii Range Complex
Affected Jurisdiction:	Kauai, Honolulu, Maui, and Hawaii Counties
Designation:	Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS)

Abstract

This Final EIS/OEIS has been prepared by the U.S. Department of the Navy (Navy) in compliance with the National Environmental Policy Act (NEPA) of 1969 (42 United States Code § 4321 et seq.); the Council on Environmental Quality (CEQ) Regulations for Implementing the Procedural Provisions of NEPA (Title 40 Code of Federal Regulations [CFR] §§ 1500-1508); Navy Procedures for Implementing NEPA (32 CFR § 775); and Executive Order 12114 (EO 12114), *Environmental Effects Abroad of Major Federal Actions*. The Navy has identified the need to support and conduct current, emerging, and future training and research, development, test, and evaluation (RDT&E) activities in the Hawaii Range Complex (HRC). The alternatives—the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3—are analyzed in this Final EIS/OEIS. All alternatives include an analysis of potential environmental impacts associated with the use of mid-frequency active (MFA) and high-frequency active (HFA) sonar. The No-action Alternative stands as no change from current levels of HRC usage and includes HRC training, support, and RDT&E activities, Major Exercises, and maintenance of the technical and logistical facilities that support these activities and exercises. Alternative 1 includes all ongoing training associated with the No-action Alternative, an increased tempo and frequency of such training (including increases in MFA and HFA sonar use), a new training event (Field Carrier Landing Practice), enhanced and future RDT&E activities, enhancements to optimize HRC capabilities, and an increased number of Major Exercises. Alternative 2 includes all of the training associated with Alternative 1 plus additional increases in the tempo and frequency of training (including additional increases in MFA and HFA sonar use), enhanced RDT&E activities, future RDT&E activities, and additional Major Exercises, such as supporting three Strike Groups training at the same time. Alternative 3 would include all of the training and RDT&E activities associated with Alternative 2. The difference between Alternative 2 and Alternative 3 is the amount of MFA/HFA sonar usage. As described under Alternative 2, Alternative 3 would provide increased flexibility in training activities by increasing the tempo and frequency of training events, future and enhanced RDT&E activities, and the addition of Major Exercises. Alternative 3 would consist of the MFA/HFA sonar usage as analyzed under the No-action Alternative. Alternative 3 is the Navy's preferred alternative.

This Final EIS/OEIS addresses potential environmental impacts that result from activities that occur under the No-action Alternative and proposed activities that would occur under Alternatives 1, 2, and 3. This EIS/OEIS also addresses changes and associated environmental analyses that were presented in the Supplement to the Draft EIS/OEIS. Environmental resource topics evaluated include air quality, airspace, biological resources (open ocean, offshore, and onshore), cultural resources, geology and soils, hazardous materials and waste, health and safety, land use, noise, socioeconomics, transportation, utilities, and water resources.

4.0 Environmental Consequences

4.0 ENVIRONMENTAL CONSEQUENCES

This chapter describes potential environmental consequences at each location that may be affected by the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3. The same resource areas addressed in Chapter 3.0 for each location are addressed in this chapter. The following sections address the potential for impacts on each environmental resource and its attributes by activity and sub-activities identified in Chapter 2.0.

Environmental consequences are discussed according to location; the Open Ocean Area is discussed first, followed by offshore and onshore discussion organized by island locations from west to east: Northwestern Hawaiian Islands, Kauai, Oahu, Maui, and Hawaii. For organizational purposes, discussions about Niihau and Kaula (although separate islands) are included under the Kauai heading because they are part of Kauai County. Similarly, discussions about Molokai are included under the Maui heading because it is part of Maui County. The last section discusses the Hawaiian Islands Humpback Whale National Marine Sanctuary. The page headers in this chapter identify which location is discussed. The rationale for not addressing certain resources for a given location is provided under each location. Table 4-1 lists each location and the section where each of the resources is addressed.

Potential environmental effects described in this section focus on the continuation of combinations of unit-level training and research, development, test, and evaluation (RDT&E) in the Hawaii Range Complex (HRC) (No-action Alternative) that have been occurring for decades and the effects of implementing Alternatives 1, 2, and 3 to the No-action Alternative. The environmental consequences assessment in the Environmental Impact Statement (EIS)/Overseas EIS (OEIS) includes estimates of the potential direct and indirect effects, long- and short-term effects, and irreversible and irretrievable resource commitments.

This EIS/OEIS describes measures required to mitigate adverse impacts. The EIS/OEIS also identifies those measures already committed to as part of current unit-level training and RDT&E, and additional mitigations (if any) which could reasonably be expected to reduce impacts if Alternative 1, 2, or 3 is implemented.

Table 4-1. Chapter 4.0 Locations and Resources

Location	Air Quality	Airspace	Biological Resources	Cultural Resources	Geology & Soils	Hazardous Materials & Waste	Health & Safety	Land Use	Noise	Socioeconomics	Transportation	Utilities	Water Resources

*A review of the 13 environmental resources against program activities determined there would be no impacts from site activities under the No-action Alternative, Alternative 1, Alternative 2, or Alternative 3.

4.1 OPEN OCEAN AREA

Table 4.1-1 lists ongoing training and RDT&E for the No-action Alternative and proposed training and RDT&E for Alternatives 1, 2, and 3 in the Open Ocean Area. Alternative 3 is the preferred alternative.

Table 4.1-1. Training and RDT&E Activities in the Open Ocean Area

Training	Research, Development, Test, and Evaluation (RDT&E)
• Air Combat Maneuver (ACM) • Air-to-Air Missile Exercise (A-A MISSILEX) • Surface-to-Air Gunnery Exercise (S-A GUNEX) • Surface-to-Air Missile Exercise (S-A MISSILEX) • Chaff Exercise (CHAFFEX) • Naval Surface Fire Support Exercise (NSFS)[1] • Visit, Board, Search, and Seizure (VBSS) • Surface-to-Surface Gunnery Exercise (S-S GUNEX)[1] • Surface-to-Surface Missile Exercise (S-S MISSILEX)[1] • Air-to-Surface Gunnery Exercise (A-S GUNEX) • Air-to-Surface Missile Exercise (A-S MISSILEX)[1] • Bombing Exercise (BOMBEX) (Sea)[1] • Sinking Exercise (SINKEX)[1] • Anti-Surface Warfare (ASUW) Torpedo Exercise (TORPEX) (Submarine-Surface) • Anti-Submarine Warfare (ASW) Tracking Exercise (TRACKEX)[2] • ASW TORPEX[2] • Major Integrated ASW Training Exercise[2] • Electronic Combat Operations • Mine Countermeasures Exercise (MCM) • Mine Neutralization[1] • Swimmer Insertion/Extraction • Command and Control (C2) (Sea) • Demolition Exercises (Sea) • Extended Echo Ranging/Improved Extended Echo Ranging (EER/IEER)[1]	• Anti-Air Warfare RDT&E • Anti-Submarine Warfare • Combat System Ship Qualification Trial • Electronic Combat/Electronic Warfare (EC/EW) • High-Frequency Radio Signals • Missile Defense • Shipboard Electronic Systems Evaluation Facility (SESEF) Quick Look • SESEF System Performance Test • Additional Chemical Simulant (Alternative 1) • Intercept Targets Launched into Pacific Missile Range Facility (PMRF) Controlled Area (Alternative 1) • Launched SM-6 from Sea-Based Platform (AEGIS) (Alternative 1) • Test Unmanned Surface Vehicles (Alternative 1) • Test Unmanned Aerial Vehicles (Alternative 1) • Test Hypersonic Vehicles (Alternative 1) • Portable Undersea Tracking Range (Alternative 1) • Large Area Tracking Range Upgrade (Alternative 1) • Enhanced Electronic Warfare Training (Alternative 1) • Expanded Training Capability for Transient Air Wings (Alternative 1) • Directed Energy (Alternative 2/3) • Advanced Hypersonic Weapon (Alternative 2/3)

Notes: 1. Modeled for explosives
2. Modeled for sonar

4.1.1 AIRSPACE—OPEN OCEAN

The potential impacts on airspace in the Open Ocean Area are discussed in terms of conflicts with the use of controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields.

4.1.1.1 NO-ACTION ALTERNATIVE (AIRSPACE—OPEN OCEAN)

4.1.1.1.1 HRC Training—No-action Alternative

The ongoing, continuing HRC training that could affect airspace includes mine laying, Surface-to-Surface Gunnery Exercises (S-S GUNEX), Surface-to-Surface Missile Exercises (S-S MISSILEX), Air-to-Surface Gunnery Exercises (A-S GUNEX), Air-to-Surface Missile Exercises

(A-S MISSILEX), Bombing Exercises (BOMBEX), Sinking Exercises (SINKEX), Anti-Submarine Warfare (ASW), Air Combat Maneuvers (ACM), Air-to-Air Missile Exercises (A-A MISSILEX), Electronic Countermeasures (ECM), Surface-to-Air Gunnery Exercises (S-A GUNEX), Surface-to-Air Missile Exercises (S-A MISSILEX), Naval Surface Fire Support (NSFS), Flare Exercises, Chaff Exercises (CHAFFEX), and Extended Echo Ranging/Improved Extended Echo Ranging (EER/IEER) Exercises as listed in Table 2.2.2.1-1.

Controlled and Uncontrolled Airspace

The Navy can accomplish the No-action Alternative without modifications or need for additional airspace to accommodate continuing training.

Special Use Airspace

Ongoing, continuing training identified above will continue to use the existing Open Ocean Area special use airspace including Warning Areas and Air Traffic Control Assigned Airspace (ATCAA) shown on Figure 3.1.1-1. Although the nature and intensity of use varies over time and by individual special use airspace area, the continuing training represents precisely the kinds of events for which the special use airspace was created. The Warning Areas are designed and set aside by the Federal Aviation Administration (FAA) to accommodate training that presents a hazard to other aircraft. As such, the continuing training does not conflict with any airspace use plans, policies, and controls. The ATCAA has been developed by the FAA to facilitate the management of aircraft moving between and adjacent to other special use airspace areas.

En Route Airways and Jet Routes

Numerous instrument flight rules (IFR), en route low altitude air traffic service routes, and IFR en route high altitude oceanic routes are used by commercial aircraft that pass through the region of influence (see Figure 3.1.1-1). However, the region of influence is relatively remote from the majority of jet routes that traverse the northern Pacific Ocean. The Navy coordinates closely with the FAA to avoid conflicts with commercial aviation.

The low altitude airways that pass through a Warning Area include V7 (through W-190), V15 (through W-188), and V16 (through W-186). There are no oceanic routes that pass through a Warning Area. Several low altitude airways pass below the Pali ATCAA near Oahu. The floor of the Pali ATCAA is above the ceiling of the low altitude routes. Two low altitude airways pass above the ceiling of the Mela North ATCAA. Navy training involving aircraft in the Open Ocean Area is conducted away from en route airways and jet routes to minimize potential airspace conflicts.

Use of the low altitude airways and high-altitude jet routes comes under the control of the Honolulu and Oakland Air Route Traffic Control Centers (ARTCCs). In addition, the Navy surveys the airspace involved in each training event either by radar or patrol aircraft. Safety regulations dictate that hazardous activities will be suspended by the Navy when it is known that any non-participating aircraft has entered any part of a training activity danger zone. The suspension lasts until the non-participating entrant has left the area or a thorough check of the suspected area has been performed. Consequently, there are no impacts on non-military aircraft.

The continuing training will be conducted in compliance with Department of Defense (DoD) Directive 4540.1, as directed by Office of the Chief of Naval Operations Instruction (OPNAVINST) 3770.4A, which specifies procedures for conducting Aircraft Operations and for missile/projectile firing. Missile and projectile firing areas shall be selected so that trajectories are clear of established oceanic air routes or areas of known surface or air activity. In addition, before conducting training that is potentially hazardous to non-participating aircraft, Notices to Airmen (NOTAMs) published by the FAA will be sent in accordance with the conditions of the directive specified in OPNAVINST 3721.20A. The increasing adoption of “Free Flight” by commercial aircraft could make the airspace coordination task somewhat more difficult, but this will still be handled by the issuance of NOTAMs. As noted in Chapter 3.0, with the full implementation of this program, the amount of clear airspace in the region of influence may decrease as pilots, whenever practical, choose their own route and file a flight plan that follows the most efficient and economical route.

All airspace outside the territorial limits is located in international airspace. Because the Open Ocean Area airspace use region of influence is in international airspace, the procedures outlined in International Civil Aviation Authority (ICAO) Document 444, *Rules of the Air and Air Traffic Services* are followed. The FAA acts as the U.S. agent for aeronautical information to the ICAO, and air traffic in the over-water region of influence is managed by the Honolulu ARTCC, and to a lesser extent, the Oakland ARTCC.

As noted above, continuing training will use the existing Open Ocean Area special use airspace and will not require either: (1) a change to an existing or planned IFR minimum flight altitude, a published or special instrument procedure, or an IFR departure procedure; or (2) a visual flight rules (VFR) operation to change from a regular flight course or altitude. Consequently, there are no airspace conflicts.

Airports and Airfields

There are no airports and airfields in the Open Ocean Area region of influence.

4.1.1.1.2 HRC RDT&E Activities—No-action Alternative

The ongoing RDT&E activities that could affect airspace include missile defense ballistic missile target flights and interceptor activities, A-S MISSILEX, A-A MISSILEX, S-A MISSILEX, and S-S MISSILEX. RDT&E activities are conducted in Pacific Missile Range Facility (PMRF) Warning Areas and the Temporary Operating Area (TOA), as shown on Figure 3.1.1-1. Table 2.2.2.5-1 lists the RDT&E activities that are a part of the No-action Alternative. Missile launches from PMRF and Kauai Test Facility will move into Open Ocean Areas soon after launch.

Controlled and Uncontrolled Airspace

No new airspace proposal or any modification to the existing controlled airspace has been identified to accommodate continuing training. Typically target and interceptor missiles will be above flight level (FL) 600 within minutes of the rocket motor firing. As such, all other local flight activities will occur at sufficient distance and altitude that the target missile and interceptor missiles will be little noticed. However, activation of the proposed stationary altitude reservation (ALTRV) procedures, where the FAA provides separation between non-participating aircraft and the missile flight test activities in the TOA for use of the airspace identified in Figure 3.1.1-1, will impact the controlled airspace available for use by non-participating aircraft for the duration of the ALTRV—usually for a matter of a few hours, with a backup day reserved for the same hours. The airspace in the TOA is not heavily used by commercial aircraft, and is far removed from the en route airways and jet routes crossing the North Pacific Ocean. The relatively sparse use of the area by commercial aircraft and the advance coordination with the FAA regarding ALTRV requirements results in minimal impacts on controlled and uncontrolled airspace from RDT&E activities.

Special Use Airspace

Ongoing RDT&E activities identified above will continue to utilize the existing Open Ocean Area special use airspace including PMRF Warning Areas shown on Figure 3.1.1-1.

Missile intercepts will continue to be conducted within either the existing special use airspace in Warning Area W-188 and W-186 controlled by PMRF or within the TOA shown in the inset on Figure 3.1.1-1. Similarly, intercept impact debris will be contained within these same areas. Missiles coming into the TOA from various locations can overfly the Papahānaumokuākea Marine National Monument. At this point in their flight, the boosters follow a ballistic trajectory and will not impact the monument. For select intercept missions, the potential exists for limited debris to fall into the Open Ocean Area off Necker and Nihoa in the Papahānaumokuākea Marine National Monument. Although the nature and intensity of use varies over time and by individual special use airspace area, the proposed activities do not represent a direct special use airspace impact due to the nature of the special use airspace and the planning and coordination between the Navy and the FAA, as described below.

Warning Areas consist of airspace over international waters in which hazardous activity may be conducted. The Warning Areas are designed and set aside by the FAA to accommodate activities that present a hazard to other aircraft. Similarly, the use of ALTRV procedures—as authorized by the Central Altitude Reservation Function, an air traffic service facility, or appropriate ARTCC (the Oakland ARTCC for the TOA)—for airspace use under prescribed conditions in the TOA will not impact special use airspace. According to the FAA Handbook, 7610.44, ALTRVs may encompass certain rocket and missile activities, and other special activities, as may be authorized by FAA approval procedures.

PMRF will coordinate with the Honolulu or Oakland ARTCC military operations specialist assigned to handle such matters and the airspace coordinator at the Honolulu Center Radar Approach using ALTRV request procedures. After receiving the proper information on each test flight, a hazard pattern will be constructed and superimposed on a chart depicting the area of activities. Ensuring that the hazard pattern will not encroach any land mass, this area is then plotted using minimum points (latitude-longitude) to form a rectangular area. This plotted area is then faxed to the military operations specialist at Honolulu or Oakland ARTCC requesting airspace with the following information: area point (latitude-longitude); date and time for primary and backup (month, day, year, Zulu time); and altitude. A copy is sent to the Honolulu Center Radar Approach Control. A follow-up phone call is made after 48 hours to verify receipt of the fax. When approval of the request of the airspace is received from the military operations specialist at Honolulu or Oakland ARTCC, PMRF will submit an ALTRV request to Central Altitude Reservation Function, which publishes the ALTRV 72 hours prior to the flight test. With these coordination and planning procedures in place, the RDT&E activities do not conflict with any airspace use plans, policies, and controls.

En Route Airways and Jet Routes

Two IFR en route low altitude airways are used by commercial aircraft that pass through the PMRF Warning Areas. The two low altitude airways are V15 (through W-188), and V16 (through W-186). Use of these low altitude airways comes under the control of the Honolulu ARTCC. In addition, during a training event, provision is made for surveillance of the affected airspace either by radar or patrol aircraft. Safety regulations dictate that hazardous activities will be suspended when it is known that any non-participating aircraft has entered any part of the training danger zone until the non-participating entrant has left the area or a thorough check of the suspected area has been performed. Therefore, potential impacts on civilian aircraft are avoided.

The airways and jet routes that traverse the Open Ocean Area airspace region of influence have the potential to be affected by RDT&E activities. However, target and defensive missile launches and missile intercepts will be conducted in compliance with DoD Directive 4540.1, as enclosed by OPNAVINST 3770.4A. DoD Directive 4540.1 specifies procedures for conducting missile and projectile firing, namely “firing areas shall be selected so that trajectories are clear of established oceanic air routes or areas of known surface or air activity” (DoD Directive 4540.1, § E5).

Before conducting a missile launch and/or intercept test, NOTAMs will be sent in accordance with the conditions of the directive specified in OPNAVINST 3721.20. In addition, to satisfy airspace safety requirements, the responsible commander will obtain approval from the Administrator, FAA, through the appropriate Navy airspace representative. Provision is made for surveillance of the affected airspace either by radar or patrol aircraft. In addition, safety regulations dictate that hazardous activities will be suspended when it is known that any non-participating aircraft have entered any part of the danger zone until the non-participating entrant has left the area or a thorough check of the suspected area has been performed.

In addition to the reasons cited above, there is a scheduling agency identified for each piece of special use airspace that will be used. The procedures for scheduling each piece of airspace are performed in accordance with letters of agreement with the controlling FAA facility, and the Honolulu and Oakland ARTCCs. Schedules are provided to the FAA facility as agreed among the agencies involved. Aircraft transiting the Open Ocean Area region of influence on one of the low-altitude airways and/or high-altitude jet routes that will be affected by flight test activities will be notified of any necessary rerouting before departing their originating airport and will be able to take on additional fuel before takeoff. Real-time airspace management involves the release of airspace to the FAA when the airspace is not in use or when extraordinary events occur that require drastic action, such as weather requiring additional airspace.

The FAA ARTCCs are responsible for air traffic flow control or management to transition air traffic. The ARTCCs provide separation services to aircraft operating on IFR flight plans and principally during the en route phases of the flight. They also provide traffic and weather advisories to airborne aircraft. Hazardous military activities are contained within the over-water Warning Areas or by using ALTRV procedures in the TOA to ensure non-participating traffic is advised or separated accordingly.

Continuing RDT&E activities will use the existing Open Ocean Area special use airspace and will not require either: (1) a change to an existing or planned IFR minimum flight altitude, a published or special instrument procedure, or an IFR departure procedure; or (2) a VFR operation to change from a regular flight course or altitude. Consequently, there are no airspace conflicts.

Airports and Airfields

There are no airports and airfields in the Open Ocean Area region of influence.

4.1.1.1.3 Major Exercises—No-action Alternative

Major Exercises such as Rim of the Pacific (RIMPAC) and Undersea Warfare Exercise (USWEX), include combinations of unit-level training and, in some cases, RDT&E activities that have been occurring in the HRC for decades. Therefore, potential impacts from a Major Exercise on the open ocean airspace will be similar to those described above for training and the RDT&E activities. The No-action Alternative includes one RIMPAC exercise (with a single aircraft carrier) and up to five USWEXs. RIMPAC planning conferences, which include coordination with the FAA, are conducted beginning in March of the year prior to each RIMPAC. Each of the USWEXs, up to five per year, will include coordination with the FAA well in advance of each 3- or 4-day exercise.

The advance planning and coordination with the FAA regarding ALTRV requirements for missile tests, scheduling of special use airspace, and coordination of Navy training relative to en route airways and jet routes, results in minimal impacts on airspace from Major Exercises.

4.1.1.2 ALTERNATIVE 1 (AIRSPACE—OPEN OCEAN)

4.1.1.2.1 Increased Tempo and Frequency of Training—Alternative 1

Alternative 1 would include increases in the number of training events as shown in Table 2.2.2.3.1-1. Training would occur in the same locations as identified for the No-action Alternative.

The potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields would be similar to those described in Section 4.1.1.1 for the No-action Alternative. The total number of training events that affect airspace would increase by approximately 16 percent above the No-action Alternative. No new airspace proposal or any modification to the existing controlled airspace would be required. Training would continue to utilize the existing Open Ocean Area special use airspace including the PMRF and Oahu Warning Areas and ATCAA shown on Figure 3.1.1-1. By appropriately containing hazardous military activities within the over-water Warning Areas or coordinating the use of the ATCAA areas, non-participating traffic is advised or separated accordingly. Therefore, potential impacts on all airspace users are minimized.

As noted above, continuing training will use the existing Open Ocean Area special use airspace and will not require either: (1) a change to an existing or planned IFR minimum flight altitude, a published or special instrument procedure, or an IFR departure procedure; or (2) a VFR operation to change from a regular flight course or altitude. The increase in training under Alternative 1 would require an increase in coordination and scheduling by the Navy and the FAA. The increase in training would be readily accommodated within the existing airspace. Consequently, there are no airspace conflicts.

4.1.1.2.2 Enhanced and Future RDT&E Activities—Alternative 1

The proposed activities include interceptor targets launched from Wake Island, Kwajalein Atoll, or Vandenberg AFB into the TOA; Standard Missile-6 (SM-6) launches from a sea-based platform; and high speed and unmanned aerial vehicle testing. The potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes would be similar to that described above for missile launches in Section 4.1.1.1.2. The intercept areas would be in the Open Ocean Area and TOA.

Alternative 1 would include increases in the number of RDT&E activities as shown in Table 2.2.2.5-1. RDT&E activities would occur in the same locations as for the No-action Alternative.

The potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields would be similar to that described in Section 4.1.1.1 for the No-action Alternative. The total number of RDT&E activities that may affect airspace would increase by approximately 6 percent above the No-action Alternative. No new airspace proposal or any modification to the existing controlled airspace would be required. The RDT&E activities would continue to utilize the existing Open Ocean Area special use airspace including the PMRF Warning Areas and ATCAA and TOA shown on Figure 3.1.1-1. By appropriately containing hazardous military activities within the over-water Warning Areas or coordinating the use of the ATCAA areas, or using ALTRV procedures in the TOA, non-participating traffic is advised or separated accordingly. The relatively sparse use of the area by commercial aircraft and the advance coordination with the FAA regarding ALTRV requirements results in minimal impacts on controlled and uncontrolled airspace from RDT&E activities. The small increase in RDT&E activities under Alternative 1 would require a minor increase in coordination and scheduling by the Navy and the FAA. The increased RDT&E activities would be readily accommodated within the existing airspace.

4.1.1.2.3 HRC Enhancements—Alternative 1

Range safety for high-energy lasers at PMRF could affect airspace. Depending on the intensity of the lasers, nomenclature would need to be added to aeronautical charts, and certain test events could require NOTAMs and Notices to Mariners (NOTMARs).

The potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields would be similar to that described above for missile launches. The establishment of laser range operational procedures, including horizontal and vertical buffers, would minimize potential impacts on aircraft. All activities would be in accordance with American National Standards Institute (ANSI) Z136.1, *Safe Use of Lasers*, which has been adopted by DoD as the governing standard for laser safety. Additional information on range safety for high-energy lasers is in Section 4.1.5, Health and Safety.

4.1.1.2.4 Major Exercises—Alternative 1

Major Exercises, such as RIMPAC and USWEX, include combinations of unit-level training and, in some cases, RDT&E activities that have been occurring in the HRC for decades. Therefore, potential impacts from a Major Exercise on the open ocean airspace would be similar to those described for training and the RDT&E activities under the No-action Alternative. RIMPAC planning conferences, which include coordination with the FAA, are conducted beginning in

March of the year prior to each RIMPAC. Each of the USWEXs, up to six per year, would include coordination with the FAA well in advance of each 3- or 4-day exercise.

The advance planning and coordination with the FAA regarding ALTRV requirements for missile tests, scheduling of special use airspace, and coordination of Navy training relative to en route airways and jet routes, results in minimal impacts on airspace from Major Exercises. The increase from one aircraft carrier to two during RIMPAC under Alternative 1 would require a minor increase in coordination and scheduling by the Navy and the FAA. The increased training would be readily accommodated within the existing airspace.

4.1.1.3 ALTERNATIVE 2 (AIRSPACE—OPEN OCEAN)

4.1.1.3.1 Increased Tempo and Frequency of Training—Alternative 2

Alternative 2 would include increases in the number of training events as shown on Table 2.2.2.3-1. Training would occur in the same locations as for the No-action Alternative.

The potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields would be similar to that described in Section 4.1.1.1 for the No-action Alternative. The total number of training events that affect airspace would increase by approximately 22 percent above the No-action Alternative. No new airspace proposal or any modification to the existing controlled airspace would be required. Training would continue to use the existing Open Ocean Area special use airspace including the PMRF and Oahu Warning Areas and ATCAA shown on Figure 3.1.1-1. By appropriately containing hazardous military activities within the over-water Warning Areas or coordinating the use of the ATCAA areas, non-participating traffic is advised or separated accordingly, thus avoiding adverse impacts on the low altitude airways and high-altitude jet routes in the region of influence.

Alternative 2 would also include increases in the number of RDT&E activities including missile defense ballistic missile target flights, Terminal High Altitude Area Defense (THAAD) interceptor activities, A-S MISSILEX, A-A MISSILEX, S-A MISSILEX, and S-S MISSILEX. RDT&E activities would occur in the same locations as for the No-action Alternative.

The potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields would be similar to that described in Section 4.1.1.1 for the No-action Alternative. The total number of RDT&E activities that may affect airspace would increase by approximately 16 percent above the No-action Alternative. No new airspace proposal or any modification to the existing controlled airspace would be required. The RDT&E activities would continue to use the existing Open Ocean Area special use airspace including the PMRF Warning Areas, ATCAA, and TOA shown on Figure 3.1.1-1. By appropriately containing hazardous military activities within the over-water Warning Areas or coordinating the use of the ATCAA areas, or using ALTRV procedures in the TOA, non-participating traffic would be advised or separated accordingly, thus avoiding adverse impacts on the low altitude airways and high-altitude jet routes in the region of influence. Due to the planning and coordination required for the use of special use airspace, the small increase in the tempo and frequency of training would be readily accommodated within the existing special use airspace.

As noted above, continuing training will use the existing Open Ocean Area special use airspace and will not require either: (1) a change to an existing or planned IFR minimum flight altitude, a published or special instrument procedure, or an IFR departure procedure; or (2) a VFR operation to change from a regular flight course or altitude. The increase in training under Alternative 1 would require an increase in coordination and scheduling by the Navy and the FAA. The increase in training would be readily accommodated within the existing airspace. Consequently, there are no airspace conflicts.

4.1.1.3.2 Enhanced and Future RDT&E Activities—Alternative 2

Future RDT&E activities include a Maritime Directed Energy Test Center at PMRF and the Advanced Hypersonic Weapon test program.

The Directed Energy Test Center, which may include a High-Energy Laser Program, would have minimal impacts on airspace due to the required electromagnetic radiation/electromagnetic interference (EMR/EMI) coordination process. As discussed in Section 4.1.1.2.3, high-energy lasers at PMRF could affect airspace. Depending on the intensity of the lasers, nomenclature would need to be added to aeronautical charts, and certain test events could require NOTAMs and NOTMARs. The potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields would be similar to that described earlier for missile launches. The establishment of laser range operational procedures, including horizontal and vertical buffers, would minimize potential impacts on aircraft. All activities would be in accordance with ANSI Z136.1, *Safe Use of Lasers*, which has been adopted by DoD as the governing standard for laser safety. Additional information on range safety for high-energy lasers is in Section 4.1.5, Health and Safety.

The Advanced Hypersonic Weapon tests would be similar to a ballistic missile test. Potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields would be similar to that described earlier for missile launches.

4.1.1.3.3 Additional Major Exercises—Multiple Strike Group Training—Alternative 2

In addition to RIMPAC and USWEX, Alternative 2 includes a Multiple Strike Group Exercise consisting of training that involves Navy assets engaging in a schedule of events battle scenario, with U.S. forces pitted against a notional opposition force. Participants use and build upon previously gained training skill sets to maintain and improve the proficiency needed for a mission-capable, deployment-ready unit. The exercise would occur over a 5- to 10-day period. The Multiple Strike Group training would involve many of the training events identified and evaluated under Sections 4.1.1.1 and 4.1.1.2, No-action Alternative and Alternative 1, including mine laying, S-S GUNEX, A-S GUNEX, S-S MISSILEX, A-S MISSILEX, BOMBEX, SINKEX, EER/IEER, ACM, A-A MISSILEX, ECM, S-A GUNEX, S-A MISSILEX, NSFS, Flare Exercises, and CHAFFEX.

Additional training includes Maritime Interdiction and Air Interdiction of Maritime Targets. These events would include a U.S. surface action group consisting of Navy surface combatants, Military Sea-Lift Command ships, and a Coast Guard Cutter. Opposition forces would consist of Navy frigates, cruisers, and destroyers, carrier air wing aircraft from the three Navy aircraft carriers, and Air Force fighter aircraft. All coordinated training would take place within the

PMRF and Oahu Warning Areas and other areas as required. The exercise may include Air Force aircraft that would operate from Hickam Air Force Base (AFB), and carrier air wing aircraft that would operate from their respective aircraft carriers. The aircraft would coordinate efforts with opposition force surface ships to locate, target, and simulate strikes against the U.S. surface action group.

The potential impacts on controlled and uncontrolled airspace, special use airspace, en route airways and jet routes, and airports and airfields would be similar to that described in Section 4.1.1.1 for the No-action Alternative. The additional types of training described in the previous paragraphs are similar to and would occur in the same areas as some of the training analyzed under the No-action Alternative. No new airspace proposal or any modification to the existing controlled airspace would be required. The Multiple Strike Group Exercises and training identified above would continue to use the existing Open Ocean Area special use airspace including the PMRF and Oahu Warning Areas and ATCAA shown on Figure 3.1.1-1. By appropriately containing hazardous military activities within the over-water Warning Areas or coordinating the use of the ATCAA areas, non-participating traffic would be advised or separated accordingly, thus avoiding adverse impacts on the low altitude airways and high-altitude jet routes in the region of influence.

The advance planning and coordination with the FAA regarding scheduling of special use airspace and coordination of Navy training relative to en route airways and jet routes would result in minimal impacts on airspace from a Multiple Strike Group exercise. The use of three aircraft carriers during the 10-day exercise would require an increase in coordination and scheduling by the Navy and the FAA. The increased training would be readily accommodated within the existing airspace.

4.1.1.4 ALTERNATIVE 3 (AIRSPACE—OPEN OCEAN)

The difference between Alternative 2 and Alternative 3 is the amount of mid-frequency active/high frequency active (MFA/HFA) sonar usage. Alternative 3 would include all of the training associated with Alternative 2 (as described in Sections 2.2.4.1 and 2.2.4.3 through 2.2.4.7). As described under Alternative 2, Alternative 3 would provide increased flexibility in training activities by increasing the tempo and frequency of training events (Table 2.2.2.3-1), future and enhanced RDT&E activities, and the addition of Major Exercises. Alternative 3 would consist of the MFA/HFA sonar usage as analyzed under the No-action Alternative. Effects on airspace under Alternative 3 would be the same as those described for Alternative 2.

4.1.2 BIOLOGICAL RESOURCES—OPEN OCEAN

Generally, impacts on biological resources are evaluated as potential losses to populations of species of concern or to important habitat resources. Criteria for assessing potential impacts on marine biological resources are based on the following:

- Loss of habitat (destruction, degradation, denial, competition)
- Over-harvesting or excessive take (accidental or intentional death, injury)
- Harassment

- Increases in exposure or susceptibility to disease and predation
- Decrease in breeding success

Collision with ordnance, missile debris, or vessels; release of contaminants from munitions constituents or expended range materials; sound; or human contact could potentially cause impacts. Impacts are considered substantial if they have the potential to result in reduction of population size of Federally listed threatened or endangered species, degradation of biologically important unique habitat, or reduction in capacity of a habitat to support species.

This section includes the following biological resource topics:

- Coral (Biological Resources—Open Ocean)
- Fish (Biological Resources—Open Ocean)
- Sea Turtles (Biological Resources—Open Ocean)
- Marine Mammals (Biological Resources—Open Ocean)
- Methodology for Analyzing Impacts on Marine Mammals
- Marine Mammals No-action Alternative (Biological Resources—Open Ocean)
- Marine Mammals Alternative 1 (Biological Resources—Open Ocean)
- Marine Mammals Alternative 2 (Biological Resources—Open Ocean)
- Marine Mammals Alternative 3 (Biological Resources—Open Ocean)
- Marine Mammal Mortality Request

4.1.2.1 CORAL (BIOLOGICAL RESOURCES—OPEN OCEAN)

4.1.2.1.1 No-action Alternative, Alternative 1, Alternative 2, and Alternative 3 (Coral—Biological Resources—Open Ocean)

As shown on Figure 3.1.2.1-1, deep sea coral within the Open Ocean Area is located in deep water and is limited in areal extent. The potential for impacts on these deep water corals from Navy training and RDT&E activities would be very limited. The Navy activities would not result in any direct impacts on the coral or degradation of water/sediment quality in the vicinity of the corals. The probability of intercept debris from a MISSILEX or expended materials from GUNEX, BOMBEX, EER/IEER, or SINKEX affecting any coral is extremely small. In addition, the debris and expended materials are spread out over a wide area so that even in the unlikely event the debris or expended materials lands on the coral, the pieces would be diffused and negligible. There is no deep water coral located in the area where SINKEX is typically conducted. Because the potential for impacts on deep sea coral is so remote, further discussion is unnecessary.

New proposed activities will be located in areas with no known coral concentration when possible. In areas that have not been mapped for coral presence, the Navy will develop appropriate habitat data and any necessary Best Management Practices and mitigations in coordination with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS). The Navy will continue to work with regulatory agencies throughout the planning and development process to minimize the potential for impacts on coral.

4.1.2.2 FISH (BIOLOGICAL RESOURCES—OPEN OCEAN)

In this section, the approach to the assessment of effects on fish is presented, as well as a review of the literature on potential effects common to most activities. These include noise disturbance and underwater detonations. Effects on fish and the distances at which behavioral effects can occur depend on the nature of the sound, the hearing ability of the fish, and species-specific behavioral responses to sound. Changes in fish behavior can, at times, reduce their catchability and thus affect fisheries.

There are two types of sound sources that are of major concern to fish and fisheries: (1) strong underwater shock pulses that can cause physical damage to fish, and (2) underwater sounds that could cause disturbance to fish and affect their biology or catchability by fishers. The following methods were used to assess potential effects of noise on fish. Received noise levels that correspond to the various types of effects on fish were evaluated. Effects include physical damage to fish, short-term behavioral reactions, long-term behavioral reactions, and changes in distribution.

Effects of Human-Generated Sound on Fish

There have been very few studies on the effects that human-generated sound may have on fish. These have been reviewed in a number of places (e.g., National Research Council 1994, 2003, Popper 2003, Popper et al. 2004, Hastings and Popper 2005), and some more recent experimental studies have provided additional insight into the issues (e.g., Govoni et al. 2003, McCauley et al. 2003, Popper et al. 2005, 2007, Song et al., 2005). Most investigations, however, have been in the gray literature (non peer-reviewed reports – see Hastings and Popper, 2005 for an extensive critical review of this material). While some of these studies provide insight into effects of sound on fish, as mentioned earlier, the majority of the gray literature studies often lack appropriate controls, statistical rigor, and/or expert analysis of the results.

There are a wide range of potential effects on fish that range from no effect at all (e.g., the fish does not detect the sound or it "ignores" the sound) to immediate mortality. In between these extremes are a range of potential effects that parallel the potential effects on fish that were illustrated by Richardson et al. (1995a). These include, but may not be limited to:

- No effect behaviorally or physiologically: The animal may not detect the signal, or the signal is not one that would elicit any response from the fish.
- Small and inconsequential behavioral effects: Fish may show a temporary "awareness" of the presence of the sound but soon return to normal activities.
- Behavioral changes that result in the fish moving from its current site: This may involve leaving a feeding or breeding ground. This effect may be temporary, in that the fish return to the site after some period of time (perhaps after a period of acclimation or when the sound terminates), or permanent.
- Temporary loss of hearing (often called Temporary Threshold Shift – TTS): This recovers over minutes, hours, or days.
- Physical damage to auditory or non-auditory tissues (e.g., swim bladder, blood vessels, brain): The damage may be only temporary, and the tissue "heals" with little impact on

fish survival, or it may be more long-term, permanent, or may result in death. Death from physical damage could be a direct effect of the tissue damage or the result of the fish being more subject to predation than a healthy individual.

Studies on effects on hearing have generally been of two types. In one set of studies, the investigators exposed fish to long-term increases in background noise to determine if there are changes in hearing, growth, or survival of the fish. Such studies were directed at developing some understanding of how fish might be affected if they lived in an area with constant and increasing shipping or in the presence of a wind farm, or in areas where there are long-term acoustic tests. Other similar environments might be aquaculture facilities or large marine aquaria. In most of these studies examining long-term exposure, the sound intensity was well below any that might be expected to have immediate damage to fish (e.g., damage tissues such as the swim bladder or blood vessels).

In the second type of studies, fish were exposed to short-duration but high-intensity signals such as might be found near a high-intensity sonar, pile driving, or seismic airgun survey. The investigators in such studies were examining whether there was not only hearing loss and other long-term effects, but also short-term effects that could result in death to the exposed fish.

Effects of Long-Duration Increases in Background Sounds on Fish

Effects of long-duration relatively low intensity sounds (e.g., below 170–180 decibels (dB) re 1 micropascal (μPa) received level ([RL]) indicate that there is little or no effect of long-term exposure on hearing generalists (e.g., Scholik and Yan, 2001, Amoser and Ladich, 2003, Smith et al., 2004a,b, Wysocki et al., 2007). The longest of these studies exposed young rainbow trout (*Oncorhynchus mykiss*) to a level of noise equivalent to one that fish would experience in an aquaculture facility (e.g., on the order of 150 dB re 1 μPa RL) for about 9 months. The investigators found no effect on hearing or on any other measures including growth and effects on the immune system as compared to fish raised at 110 dB re 1 μPa RL. The sound level used in the study would be equivalent to ambient sound in the same environment without the presence of pumps and other noise sources of an aquaculture facility (Wysocki et al., 2007).

Studies on hearing specialists have shown that there is some hearing loss after several days or weeks of exposure to increased background sounds, although the hearing loss seems to recover (e.g., Scholik and Yan, 2002; Smith et al., 2004b, 2006). Smith et al. (2004a, 2006) investigated the goldfish (*Carassius auratus*). They exposed fish to noise at 170 dB re 1 μPa and there was a clear relationship between the level of the exposure sound and the amount of hearing loss. There was also a direct correlation of level of hearing loss and the duration of exposure, up to 24-hours, after which time the maximum hearing loss was found.

Similarly, Wysocki and Ladich (2005) investigated the influence of noise exposure on the auditory sensitivity of two freshwater hearing specialists, the goldfish and the lined Raphael catfish (*Platydoras costatus*), and on a freshwater hearing generalist, a sunfish (*Lepomis gibbosus*). Baseline thresholds showed greatest hearing sensitivity around 0.5 kilohertz (kHz) in the goldfish and catfish and at 0.1 kHz in the sunfish. For the hearing specialists (goldfish and catfish), continuous white noise of 130 dB re 1 μPa RL resulted in a significant threshold shift of 23 to 44 dB. In contrast, the auditory thresholds in the hearing generalist (sunfish) declined by 7 to 11 dB.

In summary, and while data are limited to a few freshwater species, it appears that some increase in ambient noise level, even to above 170 dB re 1 μPa does not permanently alter the hearing ability of the hearing generalist species studied, even if the increase in sound level is for an extended period of time. However, this may not be the case for all hearing generalists, though it is likely that any temporary hearing loss in such species would be considerably less than for specialists receiving the same noise exposure. But, it is critical to note that more extensive data are needed on additional species, and if there are places where the ambient levels exceed 170–180 dB, it would be important to do a quantitative study of effects of long-term sound exposure at these levels.

It is also clear that there is a larger temporary hearing loss in hearing specialists. Again, however, extrapolation from the few freshwater species to other species (freshwater or marine) must be done with caution until there are data for a wider range of species, and especially species with other types of hearing specializations than those found in the species studied to date (all of which are otophysan fishes and have the same specializations to enhance hearing).

Effects of High Intensity Sounds on Fish

There is a small group of studies that discusses effects of high intensity sound on fish. However, as discussed in Hastings and Popper (2005), much of this literature has not been peer reviewed, and there are substantial issues with regard to the actual effects of these sounds on fish. More recently, however, there have been two studies of the effects of high intensity sound on fish that, using experimental approaches, provided insight into overall effects of these sounds on hearing and on auditory and non-auditory tissues. One study tested effects of seismic airguns, a highly impulsive and intense sound source, while the other study examined the effects of Surveillance Towed Array Sensor System Low-Frequency Active (SURTASS LFA) sonar. Since these studies are the first that examined effects on hearing and physiology, they will be discussed in some detail. These studies not only provide important data, but also suggest ways in which future experiments need to be conducted. This discussion will be followed by a brief overview of other studies that have been done, some of which may provide a small degree of insight into potential effects of human-generated sound on fish.

Effects of Seismic Airguns on Fish

Popper et al. (2005; Song et al., 2006) examined the effects of exposure to a seismic airgun array on three species of fish found in the Mackenzie River Delta near Inuvik, Northwest Territories, Canada. The species included a hearing specialist, the lake chub (*Couesius plumbeus*), and two hearing generalists, the northern pike (*Esox lucius*), and the broad whitefish (*Coregonus nasus*) (a salmonid). In this study, fish in cages were exposed to 5 or 20 shots from a 730 in^3 (12,000 cc) calibrated airgun array. And, unlike earlier studies, the received exposure levels were not only determined for root-mean-square (rms) sound pressure level (SPL), but also for peak sound levels and for sound equivalent levels (SELs) (e.g., average mean peak SPL 207 dB re 1 μPa RL; mean rms sound level 197 dB re 1 μPa RL; mean SEL 177 dB re 1 $\mu Pa^2 s$).

The results showed a temporary hearing loss for both lake chub and northern pike, but not for the broad whitefish, to both 5 and 20 airgun shots. Hearing loss was on the order of 20 to 25 dB at some frequencies for both the northern pike and lake chub, and full recovery of hearing took place within 18 hours after sound exposure. While a full pathological study was not conducted, fish of all three species survived the sound exposure and were alive more than 24 hours after exposure. Those fish of all three species had intact swim bladders and there was no apparent external or internal damage to other body tissues (e.g., no bleeding or grossly damaged tissues), although it is important to note that the observer in this case (unlike in the following LFA study) was not a trained pathologist. Recent examination of the ear tissues by an expert pathologist showed no damage to sensory hair cells in any of the fish exposed to sound (Song et al., 2006).

A critical result of this study was that it demonstrated differences in the effects of airguns on the hearing thresholds of different species. In effect, these results substantiate the argument made by Hastings et al. (1996) and McCauley et al. (2003) that it is difficult to extrapolate between species with regard to the effects of intense sounds.

Experiments conducted by Skalski et al. (1992), Dalen and Raknes (1985), Dalen and Knutsen (1986), and Engas et al. (1996) demonstrated that some fish were forced to the bottom and others driven from the area in response to low-frequency airgun noise. The authors speculated that catch per unit effort would return to normal quickly in their experimental area because behavior of the fish returned to normal minutes after the sounds ceased.

Effects of SURTASS LFA Sonar on Fish

Popper et al. (2007) studied the effect of SURTASS LFA on hearing, the structure of the ear, and select non-auditory systems in the rainbow trout (*Oncorhynchus mykiss*) and channel catfish (*Ictalurus punctatus*) (also Halvorsen et al., 2006).

The SURTASS LFA sonar study was conducted in an acoustic free-field environment that enabled the investigators to have a calibrated sound source and to monitor the sound field throughout the experiments. In brief, experimental fish were placed in a test tank, lowered to depth, and exposed to LFA sonar for 324 or 648 seconds, an exposure duration that is far greater than any fish in the wild would get since, in the wild, the sound source is on a vessel moving past the far slower swimming fish. For a single tone, the maximum RL was approximately 193 dB re 1 μPa at 196 Hz and the level was uniform within the test tank to within approximately ±3 dB. The signals were produced by a single SURTASS LFA sonar transmitter giving an approximate source level of 215 dB. Following exposure, hearing was measured in the test animals. Animals were also sacrificed for examination of auditory and non-auditory tissues to determine any non-hearing effects. All results from experimental animals were compared to results obtained from baseline control and control animals.

A number of results came from this study. Most importantly, no fish died as a result of exposure to the experimental source signals. Fish all appeared healthy and active until they were sacrificed or returned to the fish farm from which they were purchased. In addition, the study employed the expertise of an expert fish pathologist who used double-blind methods to analyze the tissues of the fish exposed to the sonar source, and compared these to control animals. The results clearly showed that there were no pathological effects from sound exposure including no effects on all major body tissues (brain, swim bladder, heart, liver, gonads, blood, etc.). There was no damage to the swim bladder and no bleeding as a result of LFA sonar exposure. Furthermore, there were no short- or long-term effects on ear tissue (Popper et al., 2007, also Kane et al., in preparation).

Moreover, behavior of caged fish after sound exposure was no different than that prior to tests. It is critical to note, however, that behavior of fish in a cage in no way suggests anything about how fish would respond to a comparable signal in the wild. Just as the behavior of humans exposed to a noxious stimulus might show different behavior if in a closed room as compared to being out-of-doors, it is likely that the behaviors shown by fish to stimuli will also differ, depending upon their environment.

The study also incorporated effects of sound exposure on hearing both immediately post exposure and for several days thereafter to determine if there were any long-term effects, or if hearing loss showed up at some point post exposure. Catfish and some specimens of rainbow trout showed 10-20 dB of hearing loss immediately after exposure to the LFA sonar when compared to baseline and control animals; however, another group of rainbow trout showed no hearing loss. Recovery in trout took at least 48 hours, but studies could not be completed. The different results between rainbow trout groups is difficult to understand, but may be due to developmental or genetic differences in the various groups of fish. Catfish hearing returned to, or close to, normal within about 24 hours.

Additional Sonar Data

While there are no other data on the effects of sonar on fish, there are two recent unpublished reports of some relevance since it examined the effects on fish of a mid-frequency sonar (1.5 to 6.5 kHz) on larval and juvenile fish of several species (Jørgensen et al., 2005, Kvadsheim and Sevaldsen, 2005). In this study, larval and juvenile fish were exposed to simulated sonar signals in order to investigate potential effects on survival, development, and behavior. The study used herring (*Clupea harengus*) (standard lengths 2 to 5 centimeters [cm]), Atlantic cod (*Gadus morhua*) (standard length 2 and 6 cm), saithe (*Pollachius virens*) (4 cm), and spotted wolffish (*Anarhichas minor*) (4 cm) at different developmental stages.

Fish were placed in plastic bags 3 m from the sonar source and exposed to between four and 100 pulses of 1-second duration of pure tones at 1.5, 4 and 6.5 kHz. Sound levels at the location of the fish ranged from 150 to 189 dB. There were no effects on fish behavior during or after exposure to sound (other than some startle or panic movements by herring for sounds at 1.5 kHz) and there were no effects on behavior, growth (length and weight), or survival of fish kept as long as 34 days post exposure. All exposed animals were compared to controls that received similar treatment except for actual exposure to the sound. Excellent pathology of internal organs showed no damage as a result of sound exposure. The only exception to almost full survival was exposure of two groups of herring tested with SPLs of 189 dB, where there was a post-exposure mortality of 20 to 30 percent. While these were statistically significant losses, it is important to note that this sound level was only tested once and so it is not known if this increased mortality was due to the level of the test signal or to other unknown factors.

In a follow-up unpublished analysis of these data, Kvadsheim and Sevaldsen (2005) sought to understand whether the mid-frequency continuous wave (CW) signals used by Jørgensen et al. (2005) would have a significant impact on larvae and juveniles in the wild exposed to this sonar. The investigators concluded that the extent of damage/death induced by the sonar would be below the level of loss of larval and juvenile fish from natural causes, and so no concerns should be raised. The only issue they did suggest needs to be considered is when the CW signal is at the resonance frequency of the swim bladders of small clupeids. If this is the case, the investigators predict (based on minimal data that is in need of replication) that such sounds might increase the mortality of small clupeids that have swim bladders that would resonate.

Other High Intensity Sources

A number of other sources have been examined for potential effects on fish. These have been critically and thoroughly reviewed recently by Hastings and Popper (2005) and so only brief mention will be made of a number of such studies.

One of the sources of most concern is pile driving, as occurs during the building of bridges, piers, off-shore wind farms, and the like. There have been a number of studies that suggest that the sounds from pile driving, and particularly from driving of larger piles, kill fish that are very close to the source. The source levels in such cases often exceed 230 dB re 1 μPa (peak) and there is some evidence of tissue damage accompanying exposure (e.g., Caltrans 2001, 2004, reviewed in Hastings and Popper 2005). However, there is reason for concern in analysis of such data since, in many cases, the only dead fish that were observed were those that came to the surface. It is not clear whether fish that did not come to the surface survived the exposure to the sounds, or died and were carried away by currents.

There are also a number of gray literature experimental studies that placed fish in cages at different distances from the pile driving operations and attempted to measure mortality and tissue damage as a result of sound exposure. However, in most cases the studies' (e.g., Caltrans 2001, 2004, Abbott et al. 2002, 2005, Nedwell et al. 2003) work was done with few or no controls, and the behavioral and histopathological observations done very crudely (the exception being Abbott et al. 2005). As a consequence of these limited and unpublished data, it is not possible to know the real effects of pile driving on fish.

In a widely cited unpublished report, Turnpenny et al. (1994) examined the behavior of three species of fish in a pool in response to different sounds. While this report has been cited repeatedly as being the basis for concern about the effects of human-generated sound on fish, there are substantial issues with the work that make the results unusable for helping understand the potential effects of any sound on fish, including mid- and high-frequency sounds. The problem with this study is that there was a complete lack of calibration of the sound field at different frequencies and depths in the test tank, as discussed in detail in Hastings and Popper (2005). The issue is that in enclosed chambers that have an interface with air, such as tanks and pools used by Turnpenny et al., the sound field is known to be very complex and will change significantly with frequency and depth. Thus, it is impossible to know the stimulus that was actually received by the fish. Moreover, the work done by Turnpenny et al. was not replicated by the investigators even within the study, and so it is not known if the results were artifact, or were a consequence of some uncalibrated aspects of the sound field that cannot be related, in any way, to human-generated high intensity sounds in the field, at any frequency range.

Several additional studies have examined effects of high intensity sounds on the ear. While there was no effect on ear tissue in either the SURTASS LFA study (Popper et al., 2007) or the study of effects of seismic airguns on hearing (Popper et al., 2005, Song et al., 2006), three earlier studies suggested that there may be some loss of sensory hair cells due to high intensity sources. However, none of these studies concurrently investigated effects on hearing or non-auditory tissues. Enger (1981) showed some loss of sensory cells after exposure to pure tones in the Atlantic cod. A similar result was shown for the lagena of the oscar (*Astronotus oscellatus*), a cichlid fish, after an hour of continuous exposure (Hastings et al., 1996). In neither study was the hair cell loss more than a relatively small percent of the total sensory hair cells in the hearing organs.

Most recently, McCauley et al. (2003) showed loss of a small percent of sensory hair cells in the saccule (the only end organ studied) of the pink snapper (*Pagrus auratus*), and this loss continued to increase (but never to become a major proportion of sensory cells) for up to at least 53 days post exposure. It is not known if this hair cell loss, or the ones in the Atlantic cod or oscar, would result in hearing loss since fish have tens or even hundreds of thousands of sensory hair cells in each otolithic organ (Popper and Hoxter, 1984, Lombarte and Popper, 1994) and only a small portion were affected by the sound. The question remains as to why McCauley et al. (2003) found damage to sensory hair cells while Popper et al. (2005) did not. The problem is that there are so many differences in the studies, including species, precise sound source, spectrum of the sound (the Popper et al. 2005 study was in relatively shallow water with poor low-frequency propagation), that it is hard to even speculate.

Beyond these studies, there have also been questions raised as to the effects of other sound sources such as shipping, wind farm operations, and the like. However, there are limited or no data on actual effects of the sounds produced by these sources on any aspect of fish biology.

Intraspecific Variation in Effects

One unexpected finding in several of the recent studies is that there appears to be variation in the effects of sound, and on hearing, that may be a correlated with environment, developmental history, or even genetics.

During the aforementioned LFA sonar study on rainbow trout, Popper et al. (2007) found that some fish showed a hearing loss, but other animals, obtained a year later but from the same supplier and handled precisely as the fish used in the earlier part of the study, showed no hearing loss. The conclusion reached by Popper et al. (2007) was that the differences in responses may have been related to differences in genetic stock or some aspect of early development in the two groups of fish studied.

The idea of a developmental effect was strengthened by findings of Wysocki et al. (2007) who found differences in hearing sensitivity of rainbow trout that were from the same genetic stock, but that were treated slightly differently in the egg stage. This is further supported by studies on hatchery-reared Chinook salmon (*Oncorhynchus tshawytscha*) which showed that some animals from the same stock and age class had statistical differences in their hearing capabilities that were statistically correlated with differences in otolith structure (Oxman et al., 2007). While a clear correlation could not be made between these differences in otolith structure and specific factors, there is strong reason to believe that the differences resulted from environmental effects during development.

The conclusion one must reach from these findings is that there is not only variation in effects of intense sound sources on different species, but that there may also be differences based on genetics or development. Indeed, one can go even further and suggest that there may ultimately be differences in effects of sound on fish (or lack of effects) that are related to fish age as well as development and genetics since it was shown by Popper et al. (2005) that identical seismic airgun exposures had very different effects on hearing in young-of-the-year northern pike and sexually mature animals.

Effects of Anthropogenic Sound on Behavior

There have been very few studies of the effects of anthropogenic sounds on the behavior of wild (unrestrained) fishes. This includes not only immediate effects on fish that are close to the source but also effects on fish that are further from the source.

Several studies have demonstrated that human-generated sounds may affect the behavior of at least a few species of fish. Engås et al. (1996) and Engås and Løkkeborg (2002) examined movement of fish during and after a seismic airgun study although they were not able to actually observe the behavior of fish per se. Instead, they measured catch rate of haddock and Atlantic cod as an indicator of fish behavior. These investigators found that there was a significant decline in catch rate of haddock (*Melanogrammus aeglefinus*) and Atlantic cod (*Gadus morhua*) that lasted for several days after termination of airgun use. Catch rate subsequently returned to normal. The conclusion reached by the investigators was that the decline in catch rate resulted from the fish moving away from the fishing site as a result of the airgun sounds. However, the investigators did not actually observe behavior, and it is possible that the fish just changed depth. Another alternative explanation is that the airguns actually killed the fish in the area, and the return to normal catch rate occurred because of other fish entering the fishing areas.

More recent work from the same group (Slotte et al., 2004) showed parallel results for several additional pelagic species including blue whiting and Norwegian spring spawning herring. However, unlike earlier studies from this group, Slotte et al. used fishing sonar to observe behavior of the local fish schools. They reported that fishes in the area of the airguns appeared to go to greater depths after the airgun exposure compared to their vertical position prior to the airgun usage. Moreover, the abundance of animals 30-50 km away from the ensonification increased, suggesting that migrating fish would not enter the zone of seismic activity. It should be pointed out that the results of these studies have been refuted by Gausland (2003) who, in a non peer-reviewed study, suggested that catch decline was from factors other than exposure to airguns and that the data were not statistically different than the normal variation in catch rates over several seasons.

Similarly Skalski et al. (1992) showed a 52 percent decrease in rockfish (*Sebastes* sp.) catch when the area of catch was exposed to a single airgun emission at 186-191 dB re 1 µPa (mean peak level) (see also Pearson et al., 1987, 1992). They also demonstrated that fishes would show a startle response to sounds as low as 160 dB, but this level of sound did not appear to elicit decline in catch.

Wardle et al. (2001) used a video system to examine the behaviors of fish and invertebrates on a coral reef in response to emissions from seismic airguns that were carefully calibrated and measured to have a peak level of 210 dB re 1 µPa at 16 m from the source and 195 dB re 1 µPa at 109 m from the source. They found no substantial or permanent changes in the behavior of the fish or invertebrates on the reef throughout the course of the study, and no animals appeared to leave the reef. There was no indication of any observed damage to the animals.

Culik et al. (2001) and Gearin et al. (2000) studied how noise may affect fish behavior by looking at the effects of mid-frequency sound produced by acoustic devices designed to deter marine mammals from gillnet fisheries. Gearin et al. (2000) studied responses of adult sockeye salmon (*Oncorhynchus nerka*) and sturgeon (*Acipenser* sp.) to pinger sounds. They found that fish did not exhibit any reaction or behavior change to the onset of the sounds of pingers that produced broadband energy with peaks at 2 kHz or 20 kHz. This demonstrated that the alarm was either inaudible to the salmon and sturgeon, or that neither species was disturbed by the mid-frequency sound (Gearin et al., 2000). Based on hearing threshold data (Table 3.1.2.2.3.2-1), it is highly likely that the salmonids did not hear the sounds.

Culik et al. (2001) did a very limited number of experiments to determine catch rate of herring (*Clupea harengus*) in the presence of pingers producing sounds that overlapped the frequency range of hearing of herring (2.7 kHz to over 160 kHz). They found no change in catch rate in gill nets with or without the higher frequency (> 20 kHz) sounds present, although there was an increase in catch rate with the signals from 2.7 kHz to 19 kHz (a different source than the higher frequency source). The results could mean that the fish did not “pay attention” to the higher frequency sound or that they did not hear it, but that lower frequency sounds may be attractive to fish. At the same time, it should be noted that there were no behavioral observations on the fish, and so how the fish actually responded when they detected the sound is not known.

The low-frequency (<2 kHz) sounds of large vessels or accelerating small vessels usually caused an initial avoidance response among the herring. The startle response was observed occasionally. Avoidance ended within 10 seconds of the “departure” of the vessel. After the initial response, 25 percent of the fish groups habituated to the sound of the large vessel and 75 percent of the responsive fish groups habituated to the sound of the small boat. Chapman and Hawkins (1969) also noted that fish adjust rapidly to high underwater sound levels, and Schwartz and Greer (1984) found no reactions to an echosounder and playbacks of sonar signals which were much higher than that of the MFA in the Proposed Action.

Masking

Any sound detectable by a fish can have an impact on behavior by preventing the fish from hearing biologically important sounds including those produced by prey or predators (Myrberg 1980, Popper et al. 2003). This inability to perceive biologically relevant sounds as a result of the presence of other sounds is called masking. Masking may take place whenever the received level of a signal heard by an animal exceeds ambient noise levels or the hearing threshold of the animal. Masking is found among all vertebrate groups, and the auditory system in all vertebrates, including fishes, is capable of limiting the effects of masking signals, especially when they are in a different frequency range than the signal of biological relevance (Fay, 1988, Fay and Megela-Simmons 1999).

One of the problems with existing fish masking data is that the bulk of the studies have been done with goldfish, a freshwater hearing specialist. The data on other species are much less extensive. As a result, less is known about masking in non-specialist and marine species. Tavolga (1974a, b) studied the effects of noise on pure-tone detection in two non-specialists and found that the masking effect was generally a linear function of masking level, independent of frequency. In addition, Buerkle (1968, 1969) studied five frequency bandwidths for Atlantic cod in the 20 to 340 Hz region and showed masking in all hearing ranges. Chapman and Hawkins (1973) found that ambient noise at higher sea states in the ocean have masking effects in cod, haddock, and Pollock, and similar results were suggested for several sciaenid species by Ramcharitar and Popper (2004). Thus, based on limited data, it appears that for fish, as for mammals, masking may be most problematic in the frequency region of the signal of the masker. Thus, for mid-frequency sonars, which are well outside the range of hearing of most all fish species, there is little likelihood of masking taking place for biologically relevant signals to fish since the fish will not hear the masker.

There have been a few field studies which may suggest that masking could have an impact on wild fish. Gannon et al. (2005) showed that bottlenose dolphins (*Tursiops truncatus*) move toward acoustic playbacks of the vocalization of Gulf toadfish (*Opsanus beta*). Bottlenose dolphins employ a variety of vocalizations during social communication including low-frequency pops. Toadfish may be able to best detect the low-frequency pops since their hearing is best below 1 kHz, and there is some indication that toadfish have reduced levels of calling when bottlenose dolphins approach (Remage-Healey et al. 2006). Silver perch have also been shown to decrease calls when exposed to playbacks of dolphin whistles mixed with other biological sounds (Luczkovich et al. 2000). Results of the Luczkovich et al. (2000) study, however, must be viewed with caution because it is not clear what sound may have elicited the silver perch response (Ramcharitar et al. 2006a).

Of considerable concern is that human-generated sounds could mask the ability of fish to use communication sounds, especially when the fish are communicating over some distance. In effect, the masking sound may limit the distance over which fish can communicate, thereby having an impact on important components of the behavior of fish. For example, the sciaenids, which are primarily inshore species, are probably the most active sound producers among fish, and the sounds produced by males are used to “call” females to breeding sights (Ramcharitar et al. 2001; reviewed in Ramcharitar et al. 2006a). If the females are not able to hear the reproductive sounds of the males, this could have a significant impact on the reproductive success of a population of sciaenids.

Also potentially vulnerable to masking is navigation by larval fish, although the data to support such an idea are still exceedingly limited. There is indication that larvae of some species may have the potential to navigate to juvenile and adult habitat by listening for sounds emitted from a reef (either due to animal sounds or non-biological sources such as surf action) (e.g., Higgs 2005). In a study of an Australian reef system, the sound signature emitted from fish choruses was between 0.8 and 1.6 kHz (Cato 1978) and could be detected by hydrophones 5 to 8 km (3 to 4 NM) from the reef (McCauley and Cato 2000). This bandwidth is within the detectable bandwidth of adults and larvae of the few species of reef fish that have been studied (Kenyon 1996, Myrberg 1980). At the same time, it has not been demonstrated conclusively that sound, or sound alone, is an attractant of larval fish to a reef, and the number of species tested has been very limited. Moreover, there is also evidence that larval fish may be using other kinds of sensory cues, such as chemical signals, instead of, or alongside of, sound (e.g., Atema et al. 2002, Higgs et al. 2005).

Finally, it should be noted that even if a masker prevents a larval (or any) fish from hearing biologically relevant sounds for a short period of time (e.g., while a sonar-emitting ship is passing), this may have no biological effect on the fish since they would be able to detect the relevant sounds before and after the masking, and thus would likely be able to find the source of the sounds.

Stress

Although an increase in background sound may cause stress in humans, there have been few studies on fish (e.g., Smith et al. 2004a, Remage-Healey et al. 2006, Wysocki et al. 2006, 2007). There is some indication of physiological effects on fish such as a change in hormone levels and altered behavior in some (Pickering 1981, Smith et al. 2004a, b), but not all, species tested to date (e.g., Wysocki et al. 2007). Sverdrup et al. (1994) found that Atlantic salmon subjected to up to 10 explosions to simulate seismic blasts released primary stress hormones, adrenaline and cortisol, as a biochemical response. There was no mortality. All experimental subjects returned to their normal physiological levels within 72 hours of exposure. Since stress affects human health, it seems reasonable that stress from loud sound may impact fish health, but available information is too limited to adequately address the issue.

Eggs and Larvae

One additional area of concern is whether high intensity sounds may have an impact on eggs and larvae of fish. Eggs and larvae do not move very much and so must be considered as a stationary object with regard to a moving navy sound source. Thus, the time for impact of sound is relatively small since there is no movement relative to the Navy vessel.

There have been few studies on effects of sound on eggs and larvae (reviewed extensively in Hastings and Popper 2005) and there are no definitive conclusions to be reached. At the same time, many of the studies have used non-acoustic mechanical signals such as dropping the eggs and larvae or subjecting them to explosions (e.g., Jensen and Alderice 1983, 1989, Dwyer et al. 1993). Other studies have placed the eggs and/or larvae in very small chambers (e.g., Banner and Hyatt 1973) where the acoustics are not suitable for comparison with what might happen in a free sound field (and even in the small chambers, results are highly equivocal).

Several studies did examine effects of sounds on fish eggs and larvae. One non peer-reviewed study using sounds from 115-140 dB (re 1 µPa, peak) on eggs and embryos in Lake Pend Oreille (Idaho) reported normal survival or hatching, but few data were provided to evaluate the results (Bennett et al., 1994). In another study, Kostyuchenko (1973) reported damage to eggs of several marine species at up to 20 m from a source designed to mimic seismic airguns, but few data were given as to effects. Similarly, Booman et al. (1996) investigated the effects of seismic airguns on eggs, larvae, and fry and found significant mortality in several different marine species (Atlantic cod, saithe, herring) at a variety of ages, but only when the specimens were within about 5 m of the source. The most substantial effects were to fish that were within 1.4 m of the source. While the authors suggested damage to some cells such as those of the lateral line, few data were reported and the study is in need of replication. Moreover, it should be noted that the eggs and larvae were very close to the airgun array, and at such close distances the particle velocity of the signal would be exceedingly large. However, the received sound pressure and particle velocity were not measured in this study.

Conclusions - Effects

The data obtained to date on effects of sound on fish are very limited both in terms of number of well-controlled studies and in number of species tested. Moreover, there are significant limits in the range of data available for any particular type of sound source. And finally, most of the data currently available has little to do with actual behavior of fish in response to sound in their normal environment. There is also almost nothing known about stress effects of any kind(s) of sound on fish.

Mortality and Damage to Non-auditory Tissues

The results to date show only the most limited mortality, and then only when fish are very close to an intense sound source. Thus, whereas there is evidence that fish within a few meters of a pile driving operation will potentially be killed, very limited data (and data from poorly designed experiments) suggest that fish further from the source are not killed, and may not be harmed. It should be noted, however, that these and other studies showing mortality (to any sound source) need to be extended and replicated in order to understand the effects of the most intense sound on fish.

It is also becoming a bit clearer (again, albeit from very few studies) that those species of fish tested at a distance from the source where the sound level is below source level, show no mortality and possibly no long-term effects. Of course, it is recognized that it is very difficult to extrapolate from the data available (e.g., Popper et al. 2005, 2007) since only a few sound types have been tested, and even within a single sound type there have to be questions about effects of multiple exposures and duration of exposure. Still, the results to date are of considerable interest and importance, and clearly show that exposure to many types of loud sounds may have little or no affect on fish. And, if one considers that the vast majority of fish exposed to a loud sound are probably some distance from a source, where the sound level has attenuated considerably, one can start to predict that only a very small number of animals in a large population will ever be killed or damaged by sounds.

Effects on Fish Behavior

The more critical issue, however, is the effect of human-generated sound on the behavior of wild animals, and whether exposure to the sounds will alter the behavior of fish in a manner that will affect its way of living – such as where it tries to find food or how well it can find a mate. With the exception of just a few field studies, there are no data on behavioral effects, and most of these studies are very limited in scope and all are related to seismic airguns. Because of the limited ways in which behavior of fish in these studies were “observed” (often by doing catch rates, which tell nothing about how fish really react to a sound), there really are no data on the most critical questions regarding behavior.

Indeed, the fundamental questions are how fish behave during and after exposure to a sound as compared to their “normal” pre-exposure behavior. This requires observations of a large number of animals over a large area for a considerable period of time before and after exposure to sound sources, as well as during exposure. Only with such data is it possible to tell how sounds affect overall behavior (including movement) of animals.

Increased Background Sound

In addition to questions about how fish movements change in response to sounds, there are also questions as to whether any increase in background sound has an effect on more subtle aspects of behavior, such as the ability of a fish to hear a potential mate or predator, or to glean information about its general environment. There is a body of literature that shows that the sound detection ability of fish can be “masked” by the presence of other sounds within the range of hearing of the fish. Just as a human has trouble hearing another person as the room they are in gets noisier, it is likely that the same effect occurs for fish (as well as all other animals). In effect, acoustic communication and orientation of fish may potentially be restricted by noise regimes in their environment that are within the hearing range of the fish.

While it is possible to suggest behavioral effects on fish, there have been few laboratory, and no field, studies to show the nature of any effects of increased background noise on fish behavior. At the same time, it is clear from the literature on masking in fish, as for other vertebrates, that the major effect on hearing is when the added sound is within the hearing range of the animal. Moreover, the bulk of the masking effect is at frequencies around that of the masker. Thus, a 2 kHz masker will only mask detection of sounds around 2 kHz, and a 500 Hz masker will primarily impact hearing in a band around 500 Hz.

As a consequence, if there is a background sound of 2 kHz, as might be expected from some mid-frequency sonars, and the fish in question does not hear at that frequency, there will be no masking, and no affect on any kind of behavior. Moreover, since the bulk of fish communication sounds are well below 1 kHz (e.g., Zelick et al. 1999), even if a fish is exposed to a 2 kHz masker which affects hearing at around 2 kHz, detection of biologically relevant sounds (e.g., of mates) will not be masked.

Indeed, many of the human-generated sounds in the marine environment are outside the detection range of most species of marine fish studied to date (see Figure 3.1.2.2.3.1-1 and Table 3.1.2.2.3.2-1). In particular, it appears that the majority of marine species have hearing ranges that are well below the frequencies of the mid- and high-frequency range of the operational sonars used in Navy exercises, and therefore, the sound sources do not have the potential to mask key environmental sounds. The few fish species that have been shown to be able to detect mid- and high-frequencies, such as the clupeids (herrings, shads, and relatives), do not have their best sensitivities in the range of the operational sonars. Additionally, vocal marine fish largely communicate below the range of mid- and high-frequency levels used in Navy exercises.

Implications of Temporary Hearing Loss (TTS)

Another related issue is the impact of temporary hearing loss, referred to as temporary threshold shift (TTS), on fish. This effect has been demonstrated in several fish species where investigators used exposure to either long-term increased background levels (e.g., Smith et al. 2004a) or intense, but short-term, sounds (e.g., Popper et al. 2005), as discussed above. At the same time, there is no evidence of permanent hearing loss (e.g., deafness), often referred to in the mammalian literature as permanent threshold shift (PTS), in fish. Indeed, unlike in mammals where deafness often occurs as a result of the death and thus permanent loss of sensory hair cells, sensory hair cells of the ear in fish are replaced after they are damaged or killed (Lombarte et al., 1993, Smith et al., 2006). As a consequence, any hearing loss in fish may be as temporary as the time course needed to repair or replace the sensory cells that were damaged or destroyed (e.g., Smith et al., 2006).

TTS in fish, as in mammals, is defined as a recoverable hearing loss. Generally there is recovery to normal hearing levels, but the time-course for recovery depends on the intensity and duration of the TTS-evoking signal. There are no data that allows one to “model” expected TTS in fish for different signals, and developing such a model will require far more data than currently available. Moreover, the data would have to be from a large number of fish species since there is so much variability in hearing capabilities and in auditory structure.

A fundamentally critical question regarding TTS is how much the temporary loss of hearing would impact survival of fish. During a period of hearing loss, fish will potentially be less sensitive to sounds produced by predators or prey, or to other acoustic information about their environment. The question then becomes how much TTS is behaviorally significant for survival. However, there have yet to be any studies that examine this issue.

At the same time, the majority of marine fish species are hearing generalists and so cannot hear mid- and high-frequency sonar. Thus, there is little or no likelihood of there being TTS as a result of exposure to these sonars, or any other source above 1.5 kHz. It is possible that mid-frequency sonars are detectable by some hearing specialists such as a number of sciaenid species and clupeids. However, the likelihood of TTS in these species is small since the duration of exposure of animals to a moving source is probably very low since exposure to a maximum sound level (generally well below the source level) would only be for a few seconds as the navy vessel moves by.

Stress

While the major questions on effects of sound relate to behavior of fish in the wild, a more subtle issue is whether the sounds potentially affect the animal through increased stress. In effect, even when there are no apparent direct effects on fish as manifest by hearing loss, tissue damage, or changes in behavior, it is possible that there are more subtle effects on the endocrine or immune systems that could, over a long period of time, decrease the survival or reproductive success of animals. While there have been a few studies that have looked at things such as cortisol levels in response to sound, these studies have been very limited in scope and in species studied.

Eggs and Larvae

Finally, while eggs and larvae must be of concern, the few studies of the effects of sounds on eggs and larvae do not lead to any conclusions with how sound would impact survival. And of the few potentially useful studies, most were done with sources that are very different than sonar. Instead, they employed seismic airguns or mechanical shock. While a few results suggest some potential effects on eggs and larvae, such studies need to be replicated and designed to ask direct questions about whether sounds, and particularly mid- and high-frequency sounds, would have any potential impact on eggs and larvae.

Effects of Impulsive Sounds

There are few studies on the effects of impulsive sounds on fish, and no studies that incorporated mid- or high-frequency signals. The most comprehensive studies using impulsive sounds are from seismic airguns (e.g., Popper et al. 2005, Song et al. 2006). Additional studies have included those on pile driving (reviewed in Hastings and Popper 2005) and explosives (e.g., Yelverton et al. 1975, Keevin et al. 1997, Govoni et al. 2003; reviewed in Hastings and Popper 2005).

As discussed earlier, the airgun studies on very few species resulted in a small hearing loss in several species, with complete recovery within 18 hours (Popper et al. 2005). Other species showed no hearing loss with the same exposure. There appeared to be no effects on the structure of the ear (Song et al., 2006), and a limited examination of non-auditory tissues, including the swim bladder, showed no apparent damage (Popper et al., 2005). One other study of effects of an airgun exposure showed some damage to the sensory cells of the ear (McCauley et al., 2003), but it is hard to understand the differences between the two studies. However, the two studies had different methods of exposing fish, and used different species.

There are other studies that have demonstrated some behavioral effects on fish during airgun exposure used in seismic exploration (e.g., Pearson et al., 1987, 1992, Engås et al., 1996, Engås and Løkkeborg, 2002, Slotte et al., 2004), but the data are limited and it would be very difficult to extrapolate to other species, as well as to other sound sources.

Explosive Sources

A number of studies have examined the effects of explosives on fish. These are reviewed in detail in Hastings and Popper (2005). One of the real problems with these studies is that they are highly variable and so extrapolation from one study to another, or to other sources, such as those used by the Navy, is not really possible. While many of these studies show that fish are killed if they are near the source, and there are some suggestions that there is a correlation between size of the fish and death (Yelverton et al., 1975), little is known about the very important issues of non-mortality damage in the short- and long-term, and nothing is known about effects on behavior of fish.

The major issue in explosives is that the gas oscillations induced in the swim bladder or other air bubble in fishes caused by high sound pressure levels can potentially result in tearing or rupturing of the chamber. This has been suggested to occur in some (but not all) species in several gray literature unpublished reports on effects of explosives (e.g., Alpin 1947; Coker and Hollis, 1950; Gaspin 1975; Yelverton et al., 1975), whereas other published studies do not show such rupture (e.g., the very well done peer reviewed study by Govoni et al., 2003). Key variables that appear to control the physical interaction of sound with fishes include the size of the fish relative to the wavelength of sound, mass of the fish, anatomical variation, and location of the fish in the water column relative to the sound source (e.g., Yelverton et al., 1975, Govoni et al., 2003).

Explosive blast pressure waves consist of an extremely high peak pressure with very rapid rise times (< 1 millisecond [ms]). Yelverton et al. (1975) exposed eight different species of freshwater fish to blasts of 1-lb spheres of Pentolite in an artificial pond. The test specimens ranged from 0.02 g (guppy) to 744 g (large carp) body mass and included small and large animals from each species. The fish were exposed to blasts having extremely high peak overpressures with varying impulse lengths. The investigators found what appears to be a direct correlation between body mass and the magnitude of the "impulse," characterized by the product of peak overpressure and the time it took the overpressure to rise and fall back to zero (units in psi-ms), which caused 50 percent mortality (see Hastings and Popper 2005 for detailed analysis).

One issue raised by Yelverton et al. (1975) was whether there was a difference in lethality between fish which have their swim bladders connected by a duct to the gut and fish which do not have such an opening. The issue is that it is potentially possible that a fish with such a connection could rapidly release gas from the swim bladder on compression, thereby not increasing its internal pressure. However, Yelverton et al. (1975) found no correlation between lethal effects on fish and the presence or lack of connection to the gut.

While these data suggest that fishes with both types of swim bladders are affected in the same way by explosive blasts, this may not be the case for other types of sounds, and especially those with longer rise or fall times that would allow time for a biomechanical response of the swim bladder (Hastings and Popper, 2005). Moreover, there is some evidence that the effects of explosives on fishes without a swim bladder are less than those on fishes with a swim bladder (e.g., Gaspin, 1975; Goertner et al., 1994; Keevin et al., 1997). Thus, if internal damage is, even in part, an indirect result of swim bladder (or other air bubble) damage, fishes without this organ may show very different secondary effects after exposure to high sound pressure levels. Still, it must be understood that the data on effects of impulsive sources and explosives on fish are limited in number and quality of the studies, and in the diversity of fish species studied. Thus, extrapolation from the few studies available to other species or other devices must be done with the utmost caution.

In a more recent published report, Govoni et al. (2003) found damage to a number of organs in juvenile pinfish (*Lagodon rhomboids*) and spot (*Leiostomus xanthurus*) when they were exposed to submarine detonations at a distance of 3.6 m, and most of the effects, according to the authors, were sublethal. Effects on other organ systems that would be considered irreversible (and presumably lethal) only occurred in a small percentage of fish exposed to the explosives. Moreover, there was virtually no effect on the same sized animals when they were at a distance of 7.5 m, and more pinfish than spot were affected.

Based upon currently available data it is not possible to predict specific effects of Navy impulsive sources on fish. At the same time, there are several results that are at least suggestive of potential effects that result in death or damage. First, there are data from impulsive sources such as pile driving and seismic airguns that indicate that any mortality declines with distance, presumably because of lower signal levels. Second, there is also evidence from studies of explosives (Yelverton et al., 1975) that smaller animals are more affected than larger animals. Finally, there is also some evidence that fish without an air bubble, such as flatfish and sharks and rays, are less likely to be affected by explosives and other sources than are fish with a swim bladder or other air bubble.

Yet, as indicated for other sources, the evidence of short- and long-term behavioral effects, as defined by changes in fish movement, etc., is non-existent. Thus, we still do not know if the presence of an explosion or an impulsive source at some distance, while not physically harming a fish, will alter its behavior in any significant way.

General Conclusions of Sounds on Fish

As discussed, the extent of data, and particularly scientifically peer-reviewed data, on the effects of high intensity sounds on fish is exceedingly limited. Some of these limitations include:

- Types of sources tested;
- Effects of individual sources as they vary by such things as intensity, repetition rate, spectrum, distance to the animal, etc.;
- Number of species tested with any particular source;
- The ability to extrapolate between species that are anatomically, physiologically, and/or taxonomically, different;
- Potential differences, even within a species as related to fish size (and mass) and/or developmental history;
- Differences in the sound field at the fish, even when studies have used the same type of sound source (e.g., seismic airgun);

- Poor quality experimental design and controls in many of the studies to date;
- Lack of behavioral studies that examine the effects on, and responses of, fish in their natural habitat to high intensity signals;
- Lack of studies on how sound may impact stress, and the short- and long-term effects of acoustic stress on fish; and
- Lack of studies on eggs and larvae that specifically use sounds of interest to the Navy.

At the same time, in considering potential sources that are in the mid- and high-frequency range, a number of potential effects are clearly eliminated. Most significantly, since the vast majority of fish species studied to date are hearing generalists and cannot hear sounds above 500 to 1,500 Hz (depending upon the species), there are not likely to be behavioral effects on these species from higher frequency sounds.

Moreover, even those fish species that may hear above 1.5 kHz, such as a few sciaenids and the clupeids (and relatives), have relatively poor hearing above 1.5 kHz as compared to their hearing sensitivity at lower frequencies. Thus, it is reasonable to suggest that even among the species that have hearing ranges that overlap with some mid- and high-frequency sounds, it is likely that the fish will only actually hear the sounds if the fish and source are very close to one another. And, finally, since the vast majority of sounds that are of biological relevance to fish are below 1 kHz (e.g., Zelick et al., 1999; Ladich and Popper, 2004), even if a fish detects a mid- or high-frequency sound, these sounds will not mask detection of lower frequency biologically relevant sounds.

Thus, a reasonable conclusion, even without more data, is that there will be few, and more likely no, impacts on the behavior of fish.

At the same time, it is possible that very intense mid- and high-frequency signals, and particularly explosives, could have a physical impact on fish, resulting in damage to the swim bladder and other organ systems. However, even these kinds of effects have only been shown in a few cases in response to explosives, and only when the fish has been very close to the source. Such effects have never been shown to any Navy sonar. Moreover, at greater distances (the distance clearly would depend on the intensity of the signal from the source) there appears to be little or no impact on fish, and particularly no impact on fish that do not have a swim bladder or other air bubble that would be affected by rapid pressure changes.

Underwater Detonations

Underwater detonations are possible during SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS. The weapons used in most missile and Live Fire Exercises pose little risk to fish unless the fish were near the surface at the point of impact. Machine guns (50 caliber) and close-in weapons systems (anti-missile systems) fire exclusively non-explosive ammunition. The same applies to larger weapons firing inert ordnance for training (e.g., 5-inch guns and 76-mm guns). The rounds pose an extremely low risk of a direct hit and potential to directly affect a marine species. Target area clearance procedures will again reduce this risk. A SINKEX uses a variety of live fire weapons. These rounds pose a risk only at the point of impact.

Several factors determine a fish's susceptibility to harm from underwater detonations. Most injuries in fish involve damage to air- or gas-containing organs (i.e., the swim bladder). Fish with swim bladders are vulnerable to effects of explosives, while fish without swim bladders are much more resistant (Yelverton, 1981; Young, 1991). Research has focused on the effects on the swim bladder from underwater detonations but not the ears of fish (Edds-Walton and Finneran, 2006).

For underwater demolition training, the effects on fish from a given amount of explosive depend on location, season, and many other factors. O'Keeffe (1984) provides charts that allow estimation of the potential effect on swim-bladder fish using a damage prediction method developed by Goertner (1982). O'Keeffe's parameters include the size of the fish and its location relative to the explosive source, but are independent of environmental conditions (e.g., depth of fish, explosive shot, frequency content). Table 4.1.2.2-1 lists the estimated maximum effects ranges using O'Keeffe's (1984) method for an 8-pound (lb) explosion at source depths of 1.7 fathoms (10 ft).

Table 4.1.2.2-1. Maximum Fish-Effects Ranges

Fish Weight	10 Percent Mortality Range (in feet)
1 ounce	518.3
1 pound	208.9
30 pounds	155.2

Source: O'Keefe, 1984

Potential impacts on fish from underwater demolition detonations would be negligible. A small number of fish are expected to be injured by detonation of explosive, and some fish located in proximity to the initial detonations can be expected to die. However, the overall impacts on water column habitat would be localized and transient. As training begins, the natural reaction of fish in the vicinity would be to leave the area. When training events are completed, the fish stock would be expected to return to the area.

Essential Fish Habitat

This section briefly discusses the potential impacts by the proposed actions to EFH and managed species. Despite nearshore and offshore designations of the HRC, species within all Fisheries Management Plans (FMPs) may utilize both nearshore and offshore areas during their lives, as eggs and larvae for most species are planktonic and can occur in nearshore and offshore waters, while adults may be present in nearshore and/or offshore waters. Therefore, all project activities can potentially affect a lifestage of a managed species.

Adverse effects are defined as any impact that reduces quality and/or quantity of EFH. Adverse effects may include direct or indirect physical, chemical, or biological alterations of the waters or substrate and loss of, or injury to, benthic organisms, prey species and their habitat, and other ecosystem components, if such modifications reduce the quality and/or quantity of EFH. Adverse effects on EFH may result from actions occurring within EFH or outside of EFH and may include site-specific or habitat-wide impacts, including individual, cumulative, or synergistic consequences of actions (50 CFR 600.810(a)).

Permanent, adverse impacts on EFH components are not anticipated since operations are conducted to avoid potential impacts; however, there are temporary unavoidable impacts associated with several operations that may result in temporary and localized impacts. In addition, a single operation may potentially have multiple effects on EFH. The current and proposed operations in the HRC have the potential to result in the following impacts:

- Physical disruption of open ocean habitat
- Physical destruction or adverse modification of benthic habitats
- Alteration of water or sediment quality from debris or discharge
- Cumulative impacts

Each impact and operation associated with those impacts are discussed in a separate document, *Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy, 2007b) and a summary for each proposed activity is provided. Potential impacts on FMP species include direct and indirect effects from sonar and shock waves (see discussion above and EFH document, U.S. Department of the Navy, 2007a). Numerous operations may affect benthic habitats from debris, and there may also be temporary impacts on water quality from increased turbidity or release of materials. However, due to the mitigation measures implemented to protect sensitive habitats, and the localized and temporary impacts of the Proposed Action and alternatives, it is concluded that the potential impact of the Proposed Action and alternatives on EFH for the five major FMPs and their associated management units would be minimal.

4.1.2.2.1 No-action Alternative (Fish—Biological Resources—Open Ocean)

The No-action Alternative includes a total of 1,167 hours of MFA surface ship sonar and the associated Directional Command Activated Sonobuoy System (DICASS) sonobuoy, MK-48 torpedo (an HFA source), dipping sonar, and submarine sonar (see Appendix J for a detailed description). Underwater detonations are possible during SINKEX, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS. The abundance and diversity of fish within the HRC will not measurably decrease as a result of implementation of the No-action Alternative.

HRC Training—No-action Alternative

Sonar

ASW training in HRC other than during Major Exercises includes ASW Tracking Exercise (TRACKEX) and ASW Torpedo Exercise (TORPEX) as described in Table 2.2.2.3-1 and Appendix D. The annual sonar for TRACKEX and TORPEX includes 360 hours of AN/SQS 53 and 75 hours of AN/SQS 56 MFA surface ship sonar, associated sonobuoys, MK-48 torpedo HFA sonar, dipping sonar, and submarine sonar.

HRC RDT&E Activities—No-action Alternative

Other sources such as unmanned aerial vehicles (UAVs), underwater communications, and electronic warfare systems that may be deployed in the ocean are beyond the frequency range or intensity level to affect fish. Other RDT&E activities identified as ASW do not include sonar or include very limited use of sonar and short durations (<1.5 hours). These activities will have minimal effects on fish.

Major Exercises—No-action Alternative

RIMPAC and USWEX

The training events and impacts from RIMPAC Exercises have been summarized in the RIMPAC 2006 Supplement to the 2002 RIMPAC Environmental Assessment (EA) (U.S. Department of the Navy, Commander Third Fleet, 2006). The No-action Alternative modeling included 399 hours of AN/SQS 53 and 133 hours of AN/SQS 56 surface ship sonar and associated dipping sonar, sonobuoys, and MK-48 torpedoes per RIMPAC (conducted every other year).

The training events and impacts on fish from USWEX Exercises have been summarized in the USWEX Programmatic EA/Overseas EA (OEA) (U.S. Department of the Navy, 2007b). The No-action Alternative USWEX modeling included 525 hours of AN/SQS 53 and 175 hours of AN/SQS 56 MFA sonar and associated dipping sonar and sonobuoys per year.

The potential impacts on fish from RIMPAC and USWEX sonar and underwater detonations (i.e., SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS will be similar to those described above for the HRC training.

4.1.2.2.2 Alternative 1 (Fish—Biological Resources—Open Ocean)

The increased training and RDT&E activities under Alternative 1 results in a total of 2,339 hours of MFA surface ship sonar plus the associated DICASS sonobuoy, MK-48 torpedo (an HFA source), dipping sonar, and submarine sonar (see Appendix J for a detailed description). Underwater detonations are possible during SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS.

Tempo and Frequency of Training—Alternative 1

Under Alternative 1, ASW training in HRC other than during Major Exercises includes ASW TRACKEX and ASW TORPEX as described in Table 2.2.2.3-1 and Appendix D. The annual sonar for TRACKEX and TORPEX includes 360 hours of AN/SQS 53 and 75 hours of AN/SQS 56 MFA surface ship sonar plus associated sonobuoys, MK-48 torpedo HFA sonar, dipping sonar, and submarine sonar. Potential impacts on fish from sonar and underwater detonations under Alternative 1 would be similar to those described under the No-action Alternative. Although the number of hours of underwater detonations would increase, the impacts would still be minimal.

Enhanced RDT&E Activities—Alternative 1

There are no new RDT&E activities proposed that would affect fish. Sources such as UAVs, underwater communications, and electronic warfare systems that may be deployed in the ocean are at frequency ranges or intensity levels that have no affect on fish. Other RDT&E activities identified as ASW do not include sonar or include very limited use of sonar and short durations (<1.5 hours). These activities would have minimal effects on fish.

Future RDT&E Activities—Alternative 1

There are no new or future RDT&E activities proposed that would affect marine animals. Sources such as UAVs, underwater communications, and electronic warfare systems that may be deployed in the ocean are generally transmitting above the frequency range or below the intensity level to affect marine animals. Other RDT&E activities identified as ASW do not include sonar or include very limited use of sonar and are generally of short durations (<1.5 hours). These activities would have minimal effects on fish.

HRC Enhancements—Alternative 1

There are no new HRC enhancements proposed that would affect fish. Other sources such as the Portable Undersea Tracking Range, underwater communications, and electronic warfare systems that may be deployed in the ocean are at frequency ranges or intensity levels that have no affect on fish. The Navy will continue to work with the regulatory agencies throughout the planning and development process to minimize the potential for impacts on fish.

Major Exercises—Alternative 1

RIMPAC and USWEX

The training events and impacts on fish from RIMPAC Exercises have been summarized in the RIMPAC 2006 Supplement to the 2002 RIMPAC EA (U.S. Department of the Navy, Commander Third Fleet, 2006). Alternative 1 assumes two Strike Groups and 798 hours of AN/SQS 53 and 266 hours of AN/SQS 56 MFA sonar plus associated dipping sonar, sonobuoys, and MK-48 torpedoes HFA sonar per two carrier RIMPAC (conducted every other year).

The training events and impacts on fish from USWEX Exercises have been summarized in the USWEX Programmatic EA/OEA (U.S. Department of the Navy, 2007b). Alternative 1 assumes 630 hours of AN/SQS 53 and 210 hours of AN/SQS 56 MFA sonar plus associated dipping sonar and sonobuoys for six USWEXs per year. Although the number of hours of sonar and the number of underwater detonations would increase over the No-action Alternative, the impacts would still be minimal considering the few fish species that would be able to detect sound in the frequencies of the Proposed Action and the limited exposure of juvenile fish with swim bladder resonance in the frequencies of the sound sources.

Essential Fish Habitat

Impacts on EFH are expected to be similar to those described previously for the No-action Alternative (see Section 4.1.2.2.1), and the small change in the number of exercises would not change those predictions (see *Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* [U.S. Department of the Navy, 2007b]).

4.1.2.2.3 Alternative 2 (Fish—Biological Resources—Open Ocean)

The increased training and RDT&E activities under Alternative 2 result in an increase in the number of hours of ASW training. Alternative 2 includes a total of 3,283 hours of MFA surface ship sonar plus the associated DICASS sonobuoy, MK-48 torpedo (an HFA source), dipping sonar, and submarine sonar (see Appendix J for a detailed description). Underwater detonations are possible during SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS.

Tempo and Frequency of Training—Alternative 2

ASW training for Alternative 2 other than during Major Exercises includes ASW TRACKEX and ASW TORPEX as described in Table 2.2.2.3-1 and Appendix D. The annual sonar for TRACKEX and TORPEX includes 360 hours of AN/SQS 53 and 75 hours of AN/SQS 56 MFA surface ship sonar plus associated sonobuoys, MK-48 torpedo HFA sonar, dipping sonar, and submarine sonar. Potential impacts on fish from sonar and underwater detonations under Alternative 2 would be similar to those described under the No-action Alternative. Although the number of hours of sonar and the number of underwater detonations would increase over the No-action Alternative, the impacts would still be minimal.

Enhanced RDT&E Activities—Alternative 2

There are no new RDT&E activities proposed that would affect fish. Sources such as UAVs, underwater communications, and electronic warfare systems that may be deployed in the ocean at the frequency ranges or intensity levels that have no affect on fish. Other RDT&E activities identified as ASW do not include sonar or include very limited use of sonar and short durations (<1.5 hours). These activities would have minimal effects on fish.

Future RDT&E Activities—Alternative 2

There are no new or future RDT&E activities proposed that would affect marine animals. Noise sources such as UAVs, underwater communications, and electronic warfare systems that may be deployed in the ocean are generally transmitting above the frequency range or below the intensity level to affect marine animals. Other RDT&E activities identified as ASW do not include sonar or include very limited use of sonar and are generally of short durations (<1.5 hours). These activities would have minimal effects on fish.

HRC Enhancements—Alternative 2

There are no new HRC enhancements proposed that would affect fish. Other sources such as underwater communications and electronic warfare systems that may be deployed in the ocean are at frequency ranges or intensity levels that have no affect on fish.

Major Exercises—Alternative 2

RIMPAC

The training events and impacts on fish from RIMPAC Exercises have been summarized in the RIMPAC 2006 Supplement to the 2002 RIMPAC EA (U.S. Department of the Navy, Commander Third Fleet, 2006). Alternative 2 assumes two Strike Groups and 798 hours of AN/SQS 53 and 266 hours of AN/SQS 56 MFA sonar plus dipping sonar, sonobuoys, and MK-48 torpedoes HFA sonar per two carrier RIMPAC (conducted every other year).

USWEX

The training events and impacts on fish from USWEX Exercises have been summarized in the USWEX Programmatic EA/OEA (U.S. Department of the Navy, 2007b). Alternative 2 assumes 630 hours of AN/SQS 53 and 210 hours of AN/SQS 56 MFA sonar plus dipping sonar and sonobuoys for six USWEXs per year. Although the number of hours of sonar and the number of underwater detonations would increase over the No-action Alternative, the impacts would still be minimal considering the few fish species that would be able to detect sound in the frequencies of the Proposed Action and the limited exposure of juvenile fish with swim bladder resonance in the frequencies of the sound sources.

Additional Major Exercise—Multiple Strike Group Training

With the addition of this Major Exercise, up to three Strike Groups would conduct training simultaneously in the HRC. The Strike Groups would not be homeported in Hawaii, but would stop in Hawaii en route to a final destination. The Strike Groups would be in Hawaii for up to 10 days per Multiple Strike Group exercise. Training would be provided to submarine, ship, and aircraft crews in tactics, techniques, and procedures for ASW, Defensive Counter Air, Maritime Interdiction, and operational level Command and Control (C2) of maritime forces. The Multiple Strike Group Exercise would include 708 hours of AN/SQS 53 and 236 hours of AN/SQS 56 MFA sonar, associated sonobuoys, dipping sonar, *and* MK-48 torpedo HFA sonar. Although the number of hours of sonar and the number of underwater detonations would increase over Alternative 1, the impacts would still be minimal.

Essential Fish Habitat

Impacts on EFH are expected to be similar to those described previously for the No- action Alternative (see Section 4.1.2.2.1), and the small change in the number of exercises would not change those predictions (see *Essential Fish Habitat and Coral Reef Assessment for the Hawaii Range Complex EIS/OEIS* [U.S. Department of the Navy, 2007b]).

4.1.2.2.4 Alternative 3 (Fish—Biological Resources—Open Ocean)

The difference between Alternative 2 and Alternative 3 is the amount of MFA/HFA sonar usage. Alternative 3 would include all of the training associated with Alternative 2 (as described in Sections 2.2.4.1 and 2.2.4.3 through 2.2.4.7). As described under Alternative 2, Alternative 3 would provide increased flexibility in training activities by increasing the tempo and frequency of training events (Table 2.2.2.3-1), future and enhanced RDT&E activities, and the addition of Major Exercises. Alternative 3 would consist of the MFA/HFA sonar usage as analyzed under the No-action Alternative. Potential effects on fish from non-ASW (sonar usage) training and RDT&E activities determined for Alternative 3 are the same as those analyzed for Alternative 2, Section 4.1.2.2.3.

4.1.2.3 SEA TURTLES (BIOLOGICAL RESOURCES—OPEN OCEAN)

Sonar

Extrapolation from human and marine mammal data to turtles is inappropriate given the morphological differences between the auditory systems of mammals and turtles. However, the measured hearing threshold for green turtles (and by extrapolation from this species to other hardshelled sea turtles; at least the olive ridley, loggerhead, and hawksbill) is only slightly lower than the maximum levels to which these species could be exposed. Given the lack of audiometric information, the potential for temporary threshold shifts among leatherback turtles must be classified as unknown, but would likely follow those of other sea turtles. It is not likely that a temporary threshold shift would occur at such a small margin over threshold in any species. Therefore, no threshold shifts in green, olive ridley, loggerhead, hawksbill, or leatherback turtles are expected.

As described in Chapter 3.0, sea turtle hearing is generally most sensitive between 100 Hz to 800 Hz for hard shell turtles, frequencies that are at the lower end of the sound spectrum. Although low-frequency hearing has not been studied in many sea turtle species, most of those that have been tested exhibit low audiometric and behavioral sensitivity to low-frequency sound. It appears, therefore, that if there were the potential for the MFA/HFA sonar to increase masking effects of any sea turtle species, it would be expected to be minimal as most sea turtle species are apparently low-frequency specialists. The use of low-frequency sources is not part of the Proposed Action in the HRC EIS/OEIS. Any potential role of long-range acoustical perception in sea turtles has not been studied. Anecdotal information, however, suggests that the acoustic signature of a turtle's natal beach might serve as a cue for nesting returns. Again, however, the sources used in the HRC are above sea turtle's most sensitive hearing range.

As demonstrated by Jessop et al. (2002) for breeding adult male green turtles, there is a complex relationship between stress/physiological state and plasma hormone responses. Even if sea turtles were able to sense the sonar output, it is unlikely that any physiological stress leading to endocrine and corticosteroid imbalances would result over the long term (allostatic loading) (McEwen and Lashley, 2002). Although there may be many hours of active ASW sonar events, the active "pings" of the sonar generally only occur only twice a minute, as it is necessary for the ASW operators to listen for the return echo of the sonar ping before another ping is transmitted. Given the time between pings and relative high ship speed in comparison to turtles and the relatively low hearing sensitivity even within the frequency ranges that sea turtles hear best, which is for the most part below the frequency range of MFA/HFA sonar, it is unlikely that sea turtles would be affected by this type of sonar. Based on the current available data, MFA/HFA sonar use would not affect sea turtles.

Potential Non-Acoustic Impacts

Ship Strikes

The Navy has adopted standard operating procedures (SOPs) that reduce the potential for collisions between surface vessels and sea turtles (See Chapter 6.0). On the bridge of surface ships, there will always be at least three people on watch whose duties include observing the water surface around the vessel during at-sea movements. If a sea turtle is sighted, appropriate action will be taken to avoid the animal. Given the SOPs and the relative few number of turtles and Navy vessels in the open ocean, the Navy believes collisions with sea turtles are unlikely. A study of green sea turtle strandings in the Hawaiian Archipelago from 1982-2003 showed that boat strikes and shark attacks each accounted for 2.7 percent of the 3,732 green sea turtle strandings (boat strikes are in general from small craft). Green turtle strandings attributable to boat strike were more likely from Kauai and Oahu. The most common cause of the strandings was the tumor-forming disease, fibropapillomatosis (28 percent); 49 percent of the strandings could not be attributed to any known cause (Chaloupka et al, 2004).

Torpedo Guidance Wire

The potential entanglement impact of MK-48 torpedo control wires on sea turtles is very low because the control wire is very thin (approximately 0.02 in) and has a relatively low breaking strength. In addition, when the wire is released or broken, it is relatively straight and the physical characteristics of the wire prevent it from tangling.

Torpedo Strike Impact

Given the relatively small size of sea turtles, there is negligible risk that a turtle could be struck by a torpedo during ASW training events. The potential for any harm or harassment to sea turtles is extremely low.

Because some torpedo air launch accessories remain in the marine environment, the potential for impacting sea turtles through ingestion or entanglement has been previously analyzed. Ingestion of pieces of the launch accessories is unlikely because most of those are large and metallic and will sink rapidly (U.S. Department of the Navy, 1996a).

MK-48 Torpedo Flex Hoses

The Navy analyzed the potential for the flex hoses to impact sea turtles and marine mammals. The analysis concluded that the potential entanglement impact on marine animals would be insignificant for reasons similar to those stated for the potential entanglement impact of control wires (U.S. Department of the Navy, 1996b).

Sonobuoy and Other Parachutes

Sonobuoys, lightweight torpedoes, and other devices deployed from aircraft use nylon parachutes of varying sizes. At water impact, the parachute assembly is jettisoned and sinks away from the exercise weapon or target. The parachute assembly would potentially be at the surface for a short time before sinking to the sea floor. Many large sea turtles subsist mainly on jellyfish, and the incidence of plastic bags being found in dead turtles indicates that the turtles may mistake floating plastic bags for jellyfish (Cottingham, 1989). Sea turtles also ingest pieces of polystyrene foam, monofilament fishing line, and several other kinds of synthetic drift items. However, the parachutes used on the proposed HRC are large in comparison with these animals' normal food items, and would be very difficult to ingest. Overall, the possibility of sea turtles ingesting nylon parachute fabric or being entangled in parachute assemblies is very remote.

Potential Underwater Detonation Impacts

Events involving underwater detonation involve EER/IEER, MINEX, MISSILEX, BOMBEX, SINKEX, GUNEX, and NSFS. Criteria and thresholds for estimating the impacts on marine mammals and sea turtles from a single underwater detonation event were defined and publicly vetted through the National Environmental Policy Act (NEPA) process during the environmental assessments for the two Navy ship-shock trials: the SEAWOLF Final EIS (FEIS) (U.S. Department of the Navy 1998a) and the Churchill FEIS (U.S. Department of the Navy, 2001b). During the analysis of the effects of explosions on marine mammals and sea turtles conducted by the Navy for the Churchill EIS, analysts compared the injury levels reported by the best of these experiments to the injury levels that would be predicted using the modified Goertner method and found them to be similar (U.S. Department of the Navy, 2001b, Goertner 1982). The criteria and thresholds for injury and harassment, which are the same for both sea turtles and marine mammals, are summarized in Table 4.1.2.3-1.

Table 4.1.2.3-1. Summary of Criteria and Acoustic Thresholds for Underwater Detonation Impacts on Sea Turtles and Marine Mammals

Harassment Level	Criterion	Threshold
Level A Harassment Mortality	Onset of severe lung injury	"Goertner" modified positive impulse indexed to 31 psi-ms
Injury	Tympanic membrane rupture	50 percent rate of rupture 205 dB re 1 µPa^2-s (Energy Flux Density)
Injury	Onset of slight lung injury	Goertner Modified Positive Impulse Indexed to 13 psi-ms
Level B Harassment Non-Injury	Onset Temporary Threshold Shift (TTS) (Dual Criteria)	182 dB re 1 µPa^2-s (Energy Flux Density) in any 1/3-octave band at frequencies above 100 Hz for all toothed whales (e.g., sperm whales, beaked whales); above 10 Hz for all baleen whales
Non-Injury	Onset of TTS (Dual Criteria)	23 psi peak pressure level (for small explosives; less than 2,000 lb NEW)
Non-Injury	Sub-TTS behavioral disturbance	177 dB re 1 µPa^2-s (Energy Flux Density) for multiple successive explosions

Notes: psi = pounds per square inch
µPa^2-s = squared micropascal-second
Hz = hertz
psi-ms = pounds per square inch-milliseconds
dB = decibel
NEW = net explosive weight

Injury Thresholds

When analyzing underwater detonations, two criteria are used for injury: onset of slight lung injury and 50 percent eardrum rupture (tympanic membrane [TM] rupture). These criteria are considered indicative of the onset of injury. The threshold for onset of slight lung injury is calculated for a small animal (a dolphin calf weighing 26.9 lb), and is given in terms of the "Goertner modified positive impulse," indexed to 13 psi-millisecond (ms) in the (U.S. Department of the Navy, 2001b). This threshold is conservative since the positive impulse needed to cause injury is proportional to animal mass, and therefore, larger animals require a higher impulse to cause the onset of injury. The threshold for TM rupture corresponds to a 50 percent rate of rupture (i.e., 50 percent of animals exposed to the level are expected to suffer TM rupture); this is stated in terms of an energy level value of 205 dB re 1 µPa^2-s. The criterion reflects the fact that TM rupture is not necessarily a serious or life-threatening injury, but is a useful index of possible injury that is well correlated with measures of permanent hearing impairment (e.g., Ketten 1998) indicates a 30 percent incidence of permanent threshold shift [PTS] at the same threshold).

The criterion for marine mammal mortality when analyzing underwater detonations used in the Churchill FEIS is "onset of severe lung injury." This is conservative in that it corresponds to a 1 percent chance of mortal injury, and yet any animal experiencing onset of severe lung injury is counted as a lethal exposure. The threshold is stated in terms of the Goertner (1982) modified positive impulse with value "indexed to 31 psi-ms." Since the Goertner approach depends on propagation, source/animal depths, and animal mass in a complex way, the actual impulse value corresponding to the 31-psi-ms index is a complicated calculation. Again, to be conservative, the CHURCHILL FEIS used the mass of a calf dolphin (at 26.9 lb), so that the threshold index is 30.5 psi-ms.

Harassment Thresholds

There are two thresholds for non-injurious harassment from underwater explosives. The first is temporary threshold shift (TTS), which is a temporary, recoverable, loss of hearing sensitivity (National Marine Fisheries Service, 2001a; U.S. Department of the Navy, 2001b). The second threshold, termed “sub-TTS,” applies to multiple explosions in succession (separated by less than 2 seconds). The sub-TTS threshold is used to account for behavioral disturbance significant enough to be judged as harassment, but occurring at lower sound energy levels than those that may cause TTS.

There are dual criteria for TTS when analyzing underwater detonations. The first is 182 dB re 1 squared micropascal-second (μPa^2-s) maximum Energy Flux Density Level (EL) level in any 1/3-octave band at frequencies >100 Hz for marine mammals and sea turtles. The second criterion for impact analysis when considering underwater detonations and a TTS threshold is 12 pounds per square inch (psi) peak pressure that was developed for 10,000-lb charges as part of the Churchill FEIS (U.S. Department of the Navy, 2001b; National Oceanic and Atmospheric Administration, 2005 and 2006h). It was introduced to provide a safety zone for TTS when the explosive or the animal approaches the sea surface (for which case the explosive energy is reduced but the peak pressure is not). Navy policy is to use a 23 psi criterion for explosive charges less than 2,000 lb and the 12 psi criterion for explosive charges larger than 2,000 lb. All explosives modeled for the HRC EIS/OEIS are less than 1,500 lb.

Harassment Threshold for Multiple Successive Explosions (MSE)

There may be rare occasions when MSE are part of a static location event such as during MINEX, MISSILEX, BOMBEX, SINKEX, GUNEX, and NSFS (when using other than inert weapons). For these events, the Churchill FEIS approach was extended to cover MSE events occurring at the same static location. For MSE exposures, accumulated energy over the entire training time is the natural extension for energy thresholds since energy accumulates with each subsequent shot; this is consistent with the treatment of multiple arrivals in Churchill. For positive impulse, it is consistent with Churchill FEIS to use the maximum value over all impulses received.

For MSE, the acoustic criterion for sub-TTS behavioral disturbance is used to account for behavioral effects significant enough to be judged as harassment, but occurring at lower sound energy levels than those that may cause TTS. The sub-TTS threshold is derived following the approach of the Churchill FEIS for the energy-based TTS threshold.

The research on pure-tone exposures reported in Schlundt et al. (2000) and Finneran and Schlundt (2004) provided a threshold of 192 dB re 1 μPa^2-s as the lowest TTS value. This value for pure-tone exposures is modified for explosives by (a) interpreting it as an energy metric, (b) reducing it by 10 dB to account for the time constant of the mammal ear, and (c) measuring the energy in 1/3 octave bands, the natural filter band of the ear. The resulting TTS threshold for explosives is 182 dB re 1 μPa^2-s in any 1/3 octave band. As reported by Schlundt et al. (2000) and Finneran and Schlundt (2004), instances of altered behavior in the pure-tone research generally began five dB lower than those causing TTS. The sub-TTS threshold is therefore derived by subtracting five dB from the 182 dB re 1 μPa2-s in any 1/3 octave band threshold, resulting in a 177 dB re 1 μPa^2-s (EL) sub-TTS behavioral disturbance threshold for MSE.

Preliminary modeling undertaken for other Navy compliance documents using the sub-TTS threshold of 177 dB has demonstrated that for events involving MSE using small (NEW) explosives (MINEX, GUNEX, NSFS, and underwater detonation), the footprint of the threshold for explosives onset TTS criteria based on the 23 psi pressure component dominates and supersedes any exposures at a received level involving the 177 dB EL threshold. Restated in another manner, modeling for the sub-TTS threshold should not result in any estimated impacts that are not already quantified under the larger footprint of the 23 psi criteria for small MSE. Given that modeling for sub-TTS should not, therefore, result in any additional harassment takes for MINEX, GUNEX, NSFS, and underwater detonation, analysis of potential for behavioral disturbance using the sub-TTS criteria was not undertaken for these events (MINEX, GUNEX, NSFS, and underwater detonation).

For the remainder of the MSE events (BOMBEX, SINKEX, and MISSILEX) where the sub-TTS exposures may need to be considered, these potential behavioral disturbances were estimated by extrapolation from the acoustic modeling results for the explosives TTS threshold (182 dB re 1 μPa^2-s in any 1/3 octave band). To account for the 5 dB lower sub-TTS threshold, a factor of 3.17 was applied to the TTS modeled numbers in order to extrapolate the number of sub-TTS exposures estimated for MSE events. This multiplication factor is used calculate the increased area represented by the difference between the 177 dB sub-TTS threshold and the modeled 182 dB threshold. The factor is based on the increased range 5 dB would propagate (assuming spherical spreading), where the range increases by approximately 1.78 times, resulting in a circular area increase of approximately 3.17 times that of the modeled results at 182 dB.

Potential overlap of exposures from multiple explosive events within a 24-hour period was not taken into consideration in the modeling resulting in the potential for some double counting of exposures. However, because an animal would generally move away from the area following the first explosion, the overlap is likely to be minimal.

It should be emphasized that there is a lead time for set up and clearance of any area before an event using explosives takes place (this may be 30 minutes for an underwater detonation to several hours for a SINKEX). There will, therefore, be a long period of rather intense activity before the event occurs when the area is under observation and before any detonation or live fire occurs. Ordnance cannot be released until the target area is determined clear. In addition, the event is immediately halted if sea turtles are observed within the target area and the training is delayed until the animal clears the area. These mitigation factors to determine if the area is clear, serve to minimize the risk of harming sea turtles and marine mammals.

4.1.2.3.1 No-action Alternative (Sea Turtles—Biological Resources—Open Ocean)

HRC Training—No-action Alternative

As discussed in detail above, MFA/HFA sonar use would not affect sea turtles.

Underwater detonations are possible during SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS. The weapons used in most exercises utilizing inert ordnance pose little risk to sea turtles unless they were to be near the surface at the point of impact. A turtle would have to be near the point of projectile impact to be in the affected area. Given the density of water, and the variable direction and energy loss of projectiles hitting the water, there is no accurate average answer in regard to a specific “area” or “depth.” Machine guns (0.50 caliber) and the close-in weapons systems (anti-missile systems) fire exclusively non-explosive ammunition. The same applies to larger weapons firing inert ordnance for training. Target area clearance procedures will reduce the potential for impacting a sea turtle such that impacts on sea turtles from exercises utilizing inert ordnance will be highly unlikely.

Exercises that utilize explosive ordnance pose a greater risk to sea turtles; however, the area affected by the explosive is relatively small, and target area clearance procedures will further reduce the potential for such an extremely unlikely event to occur.

Individual pieces of debris from ballistic missile intercept tests are dispersed over a large area. While a direct hit from a piece of debris would impact sea a turtle at the surface, it is extremely unlikely that this would ever occur.

The explosive payload of an EER/IEER buoy is suspended below the surface at a depth where sea turtles are unlikely to be present in the open ocean. Given the size of the ocean, It is unlikely that a sea turtle will be present in the vicinity of an EER/IEER buoy when detonated. In addition, in the rare event that a turtle is present when an EER/IEER is detonated, the depth of the approximately 4-lb charge will likely preclude there being any adverse effects.

HRC RDT&E Activities—No-action Alternative

RDT&E activities will not affect sea turtles.

Major Exercises—No-action Alternative

Underwater detonations during RIMPAC and USWEX will be similar to those described under HRC Training. Impacts on sea turtles are not anticipated given range clearance procedures, the low density of sea turtles, and the temporary nature and episodic number of the events involved.

Compliance under ESA for Sea Turtles

In accordance with ESA requirements, the Navy has undertaken Section 7 consultation with NMFS for the ongoing activities in the HRC. The Navy finds that these activities are not likely to affect green, olive ridley, loggerhead, hawksbill, or leatherback sea turtles.

4.1.2.3.2 Alternative 1 (Sea Turtles—Biological Resources—Open Ocean)

The increased training and RDT&E activities under Alternative 1 result in an increase in the number of underwater detonations during SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NFSF.

Increased Tempo and Frequency of Training—Alternative 1

Although the number of underwater detonations would increase, due to the clearance requirements for underwater detonations and exercises involving explosives, sea turtles would not be within the area, and therefore impacts are not anticipated.

Enhanced RDT&E Activities—Alternative 1

Enhanced RDT&E activities would not affect sea turtles.

Future RDT&E Activities—Alternative 1

There are no future RDT&E activities that would affect sea turtles.

HRC Enhancements—Alternative 1

There are no new HRC enhancements that would affect sea turtles. The Navy will develop appropriate habitat data and any necessary Best Management Practices and mitigations in coordination with NMFS and USFWS for new activities. The Navy will continue to work with regulatory agencies throughout the planning and development process to minimize the potential for impacts on sea turtles.

Major Exercises—Alternative 1

Underwater detonations during RIMPAC and USWEX would be similar to those described under the No-action Alternative. Due to the clearance requirements for underwater detonations and exercises involving explosives, sea turtles would not be within the area and therefore impacts are not anticipated.

Compliance under ESA for Sea Turtles

In accordance with ESA requirements, the Navy would undertake Section 7 consultation with NMFS for the proposed and ongoing activities in the HRC under Alternative 1. The Navy finds that these activities are not likely to affect green, olive ridley, loggerhead, hawksbill, or leatherback sea turtles.

4.1.2.3.3 Alternative 2 (Sea Turtles—Biological Resources—Open Ocean)

The increased training and RDT&E activities under Alternative 2 result in an increase in the number of underwater detonations during SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS.

Increased Tempo and Frequency of Training—Alternative 2

Although the number of underwater detonations would increase, due to the clearance requirements for underwater detonations and exercises involving explosives, sea turtles would not be within the area, and therefore impacts are not anticipated.

Enhanced and Future RDT&E Activities—Alternative 2

There are no enhanced or future RDT&E activities that would affect sea turtles.

HRC Enhancements—Alternative 2

There are no new HRC enhancements that would affect sea turtles.

Additional Major Exercises—Multiple Strike Group Training—Alternative 2

Up to three Strike Groups would conduct training simultaneously in the HRC. Underwater detonations during the Multiple Strike Group training would be similar to those described under the No-action Alternative for RIMPAC and USWEX. Due to the clearance requirements for underwater detonations and exercises involving explosives, sea turtles would not be within the area, and therefore impacts are not anticipated.

Compliance under ESA for Sea Turtles

In accordance with ESA requirements, the Navy would undertake Section 7 consultation with NMFS for the proposed and ongoing activities in the HRC under Alternative 2. The Navy finds that these activities are not likely to affect green, olive ridley, loggerhead, hawksbill, or leatherback sea turtles.

4.1.2.3.4 Alternative 3 (Sea Turtles—Biological Resources—Open Ocean)

The difference between Alternative 2 and Alternative 3 is the amount of MFA/HFA sonar usage. Alternative 3 would include all of the training associated with Alternative 2 (as described in Sections 2.2.4.1 and 2.2.4.3 through 2.2.4.7). As described under Alternative 2, Alternative 3 would provide increased flexibility in training activities by increasing the tempo and frequency of training events (Table 2.2.2.3-1), future and enhance RDT&E activities, and the addition of Major Exercises. Alternative 3 would consist of the MFA/HFA sonar usage as analyzed under the No-action Alternative. Potential effects on sea turtles from MFA/HFA sonar usage determined for Alternative 3 are discussed in the No-action Alternative, Section 4.1.2.3.1. Potential effects on sea turtles from non-ASW (sonar usage) training and RDT&E activities determined for Alternative 3 are the same as those analyzed for Alternative 2, Section 4.1.2.3.3.

In accordance with ESA requirements, the Navy has undertaken Section 7 consultation with NMFS for the proposed and ongoing activities in the HRC under Alternative 3 as the preferred alternative. The Navy finds that these activities are not likely to affect green, olive ridley, loggerhead, hawksbill, or leatherback sea turtles.

4.1.2.4 MARINE MAMMALS (BIOLOGICAL RESOURCES—OPEN OCEAN)

Potential impacts on marine mammals from Navy actions can occur from sources that are non-acoustic (i.e., ship strikes) and acoustic with sonar and underwater detonations being the primary acoustic concern. The Navy has and is continuing to conduct research on the effect of sound on marine mammals, the modeling of sound effects on marine mammals in areas of Navy training, and methods of reducing impacts through monitoring of marine mammals, sound reduction, and the use of mitigation measures (Chapter 6.0).

This section includes a discussion of the following topics for assessing potential impacts on marine mammals from Navy actions identified in Chapter 2.0:

- Potential Non-Acoustic Impacts
- Potential Sonar and Explosive Impacts

- Analytical Framework for Assessing Marine Mammal Response to Active Sonar
- Regulatory Framework
- Integration of Regulatory and Biological Frameworks
- Criteria and Thresholds for Physiological Effects
- Other Physiological Effects Considered
- Previous Criteria and Thresholds for Behavioral Effects
- Summary of Existing Credible Scientific Evidence Relevant to Assessing Behavioral Effects
- Cetacean Stranding Events
- Marine Mammal Mitigation Measures Related to Acoustic and Explosive Exposures
- Sonar Marine Mammal Modeling
- Explosive Source Marine Mammal Modeling

Marine Mammal Habitat

The primary source of potential marine mammal habitat impact during training and RDT&E activities within the HRC is underwater sound resulting from ASW, MISSILEX and testing, LFX (e.g., 5-inch guns) events, aerial bombardment, and underwater detonations. However, the sound does not constitute a long-term physical alteration of the water column or bottom topography, as the occurrences are of limited duration and are intermittent in time given that surface vessels associated with training move continuously and relatively rapidly through any given area. Other sources that may impact marine mammal habitat were considered and potentially include the introduction of fuel, debris, expended materials, ordnance, and chemical residues into the water column. The effects of each of these components were considered in this EIS/OEIS. Critical Habitat within the HRC for the Hawaiian monk seal was designated for beaches, sand spits, and bays out to the 20-fathom line (120 ft) for the Northwestern Hawaiian Islands (National Marine Fisheries Service, 1988). With the exception of a portion of Penguin Banks, the Hawaiian Islands Humpback Whale National Marine Sanctuary is located within 12 nautical miles (nm) of the islands, and potential impacts are discussed in the sections of this document that deal with each island.

4.1.2.4.1 Potential Non-Acoustic Impacts

Non-acoustic activities and equipment that were analyzed for potential impact on marine mammals during Navy training are discussed in this section and include ship strikes, torpedo guidance wire, torpedo strike impact, torpedo air launch accessories, MK-48 torpedo flex hoses, sonobuoys, and other expendable devices.

Ship Strikes

Ship strikes to marine mammals can cause major wounds and may occasionally cause fatalities. Whale-watching tours are becoming increasingly popular, and ship strikes have risen in recent years. In the Hawaiian Islands, ship strikes of the humpback whale are of particular concern. According to the NMFS Pacific Islands Region Marine Mammal Response Network Activity Update (dated January 2007 [National Marine Fisheries Service, 2007d]), there were nine reported collisions with humpback whales in 2006 (none involved the Navy .These collisions can also occur with commercial or Navy ships. All types of ships can hit whales, and much of the time the marine mammal is either seen too late to avoid a collision, not observed until the collision occurs, or not detected.

The most vulnerable marine mammals are those that spend extended periods of time at the surface in order to restore oxygen levels within their tissues after deep dives (e.g., sperm whale). In addition, some baleen whales, such as the northern right whale and fin whale, swim slowly and seem generally unresponsive to ship sound, making them more susceptible to ship strikes (Nowacek et al., 2004). North Pacific right whales are primarily found in the Arctic, and there are only a few recorded sightings near the Hawaiian Islands (U.S. Department of the Navy, 2005a). Fin whales are rarely seen in Hawaiian Island waters (Barlow, 2006). Most baleen whales are rare in the Hawaiian Islands with the exception of the humpback whale that occurs seasonally and generally close to shore, within 25 nm of shore (Mobley, 2004; U.S. Department of the Navy, 2005a). Hawaii is the breeding ground for humpback whales, and there are also many calves present. While calves spend a lot of time at the surface, potentially increasing their vulnerability to ship strikes, they are also very active and often breech or create disturbances at the surface raising their probability of detection.

Ship strikes with whales are a recognized source of whale mortality worldwide. Of the 11 species known to be hit by ships, the most frequently reported is the fin whale, although there have been no recent incidents of ship strikes on fin whales in the Hawaiian Islands. Whale-watching tours are becoming increasingly popular, and ship strikes have risen in recent years. In the Hawaiian Islands, ship strikes of the humpback whale are of particular concern. According to the NMFS Pacific Islands Region Marine Mammal Response Network Activity Update (dated January 2007[National Marine Fisheries Service, 2007d]), there were nine reported ship strikes with humpback whales in 2006. Whale watching could also have an effect on whales by distracting them from important biological activities such as nursing and breeding (see Katona and Kraus, 1999 for discussion of potential impacts from whale watching).

A review of recent reports on ship strikes provides some insight regarding the types of whales, locations and vessels involved, but also reveals significant gaps in the data. The Large Whale Ship Strike Database provides a summary of the 292 worldwide confirmed or possible whale/ship strikes from 1975 through 2002 (Jensen and Silber, 2003). The report notes that the database represents a minimum number of collisions, because the vast majority probably go undetected or unreported. In contrast, Navy vessels are likely to detect any strike that does occur, and they are required to report all ship strikes involving marine mammals. Overall, the percentages of Navy traffic relative to overall large shipping traffic are very small (on the order of 2 percent).

The ability of a ship to avoid a collision and to detect a collision depends on a variety of factors, including environmental conditions, ship design, size, and manning. The majority of ships participating in HRC training activities, such as Navy destroyers, have a number of advantages for avoiding ship strikes as compared to most commercial merchant vessels including the following:

- Navy ships have their bridges positioned forward, offering good visibility ahead of the bow.

- Crew size is much larger than that of merchant ships allowing for more potential observers on the bridge.
- Dedicated lookouts are posted during a training activity scanning the ocean for anything detectible in the water; anything detected is reported to the Officer of the Deck.
- Navy lookouts receive extensive training including Marine Species Awareness Training designed to provide marine species detection cues and information necessary to detect marine mammals.
- Navy ships are generally much more maneuverable than commercial merchant vessels.

The National Oceanic and Atmospheric Administration (NOAA) continues to review all shipping activities and their relationship to cumulative effects, in particular on large whale species. According to the NMFS Pacific Islands Region Marine Mammal Response Network Activity Update (dated January 2007[[National Marine Fisheries Service, 2007d]), the factors that contribute to ship strikes of whales are not clear, nor is it understood why some species appear more vulnerable than others. Nonetheless, the number of known ship strikes indicate that deaths and injuries from ships and shipping activities remain a threat to endangered large whale species.

The Navy has adopted standard SOPs that reduce the potential for ship strikes with surfaced marine mammals (See Chapter 6.0). At all times when ships are underway, there are trained observers on watch scanning the area around the ship. If a marine mammal is sighted, appropriate action will be taken to avoid the animal. Collisions with cetaceans and pinnipeds are not expected.

Torpedo Guidance Wire

The potential entanglement impact of MK-48 torpedo control wires on marine mammals is very low for the following reasons. The control wire is very thin (approximately 0.02 inch) and has a relatively low breaking strength. Even with the exception of a chance encounter with the control wire while it was sinking to the sea floor (at an estimated rate of 0.5 ft per second), a marine animal would not be vulnerable to entanglement given the low breaking strength.

- The torpedo control wire is held stationary in the water column by drag forces as it is pulled from the torpedo in a relatively straight line until its length becomes sufficient for it to form a catenary droop (U.S. Department of the Navy, 1996a). When the wire is released or broken, it is relatively straight and the physical characteristics of the wire prevent it from tangling, unlike the monofilament fishing lines and polypropylene ropes identified in the entanglement literature (U.S. Department of the Navy, 1996a). Although Heezen (1957, as cited in U.S. Department of the Navy, 1996a) theorized that the entanglement of marine mammals with undersea telecommunication cables was a direct result of the mammal coming into contact with loops in the cable (e.g., swimming through loops that then tightened around the mammal), this should not be the case for the thin torpedo guidance wires. The potential for any harm or harassment to these species is extremely low.

Torpedo Strike Impact

There is negligible risk that a marine mammal could be struck by a torpedo during ASW training events. This conclusion is based on a review of ASW torpedo design features. The torpedoes are specifically designed to ignore false targets. As a result, their homing logic does not detect or recognize the relatively small air volume associated with the lungs of marine mammals. They do not detect or home to marine mammals. In addition, there has never been a reconditioned torpedo (numbered in the thousands) that inadvertently struck a marine mammal, which would have been apparent given the fragile nature of the components at the head of the torpedo.

Torpedo Air Launch Accessories

Because some torpedo air launch accessories remain in the marine environment, the potential for impacting marine mammals through ingestion or entanglement has been previously analyzed. Ingestion of pieces of the launch accessories is unlikely because most of those are large and metallic and will sink rapidly (U.S. Department of the Navy, 1996a). With the exception of a chance encounter as the air launch accessories sink to the bottom, marine animals would only be vulnerable to entanglement or ingestion impacts if their diving and feeding behaviors place them in contact with the sea floor.

In previous studies, the Naval Ocean Systems Center identified two potential impacts of the MK-50 torpedo air launch accessories (Naval Ocean Systems Center, 1990). As the air launch accessories for the MK-46 torpedo are similar in function, materials, and size to those of the MK-50 torpedo, the following potential impacts identified by the Naval Ocean Systems Center are applicable to both torpedoes (U.S. Department of the Navy, 1996a):

- Upon water entry and engine startup, the air stabilizer would be released from the torpedo and sink to the bottom. Bottom currents may cause the air stabilizer canopy to billow, potentially posing an entanglement threat to marine animals that feed on the bottom. However, the canopy is large and highly visible compared to materials such as gill nets and nylon fishing line in which marine animals may become entangled. Thus, entanglement of marine animals in the canopy or suspension lines would be unlikely.
- Non-floating air launch accessories ranges in length from 11 to 44 inches. Because of the relatively large size of this accessory, the potential risk for ingestion of this accessory by marine animals other than bottom-feeding whales would be small. The probability of a whale coming in contact with and ingesting the air launch accessories likewise would be small.

MK-48 Torpedo Flex Hoses

The Navy analyzed the potential for the flex hoses to impact marine mammals. The analysis concluded that the potential entanglement impact on marine animals would be insignificant for reasons similar to those stated for the potential entanglement impact of control wires, specifically (U.S. Department of the Navy, 1996b):

- Due to its weight, the flex hose would rapidly sink to the bottom upon release. With the exception of a chance encounter with the flex hose while it was sinking to the sea floor, a marine animal would be vulnerable to entanglement only if its diving and feeding patterns placed it in contact with the bottom.

- Due to its stiffness, the 250-ft-long flex hose would not form loops that could entangle marine animals.

Sonobuoy and Other Parachutes

Sonobuoys, lightweight torpedoes, and other devices deployed from aircraft use nylon parachutes of varying sizes. At water impact, the parachute assembly is jettisoned and sinks away from the exercise weapon or target. The parachute assembly would potentially be at the surface for a short time before sinking to the sea floor.

Marine mammals are also subject to entanglement in marine trash, particularly anything incorporating loops or rings, hooks and lines, or sharp objects. Entanglement and the eventual drowning of a marine mammal in a parachute assembly would be unlikely, since the parachute would have to land directly on an animal, or an animal would have to swim into it before it sinks. The potential for a marine mammal to encounter an expended parachute assembly is extremely low, given the generally low probability of a marine mammal being in the immediate location of deployment. If bottom currents are present, the canopy may billow and pose an entanglement threat to marine animals with bottom-feeding habits; however, given the extreme depth in the majority of the HRC, the probability of a marine mammal encountering a parachute assembly on the sea floor and the potential for accidental entanglement in the canopy or suspension lines is considered to be unlikely.

Overall, the possibility of marine mammals ingesting nylon parachute fabric or being entangled in parachute assemblies is very remote.

4.1.2.4.2 Potential Sonar and Explosive Impacts

ASW is a primary warfare area for Navy patrol ships (surface and submarines), aircraft, and ASW helicopters. ASW aircrews must practice using sensors, including electro-optical devices, radar, magnetic anomaly detectors, sonar (including helicopter dipping sonar and both active and passive sonobuoys) in both the deep and shallow water environment. The training events being analyzed for Alternative 1 are not new and have taken place in the HRC over the past 60 years with no significant changes in the sonar equipment output in the last 30 years. Although there may be many hours of active ASW sonar events, the approximate 1-second “ping” of the sonar generally occurs no more often than twice a minute. The intermediate time when the sonar is passive is necessary so the sonar operators can detect/listen for sonar ping reflections.

The approach for estimating potential acoustic effects from ASW training within the HRC on cetacean species makes use of the methodology that was developed in cooperation with NOAA for the Navy’s Undersea Warfare Training Range (USWTR) Draft OEIS/EIS (2005), USWEX Programmatic EA/OEA (U.S. Department of the Navy, 2007b), RIMPAC EA/OEA (U.S. Department of the Navy, Commander Third Fleet, 2006), and Composite Training Unit Exercise (COMPTUEX) / Joint Task Force Exercise (JTFEX) EA/OEA (U.S. Department of the Navy, 2007c). In addition, the approach for estimating potential acoustic effects from HRC training activities on marine mammals incorporates comments received on these previous documents. The NMFS and other commenters recommended the use of an alternate methodology to evaluate when sound exposures might result in behavioral effects without corresponding physiological effects.

Training that results in potential impacts from explosives include NSFS Exercise and GUNEX (5-inch and 76-mm guns when using non-inert rounds); MISSILEX (Penguin, Maverick, and Harpoon missiles); BOMBEX (MK-82, MK-83, MK-84 when using non-inert bombs); EER/IEER (explosive charge); SINKEX (multiple ordnance); and Mine Neutralization (up to a 20-lb explosive charge).

The Difference Between MFA/HFA Sonar and Low-Frequency Active Sonar

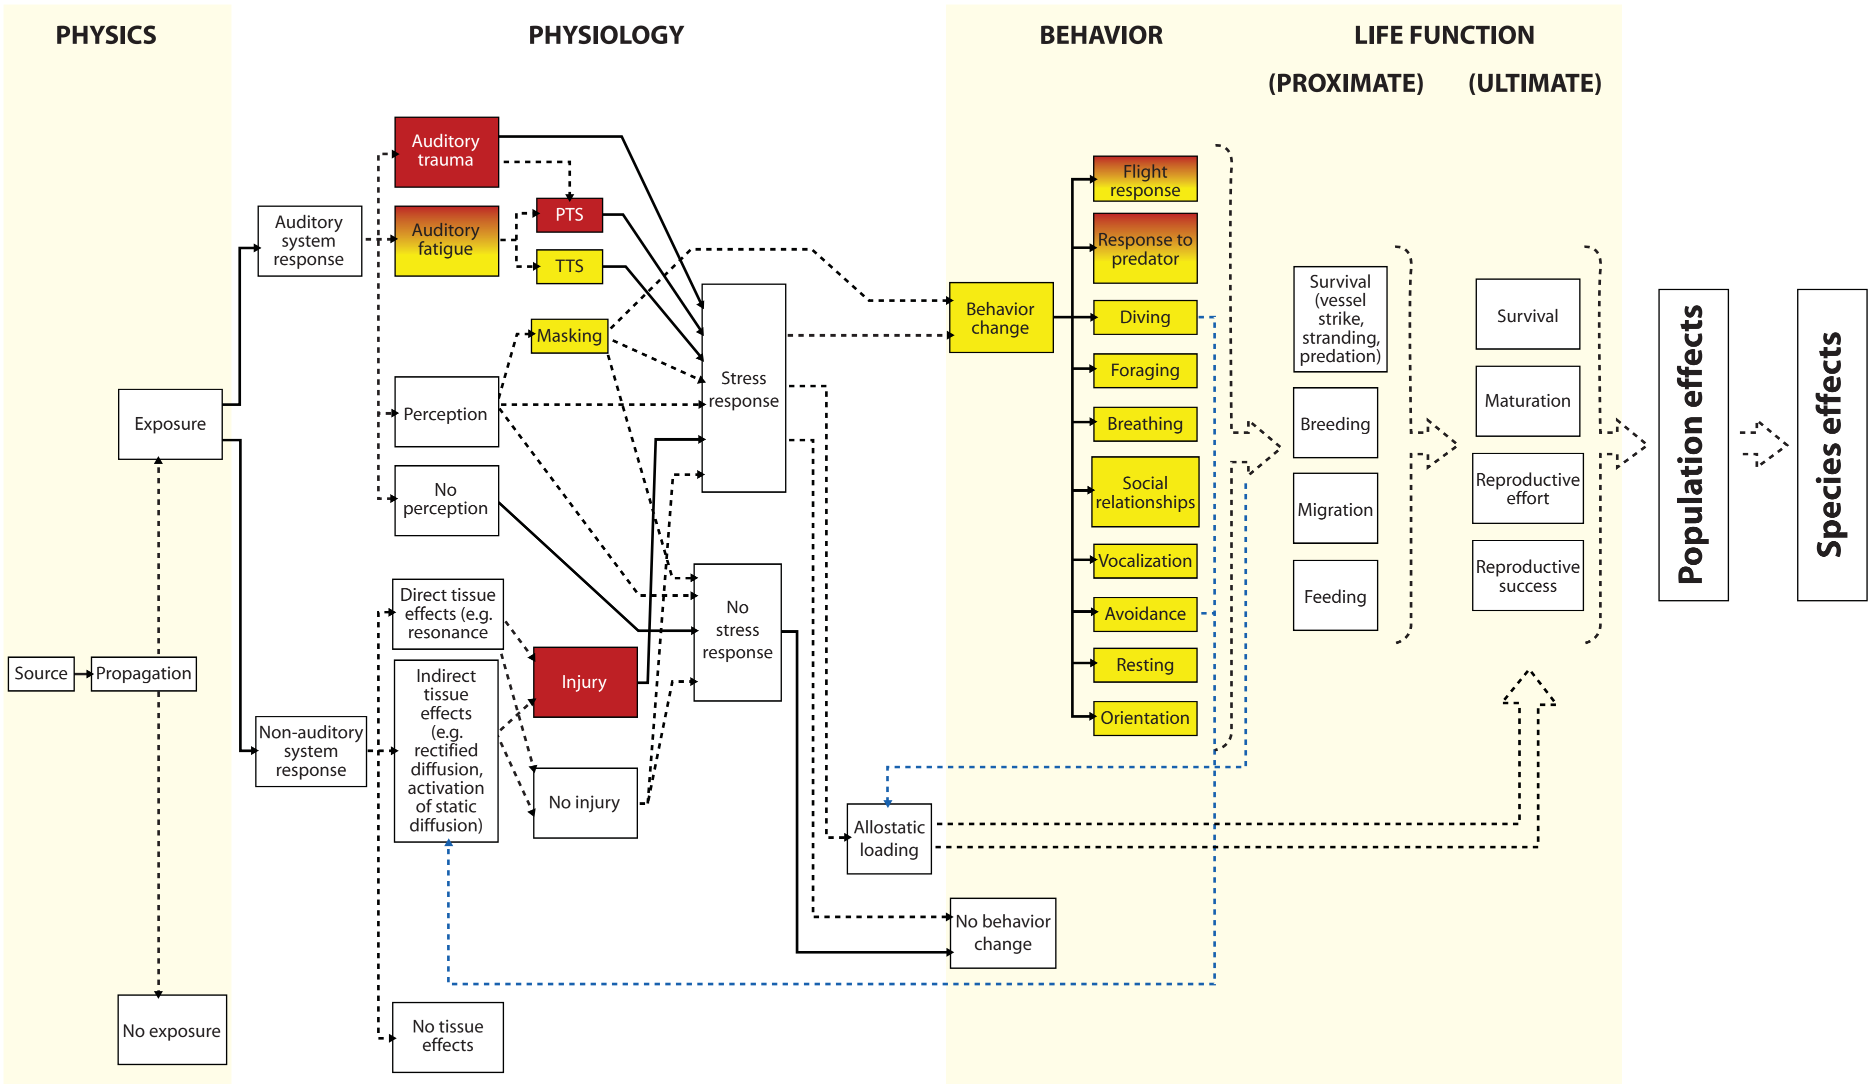
There is some confusion stemming from materials presented in reference to use of low-frequency active (LFA) sonar, which is not an action being proposed by this EIS/OEIS. MFA sonar operates in a range between 1 kHz to 10 kHz and HFA operates in a frequency range above 10 kHz. A LFA sonar system typically conducts sonar activities between 0.1 kHz to 0.5 kHz. An existing Navy LFA sonar system is the SURTASS LFA. The typical SURTASS LFA sonar signal is not a constant tone, but rather a transmission of various waveforms that vary in frequency and duration. A complete sequence of sound transmissions from LFA can last for as short as 6 seconds to as long as 100 seconds. A typical MFA/HFA sonar ping lasts approximately less than 1 second. The use of LFA is not part HRC EIS/OEIS Proposed Action.

4.1.2.4.3 Analytical Framework for Assessing Marine Mammal Response to Active Sonar

As summarized by the National Research Council, the possibility that human-generated sound could harm marine mammals or significantly interfere with their “normal” activities is an issue of increasing concern (National Research Council, 2005). This section evaluates the potential for the specific Navy acoustic sources used in the HRC to result in harassment of marine mammals.

Assessing whether a sound may disturb or injure a marine mammal involves understanding the characteristics of the acoustic sources, the marine mammals that may be present in the vicinity of the sound, and the effects that sound may have on the physiology and behavior of those marine mammals. Although it is known that sound is important for marine mammal communication, navigation, and foraging, there are many unknowns in assessing the effects and significance of the response of marine mammals to sound exposures (National Research Council, 2005). For this reason, the Navy enlisted the expertise of NMFS as the cooperating agency. Their input assisted the Navy in developing a conceptual analytical framework for evaluating what sound levels marine mammals might receive as a result of Navy training actions at HRC, whether marine mammals might respond to these exposures, and whether that response might have a mode of action on the biology or ecology of marine mammals such that the response should be considered a potential harassment. From this framework of evaluating the potential for harassment incidents to occur, an assessment of whether acoustic sources might impact populations, stocks, or species of marine mammals can be conducted.

The conceptual analytical framework (Figure 4.1.2.4.3-1) presents an overview of how the MFA/HFA sonar sources used during training are assessed to evaluate the potential for marine mammals to be exposed to an acoustic source, the potential for that exposure to result in a physiological effect or behavioral response by an animal, and the assessment of whether that



EXPLANATION

Conceptual Marine Mammal Protection Action Analytical Framework

Figure 4.1.2.4.3-1

response may result in a consequence that constitutes harassment in accordance with Marine Mammal Protection Act (MMPA) definitions. As shown on the figure, the Navy has developed acoustic models to predict when Navy training and RDT&E activities could result in injury or behavioral disturbance. Total energy models are used to predict exposures that could result in either behavioral effects or physiological effects resulting in injury or temporary physiological changes. Risk function models using sound pressure levels are used to predict exposures that could result in behavioral effects.

Each exposure could result in a wide range of potential direct physiological effects, which could then lead to a behavioral response. For the purposes of this analysis all PTS exposures are assumed to result in injury (MMPA Level A harassment), and all TTS exposures are assumed to result in significant behavioral effects (MMPA Level B harassment). The other physiological effects are also considered in the analysis, although it is unlikely that they rise to the level of injury. The potential direct effects of physiological responses which may lead to behavioral exposures are considered in light of the biology and ecology of each species in order to arrive at the mode of action or result of the potential direct effect. The intensity of the resulting mode of action can then be used to determine if the natural behavioral patterns are abandoned or significantly altered.

Finally, the physiological and behavioral responses are reviewed in light of the population effects in order to determine the potential for effects on stocks or species.

The general analytical framework for analyzing potential effects of acoustic exposures on Endangered Species Act (ESA) listed species was developed by NMFS as presented in the Biological Opinion for RIMPAC 2006 and for the USWEX Programmatic EA/OEA (National Marine Fisheries Service, 2006a, 2007b). The framework is similar to the framework presented in Figure 4.1.2.4.3-1 in that the exposures calculated by the energy level and risk function models are used to evaluate a number of proximate responses and the resulting modes of action. The fitness consequences could then be determined for individuals and populations.

The first step in the conceptual model is to estimate the potential for marine mammals to be exposed to a Navy acoustic source. Three questions are answered in this “acoustic modeling” step:

1. **What action will occur?** This requires identification of all acoustic sources that would be used in the exercises and the specific outputs of those sources. This information is provided in Appendix J.

2. **Where and when will the action occur?** The place and season of the action are important to:
   - Determine which marine mammal species are likely to be present. Species occurrence and density data (Chapter 3.0) are used to determine the subset of marine mammals that may be present when an acoustic source is operational. The species occurrence information is provided in Chapter 3.0 and the density data is provided in Appendix J.

   - Predict the underwater acoustic environment that would be encountered. The acoustic environment here refers to environmental factors that influence the propagation of underwater sound. Acoustic parameters influenced by the place, season, and time are described in Appendix J.

3. **How many marine mammals are predicted to be exposed to sound from the acoustic sources?** Sound propagation models are used to predict the received exposure level from an acoustic source, and these are coupled with species distribution and density data to estimate the accumulated received energy and sound pressure level that could be considered as potential harassment. Appendix J describes the acoustic modeling and Sections 4.1.2.5, 4.1.2.6, and 4.1.2.7 present the number of exposures predicted by the modeling.

The next steps in the analytical framework evaluate whether the sound exposures predicted by the acoustic model might cause a physiological response in a marine mammal, and if that response might cause a change in behavior. Harassment includes the concepts of potential injury (Level A Harassment) and behavioral disturbance (Level B harassment). The response assessment portion of the analytical framework examines the following question:

4. **Which potential acoustic exposures might result in harassment of marine mammals?** The predicted acoustic exposures are first considered within the context of the species biology (e.g., can a marine mammal detect the sound, and is that mammal likely to respond to that sound?). Next, if a response is predicted, what type of physiological change will occur (e.g., auditory trauma or fatigue, tissue effects from bubble formation or resonance). If a physiological change has occurred will there be a stress response (i.e., increases in heart rate, hormonal activity, respiration rate and awareness) followed by change in behavior (e.g., flight response or avoidance, changes in diving, foraging, or vocalization patterns or social behavior). Next, how will changes in behavior affect proximate life functions (e.g., survival, breeding, migration, and feeding) and ultimate life functions (e.g., survival, maturation, reproductive effort, and reproductive success). Ultimately determine, if possible with available information, what population or species/stock effects may occur. If a response is predicted, will it potentially be considered "harassment" in accordance with MMPA harassment definitions? For example, if a response to the acoustic exposure has a mode of action that results in a consequence for an individual, such as interruption of feeding, that response or repeated occurrence of that response could be considered "abandonment or significant alteration of natural behavioral patterns," and therefore the exposure(s) would cause Level B harassment.

Section 4.1.2.4.3 reviews the regulatory framework and premise for the Navy/NMFS marine mammal response analytical framework. Sections 4.1.2.5, 4.1.2.6, 4.1.2.7, and 4.1.2.8 include the analysis by species/stock for the No-action Alternative, Alternative 1, Alternative 2, and Alternative 3, presenting relevant information about the species biology and ecology to provide a context for assessing whether modeled exposures might result in incidental harassment. Each alternative includes a discussion of estimated effects on ESA listed species and a section on non-ESA listed species. The potential for harassment is considered within the context of the affected marine mammal population to assess the fitness consequence under the ESA. Particular focus on recruitment and survival are provided to analyze whether the effects of the action can be considered to have negligible impact on species or stocks under MMPA.

Literature Searches for Relevant Analytical Information

Literature searches were conducted to collect relevant reference material using published and unpublished sources. These include peer published journal articles, book chapters, monitoring or mitigation reports, Federal Register notices, environmental documents and workshop or conference reports. Recently, due to the increased concern over acoustic effects on marine animals, more information on the effects of a variety of underwater sound sources on marine animals has become available.

Literature searches using the Library of Congress' First Search and Dissertation Abstracts databases, SCOPUS, Web of Science, BioOne, Oceanic Abstracts, Cambridge Abstract's Aquatic Sciences, University of California MYLVYL, Biosis, Zoological Record Plus and Fisheries Abstracts (ASFA) database services. Specific journals that often publish marine mammal related publications (Aquatic Mammals, Journal of Mammalogy, Canadian Journal of Zoology, Marine Mammal Science), ecology (Ambio, Bioscience, Journal of Animal Ecology, Journal of Applied Ecology, Journal of the Marine Biological Association of the UK, Marine Pollution Bulletin), and bioacoustics (Journal of the Acoustical Society of America) were regularly searched for new publications. References were also obtained by contacting in the appropriate researchers in the field (commercial and academic researchers) and resource agencies (e.g. NMFS, USFWS). This allowed us to collect gray literature reports and submitted or in-press journal articles.

4.1.2.4.4 Regulatory Framework

The MMPA and ESA prohibit the unauthorized harassment of marine mammals and endangered species, and provide the regulatory processes for authorization for any such harassment that might occur incidental to an otherwise lawful activity.

The regulatory framework for estimating potential acoustic effects from HRC ASW training activities on cetacean species makes use of the methodology that was developed in cooperation with NOAA for the Navy's *Undersea Warfare Training Range (USWTR) Draft Overseas Environmental Impact Statement/Environmental Impact Statement (OEIS/EIS),* (U.S. Department of the Navy, Commander, U.S. Atlantic Fleet, 2005). Via response comment letter to USWTR received from NMFS January 30, 2006, NMFS concurred with the use of EL for the determination of physiological effects on marine mammals. Therefore, this methodology is used to estimate the annual exposure of marine mammals that may be considered Level A harassment or Level B harassment as a result of temporary, recoverable physiological effects.

In addition, the approach for estimating potential acoustic effects from HRC training activities on marine mammals makes use of the comments received on the Navy's USWTR Draft OEIS/EIS (U.S. Department of the Navy, Commander, U.S. Atlantic Fleet, 2005) and the *2006 Rim of the Pacific Supplemental Overseas Environmental Assessment* (U.S. Department of the Navy, 2006a). NMFS and other commenters recommended the use of an alternate methodology to evaluate when sound exposures might result in behavioral effects without corresponding physiological effects. As a result of these comments, this document uses a risk function approach to evaluate the potential for behavioral effects. A number of Navy actions and NOAA rulings have helped to qualify possible events deemed as "harassment" under the MMPA. As stated previously, "harassment" under the MMPA includes both potential injury (Level A), and disruptions of natural behavioral patterns to a point where they are abandoned or significantly altered (Level B). NMFS also includes mortality as a possible outcome to consider in addition to

Level A and Level B harassment. The acoustic effects analysis and exposure calculations are based on the following premises:

- Harassment that may result from Navy training described in the HRC EIS/OEIS is unintentional and incidental to those training events.
- This HRC EIS/OEIS uses an unambiguous definition of injury as defined in the USWTR Draft OEIS/EIS (U.S. Department of the Navy, Commander, U.S. Atlantic Fleet, 2005), *2006 Rim of the Pacific Supplemental Overseas Environmental Assessment* (U.S. Department of the Navy, 2006a), and in previous rulings (National Oceanic and Atmospheric Administration, 2001; 2002a): injury occurs when any biological tissue is destroyed or lost as a result of the action.
- Behavioral disruption might result in subsequent injury and injury may cause a subsequent behavioral disruption, so Level A and Level B harassment categories (defined below) can overlap and are not necessarily mutually exclusive. However, by prior ruling (National Oceanic and Atmospheric Administration, 2001; 2006b), this HRC EIS/OEIS analysis assumes that Level A and B do not overlap.
- An individual animal predicted to experience simultaneous multiple injuries, multiple disruptions, or both, is counted as a single take (see National Oceanic and Atmospheric Administration, 2001; 2006b). An animal whose behavior is disrupted by an injury has already been counted as a Level A harassment and will not also be counted as a Level B harassment. Based on the consideration of two different acoustic modeling methodologies to assess the potential for sound exposures that might result in behavioral disturbance, it is possible that the model would count a Level B TTS exposure and a Level B behavioral exposure for the same animal. Although this approach calculates the maximum potential for behavioral disturbance incidents, it is considered conservative because the actual incidents of disturbance are expected to be lower.
- The acoustic effects analysis is based on primary exposures of the action. Secondary, or indirect, effects, such as susceptibility to predation following injury and injury resulting from disrupted behavior, while possible, can only be reliably predicted in circumstances where the responses have been well documented. Consideration of secondary effects would result in Level A exposures being considered Level B exposures, and vice versa, since Level A exposure (assumed to be Level A harassment and injury) has the potential to disrupt behavior resulting in Level B harassment. In like manner, temporary physiological or behavioral disruption (Level B exposures) could be conjectured to have the potential for injury (Level A). Consideration of secondary effects would lead to circular definitions of exposures. For beaked whales, where a connection between behavioral disruption by MFA/HFA sonar and injury to beaked whales is considered a possibility (under specific operational and environmental parameters), secondary effects are considered in the discussion for each species.

4.1.2.4.5 Integration of Regulatory and Biological Frameworks

This section presents a biological framework within which potential effects can be categorized and then related to the existing regulatory framework for MMPA and ESA. The information presented in Sections 4.1.2.4.6 and 4.1.2.4.7 is used to develop specific numerical exposure thresholds and risk function curves. Exposure thresholds and risk function curves are combined with sound propagation models and species distribution data to estimate the potential exposures as presented for the No-action Alternative in Section 4.1.2.5; Alternative 1 in Section 4.1.2.6; Alternative 2 in Section 4.1.2.7; and Alternative 3 in Section 4.1.2.8.

Physiological and Behavioral Effects

Sound exposure may affect multiple biological traits of a marine animal. The biological framework proposed here is structured according to potential physiological and behavioral effects resulting from sound exposure. The range of effects may then be assessed according to MMPA and ESA regulations.

Physiology and behavior are chosen over other biological traits because:

- They are consistent with regulatory statements defining harassment by injury and harassment by disturbance.
- They are components of other biological traits that may be relevant.
- They are a more sensitive and immediate indicator of effect.

For example, ecology is not used as the basis of the framework because the ecology of an animal is dependent on the interaction of an animal with the environment. The animal’s interaction with the environment is driven both by its physiological function and its behavior, and an ecological impact may not be observable over short periods of observation. However, ecological information is considered in the analysis of the effects of individual species.

A “physiological effect” is defined here as one in which the “normal” physiological function of the animal is altered in response to sound exposure. Physiological function is any of a collection of processes ranging from biochemical reactions to mechanical interaction and operation of organs and tissues within an animal. A physiological effect may range from the most significant of impacts (i.e., mortality and serious injury) to lesser effects that would define the lower end of the physiological impact range, such as the non-injurious distortion of auditory tissues.

A “behavioral effect” is one in which the “normal” behavior or patterns of behavior of an animal are overtly disrupted in response to an acoustic exposure. Examples of behaviors of concern can be derived from the harassment definitions in the MMPA and ESA implementing regulations and Public Law (PL) 108—136 (2004).

In this EIS/OEIS the term “normal” is used to qualify distinctions between physiological and behavioral effects. Its use follows the convention of normal daily variation in physiological and behavioral function without the influence of anthropogenic acoustic sources. As a result, this EIS/OEIS uses the following definitions:

- A physiological effect is a variation in an animal’s respiratory, endocrine, hormonal, circulatory, neurological, or reproductive activity and processes, beyond the animal’s normal range of variability, in response to human activity or to an exposure to a stimulus such as active sonar.

- A behavioral effect is a variation in the pattern of an animal's breathing, feeding, resting, migratory, intraspecific behavior (such as reproduction, mating, territorial, rearing, and agonistic behavior), and interspecific behavior, beyond the animal's normal pattern of variability in response to human activity or to an exposure to a stimulus such as active sonar.

The definitions of physiological effect and behavioral effect used here are specific to this EIS/OEIS and should not be confused with more global definitions applied to the field of biology or to existing Federal law. It is reasonable to expect some physiological effects on result in subsequent behavioral effects. For example, a marine mammal that suffers a severe injury may be expected to alter diving or foraging to the degree that its variation in these behaviors is outside that which is considered normal for the species. If a physiological effect is accompanied by a behavioral effect, the overall effect is characterized as a physiological effect; physiological effects take precedence over behavioral effects with regard to their ordering. This approach provides the most conservative ordering of effects with respect to severity, provides a rational approach to dealing with the overlap of the definitions, and avoids circular arguments.

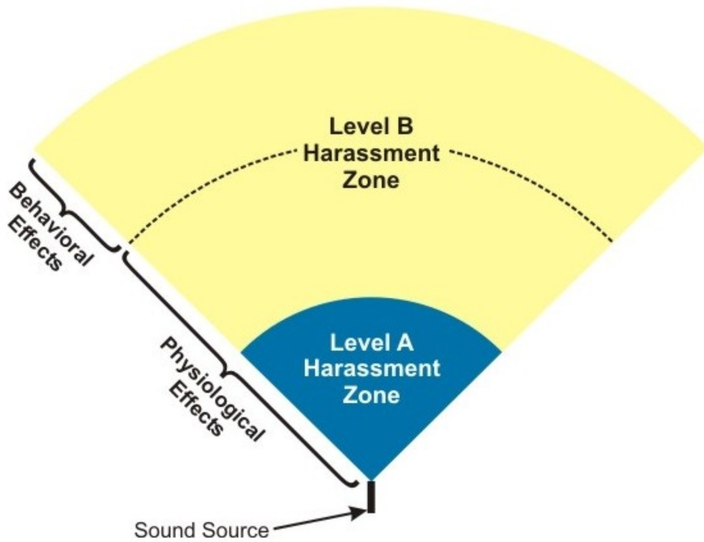
The severity of physiological effects generally decreases with decreasing sound exposure and/or increasing distance from the exposure source. The same generalization does not consistently hold for behavioral effects because they do not depend solely on the received sound level. Behavioral responses also depend on an animal's learned responses, innate response tendencies, motivational state, the pattern of the sound exposure, and the context in which the sound is presented. (Southall et al., 2007) However, to provide a tractable approach to predicting acoustic effects that is relevant to the regulatory terms of behavioral disruption, it is assumed here that the severities of behavioral effects also decrease with decreasing sound exposure and/or increasing distance from the sound source.

MMPA Level A and Level B Harassment

Categorizing potential effects as either physiological or behavioral effects allows them to be related to the harassment definitions. For military readiness events, Level A harassment includes any act that injures or has the significant potential to injure a marine mammal or marine mammal stock in the wild. Injury defined in previous rule (National Oceanic and Atmospheric Administration, 2001; 2002a), is the destruction or loss of biological tissue. The destruction or loss of biological tissue will result in an alteration of physiological function that exceeds the normal daily physiological variation of the intact tissue. For example, increased localized histamine production, edema, production of scar tissue, activation of clotting factors, white blood cell response, etc., may be expected following injury. Therefore, this EIS/OEIS assumes that all injury is qualified as a physiological effect and, to be consistent with prior actions and rulings (National Oceanic and Atmospheric Administration, 2001), all injuries (slight to severe) are considered Level A harassment.

PL 108-136 (2004) amended the MMPA definition of Level B harassment for military readiness events, which applies to this action. For military readiness events, Level B harassment is now defined as "any act that disturbs or is likely to disturb a marine mammal or marine mammal stock by causing disruption of natural behavioral patterns including, but not limited to, migration, surfacing, nursing, breeding, feeding, or sheltering to a point where such behaviors are abandoned or significantly altered." Unlike Level A harassment, which is solely associated with physiological effects, both physiological and behavioral effects may cause Level B harassment.

The volumes of ocean in which Level A and Level B harassment is predicted to occur are described as harassment zones. All marine mammals predicted to be in a zone are considered exposed to effects that could result in the corresponding level of harassment. Figure 4.1.2.4.5-1 illustrates harassment zones extending from a hypothetical, directional sound source.



Note: This figure is for illustrative purposes only and does not represent the sizes or shapes of the actual harassment zones

Figure 4.1.2.4.5-1. Harassment Zones Extending from a Hypothetical, Directional Sound Source

The Level A harassment zone extends from the source out to the distance and exposure at which the slightest amount of injury is predicted to occur. The acoustic exposure that produces the slightest degree of injury is therefore the threshold value defining the outermost limit of the Level A harassment zone. Use of the threshold associated with the onset of slight injury as the most distant point and least injurious exposure takes account of all more serious injuries by inclusion within the Level A harassment zone. The threshold used to define the outer limit of the Level A harassment zone is given in Section 4.1.2.4.6.

The Level B harassment zone begins just beyond the point of slightest injury and extends outward from that point to include all animals that may possibly experience Level B harassment. Physiological effects extend beyond the range of slightest injury to a point where slight temporary distortion of the most sensitive tissue occurs, but without destruction or loss of that tissue. The animals predicted to be in this zone are assumed to experience Level B harassment by virtue of temporary impairment of sensory function (altered physiological function) that can disrupt behavior. The criterion and threshold used to define the outer limit of physiological effects leading to Level B harassment are given in Section 4.1.2.4.6. As described earlier, some behavioral effects occur without an accompanying physiological effect. The risk function that is used to define the non-physiological behavioral effects that constitute potential Level B harassment is described in Section 4.1.2.4.9 and Appendix J.

The Navy's most powerful MFA surface ship sonar, the AN/SQS 53, has a nominal source level of 235 dB re 1 µPa at 1 m. The estimated distance to a received level at the TTS threshold (195 dB SEL) – from a 235 dB source level (a nominal 53C ping) having 1-second duration – is approximately 180 yards. The estimated distance to a received level at the PTS threshold (a 215 dB SEL) is approximately 11 yards from the 235 dB sound source. To reiterate this important point, with the sonar producing a 1-second ping at a source level 235 dB, a marine mammal would have to be within 180 yards of the sonar dome (the bow of the ship) to be exposed to a 195 dB SEL, which is the threshold for a temporary threshold shift in hearing. The Navy's standard operating procedures or mitigation measures incorporate a shutdown of sonar if marine mammals come within 200 yards of an MFA and this is after two power-down steps at 1,000 yards and 500 yards.

ESA Harm and Harassment

ESA regulations define harm as "an act which actually kills or injures" fish or wildlife (50 Code of Federal Regulations [CFR] § 222.102). ESA regulations define harassment as an "intentional or negligent act or omission which creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding, or sheltering" (50 CFR § 17.3). Under ESA there are also behavioral effects that exceed the normal daily variation in behavior, but which arise without an accompanying physiological effect.

Auditory Tissues as Indicators of Physiological Effects

The mammalian auditory system, including those of marine mammals, consists of the outer ear (vestigial in cetaceans), middle ear, inner ear, and central nervous system (Ketten 1998). Sound waves are transmitted through the middle ear to fluids within the inner ear, except in cetaceans. The inner ear contains delicate electromechanical hair cells that convert the fluid motions into neural impulses that are sent to the brain. The hair cells within the inner ear are the most vulnerable to over-stimulation by sound exposure (Yost and Nielson, 1994).

Very high sound levels may rupture the eardrum or damage the small bones in the middle ear (Yost and Nielson, 1994). Lower level exposures of sufficient duration may cause permanent or temporary hearing loss; such an effect is called a sound-induced threshold shift, or simply a threshold shift (TS) (Miller, 1974). A threshold shift may be either permanent, in which case it is termed a PTS, or it may be temporary, in which case it is termed a TTS. Still lower levels of sound may result in auditory masking, which may interfere with an animal's ability to hear other concurrent sounds.

Because the tissues of the ear appear to be the most susceptible to the physiological effects of sound and TSs tend to occur at lower exposures than other more serious auditory effects, PTS and TTS are used here as the biological indicators of physiological effects. TTS is the first indication of physiological non-injurious change and is not physical injury. The remainder of this section is, therefore, focused on TSs, including PTSs and TTSs. Because masking (without a resulting TS) is not associated with abnormal physiological function, it is not considered a physiological effect in this analysis, but rather a potential behavioral effect.

Noise-Induced Threshold Shifts

The amount of TS depends on the amplitude, duration, frequency, and temporal pattern of the sound exposure. Threshold shifts will generally increase with the amplitude and duration of sound exposure. For continuous sounds, exposures of equal energy will lead to approximately equal effects (Ward, 1997). For intermittent sounds, less TS will occur than from a continuous exposure with the same energy (some recovery will occur between exposures) (Kryter et al., 1966; Ward, 1997).

The magnitude of a TS normally decreases with the amount of time post-exposure (Miller, 1974). The amount of TS just after exposure is called the initial TS. If the TS eventually returns to zero (the threshold returns to the pre-exposure value), the TS is a TTS. Since the amount of TTS depends on the time post-exposure, it is common to use a subscript to indicate the time in minutes after exposure (Quaranta et al., 1998). For example, TTS_2 means a TTS measured 2 minutes after exposure. If the TS does not return to zero but leaves some finite amount of TS, then that remaining TS is a PTS. The distinction between PTS and TTS is based on whether there is a complete recovery of a TS following a sound exposure. Figure 4.1.2.4.5-2 shows two hypothetical TSs, one that completely recovers, a TTS, and one that does not completely recover, leaving some PTS.

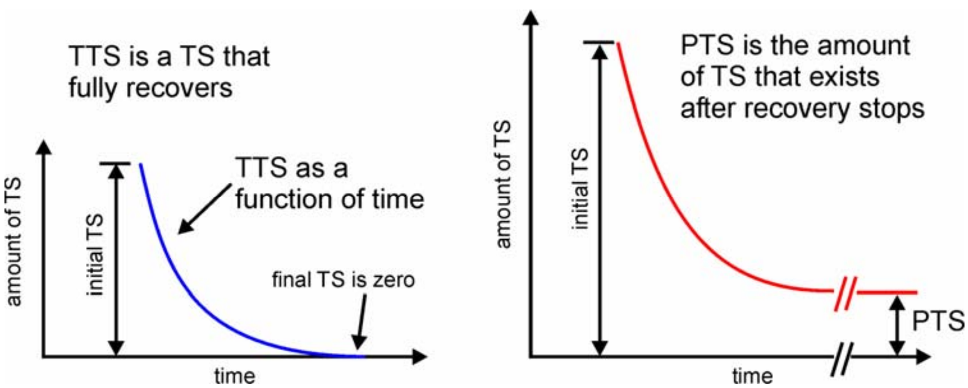


Figure 4.1.2.4.5-2. Hypothetical Temporary and Permanent Threshold Shifts

PTS, TTS, and Harassment Zones

PTS is non-recoverable and, by definition, must result from the destruction of tissues within the auditory system. PTS therefore qualifies as an injury and is classified as Level A harassment under the wording of the MMPA. In the Draft EIS/OEIS, the smallest amount of PTS (onset-PTS) is taken to be the indicator for the smallest degree of injury that can be measured. The acoustic exposure associated with onset-PTS is used to define the outer limit of the Level A harassment zone.

TTS is recoverable and, as in recent rulings (National Oceanic and Atmospheric Administration, 2001, 2002a), is considered to result from the temporary, non-injurious distortion of hearing-related tissues. Because it is considered non-injurious (there is no tissue damage), the acoustic exposure associated with onset-TTS is used to define the outer limit of the portion of the Level B harassment zone attributable to physiological effects. This follows from the concept that hearing loss potentially affects an animal's ability to react normally to the sounds around it.

Therefore, in the HRC, TTS is considered as a Level B harassment resulting from physiological effects on the auditory system.

4.1.2.4.6 Criteria and Thresholds for Physiological Effects

This section presents the effect criteria and thresholds for physiological effects of sound leading to injury and behavioral disturbance as a result of sensory impairment. Section 4.1.2.4.5 identified the tissues of the ear as being the most susceptible to physiological effects of underwater sound. PTS and TTS were determined to be the most appropriate biological indicators of physiological effects that equate to the onset of injury (Level A harassment) and behavioral disturbance (Level B harassment), respectively. This section is, therefore, focused on criteria and thresholds to predict PTS and TTS in marine mammals.

Marine mammal ears are functionally and structurally similar to terrestrial mammal ears; however, there are important differences (Ketten, 1998). The most appropriate information from which to develop PTS/TTS criteria for marine mammals would be experimental measurements of PTS and TTS from marine mammal species of interest. TTS data exist for several marine mammal species and may be used to develop meaningful TTS criteria and thresholds. Because of the ethical issues presented, PTS data do not exist for marine mammals and are unlikely to be obtained. Therefore, PTS criteria must be extrapolated using TTS criteria and estimates of the relationship between TTS and PTS.

This section begins with a review of the existing marine mammal TTS data. The review is followed by a discussion of the relationship between TTS and PTS. The specific criteria and thresholds for TTS and PTS used in this authorization request are then presented. This is followed by discussions of EL, the relationship between EL and SPL, and the use of SPL and EL in previous environmental compliance documents.

Energy Flux Density Level and Sound Pressure Level

Energy Flux Density Level (EL) is measure of the sound energy flow per unit area expressed in dB. EL is stated in dB re 1 µPa^2-s for underwater sound and dB re (20 µPa)^2-s for airborne sound.

Sound Pressure Level (SPL) is a measure of the root-mean square, or "effective," sound pressure in decibels. SPL is expressed in dB re 1 µPa for underwater sound and dB re 20 µPa for airborne sound.

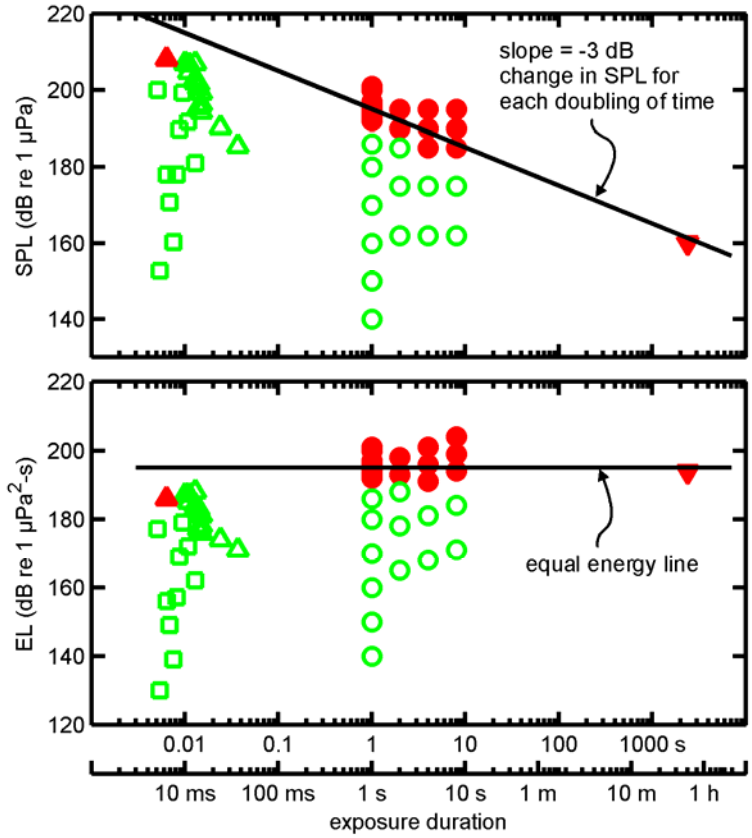
<u>TTS in Marine Mammals</u>

A number of investigators have measured TTS in marine mammals. These studies measured hearing thresholds in trained marine mammals before and after exposure to intense sounds. Some of the more important data obtained from these studies are onset-TTS levels—exposure levels sufficient to cause a just-measurable amount of TTS—often defined as 6 dB of TTS (for example, Schlundt et al., 2000). The existing cetacean TTS data are summarized in the following bullets.

- **Schlundt et al. (2000)** reported the results of TTS experiments conducted with bottlenose dolphins and beluga exposed to 1-second tones. This paper also includes a reanalysis of preliminary TTS data released in a technical report by Ridgway et al. (1997). At frequencies of 3, 10, and 20 kHz, SPLs necessary to induce measurable amounts (6 dB or more) of TTS were between 192 and 201 dB re 1 µPa (EL = 192 to 201 dB re 1 µPa^2-s). The mean exposure SPL and EL for onset-TTS were 195 dB re 1 µPa and 195 dB re 1 µPa^2-s, respectively. The sound exposure stimuli (tones) and relatively large number of test subjects (five dolphins and two belugas) make the Schlundt et al. (2000) data the most directly relevant TTS information for the scenarios described in the HRC EIS/OEIS.
- **Finneran et al. (2001, 2003, 2005)** described TTS experiments conducted with bottlenose dolphins exposed to 3-kHz tones with durations of 1, 2, 4, and 8 seconds. Small amounts of TTS (3 to 6 dB) were observed in one dolphin after exposure to ELs between 190 and 204 dB re 1 µPa^2-s. These results were consistent with the data of Schlundt et al. (2000) and showed that the Schlundt et al. (2000) data were not significantly affected by the masking sound used. These results also confirmed that, for tones with different durations, the amount of TTS is best correlated with the exposure EL rather than the exposure SPL.
- **Nachtigall et al. (2003)** measured TTS in a bottlenose dolphin exposed to octave-band sound centered at 7.5 kHz. Nachtigall et al. (2003a) reported TTSs of about 11 dB measured 10 to 15 minutes after exposure to 30 to 50 minutes of sound with SPL 179 dB re 1 µPa (EL about 213 dB re µPa^2-s). No TTS was observed after exposure to the same sound at 165 and 171 dB re 1 µPa. Nachtigall et al. (2004) reported TTSs of around 4 to 8 dB 5 minutes after exposure to 30 to 50 minutes of sound with SPL 160 dB re 1 µPa (EL about 193 to 195 dB re 1 µPa^2-s). The difference in results was attributed to faster post-exposure threshold measurement—TTS may have recovered before being detected by Nachtigall et al. (2003). These studies showed that, for long-duration exposures, lower sound pressures are required to induce TTS than are required for short-duration tones. These data also confirmed that, for the cetaceans studied, EL is the most appropriate predictor for onset-TTS.
- **Finneran et al. (2000, 2002)** conducted TTS experiments with dolphins and belugas exposed to impulsive sounds similar to those produced by distant underwater explosions and seismic waterguns. These studies showed that, for very short-duration impulsive sounds, higher sound pressures were required to induce TTS than for longer-duration tones.
- **Kastak et al. (1999a, 2005)** conducted TTS experiments with three species of pinnipeds, California sea lion, northern elephant seal and a Pacific harbor seal, exposed to continuous underwater sounds at levels of 80 and 95 dB SPL at 2.5 and 3.5 kHz for up to 50 minutes. Mean TTS shifts of up to 12.2 dB occurred with the harbor seals showing the largest shift of 28.1 dB. Increasing the sound duration had a greater effect on TTS than increasing the sound level from 80 to 95 dB.

Figure 4.1.2.4.6-1 shows the existing TTS data for cetaceans (dolphins and belugas). Individual exposures are shown in terms of SPL versus exposure duration (upper panel) and EL versus exposure duration (lower panel). Exposures that produced TTS are shown as filled symbols. Exposures that did not produce TTS are represented by open symbols. The squares and triangles represent impulsive test results from Finneran et al., 2000 and 2002, respectively. The circles show the 3-, 10-, and 20-kHz data from Schlundt et al. (2000) and the results of Finneran et al. (2003). The inverted triangle represents data from Nachtigall et al. (2004).

Figure 4.1.2.4.6-1 illustrates that the effects of the different sound exposures depend on the SPL and duration. As the duration decreases, higher SPLs are required to cause TTS. In contrast, the ELs required for TTS do not show the same type of variation with exposure duration.



Legend: Filled symbol: Exposure that produced TTS, Open symbol: Exposure that did not produce TTS
Squares: Impulsive test results from Finneran et al., 2000, Triangles: Impulsive test results from Finneran et al., 2002a, Circles: 3, 10, and 20-kHz data from Schlundt et al. (2000) and results of Finneran et al. (2003), and Inverted triangle: Data from Nachtigall et al., 2004.

Figure 4.1.2.4.6-1. Existing TTS Data for Cetaceans

The solid line in the upper panel of Figure 4.1.2.4.6-1 has a slope of -3 dB per doubling of time. This line passes through the point where the SPL is 195 dB re 1 µPa and the exposure duration is 1 second. Since EL = SPL + 10log10 (duration), doubling the duration *increases* the EL by 3 dB. Subtracting 3 dB from the SPL *decreases* the EL by 3 dB. The line with a slope of -3 dB per doubling of time, therefore, represents an *equal energy line*—all points on the line have the same EL, which is, in this case, 195 dB re 1 µPa^2-s. This line appears in the lower panel as a horizontal line at 195 dB re 1 µPa^2-s. The equal energy line at 195 dB re 1 µPa^2-s fits the tonal and sound data (the non-impulsive data) very well, despite differences in exposure duration, SPL, experimental methods, and subjects.

In summary, the existing cetacean TTS data show that, for the species studied and sounds (non-impulsive) of interest, the following is true:

- The growth and recovery of TTS are analogous to those in land mammals. This means that, as in land mammals, cetacean TSs depend on the amplitude, duration, frequency content, and temporal pattern of the sound exposure. Threshold shifts will generally increase with the amplitude and duration of sound exposure. For continuous sounds, exposures of equal energy will lead to approximately equal effects (Ward, 1997). For intermittent sounds, less TS will occur than from a continuous exposure with the same energy (some recovery will occur between exposures) (Kryter et al., 1966; Ward, 1997).
- SPL by itself is not a good predictor of onset-TTS, since the amount of TTS depends on both SPL and duration.
- Exposure EL is correlated with the amount of TTS and is a good predictor for onset-TTS for single, continuous exposures with different durations. This agrees with human TTS data presented by Ward et al. (1958, 1959).
- An energy flux density level of 195 dB re 1 µPa^2-s is the most appropriate predictor for onset-TTS from a single, continuous exposure.

<u>Relationship between TTS and PTS</u>

Since marine mammal PTS data do not exist, onset-PTS levels for these animals must be estimated using TTS data and relationships between TTS and PTS. Much of the early human TTS work was directed towards relating TTS_2 after 8 hours of sound exposure to the amount of PTS that would exist after years of similar daily exposures (e.g., Kryter et al., 1966). Although it is now acknowledged that susceptibility to PTS cannot be reliably predicted from TTS measurements, TTS data do provide insight into the amount of TS that may be induced without a PTS. Experimental studies of the growth of TTS may also be used to relate changes in exposure level to changes in the amount of TTS induced. Onset-PTS exposure levels may therefore be predicted by:

- Estimating the largest amount of TTS that may be induced without PTS. Exposures causing a TS greater than this value are assumed to cause PTS.
- Estimating the additional exposure, above the onset-TTS exposure, necessary to reach the maximum allowable amount of TTS that, again, may be induced without PTS. This is equivalent to estimating the growth rate of TTS—how much additional TTS is produced by an increase in exposure level.

Experimentally induced TTSs in marine mammals have generally been limited to around 2 to 10 dB, well below TSs that result in some PTS. Experiments with terrestrial mammals have used much larger TSs and provide more guidance on how high a TS may rise before some PTS results. Early human TTS studies reported complete recovery of TTSs as high as 50 dB after exposure to broadband sound (Ward, 1960; Ward et al., 1958, 1959). Ward et al. *(*1959) also reported slower recovery times when TTS_2 approached and exceeded 50 dB, suggesting that

50 dB of TTS_2 may represent a "critical" TTS. Miller et al. (1963) found PTS in cats after exposures that were only slightly longer in duration than those causing 40 dB of TTS. Kryter et al. (1966) stated: "A TTS_2 that approaches or exceeds 40 dB can be taken as a signal that danger to hearing is imminent." These data indicate that TSs up to 40 to 50 dB may be induced without PTS, and that 40 dB is a reasonable upper limit for TS to prevent PTS.

The small amounts of TTS produced in marine mammal studies also limit the applicability of these data to estimates of the growth rate of TTS. Fortunately, data do exist for the growth of TTS in terrestrial mammals. For moderate exposure durations (a few minutes to hours), TTS_2 varies with the logarithm of exposure time (Ward et al., 1958, 1959; Quaranta et al., 1998). For shorter exposure durations the growth of TTS with exposure time appears to be less rapid (Miller, 1974; Keeler, 1976). For very long-duration exposures, increasing the exposure time may fail to produce any additional TTS, a condition known as asymptotic threshold shift (Saunders et al., 1977; Mills et al., 1979).

Ward et al. (1958, 1959) provided detailed information on the growth of TTS in humans. Ward et al. presented the amount of TTS measured after exposure to specific SPLs and durations of broadband sound. Since the relationship between EL, SPL, and duration is known, these same data could be presented in terms of the amount of TTS produced by exposures with different ELs.

Figure 4.1.2.4.6-2 shows results from Ward et al. (1958, 1959) plotted as the amount of TTS_2 versus the exposure EL. The data in Figure 4.1.2.4.6-2(a) are from broadband (75 Hz to 10 kHz) sound exposures with durations of 12 to 102 minutes (Ward et al., 1958). The symbols represent mean TTS_2 for 13 individuals exposed to continuous sound. The solid line is a linear regression fit to all but the two data points at the lowest exposure EL. The experimental data are fit well by the regression line (R2 = 0.95). These data are important for two reasons: (1) they confirm that the amount of TTS is correlated with the exposure EL; and (2) the slope of the line allows one to estimate the additional amount of TTS produced by an increase in exposure. For example, the slope of the line in Figure 4.1.2.4.6-2(a) is approximately 1.5 dB TTS_2 per dB of EL. This means that each additional dB of EL produces 1.5 dB of additional TTS_2.

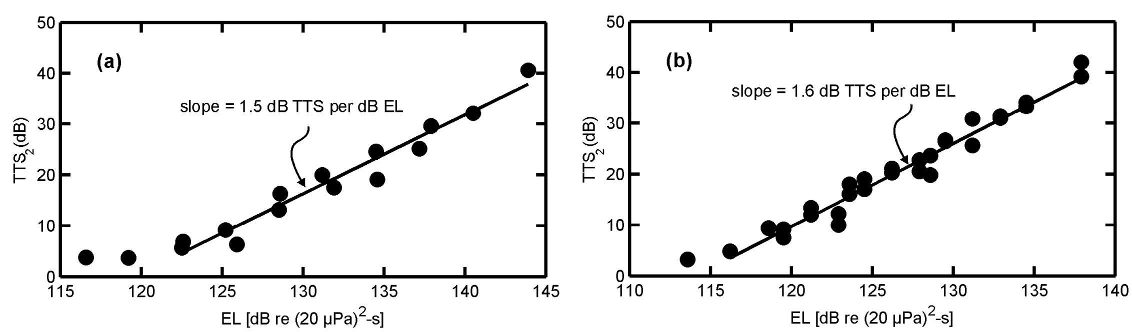


Figure 4.1.2.4.6-2. Growth of TTS versus the Exposure EL (from Ward et al., 1958, 1959)

The data in Figure 4.1.2.4.6-2(b) are from octave-band sound exposures (2.4 to 4.8 kHz) with durations of 12 to 102 minutes (Ward et al., 1959). The symbols represent mean TTS for 13 individuals exposed to continuous sound. The linear regression was fit to all but the two data points at the lowest exposure EL. The results are similar to those shown in Figure

4.1.2.4.6-2(a). The slope of the regression line fit to the mean TTS data was 1.6 dB TTS_2/dB EL. A similar procedure was carried out for the remaining data from Ward et al. *(*1959), with comparable results. Regression lines fit to the TTS versus EL data had slopes ranging from 0.76 to 1.6 dB TTS_2/dB EL, depending on the frequencies of the sound exposure and hearing test.

An estimate of 1.6 dB TTS_2 per dB increase in exposure EL is the upper range of values from Ward et al. (1958, 1959) and gives the most conservative estimate—it predicts a larger amount of TTS from the same exposure compared to the lines with smaller slopes. The difference between onset-TTS (6 dB) and the upper limit of TTS before PTS (40 dB) is 34 dB. To move from onset-TTS to onset-PTS, therefore, requires an increase in EL of 34 dB divided by 1.6 dB/dB, or approximately 21 dB. An estimate of 20 dB between exposures sufficient to cause onset-TTS and those capable of causing onset-PTS is a reasonable approximation. To summarize:

- In the absence of marine mammal PTS data, onset-PTS exposure levels may be estimated from marine mammal TTS data and PTS/TTS relationships observed in terrestrial mammals. This involves:
  - Estimating the largest amount of TTS that may be induced without PTS. Exposures causing a TS greater than this value are assumed to cause PTS.
  - Estimating the growth rate of TTS—how much additional TTS is produced by an increase in exposure level.
- A variety of terrestrial mammal data sources point toward 40 dB as a reasonable estimate of the largest amount of TS that may be induced without PTS. A conservative estimate is that continuous-type exposures producing TSs of 40 dB or more always result in some amount of PTS.
- Data from Ward et al. *(*1958, 1959) reveal a linear relationship between TTS_2 and exposure EL. A value of 1.6 dB TTS_2 per dB increase in EL is a conservative estimate of how much additional TTS is produced by an increase in exposure level for continuous-type sounds.
- There is a 34 dB TS difference between onset-TTS (6 dB) and onset-PTS (40 dB). The additional exposure above onset-TTS that is required to reach PTS is therefore 34 dB divided by 1.6 dB/dB, or approximately 21 dB.
- Exposures with ELs 20 dB above those producing TTS may be assumed to produce a PTS. This number is used as a conservative simplification of the 21 dB number derived above.

<u>Threshold Levels for Harassment to Cetaceans from Physiological Effects</u>

For this specified action, sound exposure thresholds for TTS and PTS are as presented in the following text box:

195 dB re 1 μPa^2-s received EL for TTS

215 dB re 1 μPa^2-s received EL for PTS

Cetaceans predicted to receive a sound exposure with EL of 215 dB re 1 µPa^2-s or greater are assumed to experience PTS and are counted as Level A harassment. Cetaceans predicted to receive a sound exposure with EL greater than or equal to 195 dB re 1 µPa^2-s but less than 215 dB re 1 µPa^2-s are assumed to experience TTS and are counted as Level B harassment.

Derivation of an Effect Threshold for Cetaceans

The TTS threshold is primarily based on the cetacean TTS data from Schlundt et al. (2000). Since these tests used short-duration tones similar to sonar pings, they are the most directly relevant data. The mean exposure EL required to produce onset-TTS in these tests was 195 dB re 1 µPa^2-s. This result is corroborated by the short-duration tone data of Finneran et al. (2000, 2003) and the long-duration sound data from Nachtigall et al. (2003, 2004). Together, these data demonstrate that TTS in cetaceans is correlated with the received EL and that onset-TTS exposures are fit well by an equal-energy line passing through 195 dB re 1 µPa^2-s.

The PTS threshold is based on a 20 dB increase in exposure EL over that required for onset-TTS. The 20 dB value is based on estimates from terrestrial mammal data of PTS occurring at 40 dB or more of TS, and on TS growth occurring at a rate of 1.6 dB/dB increase in exposure EL. This is conservative because: (1) 40 dB of TS is actually an upper limit for TTS used to approximate onset-PTS, and (2) the 1.6 dB/dB growth rate is the highest observed in the data from Ward et al. (1958, 1959).

Use of EL for Physiological Effect Thresholds

Effect thresholds are expressed in terms of total received EL. Energy flux density is a measure of the flow of sound energy through an area. Marine and terrestrial mammal data show that, for continuous-type sounds of interest, TTS and PTS are more closely related to the energy in the sound exposure than to the exposure SPL.

The EL for each individual ping is calculated from the following equation:

EL = SPL + 10log10(duration)

The EL includes both the ping SPL and duration. Longer-duration pings and/or higher-SPL pings will have a higher EL.

If an animal is exposed to multiple pings, the energy flux density in each individual ping is summed to calculate the total EL. Since mammalian TS data show less effect from intermittent exposures compared to continuous exposures with the same energy (Ward, 1997), basing the effect thresholds on the total received EL is a conservative approach for treating multiple pings; in reality, some recovery will occur between pings and lessen the effect of a particular exposure.

Therefore, estimates are conservative because recovery is not taken into account—intermittent exposures are considered comparable to continuous exposures.

The total EL depends on the SPL, duration, and number of pings received. The TTS and PTS thresholds do not imply any specific SPL, duration, or number of pings. The SPL and duration of each received ping are used to calculate the total EL and determine whether the received EL meets or exceeds the effect thresholds. For example, the TTS threshold would be reached through any of the following exposures:

- A single ping with SPL = 195 dB re 1 µPa and duration = 1 second.
- A single ping with SPL = 192 dB re 1 µPa and duration = 2 seconds.
- Two pings with SPL = 192 dB re 1 µPa and duration = 1 second.
- Two pings with SPL = 189 dB re 1 µPa and duration = 2 seconds.

Previous Use of EL for Physiological Effects

Energy measures have been used as a part of dual criteria for cetacean auditory effects in shock trials, which only involve impulsive-type sounds (U.S. Department of the Navy, 1998a, 2001b). These actions used 192 dB re 1 µPa^2-s as a reference point to derive a TTS threshold in terms of EL. A second TTS threshold, based on peak pressure, was also used. If either threshold was exceeded, effect was assumed.

The 192 dB re 1 µPa^2-s reference point differs from the threshold of 195 dB re 1 µPa^2-s used in this HRC EIS/OEIS. The 192 dB re 1 µPa^2-s value was based on the minimum observed by Ridgway et al. (1997) and Schlundt et al. (2000) during TTS measurements with bottlenose dolphins exposed to 1-second tones. At the time, no impulsive test data for marine mammals were available and the 1-second tonal data were considered to be the best available. The minimum value of the observed range of 192 to 201 dB re 1 µPa^2-s was used to protect against misinterpretation of the sparse data set available. The 192 dB re 1 µPa^2-s value was reduced to 182 dB re 1 µPa^2-s to accommodate the potential effects of pressure peaks in impulsive waveforms.

The additional data now available for onset-TTS in small cetaceans confirm the original range of values and increase confidence in it (Finneran et al., 2001, 2003; Nachtigall et al., 2003, 2004). The HRC EIS/OEIS, therefore, uses the more complete data available and the mean value of the entire Schlundt et al. (2000) data set (195 dB re 1 µPa^2-s), instead of the minimum of 192 dB re 1 µPa^2-s. From the standpoint of statistical sampling and prediction theory, the mean is the most appropriate predictor—the “best unbiased estimator”—of the EL at which onset-TTS should occur; predicting the number of exposures in future actions relies (in part) on using the EL at which onset-TTS will most likely occur. When that EL is applied over many pings in each of many sonar exercises, that value will provide the most accurate prediction of the actual number of exposures by onset-TTS over all of those exercises. Use of the minimum value would calculate the maximum potential of exposures because many animals counted would not have experienced onset-TTS. Further, there is no logical limiting minimum value of the distribution that would be obtained from continued successive testing. Continued testing and use of the minimum would produce more and more erroneous estimates.

<u>Summary of Physiological Effects Criteria for Cetacea</u>

PTS and TTS are used as the criteria for physiological effects resulting in injury (Level A harassment) and disturbance (Level B harassment), respectively. Sound exposure thresholds for TTS and PTS in Cetacea are 195 dB re 1 µPa^2-s received EL for TTS and 215 dB re 1 µPa^2-s received EL for PTS. The TTS threshold is primarily based on cetacean TTS data from Schlundt et al. (2000). Since these tests used short-duration tones similar to sonar pings, they are the most directly relevant data. The PTS threshold is based on a 20 dB increase in exposure EL over that required for onset-TTS. The 20 dB value is based on extrapolations from terrestrial mammal data indicating that PTS occurs at 40 dB or more of TS, and that TS growth occurring at a rate of approximately 1.6 dB/dB increase in exposure EL. The application of the model results to estimate marine mammal exposures for each species is discussed in Sections 4.1.2.5, 4.1.2.6, and 4.1.2.7.

Summary of Physiological Effects Criteria for Monk Seals

PTS and TTS are used as the criteria for physiological effects resulting in injury (Level A harassment) and disturbance (Level B harassment), respectively for the Hawaiian monk seal. As noted previously, research by Kastak et al. (1999a; 2005) provided estimates of the average SEL (EFD level) for onset-TTS for a harbor seal, sea lion, and Northern Elephant seal. Although the duration for exposure sessions duration is well beyond those typically used with tactical sonars, the frequency ranges are similar (2.5 kHz to 3.5 kHz). This data provides good estimates for the onset of TTS in pinnipeds since the researchers tested different combinations of SPL and exposure duration, and plotted the growth of TTS with an increasing energy exposure level.

Of the three pinniped groups studied by Kastak et al., elephant seals are the most closely related to the Hawaiian monk seal (the family *Monachinae*). The onset-TTS number, provided by Kastak et al. for elephant seals and used to analyze impacts on monk seals in this document, is 204 dB re 1µPa^2-s. Using the same rationale described previously for the establishment of the PTS threshold based on odontocete onset-TTS (20 dB up from onset-TTS), the PTS threshold for monk seals used in the HRC analysis is 224 dB re 1µPa^2-s.

Application of Physiological Effect Criteria for Mysticetes

Information on auditory function in mysticetes is extremely lacking. Sensitivity to low-frequency sound by baleen whales has been inferred from observed vocalization frequencies, observed reactions to playback of sounds, and anatomical analyses of the auditory system. Baleen whales are estimated to hear from 15 Hz to 20 kHz, with good sensitivity from 20 Hz to 2 kHz (Ketten, 1998). Filter-bank models of the humpback whale's ear have been developed from anatomical features of the humpback's ear and optimization techniques (Houser et al., 2001). The results suggest that humpbacks are sensitive to frequencies between 700 Hz and 10 kHz, and maximum sensitivity is between 2 kHz and 6 kHz. Research involving the recording of humpback vocalizations has found harmonics in the range up to 24~~0~~ kHz (Au et al. 2001; 2006). These results do not, however, indicate that humpbacks can actually hear those high-frequency harmonics and given that sound of that frequency attenuates rapidly over distance, those sounds would not serve as a means of communication over distance. There are no cases where the absolute sensitivity for any baleen whale species has been modeled or determined. Furthermore, there is no indication of what sorts of sound exposure may produce threshold shifts in these animals. As a result, the thresholds and criteria established for odontocetes is used to analyze potential affects from sonar use in mysticetes.

4.1.2.4.7 Other Physiological Effects Considered

The criteria and thresholds for PTS and TTS developed for odontocetes for this activity are also used for mysticetes. This generalization is based on the assumption that the empirical data at hand are representative of both groups until data collection on mysticete species shows otherwise. For the frequencies of interest for this action, there is no evidence that the total amount of energy required to induce onset-TTS and onset-PTS in mysticetes is different than that required for odontocetes.

Stress

A possible stressor for marine mammals exposed to sound, including MFA/HFA sonar, is the effect on health and physiological stress (Fair and Becker, 2000). A stimulus may cause a number of behavioral and physiological responses such as an elevated heart rate, increases in endocrine and neurological function, and decreased immune function, particularly if the animal perceives the stimulus as life threatening (Seyle, 1950; Moberg, 2000; Sapolsky, 2005). The primary response to the stressor is to move away to avoid continued exposure. Next the animal's physiological response to a stressor is to engage the autonomic nervous system with the classic "fight or flight" response. This includes changes in the cardiovascular system (increased heart rate), the gastrointestinal system (decreased digestion), the exocrine glands (increased hormone output), and the adrenal glands (increased norepinephrine). These physiological and hormonal responses are short lived and may not have significant long-term effects on an animal's health or fitness. Generally these short-term responses are not detrimental to the animal except when the health of the animal is already compromised by disease, starvation, or parasites; or the animal is chronically exposed to a stressor.

Exposure to chronic or high intensity sound sources can cause physiological stress. Acoustic exposures and physiological responses have been shown to cause stress responses (elevated respiration and increased heart rates) in humans (Jansen, 1998). Jones (1998) reported on reductions in human performance when faced with acute, repetitive exposures to acoustic disturbance. Trimper et al. (1998) reported on the physiological stress responses of osprey to low-level aircraft noise. Krausman et al. (2004) reported on the auditory (TTS) and physiology stress responses of endangered Sonoran pronghorn to military overflights. Smith et al. (2004a, 2004b) recorded sound-induced physiological stress responses in a hearing-specialist fish that was associated with TTS. Welch and Welch (1970), reported physiological and behavioral stress responses that accompanied damage to the inner ears of fish and several mammals.

Most of these responses to sound sources or other stimuli have been studied extensively in terrestrial animals but are much more difficult to determine in marine mammals. Increases in heart rate are a common reaction to acoustic disturbance in marine mammals (Miksis et al., 2001) as are small increases in the hormones norepinephrine, epinephrine, and dopamine (Romano et al., 2002; 2004). Increases in cortical steroids are more difficult to determine because blood collection procedures will also cause stress (Romano et al., 2002; 2004). A recent study, Chase Encirclement Stress Studies (CHESS), was conducted by NMFS on chronic stress effects in small odontocetes affected by the Eastern Tropical Pacific tuna fishery (Forney et al., 2002). Analysis was conducted on blood constituents, immune function, reproductive parameters, heart rate, and body temperature of small odontocetes that had been pursued and encircled by tuna fishing boats. Some effects were noted, including lower pregnancy rates, increases in norepinephrine, dopamine, ACTH and cortisol levels, heart lesions and an increase in fin and surface temperature when chased for over 75 minutes but with no change in core body temperature (Forney et al., 2002). These stress effects in small cetaceans that were actively pursued (sometimes for over 75 minutes) were relatively small and difficult to discern. It is unlikely that marine mammals exposed to MFA/HFA sonar would be exposed as long as the cetaceans in the CHESS study and would not be pursued by the Navy ships; therefore, stress effects would be minimal from the short-term exposure to sonar.

Acoustically Mediated Bubble Growth and Decompression Sickness

One suggested cause of stranding in marine mammals is by rectified diffusion (Crum and Mao, 1996), which is the process of increasing the size of a bubble by exposing it to a sound field. This process is facilitated if the environment in which the ensonified bubbles exist is supersaturated with a gas, such as nitrogen, which makes up approximately 78 percent of air. It is unlikely that the short duration of sonar pings would be able to drive bubble growth to any substantial size, if such a phenomenon occurs. Laboratory studies exposed blood and tissues for 2-3 hours to pressure and then to HFA sonar to develop bubbles *in vitro* (Crum and Mao, 2004). However, an alternative but related hypothesis has also been suggested: stable bubbles could be destabilized by high-level sound exposures such that bubble growth then occurs through static diffusion of gas out of the tissues. In such a scenario the marine mammal would need to be in a gas-supersaturated state for a long enough period of time and exposed to a continuous sound source for bubbles to become of a problematic size.

Repetitive diving in a trained marine mammal caused the blood and some tissues to accumulate gas to a greater degree than is supported by the surrounding environmental pressure but no decompression sickness symptoms were reported (Ridgway and Howard, 1979). Deeper and longer dives of some marine mammals (for example, beaked whales) are hypothetically predicted to induce greater nitrogen supersaturation (Houser et al., 2001). Studies have shown that marine mammal lung structure (both pinnipeds and cetaceans) facilitates collapse of the lungs at depths deeper than approximately 162 ft (Kooyman et al., 1970). Collapse of the lungs would force air into the non-air exchanging areas of the lungs (into the bronchioles away from the alveoli), thus significantly decreasing nitrogen diffusion into the body. Deep diving pinnipeds such as the northern elephant seal (*Mirounga angustirostris*) and Weddell seal (*Leptonychotes weddellii*) typically exhale before long deep dives, further reducing air volume in the lungs (Kooyman, et al., 1970) but cetaceans may not exhale on diving but use that air in the nasal passages for vocalizations (including echolocation in odontocetes).

Another hypothesis suggests that rapid ascent to the surface following exposure to a startling sound might produce tissue gas saturation sufficient for the evolution of nitrogen bubbles (Jepson et al., 2003). In this scenario, the rate of ascent would need to be sufficiently rapid to compromise behavioral or physiological protections against nitrogen bubble formation. Cox et al. (2006), with experts in the field of marine mammal behavior, diving, physiology, respiration physiology, pathology, anatomy, and bio-acoustics considered this to be a plausible hypothesis but required further investigation. Conversely, Fahlman et al. (2006) suggested that diving bradycardia (reduction in heart rate and circulation to the tissues), lung collapse, and slow ascent rates would reduce nitrogen uptake and thus reduce the risk of decompression sickness by 50 percent in models of marine mammals. Recent information on the diving profiles of Cuvier's (*Ziphius cavirostris*) and Blainville's (*Mesoplodon densirostris*) beaked whales in Hawaii (Baird et al., 2006) showed slower ascent rates than descent rates, but Tyack et al. (2006) showed that while these species do dive deeply (regularly exceed depths of 2,620 ft) and for long periods (48 to 68 minutes), they have significantly slower ascent rates than descent rates. Tyack et al. (2006) reported rapid ascents from deep dives in Cuvier's and Blainville's beaked whales but concluded that the natural diving behavior of beaked whales precluded them from having problems with nitrogen gas surpersaturation and embolisms. Zimmer and Tyack (2007) presented a model that suggested that repetitive shallow diving by beaked whales that may occur in response to a predator, would be above the depth for lung collapse and therefore could cause decompression sickness. There is no evidence that beaked whales dive in this manner in response to predators or sound sources and other marine mammals such as Antarctic and Galapagos fur seals, and pantropical spotted dolphins make repetitive shallow dives with no apparent decompression sickness (Kooyman and Trillmich, 1984; Kooyman et al., 1984; Baird et al., 2001).

Although theoretical predictions suggest the possibility for acoustically mediated bubble growth, there is considerable disagreement among scientists as to its likelihood (Piantadosi and Thalmann, 2004; Evans and Miller, 2003). To date, ELs predicted to cause in vivo bubble formation within diving cetaceans have not been evaluated (National Oceanic and Atmospheric Administration, 2002b). Further, although it has been argued that traumas from recent beaked whale strandings are consistent with gas emboli and bubble-induced tissue separations (Jepson et al., 2003), there is no conclusive evidence of this and complicating factors associated with introduction of gas into the venous system during necropsy or lesions occur as a result of physical trauma during stranding on the shoreline. Rommel et al (2006) reviewed several hypothetical causes of strandings in beaked whales and concluded that “It is important to note that no current hypothesis of pathogenic mechanisms resulting in acoustically-related strandings is proven.” According to Rommel et al. (2006) “The lesions observed in beaked whales that mass stranded in the Canary Islands in 2002 are consistent with, but not diagnostic of, decompression sickness.” Because evidence supporting decompression sickness in marine mammals exposed to mid- and high-frequency active sonar is debatable, no marine mammals addressed in this EIS/OEIS are given special treatment due to the possibility for acoustically mediated bubble growth.

Resonance

Another suggested cause of injury in marine mammals is air cavity resonance due to sonar exposure. Resonance is a phenomenon that exists when an object is vibrated at a frequency near its natural frequency of vibration—the particular frequency at which the object vibrates most readily. The size and geometry of an air cavity determine the frequency at which the cavity will resonate. Displacement of the cavity boundaries during resonance has been suggested as a cause of injury. Large displacements have the potential to tear tissues that surround the air space (for example, lung tissue).

Understanding resonant frequencies and the susceptibility of marine mammal air cavities to resonance is important in determining whether certain sonars have the potential to affect different cavities in different species. In 2002, NMFS convened a panel of government and private scientists to address this issue (National Oceanic and Atmospheric Administration, 2002b). They modeled and evaluated the likelihood that Navy MFA sonar caused resonance effects in beaked whales that eventually led to their stranding (U.S. Department of Commerce and U.S. Department of the Navy, 2001). The frequencies at which resonance was predicted to occur were below the frequencies utilized by the sonar systems employed. Furthermore, air cavity vibrations due to the resonance effect were not considered to be of sufficient amplitude to cause tissue damage. This EIS/OEIS assumes that similar phenomenon would not be problematic in other cetacean species.

Masking

Natural and artificial sounds can disrupt behavior by masking, or interfering with an animal's ability to hear other sounds. Masking occurs when the receipt of a sound is interfered with by a second sound at similar frequencies and at similar or higher levels. If the second sound were artificial, it could be potentially harassing if it disrupted hearing-related behavior such as communications or echolocation. It is important to distinguish TTS and PTS, which persist after the sound exposure, from masking, which occurs during the sound exposure.

Historically, principal masking concerns have been with prevailing background sound levels from natural and manmade sources (for example, Richardson et al., 1995a). Dominant examples of the latter are the accumulated sound from merchant ships and sound of seismic surveys. Both cover a wide frequency band and are long in duration.

HRC ASW training occurs in areas that are away from harbors but may include heavily traveled shipping lanes, although that is a small portion of the overall range complex. The loudest underwater sounds in the training area are those produced by sonars that are in the mid-frequency and high-frequency range.

The most dominant underwater sounds in the Hawaiian Islands during the 6-month November to April period, when humpback whales are present, are the vocalizations of the humpback whales. As detailed in Au et al. (2000), the ambient sound pressure level of 120 dB (SPL) occurs during this period as a result of thousands of whale "songs" having source levels as high as 174 dB SPL and other whale vocalizations and noises (e.g., flipper slaps) having source levels as high as 192 dB SPL (Richardson et al., 1995b).

The sonar signals are likely within the audible range of most cetaceans, but are very limited in the temporal, frequency, and spatial domains. In particular, the pulse lengths are short, the duty cycle low (number of pings per minute are low), the total number of hours of operation per year small, and the tactical sonars transmit within a narrow band of frequencies (typically less than one-third octave). Finally, high levels of sound are confined to a volume around the source and are constrained by propagation attenuation rates at mid- and high frequencies, and consist of relative short (generally less than a second) pulse lengths. For the reasons outlined above, the chance of sonar operations causing masking effects is considered negligible.

4.1.2.4.8 Previous Criteria and Thresholds for Behavioral Effects

The necessary information to conduct an assessment of behavioral effects for each species resulting from exposure to MFAS is incomplete and unavailable at this time due to the paucity of empirical data. The Navy has funded, and will continue to fund, research efforts to develop this data, but such an undertaking will require years to complete. The unavailability of such information is relevant to the ability to develop species-specific behavioral effects criterion. The science of understanding the effects of sound on marine mammals is dynamic, and the Navy is committed to the use of the best available science for evaluating potential effects from training and testing activities.

This section presents the previous effect criteria and thresholds for behavioral effects of sound leading to behavioral disturbance, and summarizes existing credible scientific evidence which is relevant to evaluating behavioral disturbance. Since TTS was and continues to be used as the biological indicator for onset of a physiological effect leading to behavioral disturbance, behavioral effects criteria are applied to exposure levels at or below those causing TTS that will result in a behavioral disturbance.

A large body of research on terrestrial animal and human response to airborne sound exists, but results from those studies are not readily extendible to the development of effect criteria and thresholds for marine mammals. For example, "annoyance" is one of several criteria used to define impact on humans from exposure to industrial sound sources. Comparable criteria cannot be developed for marine mammals because there is no acceptable method for determining whether a non-verbal animal is annoyed. Further, differences in hearing thresholds, dynamic range of the ear, and the typical exposure patterns of interest (e.g., human data tend to focus on 8-hour-long exposures) make extrapolation of human sound exposure standards inappropriate.

Behavioral observations of marine mammals exposed to anthropogenic sound sources exist (review by Richardson et al., 1995a; Southall et al., 2007); however, there are few observations and no controlled measurements of behavioral disruption of cetaceans caused by sound sources with frequencies, waveforms, durations, and repetition rates comparable to those employed by the MFA/HFA sonars to be used in the HRC. At the present time there is no consensus on how to account for behavioral effects on marine mammals exposed to continuous-type sounds (National Research Council, 2003).

History of Assessing Potential Harassment from Behavioral Effects

The prior Navy Letter of Authorization (LOA) and Incidental Harassment Authorization (IHA) requests for the Undersea Warfare Training Range (USWTR) and the Rim of the Pacific (RIMPAC) MFA sonar training respectively relied on behavioral observations of trained cetaceans exposed to intense underwater sound under controlled circumstances to develop a criterion and threshold for behavioral effects of sound based on energy flux density. These data are described in detail in Schlundt et al. (2000), Finneran et al., 2001; 2003 and Finneran and Schlundt 2004. Finneran and Schlundt (2004) analyzed behavioral observations from related TTS studies (Schlundt *et al*., 2000; Finneran *et* al. 2001, 2003) to calculate behavioral reactions as a function of known noise exposure. During the TTS experiments, four dolphins and two white whales were exposed during a total of 224 sessions to 1-s pulses between 160 and 204 dB re 1 μPa (root-mean-square SPL), at 0.4, 3, 10, 20 and 75 kHz. Finneran and Schlundt (2004) evaluated the behavioral observations in each session and determined whether a "behavioral alteration" (ranging from modifications of response behavior during hearing sessions to attacking the experimental equipment) occurred. For each frequency, the percentage of sessions in which behavioral alterations occurred was calculated as a function of received noise SPL. By pooling data across individuals and test frequencies, respective SPL levels coincident with responses by 25, 50, and 75 percent behavioral alteration were documented. 190 dB re 1 μPa^2-s (SEL) is the point at which 50 percent of the animals exposed to 3, 10, and 20 kHz tones were deemed to respond with some behavioral alteration, and the threshold that the Navy originally proposed for sub-TTS behavioral disturbance. These data represented the best available data at the time those activities were proposed because they are based on controlled, tonal sound exposures within the tactical sonar frequency range and because the species studied are closely related to the majority of animals expected to be located within the Proposed Action areas. The October 2005 USWTR Draft OEIS/EIS provided analysis to the 190 dB re 1 μPa^2-s criterion and threshold for behavioral effects, which the Navy had determined most accurately reflected scientifically-derived behavioral reactions from sound sources that are most similar to MFA sonars. A full discussion of the scientific data and use of those data to derive the 190 dB re 1 µPa^2-s threshold is presented in the original USWTR Draft OEIS/EIS (U.S. Environmental Protection Agency, 2005b).

The Navy's rationale for using energy flux density level (EL) for evaluation of behavioral effects included:

- **EL effect takes both the exposures SPL and duration into account.** Both SPL and duration of exposure affect behavioral responses to sound, so a behavioral effect threshold based on EL accounts for exposure duration.

- **EL takes into account the effects of multiple pings.** Effect thresholds based on SPL predict the same effect regardless of the number of received sounds. Previous actions using SPL-based criteria included implicit methods to account for multiple pings, such as the single-ping equivalent used in the SURTASS LFA (U.S. Department of the Navy, 2001c).

- **EL allows a rational ordering of behavior effects with physiological effects.** The effect thresholds for physiological effects are stated in terms of EL because experimental data described above showed the observed effects (TTS and PTS) are correlated best with the sound energy, not SPL. Using EL for behavioral effects allows the behavioral and physiological effects to be placed on a single exposure scale, with behavioral effects occurring at lower exposures than physiological effects.

As described above, behavioral observations of trained cetaceans exposed to intense underwater sound under controlled circumstances are an important data set in evaluating and developing a criterion and threshold for behavioral effects of sound. These behavioral response data are an important foundation for the scientific basis of the Navy's prior threshold of onset behavioral effects because of the (1) finer control over acoustic conditions; (2) greater quality and confidence in recorded sound exposures; and (3) the exposure stimuli closely match those of interest for the MFA sonar used as proposed in the HRC. Since no comparable controlled exposure data for wild animals exist, or are likely to be obtained in the near-term, the relationship between the behavioral results reported by Finneran and Schlundt (2004) and wild animals is not known. Although experienced, trained subjects may tolerate higher sound levels than inexperienced animals; it is also possible that prior experiences and resultant expectations may have made some trained subjects less tolerant of sound exposures.

In response to USWTR comments, potential differences between trained subjects and wild animals were considered by the Navy in conjunction with NMFS in the Navy's IHA application for RIMPAC 2006. At that time, NMFS recommended that the Navy include analysis of this threshold based on NMFS' evaluation of behavioral observations of marine mammals under controlled conditions, plus NMFS' interpretation of two additional studies on reactions to an alert stimuli (Nowacek et al., 2004) and analysis of the May 2003 USS SHOUP MFA sonar event (National Marine Fisheries Service, 2005a). Nowacek *et al.* (2004) conducted controlled exposure experiments on North Atlantic right whales using ship noise, social sounds of con-specifics, and an alerting stimulus (frequency modulated tonal signals between 500 Hz and 4.5 kHz). Animals were tagged with acoustic sensors (D-tags) simultaneously measured movement in three dimensions. Whales reacted strongly to alert signals at received levels of 133 – 148 dB SPL, mildly to conspecifics signals, and not at all to ship sounds or actual vessels. The alert stimulus caused whales to immediately cease foraging behavior and swim rapidly to the surface. Although SEL values were not directly reported, based on received exposure durations, approximate received values were on the order of 160 dB re 1μPa^2-s (SEL). National Marine Fisheries Service (2005) evaluated the acoustic exposures and coincident behavioral reactions of killer whales in the presence of SHOUP's use of MFA sonar in Haro Strait on May 5, 2003. In this case, none of the animals were directly fitted with acoustic dosimeters. However, based on a Naval Research Laboratory (NRL) analysis that took advantage of the fact that calibrated measurements of the sonar signals were made in situ and using advanced modeling to bound likely received exposures, estimates of received sonar signals by the killer whales were possible. Received SPL values ranged from 121 to 175 dB re 1 μPa. The most probable SEL values were 169.1 to 187.4 dB re 1μPa^2-s (SEL); worst-case estimates ranged from 177.7 to 195.8 dB re 1μPa^2-s (SEL). While researchers observing the animals during the course of sonar exposure subsequently reported unusual alterations in swimming, breathing, and diving behavior, Navy marine mammal scientists who reviewed the videotape of the event as part of the U.S. Pacific Fleet's investigation into the matter determined the behaviors of the killer whales as recorded on the video were within the species' normal range of behaviors and there were no immediate or general overt negative behavior reactions depicted (U.S. Department of the Navy, 2004b). Based on the duration and received levels of exposure and known behavioral reactions in other cetaceans, NMFS concluded that the killer whales "experienced exposure levels likely to induce behavioral reaction as a result of the 5 May 2003 sonar transmissions" (National Marine Fisheries Service, 2005). Accordingly, a conservative threshold for effect was derived compared to the regulatory definition of harassment, and Navy and NMFS agreed to the use of the 173 dB re 1 μPa^2-s threshold for the RIMPAC IHA request.

Subsequent to issuance of the RIMPAC IHA, additional public comments were received and considered. Based on this input, Navy continued to coordinate with NMFS to determine whether an alternate approach to energy flux density could be used to evaluate when a marine mammal may behaviorally be affected by MFA sound exposure. Coordination between the Navy and NMFS produced the adoption of risk function for evaluation of behavioral effects. The acoustic risk function approach for evaluating behavioral effects is described in the following section and fully considers the controlled, tonal sound exposure data in addition to comments received from the regulatory, scientific and public regarding concerns with the use of EL for evaluating the effects of sound on wild animals.

4.1.2.4.9 Summary of Existing Credible Scientific Evidence Relevant to Assessing Behavioral Effects

4.1.2.4.9.1 Background

Based on available evidence, marine animals are likely to exhibit any of a suite of potential behavioral responses or combinations of behavioral responses upon exposure to sonar transmissions. Potential behavioral responses include, but are not limited to: avoiding exposure or continued exposure; behavioral disturbance (including distress or disruption of social or foraging activity); habituation to the sound; becoming sensitized to the sound; or not responding to the sound.

Existing studies of behavioral effects of human-made sounds in marine environments remain inconclusive, partly because many of those studies have lacked adequate controls, applied only to certain kinds of exposures (which are often different from the exposures being analyzed in the study), and had limited ability to detect behavioral changes that may be significant to the biology of the animals that were being observed. These studies are further complicated by the wide variety of behavioral responses marine mammals exhibit and the fact that those responses can vary significantly by species, individuals, and the context of an exposure. In some circumstances, some individuals will continue normal behavioral activities in the presence of high levels of human-made noise. In other circumstances, the same individual or other individuals may avoid an acoustic source at much lower received levels (Richardson et al., 1995a; Wartzok et al., 2003; Southall et al., 2007). These differences within and between individuals appear to result from a complex interaction of experience, motivation, and learning that are difficult to quantify and predict.

It is possible that some marine mammal behavioral reactions to anthropogenic sound may result in strandings. Several "mass stranding" events—strandings that involve two or more individuals of the same species (excluding a single cow–calf pair)—that have occurred over the past two decades have been associated with naval operations, seismic surveys, and other anthropogenic activities that introduced sound into the marine environment. Sonar exposure has been identified as a contributing cause or factor in five specific mass stranding events: Greece in 1996; the Bahamas in March 2000; Madeira, Portugal in 2000; the Canary Islands in 2002, and Spain in 2006 (Advisory Committee Report on Acoustic Impacts on Marine Mammals, 2006).

In these circumstances, exposure to acoustic energy has been considered an indirect cause of the death of marine mammals (Cox et al., 2006). Based on studies of lesions in beaked whales that have stranded in the Canary Islands and Bahamas associated with exposure to naval exercises that involved sonar, several investigators have hypothesized that there are two potential physiological mechanisms that might explain why marine mammals stranded: tissue damage resulting from resonance effects (Ketten, 2005) and tissue damage resulting from "gas and fat embolic syndrome" (Fernandez et al., 2005; Jepson et al., 2003; 2005). It is also likely that stranding is a behavioral response to a sound under certain contextual conditions and that the subsequently observed physiological effects of the strandings (e.g., overheating, decomposition, or internal hemorrhaging from being on shore) were the result of the stranding versus exposure to sonar (Cox et al., 2006).

4.1.2.4.9.2 Development of the Risk Function

In Section 4.1.2.4.9 of the Draft EIS/OEIS, the Navy presented a dose methodology to assess the probability of Level B behavioral harassment from the effects of MFA and HFA sonar on marine mammals. Following publication of the Draft EIS/OEIS the Navy continued working with NMFS to refine the mathematically representative curve previously used, along with applicable input parameters with the purpose of increasing the accuracy of the Navy's assessment. As the regulating and cooperating agency, NMFS presented two methodologies to six scientists (marine mammalogists and acousticians from within and outside the federal government) for an independent review (National Marine Fisheries Service, 2008). Two NMFS scientists, one from the NMFS Office of Science and Technology and one from the Office of Protected Resources, then summarized the reviews from the six scientists and developed a recommendation.

One of the methodologies was a normal curve fit to a "mean of means" calculated from the mean of: (1) the estimated mean received level produced by the reconstruction of the USS SHOUP event of May 2003 in which killer whales were exposed to MFA sonar (U.S. Department of the Navy, 2004b); (2) the mean of the five maximum received levels at which Nowacek et al. (2004) observed significantly different responses of right whales to an alert stimuli; and (3) the mean of the lowest received levels from the 3 kHz data that the SPAWAR Systems Center (SSC) classified as altered behavior from Finneran and Schlundt (2004).

The second methodology was a derivation of a mathematical function used for assessing the percentage of a marine mammal population experiencing the risk of harassment under the MMPA associated with the Navy's use of the SURTASS LFA sonar (U.S. Department of the Navy, 2001c). This function is appropriate for application to instances with limited data (Feller, 1968). This methodology is subsequently identified as "the risk function" in this document.

The NMFS Office of Protected Resources made the decision to use the risk function and applicable input parameters to estimate the risk of behavioral harassment associated with exposure to MFA sonar. This determination was based on the recommendation of the two NMFS scientists; consideration of the independent reviews from six scientists; and NMFS MMPA regulations affecting the Navy's use of SURTASS LFA sonar (U.S. Department of the Navy, 2002b; National Oceanic and Atmospheric Administration, 2007b).

4.1.2.4.9.3 Methodology for Applying Risk Function

To assess the potential effects on marine mammals associated with active sonar used during training activities, the Navy together with NMFS, as a first step, investigated a series of mathematical models and methodologies that estimate the number of times individuals of the different species of marine mammals might be exposed to MFA sonar at different received levels. The Navy effects analyses assumed that the potential consequences of exposure to MFA sonar on individual animals would be a function of the received sound pressure level (dB re 1 µPa). These analyses assume that MFA sonar poses no risk, that is, does not constitute harassment to marine mammals if they are exposed to sound pressure levels from the MFA sonar below a certain basement value.

The second step of the assessment procedure requires the Navy and NMFS to identify how marine mammals are likely to respond when they are exposed to active sonar. Marine mammals can experience a variety of responses to sound including sensory impairment (permanent and temporary threshold shifts and acoustic masking), physiological responses (particular stress responses), behavioral responses, social responses that might result in reducing the fitness of individual marine mammals, and social responses that would not result in reducing the fitness of individual marine mammals.

As noted in the prior section, the Navy and NMFS have previously used acoustic thresholds to identify the number of marine mammals that might experience hearing losses (temporary or permanent) or behavioral harassment upon being exposed to MFA sonar (see Figure 4.1.2.4.9.3-1 left panel). These acoustic thresholds have been represented by either sound exposure level (related to sound energy, abbreviated as SEL), sound pressure level (abbreviated as SPL), or other metrics such as peak pressure level and acoustic impulse. The general approach has been to apply these threshold functions so that a marine mammal is counted as behaviorally harassed or experiencing hearing loss when exposed to received sound levels above a certain threshold and not counted as behaviorally harassed or experiencing hearing loss when exposed to received levels below that threshold. For example, previous Navy EISs, environmental assessments, MMPA take authorization requests, and the MMPA incidental harassment authorization (IHA) for the Navy's 2006 RIMPAC Major Exercise (National Oceanic and Atmospheric Administration, 2006i) used 173 decibel re 1 micropascal squared-second (dB re 1 μPa^2-s) as the energy threshold level (i.e., SEL) for Level B behavioral harassment for cetaceans. If the transmitted sonar accumulated energy received by a whale was above 173 dB re 1 μPa^2-s, then the animal was considered to have been behaviorally harassed. If the received accumulated energy level was below 173 dB re 1 μPa^2-s, then the animal was not treated as having been behaviorally harassed.

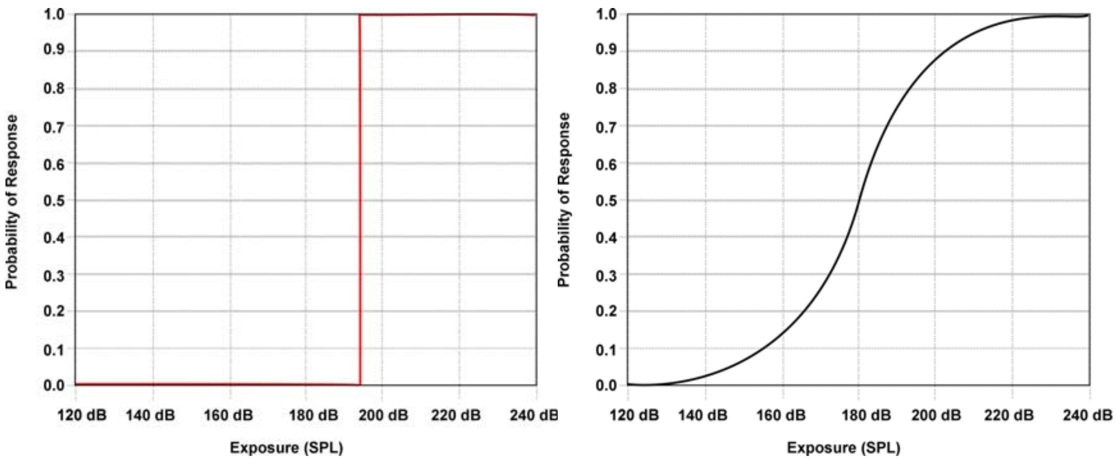

Figure 4.1.2.4.9.3-1. Step Function Versus Risk Continuum Function

Note: The left panel illustrates a typical step function with the probability of a response on the y-axis and received exposure on the x-axis. The right panel illustrates a typical risk continuum-function using the same axes. SPL is "Sound Pressure Level" in decibels referenced to 1 micropascal root mean square (1 μPa rms).

The left panel in Figure 4.1.2.4.9.3-1 illustrates a typical step-function or threshold that might also relate a sonar exposure to the probability of a response. As this figure illustrates, past Navy/NMFS acoustic thresholds assumed that every marine mammal above a particular received level (for example, to the right of the red vertical line in the figure) would exhibit identical responses to a sonar exposure. This assumed that the responses of marine mammals would not be affected by differences in acoustic conditions; differences between species and populations; differences in gender, age, reproductive status, or social behavior; or the prior experience of the individuals.

Both the Navy and NMFS agree that the studies of marine mammals in the wild and in experimental settings do not support these assumptions—different species of marine mammals and different individuals of the same species respond differently to sonar exposure. Additionally, there are specific geographic/bathymetric conditions that dictate the response of marine mammals to sonar that suggest that different populations may respond differently to sonar exposure. Further, studies of animal physiology suggest that gender, age, reproductive status, and social behavior, among other variables, probably affect how marine mammals respond to sonar exposures. (Wartzok et al., 2003; Southall et al., 2007)

Over the past several years, the Navy and NMFS have worked on developing an MFA sonar acoustic risk function to replace the acoustic thresholds used in the past to estimate the probability of marine mammals being behaviorally harassed by received levels of MFA sonar. The Navy and NMFS will continue to use acoustic thresholds to estimate temporary or permanent threshold shifts using SEL as the appropriate metric. Unlike acoustic thresholds, acoustic risk continuum functions (which are also called “exposure-response functions,” “dose-response functions,” or “stress-response functions” in other risk assessment contexts) assume that the probability of a response depends first on the “dose” (in this case, the received level of sound) and that the probability of a response increases as the “dose” increases. It is important to note that the probabilities associated with acoustic risk functions do not represent an individual’s probability of responding. Rather, the probabilities identify the proportion of an exposed population that is likely to respond to an exposure.

The right panel in Figure 4.1.2.4.9.3-1 illustrates a typical acoustic risk function that might relate an exposure, as received sound pressure level in decibels referenced to 1 μPa, to the probability of a response. As the exposure receive level increases in this figure, the probability of a response increases as well but the relationship between an exposure and a response is “linear” only in the center of the curve (that is, unit increases in exposure would produce unit increases in the probability of a response only in the center of a risk function curve). In the “tails” of an acoustic risk function curve, unit increases in exposure produce smaller increases in the probability of a response. Based on observations of various animals, including humans, the relationship represented by an acoustic risk function is a more robust predictor of the probable behavioral responses of marine mammals to sonar and other acoustic sources.

The Navy and NMFS have previously used the acoustic risk function to estimate the probable responses of marine mammals to acoustic exposures for other training and research programs. Examples of previous application include the Navy FEISs on the SURTASS LFA sonar (U.S. Department of the Navy, 2001c); the North Pacific Acoustic Laboratory experiments conducted off the Island of Kauai (Office of Naval Research, 2001), and the Supplemental EIS for SURTASS LFA sonar (U.S. Department of the Navy, 2007d).

The Navy and NMFS used two metrics to estimate the number of marine mammals that could be subject to Level B harassment (behavioral harassment and temporary threshold shift [TTS]) as defined by the MMPA, during training exercises. The agencies used acoustic risk functions with the metric of received sound pressure level (dB re 1 µPa) to estimate the number of marine mammals that might be at risk for MMPA Level B behavioral harassment as a result of being exposed to MFA sonar. The agencies will continue to use acoustic thresholds (“step-functions”) with the metric of sound exposure level (dB re 1 μPa^2-s) to estimate the number of marine mammals that might be “taken” through sensory impairment (i.e., Level A – permanent threshold shift [PTS] and Level B – TTS) as a result of being exposed to MFA sonar.

Although the Navy has not used acoustic risk functions in previous MFA sonar assessments of the potential effects of MFA sonar on marine mammals, risk functions are not new concepts for risk assessments. Common elements are contained in the process used for developing criteria for air, water, radiation, and ambient noise and for assessing the effects of sources of air, water, and noise pollution. The Environmental Protection Agency uses dose-functions to develop water quality criteria and to regulate pesticide applications (U.S. Environmental Protection Agency, 1998); the Nuclear Regulatory Commission uses dose-functions to estimate the consequences of radiation exposures (see Nuclear Regulatory Commission, 1997 and 10 Code of Federal Regulations 20.1201); the Centers for Disease Control and Prevention and the Food and Drug Administration use dose-functions as part of their assessment methods (for example, see Centers for Disease Control and Prevention, 2003, U.S. Food and Drug Administration and others, 2001); and the Occupational Safety and Health Administration uses dose-functions to assess the potential effects of noise and chemicals in occupational environments on the health of people working in those environments (for examples, see Occupational Safety and Health Administration, 1996b; Occupational Safety and Health Administration, 2006).

Risk Function Adapted from Feller (1968)

The particular acoustic risk function developed by the Navy and NMFS estimates the probability of behavioral responses that NMFS would classify as harassment for the purposes of the MMPA given exposure to specific received levels of MFA sonar. The mathematical function is derived from a solution in Feller (1968) for the probability as defined in the SURTASS LFA Sonar Final OEIS/EIS (U.S. Department of the Navy, 2001c), and relied on in the Supplemental SURTASS LFA Sonar EIS (U.S. Department of the Navy, 2007d) for the probability of MFA sonar risk for MMPA Level B behavioral harassment with input parameters modified by NMFS for MFA sonar for mysticetes, odontocetes, and pinnipeds.

In order to represent a probability of risk, the function should have a value near zero at very low exposures, and a value near one for very high exposures. One class of functions that satisfies this criterion is cumulative probability distributions, a type of cumulative distribution function. In selecting a particular functional expression for risk, several criteria were identified:

- The function must use parameters to focus discussion on areas of uncertainty;
- The function should contain a limited number of parameters;
- The function should be capable of accurately fitting experimental data; and
- The function should be reasonably convenient for algebraic manipulations.

As described in U.S. Department of the Navy (2001c), the mathematical function below is adapted from a solution in Feller (1968).

$$R = \frac{1 - \left(\frac{L-B}{K}\right)^{-A}}{1 - \left(\frac{L-B}{K}\right)^{-2A}}$$

Where: R = risk (0 – 1.0);
L = Received Level (RL) in dB;
B = basement RL in dB; (120 dB);
K = the RL increment above basement in dB at which there is 50 percent risk;
A = risk transition sharpness parameter (10) .

In order to use this function, the values of the three parameters (B, K, and A) need to be established. The values used in the development of the parameters are based on three sources of data: TTS experiments conducted at SSC and documented in Finneran, et al. (2001, 2003, and 2005; Finneran and Schlundt, 2004); reconstruction of sound fields produced by the USS SHOUP associated with the behavioral responses of killer whales observed in Haro Strait and documented in Department of Commerce (National Marine Fisheries Service, 2005a); U.S. Department of the Navy (2004b); and Fromm (2004a, 2004b); and observations of the behavioral response of North Atlantic right whales exposed to alert stimuli containing mid-frequency components documented in Nowacek et al. (2004). The input parameters, as defined by NMFS, are based on very limited data that represent the best available science at this time.

4.1.2.4.9.4 Data Sources Used for Risk Function

There is widespread consensus that cetacean response to MFA sound signals needs to be better defined using controlled experiments (Cox et al., 2006; Southall et al., 2007). The Navy is contributing to an ongoing behavioral response study in the Bahamas that is anticipated to provide some initial information on beaked whales, the species identified as the most sensitive to MFA sonar. NMFS is leading this international effort with scientists from various academic institutions and research organizations to conduct studies on how marine mammals respond to underwater sound exposures.

Until additional data is available, NMFS and the Navy have determined that the following three data sets are most applicable for the direct use in developing risk function parameters for MFA/HFA sonar. These data sets represent the only known data that specifically relate altered behavioral responses to exposure to MFA sound sources. Until applicable data sets are evaluated to better qualify harassment from HFA sources, the risk function derived for MFA sources will apply to HFA.

Data from SSC's Controlled Experiments

Most of the observations of the behavioral responses of toothed whales resulted from a series of controlled experiments on bottlenose dolphins and beluga whales conducted by researchers at SSC's facility in San Diego, California (Finneran et al., 2001, 2003, 2005; Finneran and Schlundt 2004; Schlundt et al., 2000). In experimental trials with marine mammals trained to perform tasks when prompted, scientists evaluated whether the marine mammals performed these tasks when exposed to mid-frequency tones. Altered behavior during experimental trials usually involved refusal of animals to return to the site of the sound stimulus. This refusal included what appeared to be deliberate attempts to avoid a sound exposure or to avoid the location of the exposure site during subsequent tests. (Schlundt et al., 2000, Finneran et al., 2002a) Bottlenose dolphins exposed to 1-second (sec) intense tones exhibited short-term changes in behavior above received sound levels of 178 to 193 dB re 1 μPa root mean square (rms), and beluga whales did so at received levels of 180 to 196 dB and above. Test animals sometimes vocalized after an exposure to impulsive sound from a seismic watergun (Finneran et al., 2002a). In some instances, animals exhibited aggressive behavior toward the test apparatus (Ridgway et al., 1997; Schlundt et al., 2000).

1. Finneran and Schlundt (2004) examined behavioral observations recorded by the trainers or test coordinators during the Schlundt et al. (2000) and Finneran et al. (2001, 2003, 2005) experiments featuring 1-sec tones. These included observations from 193 exposure sessions (fatiguing stimulus level > 141 dB re 1μPa) conducted by Schlundt et al. (2000) and 21 exposure sessions conducted by Finneran et al. (2001, 2003, 2005). The observations were made during exposures to sound sources at 0.4 kHz, 3 kHz, 10 kHz, 20 kHz, and 75 kHz. The TTS experiments that supported Finneran and Schlundt (2004) are further explained below:

    a. Schlundt et al. (2000) provided a detailed summary of the behavioral responses of trained marine mammals during TTS tests conducted at SSC San Diego with 1-sec tones. Schlundt et al. (2000) reported eight individual TTS experiments.

Fatiguing stimuli durations were 1-sec; exposure frequencies were 0.4 kHz, 3 kHz, 10 kHz, 20 kHz and 75 kHz. The experiments were conducted in San Diego Bay. Because of the variable ambient noise in the bay, low-level broadband masking noise was used to keep hearing thresholds consistent despite fluctuations in the ambient noise. Schlundt et al. (2000) reported that “behavioral alterations,” or deviations from the behaviors the animals being tested had been trained to exhibit, occurred as the animals were exposed to increasing fatiguing stimulus levels.

b. Finneran et al. (2001, 2003, 2005) conducted TTS experiments using tones at 3 kHz. The test method was similar to that of Schlundt et al. (2000) except the tests were conducted in a pool with very low ambient noise level (below 50 dB re 1 μPa^2/hertz [Hz]), and no masking noise was used. Two separate experiments were conducted using 1-sec tones. In the first, fatiguing sound levels were increased from 160 to 201 dB SPL. In the second experiment, fatiguing sound levels between 180 and 200 dB SPL were randomly presented.

Data from Studies of Baleen (Mysticetes) Whale Responses

The only mysticete data available resulted from a field experiments in which baleen whales (mysticetes) were exposed to a range of frequency sound sources from 120 Hz to 4500 Hz.(Nowacek et al., 2004). An alert stimulus, with a mid-frequency component, was the only portion of the study used to support the risk function input parameters.

2. Nowacek et al. (2004; 2007) documented observations of the behavioral response of North Atlantic right whales exposed to alert stimuli containing mid-frequency components. To assess risk factors involved in ship strikes, a multi-sensor acoustic tag was used to measure the responses of whales to passing ships and experimentally tested their responses to controlled sound exposures, which included recordings of ship noise, the social sounds of conspecifics and a signal designed to alert the whales. The alert signal was 18 minutes of exposure consisting of three 2-minute signals played sequentially three times over. The three signals had a 60 percent duty cycle and consisted of: (1) alternating 1-sec pure tones at 500 Hz and 850 Hz; (2) a 2-sec logarithmic down-sweep from 4,500 Hz to 500 Hz; and (3) a pair of low (1,500 Hz)-high (2,000 Hz) sine wave tones amplitude modulated at 120 Hz and each 1-sec long. The purposes of the alert signal were (a) to provoke an action from the whales via the auditory system with disharmonic signals that cover the whales’ estimated hearing range; (b) to maximize the signal to noise ratio (obtain the largest difference between background noise) and c) to provide localization cues for the whale. Five out of six whales reacted to the signal designed to elicit such behavior. Maximum received levels ranged from 133 to 148 dB re 1μPa/√Hz.

Observations of Killer Whales in Haro Strait in the Wild

In May 2003, killer whales (*Orcinus orca*) were observed exhibiting behavioral responses while USS SHOUP was engaged in MFA sonar operations in the Haro Strait in the vicinity of Puget Sound, Washington. Although these observations were made in an uncontrolled environment, the sound field associated with the sonar operations had to be estimated, and the behavioral observations were reported for groups of whales, not individual whales, the observations associated with the USS SHOUP provide the only data set available of the behavioral responses of wild, non-captive animal upon exposure to the AN/SQS-53 MFA sonar.

3. U.S. Department of Commerce (National Marine Fisheries, 2005a); U.S. Department of the Navy (2004b); Fromm (2004a, 2004b) documented reconstruction of sound fields produced by USS SHOUP associated with the behavioral response of killer whales observed in Haro Strait. Observations from this reconstruction included an approximate closest approach time which was correlated to a reconstructed estimate of received level at an approximate whale location (which ranged from 150 to 180 dB), with a mean value of 169.3 dB SPL.

4.1.2.4.9.5 Limitations of the Risk Function Data Sources

There are significant limitations and challenges to any risk function derived to estimate the probability of marine mammal behavioral responses; these are largely attributable to sparse data. Ultimately there should be multiple functions for different marine mammal taxonomic groups, but the current data are insufficient to support them. The goal is unquestionably that risk functions be based on empirical measurement.

The risk function presented here is based on three data sets that NMFS and Navy have determined are the best available science at this time. The Navy and NMFS acknowledge each of these data sets has limitations.

While NMFS considers all data sets as being weighted equally in the development of the risk function, the Navy believes the SSC San Diego data is the most rigorous and applicable for the following reasons:

- The data represents the only source of information where the researchers had complete control over and ability to quantify the noise exposure conditions.
- The altered behaviors were identifiable due to long-term observations of the animals.
- The fatiguing noise consisted of tonal exposures with limited frequencies contained in the MFA sonar bandwidth.

However, the Navy and NMFS do agree that the following are limitations associated with the three data sets used as the basis of the risk function:

- The three data sets represent the responses of only four species: trained bottlenose dolphins and beluga whales, North Atlantic right whales in the wild, and killer whales in the wild.
- None of the three data sets represent experiments designed for behavioral observations of animals exposed to MFA sonar.
- The behavioral responses of marine mammals that were observed in the wild are based solely on an estimated received level of sound exposure; they do not take into consideration (due to minimal or no supporting data):
  - Potential relationships between acoustic exposures and specific behavioral activities (e.g., feeding, reproduction, changes in diving behavior, etc.), variables such as bathymetry, or acoustic waveguides; or

– Differences in individuals, populations, or species, or the prior experiences, reproductive state, hearing sensitivity, or age of the marine mammal.

<u>SSC San Diego Trained Bottlenose Dolphins and Beluga Data Set:</u>

- The animals were trained animals in captivity; therefore, they may be more or less sensitive than cetaceans found in the wild (Domjan, 1998).
- The tests were designed to measure TTS, not behavior.
- Because the tests were designed to measure TTS, the animals were exposed to much higher levels of sound than the baseline risk function (only two of the total 193 observations were at levels below 160 dB re 1 μPa^2-s).
- The animals were not exposed in the open ocean but in a shallow bay or pool.
- The tones used in the tests were 1-second pure tones similar to MFA sonar.

<u>North Atlantic Right Whales in the Wild Data Set:</u>

- The observations of behavioral response were from exposure to alert stimuli that contained mid-frequency components but was not similar to an MFA sonar ping. The alert signal was 18 minutes of exposure consisting of three 2-minute signals played sequentially three times over. The three signals had a 60 percent duty cycle and consisted of: (1) alternating 1-sec pure tones at 500 Hz and 850 Hz; (2) a 2-sec logarithmic down-sweep from 4,500 Hz to 500 Hz; and (3) a pair of low (1,500 Hz)-high (2,000 Hz) sine wave tones amplitude modulated at 120 Hz and each 1-sec long. This 18-minute alert stimuli is in contrast to the average 1-sec ping every 30 sec in a comparatively very narrow frequency band used by military sonar.
- The purpose of the alert signal was, in part, to provoke an action from the whales through an auditory stimulus.

<u>Killer Whales in the Wild Data Set:</u>

- The observations of behavioral harassment were complicated by the fact that there were other sources of harassment in the vicinity (other vessels and their interaction with the animals during the observation).
- The observations were anecdotal and inconsistent. There were no controls during the observation period, with no way to assess the relative magnitude of the observed response as opposed to baseline conditions.

4.1.2.4.9.6 Input Parameters for the Feller-Adapted Risk Function

The values of <u>B</u>, <u>K</u>, and <u>A</u> need to be specified in order to utilize the risk function defined in Section 4.2.1.9.3 previously. The risk continuum function approximates the dose-response function in a manner analogous to pharmacological risk assessment (U.S. Department of the Navy, 2001c, Appendix A). In this case, the risk function is combined with the distribution of sound exposure levels to estimate aggregate impact on an exposed population.

4.1.2.4.9.6.1 Basement Value for Risk—The <u>B</u> Parameter

The <u>B</u> parameter defines the basement value for risk, below which the risk is so low that calculations are impractical. This 120 dB level is taken as the estimate received level (RL) below which the risk of significant change in a biologically important behavior approaches zero for the

MFA sonar risk assessment. This level is based on a broad overview of the levels at which multiple species have been reported responding to a variety of sound sources, both mid-frequency and other, was recommended by the scientists, and has been used in other publications. The Navy recognizes that for actual risk of changes in behavior to be zero, the signal-to-noise ratio of the animal must also be zero.

4.1.2.4.9.6.2 The K Parameter

NMFS and the Navy used the mean of the following values to define the midpoint of the function: (1) the mean of the lowest received levels (185.3 dB) at which individuals responded with altered behavior to 3 kHz tones in the SSC data set; (2) the estimated mean received level value of 169.3 dB produced by the reconstruction of the USS SHOUP incident in which killer whales exposed to MFA sonar (range modeled possible received levels: 150 to 180 dB); and (3) the mean of the 5 maximum received levels at which Nowacek et al. (2004) observed significantly altered responses of right whales to the alert stimuli than to the control (no input signal) is 139.2 dB SPL. The arithmetic mean of these three mean values is 165 dB SPL. The value of K is the difference between the value of B (120 dB SPL) and the 50 percent value of 165 dB SPL; therefore, K=45.

4.1.2.4.9.6.3 Risk Transition—The A Parameter

The A parameter controls how rapidly risk transitions from low to high values with increasing receive level. As A increases, the slope of the risk function increases. For very large values of A, the risk function can approximate a threshold response or step function. NMFS has recommended that Navy use A=10 as the value for odontocetes, and pinnipeds, and A=8 for mysticetes, (Figures 4.1.2.4.9.6.3-1 and 4.1.2.4.9.6.3-2) (National Marine Fisheries Service, 2008).

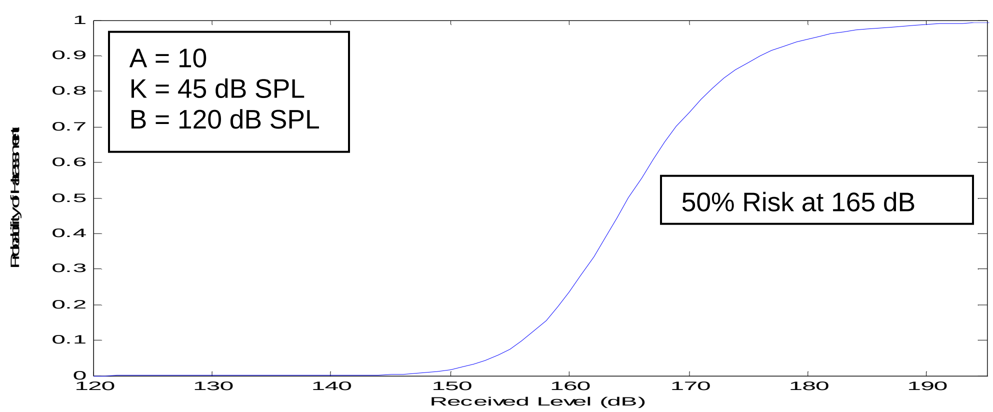

Figure 4.1.2.4.9.6.3-1. Risk Function Curve for Odontocetes (Toothed Whales) and Pinnipeds

The NMFS independent review process, described previously, provided the impetus for the selection of the parameters for the risk function curves. One scientist recommended staying close to the risk continuum concept as used in the SURTASS LFA sonar EIS. This scientist opined that both the basement and slope values; B=120 dB and A=10 respectively, from the SURTASS LFA sonar risk continuum concept are logical solutions in the absence of compelling data to select alternate values supporting the Feller-adapted risk function for MFA sonar. Another scientist indicated a steepness parameter needed to be selected, but did not recommend a value. Four scientists did not specifically address selection of a slope value. After reviewing the six scientists' recommendations, the two NMFS scientists recommended selection of A=10. Direction was provided by NMFS to use the A=10 curve for odontocetes based on the scientific review of potential risk functions explained in Section 4.1.2.4.9.2.

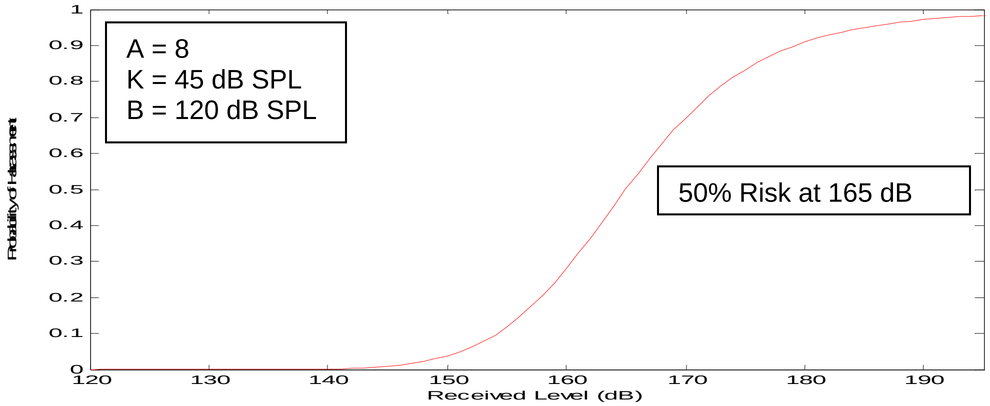

Figure 4.1.2.4.9.6.3-2. Risk Function Curve for Mysticetes (Baleen Whales)

<u>Justification for the Steepness Parameter of A=10 for the Odontocete Curve</u>

As background, a sensitivity analysis of the A=10 parameter was undertaken and presented in Appendix D of the SURTASS/LFA FEIS (U.S. Department of the Navy, 2001c). The analysis was performed to support the A=10 parameter for mysticete whales responding to a low-frequency sound source, a frequency range to which the mysticete whales are believed to be most sensitive to. The sensitivity analysis results confirmed the increased risk estimate for animals exposed to sound levels below 165 dB. Results from the Low Frequency Sound Scientific Research Program (LFS SRP) phase II research showed that whales (specifically gray whales in their case) did scale their responses with received level as supported by the A=10 parameter (Buck and Tyack, 2000). In the second phase of the LFS SRP research, migrating gray whales showed responses similar to those observed in earlier research (Malme et al., 1983, 1984) when the LF source was moored in the migration corridor (2 km [1.1 nm] from shore). The study extended those results with confirmation that a louder SL elicited a larger scale avoidance response. However, when the source was placed offshore (4 km [2.2 nm] from shore) of the migration corridor, the avoidance response was not evident. This implies that the inshore avoidance model – in which 50 percent of the whales avoid exposure to levels of 141 ± 3 dB – may not be valid for whales in proximity to an offshore source (U.S. Department of Navy, 2001c). As concluded in the SURTASS LFA Sonar Final OEIS/EIS (U.S. Department of the Navy, 2001c), the value of A=10 produces a curve that has a more gradual transition than the curves developed by the analyses of migratory gray whale studies (Malme et al., 1984; Buck and Tyack, 2000; and SURTASS LFA Sonar EIS, Subchapters 1.43, 4.2.4.3 and Appendix D, and National Marine Fisheries Service, 2008).

<u>Justification for the steepness parameter of A=8 for the Mysticete Curve</u>

The Nowacek et al. (2004) study provides the only available data source for a mysticete species behaviorally responding to a sound source (*i.e.*, alert stimuli) with frequencies in the range of tactical mid-frequency sonar (1-10 kHz), including empirical measurements of received levels

(RLs). While there are fundamental differences in the stimulus used by Nowacek et al. (2004) and tactical mid-frequency sonar (*e.g.*, source level, waveform, duration, directionality, likely range from source to receiver), they are generally similar in frequency band and the presence of modulation patterns. Thus, while they must be considered with caution in interpreting behavioral responses of mysticetes to mid-frequency sonar, they seemingly cannot be excluded from this consideration given the overwhelming lack of other information. The Nowacek et al. (2004) data indicate that five out the six North Atlantic right whales exposed to an alert stimuli "significantly altered their regular behavior and did so in identical fashion" (*i.e*., ceasing feeding and swimming to just under the surface). For these five whales, maximum RLs associated with this response ranged from root- mean-square sound (rms) pressure levels of 133-148 dB (re: 1 µPa).

When six scientists (one of them being Nowacek) were asked to independently evaluate available data for constructing a dose response curve based on a solution adapted from Feller (1968), the majority of them (4 out of 6; one being Nowacek) indicated that the Nowacek et al. (2004) data were not only appropriate but also necessary to consider in the analysis. While other parameters associated with the solution adapted from Feller (1968) were provided by many of the scientists (*i.e.*, basement parameter [B], increment above basement where there is 50 percent risk [K]), only one scientist provided a suggestion for the risk transition parameter, A.

A single curve may provide the simplest quantitative solution to estimating behavioral harassment. However, the policy decision, by NMFS-OPR, to adjust the risk transition parameter from A=10 to A=8 for mysticetes and create a separate curve was based on the fact the use of this shallower slope better reflected the increased risk of behavioral response at relatively low RLs suggested by the Nowacek et al. (2004) data. In other words, by reducing the risk transition parameter from 10 to 8, the slope of the curve for mysticetes is reduced. This results in an increase the proportion of the population being classified as behaviorally harassed at lower RLs. It also slightly reduces the estimate of behavioral response probability at quite high RLs, though this is expected to have quite little practical result owing to the very limited probability of exposures well above the mid-point of the function. This adjustment allows for a slightly more conservative approach in estimating behavioral harassment at relatively low RLs for mysticetes compared to the odontocete curve and is supported by the only dataset currently available. It should be noted that the current approach (with A=8) still yields an extremely low probability for behavioral responses at RLs between 133-148 dB, where the Nowacek data indicated significant responses in a majority of whales studied. (Note: Creating an entire curve based strictly on the Nowacek et al. [2004] data alone for mysticetes was advocated by several of the reviewers and considered inappropriate, by NMFS-OPR, since the sound source used in this study was not identical to tactical mid-frequency sonar, and there were only 5 data points available). The policy adjustment made by NMFS-OPR was also intended to capture some of the additional recommendations and considerations provided by the scientific panel (*i.e.*, the curve should be more data driven and that a greater probability of risk at lower RLs be associated with direct application of the Nowacek et al. 2004 data).

4.1.2.4.9.7 Basic Application of the Risk Function and Relation to the Current Regulatory Scheme

The risk function is used to estimate the percentage of an exposed population that is likely to exhibit behaviors that would qualify as harassment (as that term is defined by the MMPA applicable to military readiness activities, such as the Navy's testing and training with MFA sonar) at a given received level of sound. For example, at 165 dB SPL (dB re: 1µPa rms), the risk (or probability) of harassment is defined according to this function as 50 percent, and Navy/NMFS applies that by estimating that 50 percent of the individuals exposed at that received level are likely to respond by exhibiting behavior that NMFS would classify as behavioral harassment. The risk function is not applied to individual animals, only to exposed populations.

The data used to produce the risk function were compiled from four species that had been exposed to sound sources in a variety of different circumstances. As a result, the risk function represents a general relationship between acoustic exposures and behavioral responses that is then applied to specific circumstances. That is, the risk function represents a relationship that is deemed to be generally true, based on the limited, best-available science, but may not be true in specific circumstances. In particular, the risk function, as currently derived, treats the received level as the only variable that is relevant to a marine mammal's behavioral response. However, we know that many other variables—the marine mammal's gender, age, and prior experience; the activity it is engaged in during an exposure event, its distance from a sound source, the number of sound sources, and whether the sound sources are approaching or moving away from the animal—can be critically important in determining whether and how a marine mammal will respond to a sound source (Southall et al., 2007). The data that are currently available do not allow for incorporation of these other variables in the current risk functions; however, the risk function represents the best use of the data that are available.

NMFS and Navy made the decision to apply the MFA risk function curve to HFA sources due to lack of available and complete information regarding HFA sources. As more specific and applicable data become available for MFA/HFA sources, NMFS can use these data to modify the outputs generated by the risk function to make them more realistic. Ultimately, data may exist to justify the use of additional, alternate, or multi-variate functions. As mentioned above, it is known that the distance from the sound source and whether it is perceived as approaching or moving away can affect the way an animal responds to a sound (Wartzok et al., 2003). In the HRC example, animals exposed to received levels between 120 and 130 dB may be more than 65 nautical miles (131,651 yards) from a sound source (Table 4.1.2.4.9.7-1); those distances would influence whether those animals might perceive the sound source as a potential threat, and their behavioral responses to that threat. Though there are data showing marine mammal responses to sound sources at that received level, NMFS does not currently have any data that describe the response of marine mammals to sounds at that distance (or to other contextual aspects of the exposure, such as the presence of higher frequency harmonics), much less data that compare responses to similar sound levels at varying distances. However, if data were to become available that suggested animals were less likely to respond (in a manner NMFS would classify as harassment) to certain levels beyond certain distances, or that they were more likely to respond at certain closer distances, the Navy will re-evaluate the risk function to try to incorporate any additional variables into the "take" estimates.

Last, pursuant to the MMPA, an applicant is required to estimate the number of animals that will be "taken" by their activities. This estimate informs the analysis that NMFS must perform to determine whether the activity will have a "negligible impact" on the species or stock. Level B (behavioral) harassment occurs at the level of the individual(s) and does not assume any resulting population-level consequences, though there are known avenues through which behavioral disturbance of individuals can result in population-level effects. Alternately, a negligible impact finding is based on the lack of likely adverse effects on annual rates of recruitment or survival (i.e., population-level effects). An estimate of the number of Level B harassment takes, alone, is not enough information on which to base an impact determination. In addition to considering estimates of the number of marine mammals that might be "taken" through harassment, NMFS must consider other factors, such as the nature of any responses (their intensity, duration, etc.), the context of any responses (critical reproductive time or location, migration, etc.), or any of the other variables mentioned in the first paragraph (if known), as well as the number and nature of estimated Level A takes, the number of estimated mortalities, and effects on habitat. Generally speaking, the Navy and NMFS anticipate more severe effects from takes resulting from exposure to higher received levels (though this is in no way a strictly linear relationship throughout species, individuals, or circumstances) and less severe effects from takes resulting from exposure to lower received levels (Figure 4.1.2.4.9.7-1).

Table 4.1.2.4.9.7-1. Harassments at Each Received Level Band

Received Level	Distance at which Levels Occur in HRC	Percent of Harassments Occurring at Given Levels
Below 140 dB SPL	36 km–125 km	<1%
140>Level>150 dB SPL	15 km–36 km	2%
150>Level>160 dB SPL	5 km–15 km	20%
160>Level>170 dB SPL	2 km–5 km	40%
170>Level>180 dB SPL	0.6–2 km	24%
180>Level>190 dB SPL	180–560 meters	9%
Above 190 dB SPL	0–180 meters	2%
TTS (195 dB EFDL)	0–110 meters	2%
PTS (215 dB EFDL)	0–10 meters	<1%

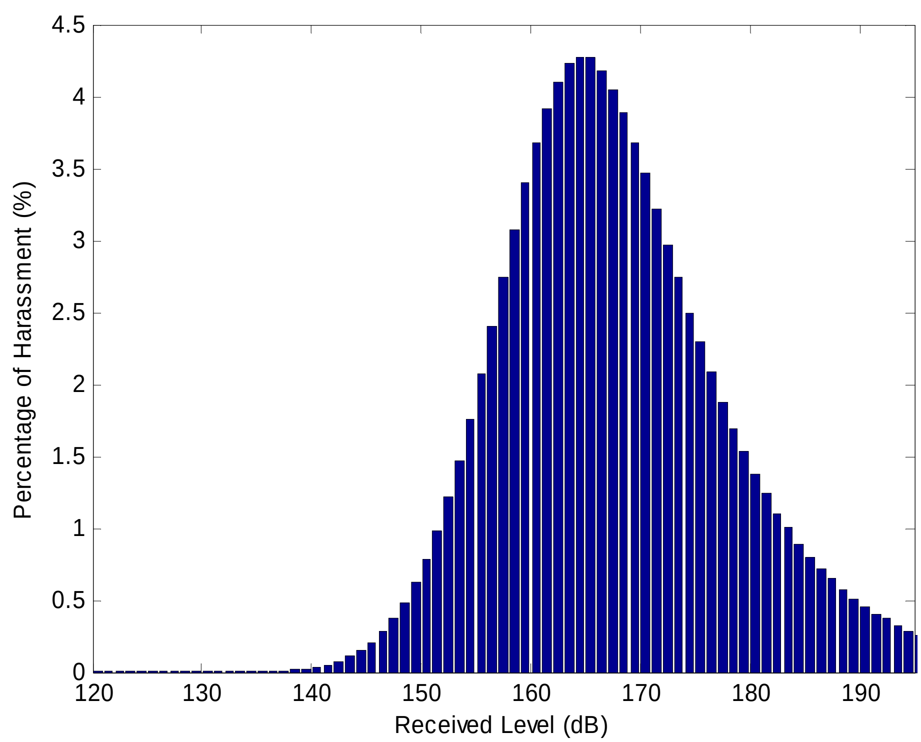

Figure 4.1.2.4.9.7-1. The Percentage of Behavioral Harassments Resulting from the Risk Function for Every 5 dB of Received Level

4.1.2.4.9.8 Navy Post Acoustic Modeling Analysis

The quantification of the acoustic modeling results includes additional analysis to increase the accuracy of the number of marine mammals affected. Table 4.1.2.4.9.8-1 provides a summary of the modeling protocols used in this analysis. Post modeling analysis includes reducing acoustic footprints where they encounter land masses, accounting for acoustic footprints for sonar sources that overlap to accurately sum the total area when multiple ships are operating together, and to better account for the maximum number of individuals of a species that could potentially be exposed to sonar within the course of one day or a discreet continuous sonar event.

Table 4.1.2.4.9.8-1. Navy Protocols Providing for Accurate Modeling Quantification of Marine Mammal Exposures

Historical Data	Sonar Positional Reporting System (SPORTS)	Annual active sonar usage data is obtained from the SPORTS database to determine the number of active sonar hours and the geographic location of those hours for modeling purposes.
Acoustic Parameters	AN/SQS-53 and AN/SQS-56	The AN/SQS-53 and the AN/SQS-56 active sonar sources separately to account for the differences in source level, frequency, and exposure effects.
	Submarine Sonar	Submarine active sonar use is included in effects analysis calculations using the SPORTS database.
Post Modeling Analysis	Land Shadow	For sound sources within the acoustic footprint of land, (approximately 65 nautical miles [nm] for the Hawaii Range Complex [HRC]) subtract the land area from the marine mammal exposure calculation.
	Multiple Ships	Correction factors are used to address the maximum potential of exposures to marine mammals resulting from multiple counting based on the acoustic footprint when there are occasions for more than one ship operating within approximately 130 nm of one another.
	Multiple Exposures	Accurate accounting for HRC training events within the course of one day or a discreet continuous sonar event: • Other HRC ASW training – 13.5 hours • RIMPAC – 12 hours • USWEX – 16 hours • Multi-strike group – 12 hours.

Pinniped

Information on the hearing abilities of the Hawaiian monk seal is limited. The range of underwater hearing in monk seals is 12 to 70 kHz, with best hearing from 12 to 28 kHz and 60 to 70 kHz (Thomas et al., 1990). This audiogram was from only one animal, and the high upper frequency range, which is high for a phocid (this taxonomic group), may not be indicative of the species. There is no information on underwater sounds, and in-air sounds are low-frequency sounds (below 1,000 Hz) such as “soft liquid bubble,” short duration guttural expiration, a roar and belching/coughing sound (Miller and Job, 1992). A pup produces a higher frequency call (1.4 kHz) that presumably is used to call its mother. The audiogram of the Hawaiian monk seal suggests they hear above MFA sonar, although the in-air sounds they produce are below MFA sonar.

For there to be an exposure to MFA/HFA sonar during ASW events in the HRC, a monk seal would have to be underwater and in the vicinity of the event to exceed the exposure thresholds discussed previously. The NMFS Recovery Plan for the Hawaiian Monk Seal notes; “Monk seals spend approximately two-thirds of their time in the water” (National Marine Fisheries Service, 2007e). The acoustic modeling’s resulting in-water exposures to monk seals has, therefore, been reduced in this analysis by one-third to account for the time monk seals are not expected to be in the water.

Modeling undertaken for monk seals does not take into consideration the effect of mitigation measures or foraging habitat preferences. Monk seals generally forage at depths of less than 100 m, but occasionally dive to depths of over 500 m. The majority of ASW training in the HRC, however, takes place in waters 4 to 8 times deeper than even this reported (500 m) maximum. It is also very rare for ASW training using MFA sonar to take place in waters as shallow as 100 m in depth. The Navy’s mitigation measures require continuous visual observation during training with active sonar. It would, therefore, be rare for a Hawaiian monk seal to be present in the vicinity of an ASW event and the potential for detection by aircraft and lookouts aboard ship should further preclude the possibility that monk seals would be in the vicinity of ASW training events. Additionally, unlike the concern over beaked whales given a limited number of strandings coincident with the use of MFA sonar use, there have been no indications that any pinniped has ever been affected by exposure to MFA sonar.

4.1.2.4.10 Cetacean Stranding Events

The Navy is very concerned about and thoroughly investigates each stranding potentially associated with sonar use to better understand these interactions. Strandings can be a single animal, but several to hundreds may be involved. An event where animals are found out of their normal habitat is considered a stranding even though animals do not necessarily end up beaching (such as the July 2004 Hanalei Mass Stranding Event; see Southall et al., 2006). Several hypotheses have been given for the mass strandings, which include the impact of shallow beach slopes on odontocete echolocation, disease or parasites, geomagnetic anomalies that affect navigation, following a food source in close to shore, avoiding predators, social interactions that cause other cetaceans to come to the aid of stranded animals, and from human actions. Generally inshore species do not strand in large numbers but usually as a single animal. This may be due to their familiarity with the coastal area, whereas some pelagic species that are unfamiliar with obstructions or sea bottom tend to strand more often in larger numbers (Woodings, 1995). The Navy has studied several stranding events in detail that may have occurred in association with Navy sonar activities. To better understand the causal factors in stranding events that may be associated with Navy sonar activities, the main factors, including bathymetry (i.e., steep drop offs), narrow channels (less than 35 nm), environmental conditions (e.g., surface ducting), and multiple sonar ships (see section on Stranding Events Associated with Navy Sonar) were compared between the different stranding events.

In a review of 70 reports of world-wide mass stranding events between 1960 and 2006, 48 (68 percent) involved beaked whales, 3 (4 percent) involved dolphins, and 14 (20 percent) involved whale species (International Whaling Commission, 2005). Cuvier’s beaked whales were involved in the greatest number of these events (48 or 68 percent), followed by sperm whales (7 or 10 percent), and Blainville’s and Gervais’ beaked whales (4 each or 6 percent). Naval training that might have involved tactical sonars are reported to have coincided with 9 (13 percent) or 10 (14 percent) of those stranding events. Between the mid-1980s and 2003 (the period reported by the International Whaling Commission, 2007), the Navy identified reports of

44 mass cetacean stranding events, of which at least 5 have been correlated with naval training that were using MFA sonar.

RIMPAC Exercises have occurred every second year since 1968, and ASW training has occurred in each of the 19 exercises that have occurred thus far. If the MFA sonar employed during those exercises killed or injured whales whenever the whales encountered the sonar, it seems likely that some mass strandings would have occurred at least once or twice over the 38-year period since 1968. With one exception, there is little evidence of a pattern in the record of strandings reported for the main Hawaiian Islands.

What is a Stranded Marine Mammal?

When a live or dead marine mammal swims or floats onto shore and becomes "beached" or incapable of returning to sea, the event is termed a "stranding" (Geraci et al., 1999; Perrin and Geraci, 2002; Geraci and Lounsbury, 2005; National Marine Fisheries Service, 2007p). The legal definition for a stranding within the United States is that "a marine mammal is dead and is (i) on a beach or shore of the United States; or (ii) in waters under the jurisdiction of the United States (including any navigable waters); or (B) a marine mammal is alive and is (i) on a beach or shore of the United States and is unable to return to the water; (ii) on a beach or shore of the United States and, although able to return to the water, is in need of apparent medical attention; or (iii) in the waters under the jurisdiction of the United States (including any navigable waters), but is unable to return to its natural habitat under its own power or without assistance." (16 U.S.C. 1421h).

The majority of animals that strand are dead or moribund (National Marine Fisheries Service, 2007p). For animals that strand alive, human intervention through medical aid and/or guidance seaward may be required for the animal to return to the sea. If unable to return to sea, rehabilitation at an appropriate facility may be determined as the best opportunity for animal survival. An event where animals are found out of their normal habitat is may be considered a stranding depending on circumstances even though animals do not necessarily end up beaching (Southhall, 2006).

Three general categories can be used to describe strandings: single, mass, and unusual mortality events. The most frequent type of stranding is a single stranding, which involves only one animal (or a mother/calf pair) (National Marine Fisheries Service, 2007p).

Mass stranding involves two or more marine mammals of the same species other than a mother/calf pair (Wilkinson, 1991), and may span one or more days and range over several miles (Simmonds and Lopez-Jurado, 1991; Frantzis, 1998; Walsh et al., 2001; Freitas, 2004). In North America, only a few species typically strand in large groups of 15 or more and include sperm whales, pilot whales, false killer whales, Atlantic white-sided dolphins, white-beaked dolphins, and rough-toothed dolphins (Odell, 1987, Walsh et al., 2001). Some species, such as pilot whales, false-killer whales, and melon-headed whales occasionally strand in groups of 50 to 150 or more (Geraci et al., 1999). All of these normally pelagic off-shore species are highly sociable and usually infrequently encountered in coastal waters. Species that commonly strand in smaller numbers include pygmy killer whales, common dolphins, bottlenose dolphins, Pacific white-sided dolphin Frasier's dolphins, gray whale and humpback whale (West Coast only), harbor porpoise, Cuvier's beaked whales, California sea lions, and harbor seals (Mazzuca et al., 1999, Norman et al., 2004, Geraci and Lounsbury, 2005).

Unusual Mortality Events (UMEs) can be a series of single strandings or mass strandings, or unexpected mortalities (i.e., die-offs) that occur under unusual circumstances (Dierauf and Gulland, 2001; Harwood, 2002; Gulland, 2006; National Marine Fisheries Service, 2007p). These events may be interrelated: for instance, at-sea die-offs lead to increased stranding frequency over a short period of time, generally within one to two months. As published by the NMFS, revised criteria for defining a UME include (National Marine Fisheries Service, 2006c):

- A marked increase in the magnitude or a marked change in the nature of morbidity, mortality, or strandings when compared with prior records.
- A temporal change in morbidity, mortality, or strandings is occurring.
- A spatial change in morbidity, mortality, or strandings is occurring.
- The species, age, or sex composition of the affected animals is different than that of animals that are normally affected.
- Affected animals exhibit similar or unusual pathologic findings, behavior patterns, clinical signs, or general physical condition (e.g., blubber thickness).
- Potentially significant morbidity, mortality, or stranding is observed in species, stocks or populations that are particularly vulnerable (e.g., listed as depleted, threatened or endangered or declining). For example, stranding of three or four right whales may be cause for great concern whereas stranding of a similar number of fin whales may not.
- Morbidity is observed concurrent with or as part of an unexplained continual decline of a marine mammal population, stock, or species.

UMEs are usually unexpected, infrequent, and may involve a significant number of marine mammal mortalities. As discussed below, unusual environmental conditions are probably responsible for most UMEs and marine mammal die-offs (Vidal and Gallo-Reynoso, 1996; Geraci et al., 1999; Walsh et al., 2001; Gulland and Hall, 2005).

United States Stranding Response Organization

Stranding events provide scientists and resource managers information not available from limited at-sea surveys, and may be the only way to learn key biological information about certain species such as distribution, seasonal occurrence, and health (Rankin, 1953; Moore et al., 2004; Geraci and Lounsbury, 2005). Necropsies are useful in attempting to determine a reason for the stranding, and are performed on stranded animals when the situation and resources allow.

In 1992, Congress amended the MMPA to establish the Marine Mammal Health and Stranding Response Program (MMHSRP) under authority of the Department of Commerce, NMFS. The MMHSRP was created out of concern started in the 1980s for marine mammal mortalities, to formalize the response process, and to focus efforts being initiated by numerous local stranding organizations and as a result of public concern.

Major elements of the MMHSRP include:

- National Marine Mammal Stranding Network
- Marine Mammal UME Program

- National Marine Mammal Tissue Bank (NMMTB) and Quality Assurance Program
- Marine Mammal Health Biomonitoring, Research, and Development
- Marine Mammal Disentanglement Network
- John H. Prescott Marine Mammal Rescue Assistance Grant Program (a.k.a. the Prescott Grant Program)
- Information Management and Dissemination. (National Marine Fisheries Service, 2007p)

The United States has a well-organized network in coastal states to respond to marine mammal strandings. Overseen by the NMFS, the National Marine Mammal Stranding Network is comprised of smaller organizations manned by professionals and volunteers from nonprofit organizations, aquaria, universities, and state and local governments trained in stranding response, animal health, and diseased investigation. Currently, 141 organizations are authorized by NMFS to respond to marine mammal strandings (National Marine Fisheries Service, 2007p). Through a National Coordinator and six regional coordinators, NMFS authorizes and oversees stranding response activities and provides specialized training for the network.

Stranding reporting and response efforts over time have been inconsistent, although effort and data quality within the United States have been improving within the last 20 years (National Marine Fisheries Service, 2007p). Given the historical inconsistency in response and reporting, however, interpretation of long-term trends in marine mammal stranding is difficult (National Marine Fisheries Service, 2007p). During the past decade (1995 – 2004), approximately 40,000 stranded marine mammals (about 12,400 are cetaceans) have been reported by the regional stranding networks, averaging 3,600 strandings reported per year (National Marine Fisheries Service, 2007p). The highest number of strandings were reported between the years 1998 and 2003 (National Marine Fisheries Service, 2007p). Detailed regional stranding information including most commonly stranded species can be found in Zimmerman (1991), Geraci and Lounsbury (2005), and National Marine Fisheries Service (2007p).

Stranding Data

Stranding events, though unfortunate, can be useful to scientists and resource managers because they can provide information that is not accessible at sea or through any other means. Necropsies are useful in attempting to assess a reason for the stranding, and are performed on stranded animals when the situation allows. Stranded animals have provided us with the opportunity to gain insight into the lives of marine mammals such as their natural history, seasonal distribution, population health, reproductive biology, environmental contaminant levels, types of interactions with humans, and the prevalence of disease and parasites. The only existing information on some cetacean species has been discovered from stranding events (National Marine Fisheries Service, 2007c).

Currently the government agency that is responsible for responding to strandings is the Marine Mammal Health and Stranding Response Program (MMHSRP) within NMFS. The National Marine Mammal Stranding Network, which is one part of the more comprehensive MMHSRP, is made up of smaller organizations partnered with NMFS to investigate marine mammal strandings. These stranding networks are established in all coastal states and consist of professionals and volunteers from nonprofit organizations, aquaria, universities, and state and local governments who are trained in stranding response. NMFS authorizes, coordinates, and participates in response activities and personnel training (National Marine Fisheries Service, 2007c). NMFS oversees stranding response via a National Coordinator and a regional coordinator in each of the NMFS regions. Stranding reporting and response efforts over time have been inconsistent and have been increasing over the past three decades, making any trends hard to interpret (National Marine Fisheries Service, 2007d). Over the past decade (1990–2000), approximately 40,000 stranded marine mammals have been reported by the regional stranding networks, averaging 3,600 strandings reported per year (National Marine Fisheries Service, 2007f). The highest number of strandings was reported between the years 1992–1993 and 1997–1998, with a peak in the number of reported strandings in 1998 totaling 5,708 (National Marine Fisheries Service, 2007f; National Marine Fisheries Service, 2007d). These have since been determined to have been El Niño years, which for a variety of reasons can have a drastic effect on marine mammals (see below). Reporting effort has been more consistent since 1994. Between 1994 and 1998 a total of 19,130 strandings were reported, with an average of 3,826 per year (National Marine Fisheries Service, 2007d). The composition of animals involved in strandings varied by region.

Peak years for cetacean strandings were in 1994 and 1999, and can be attributed to two UMEs. In 1994, 220 bottlenose dolphins stranded off Texas, which represented almost double the annual average (National Marine Fisheries Service, 2007f). It has been determined that the probable cause for these strandings was a morbillivirus outbreak. Then in 1999, 223 harbor porpoises stranded from Maine to North Carolina, representing a four-fold increase over the annual average (National Marine Fisheries Service, 2007f). The most likely cause for these strandings is interspecific aggression due to sea surface temperatures and a shift in prey species in the Mid-Atlantic (National Marine Fisheries Service, 2007f).

Table 4.1.2.4.10-1 describes numbers and composition of reported strandings during the more recent 5-year period between 2001-2005 (National Marine Fisheries Service, 2007d).

Table 4.1.2.4.10-1. Summary of the Number of Cetacean and Pinniped Strandings by Region from 2001-2005

Region	Number of Cetaceans	Number of Pinnipeds
Pacific	152	119
Southeast	3,549	55
Northeast	2,144	4,744
Southwest	49	230
Northwest	321	1,984
Alaska	152	119
Five-Year Totals	**6,636**	**7,489**

Source: National Marine Fisheries Service, 2007d; 2008

4.1.2.4.10.1 Causes of Strandings

Reports of marine mammal strandings can be traced back to ancient Greece (Walsh et al., 2001). Like any wildlife population, there are normal background mortality rates that influence marine mammal population dynamics, including starvation, predation, aging, reproductive success, and disease (Geraci et al., 1999; Carretta et al., 2007). Strandings in and of themselves may be reflective of this natural cycle or, more recently, may be the result of anthropogenic sources (i.e., human impacts). Current science suggests that multiple factors, both natural and man-made, may be acting alone or in combination to cause a marine mammal to strand (Geraci et al., 1999; Culik, 2002; Perrin and Geraci, 2002; Hoelzel, 2003; Geraci and Lounsbury, 2005; National Research Council, 2006). While post-stranding data collection and necropsies of dead animals are attempted in an effort to find a possible cause for the stranding, it is often difficult to pinpoint exactly one factor that can be blamed for any given stranding. An animal suffering from one ailment becomes susceptible to various other influences because of its weakened condition, making it difficult to determine a primary cause. In many stranding cases, scientists never learn the exact reason for the stranding.

Specific potential stranding causes can include both natural and human influenced (anthropogenic) causes listed below and described in the following sections:

Natural Stranding Causes:
- Disease
- Naturally occurring marine neurotoxins
- Weather and climatic influences
- Navigation errors
- Social cohesion
- Predation

Human Influenced (Anthropogenic) Stranding Causes:
- Fisheries interaction
- Vessel strike
- Pollution and ingestion
- Noise
- Gunshots

Natural Stranding Causes

Significant natural causes of mortality, die-offs, and stranding presented in Table 4.1.2.4.10.1-1 include disease and parasitism; marine neurotoxins from algae; navigation errors that lead to inadvertent stranding; and climatic influences that impact the distribution and abundance of potential food resources (i.e., starvation). Other natural mortality not discussed in detail includes predation by other species such as sharks (Cockcroft et al., 1989; Heithaus, 2001), killer whales (Constantine et al., 1998; Guinet et al., 2000; Pitman et al., 2001), and some species of pinniped (Hiruki et al., 1999; Robinson et al., 1999). Table 4.1.2.4.10.1.1 lists unusual mortality events for marine mammals that have been attributed to or suspected from natural causes from 1978 to 2005.

Table 4.1.2.4.10.1-1. Marine Mammal Unusual Mortality Events Attributed to or Suspected from Natural Causes 1978-2005

Year	Species and number	Location	Cause
1978	Hawaiian monk seals (50)	NW Hawaiian Islands	Ciguatoxin and maitotoxin
1979-80	Harbor seals (400)	Massachusetts	Influenza A
1982	Harbor seals	Massachusetts	Influenza A
1983	Multiple pinniped species	West coast of U.S., Galapagos	El Nino
1984	California sea lions (226)	California	Leptospirosis
1987	Sea otters (34)	Alaska	Saxitoxin
1987	Humpback whales (14)	Massachusetts	Saxitoxin
1987-88	Bottlenose dolphins (645)	Eastern seaboard (New Jersey to Florida)	Morbillivirus; Brevetoxin
1987-88	Baikal seals (80-100,000)	Lake Baikal, Russia	Canine distemper virus
1988	Harbor seals (approx 18,000)	Northern Europe	Phocine distemper virus
1990	Stripped dolphins (550)	Mediterranean Sea	Dolphin morbillivirus
1990	Bottlenose dolphins (146)	Gulf Coast, U.S.	Unknown; unusual skin lesions observed
1994	Bottlenose dolphins (72)	Texas	Morbillivirus
1995	California sea lions (222)	California	Leptospirosis
1996	Florida manatees (149)	West Coast Florida	Brevetoxin
1996	Bottlenose dolphins (30)	Mississippi	Unknown; Coincident with algal bloom
1997	Mediterranean monk seals (150)	Western Sahara, Africa	Harmful algal bloom; Morbillivirus
1997-98	California sea lions (100s)	California	El Nino
1998	California sea lions (70)	California	Domoic acid
1998	Hooker’s sea lions (60% of pups)	New Zealand	Unknown, bacteria likely
1999	Harbor porpoises	Maine to North Carolina	Oceanographic factors suggested
2000	Caspian seals (10,000)	Caspian Sea	Canine distemper virus
1999-2000	Bottlenose dolphins (115)	Panhandle of Florida	Brevetoxin
1999-2001	Gray whales (651)	Canada, U.S. West Coast, Mexico	Unknown; starvation involved
2000	California sea lions (178)	California	Leptospirosis
2000	California sea lions (184)	California	Domoic acid
2000	Harbor seals (26)	California	Unknown; Viral pneumonia suspected
2001	Bottlenose dolphins (35)	Florida	Unknown
2001	Harp seals (453)	Maine to Massachusetts	Unknown
2001	Hawaiian monk seals (11)	NW Hawaiian Islands	Malnutrition
2002	Harbor seals (approx. 25,000)	Northern Europe	Phocine distemper virus

Table 4.1.2.4.10.1-1. Marine Mammal Unusual Mortality Events Attributed to or Suspected from Natural Causes 1978-2005 (Continued)

Year	Species and number	Location	Cause
2002	Multispecies (common dolphins, California sea lions, sea otters) (approx. 500)	California	Domoic acid
2002	Hooker's sea lions	New Zealand	Pneumonia
2002	Florida manatee	West Coast of Florida	Brevetoxin
2003	Multispecies (common dolphins, California sea lions, sea otters) (approx. 500)	California	Domoic acid
2003	Beluga whales (20)	Alaska	Ecological factors
2003	Sea otters	California	Ecological factors
2003	Large whales (16 humpback, 1 fine, 1 minke, 1 pilot, 2 unknown)	Maine	Unknown; Saxitoxin and domoic acid detected in 2 of 3 humpbacks
2003-2004	Harbor seals, minke whales	Gulf of Maine	Unknown
2003	Florida manatees (96)	West Coast of Florida	Brevetoxin
2004	Bottlenose dolphins (107)	Florida Panhandle	Brevetoxin
2004	Small cetaceans (67)	Virginia	Unknown
2004	Small cetaceans	North Carolina	Unknown
2004	California sea lions (405)	Canada, U.S. West Coast	Leptospirosis
2005	Florida manatees, bottlenose dolphins (ongoing Dec 2005)	West Coast of Florida	Brevetoxin
2005	Harbor porpoises	North Carolina	Unknown
2005	California sea lions; Northern fur seals	California	Domoic acid
2005	Large whales	Eastern North Atlantic	Domoic acid suspected
2005-2006	Bottlenose dolphins	Florida	Brevetoxin suspected

Source: Data from Gulland and Hall (2007); citations for each event contained in Gulland and Hall (2007)

Disease

Marine mammals frequently suffer from a variety of diseases resulting from viral, bacterial, or parasites (National Oceanic and Atmospheric Administration, 2006e). Gulland and Hall (2005, 2007) provide a more-detailed summary of individual and population effects of marine mammal diseases.

Microparasites such as bacteria, viruses, and other microorganisms are commonly found in marine mammal habitats and usually pose little threat to a healthy animal (Geraci et al., 1999). For example, long-finned pilot whales that inhabit the waters off of the northeastern coast of the U.S. are carriers of the morbillivirus, yet have grown resistant to its usually lethal effects (Geraci et al., 1999). Since the 1980s, however, virus infections have been strongly associated with marine mammal die-offs (Domingo et al., 1992; Geraci and Lounsbury, 2005). Morbillivirus is the most significant marine mammal virus and suppresses a host's immune system, increasing risk of secondary infection (Harwood, 2002). A bottlenose dolphin UME in 1993 and 1994 was caused by infectious disease. Die-offs ranged from northwestern Florida to Texas, with an increased number of deaths as it spread (National Marine Fisheries Service, 2007d). A 2004 UME in Florida was also associated with dolphin morbillivirus (National Marine Fisheries Service, 2004a). Influenza A was responsible for the first reported mass mortality in the United States, occurring along the coast of New England in 1979-1980 (Geraci et al., 1999; Harwood, 2002). Canine distemper virus (a type of morbillivirus) has been responsible for large scale pinniped mortalities and die-offs (Grachev et al., 1989; Kennedy et al., 2000; Gulland and Hall, 2005), while a bacteria, *Leptospira pomona*, is responsible for periodic die-offs in California sea lions about every 4 years (Gulland et al., 1996; Gulland and Hall, 2005). It is difficult to determine whether microparasites commonly act as a primary pathogen, or whether they show up as a secondary infection in an already weakened animal (Geraci et al., 1999). Most marine mammal die-offs from infectious disease in the last 25 years, however, have had viruses associated with them (Simmonds and Mayer, 1997; Geraci et al., 1999; Harwood, 2002).

Macroparasites are usually large parasitic organisms and include lungworms, trematodes (parasitic flatworms), and protozoans (Geraci and St. Aubin, 1987; Geraci et al., 1999). Marine mammals can carry many different types, and have shown a robust tolerance for sizeable infestation unless compromised by illness, injury, or starvation (Morimitsu et al., 1987; Dailey et al., 1991; Geraci et al., 1999). Nasitrema, a usually benign trematode found in the head sinuses of cetaceans (Geraci et al., 1999), can cause brain damage if it migrates (Ridgway and Dailey, 1972). As a result, this worm is one of the few directly linked to stranding in the cetaceans (Dailey and Walker, 1978; Geraci et al., 1999).

Non-infectious disease, such as congenital bone pathology of the vertebral column (osteomyelitis, spondylosis deformans, and ankylosing spondylitis), has been described in several species of cetacean (Paterson, 1984; Alexander et al., 1989; Kompanje, 1995; Sweeny et al., 2005). In humans, bone pathology such as ankylosing spondylitis can impair mobility and increase vulnerability to further spinal trauma (Resnick and Niwayama, 2002). Bone pathology has been found in cases of single strandings (Paterson, 1984; Kompanje, 1995), and also in cetaceans prone to mass stranding (Sweeny et al., 2005), possibly acting as a contributing or causal influence in both types of events.

Naturally Occurring Marine Neurotoxins

Some single cell marine algae common in coastal waters, such as dinoflagellates and diatoms, produce toxic compounds that can accumulate (termed bioaccumulation) in the flesh and organs of fish and invertebrate (Geraci et al., 1999; Harwood, 2002). Marine mammals become exposed to these compounds when they eat prey contaminated by these naturally produced toxins although exposure can also occur through inhalation and skin contact (Van Dolah, 2005).

In the Gulf of Mexico and mid- to southern Atlantic states, “red tides,” a form of harmful algal bloom, are created by a dinoflagellate (*Karenia brevis*). *K. brevis* is found throughout the Gulf of Mexico and sometimes along the Atlantic coast (Van Dolah, 2005; National Marine Fisheries Service, 2007p). It produces a neurotoxin known as brevetoxin. Brevetoxin has been associated with several marine mammal UMEs within this area (Geraci, 1989; Van Dolah et al., 2003; National Marine Fisheries Service, 2004a; Flewelling et al., 2005; Van Dolah, 2005).

On the U.S. west coast and in the northeast Atlantic, several species of diatoms (microscopic marine plants) produce a toxin called domoic acid which has also been linked to marine mammal strandings (Geraci et al., 1999; Van Dolah et al., 2003; Greig et al., 2005; Van Dolah, 2005; Brodie et al., 2006; National Marine Fisheries Service, 2007p). These diatoms are widespread and can be found on the east and west coasts of the United States as well as in the Gulf of Mexico (National Marine Fisheries Service, 2007n). Domoic acid has also been known to have serious effects on public health and a variety of marine species (National Marine Fisheries Service, 2007n). Since 1998, domoic acid has been identified as the cause of mass mortalities of seabirds and marine mammals off the coast of California, and whale deaths off Georges Bank and it was suspected in mass mortalities as early as 1992 otherwise listed as “unknown neurologic disorder” (National Marine Fisheries Service, 2007n). Other algal toxins associated with marine mammal strandings include saxitoxins and ciguatoxins and are summarized by Van Dolah (2005); Ciguatoxins are common in Hawaiian reef fish.

In 2004, between March 10 and April 13, 107 bottlenose dolphins were found dead and stranded on the Florida Panhandle, along with hundreds of dead fish and marine invertebrates (National Marine Fisheries Service, 2007o). This event was declared a UME. Analyses of the dolphins found brevetoxins at high levels within the dolphin stomach contents, and at variable levels within their tissues (National Marine Fisheries Service, 2007o). Low levels of domoic acid were also detected in some of the dolphins, and a diatom that produces domoic acid (*Pseudo-nitzschia delicatissima*) was present in low to moderate levels in water samples (National Marine Fisheries Service, 2007o). In the Gulf of Mexico, two other UMEs associated with red tide involving bottlenose dolphins occurred previously in 1996, and between 1999 and 2000 (National Marine Fisheries Service, 2005h).

Insufficient information is available to determine how, or at what levels and in what combinations, environmental contaminants may affect cetaceans (Marine Mammal Commission, 2003). There is growing evidence that high contaminant burdens are associated with several physiological abnormalities, including skeletal deformations, developmental effects, reproductive and immunological disorders, and hormonal alterations (Reijnders and Aguilar, 2002). It is possible that anthropogenic chemical contaminants initially cause immunosuppression, rendering whales susceptible to opportunistic bacterial, viral, and parasitic infection (De Swart et al., 1995). Specific information regarding the potential effects of environmental contamination on marine species in the Hawaiian Islands is not available, and therefore cumulative effects cannot be determined.

Weather and Climatic Influences

Severe storms, hurricanes, typhoons, and prolonged temperature extremes may lead to localized marine mammal strandings (Geraci et al., 1999; Walsh et al., 2001). Hurricanes may have been responsible for mass strandings of pygmy killer whales in the British Virgin Islands and Gervais’ beaked whales in North Carolina (Mignucci-Giannoni et al., 2000; Norman and Mead, 2001). Storms in 1982-1983 along the California coast led to deaths of 2,000 northern elephant seal pups (Le Boeuf and Reiter, 1991). Ice movement along southern Newfoundland has forced groups of blue whales and white-beaked dolphins ashore (Sergeant, 1982). Seasonal oceanographic conditions in terms of weather, frontal systems, and local currents may also play a role in stranding (Walker et al., 2005).

The effect of large scale climatic changes to the world’s oceans and how these changes impact marine mammals and influence strandings is difficult to quantify given the broad spatial and temporal scales involved, and the cryptic movement patterns of marine mammals (Moore, 2005; Learmonth et al., 2006). The most immediate, although indirect, effect is decreased prey availability during unusual conditions. This, in turn, results in increased search effort required by marine mammals (Crocker et al., 2006), potential starvation if not successful, and corresponding stranding due directly to starvation or succumbing to disease or predation while in a more weakened, stressed state (Selzer and Payne, 1988; Geraci et al., 1999; Moore, 2005; Learmonth et al., 2006; Weise et al., 2006).

Two recent papers examined potential influences of climate fluctuation on stranding events in southern Australia, including Tasmania, an area with a history of more than 20 mass stranding since the 1920s (Evans et al., 2005; Bradshaw et al., 2005). These authors note that patterns in animal migration, survival, fecundity, population size, and strandings will revolve around the availability and distribution of food resources. In southern Australia, movement of nutrient-rich waters pushed closer to shore by periodic meridinal winds (occurring about every 12 to 14 years) may be responsible for bringing marine mammals closer to land, thus increasing the probability of stranding (Bradshaw et al., 2006). The papers conclude, however, that while an overarching model can be helpful for providing insight into the prediction of strandings, the particular reasons for each one are likely to be quite varied.

Navigational Errors

Geomagnetism

It has been hypothesized that, like some land animals, marine mammals may be able to orient to the Earth's magnetic field as a navigational cue, and that areas of local magnetic anomalies may influence strandings (Bauer et al., 1985; Klinowska, 1985; Kirschvink et al., 1986; Klinowska, 1986; Walker et al., 1992; Wartzok and Ketten, 1999). In a plot of live stranding positions in Great Britain with magnetic field maps, Klinowska (1985, 1986) observed an association between live stranding positions and magnetic field levels. In all cases, live strandings occurred at locations where magnetic minima, or lows in the magnetic fields, intersect the coastline. Kirschvink et al. (1986) plotted stranding locations on a map of magnetic data for the east coast of the United States, and were able to develop associations between stranding sites and locations where magnetic minima intersected the coast. The authors concluded that there were highly significant tendencies for cetaceans to beach themselves near these magnetic minima and coastal intersections. The results supported the hypothesis that cetaceans may have a magnetic sensory system similar to other migratory animals, and that marine magnetic topography and patterns may influence long-distance movements (Kirschvink et al., 1986). Walker et al. (1992) examined fin whale swim patterns off the northeastern U.S. continental shelf, and reported that migrating animals aligned with lows in the geometric gradient or intensity. While a similar pattern between magnetic features and marine mammal strandings at New Zealand stranding sites was not seen (Brabyn and Frew, 1994), mass strandings in Hawaii typically were found to occur within a narrow range of magnetic anomalies (Mazzuca et al., 1999).

Echolocation Disruption in Shallow Water

Some researchers believe stranding may result from reductions in the effectiveness of echolocation within shallow water, especially with the pelagic species of odontocetes who may be less familiar with coastline (Dudok van Heel, 1966; Chambers and James, 2005). For an odontocete, echoes from echolocation signals contain important information on the location and identity of underwater objects and the shoreline. The authors postulate that the gradual slope of a beach may present difficulties to the navigational systems of some cetaceans, since it is common for live strandings to occur along beaches with shallow, sandy gradients (Brabyn and

McLean, 1992; Mazzuca et al., 1999; Maldini et al., 2005; Walker et al., 2005). A contributing factor to echolocation interference in turbulent, shallow water is the presence of microbubbles from the interaction of wind, breaking waves, and currents. Additionally, ocean water near the shoreline can have an increased turbidity (e.g., floating sand or silt, particulate plant matter, etc.) due to the run-off of fresh water into the ocean, either from rainfall or from freshwater outflows (e.g., rivers and creeks). Collectively, these factors can reduce and scatter the sound energy within echolocation signals and reduce the perceptibility of returning echoes of interest.

Social Cohesion

Many pelagic species such as sperm whales, pilot whales, melon-head whales, and false killer whales, and some dolphins occur in large groups with strong social bonds between individuals. When one or more animals strand due to any number of causative events, then the entire pod may follow suit out of social cohesion (Geraci et al., 1999; Conner, 2000; Perrin and Geraci, 2002; National Marine Fisheries Service, 2007p).

Predation

Many species of marine mammal serve as prey to other animals and forms of marine life, including sharks and even other marine mammals. Predation from sharks is considered to be a contributing factor in the decline of the Hawaiian monk seal (Geraci et al., 1999). A stranded marine mammal will sometimes show signs of interactions with predators such as bites, teeth marks, and other injuries, which occasionally are severe enough to have been the primary cause of injury, death, and stranding.

Human Influenced (Anthropogenic) Causes

Over the past few decades there has been an increase in marine mammal mortalities believed to be caused by a variety of human activities (Geraci et al., 1999; National Marine Fisheries Service, 2007p), such as gunshots, ship strikes (National Oceanic and Atmospheric Administration, 2006e; Nelson et al., 2007), and other trauma and mutilations.

- Gunshot injuries are the most common man-made cause of strandings in sea lions and seals on the U.S. West Coast (National Marine Fisheries Service, 2007d).
- Every year a few northern right whales are killed within shipping lanes along the U.S. Atlantic coast, which may be enough to jeopardize stock recovery (Geraci et al., 1999).
- In 1998, two bottlenose dolphins and a calf were killed by vessel strikes in the Gulf of Mexico (National Marine Fisheries Service, 2005h).
- In 1999 there was one report of a stranded false killer whale on the Alabama coast that was classified as likely caused by fishery interactions or other human interaction due to limb mutilation (the fins and flukes of the animal had been amputated) (National Marine Fisheries Service, 2005e).
- 1,377 bottlenose dolphins were found stranded in the Gulf of Mexico from 1999 through 2003; 73 animals (11 percent) showed evidence of human interactions as the cause of death (e.g., gear entanglement, mutilations, gunshot wounds) (National Marine Fisheries Service, 2005h).

Data from strandings in which there was evidence of human interaction is available for the years 1999–2000. Table 4.1.2.4.10.1-2 provides the number of stranded marine mammals (cetaceans and pinnipeds) during this period that displayed evidence of human interactions (taken from National Marine Fisheries Service, 2007f). (Stranding data for the California region for the year 1999 is unavailable; therefore numbers are for stranded animals in 2000 only. Similarly, data is unavailable for the year 2000 in the Alaska region; numbers provided represent strandings for 1999 only.)

Table 4.1.2.4.10.1-2. Summary of Marine Mammal Strandings by Cause for Each Region from 1999-2000

Interaction	Southeast	Northeast	Northwest	California	Alaska
Fisheries	89	75	10	30	16
Vessel Strike	9	6	1	8	2
Gun Shot	6	6	12	41	4
Blunt Trauma	-	1	-	-	-
Mutilation	4	17	-	-	-
Plastic Ingestion	1	3	-	-	-

Fisheries Interaction: By-Catch, Directed Catch, and Entanglement

The incidental catch of marine mammals in commercial fisheries is a significant threat to many populations of marine mammals (Geraci et al., 1999; Baird, 2002; Culik, 2002; Carretta et al., 2004; Geraci and Lounsbury, 2005; National Marine Fisheries Service, 2007p). Interactions with fisheries and entanglement in discarded or lost gear continue to be a major factor in marine mammal deaths worldwide (Geraci et al., 1999; Nieri et al., 1999; Geraci and Lounsbury, 2005; Read et al., 2006; Zeeberg et al., 2006). For instance, baleen whales and pinnipeds have been found entangled in nets, ropes, monofilament line, and other fishing gear that has been discarded out at sea (Geraci et al., 1999; Campagna et al., 2007).

Bycatch

Bycatch is the catching of non-target species within a given fishing operation and can include non-commercially used invertebrates, fish, sea turtles, birds, and marine mammals (National Research Council, 2006). Read et al. (2006) attempted to estimate the magnitude of marine mammal bycatch in U.S. and global fisheries. Data on marine mammal bycatch within the United States was obtained from fisheries observer programs, reports of entangled stranded animals, and fishery logbooks, and was then extrapolated to estimate global bycatch by using the ratio of U.S. fishing vessels to the total number of vessels within the world's fleet (Read et al., 2006). Within U.S. fisheries, between 1990 and 1999 the mean annual bycatch of marine mammals was 6,215 animals, with a standard error of +/- 448 (Read et al., 2006). Eighty-four percent of cetacean bycatch occurred in gill-net fisheries, with dolphins and porpoises constituting most of the cetacean bycatch (Read et al., 2006). Over the decade there was a 40 percent decline in marine mammal bycatch, which was significantly lower from 1995-1999 than it was from 1990-1994 (Read et al., 2006). Read et al. (2006) suggests that this is primarily due to effective conservation measures that were implemented during this time period.

Read et al. (2006) then extrapolated this data for the same time period and calculated an annual estimate of 653,365 of marine mammals globally, with most of the world's bycatch occurring in gill-net fisheries. With global marine mammal bycatch likely to be in the hundreds of thousands every year, bycatch in fisheries will be the single greatest threat to many marine mammal populations around the world (Read et al., 2006).

Entanglement

Entanglement in fishing gear is a major cause of death or severe injury among the endangered whales. In the 2006-2007 whale season in Hawaii, the stranding network received reports of 26 entanglements (National Oceanic and Atmospheric Administration, 2006e). Entangled marine mammals may die as a result of drowning, escape with pieces of gear still attached to their bodies, or manage to be set free either of their own accord or by fishermen. Many large whales carry off gear after becoming entangled (Read et al., 2006). Many times when a marine mammal swims off with gear attached, the end result can be fatal. The gear may be become too cumbersome for the animal, or it can be wrapped around a crucial body part and tighten over time. Stranded marine mammals frequently exhibit signs of previous fishery interaction, such as scarring or gear attached to their bodies, and the cause of death for many stranded marine mammals is often attributed to such interactions (Baird and Gorgone, 2005). Marine mammals that die or are injured in fisheries activities may not wash ashore, therefore stranding data may underestimate fishery-related mortalities and serious injuries (National Marine Fisheries Service, 2005b).

From 1993 through 2003, 927 harbor porpoises were reported stranded from Maine to North Carolina, many of which had cuts and body damage suggestive of net entanglement. In 1999 it was possible to determine that the cause of death for 38 of the stranded porpoises was from fishery interactions, with one additional animal having been mutilated (right flipper and fluke cut off). In 2000, one stranded porpoise was found with monofilament line wrapped around its body and in 2003, nine stranded harbor porpoises were attributed to fishery interactions, with an additional three mutilated animals (National Marine Fisheries Service, 2005g). An estimated 78 baleen whales were killed annually in the offshore southern California/Oregon drift gillnet fishery during the 1980s (Heyning and Lewis, 1990). From 1998-2005, based on observer records, five fin whales (CA/OR/WA stock), 19 humpback whales (ENP stock), and six sperm whales (CA/OR/WA stock) were either seriously injured or killed in fisheries off the mainland west coast of the United States (California Marine Mammal Stranding Network Database, 2006).

Ship Strike

Ship strikes to marine mammals are another cause of mortality and stranding (Laist et al., 2001; Geraci and Lounsbury, 2005; De Stephanis and Urquiola, 2006). An animal at the surface could be struck directly by a ship, a surfacing animal could hit the bottom of a ship, or an animal just below the surface could be cut by a ship's propeller. The severity of injuries typically depends on the size and speed of the ship (Knowlton and Kraus, 2001; Laist et al., 2001; Vanderlaan and Taggart 2007).

In the 2006-2007 whale season in Hawaii, the stranding network saw an increase in the number of vessel collisions with whales (none involving military vessels) having recorded eight ship strikes (National Oceanic and Atmospheric Administration, 2006e). Three of these collisions with marine mammals were known to have caused injury to the animal.

An examination of all known ship strikes from all shipping sources (civilian and military) indicates ship speed is a principal factor in whether a ship strike results in death (Knowlton and Kraus 2001; Laist et al. 2001, Jensen and Silber 2003; Vanderlaan and Taggart 2007). In assessing records in which ship speed was known, Laist et al. (2001) found a direct relationship between the occurrence of a whale strike and the speed of the ship involved in the collision. While the authors concluded that most deaths occurred when a ship was traveling in excess of 13 knots, the study did not, however, take into account the historical increase in ship speed and the increase in the number of ships since records have been collected. In essence, very few modern ships transit at less than 13 knots.

Jensen and Silber (2003) detailed 292 records of known or probable ship strikes of all large whale species from 1975 to 2002. Of these, ship speed at the time of collision was reported for 58 cases. Of these cases, 39 (or 67 percent) resulted in serious injury or death (19 or 33 percent resulted in serious injury as determined by blood in the water, propeller gashes or severed tailstock, and fractured skull, jaw, vertebrae, hemorrhaging, massive bruising or other injuries noted during necropsy, and 20 or 35 percent resulted in death). Operating speeds of ships that struck various species of large whales ranged from 2 to 51 knots. The majority (79 percent) of these strikes occurred at speeds of 13 knots or greater. The average speed that resulted in serious injury or death was 18.6 knots. Pace and Silber (2005) found that the probability of death or serious injury increased rapidly with increasing ship speed. Specifically, the predicted probability of serious injury or death increased from 45 percent to 75 percent as ship speed increased from 10 to 14 knots, and exceeded 90 percent at 17 knots. Higher speeds during collisions result in greater force of impact, but higher speeds also appear to increase the chance of severe injuries or death by pulling whales toward the ship. Computer simulation modeling showed that hydrodynamic forces pulling whales toward the ship hull increase with increasing speed (Clyne, 1999; Knowlton et al., 1995).

The growth in civilian commercial ports and associated commercial ship traffic is a result in the globalization of trade. The Final Report of the NOAA International Symposium on “Shipping Noise and Marine Mammals: A Forum for Science, Management, and Technology” stated that the worldwide commercial fleet has grown from approximately 30,000 ships in 1950 to over 85,000 ships in 1998 (National Research Council, 2003; Southall, 2005). Between 1950 and 1998, the U.S. flagged fleet declined from approximately 25,000 to less than 15,000 and currently represents only a small portion of the world fleet. From 1985 to 1999, world seaborne trade doubled to 5 billion tons and currently includes 90 percent of the total world trade, with container shipping movements representing the largest volume of seaborne trade. It is unknown how international shipping volumes and densities will continue to grow. However, current statistics support the prediction that the international shipping fleet will continue to grow at the current rate or at greater rates in the future. Shipping densities in specific areas and trends in routing and ship design are as, or more, significant than the total number of ships. Densities along existing coastal routes are expected to increase both domestically and internationally. New routes are also expected to develop as new ports are opened and existing ports are expanded. Ship propulsion systems are also advancing toward faster ships operating in higher sea states for lower operating costs; and container ships are expected to become larger along certain routes (Southall, 2005).

While there are reports and statistics of whales struck by ships in U.S. waters, the magnitude of the risks of commercial ship traffic poses to marine mammal populations is difficult to quantify or estimate. In addition, there is limited information on ship strike interactions between ships and marine mammals outside of U.S. waters (De Stephanis and Urquiola, 2006). Laist et al. (2001) concluded that ship collisions may have a negligible effect on most marine mammal populations in general, except for regional based small populations where the significance of low numbers of collisions would be greater given smaller populations or populations segments.

Navy ship traffic is a small fraction of the overall U.S. commercial and fishing ship traffic. While Navy ship movements may contribute to the ship strike threat, given the lookout and mitigation measures adopted by the Navy, probability of ship strikes is greatly reduced. Furthermore, actions to avoid close interaction of Navy ships and marine mammals and sea turtles, such as maneuvering to keep away from any observed marine mammal and sea turtle are part of existing at-sea protocols and standard operating procedures. Navy ships have up to three or more dedicated and trained lookouts as well as two to three bridge watchstanders during at-sea movements who would be searching for any whales, sea turtles, or other obstacles on the water surface. Such lookouts are expected to further reduce the chances of a collision.

Ingestion of Plastic Objects and Other Marine Debris and Toxic Pollution Exposure

For many marine mammals, debris in the marine environment is a great hazard and can be harmful to wildlife. Not only is debris a hazard because of possible entanglement, animals may mistake plastics and other debris for food (National Marine Fisheries Service, 2007h). There are certain species of cetaceans, along with Florida manatees, that are more likely to eat trash, especially plastics, which is usually fatal for the animal (Geraci et al., 1999).

Between 1990 through October 1998, 215 pygmy sperm whales stranded along the U.S. Atlantic coast from New York through the Florida Keys (National Marine Fisheries Service, 2005b). Remains of plastic bags and other debris were found in the stomachs of 13 of these animals (National Marine Fisheries Service, 2005b). During the same time period, 46 dwarf sperm whale strandings occurred along the U.S. Atlantic coastline between Massachusetts and the Florida Keys (National Marine Fisheries Service, 2005e). In 1987 a pair of latex examination gloves was retrieved from the stomach of a stranded dwarf sperm whale (National Marine Fisheries Service, 2005f). From 1999–2003, 125 pygmy sperm whales were reported stranded between Maine and Puerto Rico; in one pygmy sperm whale found stranded in 2002, red plastic debris was found in the stomach along with squid beaks (National Marine Fisheries Service, 2005c).

Sperm whales and beaked whales have been known to ingest plastic debris, such as plastic bags (e.g., Evans et al., 2003; Whitehead, 2003). While this has led to mortality, the scale to which this is affecting sperm whale and beaked whale populations is unknown, Whitehead (2003) argued that it was not substantial at that time.

High concentrations of potentially toxic substances within marine mammals along with an increase in new diseases have been documented in recent years. Scientists have begun to consider the possibility of a link between pollutants and marine mammal mortality events. NMFS takes part in a marine mammal biomonitoring program not only to help assess the health and contaminant loads of marine mammals, but also to assist in determining anthropogenic impacts on marine mammals, marine food chains and marine ecosystem health. Using strandings and bycatch animals the program provides tissue/serum archiving, samples for analyses, disease monitoring and reporting and additional response during disease investigations (National Marine Fisheries Service 2007e).

The impacts of these activities are difficult to measure. However, some researchers have correlated contaminant exposure to possible adverse health effects in marine mammals. Contaminants such as organochlorines do not tend to accumulate in significant amounts in invertebrates, but do accumulate in fish and fish-eating animals. Thus, contaminant levels in planktivorous mysticetes have been reported to be one to two orders of magnitude lower compared to piscivorous odontocetes (Borell, 1993; O'Shea and Brownell, 1994; O'Hara and Rice, 1996; O'Hara et al., 1999).

The man-made chemical PCB (polychlorinated biphenyl), and the pesticide DDT (dichlorodiphenyltrichloroethane), are both considered persistent organic pollutants that are currently banned in the United States for their harmful effects in wildlife and humans (National Marine Fisheries Service, 2007d). Despite having been banned for decades in the United States, the levels of these compounds are still high in marine mammal tissue samples taken along U.S. coasts (National Marine Fisheries Service, 2007d). Both compounds are long lasting, reside in marine mammal fat tissues (especially in blubber), and can be toxic, causing effects such as reproductive impairment and immunosuppression (National Marine Fisheries Service, 2007d).

Both long-finned and short-finned pilot whales have a tendency to mass strand throughout their range. Short-finned pilot whales have been reported as stranded as far north as Rhode Island, and long-finned pilot whales as far south as South Carolina (National Marine Fisheries Service, 2005c). (For U.S. east coast stranding records, both species are lumped together and there is rarely a distinction between the two because of uncertainty in species identification [National Marine Fisheries Service, 2005c]). Since 1980 within the Northeast region alone, between 2 and 120 pilot whales have stranded annually either individually or in groups (National Marine Fisheries Service, 2005c). Between 1999 and 2003 from Maine to Florida, 126 pilot whales were reported to be stranded, including a mass stranding of 11 animals in 2000 and another mass stranding of 57 animals in 2002, both along the Massachusetts coast (National Marine Fisheries Service, 2005c).

It is unclear how much of a role human activities play in these pilot whale strandings, and toxic poisoning may be a potential human-caused source of mortality for pilot whales (National Marine Fisheries Service, 2005d). Moderate levels of PCBs and chlorinated pesticides (such as DDT, DDE, and dieldrin) have been found in pilot whale blubber (National Marine Fisheries Service, 2005d). Bioaccumulation levels have been found to be more similar in whales from the same stranding event than from animals of the same age or sex (National Marine Fisheries Service, 2005d). Numerous studies have measured high levels of toxic metals (mercury, lead, cadmium), selenium, and PCBs in pilot whales in the Faroe Islands (National Marine Fisheries

Service, 2005d). Population effects resulting from such high contamination levels are currently unknown (National Marine Fisheries Service, 2005d).

Habitat contamination and degradation may also play a role in marine mammal mortality and strandings. Some events caused by man have direct and obvious effects on marine mammals, such as oil spills (Geraci et al., 1999). But in most cases, effects of contamination will more than likely be indirect in nature, such as effects on prey species availability, or by increasing disease susceptibility (Geraci et al., 1999).

Navy ship operation between ports and exercise locations has the potential for release of small amounts of pollutant discharges into the water column. Navy ships are not a typical source, however, of either pathogens or other contaminants with bioaccumulation potential such as pesticides and PCBs. Furthermore, any ship discharges such as bilgewater and deck runoff associated with the ships would be in accordance with international and U.S. requirements for eliminating or minimizing discharges of oil, garbage, and other substances, and not likely to contribute significant changes to ocean water quality.

Ambient Sound in the Ocean

Ambient noise is environmental background noise. Marine mammals are regularly exposed to several sources of natural and anthropogenic sounds. As one of the potential stressors to marine mammal populations, noise and acoustic influences may disrupt marine mammal communication, navigational ability, and social patterns, and may or may not influence stranding. Many marine mammals use sound to communicate, navigate, locate prey, and sense their environment. Both anthropogenic and natural sounds may cause interference with these functions, although comprehension of the type and magnitude of any behavioral or physiological responses resulting from man-made sound, and how these responses may contribute to strandings, is rudimentary at best (National Marine Fisheries Service, 2007p). Marine mammals may respond both behaviorally and physiologically to sound exposure (e.g., Richardson et al., 1995a; Finneran et al., 2000; Finneran et al., 2003; Finneran et al., 2005, National Research Council, 2005; Southall et al., 2007); however, the range and magnitude of the behavioral response of marine mammals to various sound sources is highly variable and appears to depend on the species involved, the experience of the animal with the sound source, the motivation of the animal (e.g., feeding, mating), and the context of the exposure (Richardson et al., 1995a; National Research Council, 2005; Southall et al., 2007).

Natural Sound in the Ocean

There is a large and variable natural component to the ambient noise level in the ocean as a result of events such as earthquakes, rainfall, waves breaking, and lightning hitting the ocean as well as biological noises such as those from snapping shrimp and the vocalizations of marine mammals. For example, lightning hits the ocean with a resulting 260 dB SPL source level and research indicates humpback whale songs vary between 171-189 dB SPL (National Research Council 2003; Au et al, 2001). In addition, Au et al., (2000) have demonstrated an increase in ambient sound levels to 120 dB SPL coinciding with the arrival of “chorusing” humpback whales in Hawaii and peaking during the mid-February to mid-March winter season.

Anthropogenic Sound in the Ocean

Anthropogenic noise that could affect ambient noise arises from the following general types of activities in and near the sea, any combination of which, can contribute to the total noise at any one place and time. These noises include: transportation; dredging; construction; oil, gas, and mineral exploration in offshore areas; geophysical seismic and/or mapping surveys; commercial and military sonar; explosions; and ocean research activities (Richardson et al., 1995a).

Mechanical noise from commercial fishing vessels, cruise ships, cargo transports, recreational boats, and aircraft, all contribute sound into the ocean (National Research Council, 2003; 2006). Mechanical noise from Navy ships, especially those engaged in ASW, is very quiet in comparison to civilian vessels of similar or larger size. This general feature is also enhanced by the use of additional quieting technologies as a means of limiting passive detection by opposing submarines.

Several investigators have argued that anthropogenic sources of noise have increased ambient noise levels in the ocean over the last 50 years (National Research Council 1994, 2000, 2003, 2005; Richardson et al., 1995a; Jasny et al., 2005; McDonald et al., 2006). Much of this increase is due to increased shipping due to ships becoming more numerous and of larger tonnage (National Research Council, 2003; McDonald et al., 2006). Andrew et al. (2002) compared ocean ambient sound from the 1960s with the 1990s for a receiver off the California coast. The data showed an increase in ambient noise of approximately 10 dB in the frequency range of 20 to 80 Hz and 200 and 300 Hz, and about 3 dB at 100 Hz over a 33-year period.

Urick (1983) provided a discussion of the ambient noise spectrum expected in the deep ocean. Shipping, seismic activity, and weather are the primary causes of deep-water ambient noise. The ambient noise frequency spectrum can be predicted fairly accurately for most deep-water areas based primarily on known shipping traffic density and wind state (wind speed, Beaufort wind force, or sea state) (Urick, 1983). For example, for frequencies between 100 and 500 Hz, Urick (1983) estimated the average deep water ambient noise spectra to be 73 to 80 dB for areas of heavy shipping traffic and high sea states, and 46 to 58 dB for light shipping and calm seas. In contrast to deep water, ambient noise levels in shallow waters (i.e., coastal areas, bays, harbors, etc.) are subject to wide variations in level and frequency depending on time and location. The primary sources of noise include distant shipping and industrial activities, wind and waves, marine animals (Urick, 1983). At any given time and place, the ambient noise is a mixture of all of these noise variables. In addition, sound propagation is also affected by the variable shallow water conditions, including the depth, bottom slope, and type of bottom. Where the bottom is reflective, the sounds levels tend to be higher than when the bottom is absorptive.

Most observations of behavioral responses of marine mammals to the sounds produced have been limited to short-term behavioral responses, which included the cessation of feeding, resting, or social interactions. Carretta et al. (2001) and Jasny et al. (2005) identified increasing levels of anthropogenic noise as a habitat concern for whales and other marine mammals because of its potential to affect their ability to communicate. Acoustic devices have also been used in fisheries nets to prevent marine mammal entanglement and to deter seals from salmon cages (Johnson and Woodley 1998), little is known about their effects on non-target species.

Noise from Aircraft and Vessel Movement

Surface shipping is the most widespread source of anthropogenic, low frequency (0 to 1,000 Hz) noise in the oceans and may contribute to over 75 percent of all human sound in the sea (Simmonds and Hutchinson 1996, International Council for the Exploration of the Sea, 2005c). The Navy estimated that the 60,000 vessels of the world's merchant fleet, annually emit low-frequency sound into the world's oceans for the equivalent of 21.9 million days, assuming that 80 percent of the merchant ships are at sea at any one time (U.S. Department of the Navy, 2001b). Ross (1976) has estimated that between 1950 and 1975, shipping had caused a rise in ambient noise levels of 10 dB. He predicted that this would increase by another 5 dB by the beginning of the 21st century. The National Research Council (1997) estimated that the background ocean noise level at 100 Hz has been increasing by about 1.5 dB per decade since the advent of propeller-driven ships. Michel et al. (2001) suggested an association between long-term exposure to low-frequency sounds from shipping and an increased incidence of marine mammal mortalities caused by collisions with ships.

As discussed in Appendix G, airborne sound from low-flying helicopters or airplanes may be heard by marine mammals and turtles while at the surface or underwater. Responses by mammals and turtles could include hasty dives or turns, or decreased foraging (Soto et al., 2006). Whales may also slap the water with flukes or flippers, or swim away from low flying aircraft. Due to the transient nature of sounds from aircraft involved in at-sea training and their generally high altitude, such sounds would not likely cause physical effects.

Sound emitted from large vessels, particularly in the course of transit, is the principal source of noise in the ocean today, primarily due to the properties of sound emitted by civilian cargo vessels (Richardson et al., 1995a; Arveson and Vendittis, 2000). Ship propulsion and electricity generation engines, engine gearing, compressors, bilge and ballast pumps, as well as hydrodynamic flow surrounding a ship's hull and any hull protrusions contribute to a large vessels' noise emission into the marine environment. Prop-driven vessels also generate noise through cavitation, which accounts for much of the noise emitted by a large vessel depending on its travel speed. Noise emitted by large vessels can be characterized as low-frequency, continuous, and tonal. The sound pressure levels at the vessel will vary according to speed, burden, capacity and length (Richardson et al., 1995a; Arveson and Vendittis, 2000). Vessels ranging from 135 to 337 meters generate peak source sound levels from 169–200 dB between 8 Hz and 430 Hz, although Arveson and Vendittis (2000) documented components of higher frequencies (10-30 kHz) as a function of newer merchant ship engines and faster transit speeds. As noted previously, Navy ships in general and in particular those engaged in ASW, are designed to be very quiet as a means of limiting passive detection by opposing submarines.

Whales have variable responses to vessel presence or approaches, ranging from apparent tolerance to diving away from a vessel. Unfortunately, it is not always possible to determine whether the whales are responding to the vessel itself or the noise generated by the engine and cavitation around the propeller. Apart from some disruption of behavior, an animal may be unable to hear other sounds in the environment due to masking by the noise from the vessel. Any masking of environmental sounds or conspecific sounds is expected to be temporary, as noise dissipates with a vessel's transit through an area.

Vessel noise primarily raises concerns for masking of environmental and conspecific cues. However, exposure to vessel noise of sufficient intensity and/or duration can also result in temporary or permanent loss of sensitivity at a given frequency range, referred to as temporary or permanent threshold shifts (TTS or PTS). Threshold shifts are assumed to be possible in marine mammal species as a result of prolonged exposure to large vessel traffic noise due to its intensity, broad geographic range of effectiveness, and constancy.

Collectively, significant cumulative exposure to individuals, groups, or populations can occur if they exhibit site fidelity to a particular area; for example, whales that seasonally travel to a regular area to forage or breed may be more vulnerable to noise from large vessels compared to transiting whales. Any permanent threshold shift in a marine animal's hearing capability, especially at particular frequencies for which it can normally hear best, can impair its ability to perceive threats, including ships.

Most observations of behavioral responses of marine mammals to human generated sounds have been limited to short-term behavioral responses, which included the cessation of feeding, resting, or social interactions. Nowacek et al. (2007) provide a detailed summary of cetacean response to underwater noise.

Given the sound propagation of low-frequency sounds, a large vessel in this sound range can be heard 139-463 kilometers away (Ross, 1976 in Polefka, 2004). Navy vessels, however, have incorporated significant underwater ship quieting technology to reduce their acoustic signature (as compared to a similarly-sized vessel) in order to reduce their vulnerability to detection by enemy passive acoustics (Southall, 2005). Therefore, the potential for TTS or PTS from Navy vessel and aircraft movement is extremely low given that the exercises and training events are transitory in time, with vessels moving over large area of the ocean. A marine mammal or sea turtle is unlikely to be exposed long enough at high levels for TTS or PTS to occur. Any masking of environmental sounds or conspecific sounds is expected to be temporary, as noise dissipates with a Navy vessel transiting through an area. If behavioral disruptions result from the presence of aircraft or vessels, it is expected to be temporary. Animals are expected to resume their migration, feeding, or other behaviors without any threat to their survival or reproduction. However, if an animal is aware of a vessel and dives or swims away, it may successfully avoid being struck.

Commercial and Research Sonar

Almost all vessels at sea are equipped with active sonar for use in measuring the depth of the water: a fathometer. In addition, many vessels engaged in commercial or recreational fishing also use active sonar commonly referred to as "fish-finders." Both types of sonar tend to be higher in frequency and lower in power as compared to the hull mounted MFA sonar used during Navy training; however, there are many more of these sonars, and they are in use much more often and in more locations than Navy sonars.

Although seismic oil and gas research taking place elsewhere is not conducted in the Hawaiian Islands, undersea research using active sound sources does occur. Sound sources employed include powerful multibeam and sidescan sonars that are generally used for mapping the ocean floor and include both mid-frequency and high-frequency systems. During mapping surveys, these sonars are run continuously, sweeping the large areas of ocean to accurately chart the complex bathymetry present on the ocean floor.

Navy Sonar

Naval sonars are designed for three primary functions: submarine hunting, mine hunting, and shipping surveillance. The Navy employs two classes of sonars: active sonars and passive sonars. Most active military sonars operate in a limited number of areas, and are most likely not a significant contributor to a comprehensive global ocean noise budget (International Council for the Exploration of the Sea, 2005c).

The effects of MFA/HFA naval sonar on marine wildlife have not been studied as extensively as the effects of air-guns used in seismic surveys (Madsen et al., 2006; Stone and Tasker, 2006; Wilson et al., 2006; Palka and Johnson, 2007; Parente et al., 2007). Maybaum (1989, 1993) observed changes in behavior of humpbacks during playback tapes of the M-1002 system (using 203 dB re 1 µPa-m for study); specifically, a decrease in respiration, submergence, and aerial behavior rates; and an increase in speed of travel and track linearity. Direct comparison of Maybaum's results, however, with Navy MFA sonar are difficult to make. Maybaum's signal source, the commercial M-1002, is not similar to how naval mid-frequency sonar operates. In addition, behavioral responses were observed during playbacks of a control tape, (i.e., a tape with no sound signal) so interpretation of Maybaum's results are inconclusive.

In the Caribbean, sperm whales were observed to interrupt their activities by stopping echolocation and leaving the area in the presence of underwater sounds surmised (since they did not observe any vessels) to have originated from submarines using sonar (Watkins and Schevill, 1975; Watkins et al., 1985). The authors did not report receive levels from these exposures, and also got a similar reaction from artificial noise they generated by banging on their boat hull. It was unclear if the sperm whales were reacting to the sonar signal itself or to a potentially new unknown sound in general.

Research by Nowacek, et al. (2004) on North Atlantic right whales using a 18 minute signal designed to alert whales to a vessel's presence suggests that received sound levels of only 133 to 148 pressure level (decibel [dB] re 1 micropascals per meter [µPa-m]) for the duration of the sound exposure may disrupt feeding behavior. The authors did note, however, that within minutes of cessation of the source, a return to normal behavior would be expected. Direct comparison of the Nowacek et al. (2004) sound source to MFA sonar, however, is not possible given the radically different nature of the two sources. Nowacek et al.'s source was a series of non-sonar like sounds designed to purposely alert the whale, lasting several minutes, and covering a broad frequency band. Direct differences between Nowacek et al. (2004) and MFA sonar is summarized below from Nowacek et al. (2004) and Nowacek et al. (2007):

(1) Signal duration: Time difference between the two signals is significant, 18-minute signal used by Nowacek et al. verses < 1-sec for MFA sonar.
(2) Frequency modulation: Nowacek et al. contained three distinct signals containing frequency modulated sounds:
  - Alternating 1-sec pure tone at 500 and 850 Hz
  - 2-sec logarithmic down-sweep from 4500 to 500 Hz
  - Pair of low-high (1500 and 2000 Hz) sine wave tones amplitude modulated at 120 Hz.
(3) Signal to noise ratio: Nowacek et al.'s signal maximized signal to noise ratio so that it would be distinct from ambient noise and resist masking.

(4) Signal acoustic characteristics: Nowacek et al.'s signal comprised of disharmonic signals spanning northern right whales' estimated hearing range.

Given these differences, therefore, the exact cause of apparent right whale behavior noted by the authors cannot be attributed to any one component since the source was such a mix of signal types.

Beaked Whales

Recent beaked whale strandings have prompted inquiry into the relationship between high-amplitude continuous-type sound and the cause of those strandings. For example, in the stranding in the Bahamas in 2000, the Navy MFA sonar was identified as the only contributory cause that could have lead to the stranding. The Bahamas exercise entailed multiple ships using MFA sonar during transit of a long constricted channel. The Navy participated in an extensive investigation of the stranding with the NMFS. The "Joint Interim Report, Bahamas Marine Mammal Stranding Event of 15-16 March 2000" concluded that the variables to be considered in managing future risk from tactical mid-range sonar were "sound propagation characteristics (in this case a surface duct), unusual underwater bathymetry, intensive use of multiple sonar units, a constricted channel with limited egress avenues, and the presence of beaked whales that appear to be sensitive to the frequencies produced by these sonars." (U.S. Department of Commerce and U.S. Department of the Navy, 2001).

The Navy analyzed the known range of operational, biological, and environmental factors involved in the Bahamas stranding and focused on the interplay of these factors to reduce risks to beaked whales from ASW training. Mitigation measures based on the Bahamas investigation are presented in Chapter 6.0. The confluence of these factors do not occur in the Hawaiian Islands although surface ducts may be present, there are rapid changes in bathymetry over relatively short distances, and beaked whales are present where MFA sonar is used. For example, beaked whales are present at PMRF and there are a few individual beaked whales that appear to be resident in the area off of the island of Hawaii and the Alenuihaha Channel between the island of Hawaii and Maui where ASW sonar operations occur regularly (Baird et al., 2006a; McSweeney et al., 2007). Although beaked whales are visually and acoustically detected in areas where sonar use routinely takes place, there has not been a stranding of beaked whales in the Hawaiian Islands associated with the 30-year use history of the present sonar systems.

This history would suggest that the simple exposure of beaked whales to sonar is not enough to cause beaked whales to strand. Brownell et al. (2004) have suggested that the high number of beaked whale strandings in Japan between 1980 and 2004 may be related to Navy sonar use in those waters given the presence of U.S. Naval Bases and exercises off Japan. The Center for Naval Analysis compiled the history of naval exercises taking place off Japan and found there to be no correlation in time for any of the stranding events presented in Brownell et al. (2004). Like the situation in Hawaii, there are clearly beaked whales present in the waters off Japan (as evidenced by the strandings); however, there is no correlation in time to strandings and sonar use. Sonar did not cause the strandings identified by Brownell et al. (2004), and more importantly, this suggests sonar use in the presence of beaked whales over two decades has not resulted in strandings related to sonar use.

In Hawaii, there have been no detected beaked whales strandings associated with the use of MFA sonar. While the absence of evidence does not prove there have been no affects on beaked whales, 30 years of history with no evidence of any impacts or strandings would seem to indicate that problems encountered in locations far from Hawaii involving beaked whales are location and context specific and do not apply in Hawaiian waters.

It has been suggested that there is an absence of strandings and floating dead marine mammals in Hawaii related to sonar use because (it is argued) dead marine mammals will not float, are eaten by sharks, are carried out to sea, or end up on remote shorelines in Hawaii and are never discovered. In Hawaii, floating dead marine mammals have been documented as persisting for a number of days even while being consumed by sharks, and strandings occur on a regular basis on most of the islands. Typically, dead marine mammals will initially sink, then refloat, and finally sink again after substantial deterioration (Spitz, 1993). The timeline of this process will vary depending primarily upon water temperature and water depth, as well as other factors such as gut content, amount of body fat, etc., that affect bacterial and other decomposition processes. Generally, refloating occurs within a few days while final sinking may require, for a large whale, several weeks. Considering the intense use and observation of the shorelines and waters around Hawaii given prevalent fishing and tourism, the claim that a significant number of whale carcasses have been consistently missed is unreasonable, and is contrary to the Pacific Island Region Marine Mammal Response Stranding Network's regular observations of strandings and dead floating marine mammals documented in Hawaii.

Stranding Analysis

Over the past two decades, several mass stranding events involving beaked whales have been documented. While beaked whale strandings have been reported since recordkeeping began in the 1800s (Geraci and Lounsbury, 1993; Cox et al., 2006; Podesta et al., 2006), several mass strandings since have been associated with naval training that may have included MFA sonar (Simmonds and Lopez-Jurado, 1991; Frantzis, 1998; Jepson et al., 2003; Cox et al., 2006). As Cox et al. (2006) concludes, the state of science can not yet determine if a sound source such as MFA sonar alone causes beaked whale strandings, or if other factors (acoustic, biological, or environmental) must co-occur in conjunction with a sound source.

A review of historical data (mostly anecdotal) maintained by the Marine Mammal Program in the National Museum of Natural History, Smithsonian Institution reports 49 beaked whale mass stranding events between 1838 and 1999. The largest beaked whale mass stranding occurred in the 1870s in New Zealand when 28 Gray's beaked whales (*Mesoplodon grayi*) stranded. Blainville's beaked whale (*Mesoplodon densirostris*) strandings are rare, and records show that they were involved in one mass stranding in 1989 in the Canary Islands. Cuvier's beaked whales (*Ziphius cavirostris*) are the most frequently reported beaked whale to strand, with at least 19 stranding events from 1804 through 2000 (U.S. Department of the Navy and Department of Commerce, 2001). By the nature of the data, much of the historic information on strandings over the years is anecdotal, which has been condensed in various reports, and some of the data have been misquoted.

The discussion below centers on those worldwide stranding events that may have some association with naval training, and global strandings that the Navy feels are either inconclusive or can not be associated with naval training.

Naval Association

In the following sections, specific stranding events that have been putatively linked to potential sonar operations are discussed. Of note, these events represent a small overall number of animals over an 11-year period (40 animals), and not all worldwide beaked whale strandings can be linked to naval activity (International Council for the Exploration of the Sea, 2005b; 2005c; Podesta et al., 2006). Four of the five events occurred during North Atlantic Treaty Organization (NATO) exercises or events where Navy presence was limited (Greece, Portugal, Spain). One of the five events involved only Navy ships (Bahamas).

Beaked whale stranding events associated with potential naval training:

- 1996 May Greece (NATO/United States)
- 2000 March Bahamas (United States)
- 2000 May Portugal, Madeira Islands (NATO/United States)
- 2002 September Spain, Canary Islands (NATO/United States)
- 2006 January Spain, Mediterranean Sea coast (NATO/United States)

The following sections provide details and analysis concerning the five events noted above in addition to other events where MFA sonar use has been alleged to be potentially causal and/or a factor contributing to the stranding event.

4.1.2.4.10.2 Stranding Events Associated with Navy Sonar

Greece Stranding Event, May 12–13, 1996

Description

Twelve Cuvier’s beaked whales (*Ziphius cavirostris*) stranded along a 38.2-kilometer strand of the coast of the Kyparissiakos Gulf on May 12 and 13, 1996 (Frantzis, 1998). From May 11 through May 15, the NATO research vessel Alliance was conducting sonar tests with signals of 600 Hz and 3 kHz and rms SPL of 228 and 226 dB re: 1μPa, respectively (D'Amico and Verboom, 1998; D’Spain et al., 2006). The timing and the location of the testing encompassed the time and location of the whale strandings (Frantzis, 1998).

Findings

Necropsies of eight of the animals were performed, but were limited to basic external examination and sampling of stomach contents, blood, and skin. No ears or organs were collected, and no histological samples were preserved because of problems related to permits, lack of trained specialists, and lack of facilities and means (International Council for the Exploration of the Sea, 2005a).

- At least 12 of the 14 animals stranded alive in an atypical way (International Council for the Exploration of the Sea, 2005a). The spread of strandings were also atypical in location and time, as mass-strandings usually occur at the same place and at the same time (Frantzis, 1998).
- No apparent abnormalities or wounds were found (Frantzis, 2004).

- Examination of photos of the animals revealed that the eyes of at least four of the individuals were bleeding. Photos were taken soon after their death (Frantzis, 2004).
- Stomach contents contained the flesh of cephalopods, indicating that feeding had recently taken place (Frantzis, 1998).
- No unusual environmental events occurred before or during the stranding (Frantzis, 2004).

Conclusions

All available information regarding the conditions associated with this stranding were compiled, and many potential causes were examined including major pollution events, important tectonic activity, unusual physical or meteorological events, magnetic anomalies, epizootics, and conventional military activities (International Council for the Exploration of the Sea, 2005a). However, none of these potential causes coincided in time with the mass stranding, or could explain its characteristics (International Council for the Exploration of the Sea, 2005a). The robust condition of the animals, plus the recent stomach contents, is not consistent with pathogenic causes (Frantzis, 2004). In addition, environmental causes can be ruled out as there were no unusual environmental circumstances or events before or during this time period (Frantzis, 2004).

It was determined that because of the rarity of this mass stranding of Cuvier's beaked whales in the Kyparissiakos Gulf (first one in history), the probability for the two events (the military exercises and the strandings) to coincide in time and location, while being independent of each other, was extremely low (Frantzis, 1998).

Because full necropsies had not been conducted, and no abnormalities were noted, the cause of the strandings cannot be precisely determined (Cox et al., 2006). The analysis of this stranding event provided support for, but no clear evidence for, the cause-and-effect relationship of sonar operations and beaked whale strandings (Cox et al., 2006).

Bahamas Marine Mammal Stranding Event, March 15-16, 2000

Description

On March 15-16, 2000, seventeen marine mammals comprised of four different species (Cuvier's beaked whales, Blainville's beaked whales, Minke whales, and one spotted dolphin) stranded along the Northeast and Northwest Providence Channels of the Bahamas Islands (National Marine Fisheries Service, 2001b; U.S. Department of the Navy and Department of Commerce, 2001). The strandings occurred over a 36-hour period and coincided with Navy use of MFA sonar within the channel. Navy ships were involved in tactical sonar exercises for approximately 16 hours on March 15. The ships, which operated the AN/SQS-53C and AN/SQS-56, moved through the channel while emitting sonar pings approximately every 24 seconds. The timing of pings was staggered between ships and average source levels of pings varied from a nominal 235 dB SPL (AN/SQS-53C) to 223 dB SPL (AN/SQS-56). The center frequency of pings was 3.3 kHz and 6.8 to 8.2 kHz, respectively.

Because of the unusual nature and situation surrounding these strandings, a comprehensive investigation into every possible cause was quickly launched (U.S. Department of the Navy and Department of Commerce, 2001).

Strandings were first reported at the southern end of the channels, and proceeded northwest throughout March 15, 2000. It is probable that all of the strandings occurred on March 15, even though some of the animals were not found or reported until March 16. Seven of the animals died, while ten animals were returned to the water alive; however, it is unknown if these animals survived or died at sea at a later time. (U.S. Department of the Navy and Department of Commerce, 2001)

The animals that are known to have died include five Cuvier's beaked whales, one Blainville's beaked whale, and the single spotted dolphin (U.S. Department of the Navy and Department of Commerce, 2001). Six necropsies were performed, but only three out of the six (one Cuvier's beaked whale, one Blainville's beaked whale, and the spotted dolphin) were fresh enough to permit identification of pathologies by computerized tomography. Tissues from the remaining three animals were in a state of advanced decomposition at the time of inspection. Results from the spotted dolphin necropsy revealed that the animal died with systemic debilitation disease, and is considered unrelated to the rest of the mass stranding (U.S. Department of the Navy and Department of Commerce, 2001).

Findings

Based on necropsies performed on the other five beaked whales, it was preliminarily determined that they had experienced some sort of acoustic or impulse trauma which led to their stranding and ultimate demise (U.S. Department of the Navy and Department of Commerce, 2001). Detailed microscopic tissue studies followed in order to determine the source of the acoustic trauma and the mechanism by which trauma was caused.

- All five necropsied beaked whales were in good body condition, showing no signs of infection, disease, ship strike, blunt trauma, or fishery related injuries, and three still had food remains in their stomachs. (U.S. Department of the Navy and Department of Commerce, 2001).
- Auditory structural damage was discovered in four of the whales, specifically bloody effusions or hemorrhaging around the ears (U.S. Department of the Navy and Department of Commerce, 2001).
- Bilateral intracochlear and unilateral temporal region subarachnoid hemorrhage with blood clots in the lateral ventricles were found in two of the whales (U.S. Department of the Navy and Department of Commerce, 2001).
- Three of the whales had small hemorrhages in their acoustic fats (located along the jaw and in the melon) (U.S. Department of the Navy and Department of Commerce, 2001).
- Passive acoustic monitor recordings within the area during the time of the stranding showed no signs of an explosion or other geological event such as an earthquake (U.S. Department of the Navy and Department of Commerce, 2001).
- The beaked whales showed signs of overheating, physiological shock, and cardiovascular collapse, all of which commonly result in death following a stranding (U.S. Department of the Navy and Department of Commerce, 2001).

Conclusions

The post-mortem analyses of stranded beaked whales lead to the conclusion that the immediate cause of death resulted from overheating, cardiovascular collapse, and stresses associated with being stranded on land. However, the presence of subarachnoid and intracochlear hemorrhages were believed to have occurred prior to stranding and were hypothesized as being related to an acoustic event. Passive acoustic monitoring records demonstrated that no large-scale acoustic activity besides the Navy sonar exercise occurred in the times surrounding the stranding event. The mechanism by which sonar could have caused the observed traumas or caused the animals to strand was undetermined. The spotted dolphin was in overall poor condition for examination, but showed indications of long-term disease. No analysis of baleen whales (minke whale) was conducted. Baleen whale stranding events have not been associated with either low-frequency or mid-frequency sonar use (International Council for the Exploration of the Sea, 2005b, 2005c).

May 10–14, 2000 Stranding Event, Madeira Island, Portugal

Description

From May 10–14, 2000, three Cuvier's beaked whales were found stranded on two islands in the Madeira archipelago, Portugal (Cox et al., 2006)—two on Porto Santo Island, and one on the northeast coast of Madeira Island (Freitas, 2004). A fourth animal was reported floating in the Madeiran waters by fisherman, but did not come ashore (Woods Hole Oceanographic Institution, 2005).

Joint NATO amphibious training peacekeeping exercises involving participants from 17 countries took place in Portugal during May 2–15, 2000. The NATO exercises were conducted across an area that stretched from the Island of Madeira to the Gulf of Gascony, and was named "Linked Seas 2000." It involved Greek, British, Spanish, Portuguese, French, Romanian, and U.S. forces, and included 80 warships and several thousand men landing on the beaches (U.S. Army Corps of Engineers, 2001). The NATO exercises occurred concurrently with this atypical mass stranding of beaked whales (Freitas, 2004).

Findings

The bodies of the three stranded whales were examined post mortem (Woods Hole Oceanographic Institution, 2005). Two heads were taken to be examined, one intact and the other partially seared from a fire started by locals during an attempt to dispose of the corpse (Woods Hole Oceanographic Institution, 2005). Only one of the stranded whales was fresh enough (24 hours after stranding) to be necropsied (Cox et al., 2006).

- Results from the necropsy revealed evidence of hemorrhage and congestion in the right lung and both kidneys (Cox et al., 2006).
- There was also evidence of intercochlear and intracranial hemorrhage similar to that which was observed in the whales that stranded in the Bahamas event (Cox et al., 2006).
- There were no signs of blunt trauma, and no major fractures (Woods Hole Oceanographic Institution, 2005).

- The cranial sinuses and airways were found to be quite clear with little or no fluid deposition, which may indicate good preservation of tissues (Woods Hole Oceanographic Institution, 2005).

Conclusions

Several observations on the Madeira stranded beaked whales, such as the pattern of injury to the auditory system, are the same as those observed in the Bahamas strandings. Blood in and around the eyes, kidney lesions, pleural hemorrhages, and congestion in the lungs are particularly consistent with the pathologies from the whales stranded in the Bahamas, and are consistent with stress and pressure related trauma. The similarities in pathology and stranding patterns between these two events suggest that a similar pressure event may have precipitated or contributed to the strandings at both sites. (Woods Hole Oceanographic Institution, 2005)

Even though no causal link can be made between the stranding event and naval exercises, certain conditions may have existed in the exercise area that, in their aggregate, may have contributed to the marine mammal strandings (Freitas, 2004).

- Exercises were conducted in areas of at least 547 fathoms depth near a shoreline where there is a rapid change in bathymetry on the order of 547 to 3,281 fathoms occurring a cross a relatively short horizontal distance (Freitas, 2004).
- Multiple ships were operating around Madeira. It is not known if MFA sonar was used, and the specifics of the sound sources used the Linked Seas 2000 exercises, and their propagation characteristics, are unknown (Cox et al., 2006, Freitas, 2004).
- Exercises took place in an area surrounded by landmasses separated by less than 35 nm and at least 10 nm in length, or in an embayment. Exercises involving multiple ships employing MFA near land may produce sound directed towards a channel or embayment that may cut off the lines of egress for marine mammals (Freitas, 2004).

September 24, 2002 Canary Islands Stranding Event

Description

The southeastern area within the Canary Islands is well known for aggregations of beaked whales due to its ocean depths of greater than 547 fathoms within a few hundred meters of the coastline (Fernandez et al., 2005). On September 24, 2002, 14 beaked whales were found stranded on Fuerteventura and Lanzaote Islands in the Canary Islands (International Council For Exploration of the Sea, 2005a). Seven whales died, while the remaining seven live whales were returned to deeper waters (Fernandez et al., 2005). Four beaked whales were found stranded dead over the next 3 days either on the coast or floating offshore.

These strandings occurred within near proximity of an international naval exercise named Neo-Tapon 2002 that involved numerous surface warships and several submarines. Spanish naval sources indicated that tactical mid-range frequency sonar was utilized during the exercises, but no explosions occurred (Fernandez et al., 2005). Strandings began about 4 hours after the onset of MFA sonar activity (International Council For Exploration of the Sea, 2005a; Fernandez et al., 2005).

Findings

Eight Cuvier's beaked whales, one Blainville's beaked whale, and one Gervais' beaked whale were necropsied, six of them within 12 hours of stranding (Fernández et al., 2005).

- No pathogenic bacteria were isolated from the carcasses (Jepson et al., 2003)
- The animals displayed severe vascular congestion and hemorrhage especially around the tissues in the jaw, ears, brain, and kidneys, displaying marked disseminated microvascular hemorrhages associated with widespread fat emboli (Jepson et al., 2003; International Council For Exploration of the Sea, 2005a).
- Several organs contained intravascular bubbles, although definitive evidence of gas embolism *in vivo* is difficult to determine after death (Jepson et al., 2003).
- The livers of the necropsied animals were the most consistently affected organ, which contained macroscopic gas-filled cavities and had variable degrees of fibrotic encapsulation. In some animals, cavitary lesions had extensively replaced the normal tissue (Jepson et al., 2003).
- Stomachs contained a large amount of fresh and undigested contents, which suggests a rapid onset of disease and death (Fernandez et al., 2005).
- Head and neck lymph nodes were enlarged and congested, and parasites were found in the kidneys of all animals (Fernandez et al., 2005).

Conclusions

The association of NATO MFA sonar use close in space and time to the beaked whale strandings, and the similarity between this stranding event and previous beaked whale mass strandings coincident with sonar use, suggests that a similar scenario and causative mechanism of stranding may be shared between the events. Beaked whales stranded in this event demonstrated brain and auditory system injuries, hemorrhages, and congestion in multiple organs, similar to the pathological findings of the Bahamas and Madeira stranding events. In addition, the necropsy results of Canary Islands stranding event lead to the hypothesis that the presence of disseminated and widespread gas bubbles and fat emboli were indicative of nitrogen bubble formation, similar to what might be expected in decompression sickness (Jepson et al., 2003; Fernández et al., 2005). Whereas gas emboli would develop from the nitrogen gas, fat emboli would enter the blood stream from ruptured fat cells (presumably where nitrogen bubble formation occurs) or through the coalescence of lipid bodies within the blood stream.

The possibility that the gas and fat emboli found by Fernández et al. (2005) was due to nitrogen bubble formation has been hypothesized to be related to either direct activation of the bubble by sonar signals or to a behavioral response in which the beaked whales flee to the surface following sonar exposure. The first hypothesis is related to rectified diffusion (Crum and Mao, 1996), the process of increasing the size of a bubble by exposing it to a sound field. This process is facilitated if the environment in which the ensonified bubbles exist is supersaturated with gas. Repetitive diving by marine mammals can cause the blood and some tissues to accumulate gas to a greater degree than is supported by the surrounding environmental pressure (Ridgway and Howard, 1979). Deeper and longer dives of some marine mammals, such as those conducted by beaked whales, are theoretically predicted to induce greater levels of supersaturation (Houser et al., 2001). If rectified diffusion were possible in marine mammals exposed to high-level sound, conditions of tissue supersaturation could theoretically speed the rate and increase the size of bubble growth. Subsequent effects due to tissue trauma and emboli would presumably mirror those observed in humans suffering from decompression sickness.

It is unlikely that the short duration of sonar pings would be long enough to drive bubble growth to any substantial size, if such a phenomenon occurs. However, an alternative but related hypothesis has also been suggested: stable bubbles could be destabilized by high-level sound exposures such that bubble growth then occurs through static diffusion of gas out of the tissues. In such a scenario the marine mammal would need to be in a gas-supersaturated state for a long enough period of time for bubbles to become of a problematic size. The second hypothesis speculates that rapid ascent to the surface following exposure to a startling sound might produce tissue gas saturation sufficient for the evolution of nitrogen bubbles (Jepson et al., 2003; Fernández et al., 2005). In this scenario, the rate of ascent would need to be sufficiently rapid to compromise behavioral or physiological protections against nitrogen bubble formation. Tyack et al. (2006) showed that beaked whales often make rapid ascents from deep dives suggesting that it is unlikely that beaked whales would suffer from decompression sickness. Zimmer and Tyack (2007) speculated that if repetitive shallow dives that are used by beaked whales to avoid a predator or a sound source, they could accumulate high levels of nitrogen because they would be above the depth of lung collapse (above about 210 ft) and could lead to decompression sickness. There is no evidence that beaked whales dive in this manner in response to predators or sound sources and other marine mammals such as Antarctic and Galapagos fur seals, and pantropical spotted dolphins make repetitive shallow dives with no apparent decompression sickness (Kooyman and Trillmich, 1984; Kooyman et al., 1984; Baird et al., 2001). Although theoretical predictions suggest the possibility for acoustically mediated bubble growth, there is considerable disagreement among scientists as to its likelihood (Piantadosi and Thalmann, 2004). Sound exposure levels predicted to cause in vivo bubble formation within diving cetaceans have not been evaluated and are suspected as needing to be very high (Evans, 2002; Crum et al., 2005). Moore and Early (2004) reported that in analysis of sperm whale bones spanning 111 years, gas embolism symptoms were observed indicating that sperm whales may be susceptible to decompression sickness due to natural diving behavior. Further, although it has been argued that traumas from recent beaked whale strandings are consistent with gas emboli and bubble-induced tissue separations (Jepson et al., 2003), there is no conclusive evidence supporting this hypothesis, and there is concern that at least some of the pathological findings (e.g., bubble emboli) are artifacts of the necropsy. Currently, stranding networks in the United States have agreed to adopt a set of necropsy guidelines to determine, in part, the possibility and frequency with which bubble emboli can be introduced into marine mammals during necropsy procedures (Arruda et al., 2007).

January 26, 2006, Spain

Description

The Spanish Cetacean Society reported an atypical mass stranding of four beaked whales that occurred January 26, 2006, on the southeast coast of Spain, near Mojacar (Gulf of Vera) in the Western Mediterranean Sea. According to the report, two of the whales were discovered the evening of January 26 and were found to be still alive. Two other whales were discovered during the day on January 27, but had already died. A following report stated that the first three animals were located near the town of Mojacar and were examined by a team from the University of Las Palmas de Gran Canarias, with the help of the stranding network of Ecologistas en Acción Almería-PROMAR and others from the Spanish Cetacean Society. The fourth animal was found dead on the afternoon of May 27, a few kilometers north of the first three animals.

From January 25-26, 2006, Standing North Atlantic Treaty Organization (NATO) Response Force Maritime Group Two (five of seven ships including one U.S. ship under NATO Operational Control) had conducted active sonar training against a Spanish submarine within 50 nm of the stranding site.

Findings

Veterinary pathologists necropsied the two male and two female beaked whales (*Ziphius cavirostris*, family *Ziphiidae*).

Conclusions

According to the pathologists, the most likely primary cause of this type of beaked whale mass stranding event is anthropogenic acoustic activities, most probably anti-submarine MFA sonar used during the military naval exercises. However, no positive acoustic link was established as a direct cause of the stranding.

Even though no causal link can be made between the stranding event and naval exercises, certain conditions may have existed in the exercise area that, in their aggregate, may have contributed to the marine mammal strandings (Freitas, 2004).

- Exercises were conducted in areas of at least 547 fathoms depth near a shoreline where there is a rapid change in bathymetry on the order of 547 to 3,281 fathoms occurring across a relatively short horizontal distance (Freitas, 2004).
- Multiple ships (in this instance, five) were operating (in this case, MFA sonar) in the same area over extended periods of time (in this case, 20 hours) in close proximity.
- Exercises took place in an area surrounded by landmasses, or in an embayment. Exercises involving multiple ships employing MFA sonar near land may produce sound directed towards a channel or embayment that may cut off the lines of egress for marine mammals (Freitas, 2004).

4.1.2.4.10.3 Other Global Stranding Discussions

In the following sections, stranding events that have been linked to Navy activity in popular press are presented. As detailed in the individual case study conclusions, the Navy believes that there is enough to evidence available to refute allegations of impacts from MFA sonar, or at least indicate that a substantial degree of uncertainty in time and space that preclude a meaningful scientific conclusion.

May 5, 2003 USS SHOUP Washington State

On May 5, 2003 at 0855, USS SHOUP got underway from the pier at Naval Station Everett, Washington. USS SHOUP then transited from Everett through Admiralty Inlet to the west side of Whidbey Island, where at 1030 it began a training exercise. Use of USS SHOUP's MFA tactical sonar began at 1040. At 1420, USS SHOUP entered the Haro Strait at a speed of 18 knots. USS SHOUP terminated active sonar use at 1438.

Between May 2 and June 2, 2003, approximately 16 strandings involving 15 harbor porpoise and one Dall's porpoise were reported to the Northwest Marine Mammal Stranding Network. A comprehensive review of all strandings and the events involving USS SHOUP on 5 May 2003 were presented in U.S. Department of Navy (2004b). Given that the USS SHOUP was known to have operated sonar in the strait on May 5, and that supposed behavioral reactions of killer whales had been putatively linked to these sonar operations (National Marine Fisheries Service, 2005a), the NMFS undertook an analysis of whether sonar caused the strandings of the harbor porpoises.

As a result of the allegations regarding USS SHOUP, NMFS initiated a necropsy study involving 11 of the stranded animals discovered between May 2 and June 2, 2003. Gross examination, histopathology, age determination, blubber analysis, and various other analyses were conducted on each of the carcasses (Norman et al., 2004). The necropsies took place at the National Marine Mammal Laboratory in Seattle.

Findings

All of the carcasses suffered from some degree of freeze-thaw artifact that hampered gross and histological evaluations. At the time of necropsy, three of the porpoises were moderately fresh, whereas the remainder of the carcasses was considered to have moderate to advanced decomposition.

- None of the 11 necropsied harbor porpoise showed signs of acoustic trauma (National Marine Fisheries Service, 2003).
- One of the animals had fibrinous peritonitis, one had salmonellosis, and another had profound necrotizing pneumonia (Norman et al., 2004).
- Two of the five had perimortem blunt trauma injury with associated broken bones in their heads (National Marine Fisheries Service, 2003)
- No cause of death could be determined for the remaining six animals, which is consistent with the expected percentage in most marine mammal necropsies from the region (National Marine Fisheries Service, 2003). It is important to note, however, that these determinations were based only on the evidence from the necropsy so as not to be biased with regard to determinations of the potential presence or absence of acoustic trauma. The result was that other potential causal factors, such as one animal (Specimen 33NWR05005) found tangled in a fishing net, was unknown to the investigators in their determination regarding the likely cause of death.

Conclusions

The NMFS concluded from a retrospective analysis of stranding events that the number of harbor porpoise stranding events in the approximate month surrounding the USS SHOUP use of sonar was higher than expected based on annual strandings of harbor porpoises (Norman et al., 2004). In this regard, it is important to note that the number of strandings in the May-June timeframe in 2003 was also higher for the outer coast indicating a much wider phenomena than use of sonar by USS SHOUP in Puget Sound for one day in May. The conclusion by NMFS that the number of strandings in 2003 was higher is also different from that of The Whale Museum, which has documented and responded to harbor porpoise strandings since 1980 (Osborne, 2003a). According to The Whale Museum, the number of strandings as of May 15, 2003, was consistent with what was expected based on historical stranding records and was less than that occurring in certain years. For example, since 1992 the San Juan Stranding Network has documented an average of 5.8 porpoise strandings per year. In 1997 there were 12 strandings in the San Juan Islands with 23 strandings throughout the general Puget Sound area. Disregarding the discrepancy in the historical rate of porpoise strandings and its relation to the USS SHOUP, NMFS acknowledged that the intense level of media attention focused on the strandings likely resulted in an increased reporting effort by the public over that which is normally observed (Norman et al., 2004). NMFS also noted in its report that the "sample size is too small and biased to infer a specific relationship with respect to sonar usage and subsequent strandings."

Seven of the porpoises collected and analyzed died prior to USS SHOUP departing to sea on May 5, 2003. Of these seven, one, discovered on May 5, 2003, was in a state of moderate decomposition, indicating it died before May 5; the cause of death was determined to be due, most likely, to salmonella septicemia. Another porpoise, discovered at Port Angeles on May 6, 2003, was in a state of moderate decomposition, indicating that this porpoise also died prior to May 5. One stranded harbor porpoise discovered fresh on May 6 is the only animal that could potentially be linked in time to USS SHOUP's May 5 active sonar use. Necropsy results for this porpoise found no evidence of acoustic trauma. The remaining eight strandings were discovered 1 to 3 weeks after USS SHOUP's May 5 transit of the Haro Strait, making it difficult to causally link the sonar activities of USS SHOUP to the timing of the strandings. Two of the eight porpoises died from blunt trauma injury and a third suffered from parasitic infestation, which possibly contributed to its death (Norman et al., 2004). For the remaining five porpoises, NMFS was unable to identify the causes of death.

The speculative association of the harbor porpoise strandings to the use of sonar by the USS SHOUP is inconsistent with prior stranding events linked to the use of MFA sonar. Specifically, in prior events, the stranding of whales occurred over a short period of time (less than 36 hours), stranded individuals were spatially co-located, traumas in stranded animals were consistent between events, and active sonar was known or suspected to be in use. Although MFA sonar was used by USS SHOUP, the distribution of harbor porpoise strandings by location and with respect to time surrounding the event do not support the suggestion that MFA sonar was a cause of harbor porpoise strandings. Rather, a complete lack of evidence of any acoustic trauma within the harbor porpoises, and the identification of probable causes of stranding or death in several animals, further supports the conclusion that harbor porpoise strandings were unrelated to the sonar activities of the USS SHOUP.

Additional allegations regarding USS SHOUP use of sonar having caused behavioral effects on Dall's porpoise, orca, and a minke whale also arose in association with this event (see U.S. Department of Navy 2004 for a complete discussion).

Dall's Porpoise. Information regarding the observation of Dall's porpoise on May 5, 2003 came from the operator of a whale watch boat at an unspecified location. This operator reported the Dall's porpoise were seen "going north" when the SHOUP was estimated by him to be 10 miles away. Potential reasons for the Dall's movement include the pursuit of prey, the presence of harassing resident orca or predatory transient orca, vessel disturbance from one of many whale watch vessels, or multiple other unknowable reasons including the use of sonar by USS SHOUP. In short, there was nothing unusual in the observed behavior of the Dall's porpoise on 5 May 2003 and no way to assess if the otherwise normal behavior was in reaction to the use of sonar by USS SHOUP, any other potential causal factor, or a combination of factors.

Orca. Observer opinions regarding orca J-Pod behaviors on May 5, 2003 were inconsistent, ranging from the orca being “at ease with the sound” or “resting” to their being “annoyed.” One witness reported observing “low rates of surface active behavior” on behalf of the orca J-Pod, which is in conflict with that of another observer who reported variable surface activity, tail slapping and spyhopping. Witnesses also expressed the opinion that the behaviors displayed by the orca on May 5, 2003 were “extremely unusual,” although those same behaviors are observed and reported regularly on the Orca Network Website, and are behaviors listed in general references as being part of the normal repertoire of orca behaviors. Given the contradictory nature of the reports on the observed behavior of the J-Pod orca, it is impossible to determine if any unusual behaviors were present. In short, there is no way to assess if any unusual behaviors were present or if present they were in reaction to vessel disturbance from one of many nearby whale watch vessels, use of sonar by USS SHOUP, any other potential causal factor, or a combination of factors.

Minke Whale. A minke whale was reported porpoising in Haro Strait on May 5, 2003, which is a rarely observed behavior. The cause of this behavior is indeterminate given multiple potential causal factors including but not limited to the presence of predatory Transient orca, possible interaction with whale watch boats, other vessels, or USS SHOUP’s use of sonar. The behavior of the minke whale was the only unusual behavior clearly present on May 5, 2003, however, no way to given the existing information if the unusual behavior observed was in reaction to the use of sonar by USS SHOUP, any other potential causal factor, or a combination of factors.

July 3, 2004, Hanalei Bay, Kauai Stranding Event

The majority of the following information is taken from the NMFS report on the stranding event (Southall et al., 2006) but is inclusive of additional and new information not presented in the NMFS report. On the morning of July 3, 2004, between 150-200 melon-headed whales (*Peponocephala electra*) entered Hanalei Bay, Kauai. Individuals attending a canoe blessing ceremony observed the animals entering the bay at approximately 7:00 a.m. The whales were reported entering the bay in a “wave as if they were chasing fish” (Braun, 2005). The whales were moving fast, but not at maximum speed.

At 6:45 a.m. on July 3, 2004, approximately 25 nm from Hanalei Bay, active sonar was tested briefly prior to the start of an ASW event; this was about 15 minutes before the whales were observed in Hanalei Bay. At the nominal swim speed for melon-headed whales (5 to 6 knots), the whales had to be minimally within 1.5 to 2 nm of Hanalei Bay before the sonar at PMRF was activated. The whales were not in their open ocean habitat but had to be close to shore at 6:45 a.m. when the sonar was activated, to have been observed inside Hanalei Bay from the beach by 7:00 a.m. (Hanalei Bay is very large area.)

The whales stopped in the southwest portion of the bay grouping tightly with lots of spy hopping and tail slapping. As people went in the water among the whales, spy hopping increased and the pod separated into two groups with individual animals moving between the two clusters (Braun, 2005). This continued through most of the day, with the animals slowly moving south and then southeast within the bay (Braun, 2005). By about 3:00 p.m. police arrived and kept people from interacting with the animals. The Navy believes that the abnormal behavior by the whales during this time is likely the result of people and boats in the water with the whales rather than the result of sonar activities taking place 25 or more miles off the coast.

At 4:45 p.m. on July 3, 2004, the RIMPAC Battle Watch Captain received a call from an NMFS representative in Honolulu, Hawaii, reporting the sighting of as many as 200 melon-headed whales in Hanalei Bay. At 4:47 p.m., out of caution, the Battle Watch Captain directed all ships in the area to cease all active sonar transmissions.

An NMFS representative arrived at Hanalei Bay at 7:20 p.m. on July 3, 2004, and observed a tight single pod 75 yards from the southeast side of the bay (Braun, 2005). The pod was circling in a tight group and there was frequent tail slapping and minimal spy hopping. No predators were observed in the bay and no animals were reported as having fresh injuries. Occasionally one or two sub-adult sized animals broke from the tight pod and came nearer the shore to apparently chase fish and be in the shore break (Braun, 2005). The pod stayed in the bay through the night of July 3, 2004.

On July 4, 2004, a 700–800-foot rope was constructed by weaving together beach morning glory vines. This vine rope was tied between two canoes and with the assistance of 30 to 40 kayaks, by about 11:30 a.m. on July 4, 2004, the pod was coaxed out of the bay (Braun, 2005).

A single neonate melon-headed whale was observed in the bay on the afternoon of July 4, after the whale pod had left the bay. The following morning on July 5, 2004, the neonate was found stranded on Lumahai Beach. It was pushed back into the water but was found stranded dead between 9 and 10 a.m. near the Hanalei pier. NMFS collected the carcass and had it shipped to California for necropsy, tissue collection, and diagnostic imaging. Preliminary findings indicated the cause of death was starvation (Farris, 2004) and this was later confirmed upon completion of the NMFS stranding report (Southall et al., 2006).

Following the stranding event, NMFS undertook an investigation of possible causative factors of the stranding. This analysis included available information on environmental factors, biological factors, and an analysis of the potential for sonar involvement. The latter analysis included vessels that utilized MFA sonar on the afternoon and evening of July 2. These vessels were to the southeast of Kauai, on the opposite side of the island from Hanalei Bay.

Findings

NMFS concluded from the acoustic analysis that the melon-headed whales would have had to have been on the southeast side of Kauai on July 2 to have been exposed to sonar from naval vessels on that day (Southall et al., 2006). There was no indication whether the animals were in that region or whether they were elsewhere on July 2. NMFS concluded that to reach Hanalei Bay, the animals would have had to swim around the island of Kauai at a speed of 1.4-4.0 m/s for between 6.5 to 17.5 hours after having possibly heard sonar off the west coast of Oahu and/or the channel between Kauai and Oahu on July 2, to reach Hanalei Bay by 7:00 a.m. on July 3. Sonar transmissions began on July 3, 25 nm to the north of Hanalei Bay as part of an ASW event that started at 6:45 a.m. and lasted until 4:47 p.m. Propagation analysis conducted by the 3rd Fleet estimated that the level of sound from these transmissions at the mouth of Hanalei Bay could have ranged from 138-149 dB re: 1 μPa for intervals during the day when the vessels were generally pointed toward Kauai.

NMFS was unable to determine any environmental factors (e.g., harmful algal blooms, weather conditions) that may have contributed to the stranding. However, additional analysis by Navy investigators found that a full moon occurred the evening before the stranding and was coupled with a squid run (Mobley et al., 2007). One of the first observations of the whales entering the bay reported the pod came into the bay in a line "as if chasing fish" (Braun, 2005). In addition, a group of 500-700 melon-headed whales were observed to come close to shore and interact with humans in Sasanhaya Bay, Rota, on the same morning as the whales entered Hanalei Bay (Jefferson et al., 2006). Previous records further indicated that, though the entrance of melon-headed whales into the shallows is rare, it is not unprecedented. A pod of melon-headed whales entered Hilo Bay in the 1870s in a manner similar to that which occurred at Hanalei Bay in 2004.

The necropsy of the melon-headed whale calf suggested that the animal died from a lack of nutrition, possibly following separation from its mother. The calf was estimated to be approximately one week old. Although the calf appeared not to have eaten for some time, it was not possible to determine whether the calf had ever nursed after it was born. The calf showed no signs of blunt trauma or viral disease and had no indications of acoustic injury.

Conclusions

Although it is not impossible, it is unlikely that the sound level from the sonar caused the melon-headed whales to enter Hanalei Bay. This conclusion by the Navy is based on a number of factors:

1. The speculation that the whales may have been exposed to sonar the day before and then fled to Hanalei Bay is not supported by reasonable expectation of animal behavior and swim speeds. The flight response of the animals would have had to persist for many hours following the cessation of sonar transmissions. The swim speeds, though feasible for the species, are highly unlikely to be maintained for the durations proposed, particularly since the pod was a mixed group containing both adults and neonates. Whereas adults may maintain a swim speed of 4.0 m/s for some time, it is improbable that a neonate could achieve the same for a period of many hours.

2. The area between the islands of Oahu and Kauai and the PMRF training range have been used in RIMPAC exercises for more than 20 years, and are used year-round for ASW training using MFA sonar. Melon-headed whales inhabiting the waters around Kauai are likely not naive to the sound of sonar and there has never been another stranding event associated in time with ASW training at Kauai or in the Hawaiian Islands. Similarly, the waters surrounding Hawaii contain an abundance of marine mammals, many of which would have been exposed to the same sonar operations that were speculated to have affected the melon-headed whales. No other strandings were reported coincident with the RIMPAC exercises. This leaves it uncertain as to why melon-headed whales, and no other species of marine mammal, would respond to the sonar exposure by stranding.

3. At the nominal swim speed for melon-headed whales, the whales had to be within 1.5 to 2 nm of Hanalei Bay before sonar was activated on July 3. The whales were not in their open ocean habitat but had to be close to shore at 6:45 a.m. when the sonar was activated to have been observed inside Hanalei Bay from the beach by 7:00 a.m. (Hanalei Bay is very large area). This observation suggests that other potential factors could be causative of the stranding event (see below).

4. The simultaneous movement of 500-700 melon-headed whales and Risso's dolphins into Sasanhaya Bay, Rota, in the Northern Marianas Islands on the same morning as the 2004

Hanalei stranding (Jefferson et al., 2006) suggests that there may be a common factor which prompted the melon-headed whales to approach the shoreline. A full moon occurred the evening before the stranding and a run of squid was reported concomitant with the lunar activity (Mobley, et al., 2007). Thus, it is possible that the melon-headed whales were capitalizing on a lunar event that provided an opportunity for relatively easy prey capture.

Both the Rota and Hanalei Bay incidents occurred on the same day, which followed a full moon (the date was different given the international date line). Analysis of 18 live and near strandings involving melon-headed whales for which specific dates were provided (Brownell et al. 2006), plus three additional live strandings not listed in that report, revealed a non-random pattern with respect to lunar phase. The majority of stranding events tended to occur during the full and third quarter phases, with fewer during the new moon and one during the first quarter. Squid and other species of the deep scattering layer show vertical migrations responsive to lunar cycles. Lunar influences have been shown with other squid-eating species, including the foraging behavior of Galapagos fur seals and stranding patterns of north Atlantic sperm whales. (Mobley, et al., 2007) In addition, a report of a pod entering Hilo Bay in the 1870s indicates that on at least one other occasion, melon-headed whales entered a bay in a manner similar to the occurrence at Hanalei Bay in July 2004. Thus, although melon-headed whales entering shallow embayments may be an infrequent event, and every such event might be considered anomalous, there is precedent for the occurrence.

5. The received noise sound levels at the bay were estimated to range from roughly 95 – 149 dB re: 1 μPa. Received levels as a function of time of day have not been reported, so it is not possible to determine when the presumed highest levels would have occurred and for how long. Received levels, however, in the upper range would have been audible by human participants in the bay. The statement by one interviewee that he heard "pings" that lasted an hour and that they were loud enough to hurt his ears is unreliable. Received levels necessary to cause pain over the duration stated would have been observed by most individuals in the water with the animals. No other such reports were obtained from people interacting with the animals in the water.

Although NMFS concluded that sonar use was a "plausible, if not likely, contributing factor in what may have been a confluence of events" (Southall et al., 2006), this conclusion was based primarily on the basis that there was an absence of any other compelling explanation. The authors of the NMFS report on the incident were unaware, at the time of publication, of the simultaneous event in Rota. In light of the simultaneous Rota event, the Navy believes the Hanalei stranding does not appear as anomalous as initially indicated in the NMFS report, and the speculation that sonar was a likely contributing factor is weakened. The Hanalei Bay incident does not share the characteristics observed with other mass strandings of whales coincident with sonar activity (e.g., specific traumas, species composition, etc.). In addition, the inability to conclusively link or exclude the impact of other environmental factors makes a causal link between sonar and the melon-headed whale strandings highly speculative at best.

1980–2004 Beaked Whale Strandings in Japan (Brownell et al. 2004)

Description

Brownell et al. (2004) compare the historical occurrence of beaked whale strandings in Japan (where there are U.S. Naval bases), with strandings in New Zealand (which lacks a U.S. Naval base) and concluded the higher number of strandings in Japan may be related to the presence of the Navy vessels using MFA sonar. While the dates for the strandings were well documented, the authors of the study did not attempt to correlate the dates of any navy activities or exercises with the dates of the strandings.

To fully investigate the allegation made by Brownell et al. (2004), the Center for Naval Analysis (CNA) looked at the past U.S. Naval exercise schedules from 1980 to 2004 for the water around Japan in comparison to the dates for the strandings provided by Brownell et al. (2004). None of the strandings occurred during or soon (within weeks) after any U.S. Navy exercises. While the CNA analysis began by investigating the probabilistic nature of any co-occurrences, the results were a 100 percent probability the strandings and sonar use were not correlated by time. Given there was no instance of co-occurrence in over 20 years of stranding data, it can be reasonably postulated that sonar use in Japan waters by U.S. Navy vessels did not lead to any of the strandings documented by Brownell et al. (2004).

2004 Alaska Beaked Whale Strandings (June 7-16, 2004)

Description

In the timeframe between June 17 and July 19, 2004, five beaked whales were discovered at various locations along 1,600 miles of the Alaskan coastline and one was found floating (dead) at sea. Because the Navy exercise Alaska Shield/Northern Edge 2004 occurred within the approximate timeframe of these strandings, it has been alleged that sonar may have been the probable cause of these strandings.

The Alaska Shield/Northern Edge 2004 exercise consisted of a vessel tracking event followed by a vessel boarding search and seizure event. There was no ASW component to the exercise, no use of MFA sonar, and no use of explosives in the water. There were no events in the Alaska Shield/Northern Edge exercise that could have caused in any of the strandings over this 33-day period covering 1,600 mi of coastline.

North Carolina Marine Mammal Mass Stranding Event, January 15-16, 2005

Description

On January 15 and 16, 2005, 36 marine mammals comprised of 3 separate species (33 short-finned pilot whales, 1 minke whale, and 2 dwarf sperm whales) stranded alive on the beaches of North Carolina (National Marine Fisheries Service, 2007i; Hohn et al., 2006) distributed over a 69-mi area between the northern part of the state down to Cape Hatteras (National Marine Fisheries Service, 2007j). Thirty-one different species of marine mammals have been known to strand along the North Carolina coast since 1992; all three of the species involved in this stranding occasionally strand in this area (National Marine Fisheries Service, 2007j). This stranding event was determined to be a UME because live strandings of three different species in one weekend in North Carolina are extremely rare; in fact, it is the only stranding of offshore species to occur within a 2- to 3-day period in the region on record (National Marine Fisheries Service, 2007i; Hohn et al., 2006).

The Navy indicated that from January 12-14 some unit-level training with MFA sonar was conducted by vessels that were 93 to 185 km from Oregon Inlet. An expeditionary strike group was also conducting exercises to the southeast, but the closest point of active sonar transmission to the inlet was 650 km away (National Marine Fisheries Service, 2007i). The unit-level operations were not unusual for the area or time of year and the vessels were not involved in ASW exercises (National Marine Fisheries Service, 2007j). Marine mammal observers located on the Navy vessels reported that they did not detect any marine mammals (National Marine Fisheries Service, 2007i). No sonar transmissions were made on January 15-16.

The National Weather Service reported that a severe weather event moved through North Carolina on January 13 and 14. The event was caused by an intense cold front that moved into an unusually warm and moist air mass that had been persisting across the eastern United States for about a week. The weather caused flooding in the western part of the state, considerable wind damage in central regions of the state, and at least three tornadoes that were reported in the north central part of the state. Severe, sustained (1 to 4 days) winter storms are common for this region.

Findings

On January 16 and 17, 2005, 2 dwarf sperm whales, 27 pilot whales, and the single minke whale were necropsied and sampled. Because of the uniqueness of the stranding, 9 locations of interest within 25 stranded cetacean heads were examined closely. The only common finding in all of the heads was a form of sinusitis (National Marine Fisheries Service, 2007i).

- The pilot whales and the dwarf sperm whale were not considered to be emaciated, even though none of them had recently-eaten food in their stomachs (National Marine Fisheries Service, 2007i).
- The minke whale was emaciated, and it is believed that this was a dependent calf that had become separated from its mother, and was not a part of the other strandings (National Marine Fisheries Service, 2007i).
- Most biochemistry abnormalities indicated deteriorating conditions from being on land for an extended amount of time, and are believed to be a result of the stranding itself (National Marine Fisheries Service, 2007i).
- Three pilot whales showed signs of pre-existing systemic inflammation (National Marine Fisheries Service, 2007i).
- Lesions involving all organ systems were seen, but consistent lesions were not observed across species (National Oceanic and Atmospheric Administration, 2006e; Hohn et al., 2006).
- Cardiovascular disease was present in one pilot whale and one dwarf sperm whale, while musculoskeletal disease was present in two pilot whales (National Marine Fisheries Service, 2007i).
- Parasites were found and collected from 26 pilot whales and 2 dwarf sperm whales; parasite loads were considered to be within normal limits for free-ranging cetaceans (National Marine Fisheries Service, 2007i).
- There were no harmful algal blooms present along the coastline during the months prior to the strandings (National Marine Fisheries Service, 2007i; Hohn et al., 2006).
- Sonar transmissions prior to the strandings were limited in nature and did not share the concentration identified in previous events associated with MFA sonar use (Evans and England, 2001).
- The operational/environmental conditions were also dissimilar (e.g., no constrictive channel and a limited number of ships and sonar transmissions).

- However, other severe storm conditions existed in the days surrounding the strandings and the impact of these weather conditions on at-sea conditions is unknown.
- No harmful algal blooms were noted along the coastline.
- Environmental conditions that are consistent with conditions under which other mass strandings have occurred were present (a gently sloping shore, strong winds, and changes in up-welling to down-welling conditions) (National Marine Fisheries Service, 2007i).

Conclusions

Several whales had pre-existing conditions that may have contributed to the stranding, but were not determined to be the cause of the stranding event (National Oceanic and Atmospheric Administration, 2006e; National Marine Fisheries Service, 2007j). The actual cause of death for many of the whales was determined to be a result of the stranding itself (National Marine Fisheries Service, 2007j). NMFS concluded that this mass stranding event occurred simultaneously in time and space with MFA sonar naval activities, and has several features in common with other possible sonar-related stranding events (National Marine Fisheries Service, 2007i). For this reason, along with the rarity of the event, NMFS believes that it is possible that there exists a causal rather than a coincidental association between naval sonar activity and the stranding event (National Marine Fisheries Service, 2007i). But they also acknowledge that there are differences in operational and environmental characteristics between this event and other possible sonar-related stranding events (National Marine Fisheries Service, 2007i), such as constricted channels (National Marine Fisheries Service, 2007j).

Even though the stranding occurred while active military sonar was being utilized off the North Carolina coast, the investigation team was unable to determine what role, if any, military activities played in the stranding events (Hohn et al., 2006). If MFA sonar played a part in the strandings, sound propagation models indicated that received acoustic levels would depend heavily on the position of the whales relative to the source; however, because the exact location of the cetaceans is unknown it is impossible to estimate the level of their exposure to active sonar transmissions (National Marine Fisheries Service, 2007i). Evidence to support a definitive association is lacking, and consistent lesions across species and individuals that could indicate a single cause of the stranding were not found (National Marine Fisheries Service, 2007i).

Based on the physical evidence, it cannot be definitively determined if there is a causal link between the strandings and anthropogenic sonar activity and/or environmental conditions, or a combination of both (National Marine Fisheries Service, 2007i).

Causal Associations for Stranding Events

Marine mammal strandings have been a historic and ongoing occurrence attributed to a variety of causes. Over the last 50 years, increased awareness and reporting has led to more information about species affected and raised concerns about anthropogenic sources of stranding. While there has been some marine mammal mortalities potentially associated with MFA sonar effects on a small number of species (primarily limited numbers of certain species of beaked whales), the significance and actual causative reason for any impacts is still subject to continued investigation.

By comparison and as described previously, potential impacts on all species of cetaceans worldwide from fishery related mortality can be orders of magnitude more significant (100,000s of animals vice 10s of animals) (Culik, 2002; International Council for the Exploration of the Sea, 2005c; Read et al., 2006). This does not negate the influence of any mortality or additional stressor to small, regionalized sub-populations which may be at greater risk from human related mortalities (fishing, vessel strike, sound) than populations with larger oceanic level distribution or migrations. International Council for the Exploration of the Sea (2005b) noted, however, that taken in context of marine mammal populations in general, sonar is not a major threat, or significant portion of the overall ocean noise budget.

In conclusion, a constructive framework and continued research based on sound scientific principles is needed in order to avoid speculation as to stranding causes, and to further our understanding of potential effects or lack of effects from military MFA sonar (Bradshaw et al., 2005; International Council for the Exploration of the Sea, 2005c; Barlow and Gisiner, 2006; Cox et al. 2006).

Several stranding events have been associated with Navy sonar activities, but relatively few of the total stranding events that have been recorded occurred spatially or temporally with Navy sonar activities. While sonar may be a contributing factor under certain rare conditions, the presence of sonar is not a necessary condition for stranding events to occur.

A review of past stranding events associated with sonar suggests that the potential factors that may contribute to a stranding event are steep bathymetry changes, narrow channels with limited egress avenues, multiple sonar ships, surface ducting, and the presence of beaked whales that in some geographic locations may be more susceptible to sonar exposures. The most important factors appear to be the presence of a narrow channel (e.g. Bahamas and Madeira Island, Portugal) that may prevent animals from avoiding sonar exposure and multiple sonar ships within that channel. There are no narrow channels (less than 35 nm wide and 10 nm in length) in the HRC, and the ships would be spread out over a wider area, allowing animals to move away from sonar activities if they choose. In addition, beaked whales may not be more susceptible to sonar but may favor habitats that are more conducive to sonar effects.

The RIMPAC Exercises have been conducted every other year since 1968 in the HRC, and along with other ASW training events have only been implicated in one stranding event which may have been simply animals following prey into a bay (Braun, 2005; Southall et al., 2006). Given the large military presence and private and commercial vessel traffic in the Hawaiian waters, it is likely that a mass stranding event would be detected. Therefore, it is unlikely that the conditions that may have contributed to past stranding events involving Navy sonar would be present in the HRC.

Evidence has also been presented indicating that there are resident populations and potentially genetically distinct populations of cetacea in the Hawaiian Islands (McSweeney et al., 2007). This would suggest that these species of cetacea have co-existed with sonar use in the Hawaiian Islands with residency indicating the animals remain in the area despite sonar use and genetic distinction indicative that they have done so for generations (of marine mammals).

4.1.2.4.11 Marine Mammal Mitigation Measures Related To Acoustic and Explosive Exposures

Chapter 6.0 provides the complete sonar and explosives mitigation measures for the HRC. The following paragraphs provide summary information about these mitigation measures.

4.1.2.4.11.1 Acoustic Exposure Mitigation Measures

Effective training in the HRC dictates that ship, submarine, and aircraft participants utilize their sensors and train with their weapons to their optimum capabilities as required by the mission. The Navy recognizes that such use has the potential to cause behavioral disruption of some marine mammal species in the vicinity of a training event. As part of their SOPs, the Navy has developed mitigation measures that would be implemented to protect marine mammals and Federally listed species during ASW training. These mitigation measures, which are part of the No-action Alternative, include the establishment of a safety zone and procedures to power down or shut off sonar if animals are detected within the safety zone. For detailed list of mitigation measures see Chapter 6.0. While conducting ASW training, Navy ships always have two, although usually more, personnel on watch serving as lookouts. In addition to the qualified lookouts, the bridge team present at a minimum also includes an Officer of the Deck and one Junior Officer of the Deck include observing the waters in the vicinity of the ship. At night, personnel engaged in ASW events may also use night vision goggles and infra-red detectors, as appropriate, which can aid in the detection of marine mammals. Passive acoustic detection of vocalizing marine mammals is used to alert bridge lookouts to the potential presence of marine mammals in the vicinity.

Navy lookouts undergo extensive training to qualify as watchstanders. This training includes on-the-job instruction under the supervision of an experienced watchstander, followed by completion of the Personal Qualification Standard program. The Navy includes marine species awareness as part of its training for its bridge lookout personnel on ships and submarines as required training for Navy lookouts. This training addresses the lookout's role in environmental protection, laws governing the protection of marine species, Navy stewardship commitments, and general observation information to aid in avoiding interactions with marine species.

Operating procedures are implemented to maximize the ability of personnel to recognize instances when marine mammals are close aboard and avoid adverse effects. These procedures include measures such as decreasing the source level and then shutting down active tactical sonar operations when marine mammals are encountered in the vicinity of a training event. Although these mitigation measures are SOPs, their use is also reinforced through promulgation of an Environmental Annex to the Operational Order for a training event. Sonar operators on ships, submarines, and aircraft use both passive and active sonar detection indicators of marine mammals as a measure of estimating when marine mammals are close. When marine mammals are detected nearby, all ships, submarines, and aircraft engaged in ASW will reduce MFA sonar power levels in accordance with specific guidelines developed for each type of training event.

NMFS and the Navy will continue coordination on the "Communications and Response Protocol for Stranded Marine Mammal Events During Navy Operations in the Pacific Islands Region" that was prepared by NMFS Pacific Region Pacific Island Region Office to facilitate communication during RIMPAC 2006. The Navy will continue to coordinate with the Hawaii NMFS Stranding Coordinator for any unusual marine mammal behavior, including stranding, beached live or dead cetaceans, floating marine mammals, or out-of-habitat/milling live cetaceans that may occur during or shortly after Navy activities in the vicinity of the stranding.

Long-Term Effects

Navy training activities are conducted in the same general areas throughout the HRC, so marine mammal populations can be exposed to repeated training over time. However, as described earlier, this HRC EIS/OEIS assumes that short-term non-injurious sound exposure levels predicted to cause TTS or temporary behavioral disruptions qualify as Level B harassment. Application of this criterion assumes an effect even though it is highly unlikely that all behavioral disruptions or instances of TTS will result in long-term significant impacts. There are resident populations of spinner dolphins and beaked whales in several areas throughout the HRC (Andrews et al., 2006; Baird et al., 2006c) that have been exposed to Navy activities but continue to use those areas. Also, the population of humpback whales in Hawaiian waters is increasing (Mobley 2004). Although this suggests that Navy activities do not have a long-term effect on marine mammals, it does not unequivocally confirm this assumption. There will be long-term monitoring program of the marine mammal populations within the HRC.

Likelihood of Prolonged Exposure

The proposed ASW training in the HRC would not result in prolonged exposure because the vessels are constantly moving, and the flow of the activity in the HRC when ASW training occurs reduces the potential for prolonged exposure.

4.1.2.4.11.2 Explosive Source Mitigation Measures

As part of the official Navy clearance procedure before an underwater detonation or Live Fire Exercise, the target area must be inspected visually (from vessels and available aircraft) and determined to be clear. The use of non-explosive rounds or weapons only has the potential to impact marine species if they are targeted at the water or if they miss the intended target. In a SINKEX for example, most of the weapons are guided munitions and gunfire that are generally very accurate. The required clearance zone at the target areas, and training within controlled ranges, minimizes the risk to marine mammals. Open ocean clearance procedures are the same for live or inert ordnance. Whenever ships and aircraft use the ranges for missile and gunnery practice, the weapons are used under controlled circumstances involving clearance procedures to ensure cetaceans, pinnipeds, or sea turtles are not present in the target area. These involve, at a minimum, a detailed visual search of the target area by aircraft reconnaissance, range safety boats, and range controllers and passive acoustic monitoring.

Ordnance cannot be released until the target area is determined to be clear. Training events are immediately halted if cetaceans, pinnipeds, or sea turtles are observed within the target area. Training events are delayed until the animal clears the target area. All observers are in continuous communication in order to have the capability to immediately stop the training. Training can be modified as necessary to obtain a clear target area. If the area cannot be cleared, it is canceled. All of these factors serve to avoid the risk of harming cetaceans, pinnipeds, or sea turtles.

The weapons used in most missile and Live Fire Exercises pose little risk to marine mammals unless they happen to be near the point of impact. Machine guns (0.50 caliber), 5-inch guns, 76-mm guns, and close-in weapons systems (anti-missile systems) exclusively fire non-explosive ammunition. The same applies to larger weapons firing inert ordnance for training. The rounds pose an extremely low risk of a direct hit and potential to directly affect a marine species. Target area clearance procedures will reduce this risk. A SINKEX uses a variety of weapons. The inert rounds pose a risk only at the point of impact and the non-inert weapons (with the exception of a live torpedo) only pose a risk of they miss the target. Target area clearance procedures will reduce this risk. Modeling results of the potential exposures of marine mammals to underwater sound from a SINKEX are summarized in Section 4.1.2.5.1.

The Navy has developed a mitigation plan to maximize the probability of sighting any ships or protected species in the vicinity of training. In order to minimize the likelihood of taking any threatened or endangered species that may be in the area, the following monitoring plan will be adhered to:

- All weapons firing will be conducted during the period 1 hour after official sunrise to 30 minutes before official sunset.
- Extensive range clearance operations will be conducted in the hours prior to commencement of the training, ensuring that no shipping is located within the hazard range of the longest-range weapon being fired for that event.
- An exclusion zone with a radius of 1.0 nm will be established around each target. This exclusion zone is based on calculations using a 990 lb H6 net explosive weight high explosive source detonated 5 ft below the surface of the water, which yields a distance of 0.85 nm (cold season) and 0.89 nm (warm season) beyond which the received level is below the 182 dB re: 1 μPa^2-s threshold established for the WINSTON S. CHURCHILL (DDG 81) shock trials. An additional buffer of 0.5 nm will be added to account for errors, target drift, and animal movements. Additionally, a safety zone, which extends from the exclusion zone at 1.0 nm out an additional 0.5 nm, will be surveyed. Together, the zones extend out 2 nm from the target.

A series of surveillance over-flights would be conducted within the exclusion and the safety zones, prior to and during training, when feasible. Survey protocol will be as follows:

- All visual surveillance operations will be conducted by Navy personnel trained in visual surveillance. In addition to the over flights, the exclusion zone will be monitored by passive acoustic means, when assets are available.
- If a protected species observed within the exclusion zone is diving, firing will be delayed until the animal is re-sighted outside the exclusion zone, or 30 minutes has elapsed. After 30 minutes, if the animal has not been re-sighted it will be assumed to have left the exclusion zone. This is based on a typical dive time of 30 minutes for listed species of concern. The Officer conducting the exercise will determine if the listed species is in danger of being adversely affected by commencement of the training event.

There is a long lead-time for set up and clearance of the impact area before any event using explosives takes place (may be one to several hours). There will, therefore, be a long period of area monitoring before any detonation or live fire event begins. Ordnance cannot be released until the target area is determined clear. Training is immediately halted if marine mammals are observed within the target area. Training is delayed until the animals clear the target area.

Most underwater detonations take place in shallow sandy areas that are generally not used by cetacea and are not feeding and resting areas for sea turtles. These factors, along with range clearance procedures and exercise set-up times, all serve to avoid the risk of harming cetaceans, pinnipeds, or sea turtles. Post event monitoring of underwater detonations has not produced any evidence of mortality of any protected marine species.

4.1.2.4.12 Sonar Marine Mammal Modeling

4.1.2.4.12.1 Active Acoustic Devices

Tactical military sonars are designed to search for, detect, localize, classify, and track submarines. There are two types of sonars, passive and active:

- Passive sonars only listen to incoming sounds and, since they do not emit sound energy in the water, lack the potential to acoustically affect the environment.
- Active sonars generate and emit acoustic energy specifically for the purpose of obtaining information concerning a distant object from the received and processed reflected sound energy.

Modern sonar technology has developed a multitude of sonar sensor and processing systems. In concept, the simplest active sonars emit omni-directional pulses ("pings") and time the arrival of the reflected echoes from the target object to determine range. More sophisticated active sonar emits an omni-directional ping and then rapidly scans a steered receiving beam to provide directional, as well as range, information. More advanced sonars transmit multiple preformed beams, listening to echoes from several directions simultaneously and providing efficient detection of both direction and range.

The tactical military sonars to be deployed during testing and training in the HRC are designed to detect submarines in tactical operational scenarios. This task requires the use of the sonar mid-frequency range (1 kHz to 10 kHz) and the high-frequency range (above 10 kHz). The types of tactical acoustic sources that would be used in training events are discussed in the following paragraphs.

- **Surface Ship Sonars.** A variety of surface ships participate in testing and training events, including cruisers, destroyers, and frigates. Some ships (e.g., aircraft carriers) do not have any onboard active sonar systems, other than fathometers. Others, like cruisers, are equipped with active as well as passive sonars for submarine detection and tracking. For purposes of the analysis, AN/SQS-53 surface ship sonars (present on cruisers and destroyers were modeled as having the nominal source level of 235 dB re 1 µPa at 1 m and transmitting at center frequencies of 2.6 kHz and 3.3 kHz. Sonar ping transmission durations were modeled as lasting 1 second per ping every 30 seconds and omni-directional, which is a conservative assumption that will calculate the maximum potential for effects. Actual ping durations will be less than 1 second. The AN/SQS-56 sonar present on frigates were modeled as having the nominal source level of 225 dB re 1 µPa at 1 m and transmitting at a center frequency of 7.5 kHz. Effects analysis modeling used frequencies that are required in tactical deployments such as those during RIMPAC and USWEX. Details concerning the tactical use of specific frequencies and the repetition rate for the sonar pings is classified but effects were modeled based on the required tactical training setting.

- **Submarine Sonars.** Submarine sonars are used to detect and target enemy submarines and surface ships. Submarine active sonar use is very rare and in those rare instances, the duration is very brief. It is extremely unlikely that use of active sonar by submarines would have any measurable effect on marine mammals.
- **Aircraft Sonar Systems.** Aircraft sonar systems that would operate in the HRC include sonobuoys and dipping sonar. Sonobuoys may be deployed by maritime patrol aircraft or helicopters; dipping sonars are used by carrier-based helicopters. A sonobuoy is an expendable device used by aircraft for the detection of underwater acoustic energy and for conducting vertical water column temperature measurements. Most sonobuoys are passive, but some can generate active acoustic signals, as well as listen passively. Dipping sonar is an active or passive sonar device lowered on cable by helicopters to detect or maintain contact with underwater targets. During ASW training, these systems active modes are only used briefly for localization of contacts and are not used in primary search capacity. Because active mode dipping sonar use is very brief, it is extremely unlikely its use would have any effect on marine mammals. However, the AN/AQS-22 dipping sonar was modeled based on estimated use during major exercises within the HRC.
- **Torpedoes.** Torpedoes are the primary ASW weapon used by surface ships, aircraft, and submarines. The guidance systems of these weapons can be autonomous or electronically controlled from the launching platform through an attached wire. The autonomous guidance systems are acoustically based. They operate either passively, exploiting the emitted sound energy by the target, or actively, ensonifying the target with a high-frequency sonar (20 kHz) and using the received echoes for guidance. Potential impacts from the use of torpedoes on the PMRF range areas were analyzed in the PMRF Enhanced Capability EIS and, consistent with NOAA's June 3, 2002, ESA Section 7 letter to the Navy for RIMPAC 2002 and the RIMPAC 2006 Biological Opinion, the Navy determined that the activities are not likely to adversely affect ESA listed species under the jurisdiction of the NMFS. The MK-48 torpedo was modeled for active sonar transmissions during specified training within the HRC.
- **Acoustic Device Countermeasures (ADC).** ADCs are, in effect, submarine simulators that make sound to act as decoys to avert localization and/or torpedo attacks. Previous classified analysis has shown that, based on the operational characteristics (source output level and/or frequency) of these acoustic sources, the potential to affect marine mammals was unlikely.
- **Training Targets.** ASW training targets are used to simulate target submarines. They are equipped with one or a combination of the following devices: (1) acoustic projectors emanating sounds to simulate submarine acoustic signatures; (2) echo repeaters to simulate the characteristics of the echo of a particular sonar signal reflected from a specific type of submarine; and (3) magnetic sources to trigger magnetic detectors. Based on the operational characteristics (source output level and/or frequency) of these acoustic sources, the potential to affect marine mammals is low, and therefore they were not modeled for this analysis. Consistent with NOAA's June 3, 2002, ESA Section 7 letter to the Navy for RIMPAC 2002 and the RIMPAC 2006 Biological Opinion, the Navy determined that the activities are not likely to adversely affect ESA listed species under the jurisdiction of NMFS.

- **Range Sources.** Range pingers are active acoustic devices that allow each of the in-water platforms on the range (e.g., ships, submarines, target simulators, and exercise torpedoes) to be tracked by the range transducer nodes. In addition to passively tracking the pinger signal from each range participant, the range transducer nodes also are capable of transmitting acoustic signals for a limited set of functions. These functions include submarine warning signals, acoustic commands to submarine target simulators (acoustic command link), and occasional voice or data communications (received by participating ships and submarines on range). Based on the operational characteristics (source output level and/or frequency) of these acoustic sources, the potential to affect marine mammals is low, and therefore they were not modeled for this analysis. Consistent with NOAA's June 3, 2002, ESA Section 7 letter to the Navy for RIMPAC 2002 and the RIMPAC 2006 Biological Opinion, the Navy determined that the activities are not likely to adversely affect ESA listed or MMPA protected species under the jurisdiction of NMFS.

4.1.2.4.12.2 Sonar Modeling Methodology

Modeling of the effects of MFA/HFA sonar and underwater detonations was conducted using methods described in brief below. A detailed description of the representative modeling areas, sound sources, model assumptions, acoustic and oceanographic parameters, underwater sound propagation and transmission models, and diving behavior of species modeled are presented in Appendix J.

The approach for estimating potential acoustic effects from HRC ASW training on cetacean species makes use of the methodology that was developed in cooperation with NOAA for the Navy's USWTR Draft OEIS/EIS (U.S. Department of the Navy, 2005a), USWEX EA/OEA (U.S. Department of the Navy, 2007b), RIMPAC EA/OEA (U.S. Department of the Navy, Commander Third Fleet, 2006) and COMPTUEX/JTFEX EA/OEA (U.S. Department of the Navy, 2007c). The methodology is provided here to determine the number and species of marine mammals for which incidental take authorization is requested.

In order to estimate acoustic effects from HRC ASW training, acoustic sources to be used were examined with regard to their operational characteristics as described in the previous section. Ship systems such as fathometers, with acoustic source levels below 201 dB re 1 µPa at 1 m were considered and were not included in the analysis given that at this source level (201 dB re 1 µPa at 1 m) or below, a ping would attenuate rapidly over distance. In addition, these sources are generally in the high-frequency range, which also reduces the propagation characteristics. It is important to note that odontocetes (toothed whales) are believed to have functional hearing in the range between approximately 40 Hz up to 80 kHz to 150 kHz and that mysticetes (baleen whales like humpbacks) are believed to have functional hearing below this upper limit (Richardson et al., 1995c). Filter-bank models of the humpback whale's ear investigated by Houser et al., (2001) suggested that humpbacks are sensitive to frequencies between 700 Hz and 10 kHz, and maximum sensitivity is between 2 kHz and 6 kHz. Research involving the recording of humpback vocalizations has found harmonics in the range up to 240 kHz (Au et al. 2001; 2006). These results do not, however, indicate that humpbacks can actually hear those high-frequency harmonics and given that sound of that frequency attenuates rapidly over distance, those sounds would not serve as a means of communication over distance. Since systems with an operating frequency greater than 150 kHz were not analyzed in the detailed modeling as these signals attenuate rapidly resulting in very short propagation distances. These acoustic sources, therefore, did not require further examination in this analysis.

Based on the information above, only AN/SQS 53, AN/SQS 56 hull-mounted MFA tactical sonar, DICASS MFA sonobuoy, MK-48 torpedo HFA sonar, and AN/AQS 22 (MFA dipping sonar), and submarine MFA sonar were determined to have the potential to affect marine mammals protected under the MMPA and ESA during HRC ASW training events.

For modeling purposes, sonar parameters (source levels, ping length, the interval between pings, output frequencies, etc.) were based on records from training events, previous exercises, and preferred ASW tactical doctrine to reflect the sonar use expected to occur during events in the HRC. The actual sonar parameters such as output settings, distance between ASW surface, subsurface, and aerial units, their deployment patterns, and the coordinated ASW movement (speed and maneuvers) across the exercise area are classified, however, modeling used to calculate exposures to marine mammals employed actual and preferred parameters to which the participants are trained and have used during past, used during ASW events in the HRC.

Every active sonar operation includes the potential to expose marine animals in the neighboring waters. The number of animals exposed to the sonar in any such action is dictated by the propagation field, the manner in which the sonar is operated (i.e., source level, depth, frequency, pulse length, directivity, platform speed, repetition rate), and the density of each marine species.

The modeling for surface ship active tactical sonar occurred in five broad steps, listed below. Results were calculated based on typical ASW training planned for the HRC. Acoustic propagation and mammal population data are analyzed for both the summer and winter timeframe. Marine mammal survey data for the offshore area beyond 25 nm (Barlow, 2006) and survey data for offshore areas within 25 nm (Mobley et al., 2000) provided marine mammal species density for modeling.

> Step 1. Environmental Provinces. The Hawaii Operating Area (OPAREA) is divided into six marine modeling areas, and each has a unique combination of environmental conditions. These are addressed by defining eight fundamental environments in two seasons that span the variety of depths, bottom types, sound speed profiles, and sediment thicknesses found in the Hawaii OPAREA. Each marine modeling area can be quantitatively described as a unique combination of these environments.
>
> Step 2. Transmission Loss. Since sound propagates differently in these eight environments, separate transmission loss calculations must be made for each, in both seasons. The transmission loss is predicted using CASS-GRAB sound modeling software.
>
> Step 3. Exposure Volumes. The transmission loss, combined with the source characteristics, gives the energy field of a single ping. The energy of over 10 hours of pinging is summed, carefully accounting for overlap of several pings, so an accurate average exposure of an hour of pinging is calculated for each depth increment. Repeating this calculation for each environment in each season gives the hourly ensonified volume, by depth, for each environment and season.
>
> Step 4. Marine Mammal Densities. The marine mammal densities were given in two dimensions, but using sources such as the North Pacific Acoustic Laboratory EIS, the

depth regimes of these marine mammals are used to project the two dimensional densities into three dimensions. Marine mammal densities (as provided by NMFS, e.g., Barlow, 2006) have high coefficients of variation.

Step 5. Exposure Calculations. Each marine mammal's three dimensional density is multiplied by the calculated impact volume—to that marine mammal depth regime. This provides the number of marine mammal density exposures per hour for that particular marine mammal species in each depth regime. In this way, each marine mammal species' (possibly fractional) exposure count per hour is based on its density, depth habitat, and the ensonified volume by depth. The marine mammal density exposures in each depth regime are then summed to predict the expected number of marine mammals harassed by activities within the HRC annually.

The movement of various units during an ASW event is largely unconstrained and dependent on the developing tactical situation presented to the commander of the forces. The planned sonar hours, by ASW training type, are given in the discussion for each type of training event for each alternative. The product of the hours of sonar and the hourly exposure count from the model provides the total exposures.

4.1.2.4.13 Explosive Source Marine Mammal Modeling

Underwater detonation activities can occur at various depths depending on the activity (SINKEX, EER/IEER, and Mine Neutralization), but may also include activities which may have detonations at or just below the surface (BOMBEX, GUNEX, or MISSILEX). Criteria for analysis of explosives potential impact on marine species is presented in Section 4.1.2.3, having application to both sea turtles and marine mammals.

4.1.2.4.13.1 Explosive Source Exercises

The exercises that use explosives are described in the following paragraphs.

Sinking Exercise (SINKEX)

In a SINKEX, a specially prepared, deactivated vessel is deliberately sunk using multiple weapons systems. The exercise provides training to ship and aircraft crews in delivering live ordnance on a real target. The target is a decommissioned and empty, cleaned, and environmentally-remediated ship hulk. It is towed to sea and set adrift at the SINKEX location. The duration of a SINKEX is unpredictable since it ends when the target sinks, sometimes immediately after the first weapon impact and sometimes only after multiple impacts by a variety of weapons fired one at a time in a series. Typically the exercise lasts for 4 to 8 hours. In the case of multiple SINKEX targets being used for an exercise, a SINKEX may be conducted on successive or multiple days. If at the end of the SINKEX or expenditure of all training ordnance the hulk has not been sunk, it will be sunk by detonation of explosive charges placed inside the hull. No SINKEX hulks would be left adrift overnight. SINKEXs occur only occasionally during HRC exercises. Modeling for an analysis of impacts from a SINKEX assumes all weapons are live (non-inert) and that all weapons used would impact the water. Some or all of the following weapons may be employed in a SINKEX:

- Three Harpoon surface-to-surface and air-to-surface missiles
- Two to eight air-to-surface Maverick missiles

- Two to four MK-82 General Purpose Bombs
- Two Hellfire air-to-surface missiles
- One SLAM-ER air-to-surface missile
- Two-hundred and fifty rounds for a 5-inch gun
- One MK-48 heavyweight submarine-launched torpedo

Air-to-Surface Gunnery Exercise (A-S GUNEX)

A-S GUNEX training is conducted by rotary-wing aircraft against stationary targets (Floating At-Sea Target [FAST] and smoke buoy). Rotary-wing aircraft involved in this training event would include a single SH-60 using either 7.62-mm or 0.50-caliber door-mounted machine guns. A typical GUNEX will last approximately 1 hour and involve the expenditure of approximately 400 rounds of 0.50-caliber or 7.62-mm ammunition. Due to the small size of these rounds, they are not considered to have an underwater detonation impact.

Surface-to-Surface Gunnery Exercise (S-S GUNEX)

S-S GUNEX take place in the open ocean to provide gunnery practice for Navy and Coast Guard ship crews. GUNEX training conducted in the Offshore OPAREA involves stationary targets such as a MK-42 FAST or a MK-58 marker (smoke) buoy. The gun systems employed against surface targets include the 5-inch, 76-millimeter (mm), 25-mm chain gun, 20-mm Close-in Weapon System, and 0.50-caliber machine gun. Typical ordnance expenditure for a single GUNEX is a minimum of 21 rounds of 5-inch or 76-mm ammunition, and approximately 150 rounds of 25-mm or .50-caliber ammunition. Both live and inert training rounds are used. After impacting the water, the rounds and fragments sink to the bottom of the ocean. A GUNEX lasts approximately 1 to 2 hours, depending on target services and weather conditions. The 5-inch and 76-mm rounds are considered in the underwater detonation modeling as live (non-inert), although typically not all ordnance will be live.

Naval Surface Fire Support Exercise (NSFS)

Navy surface combatants conduct NSFS at PMRF on a virtual range against “Fake Island,” located on Barking Sands Tactical Underwater Range (BARSTUR). Fake Island is unique in that it is a virtual landmass simulated in three dimensions. Ships conducting fire support exercise training against targets on the island are given the coordinates and elevation of targets. PMRF is capable of tracking fired rounds to an accuracy of 30 ft. The 5-inch and 76-mm rounds fired into ocean during this exercise are considered in the underwater detonation modeling as live (non-inert) although typically not all ordnance will be live.

Air-to-Surface Missile Exercise (A-S MISSILEX)

The A-S MISSILEX consists of the attacking platform releasing a forward-fired, guided weapon at the designated towed target. The exercise involves locating the target, then designating the target, usually with a laser.

A-S MISSILEX training that does not involve the release of a live weapon can take place if the attacking platform is carrying a captive air training missile (CATM) simulating the weapon involved in the training. The CATM MISSILEX is identical to an LFX in every aspect except that a weapon is not released. The training event requires a laser-safe range as the target is designated just as in an LFX.

From 1 to 16 aircraft, carrying live, inert, or CATMs, or flying without ordnance (dry runs) are used during the exercise. At sea, seaborne powered targets (SEPTARs), Improved Surface Towed Targets (ISTTs), and excess ship hulks are used as targets. A-S MISSILEX assets include helicopters and/or 1 to 16 fixed wing aircraft with air-to-surface missiles and anti-radiation missiles (electromagnetic radiation source seeking missiles). When a high-speed anti-radiation missile (HARM) is used, the exercise is called a HARMEX. Targets include SEPTARs, ISTTs, and excess ship hulks.

Surface-to-Surface Missile Exercise (S-S MISSILEX)

S-S MISSILEX involves the attack of surface targets at sea by use of cruise missiles or other missile systems, usually by a single ship conducting training in the detection, classification, tracking, and engagement of a surface target. Engagement is usually with Harpoon missiles or Standard missiles in the surface-to-surface mode. Targets could include virtual targets or the SEPTAR or ship deployed surface target. S-S MISSILEX training is routinely conducted on individual ships with embedded training devices.

S-S MISSILEX could include 4 to 20 surface-to-surface missiles, SEPTARs, a weapons recovery boat, and a helicopter for environmental and photo evaluation. All missiles are equipped with instrumentation packages or a warhead. Surface-to-air missiles can also be used in a surface-to-surface mode. S-S MISSILEX activities are conducted within PMRF Warning Area W-188. Each exercise typically lasts 5 hours. Future S-S MISSILEX could range from 4 to 35 hours.

Bombing Exercise (BOMBEX)

Fixed-wing aircraft conduct BOMBEX (Sea) training events against stationary targets (MK 42 FAST or MK 58 smoke buoy) at sea. An aircraft will clear the area, deploy a smoke buoy or other floating target, and then set up a racetrack pattern, dropping on the target with each pass. At PMRF, a range boat might be used to deploy the target for an aircraft to attack. BOMBEX are considered in the underwater detonation modeling as live (non-inert), although typically not all bombs will be live.

Mine Neutralization

Mine Neutralization training events involve the detection, identification, evaluation, rendering safe, and disposal of mines and unexploded ordnance that constitutes a threat to ships or personnel. Mine neutralization training can be conducted by a variety of air, surface and sub-surface assets.

Tactics for neutralization of ground or bottom mines involve the diver placing a specific amount of explosives, which when detonated underwater at a specific distance from a mine results in neutralization of the mine. Floating, or moored, mines involve the diver placing a specific amount of explosives directly on the mine. Floating mines encountered by Fleet ships in open-ocean areas will be detonated at the surface. In support of an expeditionary assault, divers and Navy marine mammal assets deploy in very shallow water depths (10 to 40 ft) to locate mines and obstructions. Divers are transported to the mines by boat or helicopter. Inert dummy mines are used in the exercises. The total net explosive weight used against each mine ranges from less than 1 lb to a maximum of 20 lb.

Various types of bottom surveying equipment may be used during RIMPAC. Examples include the Canadian Route Survey System that hydrographically maps the ocean floor using multi-beam side scan sonar and the Bottom Object Inspection Vehicle used for object identification. These units can help in supporting mine detection prior to Special Warfare Operations (SPECWAROPS) and amphibious exercises.

Mine Neutralization training events take place offshore in the Pu`uloa Underwater Range (called Keahi Point in earlier documents);Naval Station Pearl Harbor; Lima Landing; Barbers Point Underwater Range off-shore of Coast Guard Air Station Barbers Point/Kalaeloa Airport (formerly Naval Air Station Barbers Point); PMRF, Kauai (Majors Bay area); PMRF and Oahu Training Areas; and in Open Ocean Areas.

All demolition activities are conducted in accordance with Commander Naval Surface Forces Pacific Instruction 3120.8F, Procedures for Disposal of Explosives at Sea/Firing of Depth Charges and Other Underwater Ordnance (U.S. Department of the Navy, 1993). Before any explosive is detonated, divers are transported a safe distance away from the explosive. Standard practices require tethered mine explosive charges in Hawaiian waters require ground mine explosive charges to be suspended 10 ft below the surface of the water.

Extended Echo Ranging and Improved Extended Echo Ranging (EER/IEER) SSQ-110

The EER/IEER Systems are airborne ASW systems used in conducting searches for submarines. These systems are made up of airborne avionics ASW acoustic processing and sonobuoys. The sonobuoys are deployed in pairs. The EER/IEER System's active sonobuoy component is the AN/SSQ-110 Sonobuoy. The AN/SSQ-110 Sonobuoy is an expendable and remote controlled sonobuoy, which will generate a sonar "ping," and the passive AN/SSQ-101 ADAR Sonobuoy, which will "listen" for the return echo of the sonar ping that has been bounced off the surface of a submarine. These sonobuoys are designed to provide underwater acoustic data necessary for naval aircrews to quickly and accurately detect submerged submarines. The sonobuoy pairs are dropped from a fixed-wing aircraft into the ocean in a predetermined pattern with a few buoys covering a very large area. Upon command from the aircraft, the first payload is released to sink to a designated operating depth and detonate generating a "ping." A second command is required from the aircraft to cause the second payload to release, detonate, and generate a second and final "ping." There is only one detonation in the total deployed pattern of buoys at a time.

Mitigation measures and modeling approaches are still being coordinated between the Navy and NMFS. Primarily, however, buoys are not dropped or activated if marine species of concern are observed or marine mammals are acoustically detected.

4.1.2.4.13.2 Explosive Source Modeling Criteria

As described in Section 4.1.2.3 for sea turtles there are several criterions for mortality, injury and TTS. The criterion for mortality for marine mammals used in the Churchill FEIS (U.S. Department of the Navy, 2001c) is "onset of severe lung injury." This is conservative in that it corresponds to a 1 percent chance of mortal injury, and yet any animal experiencing onset severe lung injury is counted as a lethal exposure.

- The threshold is stated in terms of the Goertner (1982) modified positive impulse with value "indexed to 31 psi-ms." Since the Goertner approach depends on propagation, source/animal depths, and animal mass in a complex way, the actual impulse value corresponding to the 31-psi-ms index is a complicated calculation. Again, to be conservative, CHURCHILL used the mass of a calf dolphin (at 27 lb), so that the threshold index is 30.5 psi-ms.

Two criteria are used for injury: onset of slight lung hemorrhage and 50 percent eardrum rupture (TM rupture). These criteria are considered indicative of the onset of injury.

- The threshold for onset of slight lung injury is calculated for a small animal (a dolphin calf weighing 27 lb), and is given in terms of the "Goertner modified positive impulse," indexed to 13 psi-ms in the (U.S. Department of the Navy, 2001b). This threshold is conservative since the positive impulse needed to cause injury is proportional to animal mass, and therefore, larger animals require a higher impulse to cause the onset of injury.
- The threshold for TM rupture corresponds to a 50 percent rate of rupture (i.e., 50 percent of animals exposed to the level are expected to suffer TM rupture); this is stated in terms of an EL value of 205 dB re 1 μPa^2-s. The criterion reflects the fact that TM rupture is not necessarily a serious or life-threatening injury, but is a useful index of possible injury that is well correlated with measures of permanent hearing impairment (e.g., Ketten, 1998 indicates a 30 percent incidence of PTS at the same threshold).

Three criteria are considered for non-injurious harassment or TTS, which is a temporary, recoverable, loss of hearing sensitivity (National Marine Fisheries Service, 2001a; U.S. Department of the Navy, 2001b).

- The first criterion for TTS is 182 dB re 1 μPa^2-s maximum EL level in any 1/3-octave band.
- The second criterion for estimating TTS threshold, 12 pounds per square inch (psi) peak pressure was developed for 10,000-lb charges as part of the Churchill FEIS (U.S. Department of the Navy, 2001b, [National Oceanic Atmospheric Administration, 2005, 2006h]). It was introduced to provide a safety zone for TTS when the explosive or the animal approaches the sea surface (for which case the explosive energy is reduced but the peak pressure is not). Navy policy is to use a 23 psi criterion for explosive charges less than 2,000 lb and the 12 psi criterion for explosive charges larger than 2,000 lb. All explosives modeled for the HRC EIS/OEIS are less than 1,500 lb.
- The third criterion is used for estimation of behavioral disturbance before TTS (sub-TTS) for cases with multiple successive explosions (having less than 2 seconds separation between explosions). The threshold is 177 dB re 1 μPa^2-s (EL) to account for behavioral effects significant enough to be judged as harassment, but occurring at lower sound energy levels than those that may cause TTS. Since there

may be rare occasions when multiple explosions in succession (separated by less than 2 seconds) occur during BOMBEX, GUNEX, and NSFS using other than inert rounds, the Churchill approach was extended to cover multiple exposure events at the same location. For multiple exposures, accumulated energy over the entire training time is the natural extension for energy thresholds since energy accumulates with each subsequent shot; this is consistent with the treatment of multiple arrivals in Churchill. For positive impulse, it is consistent with Churchill to use the maximum value over all impulses received. The original research on pure tone exposures reported in Schlundt et al. (2000) and Finneran and Schlundt (2004) provided the pure-tone threshold of 192 dB as the lowest TTS value. This value is modified for explosives by (a) interpreting it as an energy metric, (b) reducing it by 10 dB to account for the time constant of the mammal ear, and (c) measuring the energy in 1/3 octave bands, the natural filter band of the ear. The resulting TTS threshold for explosives is 182 dB re 1 μPa^2-s in any 1/3 octave band. As reported by Schlundt et al. (2000) and Finneran and Schlundt (2004), instances of altered behavior in the pure tone research generally began 5 dB lower than those causing TTS. The sub-TTS threshold is therefore derived by subtracting five dB from the 182 dB re 1 μPa^2-s in any 1/3 octave band threshold, resulting in a 177 dB re 1 μPa^2-s sub-TTS behavioral disturbance threshold for multiple successive explosives. Previous modeling undertaken for other Navy compliance documents using the sub-TTS 177 dB threshold has demonstrated that for most explosive events, the footprint of the explosives TTS criteria pressure component (23 psi) dominates and supersedes any exposures at a received level involving the 177 dB threshold. For analysis in the HRC EIS/OEIS, therefore, given that multiple successive explosions are rare, in consideration of range clearance procedures designed to preclude the presence of marine species within the target area, and because previous modeling efforts have not resulted in expected exposures at the sub-TTS threshold level, modeling for these rare live fire events (BOMBEX, GUNEX, and NSFS) was not undertaken.

Model Results Explanation

Acoustic exposures are evaluated based on their potential direct effects on marine mammals, and these effects are then assessed in the context of the species biology and ecology to determine if there is a mode of action that may result in the acoustic exposure warranting consideration as a harassment level effect.

A large body of research on terrestrial animal and human response to airborne sound exists, but results from those studies are not readily applicable to the development of behavioral criteria and thresholds for marine mammals. Differences in hearing thresholds, dynamic range of the ear, and the typical exposure patterns of interest (e.g., human data tend to focus on 8-hour-long exposures), and the difference between acoustics in air and in water make extrapolation of human sound exposure standards inappropriate.

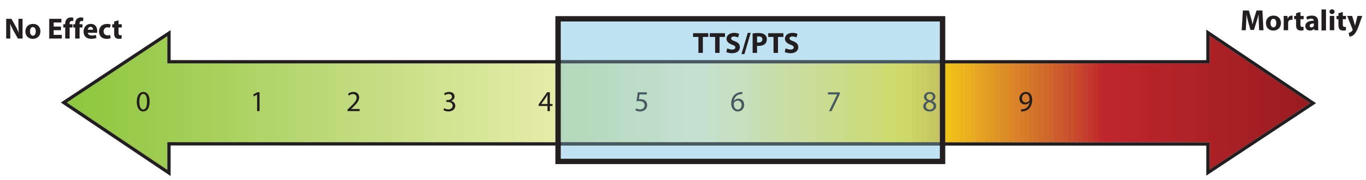
Behavioral observations of marine mammals exposed to anthropogenic sound sources exists, however, there are few observations and no controlled measurements of behavioral disruption of cetaceans caused by sound sources with frequencies, waveforms, durations, and repetition rates comparable to those employed by the tactical sonars described in this EIS/OEIS (Deecke, 2006) or for multiple explosives. Controlled studies in the laboratory have been conducted to determine physical changes (TTS) in hearing of marine mammals associated with sound exposure (Finneran et al., 2001, 2003, 2005). Research on behavioral effects has been difficult because of the difficulty and complexity of implementing controlled conditions.

At the present time there is no general scientifically accepted consensus on how to account for behavioral effects on marine mammals exposed to anthropogenic sounds including military sonar and explosions (National Research Council, 2003, National Research Council, 2005). While the first elements in Figure 4.1.2.4.13.2-1 can be easily defined (source, propagation, receiver) the remaining elements (perception, behavior, and life functions) are not well understood given the difficulties in studying marine mammals at sea (National Research Council 2005). The National Research Council (2005) acknowledges "there is not one case in which data can be integrated into models to demonstrate that noise is causing adverse affects on a marine mammal population."

For purposes of predicting the number of marine mammals that will be behaviorally harassed or sustain either temporary or permanent threshold shift, the Navy uses an acoustic impact model process with numeric criteria agreed upon with the NMFS.

There are some caveats necessary to understand in order to put these exposures in context. For instance, (1) significant scientific uncertainties are implied and carried forward in any analysis using marine mammal density data as a predictor for animal occurrence within a given geographic area; (2) there are limitations to the actual model process based on information available (animal densities, animal depth distributions, animal motion data, impact thresholds, type of sound source and intensity, behavior (involved in reproduction or foraging), previous experience and supporting statistical model); and determination of what constitutes a significant behavioral effect in a marine mammal is still unresolved (National Research Council, 2005). The sources of marine mammal densities used in this EIS/OEIS are derived from NMFS surveys (Barlow, 2003, 2006; Mobley et al., 2001a). These ship board surveys cover significant distance around the Hawaiian Islands. Although survey design includes statistical placement of survey tracks, the survey itself can only cover so much ocean area. Post-survey statistics are used to calculate animal abundances and densities (Barlow and Forney, 2007). There is often significant statistical variation inherit within the calculation of the final density values depending on how many sightings were available during a survey. Occurrence of marine mammals within any geographic area including Hawaii is highly variable and strongly correlated to oceanographic conditions, bathymetry, and ecosystem level patterns (prey abundance and distribution) (Benson et al., 2002; Moore et al., 2002; Tynan, 2005; Redfern, 2006). An example of high correlation of bathymetry in Hawaii is the distribution of humpback whales (particularly mothers with calves), generally within the 100-fathom isobath. Even as the population has increased, habitat use patterns have remained fairly constant, resulting in wider distribution over the available habitat. For some species, distribution may be even more highly influenced by relative small scale biological or oceanographic features over both short and long-term time scales (Ballance et al., 2006; Etnoyer et al., 2006; Ferguson et al., 2006; Skov et al., 2007). Unfortunately, the scientific understanding of some large scale and most small scale processes thought to influence marine mammal distribution is incomplete.

Behavioral Responses



0 - No observable response
1 - Brief orientation response (investigation / visual orientation)
2 - Moderate or multiple orientation behaviors
- Brief or minor cessation/modification of vocal behavior
- Brief or minor change in respiration rates
3 - Prolonged orientation behavior
- Individual alert behavior
- Minor changes in locomotion speed, direction, and/or dive profile but no avoidance of sound source
- Moderate change in respiration rate
- Minor cessation or modification of vocal behavior (duration < duration of source operation), including the Lombard Effect
4 - Moderate changes in locomotion speed, direction, and/or dive profile, but no avoidance of sound source
- Brief, minor shift in group distribution
- Moderate cessation or modification of vocal behavior (approximate duration of source operation)
5 - Extensive or prolonged changes in locomotion speed, direction, and/or dive profile, but not avoidance of sound source
- Moderate shift in group distribution
- Change in inter-animal distance and/or group size (aggregation or separation)
- Prolonged cessation or modifications of vocal behavior (duration > duration of source operation)
6 - Minor or moderate individual and/or group avoidance of sound source
- Brief or minor separation of females and dependent offspring
- Aggressive behavior related to noise exposure (e.g., tail/flipper slapping, fluke display, jaw clapping/gnashing teeth, abrupt directed movement, bubble clouds)
- Extended cessation or modification of vocal behavior
- Visible startle response
- Brief cessation of reproductive behavior
7 - Excessive or prolonged aggressive behavior
- Moderate separation of females and dependent offspring
- Clear antipredator response
- Severe and/or sustained avoidance of sound source
- Moderate cessation of reproductive behavior
8 - Obvious aversion and/or progressive sensitization
- Prolonged or significant separation of females and dependent offspring with disruption of acoustic reunion mechanisms
- Long-term avoidance of area (> source operation)
- Prolonged cessation of reproductive behavior
9 - Outright panic, fight, stampede, attach of conspecifics, or stranding events
- Avoidance behavior related to predator detection

Proposed Marine Mammal Response Severity Scale Spectrum to Anthropogenic Sounds in Free Ranging Marine Mammals

Figure 4.1.2.4.13.2-1

Given the uncertainties in marine mammal density estimation and localized distributions, the Navy's acoustic impact models can not currently take into account locational data for any marine mammals within specific areas of the Hawaiian Islands with the exception of generalized information for humpback whales and Hawaiian monk seals. To resolve this issue and allow modeling to precede, animals are "artificially and uniformly distributed" within the modeling provinces described in Appendix J.

Behavioral Responses

Behavioral responses to exposure from MFA and HFA sonar and underwater detonations in Hawaii can range from no response, to avoidance and behavioral reaction (Figure 4.1.2.4.13.2-1). The intensity of the behavioral responses exhibited by marine mammals depends on a number of conditions including the age, reproductive condition, experience, behavior (foraging or reproductive), species, received sound level, type of sound (impulse or continuous) and duration (including whether exposure occurs once or multiple times) of sound (Reviews by Richardson et al., 1995a; Wartzok et al., 2003; Cox et al., 2006, Nowacek et al., 2007; Southall et al., 2007). Many behavioral responses may be short term (seconds to minutes orienting to the sound source or over several hours if they move away from the sound source) and of little immediate consequence for the animal. However, certain responses may lead to a stranding or mother-offspring separation (Baraff and Weinrich, 1994; Gabriele et al., 2001). Active sonar exposure is brief as the ship is constantly moving and the animal will likely be moving as well. Generally the louder the sound source the more intense the response although duration is also very important (Southall et al., 2007). There are no exposures exceeding the PTS threshold in the Preferred Alternative (Alternative 3).

According to the severity scale response spectrum (Figure 4.1.2.1.13.2-1) proposed by Southall et al. (2007), responses classified as from 0-3 are brief and minor, those from 4-6 have a higher potential to affect foraging, reproduction, or survival and those from 7-9 are likely to affect foraging, reproduction and survival. Sonar and explosive mitigation measures (sonar power-down or shut-down zones and explosive exclusion zones) would likely prevent animals from being exposed to the loudest sonar sounds or explosive effects that could potentially result in TTS or PTS and more intense behavioral reactions (i.e. 7-9) on the response spectrum.

There are little data on the consequences of sound exposure on vital rates of marine mammals. Several studies have shown the effects of chronic noise (either continuous or multiple pulses) on marine mammal presence in an area exposed to seismic survey airguns or ship noise (e.g., Malme et al., 1984; McCauley et al., 1998; Nowacek et al., 2004). MFA sonar use in Hawaii is not new and has occurred using the same basic sonar equipment and output for over 30 years. Given this history the Navy believes that risk to marine mammals from sonar training is low. As noted previously, it has been suggested that the absence of strandings and floating dead marine mammals in Hawaii is because (it is argued) dead marine mammals will not float, are eaten by sharks, are carried out to sea, or end up on remote shorelines in Hawaii and are never discovered. In Hawaii, floating dead marine mammals persist for a number of days even while being consumed by sharks, and strandings occur on a regular basis on most of the islands. Considering the Pacific Island Region Marine Mammal Response Stranding Network's regular observations of strandings and dead floating marine mammals and the intense use and observation of the shorelines and waters around Hawaii given prevalent fishing and tourism, it is unreasonable to assume that a significant number of whale carcasses have been consistently missed.

Even for more cryptic species such as beaked whales, the main determinant of causing a stranding appears to be exposure in a limited egress areas (a long narrow channel) with multiple ships. The result is that animals may be exposed for a prolonged period rather than several sonar pings over a several minutes and the animals having no means to avoid the exposure. Under these specific circumstances and conditions MFA sonar is believed to have contributed to the stranding and mortality of a small number of beaked whales in locations other than the HRC. There are no limited egress areas (long narrow channels) in the HRC, therefore, it is unlikely that the proposed sonar use would result in any strandings. Although the Navy has substantially changed operating procedures to avoid the aggregate of circumstances that may have contributed to previous strandings, it is important that future unusual stranding events be reviewed and investigated so that any human cause of the stranding can understood and avoided.

There have been no beaked whales strandings in Hawaii associated with the use of MFA/HFA sonar. This is a critically important contextual difference between Hawaii and areas of the world where strandings have occurred (Southall et al., 2007). While the absence of evidence does not prove there have been no impacts on beaked whales, decades of history with no evidence cannot be lightly dismissed.

Temporary Threshold Shift

A temporary threshold shift is a temporary recoverable, loss of hearing sensitivity over a small range of frequencies related to the sound source to which it was exposed. The animal may not even be aware of the TTS and does not become deaf, but requires a louder sound stimulus (relative to the amount of TTS) to detect that sound within the affected frequencies. TTS may last several minutes to several days and the duration is related to the intensity of the sound source and the duration of the sound (including multiple exposures). Sonar exposures are generally short in duration and intermittent (several sonar pings per minute from a moving ship), and with mitigation measures in place, TTS in marine mammals exposed to mid- or high-frequency active sonar and underwater detonations are unlikely to occur. There is currently no information to suggest that if an animal has TTS, that it will decrease the survival rate or reproductive fitness of that animal. TTS range from a MFA sonar's 235 dB source level one second ping is approximately 110 m from the bow of the ship under nominal oceanographic conditions.

Permanent Threshold Shift

A permanent threshold shift a non-recoverable and results from the destruction of tissues within the auditory system and occur over a small range of frequencies related to the sound exposure. The animal does not become deaf but requires a louder sound stimulus (relative to the amount of PTS) to detect that sound within the affected frequencies. Sonar exposures are general short in duration and intermittent (several sonar pings per minute from a moving ship), and with mitigation measures in place, PTS in marine mammals exposed to MFA or HFA sonar is unlikely to occur. There is currently no information to suggest that if an animal has PTS that it decrease the survival rate or reproductive fitness of that animal. The distance to PTS from a MFA sonar's 235 dB source level one second ping is approximately 10 m from the bow of the ship under nominal oceanographic conditions.

Population Level Effects

Some HRC training activities will be conducted in the same general areas, so marine mammal populations could be exposed to repeated activities over time. This does not mean, however, that there will be a repetition of any effects given the vast number of variables involved. The acoustic analyses assume that short-term non-injurious sound levels predicted to cause TTS or temporary behavioral disruptions qualify as Level B harassment. However, it is unlikely that most behavioral disruptions or instances of TTS will result in long-term significant effects. The majority of the exposures modeled for the HRC would be below 170 dB SPL and are below the previously used behavioral threshold for RIMPAC, USWEX and COMPTUEX-JTFEX exercises (173 db re 1 µPa-s). Mitigation measures reduce the likelihood of exposures to sound levels that would cause significant behavioral disruption (the higher levels of 7-9 in Figure 4.1.2.4.13.2), TTS or PTS. Based on modeling the Navy has estimated that 27,570 marine mammals per year might be behaviorally harassed as a result of the Proposed Actions under the Preferred Alternative (Alternative 3). The Navy does not anticipate any mortality to result from the Proposed Actions. It is unlikely that the short term behavioral disruption would adversely affect the species or stock through effects on annual rates of recruitment or survival.

4.1.2.5 MARINE MAMMALS NO-ACTION ALTERNATIVE (BIOLOGICAL RESOURCES—OPEN OCEAN)

The discussions regarding potential impacts on fish (Section 4.1.2.2) and sea turtles (Section 4.1.2.3), as well as the discussion of non-acoustic impacts (Section 4.1.2.4.1) apply to the No-action Alternative.

4.1.2.5.1 No-action Alternative Summary of Exposures

The sonar modeling input includes a total of 1,284 hours of AN/AQS 53 and 383 hours of AN/AQS 56 tactical sonar, plus associated DICASS sonobuoy, MK-48 torpedo HFA sonar, EER/IEER, and dipping sonar modeling inputs (see of Appendix J for a detailed description of the sonar modeled). The resulting exposure numbers are generated by the model without consideration of mitigation measures that would reduce the potential for marine mammal exposures to sonar and other activities. Table 4.1.2.5.1-1 provides a summary of the total sonar exposures from all No-action Alternative ASW training that will be conducted over the course of a year. The number of exposures from each type of exercise are presented separately in Sections 4.1.2.5.5, 4.1.2.5.6, and 4.1.2.5.7.

The explosive modeling input includes Mine Neutralization, MISSILEX, BOMBEX, SINKEX, EER/IEER, GUNEX, and NSFS. The modeled explosive exposure harassment numbers by species are presented in Table 4.1.2.5.1-2. The table indicates the potential for non-injurious (Level B) harassment, as well as the onset of injury (Level A) harassment to cetaceans. Estimates for the sub-TTS behavioral threshold indicate there may be 62 exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS

Table 4.1.2.5.1-1. No-action Alternative Sonar Modeling Summary—Yearly Marine Mammal Exposures from All ASW (RIMPAC, USWEX, and Other ASW Training)

Marine Mammals	Risk Function	TTS[3]	PTS[4]
Bryde's whale	64	0	0
Fin whale[1, 2]	46	0	0
Sei whale[1, 2]	46	0	0
Humpback whale[1]	9,677	199	0
Sperm whale[1]	758	9	0
Dwarf sperm whale	2,061	35	0
Pygmy sperm whale	842	14	0
Cuvier's beaked whale	1,121	5	0
Longman's beaked whale	104	1	0
Blainville's beaked whale	347	6	0
Unidentified beaked whale	36	0	0
Bottlenose dolphin	716	17	0
False killer whale	46	0	0
Killer whale	46	0	0
Pygmy killer whale	192	4	0

Note:
[1] Endangered Species
2 Due to a lack of density data for fin and sei whales, false killer whale results were used because they have a similar size population within the HRC.
dB = decibel
µPa^2-s = squared micropascal-second
NMFS = National Marine Fisheries Service
PTS = permanent threshold shift
TM = tympanic membrane
TTS = temporary threshold shift

behavioral threshold. The modeling indicates 43 annual exposures from underwater detonations that could result in TTS. The modeling indicates no exposures from pressure from underwater detonations that could cause injury. These exposure modeling results are estimates of marine mammal underwater detonation sound exposures without consideration of standard mitigation and monitoring procedures. The implementation of the mitigation and monitoring procedures presented in Chapter 6.0 will minimize the potential for marine mammal exposure and harassment through range clearance procedures.

4.1.2.5.2 Estimated Effects on ESA Listed Species—No-action Alternative

The endangered species that may be affected as a result of implementation of the HRC No-action Alternative include the blue whale (*Balaenoptera musculus*), fin whale (*Balaenoptera physalus*), Hawaiian monk seal (*Monachus schauinslandi*) humpback whale (*Megaptera novaeangliae*), North Pacific right whale (*Eubalaena japonica*), sei whale (*Balaenoptera borealis*) and sperm whale (*Physeter macrocephalus*).

For the No-action Alternative, modeling results predict that if there were no mitigation measures in place, exposures that that are temporary, non-injurious physiological effects (TTS) or behavioral effects will occur. The modeling predicts no exposures to energy in excess of 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.

The following sections discuss the exposure of ESA listed species to sonar and to underwater detonations from all No-action ASW Exercises per year. The exposure numbers are given without consideration of mitigation measures. However, mitigation measures that are implemented during the ASW or underwater detonation will reduce the potential for marine mammal exposures. For each species the likelihood of detection is given based on systematic line transect surveys (Barlow, 2006) but the ability to detect marine mammals will depend on sea state conditions.

Blue Whale (*Balaenoptera musculus*)

There is no density information available for blue whales in Hawaiian waters given they have not been seen during any surveys. Given they are so few in number, it is unlikely that HRC MFA/HFA sonar training events will result in the exposure of any blue whales to accumulated acoustic energy in excess of any energy flux threshold or an SPL that would result in a behavioral response. No blue whales will be exposed to impulsive sound or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or cause physical injury.

Mitigation measures call for continuous visual observation during training with active sonar Given the large size (up to 98 ft) of individual blue whales (Leatherwood et al., 1982), pronounced vertical blow, and aggregation of approximately two to three animals in a group (probability of trackline detection = 0.90 in Beaufort Sea States of 6 or less; Barlow, 2003), it is likely that lookouts will detect a group of blue whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound;

and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

In the unlikely event that blue whales are exposed to MFA/HFA sonar, the anatomical information available on blue whales suggests that they are not likely to hear sounds at or above mid-frequency sounds (Ketten, 1997). There are no audiograms of baleen whales. Available information on blue whale vocalizations indicate a variety of low-frequency sounds in the 10 to 300 Hz band. Blue whales tend to react to anthropogenic sound below 1 kHz (e.g., seismic air guns), suggesting that they are more sensitive to low-frequency sounds (Richardson et al., 1995a; Croll et al., 2002). Because the MFA/HFA tactical sonar proposed for HRC ASW training is outside the frequency typically used by the blue whales, they are not likely to hear or have a physiological or behavioral response to the sonar (National Oceanic and Atmospheric Administration, 2006e).

Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of blue whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury, effects on their behavior or physiology, or abandonment of areas that are regularly used by blue whales. In accordance with ESA requirements, the Navy has undertaken Section 7 consultation with NMFS based on the determination that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect blue whales.

Fin Whale (*Balaenoptera physalus*)

There is no density information for fin whales in the Hawaiian Islands (Barlow, 2006). For purposes of acoustic effects analysis, it was assumed that the number and density of fin whales did not exceed that of false killer whales (given they have a similar reported abundance, Barlow 2006), and the modeled number of exposures for both species will therefore be the same. The risk function and Navy post-modeling analysis estimates 46 fin whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect but is not likely to adversely affect fin whales; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.5.1-1).

Modeling indicates there would be no exposures to accumulated acoustic energy above 195 dB re 1 µPa^2-s, which is the threshold established indicative of onset TTS. No fin whales will be exposed to impulsive sound or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or cause physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given the large size (up to 78 ft) of individual fin whales (Leatherwood et al., 1982), pronounced vertical blow, and mean aggregation of three animals in a group (probability of trackline detection = 0.90 in Beaufort Sea States of 6 or less; Barlow, 2003), it is likely that lookouts will detect a group of fin whales at the surface during ASW training events. Implementation of mitigation measures and probability of detecting a large fin whale reduce the likelihood of exposure and potential effects. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

In the unlikely event that fin whales are exposed to MFA/HFA sonar, the anatomical information available on fin whales suggests that they are not likely to hear mid-frequency (1 kHz to 10 kHz) sounds (Richardson et al., 1995a; Ketten, 1997). Fin whales primarily produce low-frequency calls (below 1 kHz) with source levels up to 186 dB re 1µPa at 1 m, although it is possible they produce some sounds in the range of 1.5 to 28 kHz (review by Richardson et al., 1995a; Croll et al., 2002). There are no audiograms of baleen whales, but they tend to react to anthropogenic sound below 1 kHz, suggesting that they are more sensitive to low-frequency sounds (Richardson et al., 1995a). Based on this information, if they do not hear these sounds, they are not likely to respond physiologically or behaviorally to those received levels.

In the St. Lawrence estuary area, fin whales avoided vessels with small changes in travel direction, speed and dive duration, and slow approaches by boats usually caused little response (MacFarlane, 1981). Fin whales continued to vocalize in the presence of boat sound (Edds and MacFarlane, 1987). Even though any undetected fin whales transiting the HRC may exhibit a reaction when initially exposed to active acoustic energy, field observations indicate the effects will not cause disruption of natural behavioral patterns to a point where such behavioral patterns will be abandoned or significantly altered.

Based on the model results, the nature of Navy's MFA sonar operations, behavioral patterns and acoustic abilities of fin whales, observations made during HRC training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events will likely not result in any population level effects, death or injury to fin whales. In accordance with ESA requirements, the Navy has undertaken Section 7 consultation with NMFS based on the determination that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect fin whales.

Humpback Whale (*Megaptera novaeangliae*)

The risk function and Navy post-modeling analysis estimates 9,677 humpback whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect but is not likely to adversely affect humpback whales; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.5.1-1).

Modeling indicates there would be 199 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates there would be no exposures for humpback whales to accumulated acoustic energy above 215 dB re 1 μPa^2-s.

Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral disturbance threshold. Without consideration of clearance procedures, modeling estimates five exposures from impulsive sound or pressures from underwater detonations that would exceed the TTS threshold, and no exposures that would exceed the slight injury threshold or the massive lung injury threshold (Table 4.1.2.5.1-2). Target area clearance procedures described in Section 4.1.2.5.1 would make sure there are no humpback whales within the safety zone, and therefore potential exposure of humpback whales to sound levels from underwater detonations that exceed TTS or injury levels is highly unlikely.

Mitigation measures call for continuous visual observation during training with active sonar. Given the large size (up to 53 ft) of individual humpback whales (Leatherwood et al., 1982), and pronounced vertical blow, it is very likely that lookouts would detect humpback whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

As noted previously, filter-bank models of the humpback whale's ear by Houser et al., (2001) suggest that humpbacks are sensitive to frequencies between 700 Hz and 10 kHz, and have a maximum sensitivity is between 2 kHz and 6 kHz. Recent reporting by Au et al., (2006) indicating high-frequency harmonics in humpback whale "song" at 24 kHz and beyond does not demonstrate that humpbacks can actually hear those harmonics, which may simply be correlated harmonics of the frequency fundamental. Most social vocalizations, including female vocalizations, are below 3 kHz (Silber, 1986); therefore, are below MFA sonar range. Male songs range from 20 Hz to 24 kHz, but most of the components range from 200 Hz to 3 kHz (Au et al., 2001). A single study suggested that humpback whales responded to MFA sonar (3.1-3.6 kHz re 1 μPa^2-s) sound (Maybaum, 1989). The hand-held sonar system had a sound artifact below 1,000 Hz which caused a response to the control playback (a blank tape) and may have affected the response to sonar (i.e., the humpback whale responded to the low-frequency artifact rather than the MFA sonar sound).

While acoustic modeling results indicate MFA/HFA sonar may expose humpback whales to accumulated acoustic energy levels resulting in temporary behavioral effects, these exposures would have negligible impact on annual survival, recruitment, and birth rates and not likely result in population level effects. The aggregation of humpback whales in Hawaii has been increasing at up to 7 percent annually (Mobley, 2004) despite frequent encounters with tour boats. There have been no observed or reported mother calf separations as a result of Navy activities. There have been no reported or identified humpback whale strandings in Hawaii associated with the use of MFA/HFA sonar. While the absence of evidence does not prove there have been no impacts on humpback whales, decades of history with no evidence should not be dismissed. Mitigation measures presented in Chapter 6.0 would further reduce the potential acoustic exposure.

Per Navy policy, based on the quantitative analysis results that trigger a "may affect" determination, Navy has initiated Section 7 consultation with NMFS based on the determination that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect humpback whales.

North Pacific Right Whale (*Eubalaena japonica*)

There is no density information available for North Pacific right whales in Hawaiian waters since they have not been seen during survey. Given they are so few in number, it is unlikely that HRC training events will result in the exposure of any North Pacific right whales to accumulated acoustic energy in excess of any energy flux threshold or an SPL that would result in a behavioral response. No right whales would be exposed to impulsive sound or pressures from underwater detonations that would cause TTS or physical injury.

Mitigation measures call for continuous visual observation during training with active sonar. Given their large size (up to 56 ft) of individual North Pacific right whales (Leatherwood et al., 1982), surface behavior (e.g., breaching), pronounced blow, and mean group size of approximately three animals (probability of trackline detection = 0.90 in Beaufort Sea States of 6 or less; Barlow, 2003), it is very likely that lookouts would detect a group of North Pacific right whales at the surface during ASW training events. Implementation of mitigation measures and probability of detecting a large North Pacific right whale reduce the likelihood of exposure and potential effects. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Based on the model results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of North Pacific right whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would likely not result in any population level effects, death or injury to North Pacific right whales, and will not affect their behavior, physiology or cause abandonment of areas that are regularly used by North Pacific right whales. In accordance with ESA requirements, the Navy has undertaken Section 7 consultation with NMFS based on the determination that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect North Pacific right whales.

Sei Whale (*Balaenoptera borealis*)

For purposes of the acoustic effects analysis, the same assumptions made previously regarding fin whales are also made for sei whales. It was therefore assumed that the number and density of sei whales did not exceed that of false killer whales (given they have a similar reported abundance, Barlow 2006), and the modeled number of exposures for both species would therefore be the same.

The risk function and Navy post-modeling analysis estimates 46 sei whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect but is not likely to adversely affect sei whales; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.5.1-1).

Modeling indicates there would be no exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates no exposures for sei whales to accumulated acoustic energy above 215 dB re 1 μPa^2-s. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. No sei whales would be exposed to impulsive sound or pressures from underwater detonations that would cause TTS or physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given the large size (up to 53 ft) of individual sei whales (Leatherwood et al., 1982), pronounced vertical blow, and aggregation of approximately three animals (probability of trackline detection = 0.90 in Beaufort Sea States of 6 or less; Barlow, 2003), it is likely that lookouts will detect a group of sei whales at the surface during ASW training events. Implementation of mitigation measures and probability of detecting a large sei whale reduce the likelihood of exposure and potential effects. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There is little information on the acoustic abilities of sei whales or their response to human activities. The only recorded sounds of sei whales are frequency modulated sweeps in the range of 1.5 to 3.5 kHz (Thompson et al., 1979; Knowlton et al., 1991), but it is likely that they also vocalized at frequencies below 1 kHz as do fin whales. There are no audiograms of baleen whales, but they tend to react to anthropogenic sound below 1 kHz, suggesting that they are more sensitive to low-frequency sounds (Richardson et al., 1995a). Sei whales were more difficult to approach than were fin whales and moved away from boats but were less responsive when feeding (Gunther, 1949).

Based on the model results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of sei whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not likely result in any population level effects, death or injury to sei whales. The proposed ASW Exercises may affect sei whales but are not likely to cause long-term effects on their behavior or physiology or abandonment of areas that are regularly used by sei whales. In accordance with ESA requirements, the Navy has undertaken Section 7 consultation with NMFS based on the determination that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect sei whales.

Sperm Whales (*Physeter macrocephalus*)

The risk function and Navy post-modeling analysis estimates 758 sperm whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect but is not likely to adversely affect sperm whales; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.5.1-1).

Modeling also indicates there would be nine exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates no exposures for sperm whales to accumulated acoustic energy above 215 dB re 1 μPa^2-s.

Estimates for the sub-TTS behavioral threshold indicate there may be nine exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS threshold. Without consideration of clearance procedures, there would be four exposures from impulsive sound or pressures from underwater detonations that would exceed the TTS threshold (Table 4.1.2.5.1-2). Target area clearance procedures described in Section 4.1.2.5.1 would make sure there are no sperm whales within the safety zone, and therefore potential exposure of sperm whales to sound levels that exceed TTS is highly unlikely.

Mitigation measures call for continuous visual observation during training with active sonar. Given the large size (up to 56 ft) of individual sperm whales (Leatherwood et al., 1982), pronounced blow (large and angled), mean group size of approximately seven animals (probability of trackline detection = 0.87 in Beaufort Sea States of 6 or less; Barlow, 2003; 2006), it is very likely that lookouts would detect a group of sperm whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

In the unlikely event that sperm whales are exposed to MFA/HFA sonar, the information available on sperm whales exposed to received levels of MFA sonar suggests that the response to mid-frequency (1 kHz to 10 kHz) sounds is variable (Richardson et al., 1995a). In the Caribbean, Watkins et al. (1985) observed that sperm whales exposed to 3.25 kHz to 8.4 kHz pulses interrupted their activities and left the area. The pulses were surmised to have originated from submarine sonar signals given that no vessels were observed. The authors did not report receive levels from these exposures, and also got a similar reaction from artificial noise they generated by banging on their boat hull. It was unclear if the sperm whales were reacting to the sonar signal itself or to a potentially new unknown sound in general.

Other studies involving sperm whales indicate that, after an initial disturbance, the animals return to their previous activity. During playback experiments off the Canary Islands, André et al. (1997) reported that foraging whales exposed to a 10 kHz pulsed signal did not exhibit any general avoidance reactions. When resting at the surface in a compact group, sperm whales initially reacted strongly, then ignored the signal completely (André et al., 1997).

Based on the model results, the nature of the Navy's MFA sonar training, behavioral patterns and acoustic abilities of sperm whales, observations made during past training events, and the planned implementation of procedure mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to sperm whales. The proposed ASW Exercises may affect sperm whales but are not likely to cause long-term effects on their behavior or physiology or abandonment of areas that are regularly used by sperm whales. In accordance with ESA requirements, the Navy has undertaken Section 7 consultation with NMFS based on the determination that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect sperm whales.

Hawaiian Monk Seal (*Monachus schauinslandi*)

The risk function and Navy post-modeling analysis estimates 104 Hawaiian monk seals will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect but is not likely to adversely affect Hawaiian monk seals; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.5.1-1).

Modeling also indicates there would be three exposures to accumulated acoustic energy between 204 dB and 224 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates there would be no exposures for monk seals to accumulated acoustic energy above 224 dB re 1 μPa^2-s.

As noted previously, modeling undertaken for monk seals does not take into consideration the effect of mitigation measures or foraging habitat preferences. Monk seals generally forage at depths of less than 100 m, but occasionally dive to depths of over 500 m (National Marine Fisheries Service, 2007d). The majority of ASW training in the HRC, however, takes place in waters 4 to 8 times deeper than even this known (500 m) maximum and it is very rare for ASW training to take place in waters as shallow as 100 m in depth. Additionally, mitigation measures call for continuous visual observation during training with active sonar. It would, therefore, be rare for a Hawaiian monk seal to be present in the vicinity of an ASW event and the potential for detection by aircraft and lookouts aboard ship would further preclude the possibility that monk seals would be in the vicinity of ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS threshold. There would be one exposure from impulsive sound or pressures from underwater detonations that would exceed the TTS threshold and no exposures that would exceed the injury threshold (Table 4.1.2.5.1-2). In the rare event that a monk seal was present, target area clearance procedures described in Section 4.1.2.5.1 would be used to detect monk seals within the safety zone, and therefore potential exposure of monk seals to exposures that exceed TTS is highly unlikely.

Critical habitat was designated 1986 as the area extending out to the 10-fathom depth (60 ft) for the Northwestern Hawaiian Islands (National Marine Fisheries Service, 1986). Critical habitat was extended out to the 20-fathom depth in 1988 (National Marine Fisheries Service, 1988). ASW events should not occur inside the 20-fathom isobath and given mitigation measures and range clearance procedures, activities in the HRC will not have an effect on Monk Seal Critical Habitat.

Based on the model results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of monk seals, observations made during past training events, and the planned implementation of procedure mitigation measures, the Navy finds that the training events would not likely result in any death or injury to Hawaiian monk seals. In accordance with ESA requirements, the Navy has undertaken Section 7 consultation with NMFS based on the determination that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect monk seals.

4.1.2.5.3 Estimated Exposures for Non-ESA Species—No-action Alternative

Bryde's Whale (*Balaenoptera edeni*)

The risk function and Navy post-modeling analysis estimates 64 Bryde's whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1 1).

Modeling also indicates there would be no exposures to accumulated acoustic energy above 195 dB re 1 µPa^2-s, which is the threshold established indicative of onset TTS. No Bryde's whales would be exposed to impulsive noise or pressures from underwater detonations that would exceed the sub-TTS behavioral threshold or cause physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given the large size (up to 46 ft) of individual Bryde's whales, pronounced blow, and mean group size of approximately 1.5 animals and (probability of trackline detection = 0.87 in Beaufort Sea States of 6 or less; Barlow 2003; 2006), it is very likely that lookouts would detect a group of Bryde's whales at the surface during ASW events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 64 exposures of Bryde's whale to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Bryde's whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Bryde's whales.

Minke Whale (*Balaenoptera acutorostrata*)

Despite several reports of seasonal acoustic detections of minke whales in Hawaiian waters (e.g. Rankin and Barlow, 2005), there is no density information available for minke whales in Hawaiian waters given they have rarely been visually sighted during surveys. Taken conservatively, the acoustic detections suggest that minke whales may be more common than the survey data indicates. Therefore, although acoustic effects modeling cannot be undertaken without density estimates, the Navy will assume 65 minke whales may exhibit behavioral responses that NMFS would classify as harassment under the MMPA. This exposure number is based on the modeled exposures for the Bryde's whale, another seasonal baleen whale, that has a reported abundance of 469 whales in the HRC (Barlow 2006). Based upon the Navy's protective measures, it is unlikely that HRC MFA/HFA sonar training events will result in the exposure of any minke whales to accumulated acoustic energy in excess of any energy flux threshold or an SPL that would result in a behavioral response. No minke whales would be exposed to impulsive noise or pressures from underwater detonations that would exceed the sub-TTS behavioral threshold or cause physical injury.

Mitigation measures call for continuous visual observation during training with active sonar. Given the large size (up to 27 ft) of individual minke whales (Barlow, 2003), it is possible that lookouts may detect minke whales at the surface during ASW training events although a systematic survey in the Hawaiian Islands failed to visually detect minke whales but were able to detect them acoustically (Barlow, 2006). The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Based on the model results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of minke whales, observations made during past training events, and the planned implementation mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to minke whales.

Blainville's Beaked Whale (*Mesoplodon densirostris*)

The risk function and Navy post-modeling analysis estimates 347 Blainville's beaked whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates six exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no Blainville's beaked whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s.

Modeling indicates there would be one exposure to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause physical injury (Table 4.1.2.5.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the possibility of detecting Blainville's beaked whales at the surface, any exposures should be precluded from occurring.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS threshold. Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the possibility of detecting Blainville's beaked whales at the surface, these two exposures should be precluded from occurring. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 356 exposures of Blainville's beaked whale to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Blainville's beaked whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Blainville's beaked whales.

Bottlenose Dolphin (*Tursiops truncatus*)

The risk function and Navy post-modeling analysis estimates 716 bottlenose dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 17 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no bottlenose dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s. No bottlenose dolphins would be exposed to impulsive noise or pressures from underwater detonations that would exceed the sub-TTS behavioral threshold or would cause physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given the frequent surfacing, aggregation of approximately nine animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow, 2003), it is very likely that lookouts would detect a group of bottlenose dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 733 exposures of bottlenose dolphins to potential Level B harassment annually. Based on the model results, the nature of the Navy's MFA sonar, behavioral patterns and acoustic abilities of bottlenose dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to bottlenose dolphins.

Cuvier's Beaked Whale (*Ziphius cavirostris*)

The risk function and Navy post-modeling analysis estimates 1,121 Cuvier's beaked whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates five exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no Cuvier's beaked whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s. Estimates for the sub-TTS behavioral threshold indicate there may be 15 exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS threshold. Modeling indicates there would seven exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury (Table 4.1.2.5.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the possibility of detecting Cuvier's beaked whales at the surface, these seven exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar. Given the medium size (up to 23 ft) of individual Cuvier's beaked whales (Barlow, 2006), it is possible that lookouts may detect Cuvier's beaked whales at the surface during ASW training events although beaked whales make long duration dives that may last for 45 min (Baird et al., 2006b). The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be four exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations.

There may be up to 1,148 exposures of Cuvier's beaked whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Cuvier's beaked whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Cuvier's beaked whales.

Dwarf Sperm Whale (*Kogia sima*)

The risk function and Navy post-modeling analysis estimates 2,061 dwarf sperm whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 35 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates that seven dwarf sperm whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, and 13 exposures to noise from underwater detonations that could exceed the sub-TTS behavioral threshold (Table 4.1.2.5.1-2). The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Based on the model results, behavioral patterns, acoustic abilities of dwarf sperm whales, results of past training, and the implementation of procedure mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to dwarf sperm whale. There may be up to 2,116 exposures of dwarf sperm whales to potential Level B harassment annually.

False Killer Whale (*Pseudorca crassidens*)

The risk function and Navy post-modeling analysis estimates 46 false killer whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates no exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no false killer whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s. No false killer whales would be exposed to impulsive noise or pressures from underwater detonations that would exceed the sub-TTS behavioral threshold or cause physical injury (Table 4.1.2.5.1-2).

Given their size (up to 19.7 ft) and large mean group size of 10.3 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow 2003), it is very likely that lookouts would detect a group of false killer whales at the surface. Additionally, mitigation measures call for continuous visual observation during training with active sonar; therefore, false killer whales that are present in the vicinity of ASW training events would be detected by visual observers. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 46 exposures of false killer whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of dwarf sperm whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to dwarf sperm whales.

Fraser's Dolphin (*Lagenodelphis hosei*)

The risk function and Navy post-modeling analysis estimates 1,216 Fraser's dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 19 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling also indicates that no Fraser's dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s. Estimates for the sub-TTS behavioral threshold indicate there may be six exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Modeling indicates there would be four exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or onset of massive lung injury (Table 4.1.2.5.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the high probability of detecting Fraser's dolphins at the surface, these four exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar. Given their size (up to 19.7 ft) and large mean group size of 10.3 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow 2003), it is very likely that lookouts would detect a group of false killer whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 1,245 exposures of Fraser's dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of false killer whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to false killer whales.

Killer Whale (*Orcinus orca*)

The risk function and Navy post-modeling analysis estimates 46 killer whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates that there would be no exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates that no killer whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s. No killer whales would be exposed to impulsive noise or pressures from underwater detonations that would exceed the sub-TTS threshold or cause physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given their size (up to 23 ft), conspicuous coloring, pronounced dorsal fin and large mean group size of 6.5 animals (probability of trackline detection = 0.90; Barlow, 2003), is very likely that lookouts would detect a group of killer whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 46 exposures of killer whale to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of killer whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death, or injury to killer whales.

Longman's Beaked Whale (*Indopacetus pacificus*)

The risk function and Navy post-modeling analysis estimates 104 Longman's beaked whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates one exposure to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates that no Longman's beaked whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s. No Longman's beaked whales would be exposed to impulsive noise or pressures from underwater detonations that would exceed the sub-TTS threshold or cause physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar; Given the medium size (up to 24 ft) of individual Longman's beaked whale, aggregation of approximately 17.8 animals (Barlow, 2006), it is likely that lookouts would detect a group of

Longman's beaked whale at the surface during ASW training events although beaked whales dive for long periods. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 105 exposures of Longman's beaked whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Longman's beaked whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Longman's beaked whales.

Melon-headed Whale (*Peponocephala electra*)

The risk function and Navy post-modeling analysis estimates 583 melon-headed whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 13 exposures to accumulated acoustic energy. Modeling for indicates that no melon-headed whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s. No melon-headed whales would be exposed to impulsive noise or pressures from underwater detonations that would exceed the sub-TTS threshold or cause physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar; Given their size (up to 8.2 ft) and large group size (mean of 89.2 whales) or more animals (probability of trackline detection = 1.00 in Beaufort Sea States of 6 or less; Barlow, 2003), it is very likely that lookouts would very likely detect a group of melon-headed whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 596 exposures of melon-headed whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of melon-headed whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to melon-headed whales.

Pantropical Spotted Dolphin (*Stenella attenuata*)

The risk function and Navy post-modeling analysis estimates 2,144 pantropical spotted dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Modeling indicates 49 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling also indicates one exposure to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or massive lung injury (Table 4.1.2.5.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the high probability of detecting pantropical spotted dolphins at the surface, this exposure should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar and underwater detonations. Given their frequent surfacing and large group size hundreds of animals (Leatherwood et al., 1982), mean group size of 60.0 animals in Hawaii and probability of trackline detection of 1.00 in Beaufort Sea States of 6 or less (Barlow, 2006), it is very likely that lookouts would detect a group of pantropical spotted dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 2,194 exposures of pantropical spotted dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of pantropical spotted dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to pantropical spotted dolphins.

Pygmy Killer Whale (*Feresa attenuata*)

The risk function and Navy post-modeling analysis estimates 192 pygmy killer whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates four exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for indicates that no pygmy killer whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s. No pygmy killer whales would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given their size (up to 8.5 ft) and mean group size of 14.4 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow, 2003), it is very likely that lookouts would detect a group of pygmy killer whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 196 exposures of pygmy killer whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of pygmy killer whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to pygmy killer whales.

Pygmy Sperm Whale (*Kogia breviceps*)

The risk function and Navy post-modeling analysis estimates 842 pygmy sperm whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 14 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no pygmy sperm whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s.

Estimates for the sub-TTS behavioral threshold indicate there may be four exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Modeling indicates four exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury (Table 4.1.2.4.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the possibility of detecting pygmy sperm whales at the surface, these four exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar and underwater detonations. Given their size (up to 10 ft) and behavior of resting at the surface (Leatherwood et al., 1982), it is very possible that lookouts would detect a pygmy sperm whale at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 864 exposures of pygmy sperm whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of pygmy sperm whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to pygmy sperm whales.

Risso's Dolphin (*Grampus griseus*)

The risk function and Navy post-modeling analysis estimates 486 Risso's dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 10 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates that no Risso's dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s. No Risso's dolphins would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause physical injury (Table 4.1.2.5.1-2).

Mitigation measures call for continuous visual observation during training with active sonar and underwater detonations. Given their frequent surfacing, light coloration, and large group size of up to several hundred animals (Leatherwood et al., 1982), mean group size of 15.4 dolphins in Hawaii and probability of trackline detection of 0.76 in Beaufort Sea States of 6 or less (Barlow, 2006), it is very likely that lookouts would detect a group of Risso's dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 496 exposures of Risso's dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Risso's dolphin, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Risso's dolphins.

Rough-Toothed Dolphin (*Steno bredanensis*)

The risk function and Navy post-modeling analysis estimates 1,053 rough-toothed dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 18 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for indicates that no rough-toothed dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Modeling indicates there would three exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or massive lung injury (Table 4.1.2.5.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the high probability of detecting rough-toothed dolphins at the surface, these three exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar and underwater detonations. Given their frequent surfacing and mean group size of 14.8 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow, 2006), it is very likely that lookouts would detect a group of rough-toothed dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 1,076 exposures of rough-toothed dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of rough-toothed dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to rough-toothed dolphins.

Short-finned Pilot Whale (*Globicephala macrorhynchus*)

The risk function and Navy post-modeling analysis estimates 1,751 short-finned pilot whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 40 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no short-finned pilot whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Modeling indicates there would two exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or massive lung injury (Table 4.1.2.5.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the high probability of detecting short-finned pilot whales at the surface, these two exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar. Given their size (up to 20 ft), and large mean group size of 22.5 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow 2006), it is very likely that lookouts would detect a group of short-finned pilot whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 1,795 exposures of short-finned pilot whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of short-finned pilot whales, observations made during past training events, and the planned implementation of mitigation measures, the

Navy finds that the HRC training events would not result in any population level effects, death or injury to short-finned pilot whales.

Spinner Dolphin (*Stenella longirostris*)

The risk function and Navy post-modeling analysis estimates 410 spinner dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates seven exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for indicates that no spinner dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Modeling indicates there would one exposure to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury massive lung injury (Table 4.1.2.5.1-2). Taking into consideration range clearance procedures for underwater detonation with the high probability of detecting spinner dolphins at the surface, this one exposure should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar. Given their frequent surfacing, aerobatics, and large mean group size of 31.7 animals (probability of trackline detection = 1.00 in Beaufort Sea States of 6 or less; Barlow, 2006), it is very likely that lookouts would detect a group of spinner dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 420 exposures of spinner dolphins to potential Level B harassment annually Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of spinner dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to spinner dolphins.

Striped Dolphin (*Stenella coeruleoalba*)

The risk function and Navy post-modeling analysis estimates 3,126 striped dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates 73 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for indicates no exposures to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Modeling indicates three exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or massive lung injury (Table 4.1.2.5.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the high probability of detecting striped dolphins at the surface, these three exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar. Given their frequent surfacing, aerobatics and large mean group size of 37.3 animals (probability of trackline detection = 1.00 in Beaufort Sea States of 6 or less; Barlow, 2006), it is very likely that lookouts would detect a group of striped dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 3,204 exposures of striped dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of striped dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to striped dolphins.

Unidentified Beaked Whales

The risk function and Navy post-modeling analysis estimates 36 unidentified beaked whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.5.1-1).

Modeling also indicates there would be no exposures to accumulated acoustic energy above 195 dB re 1 µPa^2-s, which is the threshold established indicative of onset TTS. No unidentified beaked whales would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause physical injury (Table 4.1.2.5.1-2). The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 36 exposures of unidentified beaked whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of unidentified beaked whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to unidentified beaked whales.

4.1.2.5.4 Summary of Compliance with MMPA and ESA—No-action Alternative

Endangered Species Act

Based on analytical risk function modeling results, NMFS conclusions in the Biological Opinions issued regarding RIMPAC 2006 and USWEX 2007, and in accordance with the ESA, the Navy finds these estimates of harassment resulting from the proposed use of MFA/HFA sonar may affect endangered blue whales, North Pacific right whales, fin whales, Hawaiian monk seals, humpback whales, sei whales, and sperm whales. Modeling results indicate no PTS exposures. Implementation of mitigation measures would further reduce the potential for TTS exposures. Based on the analysis presented in the previous section, the Navy concludes that proposed and ongoing activities in the HRC may affect but not adversely affect blue whales, North Pacific right whales, fin whales, humpback whales, sei whales, sperm whales and Hawaiian monk seals.

Mitigation measures would be implemented to minimize exposure of marine mammals to impulsive sound or sound pressures from underwater detonations that would cause injury.

Five species of sea turtles could potentially occur within the HRC. All are protected under the ESA. All available acoustic information suggests that sea turtles are likely not capable of hearing mid-frequency or high-frequency sounds in the range produced by the active sonar systems considered in this analysis. Mitigation measures would be implemented to minimize exposure of sea turtles to impulsive sound or sound pressures from underwater detonations that would cause injury.

In accordance with ESA requirements, the Navy has initiated Section 7 consultation with NMFS on the potential that HRC training may affect blue whales, North Pacific right whales, fin whales, Hawaiian monk seals, humpback whales, sei whales, and sperm whales.

Marine Mammal Protection Act

Level A Harassment of Cetaceans

Modeling results for the sum of exposures for all ASW training for a year indicate no exposures that exceeds the Level A harassment threshold. In addition, the following considerations further reduce the potential for injury from tactical sonar and underwater explosions:

- Level A zone of influence radii for tactical sonar are so small that on-board observers would readily observe an approaching marine mammal.
- Many species are large and/or travel in large pods and are easily visible from an elevated platform; a marine mammal would readily be seen from a ship or aircraft in time to implement mitigation measures.

Level B Harassment of Cetaceans

As shown in Table 4.1.2.5.1-1 for sonar, the risk function (including post-modeling analysis) plus an estimate of 64 minke whale exposures results in the estimate that 27,039 marine mammals will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. Modeling for the No-action Alternative for sonar indicates 522 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling also indicates no exposures to accumulated acoustic energy above 215 dB re 1 μPa^2-s. Should the Navy decide to implement the No-action Alternative, the effects on marine mammals will need to be considered by NMFS for purposes of MMPA authorization and ESA consultation.

Therefore, it is estimated that in total, 27,666 marine mammals will exhibit behavioral responses NMFS will classify as Level B harassment. This includes 522 TTS and 27,039 risk function exposures (26,975 plus an estimated 64 minke whales) as a result of MFA/HFA sonar use (27,561 exposures) in addition to 105 exposures (62 sub-TTS exposures and 43 TTS exposures) as a result of underwater detonations (for explosives see Table 4.1.2.5.1-2).

Mitigation measures will be in place to further minimize the potential for temporary harassment, although there is currently no data to quantify the mitigation efforts to successfully reduce the number of marine mammal exposures. The Navy has begun development of a comprehensive Monitoring Plan to determine the effectiveness of these measures. Many species of small cetaceans travel in very large pods, and therefore would be easily observed from an elevated platform. In addition, large baleen whales travel slowly and are easily observed on the surface. In the years of conducting Major Exercises in the HRC, there have been no documented incidences of harassments or beach strandings of marine mammals associated with active sonar or underwater detonations. In the one event associated with RIMPAC 2004, NMFS found sonar use was a plausible if not likely contributing factor (Southall et al., 2006) although it was later discovered that a similar event occurred on the same day in a bay at Rota Island, Northern Marianas Islands with no associated sonar (Jefferson et al., 2006). The Navy believes the 2004 event may be related to oceanographic changes that influenced prey distribution (see Southall, 2006; Ketten, 2006; Mobley et al., 2007). The HRC open ocean waters continue to support diverse populations of cetaceans.

4.1.2.5.5 HRC Training—No-action Alternative

The HRC training involving sonar includes ASW training activities as described in Table 2.2.2.3-1 and Appendix D. The No-action Alternative modeling for these activities includes analysis of surface ship and submarine MFA sonar, associated sonobuoys, MK-48 torpedo HFA sonar, and dipping sonars for activities other than occurring during Major Exercises on an annual basis. The modeled exposures for marine mammals during this ASW training, without consideration of mitigation measures are presented in 4.1.2.5.5-1 for the No-action Alternative. Effects on marine mammals from these exposures are included in the discussion in Sections 4.1.2.5.2 for ESA listed species and 4.1.2.5.3 for non-ESA listed species.

Exposures from underwater detonations (i.e., SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS are presented in the summary numbers in Table 4.1.2.5.1-2.

Table 4.1.2.5.5-1. No-action Alternative Sonar Modeling Summary—Yearly Marine Mammal Exposures from Other HRC ASW Training

Marine Mammals	Risk Function	TTS[3]	PTS[4]
Bryde's whale	14	0	0
Fin whale[1, 2]	10	0	0
Sei whale[1, 2]	10	0	0
Humpback whale[1]	1,561	57	0
Sperm whale[1]	166	2	0
Dwarf sperm whale	451	10	0
Pygmy sperm whale	185	4	0
Cuvier's beaked whale	266	1	0
Longman's beaked whale	22	0	0
Blainville's beaked whale	76	2	0
Unidentified beaked whale	9	0	0
Bottlenose dolphin	152	5	0
False killer whale	10	0	0
Killer whale	10	0	0
Pygmy killer whale	41	1	0
Short-finned pilot whale	376	12	0
Risso's dolphin	104	3	0
Melon-headed whale	125	4	0
Rough-toothed dolphin	230	5	0
Fraser's dolphin	264	5	0
Pantropical spotted dolphin	459	14	0
Spinner dolphin	89	2	0
Striped dolphin	669	21	0
Monk seal[1]	29	1	0
TOTAL	5,328	149	0

Note: [1] Endangered Species
[2] Due to a lack of density data for fin and sei whales, false killer whale results were used because they have a similar size population within the HRC.
[3] 195 dB – TTS 195-215 dB re 1 µPa^2-s; for monk seals TTS is 204-224 dB re 1 µPa^2-s (Kastak et al., 1999a; 2005)
[4] 215 dB- PTS >215 dB re 1 µPa^2-s; for monk seals PTS is >224 dB re 1 µPa^2-s (Kastak et al., 1999b; 2005)
dB = decibel
TTS = temporary threshold shift
PTS = permanent threshold shift

4.1.2.5.6 HRC RDT&E Activities—No-action Alternative

Other sources such as UAVs, underwater communications, and electronic warfare systems that may be deployed in the ocean are beyond the frequency range or intensity level to affect marine animals. Other RDT&E activities identified as ASW do not include sonar or include very limited use of sonar and short durations (<1.5 hours). These activities would have minimal effects on fish, sea turtles, and marine mammals.

4.1.2.5.7 Major Exercises—No-action Alternative

RIMPAC

The training events and impacts on marine mammals from RIMPAC Exercises were summarized in the RIMPAC 2006 Supplement to the 2002 RIMPAC EA (U.S. Department of the Navy Commander Third Fleet, 2006). The No-action Alternative modeling included 399 hours of AN/SQS 53 and 133 hours of AN/SQS 56 surface ship sonar plus dipping sonar, sonobuoys, and MK-48 torpedo high-frequency sonar per RIMPAC (conducted every other year). The modeled exposures for marine mammals during RIMPAC, without consideration of mitigation measures are presented in Table 4.1.2.5.7-1. Effects on marine mammals from these exposures are included in the discussion in Sections 4.1.2.5.2 for ESA listed species and 4.1.2.5.3 for non-ESA listed species. Exposures from underwater detonations (i.e., SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS are included in the summary numbers in Table 4.1.2.5.1-2. Sections 4.1.2.2 and 4.1.2.3 discuss the potential effects on fish and sea turtles respectively.

USWEX

The training events and impacts on marine mammals from USWEX have been summarized in the USWEX Programmatic EA/OEA (U.S. Department of the Navy, 2007b). The No-action Alternative modeling assumes there would be five USWEXs annually, including 525 hours of AN/SQS 53 and 175 hours of AN/SQS 56 surface ship sonar plus the associated dipping sonar and sonobuoys per year. The exposures for marine mammals during up to five USWEXs per year, are quantified without consideration of mitigation measures, and are presented in Table 4.1.2.5.7-2. Effects on marine mammals from these exposures are included in the discussion in Sections 4.1.2.5.2 for ESA listed species and 4.1.2.5.3 for non-ESA listed species. Exposures from underwater detonations (i.e., SINKEX, EER/IEER, A-S MISSILEX, S-S MISSILEX, BOMBEX, S-S GUNEX, and NSFS) are included in the summary numbers in Table 4.1.2.5.7-2. Sections 4.1.2.2 and 4.1.2.3 discuss the potential effects on fish and sea turtles respectively.

Table 4.1.2.5.7-1. No-action Alternative Sonar Modeling Summary—Yearly Marine Mammal Exposures for RIMPAC (Conducted Every Other Year)

Marine Mammals	Risk Function	TTS[3]	PTS[4]
Bryde's whale	19	0	0
Fin whale[1, 2]	14	0	0
Sei whale[1, 2]	14	0	0
Humpback whale[1]	0	0	-
Sperm whale[1]	245	3	0

4.1.2.6 MARINE MAMMALS ALTERNATIVE 1 (BIOLOGICAL RESOURCES—OPEN OCEAN)

The discussion under the No-action Alternative regarding potential non-acoustic impacts (Section 4.1.2.5.1) and potential ASW Impacts (Section 4.1.2.5.2) also apply for Alternative 1.

4.1.2.6.1 Alternative 1 Summary of Exposures

The increased training and RDT&E activities under Alternative 1 result in an increase in the number of hours of ASW training. The modeling input includes a total of 1,788 hours of AN/SQS 53 and 551 hours of AN/SQS 56 MFA tactical sonar plus the associated DICASS sonobuoy, MK-48 torpedo HFA sonar, and dipping sonar modeling inputs (see Appendix J for a detailed description of the sonar modeled). These exposure numbers are generated by the model without consideration of mitigation measures that would reduce the potential for marine mammal exposures to sonar. Table 4.1.2.6.1-1 provides a summary of the total sonar exposures from all Alternative 1 ASW Exercises that would be conducted over the course of a year. The number of exposures from each type of exercise are presented separately in Sections 4.1.2.6.5, 4.1.2.6.6, 4.1.2.6.7, and 4.1.2.6.8.

The explosive modeling input includes Mine Neutralization, MISSILEX, BOMBEX, SINKEX, EER/IEER, GUNEX, and NSFS. Estimates for the sub-TTS behavioral threshold indicate there may be 62 exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. The modeled explosive exposure harassment numbers by species are presented in Table 4.1.2.6.1-2. The table indicates the potential for non-injurious (Level B) harassment, as well as the onset of injury (Level A) harassment to cetaceans. The modeling indicates 73 annual exposures to pressure from underwater detonations that could result in TTS. The modeling indicates three exposures (an annual total) from pressure or acoustics from underwater detonations that could cause slight injury. These exposure modeling results are estimates of marine mammal underwater detonation sound exposures without consideration of standard mitigation and monitoring procedures. The implementation of the mitigation and monitoring procedures presented in Chapter 6.0 will minimize the potential for marine mammal exposure and harassment through range clearance procedures.

Table 4.1.2.6.1-1. Alternative 1 Sonar Modeling Summary—Yearly Marine Mammal Exposures from All ASW (RIMPAC, USWEX, and Other ASW Training)

4.1.2.6.2 Estimated Effects on ESA Listed Species—Alternative 1

The endangered species that may be affected as a result of implementation of Alternative 1 include the blue whale (*Balaenoptera musculus*), fin whale (*Balaenoptera physalus*), Hawaiian monk seal (*Monachus schauinslandi*), humpback whale (*Megaptera novaeangliae*), North Pacific right whale (*Eubalaena japonica*), sei whale (*Balaenoptera borealis*) and sperm whale (*Physeter macrocephalus*).

For Alternative 1, modeling results predict that if there were no mitigation measures in place, exposures that that are temporary, non-injurious physiological effects (TTS) or behavioral effects would occur. The modeling predicts one humpback whale exposure to energy in excess of the criteria for slight lung injury. The criteria for lung injury are extremely conservative with regard to humpback whales given that the established threshold, which corresponds to body mass in a complex manner, was based on a calf dolphin (at 26.9 lb) as compared to the approximate 4,000 lb mass of a newborn humpback whale. Mitigation measures call for continuous visual observation during training with active sonar. Given the large size (up to 53 ft) of individual humpback whales (Leatherwood et al., 1982), and pronounced vertical blow, it is very likely that lookouts would detect humpback whales at the surface during training events and preclude this exposure from occurring.

The following sections discuss the exposure of ESA listed species to sonar and underwater detonations from all Alternative 1 exercises per year. The exposure numbers are given without consideration of mitigation measures. However, mitigation measures that are implemented during the ASW and underwater detonation Exercises would reduce the potential for marine mammal exposures.

Blue Whale (*Balaenoptera musculus*)

There is no density information available for blue whales in Hawaiian waters given they have not been seen during survey. Given they are so few in number, it is unlikely that HRC MFA/HFA sonar training events will result in the exposure of any blue whales to accumulated acoustic energy in excess of any energy flux threshold or an SPL that would result in a behavioral response. No blue whales would be exposed to impulsive sound or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause TTS or physical injury. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of blue whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury, effects on their behavior or physiology, or abandonment of areas that are regularly used by blue whales. In accordance with ESA requirements, the Navy would undertake Section 7 consultation with NMFS based on the determination for Alternative 1 that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect blue whales.

Fin Whale (*Balaenoptera physalus*)

There is no density information for fin whales in the Hawaiian Islands (Barlow, 2006). For purposes of acoustic effects analysis, it was assumed that the number and density of fin whales did not exceed that of false killer whales and the modeled number of exposures for both species will therefore be the same. The risk function and Navy post-modeling analysis estimates 66 fin whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect, but is not likely to adversely affect, fin whales; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.6.1-1).

Modeling also indicates that there would be two exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates no exposures for fin whales to accumulated acoustic energy above 215 dB re 1 μPa^2-s. No fin whales would be exposed to impulsive sound or pressures from underwater detonations that would exceed the sub-TTS behavioral threshold or cause physical injury (Table 4.1.2.6.1-2). The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Based on the model results, the nature of Navy's MFA sonar operations, behavioral patterns and acoustic abilities of fin whales, observations made during HRC training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events will likely not result in any population level effects, death or injury to fin whales. In accordance with ESA requirements, the Navy would undertake Section 7 consultation with NMFS based on the determination for Alternative 1, that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect fin whales.

Humpback Whale (*Megaptera novaeangliae*)

The acoustic effects analysis for Alternative 1 based the risk function and Navy post-modeling analysis estimates 9,685 humpback whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect but is not likely to adversely affect humpback whales; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.6.1-1).

Modeling also indicates there would be 199 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling indicates no exposures for humpback whales to accumulated acoustic energy above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be five exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of clearance procedures, modeling indicates there would be nine exposures from impulsive sound or pressures from underwater detonations that would exceed the TTS threshold, one exposure that would exceed the injury threshold, and no exposures that would exceed the massive injury threshold (Table 4.1.2.6.1-2). Target area clearance procedures described in Section 4.1.2.5.1 would make sure there are no humpback whales within the safety zone, and therefore potential exposure of humpback whales to sound levels from underwater detonations that exceed TTS or injury levels is highly unlikely. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

As noted previously, filter-bank models of the humpback whale's ear by Houser et al., (2001) suggest that humpbacks are sensitive to frequencies between 700 Hz and 10 kHz, and have a maximum sensitivity is between 2 kHz and 6 kHz. Recent reporting by Au et al., (2006) indicating high-frequency harmonics in humpback whale "song" at 24 kHz and beyond does not demonstrate that humpbacks can actually hear those harmonics, which may simply be correlated harmonics of the frequency fundamental. Most social vocalizations, including female vocalizations, are below 3 kHz (Silber, 1986); therefore, are below MFA sonar range. Male songs range from 20 Hz to 24 kHz, but most of the components range from 200 Hz to 3 kHz (Au et al., 2001). A single study suggested that humpback whales responded to MFA sonar (3.1-3.6 kHz re 1 μPa^2-s) sound (Maybaum, 1989). The hand-held sonar system had a sound artifact below 1,000 Hz which caused a response to the control playback (a blank tape) and may have affected the response to sonar (i.e., the humpback whale responded to the low-frequency artifact rather than the MFA sonar sound).

While acoustic modeling results indicate MFA/HFA sonar may expose humpback whales to accumulated acoustic energy levels resulting in temporary behavioral effects, these exposures would have negligible impact on annual survival, recruitment, and birth rates and not likely result in population level effects. The aggregation of humpback whales in Hawaii has been increasing at up to 7 percent annually (Mobley, 2004) despite frequent encounters with tour boats. There have been no observed or reported mother calf separations as a result of Navy activities. There have been no reported or identified humpback whale strandings in Hawaii associated with the use of MFA/HFA sonar. While the absence of evidence does not prove there have been no impacts on humpback whales, decades of history with no evidence should not be dismissed. Mitigation measures presented in Chapter 6.0 would further reduce the potential acoustic exposure.

Per Navy policy, based on the quantitative analysis results that trigger a "may affect" determination, Navy has initiated Section 7 consultation with NMFS based on the determination that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect humpback whales.

North Pacific Right Whale (*Eubalaena japonica*)

There is no density information available for North Pacific right whales in Hawaiian waters given they have not been seen during survey. Given they are so few in number, it is unlikely that HRC MFA/HFA sonar training events will result in the exposure of any right whales to accumulated acoustic energy in excess of any energy flux threshold or an SPL that would result in a behavioral response. No right whales would be exposed to impulsive sound or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause TTS or physical injury. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Based on the model results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of North Pacific right whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would likely not result in any population level effects, death or injury to North Pacific right whales, and will not affect their behavior, physiology or cause abandonment of areas that are regularly used by North Pacific right whales. In accordance with ESA requirements, the Navy would undertake Section 7 consultation with NMFS based on the determination for Alternative 1, that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect North Pacific right whales.

Sei Whale (*Balaenoptera borealis*)

For purposes of the acoustic effects analysis, the same assumptions made previously regarding fin whales are also made for sei whales. It was therefore assumed that the number and density of sei whales did not exceed that of false killer whales, and the modeled number of exposures for both species would therefore be the same. The risk function and Navy post-modeling analysis estimates 66 sei whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect, but is not likely to adversely affect, sei whales; therefore, the Navy has initiated Section 7 consultation with NMFS (Table 4.1.2.6.1-1).

Modeling also predicts two exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling predicts no exposures for sei whales to accumulated acoustic energy above 215 dB re 1 μPa^2-s. No sei whales would be exposed to impulsive sound or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause TTS or physical injury (Table 4.1.2.6.1-2). The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Based on the model results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of sei whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not likely result in any population level effects, death or injury to sei whales. The proposed ASW Exercises may affect sei whales but are not likely to cause long-term effects on their behavior or physiology or abandonment of areas that are regularly used by sei whales. In accordance with ESA requirements, the Navy would undertake Section 7 consultation with NMFS based on the determination for Alternative 1, that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect sei whales.

Sperm Whales (*Physeter macrocephalus*)

The risk function and Navy post-modeling analysis estimates 1,067 sperm whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect, but is not likely to adversely affect, sperm whales; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.6.1-1).

Modeling also predicts 12 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling predicts no exposures for sperm whales to accumulated acoustic energy above 215 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be nine exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of clearance procedures, modeling indicates there would be five exposures from impulsive sound or pressures from underwater detonations that would exceed the TTS threshold (Table 4.1.2.6.1-2). Target area clearance procedures described in Section 4.1.2.5.1 would make sure there are no sperm whales within the safety zone, and therefore potential exposure of sperm whales to sound levels that exceed TTS is highly unlikely. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Based on the model results, the nature of the Navy's MFA sonar training, behavioral patterns and acoustic abilities of sperm whales, observations made during past training events, and the planned implementation of procedure mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to sperm whales. The proposed ASW Exercises may affect sperm whales but are not likely to cause long-term effects on their behavior or physiology or abandonment of areas that are regularly used by sperm whales. In accordance with ESA requirements, the Navy would undertake Section 7 consultation with NMFS based on the determination for Alternative 1, that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect sperm whales.

Hawaiian Monk Seal (*Monachus schauinslandi*)

The risk function and Navy post-modeling analysis estimates 147 Hawaiian monk seals will exhibit behavioral responses that NMFS will classify as harassment under the MMPA. The Navy believes this may affect, but is not likely to adversely affect, Hawaiian monk seals; therefore, the Navy has initiated ESA Section 7 consultation with NMFS (Table 4.1.2.6.1-1).

Modeling also predicts four exposures to accumulated acoustic energy between 204 dB and 224 dB re 1 µPa^2-s (the Hawaiian monk seal thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling predicts there would be no exposures for monk seals to accumulated acoustic energy above 224 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS for Hawaiian monk seals.

Modeling undertaken for monk seals does not take into consideration the effect of mitigation measures or foraging habitat preferences. Monk seals generally forage at depths of less than 100 m, but occasionally dive to depths of over 500 m. The majority of ASW training in the HRC, however, takes place in waters 4 to 8 times deeper than even this known (500 m) maximum and it is very rare for ASW training to take place in waters as shallow as 100 m in depth. Additionally, mitigation measures call for continuous visual observation during training with active sonar. It would, therefore, be rare for a Hawaiian monk seal to be present in the vicinity of an ASW event and the potential for detection by aircraft and lookouts aboard ship would further preclude the possibility that monk seals would be in the vicinity of ASW training events.

Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of clearance procedures, modeling indicates there would be two exposures from impulsive sound or pressures from underwater detonations that would exceed the TTS threshold and no exposures that would exceed the injury threshold (Table 4.1.2.6.1-2). In the rare event that a monk seal was present, target area clearance procedures described in Section 4.1.2.5.1 would be used to detect monk seals within the safety zone, and therefore potential exposure of monk seals to exposures that exceed TTS is highly unlikely. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Critical habitat was designated 1986 as the area extending out to the 10-fathom depth (60 ft) for the Northwestern Hawaiian Islands (National Marine Fisheries Service, 1986). Critical habitat was extended out to the 20-fathom depth in 1988 (National Marine Fisheries Service, 1988). ASW events should not occur inside the 20-fathom isobath and given mitigation measures and range clearance procedures, activities in the HRC will not have an effect on Monk Seal Critical Habitat.

Based on the model results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of monk seals, observations made during past training events, and the planned implementation of procedure mitigation measures, the Navy finds that the training events would not likely result in any death or injury to Hawaiian monk seals. In accordance with ESA requirements, the Navy would undertake Section 7 consultation with NMFS based on the determination for Alternative 1, that the proposed and ongoing activities in the HRC may affect but are not likely to adversely affect Hawaiian monk seals.

4.1.2.6.3 Estimated Exposures for Non-ESA Species—Alternative 1

Bryde's Whale (*Balaenoptera edeni*)

The risk function and Navy post-modeling analysis estimates 89 Bryde's whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1). Modeling indicates there would be no exposures to accumulated acoustic energy above 195 dB re 1 μPa^2-s, which is the threshold established indicative of onset TTS. Modeling for all alternatives indicates that no Bryde's whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS. No Bryde's whales would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause physical injury (Table 4.1.2.6.1-2).

Given the large size (up to 46 ft) of individual Bryde's whales, pronounced blow, and mean group size of approximately 1.5 animals and (probability of trackline detection = 0.87 in Beaufort Sea States of 6 or less; Barlow, 2003; 2006), it is very likely that lookouts would detect a group of Bryde's whales at the surface. Additionally, mitigation measures call for continuous visual observation during training with active sonar; therefore, Bryde's whales that are present in the vicinity of ASW training events may be detected by visual observers. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 89 exposures of Bryde's whale to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Bryde's whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Bryde's whales.

Minke Whale (*Balaenoptera acutorostrata*)

Despite several reports of seasonal acoustic detections of minke whales in Hawaiian waters (e.g. Rankin and Barlow, 2005), there is no density information available for minke whales in Hawaiian waters given they have rarely been visually sighted during surveys. Taken conservatively, the acoustic detections suggest that minke whales may be more common than the survey data indicates. Therefore, although acoustic effects modeling cannot be undertaken without density estimates, the Navy will assume 89 minke whales may exhibit behavioral responses that NMFS would classify as harassment under the MMPA. This exposure number is based on the modeled exposures for the Bryde's whale, another seasonal baleen whale, that has a reported abundance of 469 whales in the HRC (Barlow 2006). Based upon the Navy's protective measures, it is unlikely that HRC MFA/HFA sonar training events will result in the exposure of any minke whales to accumulated acoustic energy in excess of any energy flux threshold or an SPL that would result in a behavioral response. No minke whales would be exposed to impulsive noise or pressures from underwater detonations that would exceed the sub-TTS behavioral threshold or cause physical injury. No minke whales would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause TTS or physical injury.

Given the large size (up to 27 ft) of individual minke whales (Barlow, 2003), it is possible that lookouts may detect a minke whales at the surface although a systematic survey in the Hawaiian Islands failed to visually detect minke whales but were able to detect using acoustic methods (Barlow, 2006). Additionally, mitigation measures call for continuous visual observation during training with active sonar; therefore, minke whales that are present in the vicinity of ASW training events would be detected by visual observers. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

Based on the model results, behavioral patterns, acoustic abilities of minke whales, results of past training, and the implementation of procedure mitigation measures, the Navy finds that the

HRC training events would not result in any population level effects, death or injury to minke whales.

Blainville's Beaked Whale (*Mesoplodon densirostris*)

The risk function and Navy post-modeling analysis estimates 478 Blainville's beaked whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates nine exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no Blainville's beaked whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates there would be two exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause physical injury (Table 4.1.2.6.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the possibility of detecting Blainville's beaked whales at the surface, these two exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar. Given the size (up to 15.5 ft) of individual Blainville's beaked whales, it is possible that lookouts may detect Blainville's beaked whales at the surface although beaked whales dive for long periods. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 491 exposures of Blainville's beaked whale to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Blainville's beaked whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Blainville's beaked whales.

Bottlenose Dolphin (*Tursiops truncatus*)

The risk function and Navy post-modeling analysis estimates 994 bottlenose dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 24 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no bottlenose dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS. Modeling indicates that one bottlenose dolphin would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold and no exposures to impulsive noise or pressures from underwater detonations that would cause physical injury (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given the frequent surfacing, aggregation of approximately nine animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow, 2003), it is very likely that lookouts would detect a group of bottlenose dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 1,019 exposures of bottlenose dolphins to potential Level B harassment annually. Based on the model results, the nature of the Navy's MFA sonar, behavioral patterns and acoustic abilities of bottlenose dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to bottlenose dolphins.

Cuvier's Beaked Whale (*Ziphius cavirostris*)

The risk function and Navy post-modeling analysis estimates 1,559 Cuvier's beaked whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates seven exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no Cuvier's beaked whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be 15 exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates there would eight exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury (Table 4.1.2.6.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the possibility of detecting Cuvier's beaked whales at the surface, these exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar. Given the medium size (up to 23 ft) of individual Cuvier's beaked whales (Barlow, 2006), it is possible that lookouts may detect Cuvier's beaked whales at the surface during ASW training events although beaked whales dive for long periods (Baird et al., 2006b). The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 1,,589 exposures of Cuvier's beaked whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Cuvier's beaked whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Cuvier's beaked whales.

Dwarf Sperm Whale (*Kogia sima*)

The risk function and Navy post-modeling analysis estimates 2,827 dwarf sperm whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 48 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no dwarf sperm whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be 13 exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates 13 exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or onset of massive lung injury (Table 4.1.2.6.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the possibility of detecting pygmy sperm whales at the surface, these 13 exposures should be precluded from occurring. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 2,901 exposures of dwarf sperm whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of dwarf sperm whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the

HRC training events would not result in any population level effects, death or injury to dwarf sperm whales.

False Killer Whale (*Pseudorca crassidens*)

The risk function and Navy post-modeling analysis estimates 66 false killer whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates two exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no false killer whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS. No false killer whales would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause physical injury (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given their size (up to 19.7 ft) and large mean group size of 10.3 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow 2003), it is very likely that lookouts would detect a group of false killer whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 68 exposures of false killer whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of false killer whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to false killer whales.

Fraser's Dolphin (*Lagenodelphis hosei*)

The risk function and Navy post-modeling analysis estimates 1,674 Fraser's dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 28 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no Fraser's dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be six exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates there would be six exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or onset of massive lung injury (Table 4.1.2.6.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the high probability of detecting Fraiser's dolphins at the surface, these six exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar. Given their large aggregations, mean group size of 286.3 animals (probability of trackline detection = 1.00 in Beaufort Sea States of 6 or less; Barlow 2006), it is very likely that lookouts would detect a group of Fraser's dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 1,714 exposures of Fraser's dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Fraser's dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Fraser's dolphins.

Killer Whale (*Orcinus orca*)

The risk function and Navy post-modeling analysis estimates 66 killer whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates two exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no killer whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS. No killer whales would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause physical injury (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given their size (up to 23 ft), conspicuous coloring, pronounced dorsal fin and large mean group size of 6.5 animals (probability of trackline detection = 0.90; Barlow, 2003), is very likely that lookouts would detect a group of killer whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 68 exposures of killer whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of killer whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to killer whales.

Longman's Beaked Whale (*Indopacetus pacificus*)

The risk function and Navy post-modeling analysis estimates 145 Longman's beaked whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates two exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no Longman's beaked whale would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS. No Longman's beaked whale would be exposed to impulsive noise or pressures from underwater detonations will exceed the sub-TTS behavioral disturbance threshold or that would cause physical injury (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar; Given the medium size (up to 24 ft) of individual Longman's beaked whale, aggregation of approximately 17.8 animals (Barlow, 2006), it is likely that lookouts would detect a group of Longman's beaked whale at the surface during ASW training events although beaked whales dive for long periods. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 147 exposures of Longman's beaked whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Longman's beaked whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Longman's beaked whales.

Melon-headed Whale (*Peponocephala electra*)

The risk function and Navy post-modeling analysis estimates 811 melon-headed whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 18 exposures to accumulated acoustic energy. Modeling for Alternative 1 indicates that no melon-headed whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS. No melon-headed whales would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold. One melon-headed whale may be exposed to impulsive noise or pressures from underwater detonations that would cause TTS (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar; Given their size (up to 8.2 ft) and large group size (mean of 89.2 whales) or more animals (probability of trackline detection = 1.00 in Beaufort Sea States of 6 or less; Barlow, 2003), it is very likely that lookouts would very likely detect a group of melon-headed whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 830 exposures of melon-headed whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of melon-headed whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to melon-headed whales.

Pantropical Spotted Dolphin (*Stenella attenuata*)

The risk function and Navy post-modeling analysis estimates 2,988 pantropical spotted dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 69 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no pantropical spotted dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.

Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates three exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, one exposure to impulsive noise or pressures from underwater detonations that would cause slight physical injury, and none that would cause massive lung injury (Table 4.1.2.6.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the high probability of detecting pantropical spotted dolphins at the surface, these three exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar and underwater detonations Given their frequent surfacing and large group size hundreds of animals (Leatherwood et al., 1982), mean group size of 60.0 animals in Hawaii and probability of trackline detection of 1.00 in Beaufort Sea States of 6 or less (Barlow, 2006), it is very likely that lookouts would detect a group of pantropical spotted dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 3,060 exposures of pantropical spotted dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of pantropical spotted dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to pantropical spotted dolphins.

Pygmy Killer Whale (*Feresa attenuata*)

The risk function and Navy post-modeling analysis estimates 266 pygmy killer whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates six exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no pygmy killer whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS. No pygmy killer whales would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold or would cause physical injury (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given their size (up to 8.5 ft) and mean group size of 14.4 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow, 2003), it is likely that lookouts would detect a group of pygmy killer whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 272 exposures of pygmy killer whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of pygmy killer whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to pygmy killer whales.

Pygmy Sperm Whale (*Kogia breviceps*)

The risk function and Navy post-modeling analysis estimates 1,155 pygmy sperm whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 20 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no pygmy sperm whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be four exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates five exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury (Table 4.1.2.6.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the possibility of detecting pygmy sperm whales at the surface, these exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar and underwater detonations. Given their size (up to 10 ft) and behavior of resting at the surface (Leatherwood et al., 1982), it is very possible that lookouts would detect a pygmy sperm whale at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 1,184 exposures of pygmy sperm whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of pygmy sperm whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to pygmy sperm whales.

Risso's Dolphin (*Grampus griseus*)

The risk function and Navy post-modeling analysis estimates 675 Risso's dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 15 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no Risso's dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS. One Risso's dolphin would be exposed to impulsive noise or pressures from underwater detonations that will exceed the sub-TTS behavioral disturbance threshold and none would be exposed to levels that would cause physical injury (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar and underwater detonations. Given their frequent surfacing, light coloration, and large group size of up to several hundred animals (Leatherwood et al., 1982), mean group size of 15.4 dolphins in Hawaii and probability of trackline detection of 0.76 in Beaufort Sea States of 6 or less (Barlow, 2006), it is very likely that lookouts would detect a group of Risso's dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 691 exposures of Risso's dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of Risso's dolphin, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to Risso's dolphins.

Rough-Toothed Dolphin (*Steno bredanensis*)

The risk function and Navy post-modeling analysis estimates 1,445 rough-toothed dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 25 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 µPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no rough-toothed dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 µPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates there would be four exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or massive lung injury (Table 4.1.2.6.1-2). Given that many of these events occur in relatively shallow water and taking into consideration range clearance procedures for underwater detonation with the high probability of detecting rough-toothed dolphins at the surface, these four exposures should be precluded from occurring.

Mitigation measures call for continuous visual observation during training with active sonar and underwater detonations. Given their frequent surfacing and mean group size of 14.8 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow, 2006), it is very likely that lookouts would detect a group of rough-toothed dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 1,476 exposures of rough-toothed dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of rough-toothed dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to rough-toothed dolphins.

Short-finned Pilot Whale (*Globicephala macrorhynchus*)

The risk function and Navy post-modeling analysis estimates 2,430 short-finned pilot whales will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 56 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no short-finned pilot whales would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates there would be three exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury or massive lung injury (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given their size (up to 20 ft), and large mean group size of 22.5 animals (probability of trackline detection = 0.76 in Beaufort Sea States of 6 or less; Barlow 2006). It is very likely that lookouts would detect a group of short-finned pilot whales at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 2,491 exposures of short-finned pilot whales to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of short-finned pilot whales, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to short-finned pilot whales.

Spinner Dolphin (*Stenella longirostris*)

The risk function and Navy post-modeling analysis estimates 561 spinner dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates nine exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates that no spinner dolphins would be exposed to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.

Estimates for the sub-TTS behavioral threshold indicate there may be two exposures resulting in behavioral harassment from successive explosions in a single event involving underwater detonations. Given that successive multiple explosions are rare events and considering range clearance, it is extremely unlikely there would be any exposures exceeding the sub-TTS behavioral threshold. Without consideration of range clearance procedures, modeling indicates there would be two exposures to impulsive noise or pressures from underwater detonations of 182 dB or 23 psi, which is the threshold indicative of onset TTS, and no exposures to impulsive noise or pressures from underwater detonations that would cause slight physical injury massive lung injury (Table 4.1.2.6.1-2).

Mitigation measures call for continuous visual observation during training with active sonar. Given their frequent surfacing, aerobatics, and large mean group size of 31.7 animals (probability of trackline detection = 1.00 in Beaufort Sea States of 6 or less; Barlow, 2006), it is very likely that lookouts would detect a group of spinner dolphins at the surface during ASW training events. The implementation of mitigation measures to reduce exposure to high levels of sonar sound; and the short duration and intermittent exposure to sonar, reduces the likelihood that exposure to MFA/HFA sonar sound would cause a behavioral response that may affect vital functions (foraging, reproduction, or survival), TTS or PTS.

There may be up to 574 exposures of spinner dolphins to potential Level B harassment annually. Based on these modeling results, the nature of the Navy's MFA sonar operations, behavioral patterns and acoustic abilities of spinner dolphins, observations made during past training events, and the planned implementation of mitigation measures, the Navy finds that the HRC training events would not result in any population level effects, death or injury to spinner dolphins.

Striped Dolphin (*Stenella coeruleoalba*)

The risk function and Navy post-modeling analysis estimates 4,361 striped dolphins will exhibit behavioral responses that NMFS will classify as harassment under the MMPA (Table 4.1.2.6.1-1).

Modeling also indicates 101 exposures to accumulated acoustic energy between 195 dB and 215 dB re 1 μPa^2-s (the thresholds established to be indicative of onset TTS and onset PTS respectively). Modeling for Alternative 1 indicates no exposures to accumulated acoustic energy at or above 215 dB re 1 μPa^2-s, which is the threshold indicative of onset PTS.
